ABSTRACT BODY:

Purpose: To determine the effectiveness of subconjunctival application of a novel sirolimus liposomal formulation for the treatment of signs and symptoms of patients with moderate to severe dry eye.

Methods: A randomized, triple-blind, phase II clinical trial. A total of 38 eyes of 19 patients were included. 9 patients (18 eyes) assigned to Sham group (Sham) and 10 patients (20 eyes) to Sirolimus-loaded liposomes group (Sirolimus). Methods: Treatment group received three doses of subconjunctival liposome-encapsulated sirolimus and sham group received three doses of liposomal suspension without sirolimus. Main Outcomes Measures: Subjective (Ocular Surface Disease Index, OSDI) and objective (corrected distance visual acuity, conjunctival hyperemia, tear osmolarity, Schirmer's test, corneal/conjunctival staining and matrix metalloproteinase-9) variables were measured pre- and post-treatment. Intragroup comparisons were performed (pre-treatment and post-treatment).

Results: Sirolimus-entrapped liposomes treated group OSDI scores changed from 62.19 (\pm 6.07) to 37.8 (\pm 17.81) (p = 0.0024), and conjunctival hyperemia from 2.0 (\pm 0.68) to 0.83 (\pm 0.61) (p < 0.0001); Sham group with OSDI scores from 60.02 (\pm 14.2) to 36.02 (\pm 20.70) (p = 0.01), and conjunctival hyperemia from 1.33 (\pm 0.68) to 0.94 (\pm 0.87) (p = 0.048). All the other evaluated outcomes only showed significant differences in the Sirolimus group: corneal/conjunctival staining score (p =0.0015), lipid layer interferometry (p =0.006), and inferior meibomian gland dropout (p =0.038). No local or systemic adverse effects regarding the medication itself were reported, and the administration route was well accepted.

Conclusions: Our findings suggest that sub-conjunctival sirolimus-loaded liposomes is effective in reducing both signs and symptoms of dry eye in patients with poorly controlled moderate-severe dry eye disease, while avoiding other topical administration adverse effects. Further investigation with a larger sample size is required to determine long-term effects.

Gonçalves, Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, BRAZIL |

Commercial Relationships Disclosure (Abstract): Bruno Ferreira: Commercial Relationship: Code N (No Commercial Relationship) | Alex Higashi: Commercial Relationship: Code N (No Commercial Relationship) | Leandro Prado: Commercial Relationship: Code N (No Commercial Relationship) | Célio Gonçalves: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Hirata: Commercial Relationship: Code N (No Commercial Relationship) | Joyce Yamamoto: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: OCT-Angiography (OCT-A) has a unique ability to analyze retinal vascular plexuses, providing additional information about ocular involvement in Behçet's syndrome (BS), which manifests mainly as an occlusive retinal vasculitis. We performed a cross-sectional quantitative and qualitative assessment of parafoveal retinal vascular plexuses in Behçet's uveitis (BU) patients, comparing them with non-ocular Behçet's syndrome (NOBS) patients and healthy subjects (HS).

Methods: Twenty-six patients that met the International Criteria for Behçet's Disease (2014), 16 with BU (age 43.4 ± 12.8 years) and 10 with NOBS (40.7 ± 9 years), and 10 sex-matched HS (42.2 ± 11.7 years) were evaluated with Spectralis® OCT-A (Heidelberg Engineering, Heidelberg, Germany) (Figure 1). Five eyes with poor fixation or media opacities were excluded. Foveal avascular zone (FAZ) area and circularity index (CI) were manually measured in superficial vascular plexus (SVP), intermediate capillary plexus (ICP), and deep capillary plexus (DCP), using ImageJ (NIH, Bethesda, Maryland, USA). Parafoveal vessel density (VD) was quantified for superior, nasal, inferior, and temporal quadrants. Perifoveolar arcade disruption frequency was also evaluated. All biomarkers were correlated with age of onset, duration of disease, and episodes in BU patients. Statistical analysis was performed using generalized estimating equations with a normal distribution.

Results: Variance analysis showed a statistically significant difference ($p < 0.05$) in global VD between BU and NOBS groups and between BU and HS groups in ICP (nasal and inferior quadrants) and DCP (all quadrants) (Figure 2). No differences for CI, temporal VD in SVP and ICP, and perifoveolar arcade disruption were found among the groups ($p > 0.05$). FAZ area and other VD parameters were significantly different only between BU and HS. In the BU group, the Pearson correlation coefficient showed the age of onset has an inverse correlation with the FAZ area ($r = -0.460$) and a positive correlation with VD in SVP ($r = 0.447$).

Conclusions: In patients with BU, the deeper the retinal vascular layer, the lower is the VD. Nasal and inferior quadrants are the most affected, while the temporal quadrant is relatively spared. The age of onset seems to be a predictor for parafoveal vascular changes in BS. None biomarker showed a statistically significant difference between NOBS patients and HS.

SUBMITTER (NAME ONLY): Sarah Atta

TITLE: Serratia marcescens Keratitis: Clinical Features, Risk Factors, Treatment, and Outcomes

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Atta, R.P. Kowalski, V. Jhanji, Department of Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|C. Perera, Department of Ophthalmology, Stanford University School of Medicine, Stanford, California, UNITED STATES|R.P. Kowalski, The Charles T. Campbell Ophthalmic Microbiology Laboratory, University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sarah Atta: Commercial Relationship: Code N (No Commercial Relationship) | Chandrashan Perera: Commercial Relationship: Code N (No Commercial Relationship) | Regis Kowalski: Commercial Relationship: Code N (No Commercial Relationship) | Vishal Jhanji: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To provide an up-to-date clinical characterization of Serratia marcescens keratitis and to assess changes in the microbiological spectrum and clinical trends of the infection over time.

Methods: Forty-six culture-proven cases (46 eyes) of Serratia marcescens ocular infection diagnosed and treated at the University of Pittsburgh Eye Center between Feb 2002-Feb 2020 were included in this retrospective, observational case series and reviewed for clinical and microbiological characteristics. Data collected from patient records included demographics, ocular and systemic risk factors, follow-up length, initial and final visual acuity, symptom duration prior to presentation, infiltrate size and shape, medical management, adjunctive management, time to defect closure, duration of treatment, microbiological characteristics, and antibiotic susceptibilities.

Results: Mean presenting age was 46.8 years with mean follow-up time of 329 days. Prevalent ocular comorbidities were contact lens use (68.6%), history of corneal disease (52.9%), lid pathology (25.5%), and glaucoma (15.7%). Systemic comorbidities were present in 58.8% of patients, with systemic atopy (49.0%) and immunosuppression (37.3%) being most common. Average treatment duration was 152 days, with most common administration of fluoroquinolones (76.5%) and fortified antibiotics (60.8%). Visual outcomes generally improved with treatment, with an average initial visual acuity (VA) of 1.3 logMar and final VA of 0.86 logMar. Worse final VA was associated with glaucoma ($p=0.038$), hypopyon ($p=0.045$), older age (0.000), worse initial VA ($p=0.009$), longer time to defect closure ($p=0.020$), and larger infiltrate ($p=0.037$). All cases showed antibiotic sensitivity to ciprofloxacin (100%), and most showed resistance to cefazolin (80.4%). No significant changes in clinical profile or treatment were observed over the 18-year period.

Conclusions: S. marcescens keratitis is associated with contact lens use and poor ocular surface. Fluoroquinolones and fortified antibiotics have shown effective management and improved visual outcomes. Worse outcomes are associated with older age and worse severity at presentation. Microbiological and clinical trends of this ocular infection have remained constant over nearly 20 years.

SUBMITTER (NAME ONLY): Mashael Al-Namaeh

TITLE: Parkinson's Disease and Convergence Insufficiency: A Meta-Analysis

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Al-Namaeh, School of Health and Social Care, Optometry Department, Oulu University of Applied Sciences, Oulu, FINLAND|

Commercial Relationships Disclosure (Abstract): Mashael Al-Namaeh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A key manifestation of Parkinson's disease (PD) is visual impairment. Cognitive impairment has been found to commonly overlap with convergence insufficiency (CI) in PD and is associated with significantly greater near point convergence (NPC) distance. Difficulty reading and diplopia were the most often reported symptoms of CI in PD. The prevalence of CI is greater among patients with PD. No meta-analysis examined this subject; therefore, our aim was to assess the relationship between PD and CI.

Methods: This meta-analysis study has followed the standards and guidelines of Preferred Reporting Items for Systematic Reviews and Meta Analyses (PRISMA). PubMed search was used with the terms "Parkinson's Disease" AND "Convergence insufficiency ". The results showed 1,563 articles, 11 articles met the inclusion criteria, 8 articles were used for the CI screening survey as the primary outcome and 3 articles were used for the NPC distance (cm) as the secondary outcome. The random effects meta-analysis was used. Heterogeneity was evaluated with I^2 statistics, publication bias with Funnel plot, Egger's and Begg's tests.

Results: The database search resulted in 8 studies with a total of 1,520 PD patients and 905 control subjects for the primary outcome and a total of 103 PD patients and 52 control subjects for the secondary outcome. Relative to the control group, the PD group has high odds ratio (OR(s)) of CI clinical diagnosis (ORs = 3.67, 95%CI [2.71, 4.95]; $P < 0.00001$). In addition, PD group showed a statistically significant increase in NPC distance using mean difference (MD) compared to the control group (MD = 4.97; 95%CI [1.33, 8.61]; $P = 0.007$). No evidence of publication bias was detected.

Conclusions: These data suggest that the PD group increased the likelihood of CI visual symptoms and increased NPC distance compared to control group. These findings indicate that regular eye exam is very important for patients with PD. In addition, patients with objective findings of CI, if symptomatic or not, may have a high risk of cognitive impairment. Eye clinicians should have a high assumption for cognitive impairment in CI patients.

TITLE: Involvement of lens in Retinoblastoma (RB)- Challenging the concept of lens immunity and proposal for lens features to be defined in classification systems

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Khetan, P. Maitra, Ocular Oncology and Vitreoretina, Sankara Nethralaya, Chennai, Tamil Nadu, INDIA|

Commercial Relationships Disclosure (Abstract): Vikas Khetan: Commercial Relationship: Code N (No Commercial Relationship) | Puja Maitra: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In Retinoblastoma (RB) the crystalline lens is believed to have hypothetic “tumorous immunity” and is usually unaffected and clear. We aim to highlight four cases of RB with lens involvement with a histopathological (HPE) correlation of the same after enucleation. We believe that lens features should be defined in classification systems of RB.

Methods: We report 4 eyes with lens involvement with RB at presentation in 4 children aged between 2 months to 2 years. 3 out of 4 children had bilateral RB. 3 out of 4 eyes had subluxation of clear lens out of which one eye also had tumor infiltrating into the lens. The mechanism of subluxation was hypothesized as secondary to ciliary staphyloma possible due to zonular stretching in one eye and zonular degradation secondary to orbital cellulitis in another, both confirmed on HPE. The subluxation was noted clinically in all 3 eyes and confirmed on imaging and HPE. 1 out of 4 cases had absent lens, also confirmed on imaging and HPE. 3 out of 4 cases received systemic chemotherapy before enucleation. All 4 eyes were ultimately diagnosed to have advanced RB, (3 out of 4 had group E tumors as per IIRC, and 1 eye had orbital RB) all requiring enucleation ultimately.

Results: 4 of 4 eyes needed Enucleation.

Unexplained anterior segment findings should raise suspicion and mass lesions must be ruled out before any planned interventions. RB presenting with a subluxated or absent lens is scarcely reported and most often the mechanisms are not clearly understood. Lens involvement may be a consequence of the clinical course of the tumor, possibly a surrogate marker suggesting advanced nature or chronicity. Visual rehabilitation is impossible in such eyes with active tumor and eye salvage is seldom possible due to advanced anatomical damage.

Conclusions: In our experience as these eyes ultimately require enucleation, we propose that lens features should be defined and considered in classification systems of retinoblastoma and lens subluxation and infiltration could be considered a feature of Group E.

TITLE:

Axial length is associated with individual differences in ON- and OFF- pattern detection

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Hogue, C.P. Taylor, Vision Science, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): William Hogue: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Taylor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The ON and OFF visual pathways have different spatial tuning and cortical connectivity. The ON and OFF pathways may play a role in emmetropization. Currently, the literature on the mechanisms that control choroidal thickness and emmetropization is, at best, immature. We measured individual differences in two detection tasks to explore the role contrast polarity plays in emmetropization.

Methods:

39 observers completed four one-hour sessions of psychophysical testing. We screened for a history of ocular disease, refractive surgery, or the use of ortho-k lenses. Refractive error was measured with a wavefront aberrometer and axial-length with an ocular biometer. Psychophysical detection and identification thresholds for two tasks were measured. The stimuli were Sloan Letters and Difference of Gaussians (DoG). The contrast polarity of the stimuli was either positive (ON) or negative (OFF). In the identification task, contrast sensitivity for the ten Sloan letters was measured. The detection task measured contrast sensitivity via a two-interval forced-choice task with a DoG stimulus as the target and a blank foil interval. Sessions consisted of either positive ON- or negative OFF- contrast on a grey background and never both. The two tasks were interleaved randomly during a single session of sub-blocks of 150 trials.

Results:

We found the ratio of OFF/ON sensitivities defined as $ONOFF_{index} = (con - coff) / (con + coff)$ increased as axial-length increased with a Difference of Gaussian (DoG) target ($r=0.41$, $P<0.01$). The lack of effect for letters is curious because we did not replicate a previous study that found an effect in an ON/OFF letter identification task ($r=-0.017$, $P=0.92$). Sensitivity decreased with axial length for all conditions. DoG ON ($r=0.33$, $P<0.05$), DoG OFF ($r=0.48$, $P<0.001$), Letters ON ($r=0.47$, $P<0.01$), Letters OFF ($r=0.41$, $P<0.01$).

Conclusions:

Natural scenes contain more information in the OFF than ON visual channels. The altered balance of OFF/ON thresholds for DoG provides a conceptual link between altered retinal ganglion cell sensitivity and the evidence that time spent outdoors slows the progression or onset of myopia.

ABSTRACT BODY:

Purpose: To determine light discomfort thresholds quantitatively using a new clinical device on a large sample of healthy adult humans, reliability and relationship with biometric and optical parameters.

Methods: A total of 489 healthy subjects with ages ranging from 20 to 70 years (241 men, 248 women), were examined with the LUMIZ™ 100 (Essilor Intl., France), a new handheld, portable, clinical device for the determination of light discomfort thresholds. Instructions were given by means of a recorded video to ensure homogeneity in the explanations. A mock-up test was carried out prior to measurement. Two thresholds, “just perceptible” and “really disturbing” discomfort, were determined for three light presentation protocols (Continuous warm, Continuous cold, and flashing warm), using two different LED sources (Warm:4000°K, and Cold:6500°K). Iris color and skin pigmentation level were classified, and subjective manifest refraction was also determined.

Results: Discomfort thresholds are well distributed across the range of intensities. Intrasection intraclass correlation coefficients were higher than 0.80 for all thresholds. First measurement was representative of the median of three. There was no effect of age on discomfort thresholds ($r^2 < 0.1$, $p = 0.30$), nor affected reliability of the measurements ($p = 0.368$). For the considered population, women have lower discomfort thresholds than men ($p < 0.001$). Subjects with high self-perceived light sensitivity tend to have lower discomfort threshold and vice versa ($p < 0.001$). No effect on discomfort thresholds was found for ametropia ($p = 0.45$), nor was any link with pupil size, axial length or wavefront aberrations in this sample. There was no significant representation of iris color or skin tone to allow for statistical significance of the effect, although a trend for green eyes to have lower thresholds was observed.

Conclusions: The new device is reliable for the clinical determination of light discomfort thresholds on healthy subjects. Nor age, refractive error, or biometric parameters seem to have an effect on discomfort thresholds. Women tend to have lower thresholds than men. The new device is useful for the quantitative determination of light discomfort in healthy subjects. Applications in diseased eyes and filter treatments are to be explored.

Commercial Relationships Disclosure (Abstract): Benjamin Meyer: Commercial Relationship: Code N (No Commercial Relationship) | Benson Chen: Commercial Relationship: Code N (No Commercial Relationship) | Amit Saindane: Commercial Relationship: Code N (No Commercial Relationship) | Beau Bruce: Commercial Relationship: Code N (No Commercial Relationship) | Nancy Newman: Commercial Relationship: Code N (No Commercial Relationship) | Valerie Biousse: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: MRI signs suggesting intracranial hypertension are common in patients with idiopathic intracranial hypertension (IIH), but are also incidentally detected in asymptomatic patients and those with primary headache syndromes, prompting neuro-ophthalmology consultations and investigations. We aimed to prospectively identify the prevalence and significance of MRI signs of intracranial hypertension (MRI-IH) in patients imaged for any clinical indication.

Methods: Prospective study evaluating 296 consecutive patients undergoing outpatient brain MRI and non-mydratic fundus photography immediately following MRI. Photographs were reviewed for papilledema and MRIs read for MRI-IH. Univariate analysis with Fisher's exact test or t-test was performed.

Results: Indications for MRI were brain neoplasm (27.7%), multiple sclerosis (MS)/MS-mimics (18.6%), seizure (17.9%), headache (8.8%), and other non-headache neurologic symptoms (19.6%). Four patients (1.4%) had known IIH. MRI-IH (N, %) included: empty sella (98, 33.1%); enlarged Meckel cave (47, 15.9%); meningocele/cephalocele (4, 1.4%); transverse venous sinus stenosis (TSS) (7/198, 3.6%); cerebellar tonsillar ectopia (4, 1.4%); scleral flattening (2, 0.7%); increased perioptic CSF (32, 10.8%); and increased optic nerve tortuosity (23, 7.8%). Overall, 51% patients exhibited no MRI-IH, 32.8% one sign, 10.8% two signs, 3.7% three signs, and 1.7% had \geq four signs. Five patients (1.7%) had definite papilledema on fundus photographs; two (0.7%) had questionable papilledema. Patients with definite papilledema had significantly increased average BMI (37.6 vs 27.5 kg/m²; P=0.038), history of IIH (40% vs 1%; P=0.001), increased optic nerve tortuosity (60% vs 7%; P=0.004), TSS (50% vs 3%; P=0.006), and \geq four MRI-IH (40% vs 1%; P=0.002), compared to patients without papilledema. Other MRI-IH were not significant, nor were having one, two, or three signs.

Conclusions: MRI-IH were encountered in almost half the patients in this prospective study of outpatients undergoing brain MRI for various clinical indications. However, definite papilledema was only detected in 1.7% patients, questioning the need to perform systematic investigations for patients with incidentally detected MRI-IH.

ABSTRACT BODY:

Purpose: Obesity and visual impairment are public health challenges worldwide. The relationship between obesity and age-related eye diseases including cataract, glaucoma, age-related macular degeneration (AMD) and diabetic retinopathy (DR) have remained elusive. This report summarizes evidence from prospective studies evaluating the associations between obesity and age-related eye diseases.

Methods: We conducted a systematic review of three electronic databases for longitudinal population-based studies on adults which described associations between measures of obesity including body mass index (BMI), waist-circumference (WC), and waist-to-hip ratio (WHR), and age-related eye diseases. Study quality was assessed using an adapted Newcastle-Ottawa Scale. We compared results between Western, non-Western and specifically Asian populations.

Results: Our search yielded 1731 articles, of which 14, 10, 16 and 8 articles met our eligibility criteria for cataract, glaucoma, AMD and DR, respectively. Obesity was assessed by BMI (n=46), WC (n=8) and WHR (n=7). BMI-defined obesity was positively associated with incident cataract, incident any AMD and incident DR in Western populations, but in Asian populations associations for incident any AMD were not significant and associations for incident DR were inverse. WC-defined obesity was associated with incident glaucoma in non-Western populations. WHR-defined obesity but not BMI-defined obesity was associated with the incidence or progression of AMD in two Western studies.

Conclusions: Overall, we found strong evidence supporting associations between obesity and age-related eye diseases, although the results vary depending on the population studied and measure of obesity used. Further research on obesity, weight loss and physical activity as risk factors for age-related eye diseases is warranted to support clinical and public health recommendations.

ABSTRACT BODY:

Purpose: Patients with neovascular age-related macular degeneration (nAMD) are currently treated with anti-vascular endothelial growth factor (anti-VEGF). However, the benefit of the anti-VEGF treatment is diminished in the long-term due to appearance of atrophy. We tested whether KNP-301, a dual inhibitor of C3b of the complement system and VEGF, could reduce the formation of choroidal neovascularization (CNV) and retinal degeneration using mouse models of nAMD and dry-AMD.

Methods: The binding kinetics of KNP-301 with C3b and VEGF165 were tested using surface plasmon resonance assay. The activation of the alternative complement pathway and the classical complement pathway was evaluated with human C1q-depleted serum and human factor B-depleted serum, respectively. Three laser lesions were executed on the right eye of C57BL/6JRj mice to induce CNV. Test compounds were administrated by intravitreal (IVT) injection (2 µl/eye) immediately after lasering. The CNV lesions were monitored using fluorescein angiography and spectral domain optical coherence tomography. NaIO₃ was injected intravenously to induce retinal degeneration in C57BL/6 mice. Test compounds were administrated by IVT injection (1.5 µl/eye). The outer nuclear layer (ONL) thickness was determined by immunofluorescent staining. The ocular pharmacokinetics (PK) of KNP-301 was determined in vitreous humor of New Zealand White Rabbits.

Results: KNP-301 demonstrated binding to both C3b (KD = 4.34 nM) and human VEGF165 (KD = 6.28 pM). KNP-301 selectively inhibited the alternative pathway in a dose-dependent manner (EC50 = 330 nM), whereas the classical pathway was not inhibited. Mice treated with either a mouse surrogate of KNP-301 (n=14) or aflibercept (n=10) had a significantly lower grading of CNV leak compared to vehicle treatment group (n=13; Fisher's exact test, p≤0.0045 for all). Moreover, mice treated with the mouse surrogate of KNP-301 (n=10) showed reduced ONL thickness compared to mice treated with vehicle control (n=10). Lastly, the half-life of KNP-301 in vitreous humor was 2.5 fold greater than aflibercept.

Conclusions: Our study showed that KNP-301 binds to C3b and VEGF, and selectively inhibits the alternative pathway of the complement system. Moreover, the mouse surrogate of KNP-301 significantly inhibits the formation of CNV and prevents retinal degeneration in mouse models of n-AMD and dry-AMD.

ABSTRACT BODY:

Purpose: Optic nerve (ONC) and chorioretinal (CRC) coloboma are associated with acquired retinal detachment. The risk during early childhood remains unclear. We determined the incidence and age at onset during childhood of acquired retinal detachment in children with coloboma.

Methods: Retrospective cohort study of children with ONC and/or CRC, examined prior to age 18 years between 2009 and 2020 at a pediatric ophthalmology outpatient clinic. Eyes with presumed congenital retinal detachment or retinal dysplasia were excluded. Primary outcomes were incidence and age at diagnosis of acquired retinal detachment.

Results: We studied 387 eyes of 258 children, median age 6.59 years (range 0.04-18 years). Colobomas were bilateral in 129 (50%) children; 288 (74.4%) eyes had ONC, 236 (61%) eyes had CRC, and 137 (35.4%) eyes had both. Among CRC, the macula and periphery were involved in 141 eyes (59.7%) and periphery only in 90 eyes (38.1%). Two eyes of two children had acquired retinal detachment at ages 7 and 14 years (0.52% per eye, 95% CI: 0.06%-1.85%), of which one eye had both ONC and CRC and both eyes had CRC involving the macula and periphery.

Conclusions: Acquired retinal detachment associated with coloboma occurs during childhood but the risk is lower than previously reported. Periodic screening fundus examinations should be performed. The utility of prophylactic laser retinopexy during childhood in eyes with ONC/CRC requires further investigation.

TITLE: Beyond BPES: A case series of non-BPES blepharophimosis syndromes

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.J. Nguyen, D. Prat, K.E. Revere, J.A. Katowitz, W. Katowitz, The Children's Hospital of Philadelphia Division of Ophthalmology, Philadelphia, Pennsylvania, UNITED STATES|B.J. Nguyen, K.E. Revere, W. Katowitz, Scheie Eye Institute, Philadelphia, Pennsylvania, UNITED STATES|A. Strong, Children's Hospital of Philadelphia Division of Human Genetics, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Brian Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Daphna Prat: Commercial Relationship: Code N (No Commercial Relationship) | Alanna Strong: Commercial Relationship: Code N (No Commercial Relationship) | Karen Revere: Commercial Relationship: Code N (No Commercial Relationship) | James Katowitz: Commercial Relationship: Code N (No Commercial Relationship) | William Katowitz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this retrospective case series was to determine the incidence of patients and describe cases with different diagnoses than Blepharophimosis-Ptoxis-Epicanthus Inversus Syndrome (BPES) initially presenting with eyelid manifestations of blepharophimosis, suspected to have BPES.

Methods: A retrospective review of consecutive cases of blepharophimosis at the Children's Hospital of Philadelphia was performed over a 12 year period (2009-2020). Genetic diagnosis was considered for the differential diagnosis of BPES: Dubowitz, Schwartz-Jampel, Marden-Walker, Ohdo Blepharophimosis, Malpuech-Michels-Mingarelli-Carnevale, Smith-Lemli-Opitz, and Koolen de Vries syndromes. (Table 1) Furthermore, any genetic mutation that included FOXL2 but was associated with adjacent mutations were included.

Results: 137 consecutive patients with blepharophimosis were identified. 9 patients (7%) were diagnosed with systemic or other syndromic disorders other than BPES. Alternative diagnoses included Dubowitz syndrome (n=2), Ohdo syndrome (n=1), 22q11.2 duplication (n=1), and 3q22 deletion (n=2) which represented FOXL2 mutations with adjacent mutations. Three patients had multiple systemic abnormalities without a definite genetic diagnosis. Genetic evaluation was critical in all cases and allowed the patients to benefit from multi-disciplinary care such as immunology, oncology, endocrinology, gastroenterology, and cardiology. The clinical and genetic characteristics reflected among these 9 patients are in Table 2.

Conclusions: Although blepharophimosis is most commonly associated with BPES, genetic investigation into other alternative syndromes is often warranted in the presence of other systemic disorders to provide comprehensive patient care to this unique pediatric population.

TITLE: Risk factors for onset or progression of posterior vitreous detachment at the vitreomacular interface after cataract surgery

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Jeon, Keye Eye Center, KOREA (THE REPUBLIC OF)

Commercial Relationships Disclosure (Abstract): Sohee Jeon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the incidence and the risk factors for onset or progression of posterior vitreous detachment (PVD) at the vitreomacular interface (VMI) after cataract surgery.

Methods: Patients with a history of phacoemulsification from April 2018 to April 2019 at the KEYE Eye Center, Seoul, Korea, and postoperative monitoring for more than 2 months were retrospectively reviewed. Cox proportional hazard ratios for the onset or development of PVD after cataract surgery in the presence of selected risk factors and demographic data were calculated. To evaluate the ocular risk factors, various ocular metrics including spherical equivalent (SE), axial length (AXL), anterior chamber depth, lens thickness, central subfield thickness, PVD status at macular and optic nerve head (ONH), peripapillary retinal nerve fiber layer thickness, and ONH parameters from optical coherent tomography (OCT) scans were used for the analysis.

Results: Among 988 eyes without PVD at baseline, 174 eyes (17.6%) showed changes in the VMI. Univariate analysis showed that age, SE, AXL, PVD status at macular and ONH, and average and vertical cup-disc ratios (CDRs) were significantly associated with the PVD onset or development ($P = .046$, $P = .004$, $P = .040$, $P < .001$, $P < .001$, $P = .008$, and $P = .042$, respectively). In a multivariate analysis, PVD status at macular and ONH, and smaller CDR were associated with PVD onset or progression after cataract surgery after adjustment of age, SE, and AXL ($P < .001$, $P < .001$ and $P = .005$, respectively).

Conclusions: The risk of PVD onset or progression was dependent on PVD status and the CDR detected on OCT scans, not on age or AXL, in a large patient cohort. Patients who show risk factors on OCT should be monitored carefully during the postoperative period.

TITLE: Pain control for corneal abrasions: a meta-analysis of six topical interventions

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Yu, D. Armstrong, D. Johnson, Queen's University, Kingston, Ontario, CANADA|A. Kirubarajan, M. Yau, University of Toronto, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Caberry Yu: Commercial Relationship: Code N (No Commercial Relationship) | Abirami Kirubarajan: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Yau: Commercial Relationship: Code N (No Commercial Relationship) | Dawn Armstrong: Commercial Relationship: Code N (No Commercial Relationship) | Davin Johnson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Highly variable practice patterns exist with regards to management of pain and discomfort from corneal abrasions. This meta-analysis was conducted to evaluate the efficacy and safety of six topical pain therapies: topical anesthetics, non-steroidal anti-inflammatory drugs (NSAIDs), cycloplegics, steroids, pressure patching, and bandage contact lens (BCL).

Methods: The protocol followed PRISMA guidelines and was published on PROSPERO. MEDLINE, EMBASE, CENTRAL, and Web of Science were searched to December 2020. Primary studies comparing topical pain therapies to other therapy or control were included. Primary outcomes included percentage of abrasions healed and pain control at 24, 48, and 72 hours. Secondary outcomes included use of oral analgesia, and incidence of complications. Risk of bias was assessed using the Cochrane guidelines and the MINORS criteria. Quality of evidence for estimates was assessed by the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) tool. Subgroup analysis was conducted for heterogeneity.

Results: Overall, 31 RCTs and 2 cohort studies (4,167 patients) were analyzed. Risk of bias was low for most studies. Topical NSAIDs showed significantly reduced pain scores at 24 hours (RR -0.69, 95% CI [-0.98, -0.41]) and 48 hours (RR -0.56, 95% CI [-1.02, -0.10]), and lower oral analgesia use (RR 0.47, 95% CI [0.33, 0.66]) compared to control (Figure 1). Topical anesthetics, cycloplegics, patching, and BCL did not result in significant reduction in pain scores or oral analgesia use, although there were limited studies of high methodological quality. No studies examined topical steroids. No intervention resulted in significant healing delays or higher complication rates compared to controls. GRADE certainty of evidence ranged from low to moderate for outcomes (Figure 2).

Conclusions: Available evidence suggests that topical NSAIDs significantly reduce pain from corneal abrasions in the first 48 hours and led to lower oral analgesia use without increased rates of complications or delays in healing. There is limited evidence to support or refute the efficacy and safety of other therapies.

Commercial Relationships Disclosure (Abstract): Joshua Canavan: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Koons: Commercial Relationship: Code N (No Commercial Relationship) | Ashraf Mahmoud: Commercial Relationship: Code N (No Commercial Relationship) | Gloria Fleming: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Roberts: Commercial Relationship(s);Oculus Optikgeräte GmbH:Code C (Consultant);Ziemer Ophthalmic Systems AG:Code C (Consultant);Optimo Medical AG:Code C (Consultant) | Phillip Yuhas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The prevalence and severity of primary open-angle glaucoma is higher and worse in Black than in Caucasian populations. The mechanism for this disparity remains unknown, but differences in ocular biomechanics between the groups may contribute. We investigated corneal and scleral stiffness responses in the eyes of healthy individuals with Sub-Saharan African (SSA), European (EUR), and mixed-race (MIX) ancestry to determine baseline biomechanical data.

Methods: Adult subjects without a history of ocular disease were recruited and categorized into SSA (n = 40 eyes, mean age \pm SD = 37.3 \pm 13.1 years, 65.00% female), EUR (n = 84 eyes, age = 34.9 \pm 14.6 years, 59.52% female), and MIX (n = 36 eyes, age = 31.7 \pm 13.4 years, 61.11% female) cohorts based on self-reporting of ancestry. For each subject, corneal hysteresis (CH) was measured using the Ocular Response Analyzer. The CorVis ST was used to measure central corneal thickness (CCT) and biomechanically corrected intraocular pressure (bIOP), as well as to derive in vivo corneal (SP-A1) and scleral (SP-HC) stiffness parameters. Additionally, intraocular pressure (IOP) was measured using Goldmann applanation tonometry (GAT) and Pascal dynamic contour tonometry (DCT). For each device, three reliable measurements were taken and averaged in both eyes. ANCOVA was used for statistical analysis with bIOP and CCT as covariates and a significance threshold of $p < 0.05$.

Results: There was no significant difference ($p > 0.05$) between cohorts for measurements of CH, SP-A1, GAT IOP, DCT IOP, bIOP, or CCT. Mean SP-HC \pm SD was 14.37 \pm 4.07 mmHg/mm in the SSA cohort, 13.86 \pm 2.73 mmHg/mm in the EUR cohort, and 14.72 \pm 3.18 mmHg/mm in the MIX cohort. When adjusted for CCT and the greater IOP in the MIX cohort, mean SP-HC was significantly higher in the SSA cohort compared to both the EUR ($p = 0.0019$) and MIX ($p = 0.0404$) cohorts.

Conclusions: Our results suggest there is greater scleral stiffness in individuals of SSA descent than in individuals of EUR and MIX descent, independent of other ocular biomechanical parameters. It is possible that higher scleral stiffness in the SSA cohort could contribute to the pathophysiology of primary open-angle glaucoma. The ramifications of this finding warrant further investigation.

ABSTRACT BODY:

Purpose: Glaucoma is the most important threat to vision after Boston keratoprosthesis (KPro) surgery. Although inflammatory cytokines are involved in glaucoma pathogenesis, their role in KPro-associated glaucoma is unknown. We performed a cross-sectional study to determine cytokine levels in the tear film of Boston keratoprosthesis (KPro) patients with and without glaucoma, relative to controls, and correlate levels with clinical parameters.

Methods: The study enrolled 58 eyes from 58 patients: 48 KPro eyes (mean age 67.2 years), including 41 with glaucoma and 7 without, and 10 healthy controls (mean age 68.0 years). Tears were collected by micropipette after saline instillation. 27 cytokines were measured by multiplex bead immunoassay. Clinical parameters assessed in all KPro eyes included intraocular pressure (IOP), cup-to-disk ratio (CDR), visual acuity, retinal nerve fiber layer, topical medications, and angle closure. Cytokine level differences between groups were analyzed by non-parametric tests, and correlations with clinical parameters by Spearman's test.

Results: Mean time from KPro to tear sampling was 7.9 ± 3.5 years. Levels of TNF- α , IL-1 β , FGF-2, IFN- γ were significantly higher in KPro with glaucoma compared to KPro without ($p=0.020$; 0.008 ; 0.043 ; 0.018 , respectively). Both KPro groups had similar characteristics, diagnoses, and topical antibiotic/steroid regimen. Levels of IL-1Ra, IL-15, VEGF, RANTES were significantly higher in KPro with glaucoma compared to controls ($p<0.001$; 0.034 ; <0.001 ; 0.001 , respectively). IL-1 β and IFN- γ levels were positively correlated with CDR ($r=0.309$, $p=0.039$ and $r=0.452$, $p=0.006$, respectively) and IOP ($r=0.292$, $p=0.047$ and $r=0.368$, $p=0.023$, respectively). TNF- α and FGF-2 levels were positively correlated with CDR ($r=0.348$, $p=0.022$ and $r=0.344$, $p=0.021$, respectively).

Conclusions: TNF- α , IL-1 β , FGF-2, IFN- γ are elevated in tear fluid of KPro patients with glaucoma and correlate with CDR and IOP. These results show, for the first time in humans, concordance with reported elevations of TNF- α and IL-1 β in murine KPro model. Ocular surface inflammation may reflect inflammatory processes of KPro glaucoma.

ABSTRACT BODY:

Purpose: Advanced glycation end products (AGEs) are toxic compounds resulting from the non-enzymatic modification of biomolecules by sugars or their metabolites. AGEs are pathologically linked to AMD and diabetic retinopathy and anti-AGEs detoxifying systems are proposed as therapeutic targets to fight pathological dysfunction associated with AGE accumulation. The primary mechanism for detoxifying the reactive intermediates of glycation is the glyoxalase system, the limiting reaction of which is the enzyme glyoxalase 1 (GLO1). Information about the glyoxalase system in ocular tissues is limited.

In this study we evaluate the role of glyoxalase system in retinal tissues and we hypothesize that high level of glyoxalase activity prevents AGE accumulation under non-stressed conditions, and thereby protects against toxicity derived from glycative stress.

Methods: We dissected retina, RPE/choroid and lens along with other non-ocular tissues from 2 month-old wild type C57BL/6J mice. We quantified the GLO1 activity in cytosolic extracts of tissues and carried out a comparative analysis. GLO1 activity was determined spectrophotometrically as the initial rate of formation of S-D-lactoylglutathione. As a positive control, a comparative analysis was also carried out in ocular tissues from transgenic mice overexpressing Glo1 on C57BL/6J (B6) background. Western blotting and immunohistochemistry, using antibodies that specifically recognize GLO1, were performed to quantify protein levels and location of GLO1 in retinal tissue.

Results: Glyoxalase activity was detected in all tissues. The relative order of GLO1 specific activity was retina> liver> kidney> brain> heart> RPE/choroid >lens. Glyoxalase activity is clearly tissue-dependent. When compared to non-ocular tissues, the retinal rate of detoxification was about 2-fold, 8.5-fold, 3.5-fold and 4.5-fold greater than liver, heart, kidney and brain, respectively. Regarding ocular tissues, neuroretinal activity was about 9-fold and 13-fold greater than in the RPE/choroid and lens, respectively. Biochemical and morphological examination of retinal tissues corroborate the highest level of GLO1 expression in neuroretina. GLO1 activity in transgenic mice overexpressing Glo1 was about 3.7-fold and 2.2-fold in retina and RPE/choroid, respectively.

Conclusions: The neuroretina has the highest level of retinal GLO1 activity, suggesting an important protective role against AGEs-derived damage in retina.

ABSTRACT BODY:

Purpose: Two Phase 3 multicenter clinical trials, RESCUE (NCT02652767) and REVERSE (NCT02652780), showed unexpected sustained bilateral improvement of best-corrected visual acuity (BCVA) following unilateral injection of rAAV2/2-ND4 gene therapy in patients with Leber hereditary optic neuropathy (LHON). In this study, we compared the treatment effect of rAAV2/2-ND4 with an external control group of untreated patients.

Methods: The treated population consisted of 76 ND4-LHON subjects injected unilaterally with rAAV2/2-ND4 in the RESCUE and REVERSE trials, of which 62 subjects enrolled in a long-term follow-up study (NCT03406104). The untreated population included a total of 208 subjects: 23 ND4-LHON subjects enrolled in the REALITY LHON Registry (NCT03295071) and 185 ND4-LHON subjects with individual patient-level data collected from 10 natural history studies in the literature. To allow for comparison with the treated population, the untreated population included only patients who were at least 15 years old at onset of vision loss. A Locally Estimated Scatterplot Smoothing (LOESS), non-parametric, local regression model was used to represent the evolution of BCVA over time. Comparison of BCVA between treated and untreated patients was performed at 12, 18, 24, 36 and 48 months after onset of vision loss.

Results: BCVA evolution in the treated patients showed gradual, progressive, and sustained improvement from Month 12 to the last available observation (on average 51.5 months), whereas no recovery was observed in the untreated patients. At Month 48, mean BCVA was 1.26 LogMAR for treated patients and 1.59 LogMAR for untreated patients, which is a difference of 0.33 LogMAR or 16.5 ETDRS letters equivalent ($p < 0.01$ for Kruskal-Wallis and repeated

measures tests).

Conclusions: This indirect comparison of 76 treated patients with an external control group of 208 untreated patients showed a clinically meaningful effect of gene therapy on visual outcomes in ND4-LHON patients.

ABSTRACT BODY:

Purpose: Central corneal thickness (CCT) measurements vary following corneal cross-linking (CXL), depending on the instruments used. We sought to explain this discrepancy by investigating the consequences of a proposed unexpected change in corneal refractive index (n_c) on Scheimpflug imaging and optical coherence tomography (OCT) measurements of CCT.

Methods: We developed two theoretical models to test the effect of a change in n_c on CCT. Our Scheimpflug model used existing equations that utilize a side viewing angle of an optical section of cornea illuminated by a central slit to predict CCT. Similarly, our OCT model used existing equations that describe optical path length (OPL) to predict CCT. Predicted CCT was calculated for a range of n_c values in both models. CCT measurement error was defined as the difference between the CCT measurement at the instrument-assumed index of 1.376 ($CCT_{1.376}$) and the predicted CCT at other indices (CCT_n). This error was plotted versus n_c to analyze the effect a change in n_c would have on predicted CCT for both models. To quantify the effect, we calculated the percent error in predicted CCT measurements and plotted it versus percent increase of n_c for both models.

Results: Our Scheimpflug model produced a positive association between predicted CCT and n_c . It also suggested a negative association between CCT measurement error ($CCT_{1.376} - CCT_n$) and n_c , which was quantified as a 0.822% reduction in CCT for every 1% increase in n_c (Fig1). In contrast, our OCT model produced a negative association between predicted CCT and n_c with a positive association between CCT measurement error and n_c , resulting in a 0.983% increase in CCT for every 1% increase in n_c (Fig2).

Conclusions: Our models suggest that an unknown increase in n_c results in underestimation of CCT from Scheimpflug-based devices, and, conversely, overestimation of CCT from OCT devices. These results suggest that a change in n_c after CXL introduces artifact in optical CCT measurement techniques. Our predictions are consistent with literature reports of CCT 2 weeks after CXL that show a 9.7 μ m increase when measured with OCT yet a 16 μ m decrease when measured by Scheimpflug (Antonios et al. 2016).

ABSTRACT BODY:

Purpose: Diabetes is a risk factor of Alzheimer's disease (AD), however data on the association between diabetic retinopathy (DR) and AD is limited. Both DR and AD may be viewed as progressive neurovascular disorders and we therefore hypothesized that DR predicts risk of AD. The present study investigates DR as a risk marker of 5-year incident AD.

Methods: We performed a register-based national cohort study, including 134,327 persons with diabetes above 60 years of age, who had attended DR screening, and 651,936 age- and gender-matched persons without diabetes. We investigated the association between DR and AD, both cross-sectionally and prospectively with data collected between 2013 and 2018. AD was defined according to the International Classification of Diseases codes G30* or F00*, as given by the Danish National Patient Registry. To evaluate the risk of present and incident AD among persons with DR, a multivariable logistic regression model and a Cox proportional hazard model were used, adjusting for age, gender, civil status, use of antihypertensive and lipid lowering medication, depression and an adjusted Charlson comorbidity index.

Results: At baseline, the prevalence of AD was 0.7% and 1.3% among persons with and without diabetes respectively. In a multivariable regression model, persons with diabetes were less likely to have AD at baseline (adjusted OR 0.63, 95% CI 0.58-0.67). During follow up, incident AD was registered in 1,454 (0.40%) and 6,796 (0.39%) persons with and without diabetes, respectively. Compared to persons without diabetes, persons with diabetes and no DR had a lower risk to develop AD (adjusted HR 0.88, 95% CI 0.82-0.94), while persons with diabetes and DR had higher risk of AD (adjusted HR 1.24, 95% CI 1.08-1.43). Still, when persons with diabetes without DR were used as references, a higher risk of incident AD was observed in persons with DR (adjusted HR 1.34, 95% CI 1.17-1.52).

Conclusions: In the present nationwide cohort study individuals with diabetes without DR were less likely to develop AD compared to persons without diabetes. However, individuals with DR had a 34% higher risk of incident AD compared to persons with diabetes without DR. Identification of risk or early detection of AD may provide the opportunity to treat modifiable risk factors to slow or prevent disease progression, or provide adequate help at an earlier stage.

ABSTRACT BODY:

Purpose: Certain systemic conditions are reported to be risk factors for dry eye disease (DED), but their associations with DED severity are not well studied. We evaluated whether systemic conditions reported to be DED risk factors are associated with the severity of DED signs and symptoms via secondary analysis of data from the DREAM Study, a large-scale multi-center randomized clinical trial of patients with moderate-to-severe DED.

Methods: 535 patients with moderate-to-severe DED from 27 US centers reported their medical history at baseline. At baseline, 6 months, and 12 months, patients were assessed for DED symptoms using the Ocular Surface Disease Index (OSDI) and for six DED signs: tear break-up time, Schirmer's test with anesthesia, corneal staining, conjunctival staining, tear osmolality, and meibomian gland dysfunction. A composite signs severity score with range 0 to 1, with 1 being most severe, was calculated from the six DED signs. We analyzed the associations of systemic conditions reported as potential DED risk factors with the severity of DED signs and symptoms using generalized linear regression models adjusted by age, sex, race, and visit. To be included, conditions had at least 25 patients.

Results: The mean±SD age was 58±13.2 years, and 81% were female. More severe DED signs were significantly associated with Sjögren's syndrome (composite mean±SD: 0.52±0.17 with disease vs. 0.43±0.13 without disease, $p<0.001$), facial rosacea (0.47±0.13 vs. 0.43±0.13, $p=0.002$), rheumatoid arthritis (0.47±0.14 vs. 0.42±0.12, $p=0.002$), peripheral artery disease (0.50±0.14 vs. 0.43±0.13, $p<0.001$), and daily smoking history (0.45±0.13 vs. 0.43±0.13, $p=0.047$) (Table 1). Thyroid dysfunction, osteoarthritis, diabetes, irritable bowel syndrome, hypercholesterolemia, hypertension, and hypertriglyceridemia were not significantly associated with DED signs. No conditions were significantly associated with OSDI (Table 2).

Conclusions: In this large, well-characterized cohort of DED patients assessed under standardized procedures, the presence of certain systemic diseases and smoking were associated with more severe DED signs. The profile of significant DED signs varied by systemic condition, reflecting different DED etiologies. Understanding the systemic conditions and underlying etiologies that predispose some patients to more severe DED can improve management.

ABSTRACT BODY:

Purpose: Patients are increasingly seeking information about treatment options for diseases including glaucoma from the internet. Sites like YouTube are easily accessible, though remain largely unregulated. This study evaluated the quality and accuracy of YouTube videos on glaucoma treatment.

Methods: A comprehensive search of “glaucoma” and “eye pressure” combined with “treatment” or “cure” was done on YouTube. To best approximate videos patients are viewing, we included only videos with at least 20,000 views and 15 views per day. Videos were excluded if they were not in English or about humans. Videos were categorized as educational, testimonial, or advert and reviewed by a two reviewers using a modified Currency, Relevance, Authority, Accuracy, and criteria. IRB exemption was obtained from Yale University.

Results: Overall, 61 videos met the inclusion criteria and 36 were excluded (30 because of language). Of those included, 80% were educational, 13% were testimonials, and 7% were adverts. The inter-rater reliability was acceptable after kappa values were calculated. 28% of videos were graded as misinformation or misleading. Average scores for each category are shown in Table 1. Audio and video quality scores were similar between categories. Higher accuracy and comprehensiveness scores were seen for educational videos. Although 64% of videos addressed the question of what is glaucoma, less than 50% discussed the course of untreated disease or the goals of treatment and only 8.2% discussed the risks of the proposed treatment options.

Conclusions: Patients are increasingly using YouTube for medical information. This study found that many videos lack useful information and some actually provide information that may be detrimental. Physicians should be aware of this risk and educate patients appropriately.

TITLE: A Smartphone-Based Application to Support Recovery from Retinal Detachment Repair

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Diaz, A. Kunkler, L.J. Haddock, J. Townsend, H.W. Flynn, Bascom Palmer Eye Institute, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Danny Diaz: Commercial Relationship: Code N (No Commercial Relationship) | Anne Kunkler: Commercial Relationship: Code N (No Commercial Relationship) | Luis Haddock: Commercial Relationship: Code N (No Commercial Relationship) | Justin Townsend: Commercial Relationship: Code N (No Commercial Relationship) | Harry Flynn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the design and development of a novel smartphone-based application aimed at helping patients maintain correct post-operative head positioning following retinal detachment repair.

Methods: An application to assist patients in recovering from retinal detachment repair was developed for the iPhone (Apple, Cupertino, CA) operating system (iOS). The application was written using the Swift programming language within the Xcode developer toolset and iOS software development kit (SDK). The Core Motion framework as part of the iOS SDK was utilized in order to capture motion- and environment-related data from onboard sensors (i.e gyroscope and accelerometer) on the iOS device. An algorithm was developed that processed and saved raw motion-related data including device orientation in three-dimensional space. The gyroscopic data is processed prior to use in order to remove bias from other factors, such as gravity. This user-initiated and refined data is then used to guide patients into the correct head position for optimal recovery.

Results: This user-friendly smartphone application consists of tutorial as well as physician and patient specific sections. Within the physician tab the provider is allowed to set the desired postoperative head position by moving the smartphone in three-dimensional space. The obtained gyroscopic positional data (primarily in the Z and X axes) is then parsed and translated into a series of stepwise instructions for patients to follow. By accurately following the outlined steps, patients can reliably be redirected into the desired position.

Conclusions: Correct post-operative positioning following retinal detachment repair facilitates recovery. The ability to precisely and accurately save the desired postoperative head position allows patients and providers previously unavailable control over recovery following retinal detachment repair. Smartphone-based mobile ophthalmic applications are increasingly being developed and, if evidence-based, are poised to offer tremendous clinical value in daily practice. Clinical studies aimed at validating the reliability and utility of this application in retinal detachment repair are underway.

TITLE: Electroretinography (ERG) Amplitude Changes in A Rat Retinal Ischemia Model

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Zhong, Ocular, Toxikon Corporation, BEDFORD, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lichun Zhong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To demonstrate the functional changes of the retina monitored by ERG in a rat retinal ischemia model, which is for screening new therapies of retinal degeneration.

Methods: 12 Brown Norway male rats were randomized by body weight into 2 groups, 6 animals per group. After animals were sedated on Day 0, lateral conjunctival peritomy and disinsertion of the lateral rectus muscle were performed on the right eye per animal in Group 2 and the optic nerve sheath was exposed by blunt dissection and ligated with a 6-0 nylon suture until retinal vessel blood flow ceases (ischemia), as visualized by the operating microscope. After 60 minutes, the suture was removed. The same procedure was performed on the right eyes in Group 1 without ligation of the optic nerve sheath. The left eyes in all groups had no procedure and as the contralateral eyes. On Day 28, Dark and Light adapted ERG was performed on both eyes at all eyes at all animals.

Results: In the Group 2, the mean b-wave of 32.61 (μV) in the right eyes was reduced compared to 155.27(μV) in the left eyes in the Dark Rod Response; the mean b-wave of 45.57 (μV) in the right eyes was reduced compared to 238.80 (μV) in the left eyes in the Dark Maximal Response; the mean Peak-wave of 12.66 (μV) and the mean Trough-wave of -7.29 (μV) in the right eyes were reduced compared to 88.64 (μV) and -35.54 (μV), respectively, in the left eyes in the Dark Oscillatory Potential; the mean b-wave of 23.66 (μV) in the right eyes was reduced compared to 129.47 (μV) in the left eyes in the Light Single White Flash; and the mean Peak-wave of 4.82 (μV) in the right eyes was reduced compared to 22.70 (μV) in the left eyes in the Light 30 Hz Flicker. In the right eyes, the mean b-wave of 32.61 (μV) in Group 2 was reduced compared to 172.12 (μV) in Group 1 in the Dark Rod Response; the mean Peak-wave 12.66 (μV) in Group 2 was reduced compared to 62.09 (μV) in Group 1 in the Dark Oscillatory Potential; the mean b-wave of 23.66 (μV) in Group 2 was reduced compared to 92.43 (μV) in Group 1 in the Light Single White Flash; and the mean Peak-wave of 4.82 (μV) in Group 2 was reduced compared to 22.68 (μV) in Group 1 in the Light 30 Hz Flicker.

Conclusions: The ERG Amplitude Changes indicated that the ischemia procedure caused damage of the retinal cells and resulted in the retinal disfunction.

ABSTRACT BODY:

Purpose: To investigate the association between time of occurrence of intraocular pressure (IOP) peaks during the water drinking test (WDT) and the level of visual field damage in a cohort of primary open-angle glaucoma patients.

Methods: Medical records of 98 eyes from 49 consecutive primary open-angle glaucoma patients followed in a referral clinical practice were included in the study. The relationship between the time when IOP peaks occurred during the WDT and the visual field mean deviation (MD) assessed with 24-2 visual field was tested with mixed-effects linear regression models. The within-patient analysis was performed in patients with asymmetric visual fields (>3dB difference), using a binomial probability test.

Results: The time IOP peaks occurred was significantly associated with the MD value when adjusting for the number of medications in the cohort ($P<0.01$), but not between eyes of the same patient ($P=0.89$). The higher the IOP peaks and the later they occurred (interaction, IOP x Time) was also statistically significant both between ($P<0.01$) and within patients ($P<0.01$). No significant association was found between IOP peak values alone and visual field severity between patients ($P=0.07$), but it was significant within patients ($P<0.01$).

Conclusions: The time of occurrence of IOP peaks measured during the WDT was associated with glaucoma severity among treated primary open angle glaucoma patients. Both magnitude and time of peak should be taken into account when performing this stress test.

ABSTRACT BODY:

Purpose: Adrenomedullin-2 (AM2) (or intermedin), a member of the calcitonin gene-related peptide family, is a peptide which possesses a variety of physiological functions. Previously, we reported the therapeutic possibility of intravitreal injection of AM2 by using laser-induced choroidal neovascularization model (LI-CNV) and oxygen-induced retinopathy model (OIR) in mice (ARVO 2020). In the present study, we further investigated the pathophysiological roles of AM2 in ocular neovascularization by systemic administration of AM2 in mice and using AM2 knockout mice (AM2^{-/-}).

Methods: Wild-type mice (WT) were subjected to LI-CNV and the effect of systemic administration of AM2 using osmotic pump was investigated. Next, we established AM2 knockout mice (AM2^{-/-}) by genome editing. LI-CNV was compared between AM2^{-/-} and WT. To establish OIR, 7-day-old (P7) neonatal mice were subjected to hyperoxia (75% oxygen) for 5 days and returned to room air from P12 to 17. OIR was compared between AM2^{-/-} and WT.

Results: In LI-CNV, AM2-administration significantly reduced the CNV area and α SMA immunostaining-positive fibrosis area, and significantly suppressed the expression of genes encoding VEGF-A, VEGF-R2, CD68, CTGF, and p22phox in the choroid. Contrary to AM2-administration, CNV area and fibrosis area were increased in AM2^{-/-}. No apparent difference was observed in the retinal vessels of P7 and P12 between WT and AM2^{-/-}. There was no difference in the pathogenic angiogenic area of P17, however, the avascular area was reduced in AM2^{-/-} compared to WT.

Conclusions: AM2 is expected as a therapeutic target of ocular neovascular diseases. AM2 may affect both retinal and choroidal neovascularization, but the effect may be more pronounced in the choroidal neovascularization.

TITLE: Comparison of Optic Nerve Sheath Material Properties in male and female rhesus macaque

SESSION TITLE: Optic Neuropathies - Pathophysiology and Therapies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Dattilo, C.R. Ethier, Ophthalmology, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|M. Dattilo, D. Brown, C.R. Ethier, Biomedical Engineering, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Dattilo: Commercial Relationship: Code N (No Commercial Relationship) | Dillon Brown: Commercial Relationship: Code N (No Commercial Relationship) | C Ethier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although optic nerve sheath (ONS) changes have been described in several ophthalmic disorders, such as idiopathic intracranial hypertension (IIH), ONS biomechanical properties remain poorly understood, particularly in humans. Recently, inverse finite element modeling (iFEM) of human ONS has estimated that males have stiffer ONSs than females. Although several prior studies have described ONS biomechanical properties, the effect of gender was not assessed in those studies.

Methods: In preparation for testing human tissue, the ONS from one male and one female rhesus macaque (rONS) was dissected from the ON and placed in 1X PBS. A cylindrical sample of rONS (1 mm diameter), obtained using a biopsy punch, was placed on a MicroTester platform (CellScale, Ontario, Canada) in a temperature-controlled fluid bath (PBS at 37°C). Samples were pre-loaded with a compressive tare load of 500 uN, allowed to equilibrate, and then subjected to a 3-step stress relaxation protocol (5-15% compressive strain). Data from each step were analyzed independently using poroelastic theory to determine rONS through-plane compressive modulus and in-plane tensile modulus.

Results: Female rONS compressive modulus was 4.7 kPa at 5% strain and increased to 8.8 kPa at 15% strain; tensile modulus was 35.1 kPa at 5% strain and increased to 116.9 kPa at 15% strain. Male rONS compressive modulus was 11.5 kPa at 5% strain and increased to 13.6 kPa at 15% strain; tensile modulus was 78.9 kPa at 5% strain and increased to 237.6 kPa at 15% strain.

Conclusions: Female rONS showed lower compressive and tensile moduli compared to male rONS, consistent with recently published iFEM data in humans. Although based on small sample numbers, this data suggests that human ONS biomechanical properties may also exhibit a gender difference. Further understanding of this difference may provide insights into the pathophysiology of IIH and may lead to the development of novel IIH treatments.

ABSTRACT BODY:

Purpose: The purpose of this study was to preliminarily determine the safety and efficacy of Direct Selective Laser Trabeculoplasty (DSLTL) applied automatically without a gonioscope at various energies to the limbus overlying the trabecular meshwork in lowering intra ocular pressure (IOP) in open angle glaucoma (OAG).

Methods: Fifteen eyes of 15 patients (1 eye with exfoliative glaucoma, 4 with normal tension glaucoma and 10 with OAG) were treated by the DSLTL device. The mean age was 66.2 ± 8.2 years and 66% were males. Pre-medicated patients were washed out from their glaucoma medications for two weeks. The DSLTL treatment included 100-120 sequential non-contact 532 nm, Q-switched laser shots applied automatically directly on the limbus using image analysis of the limbus location and an eye tracking system monitoring both eye and laser beam location. Before each laser was spot was applied, multiple safety checks were automatically performed. Laser energies between 0.8 to 1.4 mJ/shot were used. The total duration of the irradiation was 2.3 seconds.

Results: In the six patients who were treated with 1.0 mJ/shot, the IOP was reduced from a baseline of 26.8 ± 2.0 mmHg by $26.6 \pm 15.1\%$, $18.8 \pm 11.5\%$ & $16.2 \pm 23.5\%$ at 1 month, 3 months & 6 months respectively.

In the six patients treated with 1.4 mJ/shot, the equivalent IOP percent reduction from a baseline of 26.7 ± 3.2 mmHg was $20.6 \pm 11.7\%$, $25.6 \pm 12.9\%$ & $26.9 \pm 7.1\%$ respectively.

One case of transient reduction in visual acuity and four cases of minor sub-conjunctival hemorrhages occurred. All side effects resolved spontaneously without sequelae within one day to one week. There were no serious adverse events.

Conclusions: This early experience shows the automated non-contact rapid DSLTL as a promising new modality in the treatment of POAG. Higher energy gave better-sustained results. Randomized Controlled studies with more patients are being conducted in order to validate these initial results in POAG patients

Hertle, Summa Health System, Akron, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Richard Hertle: Commercial Relationship: Code N (No Commercial Relationship) | Ferhat Evliyaoglu: Commercial Relationship: Code N (No Commercial Relationship) | Bayley McRitchie: Commercial Relationship: Code N (No Commercial Relationship) | Ana Juric De Paula: Commercial Relationship: Code N (No Commercial Relationship) | Isabella Ricker: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the demographic and clinical characteristics of a large, international cohort of childhood patients with nystagmus.

Methods: This is a prospective, cohort analysis of demographic and clinical characteristics in 600 patients with nystagmus in infancy and childhood. Data collected included: 1) demography, 2) nystagmus type, 3) clinical characteristics, 4) associated ophthalmic conditions, 5) associated non-ophthalmic conditions, 6) special testing findings and 7) treatments.

Results: Between 2010-20 1,774 patients from 35 states and 26 countries with nystagmus were evaluated at Akron Children's Hospital. We are reporting on 600 infants and children (<18 years of age) whose data were collected prospectively as part of an IRB approved registry. Age ranged from birth to 18 yrs (mean 15.2 yrs), 58% were female, 35% were other than Caucasian, 75% had infantile nystagmus syndrome, 18% had acquired nystagmus, 6% had fusion maldevelopment nystagmus syndrome, 81% had strabismus, 52% had an anomalous head posture, 92% had a significant refractive error, 74% of patients had an associated ophthalmic abnormality (excluding ametropia), 63% had an associated systemic condition (most commonly albinism 35%). Targeted, genetic testing for inherited eye disease was positive in 76 of 156 (49%) tested patients. Special testing showed abnormalities of electrophysiological testing and/or imaging (other than eye movement recordings (EMR), in 67%. EMR's were an essential part of classifying nystagmus types and clearly differentiated infantile from acquired forms of nystagmus as well as characterizing (a) periodicity and gaze, monocular and vergence changes. Optical, medical or surgical treatments were performed together or in part in 95% of patients.

Conclusions: The prevalence of nystagmus in the general population is estimated to be 24/10,000 and in infancy 14/10,000. Although nystagmus can result from a variety of conditions, eye movement recordings provide a path towards accurate diagnosis and classification. There is a high prevalence of underlying genetic, ocular and/or systemic conditions requiring special testing as part of a diagnostic routine. Clinical treatments are available and of benefit to the vast majority of patients.

ABSTRACT BODY:

Purpose: Ahmed glaucoma valve (AGV) implant placement in conjunction with pan retinal photocoagulation (PRP) is frequently used in the management of neovascular glaucoma (NVG). AGV can be placed either in the pars plana (PP) or anterior chamber (AC). PRP can be performed in the office or intraoperatively with pars plana vitrectomy (PPV). This study compared the outcomes between PP AGV with PPV and endolaser (EL) versus AC AGV with in office PRP.

Methods: This is a retrospective study that investigated all AGV implants in patients with NVG at the University of Rochester Medical Center between 1/2010 and 1/2020. We performed a chart review to compare the outcomes between patients who underwent AGV in the setting of NVG: group 1 (PP AGV + PPV/EL) and group 2 (AC AGV + PRP). The outcome measures were intraocular pressure (IOP, mmHg) and visual acuity (VA, LogMar). The change in IOP and VA between these two groups, adjusted for preoperative lens status, was compared at 6-month and 1-year intervals using the analysis of variance.

Results: Both groups consisted of 15 subject eyes at baseline. Eleven (73%) eyes were pseudophakic in group 1 while 3 (20%) eyes were pseudophakic in group 2. The mean baseline IOP (38.6 ± 6.6 vs. 43.0 ± 8.9 mmHg) and VA (1.4 ± 0.7 vs. 1.3 ± 0.8 LogMar) were similar between groups 1 and 2. The adjusted change in IOP between groups 1 and 2 was not statistically significant at 6 months (-20.5 ± 6.1 vs. -25.6 ± 9.5 mmHg, $p = 0.11$) and 1 year (-23.8 ± 10.3 vs. -27.9 ± 11.0 mmHg, $p = 0.38$). The adjusted change in VA between groups 1 and 2 was also not statistically significant at 6 months (-0.04 ± 0.60 vs. -0.28 ± 0.66 LogMar, $p = 0.32$) and 1 year (0.12 ± 0.68 vs. -0.40 ± 0.72 LogMar, $p = 0.10$). In group 1, 2 eyes had foveal macular edema, 1 developed a retinal detachment, and 1 had rapid cataract progression. In group 2, 1 eye required a tube revision, 1 required further transscleral laser therapy, and 2 had cataract surgery.

Conclusions: PP AGV + PPV/EL and AC AGV + PRP were both effective in lowering IOP, and there was no significant difference between them. There was a trend toward better VA at 1 year in group 2, but this was not statistically significant. A prospective study and larger sample size is needed to address this question and further evaluate the outcomes of both treatment modalities.

ABSTRACT BODY:

Purpose: The dynamic course of sulfur mustard (SM) induced ocular insult is characterized by an acute phase, which may be continued to a chronic phase or a quiescent period followed by a late pathology. The aim of this study was to evaluate the efficacy of ziv-aflibercept (Zaltrap) or aflibercept (Eylea) in preventing or ameliorating the corneal insult specifically the late phase induced neovascularization following ocular exposure to SM in the rabbit model.

Methods: Chemical SM burn was induced in the right eyes of NZW rabbits by vapor exposure. Zaltrap (2mg) was applied once by subconjunctival injection at 2h, 9 days or at 4 weeks post exposure. Eylea (2mg), the ocular specific preparation, was administered 4 weeks post SM exposure and following an initial one week treatment with 0.1% dexamethasone.

Non-treated exposed eyes served as controls. A clinical follow-up was performed for up-to 5-12 weeks following exposure and digital photographs of the cornea were taken for measurement of blood vessel length using an image analysis software. Eyes were taken for histological evaluation and extent of NV was determined by using H&E and Masson Trichrome staining.

Results: A single subconjunctival treatment of VEGF-trap 2h or 9 days post exposure presented a slight benefit in reducing the severity of the injury and in postponing the late induced NV growth. However in the group receiving treatment at 4 weeks following exposure, a significant reduced extent of existing NV was already seen at one week following injection, an effect which lasted for at least 8 weeks. The extensive reduction in existing corneal NV in the VEGF-trap treated group was confirmed by histological evaluation. Finally, eyes receiving the steroidal treatment during the first week and the ocular preparation of VEGF-trap following NV detection presented a significant reduction in corneal NV as compared to the steroid only treated group.

Conclusions: Subconjunctival Zaltrap or the combination of dexamethasone followed by Eylea treatment presented a long-term significant benefit in corneal NV reduction following ocular chemical exposure when used against existing NV rather than as a post exposure prophylactic treatment. These findings show the robust anti-angiogenic efficacy of both Eylea and Zaltrap and demonstrate the advantage of this treatment, in ameliorating corneal NV and protecting the ocular surface.

ABSTRACT BODY:

Purpose: Stable positioning of an intraocular lens (IOL) in the capsular bag following cataract surgery is important for successful visual outcomes. Wound-healing events modify the capsular bag and can affect IOL stability. We therefore conducted a study to assess IOL/capsular bag interactions in a human in vitro capsular bag model over a three-month experimental period.

Methods: Capsulorhexis and lens extraction performed on human donor eyes generated suspended capsular bags (5 match-paired experiments). Preparations were secured by pinning the ciliary body to a silicone ring and maintained in 6 mL of medium for 84 days: days 1–3, 5% human serum and 10 ng/mL transforming growth factor β (TGF β 2); days 4–7, 2% human serum and 1 ng/mL TGF β 2; days 8–14, 1% human serum and 0.1 ng/mL TGF β 2; days 15–84, serum-free EMEM. A CT LUCIA 611PY IOL was implanted in all preparations. Quantitative measures were determined from whole bag images captured weekly. Images were registered and analysed in ImageJ to determine capsular bag area; distortion; angle of contact; and a fusion footprint associated with connection between the anterior and posterior capsules.

Results: Following surgery and IOL implantation, capsular bags appeared distorted, such that a long axis formed between the haptics relative to the non-haptic regions (short axis). The angle of contact between the haptics and the bag periphery inversely correlated to capsular bag area. Growth on the peripheral posterior capsule was observed 1 week after surgery and behind the IOL within 1 month. As coverage of the posterior capsule progressed matrix contraction/wrinkles were observed. Fusion footprints formed in non-haptic regions of the peripheral bag. Refractive structures formed in fusion footprint regions in the latter months of culture. Over time, the capsular bag area reduced, while the long/short axis ratio and angle of contact increased. End-point analysis revealed strong interaction between the CT LUCIA 611PY optic edge and the capsule. An indent in the posterior capsule was evident and cell density was greater peripheral to this mark.

Conclusions: The three-month graded model presents features of fibrotic and regenerative posterior capsule opacification and allows IOL/capsular bag interactions to be quantified and compared over time. The CT LUCIA 611PY IOL is stable within the bag and exhibits a strong optic barrier effect.

TITLE: Spectral Properties of Glare or Positive Dysphotopsia for Different Types of Intraocular Lenses

SESSION TITLE: Aspects of Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Das, Alcon Laboratories Inc, Fort Worth, Texas, UNITED STATES|A. Kalapala, The University of Texas at Arlington College of Engineering, Arlington, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kamal Das: Commercial Relationship(s);Alcon Research Ltd:Code E (Employment) | Akhil Kalapala: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The wavelength dependence of positive dysphotopsia (PD) or glare due to light emitting diodes (LEDs) for intraocular lenses (IOLs) has not been found in the literature. The increased prevalence of LED light sources introduces new concerns for the spectral effects of PD or glare for IOLs. This study compares the glare for four commercially available IOL models with different material types and design features using an optical bench with LED sources.

Methods: Four separate monofocal IOL models (Alcon Clareon CNA0T0, Alcon AcrySof SN60WF, JNJ Tecnis ZCB00, and Hoya Vivinex XY1) of mid-diopter power were used to measure PD or glare-type photic phenomenon. Three LED sources of 480 nm, 555 nm and 640 nm wavelengths and a white light source were used for over a range of off-axis angles of illumination at 5 mm pupil to measure the glare from each IOL. Non-sequential ray trace simulation analysis and Fresnel based reflection and transmission coefficients were obtained to characterize the off-axis glare for these IOLs.

Results: For any given off-axis angle of incidence, the reflection and transmission properties of IOL glare may change as a function of wavelength. Both the measured reflected and transmitted glare for ZCB00 and XY1 are higher than CNA0T0 and SN60WF for white light and at 480, 555 and 640 nm from LEDs. While the transmitted reflection angle theoretically decreases with increasing wavelength, the transmitted glare for ZCB00 and XY1 increases when increasing the wavelength. This is explained by optical properties of the Fresnel reflection and transmission coefficients.

Conclusions: This is the first reported study that evaluates the wavelength dependence of PD or glare type photic phenomenon in IOLs. The reflected glare decreases with wavelength, while transmitted glare, which is an order of magnitude higher than the reflected glare, increases with wavelength. The measured reflected and transmitted glare spectra are observed to be in close agreement with Fresnel's equations. Both the transmitted and reflected glare for Clareon CNA0T0 and AcrySof SN60WF resulting from white light and at 480, 555 and 640 nm LEDs are lower compared to Tecnis ZCB00 and Vivinex XY1 IOLs.

ABSTRACT BODY:

Purpose: To determine the efficacy and complications of the Susanna glaucoma drainage device (SGDD) implant in refractory glaucoma.

Methods: Retrospective study. Medical records from consecutive glaucoma patients followed in a private clinical practice were included in the study. All patients that had undergone SGDD implant surgery from the period of September 2016 to July 2019 were included. All surgeries were done by the same surgeon (RSJ). Primary outcome was surgical failure, defined as IOP>18 mmHg and/or less than 20% IOP reduction from baseline, IOP less than 5 mmHg, reoperation for glaucoma need of implant removal or loss of light perception vision. Secondary outcomes included mean IOP, use of supplemental medical therapy, and complications.

Results: 22 eyes were analyzed. Mean patient age was 63 ± 15 (range: 27 to 87) years. Mean IOP decreased from 23 ± 7 mmHg to 11 ± 8 mmHg ($P<0.001$, paired t-test) at an average of 18 ± 9 months after the tube implant. The mean SD number of glaucoma medications was reduced from 3.3 ± 1 to 1.5 ± 1.2 at the last postoperative visit ($P<0.01$, paired t-test). No early postoperative complications occurred. There was one case of persistent hypotony that was solved with tube ligation. Failure due to high IOP occurred in two cases. There was no extrusion or erosion of the tube or the plate.

Conclusions: The SGDD presented a 13.6% failure rate with very few complications, being an efficient and safe alternative for refractory glaucoma.

ABSTRACT BODY:

Purpose: The majority of ocular pathologies seen in patients with diabetic retinopathy are a result of damage to the retinal vasculature, which leads to microaneurysms, hemorrhage, and eventually neovascularization. The first step in the pathogenesis of these conditions is derived from the loss of Human Retinal Pericytes (HRPs), which are cells essential to the preservation of the integrity of the retinal vasculature. Platelet-derived growth factor BB (PDGF-BB) is the primary promotor of growth and recruitment for HRPs.

Patients with non-proliferative diabetic retinopathy (NPDR) produce lower levels of PDGF-BB than in normal conditions, which could contribute to the loss of pericytes early in diabetic retinopathy. The purpose of this study is to evaluate the effect of PDGF-BB on HRPs in vitro to determine whether or not the longevity of the HRPs can be preserved with the intent of contributing to development of therapeutic interventions for patients with diabetic retinopathy.

Methods: Three groups of HRPs were treated with three different concentrations of PDGF-BB which correlate to concentrations found in patients with proliferative diabetic retinopathy (PDR), NPDR, and normal conditions. The control group was not treated. After 24 and 48 hours the viable cells were counted by tripan blue measurements. The results were reported by evaluating viable cells at 24 and 48 hours, growth of each group between these time periods, and significant growth differences between groups at each time period. Each group was grown in triplicates and an average from these triplicates was used during analysis.

Results: Pertaining to viability, the NPDR group was the only one with a significant result at 24 hours. Growth difference analysis was significant for the PDR group at the 24-hour period. Growth difference between all groups was significant at the 24 hours mark but not at 48.

Conclusions: Significant results were only seen at the 24 hours period which is thought to be a result of the well space not being large enough to accommodate growth beyond the 24-hour time frame. The finding of a statistically significant difference at 24 hours but not 48 hours further suggests this as a possible complication as well. That being said, significant growth difference was seen with the PDR group, which was treated with high levels of PDGF-BB. This finding is consistent with the hypothesis that PDGF-BB levels encourage the growth of HRP cells.

ABSTRACT BODY:

Purpose: Characterize the differences in conjunctival microbiome profiles based on two minor variations in a standard next generation sequencing (NGS) library preparation technique to facilitate production of 16S rRNA metagenomics data from extremely low yield specimens. Results were analyzed with three different 16S bioinformatics pipelines. In addition, DNA shotgun sequencing was also performed and results were compared with the 16S analysis.

Methods: Seven subjects were enrolled. Conjunctival samples were taken bilaterally and combined into a single vial with DNA preservative for sequencing. After extraction, the DNA yield was insufficient for typical 16S rRNA NGS processing according to standard protocols. Given the low DNA yield, the 16S rRNA library preparation was altered to enable analysis of the specimens. Two separate methods were tried, and both produced metagenomics profiles for all of the samples. One involved following the library prep protocol as directed with the modification of loading as much sample possible even when no DNA was detected. The second involved an additional round of index PCR with the products from the first round utilized in the second so that sufficient DNA for preparation of the NGS library for sequencing was produced.

Results: The additional round of PCR produced an average of over 500,000 reads per sample but required removal of contaminant taxa based on results from the negative control. Without the additional round of PCR contaminant taxa was far less prevalent in the negative control but there was only an average of a little over 12,000 reads per sample. Both 16S methods and all three bioinformatics pipelines utilized produced similar results. Shotgun sequencing results correlated to the extent expected with the 16S results.

Conclusions: There was very little variability between the different 16S sequencing techniques in regards to the most common bacteria. Even though there were only subtle differences in the 16S metagenomics profiles of the specimens, additional studies are needed before definitive recommendations regarding the use of a second round of PCR to increase read or utilizing the costlier shotgun sequencing approach provides an optimal assessment of the ocular surface microbiome.

Commercial Relationships Disclosure (Abstract): john yan: Commercial Relationship: Code N (No Commercial Relationship) | Aditya Uppuluri: Commercial Relationship: Code N (No Commercial Relationship) | Marco Zarbin: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze trends in ocular injuries related to usage of welding equipment from 2010 to 2019.

Methods: Using the Consumer Product Safety Commission's National Electronic Injury Surveillance System (NEISS) Database, we queried data from January 1st 2010 to December 31st 2019 using the corresponding product code for welding equipment (896). Results were stratified by year, and standard descriptive statistical methods were applied to components including gender, age, diagnoses, and ED disposition. Circumstances leading up to the injuries were reviewed as well.

Results: Between 2010 and 2019, NEISS estimated a total of 109,127 welding-associated ocular injuries in the United States (95% CI, 86937-131316). The estimates show a decreasing trend in cases from 13,415 (95% CI, 9979-16851) in 2010 to 6,944 (95% CI, 4868-9020) in 2019. The overwhelming majority of cases occurred in men (98.2%) and predominantly in the 10-49 year age range (83.8%). Overall, 3.3% of cases involved spectators. The top three ocular injury diagnoses were flash burns from welding arc UV radiation emissions (62.1%), foreign body implantation (19.6%), and contusions/abrasions (11.1%). Notably, the number of radiation injuries trended down from 9,286 (69.2% of injuries) in 2010 to 4023 (27.9% of injuries) in 2019 while injuries due to foreign bodies did not show a clear trend. 16.2% of patients diagnosed with foreign body injury reported using protective eyewear, while 15.3% of patients with radiation burn injuries reported wearing eye protection. Interestingly, 44.2% of welding-associated ocular injuries involved both eyes. Radiation injury contributed to 90.1% of cases with bilateral injury, while a majority of unilateral injuries were due to foreign bodies. With respect to a documented location, 38.9% occurred at home and 4.5% occurred in a school setting. Most patients (99.9%) were treated in the emergency department and discharged; only 0.1% were admitted to the hospital for further management. No open globe injuries were reported.

Conclusions: The data suggests that number of ocular injuries related to welding has decreased significantly over the past 10 years. The most common injuries were radiation burns, foreign body disruption, and contusions/abrasions of the eye. Patients were predominantly men and between the ages of 10 and 49. Of note, almost half of all ocular injuries due to welding were bilateral, and 3% of ocular injuries were seen in spectators.

ABSTRACT BODY:

Purpose: Shock is defined as the progression of organ disorder ; however, the evaluation method has not been established. We tested the hypothesis that ocular blood flow reflects the systemic organ blood flow, such as that in the kidneys and intestines, using an experimental rabbit model of hemorrhagic shock.

Methods: We used ten New Zealand white rabbits and administered general anesthesia. A catheter was placed in the brachial artery to measure their mean arterial blood pressure (MAP). Blood flow in the intestines and kidneys was measured using an ultrasonic blood flow meter at the mesenteric artery and the renal artery exposed on laparotomy. For the measurement of ocular blood flow, laser speckle flowgraphy that can evaluate the ocular blood flow non-invasively, was used. The mean blur rate (MBR) that is a blood flow index specific to laser speckle flowgraphy, was measured in the retinal vessels (RV) and choroid (CH). To create a shock state, blood was removed at a rate of 1 mL/min for 30 min. After an observation time of 20 min, blood was returned over a period of 15 min. Each parameter was evaluated as per the rate of change from the reference value before blood removal.

Results: MBR in RV and CH, intestinal and renal blood flow, and MAP were significantly decreased by the blood removal operation and recovered nearly to the reference value by the blood return operation. The rate of change at the end of blood removal was MAP, 69.4%; kidney, 43.5%; intestine, 54.8%; MBR-RV, 42.3%; and MBR-CH, 55.5%. The rates of change between MBR-RV and kidney and between MBR-CH and intestine were similar, and no significant difference was observed. MBR-RV and MBR-CH showed a significant positive correlation with MAP ($r = 0.87, 0.73$), with renal blood flow($r = 0.66, 0.59$) and with intestinal blood flow($r = 0.84, 0.61$).

Conclusions: Ocular blood flow reflected the renal and intestinal blood flow during the progression and recovery of hemorrhagic shock in white rabbits.

TITLE: The contribution of axonal cytoskeleton to retinal nerve fiber layer reflectance

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Huang, Y.Z. Spector, W. Kong, Bascom Palmer Eye Institute, University of Miami School of Medicine, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Xiang-Run Huang: Commercial Relationship: Code N (No Commercial Relationship) | Ye Spector: Commercial Relationship: Code N (No Commercial Relationship) | Wei Kong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal nerve fiber layer (RNFL) reflectance is often assessed in clinical diagnosis of glaucoma. This study investigated the relationships between RNFL reflectance and axonal cytoskeleton, including microtubules (MTs), F-actin and neurofilaments (NFs).

Methods: Whole-mounted rat retinas were imaged at 500 nm by means of imaging reflectometry. Reflectance (R) of nerve fiber bundles was measured in normal retinas and retinas treated with colchicine. After the measurements, retinas were fixed for immunohistological staining. Confocal images were used to measure bundle thickness (T) and count the strings of MTs, F-actin and NFs within bundles (Fig. 1A-C). Reflectance per unit thickness ($\sigma = R/T$) and string density (d) were calculated.

Results: In normal RNFL, σ was correlated with d_{MT} ($r = 0.85$) and $d_{F-actin}$ ($r = 0.53$) but not d_{NF} ($r = 0.03$) (Fig. 1D-F). By assuming incoherent scattering of cytostructure, linear regression was used to describe the relationship between d and σ . The σ -intercept for d_{MT} vs. σ was 0.046 (%/ μm) which was 66% of the mean σ of normal bundles. The σ -intercept for $d_{F-actin}$ vs. σ was 0.055 (%/ μm) or 81% of the mean. In colchicine treated retinas σ , d_{MT} and $d_{F-actin}$ decreased significantly ($p < 0.001$); however, d_{NF} did not change ($p = 0.08$). The mean σ was reduced to 0.043 (%/ μm) which was a 38% reduction from the normal σ . With the linear model for d_{MT} (Fig. 1D), the reduction was estimated to contain a 22% reduction due to loss of MTs (solid black circle) and 16% due to change of scattering components other than MTs. For F-actin (Fig. 1E), the reduction was estimated to contain a 6% reduction due to loss of F-actin and 32% due to loss of MTs and changes of other unknown components.

Conclusions: Colchicine, a MT depolymerizing agent, also damages F-actin and other unknown structures. In normal retinas the contributions of MTs and F-actin to RNFL reflectance are not more than 34% and 19%, respectively. There are other structures contributing significantly to RNFL reflectance.

TITLE: Epithelial-Mesenchymal Transition (EMT) induced by AQP0-deficiency during cataractogenesis

SESSION TITLE: Lens Physiology and Transport

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W. Lo, S.K. Biswas, Neurobiology, Morehouse School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Woo-Kuen Lo: Commercial Relationship: Code N (No Commercial Relationship) | Sondip Biswas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The water transport is conducted by AQP0 for fiber cells and AQP1 for epithelium in the lens. We have previously shown that AQP0 deficiency in fiber cells causes significant upregulation of AQP1 in the epithelium. The increase in water influx from the epithelium caused further damage to the underlying fiber-cell mass. Enlarged anterior lens suture spaces and swollen fiber cells were frequently observed. Here, we report that AQP0-deficiency also induces EMT and connexins (Cx43 & Cx50) changes in lens epithelium.

Methods: EMT markers (α -actin, fibronectin, vimentin), AQP1, and Cx43 & Cx50 antibodies were used to examine lenses from WT, AQP0^{-/-}, and AQP0^{+/-} mice (P4-16wks old) in this study.

Results: By confocal immunolabeling on frozen sections, all WT lenses showed negative labeling for α -actin, fibronectin, and vimentin antibodies. In contrast, α -actin (α -SMA) was strongly labeled in the entire epithelial layer in AQP0^{-/-} lenses at P8 and older. Several distinct clusters of labeled epithelial cells with multiple layers were seen overlying the anterior lens sutures. However, strongly labeled fibronectin was mainly found in the detached clusters of EMT cells in the fiber-cell mass. At 2 weeks old, the migrated clusters of mesenchymal cells have reached the lens nucleus, seemingly via the enlarged lens sutures. The migrated mesenchymal cells in the lens nucleus showed positively labeled α -actin, fibronectin, and AQP1 antibodies. A similar pattern of EMT also occurred in the AQP0^{+/-} lenses, suggesting that partial deficiency of AQP0 was able to induce EMT in lens epithelium. By TEM analysis, 5-7 nm F-actin and 10 nm vimentin filaments were seen extensively distributed in EMT cells. Furthermore, since EMT causes epithelial structural changes, we examined possible alterations of Cx43 and Cx50 in epithelial whole mounts. While Cx43 labeling showed only a slight decrease, the labeling of Cx50 was dramatically reduced in the epithelium in AQP0^{-/-} lenses with age, suggesting that cell-cell communication between the epithelium and fiber cells at the interface was significantly reduced during the EMT process.

Conclusions: This study uncovers for the first time that AQP0 deficiency in lens fibers can induce EMT in anterior epithelial cells. As a result, some epithelial-mesenchymal cells can migrate into damaged nuclear fiber cells in the lens core, apparently through the enlarged anterior lens suture spaces.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is a set of >60 hereditary retinal diseases characterized by degeneration of rod, then cone photoreceptors. It is typically diagnosed in adolescence and patients lose vision during adulthood. Gene therapy has been approved for only one gene in RP and developing gene therapies for >60 genetic causes is time consuming and costly. Therefore, we investigated retinal cellular responses to photoreceptor abnormalities in a mouse RP model to find a potential generic target to treat RP.

Methods: Cellular responses in each major retinal cell type in RP model (P23H; mutation of rhodopsin) and wild-type mice were analyzed using single-cell transcriptomics. Morphological changes were examined in P23H and wild-type mice retinas with OCT and immunohistochemistry (IHC) staining.

Results: OCT analysis showed thinning of the outer nuclear layer (ONL) and IS/OS layer in P23H versus wild-type mice at one-month old ($p < 0.001$). Genes involved in IS/OS segments, photoreceptor cell cilia, and photoreceptor development were significantly decreased in both rod and cone clusters, in line with the structural changes seen with immunohistochemistry. The genes involved in energy production and metabolic pathways associated with this loss were notably decreased in both rods and cones. Furthermore, in the Müller glia/astrocyte cluster, there was a remarkable up-regulation in pathways responsible for photoreceptor maintenance, which was decreased in rods and cones.

Conclusions: Enhancing photoreceptor metabolism and modulating Müller glial responses may potentially serve as a generic approach to protect against retinal degeneration in RP.

ABSTRACT BODY:

Purpose: The primary cause of retinopathy of prematurity (ROP) is delayed retinal vascularization of immature retinas after preterm birth (phase I ROP). Neonatal metabolic dysfunction (hyperglycemia and dyslipidemia) occurring in the first few weeks of life is a very important but understudied (and potentially treatable) risk factor for phase I ROP. In term infants, blood fibroblast growth factor 21 (FGF21) levels increase beginning 2 days after birth and FGF21 levels positively correlate with postnatal growth. However, in preterm infants, FGF21 levels are very low, detectable in only 69% of preterm infants at postnatal week 1. We investigated if FGF21 promotes retinal vessel growth in phase I ROP utilizing a recently developed phase I ROP mouse model.

Methods: Neonatal metabolic dysfunction was induced with intraperitoneal (i.p.) injection of streptozotocin in mice from postnatal (P) day 1 to 9. At P10, retinal vessel growth was evaluated in FGF21- (i.p. from P7 to P9) vs vehicle-treated C57BL/6J (n=14-16), FGF21-knockout vs FGF21 wild-type mice (n=15-22). Co-treatment of FGF21 with intravitreal siRNA Acaca (the key enzyme in de novo fatty acid synthesis) or control (n=8-9), or i.p. etomoxir (CPT1A inhibitor) or control (n=8-9) in C57BL/6J mice was also conducted. Retinal metabolic enzyme levels were measured with quantitative proteomics and retinal lipid levels were analyzed with lipidomics. Both male and female mice were used. Littermate controls were used for drug treatment. Unpaired t test was used for statistical analysis.

Results: In mice modeling phase I ROP, FGF21 administration promoted ($P<0.001$) and FGF21 deficiency ($P<0.01$) worsened retinal vessel growth. Blocking retinal Acaca expression partially attenuated ($P<0.05$), while inhibiting CPT1A with etomoxir greatly decreased ($P<0.01$) FGF21 protection in retinal vessel growth. FGF21 did not change the protein levels of retinal metabolic enzymes. FGF21 reduced retinal lipid levels.

Conclusions: FGF21 protects against retinal vascular developmental delay in phase I ROP, possibly through modulating retinal lipid metabolism.

ABSTRACT BODY:

Purpose: To describe epidemiologic trends in consumer product-related pediatric ocular injuries from 2010-2019.

Methods: This retrospective epidemiological study utilizes data from the National Electronic Injury Surveillance System. Inclusion criteria for this study were: eye injury in patients aged between 1 and 20 years separated into 4 groups: 1-5, 6-10, 11-15 and 16-20 and injury occurring between 2010-2019.

Results: There were an estimated 636,582 ocular injuries in children ages 1-20 with an average age of 9.7 years (SD=5.92) presenting to US EDs; 416,378 (65.4%) were males with a male-to-female ratio of 1.9:1. The incidence of injury in males showed a downward trend over the span of the study while the rate in females remained the same. The greatest number of injuries occurred in the 1-5 age group (31.2%) followed by 6-10 (25.0%), 16-20 (22.4%) and 11-15 years (21.4%). The total number of injuries trended down from 65,724 in 2010 to 56,895 in 2019 as shown in Figure 1. Similarly, the incidence of ocular injury per 1 million persons across the same time period also trended downward.

The incidence and frequency of open globe injury displayed a positive trend over this time span. Ocular contusion was the most common diagnosis (45.7%) for the entire group. The most common location of injury was at home (41.7%). Most patients (96.2%) were released from the ED. Fewer than 1% of all ocular injuries were admitted to the hospital. Most ocular injuries occurred in the summer months (May, June and July) and were higher on the weekend compared to a weekday. In all pediatric patients, 27.7% of injuries were sports-related followed by detergents/chemicals (15.9%), toys (11.2%), home workshop equipment (7.5%), kitchenware (5.0%) and home furniture (4.4%), comprising the top 70% of consumer product categories in the entire population. Detergents/chemicals accounted for the most common cause of injury in the youngest age group (Figure 2).

Conclusions: The frequency and rate of pediatric ocular injuries trended downwards nationally over the last decade. Sports and non-powder guns caused the greatest amount of eye injuries in the older pediatric cohorts (11-15 and 16-20 age groups), while detergents/chemicals accounted for nearly 1/3 of all injuries in younger children (0-5).

ABSTRACT BODY:

Purpose: To validate the richness, heterogeneity and composition of the gut microbiome and colonic monocytic populations in C57BL/6 and BALB/c mice locally housed.

Methods: Female (8-9 weeks) C57BL/6 and BALB/c mice were housed in separate cages, 3-5 mice/cage and acclimatized in our animal facility for one week. Then, caeca were removed, DNA isolated from their contents and 16S rRNA gene sequencing of the V4 region done. Differences in microbial α - and β -diversity were evaluated for each group. Flow cytometry analyzed populations of colonic macrophages and inflammatory monocytes between the two mouse strains before and after ($n=3/\text{group/time}$) corneal infection with 1×10^6 CFU *Pseudomonas aeruginosa* (ATCC strain 19660).

Results: No differences in microbial richness were observed between the two mouse strains. However, bacterial heterogeneity and evenness were significantly reduced in the C57BL/6 vs BALB/c strain. The two groups also differed significantly in the composition and structure of their gut microbiomes. Data indicated increases in the relative abundance of Firmicutes and Verrucomicrobia specific to the BALB/c strain. In contrast, Bacteroidetes were increased in C57BL/6 mice. We also observed increased relative abundance in two species, *B. thetaiotaomicron* and *L. johnsonii* in C57BL/6 mice, agreeing with previous work by other research teams. Flow cytometry of colonic cells revealed no intrastrain differences in inflammatory monocytes between ocularly infected and uninfected mice. However, a significant increase in the number of colonic inflammatory monocytes was detected when comparing C57BL/6 with BALB/c infected mice.

Conclusions: We confirmed that two genetically different strains of mice show differences in the composition and structure of their gut microbiome. We provide evidence that ocularly infected C57BL/6 vs BALB/c mice have an increased number of inflammatory monocytes in the colon which may hold relevancy for their disparate response to corneal infection with *Pseudomonas aeruginosa*.

TITLE: Upper eyelid weighting for facial palsy results in contralateral upper eyelid elevation

SESSION TITLE: Neuro-Ophthalmology and Oculoplastics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Karlin, C. Le, D. Rootman, Orbital and Ophthalmic Plastic Surgery, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Justin Karlin: Commercial Relationship: Code N (No Commercial Relationship) | Christina Le: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Rootman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We examine the effect of eyelid weighting on the position of the ipsilateral and contralateral upper eyelid.

Methods: This cross-sectional cohort study included patients with unilateral facial palsy who underwent surgical upper eyelid weight implantation. Photographs were obtained in primary position parallel to the plane of the camera. The primary outcome measures were ipsilateral and contralateral margin to reflex distance 1 (MRD1), preoperatively and postoperatively. Postoperative MRD1 difference (symmetry) was assessed as a secondary outcome measure. Weight mass was examined as a covariate in predicting the magnitude of the effect.

Results: Twenty-two patients (16 female, 6 male) met inclusion criteria. Following eyelid weight implantation, contralateral (unweighted) MRD1 increased (mean 0.61 mm, standard deviation [SD] 1.23 mm, $p < 0.05$). Ipsilateral (weighted) MRD1 decreased, although not significantly (mean -0.41 mm, SD 0.94 mm, $p = 0.06$). Preoperatively, there was no significant MRD1 difference between the weighted and unweighted sides (mean difference -0.27, SD 1.94 mm, $p = 0.52$). Postoperatively, there was a significant difference in MRD1 between the weighted and unweighted eyelids (mean -1.29, SD 1.87 mm, $p < 0.05$). Weight mass was not a significant predictor of change in ipsilateral or contralateral MRD1 ($p = 0.54$, $p = 0.96$, respectively) following surgery.

Conclusions: Patients with facial nerve palsy undergoing unilateral insertion of an eyelid weight experience contralateral eyelid elevation, and demonstrate decreased postoperative upper eyelid height symmetry. These data highlight a heretofore undescribed manifestation of Hering's law, and add to the overall understanding of how eyelid height is regulated.

ABSTRACT BODY:

Purpose: Risk factors for the development of vitreous hemorrhage (VH) in patients with proliferative diabetic retinopathy (PDR) are not completely understood. We performed a prospective, observational clinical study to investigate the association between neovascularization features on WF SS-OCTA and the development of VH in eyes with PDR.

Methods: Patients with type 1 or type 2 diabetes mellitus and PDR without VH at baseline were included. All patients were imaged with WF SS-OCTA (Montage 15mm×15mm and HD-51 Line scan) at baseline. Images were independently evaluated by two graders for WF SS-OCTA metrics defined a priori. Mixed effects logistic regression models (outcome: occurrence of VH) and mixed effects Cox proportional-hazards models (outcome: time to occurrence of VH) were used for statistical analyses.

Results: Fifty-five eyes of 45 subjects were included. Over a median follow-up of 280 days (range: 28-534 days), 7 of 55 PDR eyes (12.73%) developed VH during the follow-up period. Presence of forward neovascularization (NV), defined as NV that traverse the posterior hyaloid face into the vitreous (odds ratio [OR]=2.56, P=0.007), larger flow area of NV (OR=1.36, P=0.039), and intraocular pressure greater than 21 mmHg (OR=31.20, P<0.001) were significantly associated with the occurrence of VH. Similarly, number of forward NV (hazard ratio [HR]=2.71 per 1 forward NV increase, P=0.01) and larger flow area of NV (HR=1.39 per mm² increase, P=0.02) were associated with time to occurrence of VH.

Conclusions: The number of forward NVs and NV flow area as measured by WF SS-OCTA were associated with the development of diabetic vitreous hemorrhage. Larger sample sizes with a greater duration of follow-up along with an examination of systemic factors and ophthalmic interventions (e.g. PRP, anti-VEGF) are needed to validate imaging biomarkers for the prediction of diabetic VH.

TITLE: Ethnic differences in the prevalence of ocular disease among hospitalized older adults with obesity

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Chen, Rutgers Robert Wood Johnson Medical School, Piscataway, New Jersey, UNITED STATES|A. Uppuluri, M.A. Zabin, N. Bhagat, Department Of Ophthalmology & Visual Science, New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amy Chen: Commercial Relationship: Code N (No Commercial Relationship) | Aditya Uppuluri: Commercial Relationship: Code N (No Commercial Relationship) | Marco Zabin: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify ethnic differences in the prevalence of ocular diseases (non-traumatic) in obese patients over age 65.

Methods: Inpatients ≥ 65 years of age and diagnosed with ≥ 1 non-traumatic ocular disease between 2012-2014 were identified from the National Inpatient Sample (NIS), a nationally representative database of US hospitalizations. Demographics, ethnicity, duration and cost of hospital stay, comorbidities, and insurance status were recorded. Chi-squared analysis was used to calculate the prevalence of ocular disorders in obese vs. non-obese patients for each ethnic group using $p < 0.05$ as being significant. Cases were defined as obese patients with ocular diseases; the age and sex-matched control group consisted of non-obese patients with ocular diseases. The ratio of cases to controls was 1 to 5. The primary outcome was the prevalence of ocular disorders.

Results: 1,160,400 inpatients with non-traumatic ocular diseases were identified in the 3-year period; 193,615 (16.7%) were obese and had complete racial demographic information for categorization as non-Hispanic White, Hispanic, African American, Asian/Pacific-Islander, or Native American. With respect to ethnicity, prevalence of the following ocular diseases was higher in obese than non-obese patients: diabetic retinopathy (DR) in all ethnicities, ocular hypertension (OHTN) in all except Native Americans ($p < 0.03$); primary open-angle glaucoma (POAG) in all except Asian/Pacific-Islanders ($p < 0.001$); age related macular degeneration (AMD) in all except non-Hispanic Whites ($P < 0.001$); retinal vein occlusion (RVO) only among non-Hispanic Whites ($P < 0.001$); retinal artery occlusion (RAO) in all except African Americans ($p < 0.002$). Across all ethnicities, obese patients were more likely than non-obese patients to have hypertension ($p < 0.001$), hyperlipidemia ($p < 0.001$), and diabetes mellitus with or without chronic complications ($p < 0.001$). Among all obese patients, POAG was most prevalent in African Americans, DR was most prevalent in Asian/Pacific-Islanders and Native Americans, and AMD and RAO were most prevalent in Non-Hispanic Whites.

Conclusions: Within most ethnic groups, higher prevalence of DR, OHTN, POAG, AMD, RVO and RAO was found among obese adults ≥ 65 years old compared to non-obese controls. Within this NIS inpatient cohort, significant ethnic disparities were observed in the prevalence of ocular diseases in obese elderly patients.

TITLE: Computerized analysis of retinal vascular growth following intravitreal bevacizumab monotherapy in retinopathy of prematurity until the age of three years

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.D. Hammer, S. Agarwal-Sinha, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|H. Nguyen, J. Palmer, S. Rowlinson, Biomedical Engineering, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jon Hammer: Commercial Relationship: Code N (No Commercial Relationship) | Henry Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Palmer: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Rowlinson: Commercial Relationship: Code N (No Commercial Relationship) | Swati Agarwal-Sinha: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To measure retinal vessel growth post-intravitreal bevacizumab monotherapy (IVB) for retinopathy of prematurity (ROP) over time on serial fluorescein angiographic (FA) sessions until three years of age.

Methods: Serial angiographic images taken post-IVB on 4 serial examinations were analyzed starting at average 66 weeks post-menstrual age (PMA) with repeat imaging every 8 months until 3 years of age. The retinal vessel length was manually measured in ImageJ software from the temporal margin of the optic disc through the foveal center to the temporal vascular-avascular junction and vascular length at the different time points were compared.

Results: Seventy eyes in 35 infants treated for type-1 ROP were included, 63 eyes were treated with IVB and 7 eyes untreated. The mean retinal vessel length was 14.177 mm at time point #1 (66.2 weeks PMA) and 13.761 mm including all 4 FA sessions (range 44-234 weeks PMA). Paired t-tests compared the retinal vascular length of each individual eye over time and showed no statistically significant growth from the first FA at 66.2 weeks PMA until 3 years of chronological age. From time point #2 to #1 (N=30) the difference was -0.117 ± 0.785 mm (95% CI -0.416 to +0.176, $p=0.42$), from #3 to #1 (N=15) the difference was $+0.060 \pm 0.854$ mm (95% CI -0.413 to +0.533, $p=0.79$), and from #4 to #1 (N=7) the difference was -0.404 ± 1.32 mm (95% CI -1.628 to +0.820, $p=0.45$). Even the eyes with recurrence (n=6) and untreated eyes (n=7) showed no significant change in vascular growth over time.

Conclusions: Retinal vascular length measured angiographically post-IVB monotherapy treatment in ROP showed no significant vascular growth on serial examinations from 66 weeks PMA until three years of age. The persistent chronic vascular arrest and the inhibition of normal angiogenesis post-treatment with anti-VEGF monotherapy accounts for a longitudinal study in infants with ROP for dose titration and longer follow-up to study the vascular growth and recovery in the infants until adulthood.

TITLE: Association between uveitis and an increased risk of inflammatory bowel disease

SESSION TITLE: Microbiota and the Gut-Eye Axis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Lo, Department of Medical Education, Taichung Veterans General Hospital, Taichung, TAIWAN|T. Lo, Y. Chen, School of Medicine, National Yang-Ming University, Taipei, TAIWAN|Y. Chen, Department of Ophthalmology, Taichung Veterans General Hospital, Taichung, TAIWAN|

Commercial Relationships Disclosure (Abstract): Tzu-Chen Lo: Commercial Relationship: Code N (No Commercial Relationship) | Yu-Yen Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the potential association between uveitis and an increased risk of developing Inflammatory bowel disease (IBD).

Methods: The whole population cohort was collected retrospectively from the Taiwan National Health Insurance Research Database between January 1, 2001, and December 31, 2013. A total of 198,923 subjects with uveitis were enrolled in the uveitis group, and 397,846 subjects without uveitis were enrolled in the comparison group. The two groups were matched on age, gender and index date. They were compared in the cumulative incidence of subsequent IBD during the study period. Adjusted hazard ratio (HR) of IBD corresponding to uveitis was generated by multivariate cox regression model after adjustment of hypertension, diabetes, hyperlipidemia, obesity and smoking. Furthermore, the HRs of Crohn's disease (CD) and ulcerative colitis (UC), which are subtypes of IBD, were calculated separately.

Results: The mean age of the cohort was 47.7 years. Uveitis patients had significantly higher proportions of hypertension, diabetes, hyperlipidemia, obesity and smoking than the comparisons. A significantly higher cumulative incidence of IBD was found in the uveitis group than in the non-uveitis group (4.13% vs. 1.48%, $p < 0.0001$). Under the univariate cox regression analysis, patients with uveitis had a significantly higher risk of IBD compared to those without uveitis (HR=1.47; 95% confidence interval [CI]: 1.43-1.52, $p < 0.0001$). The result remains significant in the multivariate regression model, with an adjusted HR of 1.44 (95% CI: 1.39-1.49, $p < 0.0001$). Moreover, when analyzed separately, uveitis was significantly associated with an increased risk of Crohn's disease (adjusted HR=1.49; 95% CI: 1.44-1.54), but not significantly associated with ulcerative colitis (adjusted HR=1.03; 95% CI: 0.92-1.15).

Conclusions: People with uveitis are at significantly greater risk of developing IBD than individuals without uveitis.

TITLE: Role of AMP-activated protein kinase (AMPK) in corneal epithelial cells stimulated by fungi

SESSION TITLE: Corneal epithelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Zhang, C. Wang, J. Wei, W. Si, J. Yue, Y. Xie, Zhengzhou University People's Hospital, Henan Provincial People's Hospital, Henan Eye Institute, CHINA

Commercial Relationships Disclosure (Abstract): Hongmin Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Chun-mei Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jingjing Wei: Commercial Relationship: Code N (No Commercial Relationship) | Wei Si: Commercial Relationship: Code N (No Commercial Relationship) | Juan Yue: Commercial Relationship: Code N (No Commercial Relationship) | Yanting Xie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the role of AMP-activated protein kinase (AMPK) in corneal epithelial cells stimulated by fungi.

Methods: The non-toxic concentration range of AMPK phosphorylation agonist AICAR and inhibitor Compound C on corneal epithelial cells was screened by real-time marker-free multifunctional analyzer. Western Blot method was used to detect the expression of p-AMPK in corneal epithelial cells induced by AICAR and Compound C, and to screen the optimal concentration and time of drug action. The epithelial cells were divided into the corneal epithelial cell (C) group, corneal epithelial cell + spore (C+S) group, corneal epithelial cell + spore + AICAR (C+S+A) group, corneal epithelial cell + spore + Compound C (C+S+CC) group. Western Blot method was used to detect the expression of AMPK and p-AMPK in corneal epithelial cells. ELISA method was used to detect the expression of IL-6 in the culture supernatant of corneal epithelial cells.

Results: The cell index of 100μM, 300μM, 500μM, 1000 μM AICAR group and 10μM, 12.5μM Compound C group were not increased statistically than that in the corneal epithelial cells group at 24h, 36h, 48h, 72h time point ($P > 0.05$). The AICAR 1000μM group at 4h time point had the highest AMPK phosphorylation level in all AICAR concentration and time point groups ($P < 0.05$). The AMPK phosphorylation level in the Compound C 10μM group was higher than that in the other Compound C concentration groups ($P < 0.05$). Therefore, 1000μM and 4h was selected as the optimal concentration and time point for AICAR and 10μM group for Compound C. The AMPK phosphorylation level was higher in C+S group than that in group C ($P < 0.01$). The AMPK phosphorylation levels were higher in the C+S+A group than that in the C+S group ($P < 0.05$). The AMPK phosphorylation levels were lower in the C+S + CC group compared than that in the C+S group ($P < 0.05$). The IL-6 expression in group C+S was higher in C+S group than that in group C ($P < 0.01$) and C+S + CC group ($P < 0.05$).

Conclusions: Corneal epithelial cells had AMPK phosphorylation expression, and the AMPK phosphorylation and IL-6 secretion were increased after fungal spores stimulate. AMPK phosphorylation and IL-6 may play an important role in corneal antifungal infection.

TITLE: Hyperspectral refractomics and the spatial frequency sweet spot for emmetropization

SESSION TITLE: Refractive Error, Emmetropization and Ocular Development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Gawne, T.T. Norton, Optometry and Vision Science, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|R. Grytz, Ophthalmology, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Timothy Gawne: Commercial Relationship(s);UAB Provisional Patent:Code P (Patent) | Rafael Grytz: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Norton: Commercial Relationship(s);UAB Provisional Patent:Code P (Patent)

ABSTRACT BODY:

Purpose: A feedback mechanism in the post-natal developing eye uses visual cues to control its axial elongation to achieve and maintain good focus, a process termed emmetropization. Here we present a model of how the human retina could use chromatic cues to determine the magnitude and sign of defocus in complex visual scenes integrated across the entire visual spectrum, that is, using hyperspectral images.

Methods: We extended a model based on tree shrews (Gawne and Norton 2020) to the human eye, assuming that the activities of human medium- and long-wavelength sensitive cones ("M+LWS") are added together as a single value. We applied this model to 26 hyperspectral images of real-world scenes (Chakrabarty and Zickler 2011). For each hyperspectral image we calculated the radially averaged spatial frequency spectra for both SWS and M+LWS cone classes at several levels of simulated defocus. We define a "hyperspectral drive" as the difference between the averaged signal amplitude of the two cones classes, SWS - (M+LWS), at different spatial frequencies.

Results: Fig.1 illustrates the hyperspectral drive as a function of image defocus for six representative spatial frequencies. At 0.25 and 0.5 cycled per degree (CPD), the drive is highly variable and not very accurate (drive not consistently zero at 0 D defocus). At 1 CPD the drive function is less variable across scenes and more accurate. At 2 CPD the drive is even less variable and still accurate, but loses effectiveness beyond about ± 2 D of defocus. At 10 CPD, the range of the drive function shrinks to less than ± 1 D.

Conclusions: Emmetropization likely uses multiple visual cues, and even for chromatic ones, likely integrates them across some range of spatial frequencies. However, this analysis suggests that there is a "sweet spot" for the use of chromatic signals in emmetropization roughly in the range of 1-2 CPD, within the resolution of the widely-spaced SWS cones.

ABSTRACT BODY:

Purpose: Choroidal vascularity index (CVI) is the proportion of luminal area to total choroidal area, and has been shown to be a sensitive parameter for detecting choroidal vascular changes in a range of ocular and systemic diseases. The purpose of this study is to evaluate the longitudinal changes in CVI in active and inactive patients with intermediate uveitis (IU).

Methods: Enhanced-depth optical coherence tomography (EDI-OCT) images of IU patients were retrospectively reviewed. The subfoveal choroidal area within the central 1500 μm of the macula was segmented into luminal area and stromal area using an image binarization tool (ImageJ software; Bethesda, MD USA). Choroidal parameters including subfoveal choroidal thickness (SCT), total choroidal area (TCA), luminal area (LA), stromal area (SA) and CVI were compared between baseline and follow-up visits among patients with active and inactive IU.

Results: Twenty patients with active IU (36 eyes; mean age 32.75 ± 17.00) and twelve patients with inactive IU (21 eyes; mean age 34.3 ± 22) were included. At baseline, no difference of CVI, LA, SA, TCA, and SCT was noted between two groups. After follow-up, CVI and LA in active IU eyes significantly increased from $66.80 \pm 3.36\%$ to $68.36 \pm 4.32\%$ ($P = 0.02$), and 0.93 ± 0.21 to $0.99 \pm 0.21 \text{ mm}^2$ ($P = 0.001$) while SCT did not significantly change (325.50 ± 68.07 to $331.03 \pm 63.05 \mu\text{m}$, $P = 0.335$). In patients with inactive IU, CVI did not significantly change after follow-up ($66.49 \pm 4.03\%$ to $66.78 \pm 3.90\%$, $P = 0.690$).

Conclusions: Our results show that in eyes with active intermediate uveitis, the CVI increased significantly on follow up following resolution of inflammation, which may be the result of increased vascularization of the choroid after treatment. Further studies are needed to evaluate the role of CVI as a biomarker for monitoring treatment response in uveitis patients.

ABSTRACT BODY:

Purpose: The purpose of this study was to uncover which treatment outcomes retinoblastoma survivors and their parents' value. Retinoblastoma is an aggressive pediatric eye cancer. Patient-reported outcome measures – instruments that measure any outcome related to health that are directly reported by patients themselves – reveal important insights on how patients perceive their own health. Currently, no widely used or validated measure for the assessment of retinoblastoma outcomes exists.

Methods: This qualitative, cross-sectional study included Canadian retinoblastoma survivors aged 6 years and older, and parents of retinoblastoma survivors. Participants who did not demonstrate fluency in English were excluded. Study subjects participated in semi-structured interviews or focus groups, either in person at The Hospital for Sick Children, Toronto, Canada, or through secure videoconference, between March 3, 2019, and January 25, 2020. Iterative rounds of opening coding, codebook development, and co-researcher analysis, were utilized to identify key emergent themes and subthemes.

Results: Seventeen adults (8 survivors, 9 parents) participated in 6 focus groups. Nine pediatric survivors participated in individual interviews, five children aged 6-9, and 4 adolescents, aged 11-16. Four common themes emerged from all participant groups: (1) Definition of treatment success, (2) Enucleation – acceptance and challenges, (3) Treatment outcomes to measure, and (4) Need for outcome reporting. An additional, unique theme was identified in all pediatric discussions: (1) Worries and coping mechanisms. Treatment outcomes deemed valuable were related to the following domains: psychosocial outcomes, daily functioning, functional vision, retinoblastoma education, cosmetic outcomes, and secondary eye conditions.

Conclusions: This study represents the first stage in the development of a retinoblastoma-specific patient-reported outcome measure. Further, this work represents the first study of its kind for the retinoblastoma population and is novel in its inclusion of pediatric survivors as young as 6 years of age. The findings reveal insight into what outcomes are valued by survivors after treatment and offers promise to improve outcomes assessment for retinoblastoma.

TITLE: Associations between hematologic value with ocular and brain findings in children with sickle cell disease

SESSION TITLE: Pediatric ophthalmology and Systemic Disorders

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Jin, Surgery/Ophthalmology, Nemours A. I. duPont Hospital for Children, Wilmington, Delaware, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jing Jin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A critical knowledge gap exists in how systemic disease markers relate to the clinical manifestations of sickle cell retinopathy (SCR). This prospective observational study investigated the link between hematologic values and retinal injury on OCT and cerebrovascular disease (CVD).

Methods: 73 patients (38 males), aged 5-20 years with sickle cell disease (SCD) (68 SS and 5 S β 0 thalassemia) underwent funduscopy and SD-OCT imaging. 52 of these patients had brain MRI, 49 of the 52 also had MRA. Data on CVD include history of stroke, silent cerebral infarct (SCI) by MRI, cerebral arteriopathy by MRA and abnormal transcranial Doppler (TCD). Hematologic values and markers of hemolysis were collected. X^2 and Fisher's exact tests of proportions were used to compare frequency of abnormal findings across subpopulations. For continuous variables, 2-tailed, unpaired t tests were used for age and Mann-Whitney test were used for blood tests results. P values of <.05 were considered statistically significant.

Results: While funduscopy findings in our cohort showed no correlation with CVD, 20/21 patients with CVD had evidence of SCR by OCT (p=0.008). The outcome of OCT detecting retinal injury from SCD had 95.24% sensitivity (95% CI 76.18% to 99.88%) and 38.71% specificity (95% CI 21.85% to 57.81%) of showing SCI by MRI. There was no significant correlation between OCT findings and abnormal TCD. Correlations of hematologic values with OCT and CVD are demonstrated in the table.

A logistic regression model was statistically significant (p = 0.000). The model explained 58.0% of the variance in SCI and correctly classified 84.6% of cases as with or without SCI. For each unit increase of reticulocyte, there was 1.43 times increase in the odds of SCI. Subjects with abnormal OCT were 11.5 times more likely to exhibit SCI on MRI. Increasing WBC, higher indirect bilirubin and AST were associated with an increased likelihood of having SCI.

Conclusions: A correlation between abnormal OCT and CVD strongly suggesting that retinal OCT may aid in detection and monitoring SCD related CVD. A significant correlation between higher reticulocyte percentage, higher AST and abnormal OCT, stroke and SCI suggests that retinopathy may be another component of the hemolytic sub-phenotype of SCD and that patients with higher levels of hemolysis may benefit from closer monitoring for the development of SCR and brain damage.

ABSTRACT BODY:

Purpose: To compare patient satisfaction for telemedicine visits to traditional in-person clinical visits during the COVID-19 pandemic in the Ophthalmology Department at Boston Medical Center (BMC), the largest academic safety-net hospital in New England.

Methods: Patient satisfaction surveys using the NRC Health platform were sent to all patients in their preferred language following eye clinic visits at BMC from June to October 2020. Three visit types were studied: 1) virtual visits via telephone or video conferencing, 2) hybrid visits with protocol-driven set of undilated imaging (e.g. OCT, fundus photos, visual fields), visual acuity, and intraocular pressure obtained by a trained technician, followed by a virtual visit with the physician within 1-2 weeks, and 3) traditional in-person visits. Two-tailed Student's t-test was used to compare survey responses of telemedicine to traditional visits in 4 questions: 1) trust in provider (4-point scale, "trust"), 2) felt provider listened (4-point scale, "listened"), 3) satisfied with amount of time spent with provider (4-point scale, "time"), and 4) recommend provider to other patients (10-point scale, "recommend"). Additionally, responses between English and non-English speakers, requiring trained interpreter services, were compared.

Results: A total of 793 visits were included (44 virtual, 56 hybrid, 693 traditional). The majority of telemedicine visits were from the retina and optometry services (Figure 1). There was no statistically significant difference in "trust", "listened", "time", or "recommend" when comparing virtual or hybrid visits to traditional visits (Table 1a). Non-English speakers had statistically significant lower scores in "trust", "listened", and "time" with no difference in "recommend" when compared to English speakers (Table 1b). When stratified by visit type, non-English speakers had a trend towards a lower score in "trust" for both virtual and hybrid groups.

Conclusions: Telemedicine provides patients access to clinical care with decreased risk of infection during the COVID-19 pandemic. Non-English speakers tended to have less trust in the physician for all visit types, which should be considered when communicating with patients. Overall, we found that patients were equally satisfied with telemedicine visits as with traditional in-person visits in a hospital-based academic eye clinic.

ABSTRACT BODY:

Purpose: The choriocapillaris layer in the eye is one of the densest layers of capillary vasculature in humans and may be affected by early microvascular changes as a result of uncontrolled systemic hypertension. To examine the choriocapillaris microvasculature using a non-invasive swept-source optical coherence tomography angiography (SS-OCTA) in healthy controls and hypertensive patients and determined possible correlations with BP and renal parameters.

Methods: A prospective study of 41 healthy controls and 71 hypertensive patients with varying blood pressure (BP) control. BP levels, serum creatinine and urine microalbumin/creatinine ratio (MCR) specimens were collected. The estimated glomerular filtration rate (eGFR) was calculated based on CKD-EPI Creatinine Equation. The main outcome was choriocapillaris flow deficits (CFD) metrics (density, size and numbers).

Results: The CFD occupied a larger area and were fewer in number in the hypertensive patients with poor BP control ($407 \pm 10 \mu\text{m}^2$; 3260 ± 61) compared to the hypertensives with good BP control ($369 \pm 5 \mu\text{m}^2$; 3551 ± 41) and healthy controls ($365 \pm 11 \mu\text{m}^2$; 3581 ± 84). Higher systolic BP ($\beta=9.90$, 95% CI, 2.86 to 16.93), lower eGFR ($\beta = -0.85$; 95% CI, -1.58 to -0.13) and higher urine MCR ($\beta=1.53$, 95%CI, 0.32 to 2.78) were associated with larger areas of CFD. Similar significant associations with systolic BP, eGFR and urine MCR were found with number of CFD.

Conclusions: These findings highlight the potential role of choriocapillaris imaging using SS-OCTA as an indicator of systemic microvascular abnormalities secondary to hypertensive disease.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) provides vital metabolic support for photoreceptor cells. Many RPE proteins thought to be important for the maintenance of retinal health. For these reasons, there is great interest in studying gene function in the RPE through conditional knockout experiments using the Cre-LoxP system. Mouse lines reported to date that have been engineered to express Cre specifically in the RPE suffer from various inadequacies, most notably mosaic Cre expression, lack of tissue specificity, and long-term toxicity to the RPE. In this study, we aimed to overcome these challenges by generating a novel inducible Cre mouse line that exploits the endogenous promoter of the RPE-specific 65 kDa protein (RPE65).

Methods: A P2A-CreER^{T2} coding sequence was fused in frame with the endogenous Rpe65 gene by homologous recombination for bicistronic gene expression. Following removal of the neomycin selection cassette and backcrossing onto the C57BL/6J background, the Rpe65^{CreERT2} mice were bred with the mT/mG reporter mouse line to assess Cre recombinase activity as well as 129s and C57BL6/J mice expressing the L450 variant of Rpe65 to assess retinal morphology and visual cycle kinetics.

Results: The Rpe65^{CreERT2} mice were fully viable and had no gross morphological abnormalities. Mice heterozygous for the RPE65^{CreERT2} allele were able to recombine the mT/mG reporter with an efficiency of ~99% upon tamoxifen induction at both P21 and P50. Cre activity was found exclusively within the RPE as assessed by retinal cryo-sections. Tamoxifen-independent activity was negligible with < 1% of RPE cells converted at both P21 and P50. RPE65 expression from the knock-in allele was minimal. Dark-adapted ERG responses were normal in these mice. Also, visual chromophore recovery was normal in Rpe65^{CreERT2/Wt(M450)} and Rpe65^{CreERT2/Wt(L450)} mice. Heterozygous mice did not display any signs of RPE pathology following treatment with tamoxifen.

Conclusions: This study demonstrates that CreER^{T2} expression via cotranslational cleavage from the native Rpe65 locus overcomes previously reported difficulties with RPE-directed Cre mice. The mice we report here exhibit highly efficient, tamoxifen-inducible Cre activity specifically in the RPE and do not display evidence of RPE toxicity. These mice will be useful for future studies of gene function specifically in the RPE.

TITLE: Intraoperative Intravitreal Injection of Anti-VEGF During Phacoemulsification Surgery to Prevent the Incidence of Diabetic Macular Edema and Enhance Postoperative Visual Outcome

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Tseng, C. Yen, Ophthalmology, Taipei City Hospital, Taipei, TAIWAN|P. Tseng, University of Taipei, Taipei, TAIWAN|C. Yang, National Taiwan University College of Medicine, Taipei, Taipei, TAIWAN|C. Yang, Ophthalmology, National Taiwan University Hospital, Taipei, TAIWAN|

Commercial Relationships Disclosure (Abstract): Pochen Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Chu-Yu Yen: Commercial Relationship: Code N (No Commercial Relationship) | Chang-Hao Yang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The DRCR.net implicated cataract surgeries increased the risk of postoperative diabetes macular edema (DME) in 16 weeks and worsening of postoperative visual outcome. Whether concurrently anti-VEGF injection in cataract surgery in diabetic patients decrease the risk of DME has not been investigated.

Methods: A retrospective observational study was conducted from 2016/01/01 to 2020/10/31. All patients were diagnosed with diabetic mellitus prior to the operation. DME was defined as central subfield thickness (CST) 300 μ m or more. Epiretinal membrane or tractional maculopathy were excluded. All the cataract surgeries were done by a single surgeon with phacoemulsification and posterior chamber intraocular ocular lens implantation in the capsular bag without any posterior capsular tear or any other intra- or post-operative complications. We concurrently perform cataract surgery and intravitreal injection of 2 mg aflibercept (0.05 mL) in 43 eyes. The control group only received cataract surgery without intravitreal injection in 65 eyes. We analyzed the post-operative visual acuity, CST changes and the incidence of post-operative DME. CST was measured by spectral domain optical coherence tomography (Optovue, Inc, Fremont, California) prior and three months after surgery.

Results: 108 eyes in 74 patients were included. 43 eyes received cataract surgery and intravitreal injection concurrently, in which 8 eyes were found pre-operation DME (group A) and 35 eyes not (group C). 65 eyes received cataract surgery only, and 11 of which were found pre-operation DME (group B) and 54 not (group D).

CST was decreased in patients with DME in group A but increased in group B (-3.3 ± 47.3 μ m versus 28.0 ± 35.2 μ m) (fig 1.). The visual acuity improved significantly in group A than group B ($p < 0.01$) (fig 2.). There was no significantly different in CST changes, incidence of postoperative CME (8.5% and 9.2 % respectively) and visual acuity between Group C and D.

Conclusions: This study showed that if diabetic patients were diagnosed as DME postoperatively, concurrently intravitreal injection of anti-VEGF in cataract surgery may be beneficial in decreasing postoperative CST and improving visual acuity. If there is no preoperative DME initially, the role of anti-VEGF may not be highlighted.

TITLE: Platelets enhance the antifungal activity of neutrophils

SESSION TITLE: Pathobiology of Ocular Infections

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W. Si, H. Zhang, S. Liu, Zhengzhou University People's Hospital, Henan Provincial People's Hospital, Henan Eye Institute, CHINA | F. Zhang, People's Hospital of Dezhou, CHINA |

Commercial Relationships Disclosure (Abstract): Wei Si: Commercial Relationship: Code N (No Commercial Relationship) | Fenfen Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Hongmin Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Susu Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the previous experiment, platelet, neutrophil aggregation were observed in the focus area of fungal keratitis in mice, but the relationship between platelet and neutrophil was not clear. Therefore, the effects and mechanisms of the antifungal activity of neutrophils enhanced by platelets were studied.

Methods: All fungi used for experiments was the standard strain of *Fusarium solani*. Neutrophils and platelets were drawn from human peripheral venous and purified from whole blood respectively. Three groups were divided in this experiments: spore (S) group, spore + neutrophil (S+N) group co-incubated spores and isolated neutrophils together and spore + neutrophil + platelet (S+N+PL) group co-incubated spores, isolated neutrophils and platelets. The growth of fungi or neutrophils or platelets was observed and the pictures were took at specified time points used by a spinning disk confocal microscope. The rate of phagocytosis, spore germination, hyphae length and apoptosis in each group were calculated.

Results: The rate of phagocytosis of neutrophils in S+N+PL group were higher at 1h, 2h and 4h compared with that in S+N group ($P < 0.05$). The rate of spore germination was lower in S+N+PL group compared with that in S+N group ($P < 0.05$). In addition, with longer incubated time, the apoptosis of neutrophils grown higher. Until 18h, the apoptosis rate of N group was grown as high as 74.56%. The highest apoptosis rate of neutrophils was in N group, followed by S+N group and S+N+PL group at each time point ($P = 0.000$). The apoptosis rate in S+N group was significantly higher than that in S+N+PL group at 6h, 10h, 14h and 18h ($P < 0.01$).

Conclusions: Platelets could enhance neutrophils to engulf fungal spores, restrict fungal germination, delay the hyphae growth and reduce apoptosis of neutrophil. These results indicated that the platelets play an important role in anti-fungal field.

Commercial Relationships Disclosure (Abstract): Ivan Seah: Commercial Relationship: Code N (No Commercial Relationship) | Zengping Liu: Commercial Relationship: Code N (No Commercial Relationship) | Gavin Siew Wei Tan: Commercial Relationship: Code N (No Commercial Relationship) | Veluchamy Barathi: Commercial Relationship: Code N (No Commercial Relationship) | Gopal Lingam: Commercial Relationship: Code N (No Commercial Relationship) | Xinyi Su: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal degenerations are a heterogenous group of conditions which differ in pathophysiology but are characterised by the demise of photoreceptors. The non-human primate (NHP) model is important for such studies due to the presence of an anatomical macula, which is not seen in other animals. While there have been attempts to create NHP models using systemic or intravitreal delivery of retinotoxic agents, these are associated with increased systemic complications and uncontrollable distribution of retinal lesions.

Ophthalmic lasers are useful for creating animal models of retinal diseases. As compared to the traditional argon laser, the micropulse (MP) laser delivers lower energy but repetitive series of short pulses. This may allow selective and consistent destruction of photoreceptors without damaging the Bruch's membrane. Thus, it may avoid choroidal neovascularisation (CNV) which has a different pathogenesis. In this abstract, we investigate the utility of the MP laser in creating a NHP model of degenerative retinal diseases.

Methods: A *Macaca fascicularis* was used to create the RD model using the IQ 532 Micropulse Laser (Iridex) with a TxCell scanning laser delivery device and a Volk HR centralis contact lens (Volk Optical Inc) with a 74° degree field of view. 4 settings were tested for their ability to cause selective photoreceptor damage:

A: 66J/m^2 Fluence: Duty cycles of 2% (0.2ms pulse "on", 9.8ms pulse "off"), Power 2000mW

B: 33J/m^2 Fluence: Duty cycles of 1% (0.1ms pulse "on", 9.0ms pulse "off"), Power 2000mW

C: 49.5J/m^2 Fluence: Duty cycles of 1.5% (0.15ms pulse "on", 9.8ms pulse "off"), Power 2000mW

D: 37.125J/m^2 Fluence: Duty cycles of 1.5% (0.15ms pulse "on", 9.8ms pulse "off"), Power 1500mW

Optical coherence tomography and autofluorescence of the macula were done on Day 0, 7 and 20 from the initial procedure. Histological analysis was done after 20 days.

Results: Of the 4 settings, Settings A, C and D were able to achieve photoreceptor damage reflected on imaging. Only Setting A was associated with CNV development after 20 days. Photoreceptor damage was not achieved with Setting B.

Conclusions: At specific settings, the MP laser can potentially be used for the creation of a NHP model of RD. Further investigations including electroretinography and transcriptional analyses are required for validation of this model.

ABSTRACT BODY:

Purpose: Erythropoietin (EPO) signaling through its receptor (EPOR) is believed to exacerbate neovascular age-related macular degeneration (AMD) pathology, but it is unknown if EPOR signaling has a direct effect on either endothelial cells (ECs) or macrophages (MΦs) recruited to the choroid that release angiogenic factors. We addressed the hypothesis that EPOR signaling increases choroidal neovascularization (CNV) by direct effects on endothelial cells (ECs). We used the murine laser-induced CNV model comparing tamoxifen-inducible EC- or MΦ-specific EPOR knockout mice.

Methods: Offspring from $Cdh5-CreERT2^{+/+}$ or $Cx3cr1-CreERT2^{+/+}$ crossed with $Rosa26-tdTomato^{flox/flox}$ mice were bred with $EpoR^{flox/flox}$ mice to generate $Cdh5-CreERT2^{+/-};Rosa26-tdTomato^{flox/flox};EpoR^{flox/flox}$ (EPOR^{iΔEC}) or $Cx3cr1-CreERT2^{+/-};Rosa26-tdTomato^{flox/flox};EpoR^{flox/flox}$ (EPOR^{iΔMΦ}), respectively, and appropriate Cre-negative littermate controls (EPOR^{fl}). 4-week old EPOR^{iΔEC}, EPOR^{iΔMΦ}, and EPOR^{fl} received intraperitoneal tamoxifen treatment every other day for one week. Two weeks later, laser injury was performed with the Phoenix Micron IV laser module. One week after laser, choroids were dissected and stained with isolectin-B4 to label CNV. Z-stacks of CNV lesions were captured using a confocal microscope, and CNV volumes were calculated using IMARIS software and verified by a masked reviewer. Data were analyzed using a multilevel linear regression model with laser spots nested within the same eye and normalized to the EPOR^{fl} mice.

Results: EPOR^{iΔEC} mice had 20% smaller lesions than EPOR^{fl} mice ($p=0.37$), whereas EPOR^{iΔMΦ} mice had similar sized lesions as EPOR^{fl} mice ($p=0.76$). Stratification based on sex revealed a 47% reduction in average CNV volume in male EPOR^{iΔEC} compared to male EPOR^{fl} mice ($p=0.03$), but not in female EPOR^{iΔEC} compared to female EPOR^{fl} mice ($p=0.62$). Male EPOR^{iΔMΦ} compared to male EPOR^{fl} mice ($p=0.35$) or female EPOR^{iΔMΦ} compared to female EPOR^{fl} mice ($p=0.18$) did not have significant changes in CNV volume.

Conclusions: EPOR^{iΔEC} with reduced EPOR signaling in ECs developed smaller lesions in males, whereas EPOR^{iΔMΦ} with reduced EPOR signaling in MΦs had no difference. These results support the hypothesis that EPOR signaling in ECs is important in CNV. Further study is required to determine mechanisms involved in choroidal ECs and address potential tamoxifen effect on laser-induced CNV in female mice.

TITLE: Exposure to Porphyromonas gingivalis and Modifiable Risk Factors Modulates Risk for Early Diabetic Retinopathy

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Chiu, A. Kantarci, T.E. Van Dyke, W. Shi, The Forsyth Institute, Cambridge, Massachusetts, UNITED STATES|M. Chang, The Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chung-Jung Chiu: Commercial Relationship: Code N (No Commercial Relationship) | Min-Lee Chang: Commercial Relationship: Code N (No Commercial Relationship) | Alpdogan Kantarci: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Van Dyke: Commercial Relationship: Code N (No Commercial Relationship) | Wen Yuan Shi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We hypothesized that exposure to Porphyromonas gingivalis (P. g.) increases the risk for early diabetic retinopathy (DR) and that the risk can be modulated.

Methods: 116 early DR cases were identified, and 116 non-DR controls were selected randomly by frequency matching for age, sex, race, and education from the US Third National Health and Nutrition Examination Survey. DR was assessed using non-mydratic fundus photographs and graded by trained graders using the Modified Airlie House Classification scheme and the Early Treatment for Diabetic Retinopathy Study severity scale. Serum P. g. immunoglobulin G (IgG) antibody (Ab) was measured in enzyme-linked immunosorbent assay units. Logistic regression was used to relate serum P. g. IgG Ab levels to the risk for early DR.

Results: Per tenfold increase in P. g. IgG Ab levels, there was an over 60% increased risk for early DR (odds ratio=1.64; 95% confident interval: 1.36 – 1.97) and a linear trend was noted for the estimated probabilities of early DR at various P. g. IgG Ab levels (p for trend=0.0053). The analysis also suggested that moderate alcohol consumption (less than 12 drinks in the past 12 months; p for interaction=0.0003) and maintaining a normal serum glycated hemoglobin level (HbA1c≤5.7 %; p for interaction<0.0001) helped reduce the P. g.-related DR risk.

Conclusions: The increased P. g.-related DR risk could be alleviated by managing alcohol consumption and maintaining a normal blood glucose level. Findings from this study provide new directions for developing novel therapeutics and prevention strategies for DR.

TITLE: Environmental circadian disruption alters rod signaling and bipolar cell structure in mice

SESSION TITLE: Retinal neurodegeneration and protection

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K. Baba, I. Roberts, H. Duong, G. Tosini, Morehouse School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kenkichi Baba: Commercial Relationship: Code N (No Commercial Relationship) | Imani Roberts: Commercial Relationship: Code N (No Commercial Relationship) | Hao Duong: Commercial Relationship: Code N (No Commercial Relationship) | Gianluca Tosini: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The circadian clock plays important roles in the regulation of retinal functions and physiology. Previous study has indicated that removal of the clock gene, Bmal1, from the neural retina alters photosensitivity, spectral identity and cone viability during aging in mice. Environmental circadian disruption (ECD, e.g. shift work, jet lag, living in Arctic etc.) has been shown to be deleterious for the health, but no study has investigated the effect of ECD in the retina. In this study we investigated the effect of ECD on the retina functioning and circuitry.

Methods: PER2::LUC and C57BL/6 mice were placed in a light tight isolated chamber and expose to ECD light cycles by advancing the time of light-on at 6 hours/week for 4 weeks. For control group, mice were exposed to a 12/12 Light/Dark cycle without any shifts. After 4 weeks of ECD, PER2::LUC mice (4-5 mo. old) were sacrificed and the retina, the retinal pigment epithelium (RPE) and the cornea were isolated and cultured for bioluminescence measurement. C57BL/6 mice (3 mo. old) were also exposed to ECD and subjected to both scotopic and photic electroretinogram (ERG) recording at the end of the fourth week. Retinal circuitry and morphology of C57BL/6 mice was evaluated by immunostaining (peanut agglutinin for cone photoreceptors, anti-PKC α for rod bipolar cell, anti-PSD95 for postsynaptic density).

Results: The circadian rhythm in PER2::LUC bioluminescence revealed that ECD altered circadian phase and period in retina and RPE but not in cornea. The amplitude of scotopic b-wave was significantly decreased in the mice subject to ECD. Consistently with this observation the dendric branching of rod bipolar cells was also reduced. The amplitude of photic ERG and the viability of the cone photoreceptors were not affected by ECD.

Conclusions: Our data indicate that the ECD affect the retinal circadian system, the retinal functioning and circuitry. Our results suggest that disruption of circadian rhythms may induce visual impairment.

TITLE: The sustained release of genipin with a Drug Delivery System inhibit an axial length elongation in the guinea pigs for 21 days

SESSION TITLE: Molecular and Structural

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kawai, T. Nakamura, Y. Kato, M. Nakatani, T. Ueno, Bioengineering Institute, R&D Div, Nidek Co., Ltd, Aichi, JAPAN|

Commercial Relationships Disclosure (Abstract): Toshihiro Kawai: Commercial Relationship(s);NIDEK CO.,LTD:Code E (Employment) | Takao Nakamura: Commercial Relationship(s);NIDEK CO.,LTD:Code E (Employment) | Yoshitaka Kato: Commercial Relationship(s);NIDEK CO.,LTD:Code E (Employment) | Masayoshi Nakatani: Commercial Relationship(s);NIDEK CO.,LTD:Code E (Employment) | Tokio Ueno: Commercial Relationship(s);NIDEK CO.,LTD:Code E (Employment)

ABSTRACT BODY:

Purpose: We evaluated an inhibitory effect of axial length (AL) elongation on form deprivation (FD) model in guinea pigs after a natural collagen crosslinker, genipin sustained release formulation (GSRF) injection.

Methods: Thirty-seven 3-week-old pigmented guinea pigs underwent monocular FD with diffusers for 21 days. Genipin solution was injected into Tenon capsule on FD eyes. Experimental design was assigned to 4 groups: Control Group (n = 9) , Single dose Group (100 μ L of 0.5% genipin solution at the 0th day, n = 10) , Multiple dose Group (100 μ L of 0.5% genipin solution at days 0, 7, and 14, n = 8) , and GSRF Group (30 μ L of 1.4% GSRF at the 0th day, n = 10) .

AL was measured before and after FD by A-scan ultrasonography (NIDEK US-4000). Two-tailed Student's t-test was used for statistical analysis.

Results: The AL elongation was 0.38 ± 0.10 mm, 0.37 ± 0.12 mm, -0.02 ± 0.13 mm, and -0.03 ± 0.09 mm in the Control Group, Single dose Group, Multiple dose Group, and GSRF Group, respectively (mean \pm SD).

GSRF Group significantly inhibited the AL elongation compared to Control Group ($p = 0.005$) and Single dose Group ($p = 0.012$).

Furthermore, there was no significant difference in AL elongation between GSRF Group and Multiple dose Group ($p = 0.942$).

Conclusions: In the FD guinea pig model, single injection of GSRF showed an inhibitory effect on AL elongation for at least 21 days.

Further studies are needed to examine the safety and stability of GSRF.

ABSTRACT BODY:

Purpose: Geographic atrophy (GA) growth in patients with non-neovascular age-related macular degeneration (NNAMD) is often measured from color fundus photography (CFP) and fundus autofluorescence (FAF). There is limited research on using the native sub-RPE (retinal pigment epithelium) illumination on the Zeiss Cirrus system to estimate GA area. In this study we assessed the ability to measure progression of geographic atrophy using sub-RPE illumination as measured on optical coherence tomography.

Methods: This is a retrospective review of NNAMD patients and at least 2 year follow-up. One follow-up visit was chosen yearly throughout follow-up for analysis. GA area was measured using sub-RPE illumination area (IA) from the Advanced RPE Analysis feature of FORUM Viewer (Carl Zeiss Meditec, Inc.). This feature measures the area (mm²) exhibiting sub-RPE hyper-reflectance within a 2.5 mm radius from the fovea. Central subfield thickness (CST, µm) and logMAR visual acuity (VA) were also obtained for each visit.

Results: 1051 eyes of 529 patients were included in the study. 383 eyes (36.4%) converted to neovascular AMD. 790 NNAMD eyes were analyzed with a mean follow-up length of 5.4 years and a mean age of 77. Mean baseline

measurements for IA, CST, and logMAR VA were 1.81 mm^2 , $252.1 \text{ }\mu\text{m}$, and 0.34, respectively. The mean GA growth as measured by IA was $0.42 \text{ mm}^2/\text{year}$. The mean change in CST was $-3.48 \text{ }\mu\text{m}/\text{year}$, and the mean worsening of logMAR VA was 0.06/year.

Eyes were categorized into 5 subgroups by initial presentation of IA in mm^2 : 0-2 (n=575), 2-4 (n=88), 4-6 (n=45), 6-12 (n=65), and 12-18 (n=16). The mean growth rate of each subgroup was $0.37 \text{ mm}^2/\text{year}$ (± 0.55), $0.73 \text{ mm}^2/\text{year}$ (± 0.85), $0.53 \text{ mm}^2/\text{year}$ (± 1.06), $0.50 \text{ mm}^2/\text{year}$ (± 1.14), and $0.06 \text{ mm}^2/\text{year}$ (± 0.67), respectively. Those exhibiting the highest IA growth rate (top 10%, n=79) had a mean growth rate of $1.88 \text{ mm}^2/\text{year}$ (± 0.49).

Conclusions: Sub-RPE illumination area as measured on OCT can be used to estimate the growth of geographic atrophy in NAMD. IA growth correlates with worsening in logMAR VA and reduction in CST. These measurements should be compared to the current gold standards of GA measurement to determine if it can be used as an outcome measure of clinical research.

ABSTRACT BODY:

Purpose: While topical anesthetic agents achieve excellent anesthesia on the external surface of the eye, they do not numb the internal aspect of the pars plana, which is extremely sensitive. Patients often report moderate to severe discomfort during intravitreal injections with currently available analgesics. Articaine is an amide local anesthetic that blocks the generation and conduction of nerve impulses and was selected because of its ability to penetrate soft tissue and bone. Articaine is approved for dental injection. Nonclinical IND-enabling studies were conducted with articaine ophthalmic solution (AG-920) to support clinical development.

Methods: AG-920 was evaluated in pharmacodynamic, ocular distribution, and ocular toxicity and toxicokinetic studies in rabbit, and articaine was evaluated for melanin binding in vitro. Animals received a single bilateral topical ocular administration of two 35 µL drops of AG-920 with a 30-second dosing interval. Efficacy was assessed by Cochet-Bonnet esthesiometry, plasma and ocular matrices were analyzed with LC-MS/MS methods, and ophthalmic exams, intraocular pressure (IOP), pachymetry, and ocular histopathology were included in the toxicity studies.

Results: Ocular anesthetic effect was observed for 20 minutes post-dose. Articaine did not significantly bind melanin, and ocular distribution data showed that AG-920 penetrated the globe following topical administration, delivering articaine to the target tissue and rapidly metabolizing to the inactive metabolite. Systemic exposure was minimal, peaked at 15 minutes, and declined quickly. AG-920 was well tolerated in the rabbit, with no tolerability or toxicity findings noted in any ocular or systemic toxicology endpoint. The No Observed Adverse Effect Level was the highest dose administered, 5.6 mg/eye (11.2 mg/animal or 6.6 mg/kg).

Conclusions: These data demonstrate that AG-920 induces ocular anesthesia, delivers articaine to the target ocular tissues, and was well tolerated in nonclinical studies. The ocular anesthetic activity and safety of AG-920 is currently being evaluated in human subjects (NCT04513652).

ABSTRACT BODY:

Purpose: Subretinal injection is a commonly used method to deliver retinal gene therapy. Recording and evaluating parameters of the surgical procedure including the site of the injection(s), bleb locations, duration of injection and other parameters could compliment the understanding of treatment efficacy and safety. The goal of this study is to use our surgical experience with post FDA-approval voretigene neparvovec gene therapy to develop a grading procedure of the surgical steps using surgical videos and intra-operative optical coherence tomography (iOCT) that may be applied by the Casey Reading Center (CRC).

Methods: 12 eyes of six patients underwent pars plana vitrectomy with subretinal injection of voretigene neparvovec-rzyl (Luxturna®) in patients diagnosed with RPE65 mutation-associated retinopathy. The grading procedure was developed by reviewing intra-operative images and iOCT surgical videos. The following sequential steps of the surgery were carefully reviewed and analyzed: core vitrectomy, pre-bleb placement, vector injection, post-injection posterior pole exam and air-fluid exchange. A surgery evaluation grading form was developed in collaboration with vitreoretinal surgeons and utilized by an experienced grader for each surgical procedure.

Results: Video interpretation was useful in delineating bleb location, number of injections and total bleb injection time. Critical features of the procedure and dynamic intraoperative events could be identified and catalogued using the surgical videos (Table 1). Figure 1 shows representative still images captured from iOCT videos.

Conclusions: This standardized analysis of the surgical procedure with intraoperative video and iOCT is useful to study and understand the variability associated with subretinal surgery. This pilot study demonstrated that pre-blebs and blebs were visualized in all cases without apparent loss in volume, that a wide range of subretinal injection times could be accurately measured, and that foveal detachment could be confirmed in 64% of cases. Implementation of the CRC intraoperative surgical grading procedures may contribute to an improved understanding of efficacy and safety of other subretinal delivery of gene and cell-based therapies.

ABSTRACT BODY:

Purpose: The cost of eyeglasses is variably covered by medical insurance and thus is a significant barrier for patients in lower socioeconomic classes. This study seeks to evaluate the efficacy of Recycle Vision (RV) at Los Angeles County + University of Southern California (LAC+USC) Medical Center Eye Clinic, a monthly clinic run by volunteer medical students that provides free donated eyeglasses, through patient quality surveys of RV clinic attendees.

Methods: A convenience sample of 30 patients were surveyed upon initial visit between August 1, 2019 to December 31, 2019 on their perceived level of ease in completing daily tasks prior to visiting RV clinic, level of satisfaction with previous glasses, and reasons why they previously did not seek eyeglasses. Patients' prescriptions were matched with available eyeglasses based on spherical equivalent and axis of astigmatism using Winglasses software algorithm; patients selected their glasses from these presented options based on subjective improvement of visual acuity. They then completed a phone follow-up survey 1 month after initial visit to gauge satisfaction with the services of RV and perceived changes in ease of completing daily tasks after visiting RV clinic.

Results: Of the 30 study participants, 90% received eyeglasses from RV, with average reported improvement in ease of daily activities of 3.96 (SD 1.13) on a scale of 1 to 5. 67% responded that if RV clinic did not exist, they would not have obtained glasses elsewhere. Cost was the most commonly cited barrier (70%); other barriers cited by patients are listed in Figure 1. On follow-up survey, on a scale of 1 to 5 (5 being greatest), the average likelihood of patients referring a friend/family member to RV was 4.07 (SD 1.14).

Conclusions: The majority of patients who visited RV received free eyeglasses and had subsequent improvement in their quality of life. This study demonstrates that programs offering free eyeglasses are effective at correcting refractive error and can offer a practical public health solution to improving functional visual acuity for underserved populations.

ABSTRACT BODY:

Purpose: Eye diseases and visual impairment are common in older people accessing aged care services. Once admitted into a residential aged care facility, older people are less likely to have access to an eye health care service. The objective was to evaluate the burden of eye diseases, utilisation of eye health care services and ophthalmic medications among older people living in residential aged care facilities in Australia

Methods: A retrospective cross-sectional study was conducted using linked national aged care and health care data from the Registry of Senior Australians; a national cohort of people who entered permanent residential aged care facilities between 2008 and 2015. The prevalence (95% confidence interval (CI)) of eye diseases by year, eye health care services and ophthalmic medication use within a year of entry into the service were evaluated. Poisson regression models were used to estimate crude and adjusted prevalence ratio (PR) to evaluate change in prevalence of eye diseases over the study period.

Results: Of 409,186 people aged ≥ 65 years included in the study, 43.8% (95%CI, 43.7%-44.0%) had an eye condition. Among those 32.9% (95%CI, 32.7%-33.0%), 19.7% (95%CI, 19.6%-19.8%), 13.6% (13.5%-13.7%) and 8% (7.9%-8.1%) had a chronic eye disease, acute eye disease, glaucoma and cataract, respectively. Prevalence for any eye disease (PR: 0.99, $P < 0.001$), chronic (PR: 0.99, $P < 0.001$) and acute eye diseases (PR: 0.97) slightly decreased over the study period but remained stable for glaucoma (PR: 1.01, $P < 0.001$) and cataract (PR: 1.00, $P < 0.001$). Among those with any eye disease, less than half (46.5%) used at least one eye health service and more than two thirds (70.5%) used one ophthalmic medication. The most accessed eye health care service was optometric services (41.7%) and the most used ophthalmic medication was anti-infective eye drops (37.2%).

Conclusions: The burden of people with an eye disease accessing residential aged care service in Australia was high, however the use of eye health care services was low. Understanding the profile of older people with an eye disease in residential aged care facilities and their access to eye health care services and medications can provide evidence for appropriate resource allocation and evaluation of future eye health care needs in this population.

ABSTRACT BODY:

Purpose: To evaluate the association of early childhood progression of spherical equivalent (SE) with high myopia (HM) in teenagers in the Singapore Cohort of Risk factors for Myopia (SCORM).

Methods: We included 1051 SCORM children followed over a mean follow-up of 6.9 ± 1.0 years from baseline (6-11 years-old) until their teenage years (12-19 years-old). Cycloplegic autorefractometry and AL measurements were performed yearly. Three-year SE and axial length (AL) progression in childhood, baseline SE and AL, and parental myopia were evaluated using multivariable logistic or linear regression models, with predictive performance of risk factors assessed using the area under the curve (AUC). The outcomes in teenagers were HM ($SE \leq -5$ D), $AL \geq 25$ mm, SE and AL.

Results: At the last visit, 20% of teenagers had HM and 35% had $AL \geq 25$ mm. In multivariate regression analyses, every -0.3 D/year increase in 3-year initial SE progression and every 0.2 mm/year increase in 3-year initial AL progression were associated with a -1.14 D greater teenage SE and 0.54 mm greater teenage AL ($p < 0.001$). The AUC (95% CI) of a combination of 3-year SE progression, baseline SE and parental myopia for teenage HM was 0.98 (0.98-0.99). The AUC for 3-year AL progression, baseline AL and parental myopia for teenage $AL \geq 25$ mm was 0.95 (0.94-0.97).

Conclusions: Three-year myopia progression in early childhood combined with baseline SE or AL, and parental myopia, were good predictors of teenage HM. Clinicians may use this combination of factors to guide timing of interventions, potentially reducing the risk of HM later in life.

ABSTRACT BODY:

Purpose: Despite ocular trauma being an important cause of vision loss worldwide, there is currently a lack of consensus on the optimal management for traumatic injuries.

Our objective is to summarize global preferred practice patterns for the management of ophthalmic trauma.

Methods: An online survey was distributed to 42 trauma centers throughout 6 continents to assess institutional management practice patterns for eye emergencies including open globe injuries, hyphema, and orbital fractures.

Results: Responses were collected from 32 institutions (response rate 32/42, 76.2%) that were distributed across Asia (37.5%), North America (34.4%), South America (12.5%), Africa (9.4%), and Europe (6.3%). The respondents practiced ophthalmology for a median of 15.5 (IQR 9, 20) years after residency. The majority of institutions (n=24, 75.0%) have ophthalmology coverage 24 hours per day each day; of those that do not, 8 (100%) have on-call ophthalmology coverage available within one hour of notification. Most institutions (n=25, 78.1%) routinely administer pre-operative systemic antibiotics for open globe injuries, while 31.3% (n=10) administer pre-operative topical antibiotics. Oral ciprofloxacin was most preferred for systemic antibiotics (n=5, 15.6%), while moxifloxacin was most popular for topical (n=6, 18.8%), but respondents lacked consensus. Around half of the institutions also administer intraoperative antibiotics during the time of open globe injury repair (n=17, 53.1%), while many (n=29, 87.9%) administer topical steroids post-operatively. Regarding hyphema management, 93.8% (n=30) of responding institutions administer topical steroids, with prednisolone as the preferred medication for many (n=29, 90.6%). Respondents also disagreed on the routine disposition for hyphema patients, with 25.0% (n=8) admitting all hyphema patients to the hospital. For patients presenting with orbital fractures, 18 centers (56.3%) give systemic antibiotics to prevent infection, while 9 (28.1%) administer systemic steroids to quell inflammation.

Conclusions: Preferred management practices for ocular trauma-related eye emergencies vary widely. Evidence-based consensus guidelines for the management of ophthalmic trauma are needed to ensure the highest quality of management for all ophthalmic trauma cases.

ABSTRACT BODY:

Purpose: The neovascular form of age-related macular degeneration has been reported to be less frequent among individuals self-identifying as Black, suggesting that darker fundus pigmentation due to increased concentration of melanin within uveal melanocytes may affect retinal abnormalities. Whether this association is found in other retinal conditions, such as pathologic myopia (PM), has not been evaluated to our knowledge. Therefore, we investigated retinal characteristics of PM among patients who self-identified as Black.

Methods: Retrospective review of medical records was performed of adult patients who self-identified as Black with ICD codes consistent with PM followed by retina specialists at the Retina Division, Department of Ophthalmology, Johns Hopkins Hospital, Baltimore, MD. For a comparison group, a similar review was done for only one of the retina specialists, among patients with PM who did not self-identify as Black. Data collection included central subfield thickness (CST) on optical coherence tomography (OCT) based on the most recently obtained OCT between January 2005 and December 2019.

Results: Among 7 retina specialists, 428 patients were ICD coded for PM and 60 of those patients (14%) self-identified as Black. In comparison, 2,026 (22%) of all 10,012 patients seen in the Retina Division self-identified as Black in 2014. Of the 368 patients who did not self-identify as Black, 63 patients from a single retina specialist were used as a comparison group. OCT images were available for 35 (58%) of the 60 black patients and 46 (73%) of the 63 patients in the comparison group. Mean (\pm SD) CST in the right eye was 260 ± 77 μ m in the Black patients and 296 ± 98 μ m in the comparison group, while median (25th, 75th quartiles) CST in the right eye was 259 μ m (218, 280) in black patients and 281 μ m (256, 319) in the comparison group.

Conclusions: While the retrospective design and multiple confounding factors that can affect CST—such as retinal detachment, choroidal neovascularization, or retinal atrophy—preclude formal statistical analyses, these preliminary investigations suggest there may be differences in CST among patients with PM who self-identify as Black and those who do not. A prospective cross-sectional study is planned to characterize PM in these patient populations in greater detail.

ABSTRACT BODY:

Purpose: Vision-related quality of life (VRQoL) is a patient-centered metric that is utilized to examine the impact of geographic atrophy (GA) in patients with age-related macular degeneration (AMD). However, little is known about the relationship between VRQoL and functional and structural GA biomarkers such as lesion area, and prior work has not accounted for GA lesion location. Thus, we examined the influence of the topographic distribution of GA on VRQoL.

Methods: We manually segmented GA lesions on color fundus photographs of 161 Age-Related Eye Disease Study (AREDS) participants with nonexudative AMD. For each participant, we calculated the total area of atrophy in the better eye (eye with least atrophy) and the worse eye (eye with most atrophy), as well as the area of atrophy in each of the nine subfields of the Early Treatment for Diabetic Retinopathy Study (ETDRS) grid for each eye. VRQoL had been measured using the National Eye Institute Visual Function Questionnaire (NEI-VFQ). We assessed associations between VRQoL and area of atrophy in each topographic region of the better and worse eye utilizing linear mixed-effects models while controlling for age, gender, and the presence of bilateral disease.

Results: There was no significant association between VRQoL and total area of atrophy in the better eye (β , -0.22; 95% confidence interval [CI], -0.84 to 0.40; $p = 0.49$) or worse eye (β , -0.27; 95% CI, -0.73 to 0.19; $p = 0.25$). When examining the topographic distribution of GA in the better eye, lower VRQoL was significantly associated with greater area of atrophy in the central 1-mm-diameter zone (β , -3.65; 95% CI, -6.85 to -0.45; $p = 0.026$), but not with area of atrophy in any of the other eight ETDRS subfields. In the worse eye, VRQoL was not significantly associated with area of atrophy in any topographic subfield.

Conclusions: In this cohort, area of atrophy in the central 1-mm-diameter zone of the better eye was the only measure of atrophy that was significantly associated with VRQoL. Although GA area in the worse eye is often used as a structural endpoint in clinical trials, this measure was not associated with VRQoL and, thus, may not fully capture the effects of disease progression or interventions on VRQoL in patients with GA secondary to nonexudative AMD.

TITLE: Atropine in intermittent exotropia

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Tejedor, Neuroscience, Universidad Autonoma de Madrid, Madrid, Madrid, SPAIN|J. Tejedor, F. Gutiérrez-Carmona, Ophthalmology, Hospital Universitario Ramon y Cajal, Madrid, Madrid, SPAIN|F. Gutiérrez-Carmona, Surgery, Universidad Alfonso X El Sabio, Villanueva de la Canada, Comunidad de Madrid, SPAIN|

Commercial Relationships Disclosure (Abstract): Jaime Tejedor: Commercial Relationship: Code N (No Commercial Relationship) | Francisco J Gutiérrez-Carmona: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the effect of atropine on the evolution, control, deviation angle, suppression, and stereoacuity of intermittent exotropia (IXT)

Methods: In a pilot study, twenty-three patients with basic or simulated divergence excess (proximal convergence excess) IXT, aged 3-6 years old, and fair to poor control (≥ 3 by revised Newcastle Control Score, NCS) were randomly assigned to atropine once a week ($n=13$) or 2h of occlusion daily ($n=10$) in the eye preferred for fixation. Deviation angle (PD) by prism and alternate cover test (APCT) at distance and near after 45 minutes of occlusion, followed by +3.00 D lens at near, stereoacuity (log arcsec), suppression by Bagolini and Worth 4 dot test (WFD), were measured before and after 6 months of treatment. Deterioration in control (NCS), angle or stereoacuity were the outcome variables studied. Variables were compared using nonparametric tests (Mann-Whitney, Wilcoxon, Fisher exact test), and the influence of potential confounding variables was studied (including age, initial deviation and degree of deviation control, and initial stereoacuity) using nonparametric tests and bootstrap multiple regression.

Results: Amblyopia was not observed in this cohort. Deterioration, defined as 3-point increase in the revised NCS, impairment of 2-octave or more in stereoacuity or 8-PD increase in distance deviation by APCT, was not observed in any case during the study period. Change in APCT at distance (-3.07 vs -3 PD, $p=0.9$) and near (-2.30 vs -1.50 PD, $p=0.4$), change in stereoacuity at near (-0.04 vs -0.02 log arcsec, $p=0.7$), and in revised NCS (-1.3 vs -1.9, $p=0.2$) were not significantly different between the two groups. Although suppression was more frequently detected in the atropine than occlusion group by Bagolini (6/13 vs 2/10, $p=0.3$) and WFD at distance (5/13 vs 3/10, $p=0.6$) at near (4/13 vs 1/10, $p=0.3$), differences did not reach significance. Age, initial deviation, revised NCS, and stereoacuity were not significant confounding variables ($p=0.2$; 0.4; 0.1; 0.6, respectively).

Conclusions: Although these are preliminary data of a pilot study that require confirmation, atropine is not different from occlusion in the control of basic or simulated divergence excess IXT at short or middle term.

ABSTRACT BODY:

Purpose: To discover the occurrence of Herpes Simplex Virus type 1 and 2 (HSV) and Varicella Zoster Virus (VZV) DNA in transplanted corneas using polymerase chain reaction (PCR), and to determine the relationship between latent HSV-1 and VZV with the occurrence of herpetic eye disease in recipients and graft failure.

Methods: Eighty-eight (88) corneas were morphologically evaluated before surgery by slit-lamp examination and CellChek® specular microscopy. Excluded corneas were tested for HBV, HCV, and HIV by donor serological assessment, a low cell count (under 2,300 cells /mm³), corneal scars, and abnormal endothelial cell morphology. Transplanted corneas were sampled for HSV 1,2 and VZV DNA by PCR. All eyes transplanted with the donor corneas were evaluated and followed for corneal transparency, endothelial cells morphology, and number by specular microscopy signs for ocular inflammation, intraocular pressure, and anterior segment optical coherence tomography (OCT).

Results: HSV-1 DNA was detected in five transplanted corneas out of the 88 that were examined (5.7%). HSV-2 was not detected in any cornea, and VZV in one cornea out of 82 examined (1.2%). Four of the positive corneas were used in descemet membrane endothelial keratoplasty (DMEK) surgeries. One for a combined DMEK/anterior vitrectomy/ iridoplasty surgery and one as a tectonic graft. One recipient (16.7%) developed herpes dendritic epitheliopathy and keratouveitis 12 months after transplant though the graft remained clear after treatment. One cornea was used for a tectonic graft and stayed edematous at 20 months follow - up. The rest of the corneas stayed clear.

Conclusions: Herpes viruses, especially HSV-1, may be PCR DNA positive in morphologically normal donor corneas. Recipients of herpes positive corneal grafts are at risk for herpetic eye disease. Further evaluation with a bigger sample size and a longer follow-up time is needed to establish a clinical correlation to donor graft survival and to recipient ocular infection with HSV. Positive samples will be evaluated for reverse transcriptase PCR (RT-PCR) to evaluate HSV latency and infectivity.

ABSTRACT BODY:

Purpose: African Americans have a greater prevalence of open angle glaucoma (OAG) and exposure to traffic-related air pollution (TRAP). We investigated whether glaucomatous vascular changes were related to exposure of nitrogen dioxide (NO₂) and particulate matter with aerodynamic diameter < 2.5 µm (PM_{2.5}) in the African American Eye Disease Study (AFEDS).

Methods: The AFEDS is a cross-sectional, population-based cohort study conducted from 2014–2018 of 6,347 self-reported African Americans aged 40 years or older residing in 32 US census tracts of Inglewood, California. Participants completed in-home interviews and detailed eye exams including optical coherence tomography angiography (OCTA) imaging. Perfusion of radial peripapillary capillaries in healthy eyes was measured as vessel area density (VAD) calculated over 6x6 mm images centered on the optic nerve head. Exposures to NO₂ (ppb) and PM_{2.5} (µg/m³) were estimated from spatiotemporal generalized additive models created using the EPA's Air Quality System data. Hierarchical linear regression models of VAD on NO₂ and PM_{2.5} were progressively adjusted for (1) sex and age; (2) education, employment, and income; (3) body mass index, glycated hemoglobin, duration of diabetes, systolic blood pressure, ever-smoking, and health insurance; and (4) axial length, OCTA signal strength, and vision insurance.

Results: AFEDS participants (n = 1,009) were on average 58.3 years old, 64.2% female, 50% employed, 61% earned ≥ \$40,000, and had 14.3 years of education. In the first three hierarchical models, lower VAD was associated with mean NO₂ and PM_{2.5} exposure (P < 0.05). Associations in the fully adjusted models were not significant, but in the expected direction; VAD was -0.160 (95% CI: -0.377, 0.056) percent lower per 10-ppb increase in NO₂, and -0.271 (95% CI: -0.588, 0.045) percent lower per 10 µg/m³ increase in PM_{2.5}. Differences in VAD equated to an increased age of 1.6 years for NO₂ and 2.7 years for PM_{2.5}.

Conclusions: We found an inverse relationship between peripapillary perfusion and TRAP after adjusting for sociodemographic and clinical covariates. Associations further adjusted for ophthalmic measures were not significant, which may be due to a small true effect and overadjustment. These findings complement an emerging body of evidence that TRAP may be related to eye disease and could contribute to disparities in OAG for African Americans.

ABSTRACT BODY:

Purpose: Impaired visual function may contribute to suboptimal glycemic control in diabetes mellitus. However, since prior studies examining changes in hemoglobin A1c (HbA1c) after cataract surgery have shown mixed results, it is unclear whether visual dysfunction from a clinically significant cataract affects glycemic control. We performed a retrospective, observational study to evaluate whether HbA1c levels change after cataract surgery.

Methods: As a pilot study we evaluated HbA1c in all patients who underwent cataract surgery at our institution in 2019 with HbA1c levels drawn both 0-90 days prior to and 90-180 days after cataract surgery. The primary outcome measure was the difference in HbA1c before and after cataract surgery for all study subjects. We performed subgroup analysis by age, based on the average, and in those with a pre-operative HbA1c ≥ 8 . The pre-operative HbA1c cut off ≥ 8 was selected before analysis of data. HbA1c levels before and after cataract surgery were compared using a paired, two-tailed t-test in SPSS. We then expanded this study to include all patients who underwent cataract surgery from 2015-2019 with the same inclusion criteria as the pilot study in addition to HbA1c levels 690-780 days after surgery, if available.

Results: In the pilot study the mean and median ages of 102 study subjects was 71 years. There were 97 males and 5 females. Pairwise comparison of pre- versus post-operative HbA1c showed significantly lower post-operative HbA1c, with more reduction in older subjects and those with higher pre-operative HbA1c (Table 1). In the expanded study the mean and median ages of 436 subjects were 71.8 and 71 years, respectively. There were 424 males and 12 females. Pairwise comparison of pre- versus post-operative HbA1c showed a trend toward HbA1c reduction at 90-180 days, with a significant reduction in older subjects and those with higher pre-operative HbA1c, and this effect was sustained 690-780 days after surgery (Table 2).

Conclusions: Glycemic control improved after cataract surgery, with more improvement in older subjects and subjects with higher pre-operative HbA1c values.

ABSTRACT BODY:

Purpose: To determine the survival of patients with neovascular glaucoma (NVG) after tube shunt implant or cyclodestructive procedure, and to assess whether clinical factors are predictive of survival.

Methods: A retrospective chart review was performed of patients with NVG who underwent tube shunt implant and/or cyclodestructive procedures (cyclophotocoagulation and cyclocryotherapy) between January 2002 and December 2019 at the Minneapolis Veterans Affairs Medical Center (VAMC). Patient survival was compared to the age and gender matched Minnesota population. Univariate and regression analyses were used to evaluate the correlation of specific clinical parameters with survival.

Results: A total of 39 patients and 41 eyes were included. Tube shunt alone was implanted in 30 (73.2%) eyes, cyclodestruction alone was performed in 9 eyes (22%), and 2 eyes (4.9%) underwent both procedures. The mean (median) age at first operation was 70.2 (70) years. The most common etiology of NVG was diabetic retinopathy (DR) in 20 eyes (48.8%), followed by central retinal vein occlusion in 14 eyes (34.1%). Diagnoses of cardiovascular diseases and diabetes were found in 38 patients (97.4%) and 33 patients (84.6%), respectively. At post-operative 5-year follow-up, survival rate of the NVG patients was 56% compared to 80% in controls. There was no difference in survival between patients with NVG secondary to DR and those from other etiologies, although patients with NVG caused by DR had their first procedure at a younger age ($p = 0.036$). Preoperative visual acuity, maximum intraocular pressure (IOP), creatinine, HbA1c, and postoperative IOP at 6 months were not associated with survival.

Conclusions: In the Minneapolis VAMC population, NVG patients had a lower survival rate than the matched Minnesota population. Most patients had vasculopathic risk factors. The etiology of NVG was not associated with survival. Ophthalmologists should consider the shorter survival when planning surgery for NVG patients and recommend a multi-disciplinary approach to optimize their care.

ABSTRACT BODY:

Purpose: To study epithelial basement membrane (EBM) regeneration after photorefractive keratectomy (PRK) injuries that healed with and without stromal fibrosis.

Methods: One hundred sixteen rabbits had either no surgery, -4.5 diopter (D) PRK, or -9D PRK. Immunohistochemistry (IHC) was performed on cryofixed corneas at time points from unwounded to eight weeks, with four corneas at each time point in each group. Multiplex IHC was performed for laminin alpha 5, laminin beta 3, perlecan, and/or nidogen-1, keratocan, vimentin, and alpha-smooth muscle actin (SMA). Corneas at the one month peak for myofibroblast and fibrosis development were evaluated using Imaris 3D analysis.

Results: Laminin alpha-5, laminin beta 3, and nidogen-1 were incorporated into nascent EBMs. Defective perlecan incorporation in the nascent EBM was noted in corneas that developed large numbers of myofibroblasts and fibrosis in the anterior stroma.

Conclusions: Defective incorporation of transforming growth factor (TGF)-beta-modulating perlecan into the regenerating EBM by subepithelial myofibroblasts, and likely their precursor cells, underlies the development of stromal fibrosis after corneal injury.

ABSTRACT BODY:

Purpose: To determine the retinal tissue perfusion (RTP) and its relation to cognitive function in healthy older people after an 8-week high-speed circuit resistance training program (HSCT).

Methods: Eleven subjects in the HSCT group and seven age-matched non-training controls (CON) were recruited. The HSCT group trained 3 times per week for 8 weeks, while CON performed no formal training. One eye of each subject in both groups was imaged at baseline and at an 8-week follow-up, using a Retinal Function Imager to measure retinal blood flow (RBF). Retinal tissue perfusion (RTP) was calculated as RBF divided by the corresponding tissue volume. Cognitive function was assessed during both visits using the NIH Toolbox Fluid Cognition Battery.

Results: RTP was $2.99 \pm 0.91 \text{ nl s}^{-1} \text{ mm}^{-3}$ (mean \pm SD) at baseline and significantly increased to $3.77 \pm 0.86 \text{ nl s}^{-1} \text{ mm}^{-3}$ after training ($P < 0.001$) in the HSCT group, reflecting an increase of 26%. In the HSCT group, the Pattern Comparison Processing Speed Test (PAT) and Fluid Cognition Composite Score (FCS) were significantly increased after HSCT ($P = 0.01$). Furthermore, the changes in Flanker Inhibitory Control and Attention Test (FLNK) were positively correlated to increases in RTP ($r = 0.80$, $P = 0.003$).

Conclusions: This is the first prospective study to demonstrate that the increased RTP after HSCT was related to improved cognition in cognitively-normal elders, indicating RTP could be an imaging marker for monitoring cognitive changes due to physical activity in the elderly.

ABSTRACT BODY:

Purpose: Stargardt Disease type 1 (STGD1) is the most common inherited macular degeneration. Several treatment approaches including pharmacotherapy, gene therapy, and stem cell therapy are in clinical trials. Fixation stability (FS) and location (FL) describe important dimensions of visual function but there is limited data on how they are affected by disease over time. Here, we present longitudinal changes of FS and FL over 24 months in STGD1 from the international, prospective, multicenter ProgStar study (NCT01977846).

Methods: Over 5 study visits every 6 months, patients with a molecular diagnosis of STGD1 completed separate fixation exams of roughly 30 seconds using the MP-1 Microperimeter (Nidek). FS was expressed through the 68.3 %-Bivariate Contour Ellipse Area (BCEA), FL through the distance of the barycenter of all fixation events from the fovea as determined on OCT images.

Results: At baseline, 239 patients (105 males, 44 %) and 459 eyes with a median age of 32 years (mean \pm SD, 33.8 \pm 15.2 years) were included. The baseline mean log BCEA was $0.75 \pm 1.29 \log \text{deg}^2$ and the mean FL was $6.45 \pm 4.52 \text{ deg}$. Although the mean log BCEA did not monotonically increase from visit to visit, the overall yearly increase in log BCEA was $0.124 \log \text{deg}^2$ (99% CI, 0.063-0.185). It was not different during the first year compared to the second year. The increase was faster in eyes without flecks outside of the vascular arcades and depended on baseline BCEA. Looking at the subset of the better of two eyes resulted in a yearly increase in log BCEA of $0.138 \log \text{deg}^2$ (99% CI, 0.045, 0.230) and confirmed the observed association with baseline BCEA.

Conclusions: Fixation parameters may serve as useful secondary endpoints to longitudinally describe visual dysfunction.

TITLE: Effect of zoster vaccination on rates of herpes zoster ophthalmicus and herpes zoster in Australia

SESSION TITLE: Antimicrobials and Immunomodulators

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Phakey, S. Rogers, L.L. Lim, Centre for Eye Research Australia, Royal Victorian Eye and Ear Hospital, East Melbourne, Victoria, AUSTRALIA|A.J. Hall, Department of Ophthalmology, Alfred Health, Melbourne, Victoria, AUSTRALIA|A.J. Hall, Department of Surgery, Monash University, Clayton, Victoria, AUSTRALIA|L.L. Lim, Ophthalmology, Department of Surgery, The University of Melbourne, Melbourne, Victoria, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Sachin Phakey: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Rogers: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Hall: Commercial Relationship: Code N (No Commercial Relationship) | Lyndell Lim: Commercial Relationship(s);Allergan:Code F (Financial Support);Allergan:Code C (Consultant);Bayer:Code F (Financial Support);Novartis:Code R (Recipient);Novotech:Code C (Consultant)

ABSTRACT BODY:

Purpose: Few population-based studies examine the effect of zoster vaccination on rates of herpes zoster ophthalmicus (HZO) and herpes zoster (HZ). The aim of this retrospective time-trend analysis was to examine rates of HZO and HZ in Australia over time, both in the immunocompetent and immunocompromised. We hypothesised HZO and HZ rates would decrease in immunocompetent individuals following the introduction of the live-attenuated zoster vaccine (Zostavax[®]) on Australia's National Immunisation Program (NIP) in 2016. The NIP allows 70-79-year-olds to receive Zostavax[®] for free. The recombinant subunit zoster vaccine (Shingrix[®]) is not available via Australia's NIP.

Methods: We analysed all antiviral prescriptions dispensed for the treatment of HZO and HZ in Australia from 1994 to 2019, as recorded by the Australian Pharmaceutical Benefits Scheme and Repatriation Pharmaceutical Benefits Scheme. We calculated annual prescription rates to descriptively explore HZO and HZ incidence over time.

Results: Amongst immunocompetent individuals, rates of HZO and HZ increased 1.90-fold in the period 1998-2015, before decreasing 0.48-fold between 2016-2019 (Figure). Amongst immunocompromised individuals, rates of HZ increased throughout the study period, rising 8.50-fold between 2006 (year data first available) and 2019.

Conclusions: The introduction of Zostavax[®] on Australia's NIP coincided with reduced rates of HZO and HZ in immunocompetent individuals, highlighting the likely beneficial effect of zoster vaccination within the Australian population. Ophthalmologists should remain alert to HZO in immunocompromised patients, whose immune status may be a contraindication to live zoster vaccination, with zoster rates rising amongst the immunocompromised, even after the introduction of Zostavax[®].

ABSTRACT BODY:

Purpose: The sight threatening sulfur mustard (SM) induced ocular injury presents specific symptoms for each clinical stage. While the acute injury is characterized by erosions and severe inflammation, the chronic or late pathology that develops only in part of the eyes, is clinically expressed by corneal epithelial defects and neovascularization (NV). The pathological mechanisms underlying this injury are still under research and treatment is insufficient. Based on the results of RNA sequencing of corneas at 4 weeks post exposure, 5 mRNAs that were significantly elevated and were not studied previously in the context of SM-induced ocular injury were selected for further research. The expression pattern in both the cornea and the limbus at additional time points during the course of the injury was studied in the rabbit model.

Methods: Rabbit eyes were exposed to SM vapor and a clinical follow-up was carried out up to 4 weeks. Corneal and limbal tissues were collected at 48h, 1w and 4w post exposure and MMP-1, MMP-10, IRS-1, NGF and IL-33 mRNA levels were measured using real time PCR.

Results: Typical SM-induced ocular injury developed, including an acute injury that was partially resolved within a week in all of the exposed eyes, followed by an irreversible late pathology in 50%-80% of the eyes, beginning at 2w. Significant elevations were seen in the mRNA levels of the studied factors, however each factor presented a unique expression pattern. At the peak of the acute injury, at 48 h, significantly higher levels of corneal and limbal MMP-1, MMP-10 and NGF and corneal IRS-1 were found. At 1w, corneal and limbal MMP-1 and MMP-10 and corneal NGF, IRS-1 and IL33 levels were significantly elevated compared to naïve. During the late pathology, at 4w, significantly higher levels of corneal MMP-1, MMP-10, NGF and IRS-1 were found, with no change in the limbal levels.

Conclusions: The mRNA levels of the studied factors changed throughout the dynamic clinical course of the ocular injury and between the cornea and the limbus, mainly during the late pathology. The results suggest a possible involvement of these factors in the pathological processes in different ocular tissues at specific stages of the injury and may point out towards stage-specific therapeutic options.

TITLE: Factors Affecting Rates of Genetic Testing for Inherited Retinal Degenerations

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.Y. Zhao, K.E. Branham, D. Schlegel, A.T. Fahim, T. Jayasundera, W K Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Peter Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Kari Branham: Commercial Relationship: Code N (No Commercial Relationship) | Dana Schlegel: Commercial Relationship: Code N (No Commercial Relationship) | Abigail Fahim: Commercial Relationship: Code N (No Commercial Relationship) | Thiran Jayasundera: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Factors affecting rates of genetic testing for inherited retinal degenerations have not been characterized. We analyzed effect of launch of the My Retina Tracker Genetic Testing Study (MRT-GTS) research registry and associations with patient characteristics.

Methods: We performed retrospective chart review of new patients evaluated at an eye center between July 2016 and June 2018, analyzing rates of genetic testing 12 months pre- and post-launch of MRT-GTS, which launched locally in June 2017. We determined odds ratios (ORs) of association between patient characteristics and rates of obtaining genetic testing. We examined the proportion of test results returned within 90 days of the initial clinic evaluation.

Results: Among 369 patients (age 39.5 years, SD 20.8), 144 were evaluated in the pre-MRT-GTS period and 225 in the post-period. The pre-MRT-GTS rate of successfully obtaining testing was 51.4% (95% CI, 42.6–60.2%). Post-launch, the testing rate increased by 28.9 percentage points (95% CI, 16.7–41.1%; $P < .001$). Patient factors that increased odds of testing were eligibility for MRT-GTS (OR, 14.15; 95% CI, 7.36–27.24; $P < .001$) and worse visual acuity (logMAR +1.0) in the better-seeing eye (OR, 1.92; 95% CI, 1.27–2.91; $P < .01$). Odds were decreased for those identifying as African-American (OR, 0.10; 95% CI, 0.04–0.24; $P < .001$) or other race (OR, 0.37; 95% CI, 0.15–0.91; $P < .05$), and when the primary language was not English (OR, 0.13; 95% CI, 0.03–0.55; $P < .01$). The proportion of test results reported within 90 days was 81.5% (95% CI, 74.8–86.4%) when eligible for MRT-GTS and 48.1% (95% CI, 35.6–58.1%) when not eligible ($P < .001$).

Conclusions: Demographic and clinical factors affect decisions to pursue genetic testing. There was an increase in testing rates after launch of MRT-GTS. Collaborations between non-profit organizations, industry, and the public sector to fund testing help to identify the genetic cause of disease, a critical stepping stone to developing therapies.

TITLE: Risk of Requiring Glaucoma Surgery following Intravitreal anti-VEGF Injections: A Case-Control Study

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Lo, B. Zack, The University of British Columbia Faculty of Medicine, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure (Abstract): Cody Lo: Commercial Relationship: Code N (No Commercial Relationship) | Barend Zack: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has been suggested that intravitreal anti-VEGF injections (IVIs) can accelerate progression of glaucoma but the risk of any IVI exposure on needing glaucoma surgery is not clear. This case-control study determines the increased risk associated with IVIs and the need for glaucoma surgery.

Methods: Participants were collected from a glaucoma specialist practice in British Columbia, Canada with a diagnosis of glaucoma, glaucoma suspect, or ocular hypertension and seen between January 1, 2017 – December 31, 2019. Cases were defined as having at least one glaucoma procedural intervention (not combined with cataract surgery) within this timeframe. Controls had no surgical interventions for their glaucoma and were recruited in a 2:1 ratio to cases with age and sex matching. Clinical data was collected for each participant's most recent follow up visit within the timeframe including whether the participant had any previous exposure to IVIs. Rates of previous IVI exposure amongst surgical glaucoma cases were compared to non-surgical controls to calculate an odds ratio. Ethics approval was obtained from the University of British Columbia ethics board.

Results: A total of 133 surgical glaucoma cases and 266 non-surgical glaucoma controls were recruited with no significant difference in demographic information. The average age in years being 71.9 in cases and 73.8 in controls. The cohort was 57% male in cases and 53% in controls. The distribution of glaucoma diagnoses and retinal indications for IVIs were similar amongst both cases and controls. Cases used a significantly ($P < 0.001$) larger number of topical medications (3.54) compared to controls (2.27). There was also a significant ($P < 0.001$) difference in average IOP between cases (25.69 mm Hg) and controls (15.03 mm Hg). The crude odds ratio for glaucoma surgery amongst those with any IVI exposure was 6.69 (95% CI 3.52-12.73). The adjusted odds ratio using multivariate logistic regression for this association was 8.49 (95% CI 4.20-17.18) when adjusting for age, sex, and medical comorbidities such as hypertension and diabetes.

Conclusions: This study demonstrates that any previous exposure to IVIs is associated with a significantly higher risk of glaucoma surgery amongst patients with glaucoma. As the use of IVIs continues to increase, it is important for providers to be aware of this risk particularly in those with pre-existing glaucoma.

ABSTRACT BODY:

Purpose: Knowing the natural history of vision loss is key to select the appropriate endpoints and best interpret response to treatments. The purpose of this study was to compare the natural history of visual function change in a cohort of patients affected with retinal degeneration due to biallelic variants in BBS1 and BBS10 genes.

Methods: Design: Global, multicenter, retrospective chart review.

Patients were recruited from 9 participating academic centers from 6 countries (Belgium, Canada, France, New Zealand, Switzerland and USA). Inclusion criteria were: 1) female or male subjects with a clinical diagnosis of retinal dystrophy, 2) molecularly confirmed biallelic disease-causing variants in BBS1 or BBS10 and 3) measures of visual function for at least one visit. Retrospective data collected included age, onset of symptoms, visual acuity (VA) and genotypes. When possible we also collected data on refractive error, optical coherence tomography (OCT), kinetic perimetry (VF), electroretinography (ERG), and the systemic phenotype.

Results: 67 individuals had biallelic pathogenic variants in BBS1 (n=38; 20 females and 18 males); or BBS10 (n=29; 14 females and 15 males). Overall, the mean follow-up period was 10 years (range 0-33.9 years). Missense variants were the most common for BBS1-patients, and frameshift for BBS10. Extraocular signs were documented in 97% of BBS1-patients and in 92% of BBS10-patients. When ERGs were recordable, rod-cone dystrophy (RCD) was observed in 82% (23/28) of BBS1- and 73% (8/11) of BBS10-patients; cone-rod dystrophy (CORD) was seen in 18% of BBS1 only, and cone dystrophy (COD) was only seen in three BBS10-patients. ERGs were non-detectable earlier in BBS10-patients than in BBS1-patients. Similarly, VA and VF declined more rapidly in BBS10-compared to BBS1-patients.

Conclusions: Retinal degeneration appears earlier and is more severe in BBS10-patients compared to those with BBS1 variants. Non syndromic retinal degeneration was observed in both groups. The course of change of visual function appears to be related to genetic subtypes of BBS.

ABSTRACT BODY:

Purpose: To compare automated machine learning (AutoML) to transfer learning (Inception) for disc hemorrhage (DH) identification.

Methods: This study was a retrospective analysis of fundus photographs obtained from the Ocular Hypertension Treatment Study, New York Eye and Ear Infirmary of Mt. Sinai, Massachusetts Eye and Ear, Thessaloniki Eye Study, and GONE datasets. High magnification fundus photographs of different resolutions and sources centered on the optic disc were included. Ground truth was established by the consensus of grades from two masked glaucoma specialists. Images were graded independently and disagreements in grading were resolved via adjudication, ungradable images were excluded. The complete dataset was split into training (80%), validation (10%), and test (10%). An automated machine learning model (AutoML), which tunes model hyperparameters without user engagement, was trained to distinguish disc hemorrhage (DH) positive and DH negative images. After training and validation, AutoML evaluated the model against a subset of test images, providing Precision and Recall data for each confidence threshold from 0 to 1. This process yields a binary classification model that predicts DH based on the returned probability at a given confidence threshold. A hard-coded convolutional neural network model based on the widely used InceptionV3 architecture was trained on the same data set. The performance of each model on an identical test set was then evaluated.

Results: A total of 897 images were included, 314 DH positive and 583 DH negative. The AutoML model achieved an area under the precision-recall curve (AUPRC) of 0.923, a sensitivity of 85% and specificity and 86%. For the hard-coded deep learning model, AUPRC was 0.82 with a sensitivity and specificity of 83% and 60%, respectively. The Inception model attention maps help visualize what parts of an image contributed most to a prediction (Fig 1).

Conclusions: The AutoML algorithm performance was high and showed good concordance with a traditional hard-coded algorithm. AutoML offers a low clearance method for clinicians without programming expertise to develop and deploy deep learning solutions.

TITLE: Smoking, Lung Disease and Other Factors Associated with the Long Anterior Zonule (LAZ) Trait

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.K. Roberts, T.L. Newman, J.M. McMahon, C.E. Morettin, M.F. Roberts, Illinois College of Optometry, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Daniel Roberts: Commercial Relationship: Code N (No Commercial Relationship) | Tricia Newman: Commercial Relationship: Code N (No Commercial Relationship) | Janice McMahon: Commercial Relationship: Code N (No Commercial Relationship) | Christina Morettin: Commercial Relationship: Code N (No Commercial Relationship) | Mary Roberts: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The long anterior zonule (LAZ) trait is characterized by anomalous zonule-like fibers present on the anterior lens capsule central to the normal zonule insertion zone. At least two varieties have been described. One rare type is associated with late-onset retinal degeneration (L-ORD) and caused by a S163R mutation in the C1q tumor necrosis factor-related protein 5 gene (C1QTNF5/CTRP5). The other variety is idiopathic, may have prevalence near 2%, and has predilection for hyperopic females with age >50 years. Both varieties may exhibit pigment dispersion, and there is potential association with glaucoma. With an ongoing study, we report further on potential health associations with LAZ.

Methods: Several practitioners in an urban, academic primary eye care center in Chicago, IL, USA evaluated consenting patients for LAZ from 2011 to 2018. To supplement clinical findings, questionnaires were used to obtain information related to lifestyle and demographics. Variables assessed included ocular and general health status, education, smoking, alcohol use, and height/weight for calculation of body mass index. Multivariate logistic regression was used to assess relationships to LAZ presence.

Results: The analysis included 3,494 total subjects (65.0% female, 82.3% African American), with mean age of 50.6 ± 15.4 years (18-98 years). Subjects with >trace LAZ in either eye (N=131, 80.2% female, 90.8% African American) with mean age of 63.4 ± 11.7 years (35-92 years). Mean sphere-equivalent refractive error of LAZ subjects was $+0.48D \pm 2.28D$ (-10.44D to 7.69D) vs. $-0.94D \pm 2.8D$ (-28.38D to 7.56D) for those without LAZ. Controlling for age, female gender, and hyperopic refractive error, strongest associations occurred with elevated body mass index, hypertension, and smoking in packyears ($P < 0.05$). In addition, there was strong association with non-asthma-related lung disease, with LAZ subjects being 2.5x (OR=2.52; 95% CI=1.35 to 4.72, $P=0.004$) more likely to exhibit lung disease than people without LAZ.

Conclusions: In addition to strong associations with age, female gender, and hyperopic refractive error, this analysis further suggests LAZ has relationship to adverse health factors including elevated body mass index, hypertension, history of smoking and non-asthma-related lung disease.

TITLE: Intraretinal cystoid spaces in acute Vogt–Koyanagi–Harada disease

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.F. Missaka, M. Goldbaum, C.G. Machado, F. Silveira Souto, M.M. Lavezzo, P.F. Nóbrega, M.K. Oyamada, C.E. Hirata, J.H. Yamamoto, Ophthalmology, University of São Paulo, São Paulo, São Paulo, BRAZIL|V.M. Sakata, Ophthalmology, Universidade Federal do Parana, Curitiba, PR, BRAZIL|

Commercial Relationships Disclosure (Abstract): Ruy Missaka: Commercial Relationship: Code N (No Commercial Relationship) | Mauro Goldbaum: Commercial Relationship: Code N (No Commercial Relationship) | Cleide Machado: Commercial Relationship: Code N (No Commercial Relationship) | Fernanda Maria Silveira Souto: Commercial Relationship: Code N (No Commercial Relationship) | Marcelo Lavezzo: Commercial Relationship: Code N (No Commercial Relationship) | Viviane Sakata: Commercial Relationship: Code N (No Commercial Relationship) | Priscilla Nóbrega: Commercial Relationship: Code N (No Commercial Relationship) | Maria Oyamada: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Hirata: Commercial Relationship: Code N (No Commercial Relationship) | Joyce Yamamoto: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To present intraretinal cystoid spaces observed in spectral-domain optical coherence tomography (SD-OCT) images of eyes with acute Vogt-Koyanagi-Harada disease (VKHD).

Methods: Retrospective and descriptive study with VKHD patients who presented intraretinal cystoid spaces in the acute phase. All patients were followed for a minimum of one year from disease onset with predefined treatment protocols and systematic evaluation. We reviewed conventional OCT images, enhanced depth SD-OCT images (HRA+OCT, Heidelberg), including serial sections through the macula obtained at the initial visit and during the follow-up until complete resolution of serous retinal detachment.

Results: Twenty-nine patients (58 eyes) were evaluated. Of these, 8 patients (7 women, 12 eyes [20%]; mean age 34.6 ± 10.2 years) had intraretinal cystoid spaces (IRCS) at baseline (M0) and/or at first month of follow-up (M1) (Table 1). In this group, the mean time to start treatment was 29.2 ± 13.5 days. All these patients were treated with high-dose corticosteroid; six patients (75%) received additional early azathioprine until the second month of follow-up. In the group with cystoid spaces, the mean visual acuity (VA) at M0 was $1.70 \pm 0.5 \log \text{MAR}$ and at M1 was $0.55 \pm 0.65 \log \text{MAR}$. In 9 eyes, VA improvement was observed at M1, while in 3 eyes VA did not ameliorate. With 1 year of follow-up, VA was $0.07 \pm 0.2 \log \text{MAR}$. At M0/M1, on SD-OCT, all eyes with cystoid spaces had concomitant serous retinal detachment (SRD), and in 3 eyes there was a split in the inner photoreceptor myoid zone (bacillary detachment). We observed a slight increase in the density of the IRCS compared to the subretinal fluid in the SRD (Figure 1), with a significant variation in the mean optical density ratio (ODR) among them (0.36 ± 0.14 and 0.21 ± 0.09 , respectively; $P = 0.008$).

Conclusions: Even though cystoids spaces have been described in early SD-OCT literature in acute VKHD, detailed and better definition of SD-OCT findings relocated previous findings as serous retinal detachment or more recently as bacillary detachment. Intraretinal cystoid spaces, affecting inner and/or external nuclear layers, as described here, have not been reported till far. We hypothesize that our findings may be due to the action of inflammatory mediators, but studies are needed to understand its relevance since all patients had good VA during the follow-up.

TITLE: Proteomic identification of candidate biomarkers that distinguish lens-induced uveitis from infectious endophthalmitis

SESSION TITLE: Innate and Adaptive Immune Cells in Humans and Animal Models of Immune Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Al Moujahed, G. Velez, J. Vu, V.B. Mahajan, Ophthalmology, Stanford University School of Medicine, Palo Alto, California, UNITED STATES|G. Velez, P. Ferguson, A. Bassuk, University of Iowa, Iowa, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ahmad Al Moujahed: Commercial Relationship: Code N (No Commercial Relationship) | Gabriel Velez: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Vu: Commercial Relationship: Code N (No Commercial Relationship) | Polly Ferguson: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Bassuk: Commercial Relationship: Code N (No Commercial Relationship) | Vinit Mahajan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lens-induced uveitis (LIU) is an intraocular inflammatory condition that occurs following aggravation of the lens capsule and release of lens proteins into the eye. The diagnosis of LIU can be challenging and distinguishing it from other causes of intraocular inflammation, including postoperative endophthalmitis, can be difficult. The purpose of this study is to profile vitreous protein expression of LIU and infectious endophthalmitis patients.

Methods: Liquid vitreous biopsies were collected from 3 groups: control subjects (n = 4) undergoing pars plana vitrectomy to repair an idiopathic macular hole (IMH), test subjects with lens-induced uveitis (n=9), and test subjects (n = 6) with infectious endophthalmitis. Vitreous samples were analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS) and proteins were identified and quantified using a data-independent approach (DIA). Protein expression changes (i.e., relative intensities) were evaluated by analysis of variance (1-way ANOVA; significant p-value <0.05), gene ontology, and pathway analysis, to identify candidate biomarkers and pathways for prospective studies.

Results: We identified a mean of 399 proteins in control (IMH), 385 in LIU, and 419 in endophthalmitis vitreous. In LIU vitreous, 45 proteins were significantly differentially expressed proteins (20 upregulated and 25 downregulated) compared to controls, including lens-specific proteins (i.e. crystallins). Endophthalmitis vitreous exhibited 149 significantly differentially expressed proteins (87 upregulated and 62 downregulated) compared to controls and was characterized by the presence of elevated neutrophil specific markers. A total of 134 proteins were differentially expressed between LIU and endophthalmitis samples (55 upregulated and 79 downregulated) and lens-specific proteins were the greatest unregulated proteins in LIU samples.

Conclusions: The LIU vitreous proteome is characterized by the upregulation of crystallins while endophthalmitis samples are distinguished by the presence of proteins related to neutrophil degranulation and microbial antigen presentation. This is the first proteomic study to identify possible biomarkers in the vitreous for diagnosing LIU and differentiating it from infectious endophthalmitis.

TITLE: Biophysical interactions of essential fatty acids with human tears

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Mudgil, Western Sydney University School of Medicine, Penrith South DC, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Poonam Mudgil: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dietary intake of essential fatty acids (EFAs) is recommended for relieving symptoms of dry eye disease as it is thought to reduce inflammation at the ocular surface, although conflicting reports also exist. Topical application of EFAs to the ocular surface is also being investigated. Fatty acids are surfactants and their topical delivery into tears can alter the tear stability which plays an important role in dry eye. While previous studies investigated interactions of EFAs with meibomian lipids, this study aimed at investigating the biophysical interactions of EFAs with human tears to determine the efficacy of EFAs for topical ocular application.

Methods: Human tears from asymptomatic volunteers were collected with informed consent. Pressure-area profiles and rheology of surface films of human tears, EFAs (LA - linoleic acid and ALA - α -linolenic acid), and mixtures of EFAs with tears were studied using Langmuir trough technology on an artificial tear solution at the physiological pH and temperature. The compressibility and elasticity of surface films were determined from pressure-area profiles.

Results: Pressure-area profiles indicated that tears formed a highly compressible, non-collapsible surface film with a maximum surface pressure of 35mN/m. The surface film of LA was also highly compressible, comparable with that of tears, with a maximum surface pressure of 30mN/m but the surface film of ALA was very expanded and showed very low surface pressure with a maximum of 5mN/m. The elasticity of surface films of tears and LA increased with the compression of the films till phase transition followed by a decrease. Elasticity of ALA remained very low. LA and ALA when mixed with tears did not increase the surface pressure or elasticity of the mixed films in comparison with that of tears alone.

Conclusions: Whole tears possess surface active properties better than those reported for meibomian lipids. This is likely due to the contribution from surfactant proteins in addition to the lipids in tears. Addition of small amounts of EFAs does not give a profound effect on the biophysical properties of tears because whole tears have their own robust surface active characteristics. Future studies with tears from dry eye patients, higher amounts of EFAs, and interactions of EFAs with tear proteins will help in determining possible benefits of topical application of EFAs to the ocular surface.

TITLE: NF- κ B-regulated Cross-talk between Astroglia and Microglia for Neuroinflammation in Experimental Glaucoma

SESSION TITLE: Neurodegeneration and neuroprotection

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Tezel, X. Yang, Q. Zeng, Ophthalmology, Columbia University, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gulgun Tezel: Commercial Relationship: Code N (No Commercial Relationship) | Xiangjun Yang: Commercial Relationship: Code N (No Commercial Relationship) | Qun Zeng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Astroglia and microglia play synchronic/complementary roles during neuroinflammation in glaucoma; however, how they interplay and regulate each other's phenotype and immune functions is not fully understood. To improve the understanding of astroglia-microglia intersignaling for neuroinflammation in experimental glaucoma, this study analyzed microglia responses to astroglial NF- κ B inhibition.

Methods: Ocular hypertension was induced by anterior chamber microbead injections in mice with conditional deletion of p65 in astroglia (crossbreds of p65^{f/f} and GFAP-cre/ERT2) and controls (p65^{f/f}), and astroglia and microglia responses were analyzed through a 12-weeks period. Morphological responses were determined in retinal whole mounts and optic nerve sections by analyzing the intensity and coverage of immunolabeling for specific markers (GFAP or Iba1). Inflammatory responses, and A1/A2 and M1/M2 phenotypes, were evaluated by cytokine/chemokine profiling in isolated astroglia and microglia samples and immunolabeling of retina and optic nerve tissues.

Results: Besides decreased inflammatory activity of p65-deleted astroglia, a prominent decrease was detectable in microglia responses. The morphological response of microglia to ocular hypertension (a shift from ramified morphology to reactive morphology) was less prominent, and the intensity and coverage of Iba1 immunolabeling were over 30% less in ocular hypertensive eyes of GFAP/p65 mice than ocular hypertensive p65^{f/f} controls (P = 0.001, P = 0.01, respectively). In addition, similar to p65-deleted astroglia (that were C3- with lower titers of NF- κ B-regulated pro-inflammatory cytokines, such as ILs, TNF- α , IFN- γ), the pro-inflammatory cytokine response of microglia was significantly lower in ocular hypertensive GFAP/p65 mice than ocular hypertensive p65^{f/f} controls (P < 0.02). The reduced microglial response to experimental glaucoma should not be related to decreased neuron injury in GFAP/p65 mice, since parallel studies of RGC-protective treatments did not detect a similar response.

Conclusions: These findings support the importance of astroglia-derived factors to shape microglia responses during glaucomatous neurodegeneration. Astroglial NF- κ B-regulated cytokines/chemokines appear to critically modulate direct communication, and the amplifying relay effects, between astroglia and microglia during neuroinflammation in experimental glaucoma.

TITLE: Accuracy of self-selected magnifiers amongst patients with vision impairment

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. yip, A.L. Softing Hataye, M. Schornack, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): wing yip: Commercial Relationship: Code N (No Commercial Relationship) | Alaina Softing Hataye: Commercial Relationship: Code N (No Commercial Relationship) | Muriel Schornack: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vision rehabilitation involves evaluation of individual patient visual needs, prescription of specific level of magnification to meet these needs, and training on how to use prescribed devices. Although magnification devices are commercially available without prescription, there is no standardized method of labeling such devices, nor are there guidelines to help consumers select the appropriate level of magnification for their visual needs and level of visual impairment. We performed a retrospective study to compare magnification power of patients' self-selected magnifier (SSM) and their level of satisfaction with the SSM to the device prescribed by a low vision specialist.

Methods: Retrospective record review of patients who brought in their own SSM's to their initial low vision consultations between January 1, 2019 and March 30, 2020. The following information was abstracted from the medical record: age, gender, ocular history, source of SSM, visual acuity, visual goals, power of SSM, prescribed magnification and patient preference of self-selected compared to prescribed magnifier. Descriptive statistics are presented.

Results: A total of 50 patients were identified. Average patient age was 83 ± 10 years (range: 51-100); male/female distribution was 12/38 (24%/76%). The average visual acuity in the better seeing eye was 0.51 logMAR, average visual acuity in the worse seeing eye was 0.22 logMAR. Eight (16%) patients had more than one magnifier. In 48 patients (96%), SSM power was incorrect based upon clinical examination and evaluation of patients' visual needs. Forty eight (96%) patients preferred the doctor-prescribed magnifier compared to the device that they had procured on their own. In 45 patients (90%), power of the SSM was less than what the doctor prescribed; SSMs were an average of 5 diopters less than what was prescribed by the low vision specialist. Only 16 (32%) of the SSM incorporated a light source into the device.

Conclusions: Magnification provided by a majority of patients' SSM's was not sufficient to meet the patients' visual needs. A majority of patients preferred the doctor-prescribed power over that which was provided by their SSM. These findings suggest that patients may be more likely to achieve success with prescribed low vision aids compared to over-the-counter devices obtained without a prescription.

TITLE: Virulence assessment of the L -2-amino-4-methoxy-trans3-butenoic acid producing keratitis associated *Pseudomonas aeruginosa*

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.M. Metzger, M. Kovach, Biology & Geology, Baldwin Wallace University, Berea, Ohio, UNITED STATES|R. Bouhenni, Ophthalmology, Akron Children's Hospital, Akron, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Leah Metzger: Commercial Relationship: Code N (No Commercial Relationship) | Michael Kovach: Commercial Relationship: Code N (No Commercial Relationship) | Rachida Bouhenni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously reported that the keratitis associated *Pseudomonas aeruginosa* produces the toxin L-2-amino-4-methoxy-trans-3-butenoic acid (AMB). In this study we sought to investigate the virulence of the AMB producing strain (E3) compared to the AMB mutant strain (PA3202), its parent strain (PAO1) and the non-virulent lab strain (ATCC 10145).

Methods: *Pseudomonas aeruginosa* strains (E3, PAO1, PA2302 and ATCC 10145) were grown in Luria-Bertani (LB). Overnight cultures were diluted 1:100 in LB and grown to an optical density of 0.3 to 0.4 at 600 nm, washed 1X with sterile PBS and diluted to an $A_{600} = \sim 0.05$ (0.046 – 0.048). A 10- μ l aliquot of each dilution was then injected into *G. mellonella* larvae (n=25/strain) via the hindmost left proleg. PBS was used as the negative control. The Health Index Score (HIS), which determines virulence, was calculated at 8 hours and 20 hours post infection. The time to death of the larvae was determined and used to create Kaplan-Meier survival curves. One-way analysis of variance (ANOVA) was used for statistical analysis to determine significance in differences in virulence between strains.

Results: At 8 hours post infection, the health index scores for all strains was similar and ranged from 7.8 ± 1.08 to 8.48 ± 0.5 . At 20 hours post infection, the health index score was significantly lower for the larvae injected with the keratitis associated *P. aeruginosa* E3 compared to those injected with the AMB mutant strain PA2303 and its parent strain PAO1 (0.48 ± 1.4 vs. 6.0 ± 1.5 and 1.76 ± 2.04 , $p > 0.001$). Larvae injected with ATCC 10145 and PBS had the highest health index scores (6.72 ± 1.17 and 7.28 ± 1.45 respectively), which were similar to those recorded at 8 hours post infection.

Conclusions: Results from this study confirm that the keratitis associated *P. aeruginosa* strain is highly virulent compared to the other strains tested, possibly due to its ability to produce AMB. This study will add more insight into the pathogenesis of *Pseudomonas* associated keratitis and will help develop novel antimicrobial agents for the treatment of ocular infections caused by *P. aeruginosa* such as those that result from the wear of contact lenses.

TITLE: Effect of Dexamethasone Intracameral Drug-Delivery Suspension on Macular Thickness after Vitreoretinal Surgery

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.F. Kiernan, The Eye Associates of Manatee, Sarasota, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Daniel Kiernan: Commercial Relationship(s);Eyepoint Pharmaceuticals:Code F (Financial Support);Eyepoint Pharmaceuticals:Code C (Consultant);Eyepoint Pharmaceuticals:Code R (Recipient)

ABSTRACT BODY:

Purpose: To analyze the effect of treatment with an anterior chamber intracameral dexamethasone drug-delivery suspension (Dexycu; EyePoint Pharmaceuticals, Watertown, MA) on optical coherence tomography-measured macular thickness (OCT MT) in patients undergoing retinal surgery compared to post-operative treatment with topical corticosteroids.

Methods: Post Hoc analysis of a retrospective case-matched comparison of patients undergoing initial retinal surgery by a single surgeon. 27 eyes of 27 patients received intracameral dexamethasone at the time of surgery and were compared to 27 eyes of 27 patients who received daily post-operative corticosteroid eye drops over 4 weeks. The primary outcome was change of OCT MT before and 8 weeks after surgery. Secondary outcomes were changes of OCT MT before and 4 and 12 weeks after surgery. A paired T-test was used for statistical analysis.

Results: Baseline OCT MT was 317 um in the topical steroid-treated group and 332 um in the intracameral dexamethasone treatment group ($p=0.839$). Post-operatively at 8 weeks the average OCT MT change was +43.7 um ($p=0.0003$) in the topical steroid treated group and -22.4 um ($p=0.0082$) in the intracameral dexamethasone treatment group. At post-operative weeks 4 and 12, the topical steroid-treated group had increased OCT MT compared to baseline (36.3 and 4.67 um, $p=0.0002$ and 0.579) whereas the intracameral dexamethasone treatment group had decreased OCT MT (-18.78 and -22.61 um, $p=0.027$ and 0.007). Patients treated with topical steroids for 1 month after surgery had an average OCT MT that was 51 and 53 um greater ($p=0.0175$ and 0.019 respectively) at 4 and 8 weeks post-operatively than those who received the intracameral dexamethasone suspension at the time of surgery.

Conclusions: Intracameral dexamethasone drug-delivery suspension placed in the anterior chamber after vitreoretinal surgery was associated with a significant reduction in macular thickness up to 12 weeks following vitreoretinal surgery, whereas patients receiving daily topical corticosteroids demonstrated significantly more OCT MT at 4 and 8 weeks post-operatively. These results indicate a greater benefit of intracameral dexamethasone drug-delivery suspension for preventing post-operative causes of increased macular thickness including cystoid macular edema compared to topical anti-inflammatory treatment among patients undergoing vitreoretinal surgery.

ABSTRACT BODY:

Purpose: Partnerships represent an important yet under-researched modality in global eye care. We investigated ophthalmic partnerships between high-income country (HIC) and low- and middle-income country (LMIC) stakeholders and characterized them by 'Training' and 'Engagement' to better understand and address disparities in global ophthalmic surgical care.

Methods: A web search was conducted to identify stakeholders participating in the delivery and/or capacity building of ophthalmic services from 2010 - 2019 based on publicly available data. Partnerships were defined through clinical activities, education and training, and/or research support. Descriptive data on current ophthalmic partnerships was collected from published reports, literature reviews, and information on stakeholder webpages. Individual partnerships were separately classified by the extent of engagement and training patterned off criteria from a similar study in global neurosurgery; grade I represented the least and grade III the most extensive engagement and training. Data were analyzed using descriptive statistics and geospatial mapping.

Results: In total, 209 unique HIC - LMIC partnerships encompassing 92 unique countries were described. The most common HIC partners were from North America (123; 59%) and Europe (75; 36%); the most common LMIC partners were from Africa (103; 49%) and the Asia-Pacific (54; 26%). Partnerships most frequently provided services in cataract (48%), glaucoma (25%), and diabetic retinopathy (25%). The most common engagement classifications were grade I (35%) or II (39%) and training classifications were grade I (60%) or II (23%). A majority of partnerships utilized a coordinating agency (147; 70%). Finally, LMIC-based researchers first- or co-authored 61% of all peer-reviewed publications documented in the data set.

Conclusions: Transnational ophthalmic partnerships exist with varying degrees of both engagement and training. Research collaboration and direct services are two current areas of partnership strength in global ophthalmology, while LMIC-directed training programs need improvement relative to other surgical fields.

ABSTRACT BODY:

Purpose: Extracellular matrix in the central nervous system comprises a complex macromolecular combination of proteins and polysaccharides that provides a substrate for maintenance of neurons and their axons. Glaucoma and other optic neuropathies involve degradation of the extracellular matrix in the retina and optic nerve head, through which unmyelinated retinal ganglion cell axons pass in forming the optic nerve proper. This degradation also affects collagen fibers, which are a major constituent of the matrix. Here we tested whether collagen mimetic peptides (CMPs), which repair damaged collagen, promote (1) survival and neurite outgrowth of neurons in vitro stressed by collagen degradation and (2) ganglion cell axon function in an inducible mouse model of glaucoma.

Methods: For in vitro studies, we compared neurite outgrowth of dorsal root ganglion cells (DRGs) plated on partially digested type 1 collagen and treated either with CMP or vehicle. For in vivo testing of efficacy, we elevated ocular pressure unilaterally in mice using microbead occlusion and measured anterograde axonal transport of cholera toxin B to the superior colliculus following topical CMP treatment vs. vehicle.

Results: In vitro, DRG neurons on damaged collagen treated with CMP demonstrated increased dendritic field area ($p \leq 0.03$) and neurite length ($p \leq 0.02$) compared to untreated, while neurite length in treated collagen also exceeded by 70% length in naïve collagen ($p = 0.002$). In vivo, following three weeks of elevated ocular pressure (+35%), treatment with CMP's significantly protected axon transport vs untreated ($p < 0.01$).

Conclusions: Our results emphasize the critical role intact collagen plays in maintaining ECM and neuronal function. CMPs offer therapeutic potential for use in neuroprotective or reparative regimens designed to promote neurite growth and axon function in glaucoma and other optic neuropathies

ABSTRACT BODY:

Purpose: The Mayan population in Guatemala is understudied within vision research. This observational cohort of individuals seeking eye care may help identify unique clinical, demographic, environmental, and genetic factors for blinding eye disease. This study will serve to (a) identify the ocular health needs within this population and (b) any possible modifiable risk factors.

Methods: We conducted a cross-sectional study with 126 participants. Each received an eye exam, provided a blood sample, and were administered a standardized epidemiological questionnaire at the Lion's Eye Hospital in Salama, Guatemala. Interpreters were available for translation to the patients' native dialect. We also performed a genome-wide association study using Illumina's HumanOmni2.5-8 chip to examine SNPs. We used quality control measures and performed a logistic regression analysis to determine which genetic components were associated with eye disease.

Results: The population was 46% male, and the average age was 65.2. We found that the most prevalent eye conditions were cataracts (54.8%), followed by pseudoexfoliation syndrome (PXF) (24.6%). The population with both conditions was 22.2%. We conducted multivariate analyses to determine which epidemiological factors were significantly associated with the population's eye conditions at $p < .05$. In our epidemiological analysis, including 121 participants for completeness, we found that eye disease was significantly more likely with advanced age. Cataracts were significantly more common among those living in the 10 districts with the least resources. Furthermore, having cataracts was associated with a greater likelihood of PXF after adjusting for age and sex. In our genetic analysis, the SNP most significantly associated with PXF is within the gene KSR2 ($p < 1 \times 10^{-5}$). Several SNPs were associated with Cataracts at Genome-Wide significance adjusting for covariates ($p < 5 \times 10^{-8}$). Almost three-quarters of these SNPs lie within 13 genes, with the majority of genes having only one significant SNP.

Conclusions: To the best of our knowledge utilizing PhenGenI, these SNPs and genes have not been previously associated with cataracts, glaucoma, or PXF. This study can aid in understanding the prevalence of eye conditions in this population but may also inform public health planning and delivering of quality, accessible and relevant health and preventative care within Guatemala.

TITLE: Incidence of periocular pain following intravitreal injections: which factors really matter?

SESSION TITLE: Diabetic macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.Z. Soliman, J. De La Torre, M. Ellman, Southwest Eye Institute, El Paso, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ahmed Soliman: Commercial Relationship: Code N (No Commercial Relationship) | Javier De La Torre: Commercial Relationship: Code N (No Commercial Relationship) | Marc Ellman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the different factors correlating with pain severity following intravitreal injections.

Methods: All injections were performed by the same doctor (AZS). Patients were anesthetized either with drops only or with a subconjunctival injection of 0.1 cc of lidocaine 2%. The injections were performed with either a 30 or 32 gauge needle. Patients were randomly assigned into four groups: topical with 30 G needle (group A), topical with 32 G needle (group B), subconjunctival with 30 G (group C) and subconjunctival with 32 G (Group D). The visual analog scale (VAS) was used to assess pain. Primary study variables were the relationship between pain severity and anesthesia type, needle size, number of previous injections, age, sex, lens status and indication for injection. Secondary variables included best-corrected visual acuity (BCVA) and central macular thickness (CMT) changes 1 month post injection.

Results: 100 eyes of 100 patients were included in the study. Each group included 25 eyes. Sixty two patients were females (62%) and 38 were males (38%). Overall mean pain score was 2.73 ± 1.89 . Indications for injection were diabetic macular edema (81%), neovascular age-related macular degeneration (6%), and macular edema secondary to retinal vein occlusion (13%). The mean VAS scores in groups A, B, C and D were 4.1 ± 2 , 2.9 ± 2.3 , 1.9 ± 1.7 and 1.7 ± 2.1 , respectively. Pain severity was significantly correlated with anesthetic type ($p < 0.001$) and needle size ($p < 0.001$); A negative correlation existed between pain score and number of previous injections ($p = 0.03$). Pain severity was not associated with age ($p = 0.59$), sex ($p = 0.45$), lens status ($p = 0.48$), vitreous reflux ($p = 0.65$) or indication for injection ($p = 0.37$). No significant complications were observed.

Conclusions: Using subconjunctival anesthesia and a smaller needle size were associated with less pain during intravitreal injections. These results need to be validated in larger studies. However, adopting these changes can help increase patient comfort during the injection.

TITLE: Idiopathic Orbital Inflammation Refractory to Rituximab but Sensitive to Methotrexate

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Munda, A. Harrison, A. Mokhtarzadeh, S.R. Montezuma, D. Koozekanani, M.S. Lee, C. McClelland, J.H. Hou, K.R. Armbrust, J. Yamanuha, Ophthalmology, University of Minnesota System, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rusdeep Munda: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Harrison: Commercial Relationship: Code N (No Commercial Relationship) | Ali Mokhtarzadeh: Commercial Relationship: Code N (No Commercial Relationship) | Sandra Montezuma: Commercial Relationship: Code N (No Commercial Relationship) | Dara Koozekanani: Commercial Relationship: Code N (No Commercial Relationship) | Michael Lee: Commercial Relationship: Code N (No Commercial Relationship) | Collin McClelland: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Hou: Commercial Relationship: Code N (No Commercial Relationship) | Karen Armbrust: Commercial Relationship: Code N (No Commercial Relationship) | Justin Yamanuha: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Idiopathic orbital inflammation (IOI) represents a spectrum of non-infectious orbital processes that are managed with corticosteroids and/or steroid sparing immunosuppressive therapies in refractory or recurrent cases. We present two patients with IOI who were resistant to rituximab infusions but subsequently responded to oral methotrexate (MTX).

Methods: Case series

Results: Patient #1: A 73-year old man with a 16-year history of biopsy-proven recurrent left IOI involving the inferior rectus (Fig. 1a) presented with diplopia and persistent optic disc edema (ODE) (Fig. 2a) first noted 5 months prior. Previous treatments included prednisone up to 80 mg daily, orbital triamcinolone injections, and two rituximab infusion courses without improvement. He was started on oral MTX 15 mg weekly with a taper of prednisone. His ODE and diplopia improved at 6 weeks; however, treatment was discontinued after six months due to his concerns related to COVID-19. All findings resolved three months after stopping MTX.

Patient #2: A 67-year old woman presented with a 3-year history of a right orbital mass involving the lacrimal gland and extraocular muscles (Fig. 1b) causing proptosis and diplopia. Orbital biopsy showed chronic inflammatory changes and was negative for IgG4 or lymphoma. Systemic inflammatory and infectious workup was unremarkable. She had minimal improvement in proptosis and diplopia after two courses of rituximab with intermittent oral prednisone. She later presented with ODE, cystoid macular edema, and an inferotemporal exudative retinal detachment (RD) (Fig. 2b). The ocular manifestations improved with a 10 day course of prednisone 40 mg/day but recurred on prednisone taper. All findings resolved after 2 months of MTX 20 mg weekly.

Conclusions: While anti-metabolites are typically used early in the course of recurrent IOI with rituximab reserved for more recalcitrant disease, this study demonstrates that MTX may provide benefit for IOI refractory to rituximab with secondary ocular manifestations. This may be due to more gradual suppression of the immune system with MTX.

ABSTRACT BODY:

Purpose: To compare corneal/scleral stiffness from air puff deformation in Normal (NL), Primary Open Angle Glaucoma (POAG) without history of prostaglandin analog (PGA) treatment and with current/former PGA treatment (POAG-PGA), as well as Ocular Hypertension with (OHT-PGA) and without PGA treatment (OHT).

Methods: A prospective crosssectional study of 253 subjects was conducted: 387 eyes of 194 NL, 54 eyes of 29 POAG-PGA, 19 eyes of 11 POAG, 12 eyes of 6 OHT-PGA, and 26 eyes of 13 OHT subjects. Ganglion Cell Complex (GCC) from Optical Coherence Tomography was measured on all subjects. Cup/disc ratio (C/D) and mean deviation (MD) from visual field exams were extracted from the medical records of both OHT and both POAG cohorts. Biomechanical response from Corvis ST was evaluated with corneal parameters, Integrated Inverse Radius (IntInvRad) and stiffness parameter (SP) at first applanation (SP-A1). Scleral stiffness at highest concavity (SP-HC) was included. MANCOVA was performed with IOP from Dynamic Contour Tonometry (DCT), pachymetry and age as covariates for biomechanical parameters. GCC, C/D, and MD were compared with age as a covariate. Statistical significance threshold was set to $p < 0.05$.

Results: SP-A1 was not different between any group. NL showed a less stiff corneal response in IntInvRad than OHT ($p=0.0030$) and OHT-PGA ($p=0.0059$), which were not different than each other. OHT had a significantly stiffer scleral response in SP-HC ($p < 0.0001$) than all other cohorts, including OHT-PGA ($p=0.0003$) which was stiffer than NL ($p=0.0152$) and POAG ($p=0.0053$). NL, POAG and POAG-PGA were not different than each other. GCC was thickest ($p < 0.0001$) in NL than all cohorts except OHT, which was thicker than OHT-PGA ($p=0.0085$) and both POAG cohorts ($p < 0.001$). C/D was not different between POAG and POAG-PGA, but greater than both OHT cohorts ($p < 0.0005$) which were not different from each other. MD was significantly worse in POAG-PGA than POAG ($p=0.0029$). No other cohorts were different.

Conclusions: PGA treatment resulted in a less stiff scleral response in OHT with thinner GCC, consistent with site of action of PGA and reports of greater response in stiffer eyes at baseline. Although there was no difference in scleral stiffness with PGA in POAG, MD was worse with PGA treatment. It is not clear whether PGA resulted in thinner GCC in OHT and worse MD in POAG, or if these eyes were more advanced at baseline.

ABSTRACT BODY:

Purpose: To assess whether variations in healthcare utilization and access are associated with increased risk of developing proliferative diabetic retinopathy (PDR) or related complications.

Methods: We identified 1,882 adult participants in the NIH All of Us Research Program data repository with diabetic retinopathy (DR) based on diagnostic billing codes. Electronic health record data regarding comorbidities, laboratory values, and procedures were extracted. Healthcare utilization and access were assessed using participant responses to surveys on frequency of medical care, ability to afford care, and reasons for delaying medical care. Multivariable logistic regression with bi-directional stepwise variable selection was performed from a wide range of predictors to assess whether social determinants were associated with increased risk of developing PDR or related complications (e.g. neovascular glaucoma). Statistical significance was defined as $p < 0.05$.

Results: The mean (standard deviation) age of 1882 adults with DR enrolled in All of Us was 63.7 (11.0) years. The majority (57.3%) were female. 36.9% identified as Hispanic or Latino. 13.1% of DR patients had not spoken to an eye doctor in the past 12 months, and 10-20% of patients endorsed several reasons for avoiding or delaying care, including financial concerns and transportation (Figure 1). The number of eye doctor visits (odds ratio [OR] 1.46, 95% confidence interval [CI] 1.07-1.99, $p=0.02$) and diabetic kidney disease (OR 3.88, 95% CI 1.37-11.07, $p=0.01$) were associated with increased odds of developing PDR and related complications. Significant social determinants included healthcare coverage not accepted by provider (OR 3.48, 95% CI 1.35-12.10, $p=0.02$) and inability to afford general healthcare provider (OR 8.42, 95% CI 1.12-74.3, $p=0.04$) (Table 1).

Conclusions: Understanding the social determinants that influence risk for developing complications can help inform population health interventions. Nationwide data with diverse enrollment demonstrate that some DR patients face substantial barriers to healthcare access.

TITLE: To compare the accuracy of intraocular lens calculation formulas in the prediction of postoperative refraction in eyes with short axial length (<22mm)

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Shirke, N. Gupta, S. Ahmed, Ophthalmology, Northern health, Victoria, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Sheetal Shirke: Commercial Relationship: Code N (No Commercial Relationship) | Nishant Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Suheb Ahmed: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Accurate intraocular lens (IOL) power calculation in cataract surgery is very important to achieve the postoperative target refraction and high patient satisfaction. For short eyes, the IOL power calculation formulas are less accurate than normal, which presents challenges for cataract surgeons. In this study, we aim to compare the refractive outcome using different IOL calculation formulas (Barrett Universal II, Haigis, Hoffer Q, Holladay 1, Olsen, and SRK-T, Hill BRF II, Kane and EVO 2.0)

Methods: This was a retrospective chart review conducted for adult patients who underwent uncomplicated cataract surgery with implantation of monofocal posterior chamber intra ocular lens at Broadmeadows hospital during Jan 2012- Jan 2020. All patients received implantation of an Acrysof IQ SN60WF. Post op refraction was done at minimum 4 weeks post operatively. In patients whose both eyes satisfied the inclusion criteria, only one eye as randomly selected. Post op mean refractive error (ME) and mean absolute refractive error (MAE) were calculated, before and after adjusting the mean to zero, for each formula and compared.

Results: Total 129 eyes were included. Mean post op refraction was - 0.61D. Olsen formula had least ME (-0.13D). Mean MAE was minimal for EVO formula before and after adjusting mean to zero (0.47 and 0.46 respectively). EVO formula also had maximum number of eyes within 0.25D and 0.5D. There was no statistically significant difference in absolute predictive error after adjusting the mean to zero among these formulas.

Conclusions: The refractive outcome was significantly myopic than expected. EVO formula gave least absolute error after adjusting to zero though there was no statistical difference among the formulae.

TITLE: Safety Margins of Anti-VEGF Therapy using Treat and Extend Treatment Protocol – Lessons from the COVID-19 Pandemic

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Navarrete, B. Vofo, K. Matos, A. Rivera, J. Levy, I. Chowers, Ophthalmology, Hadassah Medical Center, Jerusalem, Jerusalem, ISRAEL]

Commercial Relationships Disclosure (Abstract): Ana Navarrete: Commercial Relationship: Code N (No Commercial Relationship) | Brice Vofo: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Matos: Commercial Relationship: Code N (No Commercial Relationship) | Antonio Rivera: Commercial Relationship: Code N (No Commercial Relationship) | Jaime Levy: Commercial Relationship: Code N (No Commercial Relationship) | Itay Chowers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the consequences of delaying intravitreal (IVI) anti-vascular endothelial growth factor (VEGF) therapy in patients under treat-and-extend (TAE) protocol.

Methods: A retrospective review of medical records of a consecutive group of patients receiving IVI using TAE protocol before and during the COVID-19 pandemic. Data collected included diagnosis, demographics, treatment schedule, compound used and anatomical outcome according to spectral-domain optical coherence tomography (SD-OCT).

Results: A total of 923 eyes (691 patients) were included; 58.8% (543 eyes) were treated for neovascular age-related macular degeneration (nvAMD), 25% (231 eyes) had diabetic macular edema (DME), and 16.2% (149 eyes) with retinal vein occlusion (RVO). The average patient age (\pm SD) was 74.5 ± 11.7 years. The Female/male ratio was 1.08:1. Delayed therapy during the pandemic (≥ 7 days) occurred in 56.3% of the eyes. This included 56.2%, 61.5%, 49.0% of nvAMD, DME and RVO patients respectively. The overall average delay (\pm SD) was 15.3 ± 23.4 days. RVO patients were on average less late (9.3 ± 16.1 days) compared to nvAMD (15.8 ± 23.8) and DME (18.2 ± 25.6) eyes ($P=0.002$). Multivariate analysis showed that in nvAMD duration of the disease and type of anti-VEGF were predictors of the number of days late ($P=0.011$ and 0.019). In eyes ≥ 7 days late, 45.7%, 58.5%, and 58.9% of nvAMD, DME, and RVO eyes respectively showed an increase in central subfield thickness (CST). Worsening was related to absolute numbers of days late, and not to the percentage of delay of the recommended interval. A positive correlation was found between delay to treatment and an increase in CST.

Conclusions: Delaying IVI in eyes under TAE regimen was common during the COVID-19 pandemic. These delays were associated with macular thickening having potential visual consequences.

TITLE: A pilot study on the effect of high pass spectral filters on chromatic contrast sensitivity

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Nankivil, N. Franklin, J. Xu, J. Buch, Research & Development, Johnson & Johnson Vision, Florida, UNITED STATES]

Commercial Relationships Disclosure (Abstract): Derek Nankivil: Commercial Relationship(s);Johnson & Johnson Vision Care Inc.:Code E (Employment);Johnson & Johnson Vision Care Inc.:Code I (Personal Financial Interest);Johnson & Johnson Vision Care Inc.:Code P (Patent);Johnson & Johnson Vision Care Inc.:Code R (Recipient) | Nicole Franklin: Commercial Relationship(s);Johnson and Johnson Vision Care Inc.:Code E (Employment);Johnson and Johnson Vision Care Inc.:Code I (Personal Financial Interest) | Jie Xu: Commercial Relationship(s);Johnson & Johnson Vision Care Inc.:Code E (Employment);Johnson & Johnson Vision Care Inc.:Code I (Personal Financial Interest) | John Buch: Commercial Relationship(s);Johnson & Johnson Vision Care Inc.:Code E (Employment);Johnson & Johnson Vision Care Inc.:Code I (Personal Financial Interest);Johnson & Johnson Vision Care Inc.:Code P (Patent);Johnson & Johnson Vision Care Inc.:Code R (Recipient)

ABSTRACT BODY:

Purpose: Some patients express a preference for visual aids that include a high pass spectral filter (HPSF) (Clark, 1969). Although not demonstrated directly, research suggests that a filter, such as that provided by macular pigment, may improve chromatic contrast (Hammond, Fletcher & Elliott, 2013). We hypothesize that some HPSFs enhance chromatic contrast sensitivity.

Methods: To test this hypothesis, a single-site, subject-masked, 6x6 crossover, controlled, randomized, non-dispensing study was conducted. Heterochromatic flicker photometry (HCFP) was utilized to ensure that the stimuli were isoluminant. Results from the HCFP experiment were used to adjust the intensity of one component of the Gabor stimulus so that the stimuli were individualized for each subject. Each color axis was set at the nominal values, representative of the standard observer. Binocular chromatic contrast sensitivity functions (CCSFs) were measured along both the Protan (red-green) and Tritan (blue-yellow) axes with six different filters: UV control, ND control, 419nm HPSF, 437nm HPSF, 456nm HPSF, 476nm HPSF. Sensitivity thresholds were determined at seven spatial frequencies: 0.2, 0.4, 0.6, 1, 2, 4 and 6cpd. Both HCFP and CCSF experiments were conducted with a commercial visual function assessment system utilizing a 32in display located 1.5m from the subject (Metropsis, Cambridge Research Systems Ltd., Kent, UK). In total, 20 subjects completed the study per-protocol. The ratio of the area under the curve (AUC) of the CCSFs (test:control) were computed.

Results: With Protan stimuli, AUC CCSF ratios were 1.07, 1.10, 0.93 and 0.92 for the 419nm, 437nm, 456nm, and 476nm HPSFs, respectively. With Tritan stimuli, AUC CCSF ratios were 0.87, 0.97, 0.74 and 0.73 for the 419nm, 437nm, 456nm, and 476nm HPSFs, respectively. Results demonstrate that HPSFs blocking components nominally below 440nm appear to improve CCSF along the Protan axis. Other, more aggressive, HPSFs decrease CCSF along the Tritan axis.

Conclusions: Thus, we provide evidence that supports the notion that patient reported preferences for certain HPSFs are, at least in part, motivated by an improvement in chromatic contrast sensitivity.

SUBMITTER (NAME ONLY): Luminita Tarita-Nistor

TITLE: Perceptual grouping during binocular rivalry in mild glaucoma

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Tarita-Nistor, G. Issashar Leibovitzh, Krembil Research Institute, Toronto, Ontario, CANADA | Y. Buys, G. Trope, Ophthalmology and Vision Science, University of Toronto, Toronto, Ontario, CANADA |

Commercial Relationships Disclosure (Abstract): Luminita Tarita-Nistor: Commercial Relationship: Code N (No Commercial Relationship) | Galia Issashar Leibovitzh: Commercial Relationship: Code N (No Commercial Relationship) | Yvonne Buys: Commercial Relationship: Code N (No Commercial Relationship) | Graham Trope: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Studies on binocular rivalry point to a dysregulation in inter-hemispheric transfer in patients with mild glaucoma. During binocular rivalry, spatially separated stimuli with common features tend to group together; the grouping is mediated by lateral connections of the cortical hypercolumns. In this observational, case-control study we tested perceptual grouping during intra- and inter-hemispheric binocular rivalry to probe the strength of neural connectivity involved in early visual processing in patients with mild glaucoma.

Methods: Eight patients (4F/4M) with glaucoma with a visual field mean deviation better than -2dB and 9 (5F/4M) age-matched healthy controls participated. The 2 groups were equivalent in visual acuity and stereo-acuity. Rivalry stimuli were 1.8 deg-diameter discs, containing horizontal or vertical sine wave gratings (spatial frequency of 4 cpd), viewed dichoptically. In a control condition, the stimuli were presented centrally. To test grouping, 2 spatially separated adjacent rivalry stimuli were presented eccentrically to the same or different eyes and to the same or different hemifields. The outcome measures were time of exclusive dominance of the percept with synchronized orientations (i.e., both horizontal or both vertical) and rivalry rate.

Results: Mixed factorial ANOVAs showed that for both groups, synchronized dominance was longer when identical stimuli were presented to the same eye (i.e., both horizontal to one eye and both vertical to the other eye) than to different eyes irrespective of the hemifield ($p < .001$, partial $\eta^2 = 0.85$). Rivalry rates were significantly lower in the glaucoma group than in the control group across all conditions ($p < .001$, partial $\eta^2 = 0.27$). For the control group, rivalry rates for the central, same eye/same hemifield, and same eye/different hemifields conditions were identically high, but for the glaucoma group, the highest rivalry rate was observed for the same eye/same hemifield condition where no inter-hemispheric transfer was involved.

Conclusions: In addition to an inter-hemispheric transfer dysfunction, the results show impairment in perceptual grouping during rivalry in patients with mild glaucoma, suggesting that the strength of the lateral connectivity of the hypercolumns in the primary visual cortex is diminished. These deficits may have implications for higher levels of visual processing such as object recognition and scene segmentation.

ABSTRACT BODY:

Purpose: Cytochrome P450 1B1 (CYP1B1) mutations are the most frequent cause of Primary Congenital Glaucoma (PCG) globally; however, the mechanism/s by which the mutations cause glaucoma has not been yet elucidated. The purpose of this work was to investigate the binding ability of CYP1B1 to all trans retinal (t-RAL) and its effect on p53 protein levels and downstream pathways in human trabecular meshwork (HTM) cells.

Methods: Protein-ligand binding studies were performed using molecular docking where Alpha naphthoflavone and 17 β estradiol were used as positive controls, and microscale thermophoresis (MST) using wild type and G61E mutant CYP1B1. Expression of p53 and GADD45 was assessed by western blot in triplicate using protein extracted from primary HTM cells (from an 11-month-old donor) treated with different concentrations of t-RAL. Relative band densities were determined by densitometry and differences between control and each of the treatment groups were determined by using ANOVA. $p \leq 0.05$ was considered significant.

Results: Molecular docking showed a binding affinity of CYP1B1 for t-RAL that was 1.5 and 2-fold higher than Alpha naphthoflavone and 17 β estradiol respectively. With MST, the binding affinity of CYP1B1 to t-RAL was 3.5-fold greater in the wild type CYP1B1 compared to the mutant. t-RAL bound to wild type CYP1B1 with an average KD of 3338.75 ± 115.18 nM and to the mutant CYP1B1 with an average KD of 11608.05 ± 2289.5 nM ($p=0.036$). The average EC50 was 2764.55 ± 139.5 and 4313 ± 41.5 for wild type and mutant respectively. Treatment of HTM cells with t-RAL increased p53 and GADD45 expression in a dose-dependent manner. When compared to the control, p53 increased significantly by 1.92 and 3.3-fold in the 1 μ M ($p=0.03$) and 5 μ M ($p=0.01$) of t-RAL treatments respectively, whereas GADD45 increased by 1.25 and 3.48-fold in the 1 μ M ($p=0.03$) and 5 μ M ($p=0.001$) of t-RAL treatments respectively.

Conclusions: These results suggest that CYP1B1 binds to t-RAL and may be involved in retinoic acid synthesis, and that mutations in CYP1B1 lead to t-RAL accumulation in the trabecular meshwork. The latter induces cellular stress and activates p53 resulting in the subsequent growth arrest phenotype like that seen in PCG. This study will help in shedding light on the pathophysiology of PCG and other diseases caused by mutations in CYP1B1.

TITLE: What objects do people use a smartphone magnification app to help with viewing?

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Luo, A. Shubham, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gang Luo: Commercial Relationship: Code N (No Commercial Relationship) | Anurag Shubham: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many visually impaired people are using smartphone magnification apps to help see the fine details. The visual tasks performed with the vision assistance apps in their daily lives are largely unknown. Analytics studies on the visual targets viewed by the users can provide valuable insights into their visual demands.

Methods: The SuperVision Magnifier iOS app, which is free to the public, was used to collect data from people using the app in their daily lives. The images captured by the phone cameras were processed by Azure computer vision cloud service for object recognition. Only one image was processed for each app launch. The images were neither saved nor visually reviewed. The app received the object tags (e.g. text, person, child art), and uploaded the data to the Umeng analytics server for tallying in an aggregated manner, without any individually identifiable information being saved. Data across 31 days were downloaded and analyzed offline. More than 1000 types of object tags were grouped into 10 categories- Text, Indoor, Art, Human, Electronics, Outdoor, Food, Animal, Plant, and Others. The data collection and analysis were conducted separately for app users with at least one iOS vision accessibility option (e.g. voiceover, color inverted) toggled on. It is assumed these accessibility users had more severe vision loss than the other users.

Results: In total, 152,819 images from about 25,000 users were successfully processed by the Azure server. Textual targets appeared in 41.1% of the images for the accessibility users, and 29.8% for non-accessibility users. Among the non-textual targets, the top 4 categories were Indoor scene (31.3% and 37.7%), Art (7.4% and 7.4%), Human (6.5% and 10.3%), Electronics (5.7% and 6.0%) for accessibility users and non-accessibility users, respectively. Examining if one non-textual category was more than another non-textual category, it was found that the two groups of users were different in only 2 out of 36 category comparisons. According to the proportion test, the difference was not statistically significant ($p=0.08$, $z=1.43$).

Conclusions: The vision assistance app was used for reading text in about 30 to 40 percent of cases. People with more severe vision loss more frequently needed help with text reading. The majority of visual targets were non-textual, for which the visual demands may be similar for users with different severity of vision loss when grouping broadly.

ABSTRACT BODY:

Purpose: In the pathogenesis of diabetic retinopathy, retinal capillary cells undergo accelerated apoptosis, and mitochondria dysfunction is considered as one of the mechanisms underlying in their death. Mitochondria are dynamic structures, and depending on the energy demand, they continuously fuse and divide. Mitochondrial fission is mediated by GTPase dynamin-related protein 1 (Drp1), and Drp1 activity is modulated by posttranslational modifications including phosphorylation and S-nitrosylation. While phosphorylation at Ser616 of Drp1 facilitates its recruitment to the surface of the mitochondria, S-nitrosylation facilitates phosphorylation at Ser616. Mitochondrial fission protein 1 (Fis1) and mitochondrial fission factor (Mff) serve as key receptors for Drp1 to promote mitochondrial fission. The aim of this study was to investigate the putative mechanisms underlying the activation of Drp1 in the development of diabetic retinopathy.

Methods: Drp1 S-nitrosylation and phosphorylation and Fis1 expression were quantified in the human retinal endothelial cells (HRECs), incubated in normal (NG) or high (HG) glucose for 96 hours by immunofluorescence microscopy and by Western blotting. Role of Drp1 in the regulation of mitochondrial fission, ROS generation and membrane depolarization, respectively, were detected using Mitotracker green, MitoSox and JC1 assays. To transition to the in vivo model, gene and protein expressions of Drp1, Fis1 and Mff were quantified by qRT-PCR and Western blotting in the retinal microvessel from streptozotocin induced-diabetic rats.

Results: Hyperglycemia elevated Drp1 S-nitrosylation and Ser616 phosphorylation, and also increased its co-localization in the mitochondrial outer membrane. Regulation of nitrosylation prevented glucose-induced phosphorylation of Drp1, and Drp1-siRNA ameliorated fragmentation of the mitochondria, superoxide production and membrane potential. Consistent with the in vitro model, retinal microvasculature from diabetic rats, compared to the age-matched nondiabetic rats, had increased Drp1-Ser616 phosphorylation and Fis1 and Mff expressions.

Conclusions: Due to posttranslational modifications of Drp1 in hyperglycemia, its translocation inside the mitochondria is increased, and mitochondrial integrity is disturbed. Thus, targeting Drp1 may serve as a potential therapy to halt the development of diabetic retinopathy.

ABSTRACT BODY:

Purpose: Social determinants of health (SDoH) have been shown to be important in the management of eye diseases, yet these data are frequently missing in electronic health record (EHR) data derived from routine clinical care. We queried a large national database to quantify and characterize SDoH data coverage to inform future research efforts.

Methods: We queried the NIH All of Us data repository, the product of a nationwide prospective cohort study that includes EHR and survey data. Adults with diabetic retinopathy (DR), glaucoma, cataracts, or age-related macular degeneration (AMD) were identified using ICD diagnosis codes and survey responses. The primary outcome of interest was SDoH data coverage, characterized by the proportion of each disease cohort with available data regarding general demographics and socioeconomic factors (Table 1). Variations in SDoH data coverage across cohorts were analyzed with chi-squared testing. Statistical significance was defined as $p < 0.05$.

Results: We identified 23,806 unique adult patients of which 2246 had DR, 13,448 had glaucoma, 6634 had cataracts, and 1478 had AMD. Survey completion rates were high (99.5%-100%) across all cohorts for demographic information, overall health, income, education, and lifestyle. However, healthcare access (12.7%-29.4%), housing (0.7%-1.1%), social isolation (0.2%-0.3%), and food security (0-0.1%) showed significantly lower response rates (Figure 1). Additionally, the proportion of patients reporting healthcare access varied significantly across different disease cohorts ($p < 0.001$), with the lowest in DR patients at 12.7% vs. AMD patients at 29.4%.

Conclusions: SDoH data play a significant role in understanding the risk factors and management for common eye conditions, yet data coverage is highly variable in All of Us. This highlights the need for researchers and clinicians to be proactive about gathering these data in order to assemble complete data sets. Further research is needed to identify barriers to collecting patient data and examine the availability of SDoH data in local EHRs to understand the impact on direct clinical care.

ABSTRACT BODY:

Purpose: evaluate the efficacy and safety of intravitreal 0.19 mg fluocinolone acetonide (FAC) micro implant (ILUVIEN®) in patients with chronic diabetic macular edema (cDME). This is defined as edema that persists or recurs despite treatment.

Methods: observational prospective study recruiting subjects with cDME. Inclusion criteria: cDME for at least 2 years documented with OCT imaging, pseudophakia, previous treatments with laser photocoagulation, intravitreal injections of anti-VEGF and/or dexamethasone. Exclusion criteria: phakia, ocular hypertension, glaucoma, previous vitrectomy. Outcome measures included best-corrected visual acuity (BVCA), intraocular pressure (IOP), and central macular thickness (CMT), measured one, three (T3), six (T6), and twelve (T12) months post-injection. Data was compared with the Friedman test and significance was set at $p < 0.05$.

Results: 18 eyes with a median duration of cDME of 45 months [25 - 118 months]. 77% of subjects either maintained or improved their BVCA (Fig. 1 and 2). 17% and 33% of subjects showed an improvement of 15 ETDRS letters or more at 3 and 12 months respectively (Fig. 3). 17% and 28% of subjects showed a CMT < 250 microns at 3 and 12 months respectively (Fig. 4). The median change in CMT thickness was of -370 and -373.5 microns at 3- and 12-months post-injection respectively (p -value is .025). Changes in median IOP at 3- and 12-months post-injection were not statistically significant (p -value is .210). Ocular hypertension (OHT) was detected in 2 eyes (11%) one-week post-injection.

Conclusions: the FAC micro implant has proved efficacy in improving and/or maintaining BVCA in 77% of patients with cDME up to 12 months post-injection. Ocular hypertension is the most common side effect in pseudophakic patients but generally responds well to topical pressure-lowering medications.

TITLE: The Prevalence of Retinal Detachment and Associated Comorbidities Over a 5-year Period

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Abdelhady, Lehigh Valley Health Network, Allentown, Pennsylvania, UNITED STATES|J. Gaughan, C. Schorr, Cooper University Health Care, Camden, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ahmed Abdelhady: Commercial Relationship: Code N (No Commercial Relationship) | John Gaughan: Commercial Relationship: Code N (No Commercial Relationship) | Christa Schorr: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal Detachment (RD) has a modest incidence with a lifetime risk of 3% by age 85 and is classified as a true ophthalmic emergency. Left untreated, RD frequently leads to blindness in the affected eye. This is unfortunate and sometimes inevitable, as patients often present to their general practitioner after their central vision has been compromised. Studies have demonstrated that RD is associated with events such as myopia, cataract surgery and trauma. The purpose of this descriptive study is to describe the demographics, comorbidities and socioeconomic factors associated with retinal detachment. These results will guide further research comparing identified factors to patients without retinal detachment.

Methods: We used the Healthcare Cost and Utilization Project, National Inpatient Sample database, to identify patients with a discharge diagnosis of RD (ICD-9/10 codes, 36.1, H33) between 2012-2016. The Elixhauser Comorbidity Index was used to identify comorbid conditions and the comorbidity burden. Demographic, geographical, socioeconomic factors and incidence of blindness were evaluated. Continuous data are reported as mean (SD), descriptive statistics are presented as frequency and percentage.

Results: A total of 6985 patients with RD were identified. The mean age was 59 (SD, 19.69) years, 56% (n=3,788) were male, and 60% (n=3,909) were of white race. Most patients (73%, n=4,970) were discharged from urban teaching hospitals and 33% (2,240) were from the southern US region. Thirty percent of RD patients had an annual income lower than \$42K and 52% (3,544) had Medicare insurance. The most frequent comorbidities were hypertension (59%), diabetes mellitus (36%), anemia (24%), and renal disease 23%. Blindness was present in 6.5% of RD patients.

Conclusions: In this study, the incidence of retinal detachment is low. Blindness occurred in less than 7% of patients. RD patients present most often to urban teaching hospitals with common chronic health conditions. Clinicians should understand the influence that these comorbid conditions, demographic and socioeconomic factors have in the emergent treatment of RD to avoid adverse outcomes.

TITLE: Correlation of macula thickness parameters in healthy subjects acquired using SDOCT structural-only and angiography all-in-one scans

SESSION TITLE: Imaging of posterior segment I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Fard, K. Makedonsky, A. Kolli, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ali Fard: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Katherine Makedonsky: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Archana Kolli: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: With the introduction of optical coherence tomography angiography (OCTA) in clinical OCT devices, one must acquire two separate scans (structural OCT and OCTA) in order to access both the wealth of angiography information and structural metrics such as macula thickness. This is also required to be able to compare the macula thickness parameters with prior scans of the same eye. The purpose of this study is to demonstrate that an all-in-one OCTA scan can provide comparable structural metrics to those acquired using the structural-only scan.

Methods: In this study we designed and implemented a prototype all-in-one OCTA 6x6 mm scan (490 A-scans/B-scan, 490 B-scans, 2 repetitions) in CIRRUSTM 6000 AngioPlex (ZEISS, Dublin, CA). B-scans acquired using this prototype OCTA scan were down-sampled to 200x200 A-scans per cube using nearest neighbor interpolation method, in order to compare with structural B-scans acquired using Macula Cube 200x200.

Ten healthy subjects (N=10) were scanned using the prototype scan and Macula Cube 200x200 under an IRB-approved study. The macula thickness analysis was applied on both datasets and the resultant values were compared using Bland-Altman plots.

Results: Figure 1 shows examples of angiography en face, structural en face, and OCT B-scans acquired using these two scan types. The all-in-one OCTA 6x6mm scan provides superior angiography en face and OCT B-scan image quality compared with Macula Cube 200x200 scan. Figure 2 shows the Bland-Altman plots for four inner quadrants (superior, nasal, inferior, temporal) and the central region of the ETDRS grid. The analysis shows good correlation ($r^2 > 0.92$) and low coefficient of variance ($CV < 1.3\%$) in all regions.

Conclusions: Our results demonstrate good correlation between macula thickness parameters acquired using a structural OCT scan and an all-in-one OCTA scan. This finding can potentially eliminate the need for acquiring multiple OCT/A scans in order to obtain both angiography and structural metrics, while maintaining data equivalency with prior scans of the same eye.

ABSTRACT BODY:

Purpose: Visual impairment is a major risk factor for gait disturbances in glaucoma. Previously reported gait changes obtained in the laboratory setting may not accurately reflect one's free-living ambulatory behavior. The objectives of this study were to: 1) compare lab-measured and real-world cadences in glaucoma patients, and 2) explore the relationship between each cadence metric with visual field (VF) damage.

Methods: Demographics and health data were acquired on 242 participants of the Falls in Glaucoma Study. Visual field testing results on each eye were combined into an integrated visual field (IVF) sensitivity to judge glaucoma severity. Cadence was defined as the average number of steps taken per minute. Lab-measured (gait mat) cadence was obtained using a GAITRite electronic walkway at the baseline clinical evaluation. Real-world cadence was estimated as the peak 1-min cadence using 7-day GPS and accelerometer data. Peak 1-min cadence was calculated as the highest cadence value for a single minute on each individual day, averaged over all valid days of the 7-day accelerometer trial. Average peak at-home and away from home cadences were calculated in the same fashion, with subject location determined by GPS data. Negative binomial regression models were used to determine the association between cadence metrics and VF damage.

Results: Study participant characteristics are described in Table 1. Mean gait mat cadence was greater than the mean real-world cadence (107 vs. 91 steps/min; $P < 0.001$), with intra-person gait mat and real-world cadences demonstrating only weak positive correlation ($r = 0.29$; $P < 0.001$). VF damage showed no association with gait mat cadence ($RR = 1.01$; 95%CI, 0.99-1.02; $P = 0.50$), but each 5-dB decrement in IVF was associated with a 6% slower real-world cadence ($RR = 0.94$, 95%CI, 0.90-0.97; $P = 0.001$) (Table 2). Associations of real-world cadence with IVF sensitivity persisted for both at-home ($RR = 0.94$; 95%CI, 0.89-0.99; $P = 0.03$) and away from home cadences ($RR = 0.96$; 95%CI, 0.92-0.99; $P = 0.02$) (Table 2).

Conclusions: Lab-measured cadence largely overestimates and poorly correlates with real-world cadence in patients with glaucoma. Greater VF damage was found to be associated with slower real-world cadence. Our findings indicate that gait metrics that are obtained in a controlled environment may not accurately reflect the free-living ambulatory behaviors of glaucoma patients.

TITLE: In Vivo Approach to Estimate Ocular Rigidity and to Compare Biomechanical and Biometry Characteristics in Humans

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Ma, S.E. Moroi, C.J. Roberts, Department of Ophthalmology and Visual Sciences, The Ohio State University, Columbus, Ohio, UNITED STATES|C.J. Roberts, Department of Biomedical Engineering, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yanhui Ma: Commercial Relationship: Code N (No Commercial Relationship) | Sayoko Moroi: Commercial Relationship(s);Wolters Kluwer Health:Code R (Recipient) | Cynthia Roberts: Commercial Relationship(s);OCULUS Optikgeräte GmbH:Code C (Consultant);Ziemer Ophthalmic Systems AG:Code C (Consultant);Optimo Medical AG:Code C (Consultant)

ABSTRACT BODY:

Purpose: Our purpose was to use dynamic optical coherence tomography (OCT) video to estimate ocular rigidity. Furthermore, we evaluated the relationship between ocular rigidity and the biomechanical and biometry characteristics of the human eye.

Methods: Ocular rigidity was calculated using Friedenwald's empirical equation which estimates the change in intraocular pressure (IOP) produced by volumetric changes of the eye due to choroidal pulsations with each heartbeat. High-speed OCT video was utilized to noninvasively measure changes in choroidal volume through time-series analysis. A control-case study design was based on 23 healthy controls and 6 glaucoma cases. Multiple diagnostic modalities were performed during the same visit including Spectralis OCT for nerve head video, Pascal Dynamic Contour Tonometry for IOP and ocular pulse amplitude (OPA) measurement, Corvis ST for measuring dynamic biomechanical response, and Pentacam for characterizing biometry dimensions of the eye.

Results: Ocular rigidity in glaucoma was significantly larger than in healthy eyes ($p=0.039$). Negative correlations of ocular rigidity were found with axial length ($n=29$, $p=0.003$), and anterior chamber volume ($p=0.0002$). A stronger correlation of ocular rigidity was observed with the stiffness parameter at the highest concavity (SP-HC; $R=0.62$, $p=0.0005$) quantifying scleral stiffness, than at the first applanation (SP-A1; $R=0.41$, $p=0.033$) quantifying corneal stiffness. In addition, there was a positive correlation between the ocular rigidity and the static pressure-volume ratio (P/V ratio) ($p<0.0001$) (see Fig.1).

Conclusions: Ocular rigidity was noninvasively assessed using OCT video and OPA in a clinical setting. The strong correlation of ocular rigidity with biomechanical parameters, SP-HC and P/V ratio, demonstrated the validity of the ocular rigidity estimation. These in vivo methods offer an important approach to investigate the role of ocular biomechanics in glaucoma. Higher ocular rigidity in glaucoma offers evidence that the scleral stiffness is a contributing factor to the pathogenesis of glaucoma.

ABSTRACT BODY:

Purpose: To quantify retinal structural, vascular, and functional changes in patients with relapsing-remitting MS (RRMS) over 1 year.

Methods: Eighty-eight eyes of 44 patients with RRMS underwent assessments of low contrast letter acuity (LCLA), retinal ganglion cell function detected by the steady-state Pattern Electroretinogram (PERG), axonal microstructural integrity measured as birefringence, intraretinal layer thicknesses by ultra-high resolution optical coherence tomography (OCT), volumetric vessel density (VVD) by OCT angiography, and retinal tissue perfusion (RTP) by the Retinal Function Imager (RFI). All measurements were performed at baseline and 1-year follow-up. The impacts of disease activities and a history of optical neuritis (ON) were analyzed.

Results: Compared to baseline, there were no significant differences in all variables ($P > 0.05$), except for the axonal birefringence and RFI measurements. The birefringence's of retinal fiber layer at the temporal and superior quadrants was significantly decreased at follow-up ($P < 0.05$). The retinal blood flow and RTP were significantly increased at follow-up ($P < 0.05$). In the sub-group with ON, significantly longer PERG latency and decreased VVD in the retina were observed at follow-up ($P < 0.05$). In patients with improved LCLA, significantly increased RTP and decreased VVD ($P < 0.05$) were also observed.

Conclusions: This is the first longitudinal study that assessed the RTP and VVD, along with other retinal structural and functional parameters in MS. The recovery of retinal vascular function occurred with the improved LCLA, suggesting that these measurements may be associated with disease progression and therapeutic efficacy.

ABSTRACT BODY:

Purpose: Many diseases such as age-related macular degeneration (AMD) are classified based on human-defined rubrics that are prone to bias. Supervised neural networks are trained using human-generated labels that require labor-intensive annotations and are restricted to the specific trained tasks. Here, we employ unsupervised learning which organizes fundus images based only on visual similarity to determine AMD severity and identify ocular features without the confines of human definitions or labels.

Methods: We trained an unsupervised deep neural network with Non-Parametric Instance Discrimination (NPID) using 100,848 human-graded fundus images from 4757 participants from the Age-Related Eye Disease Study (AREDS) to grade AMD severity using 2-step, 4-step, and 9-step classification schemes. We compared balanced and unbalanced accuracies of NPID against published supervised networks and ophthalmologists, explored network behavior using hierarchical learning of image subsets and spherical k-means clustering of feature vectors, then searched for ocular features that can be identified without labels.

Results: Unsupervised NPID demonstrated versatility across different AMD classification schemes without re-training, and achieved balanced accuracies comparable to supervised networks or human ophthalmologists in classifying advanced AMD (82% vs. 81% or 89%), referable AMD (87% vs. 92% or 96%), or on the 4-step AMD severity scale (65% vs. 63% or 67%), despite never directly learning these labels. Drusen area drove network predictions on the 4-step scale, while depigmentation and geographic atrophy (GA) areas correlated with advanced AMD classes. Unsupervised learning identified grader-mislabeled images and revealed susceptibility of some classes within the more granular 9-step AMD scale to misclassification by both ophthalmologists and neural networks. Importantly, unsupervised learning enabled data-driven discovery of AMD features such as GA and other ocular phenotypes of the choroid (e.g. tessellated or blonde fundi), vitreous (e.g. asteroid hyalosis), and lens (e.g. nuclear cataracts), that were not pre-defined by human labels.

Conclusions: Unsupervised learning enables automated AMD severity grading comparable to ophthalmologists and supervised networks, reveals biases of human-defined AMD classification systems, and allows unbiased, data-driven discovery of AMD and non-AMD ocular phenotypes.

ABSTRACT BODY:

Purpose: To quantify and to analyze the relative cost of various glaucoma surgical procedures and selective laser trabeculoplasty (SLT) per mm Hg intraocular pressure (IOP) reduction (\$/mmHg).

Methods: Published glaucoma treatment studies were reviewed to quantitate the reduction of mean IOP and glaucoma medications for a given treatment modality. Medicare allowable costs were used to calculate a newly introduced parameter - cost per mmHg IOP reduction- at 1,2,3,4 and 5 years postoperatively. Medicare-allowable fee data for 2020 were obtained from Centers for Medicare and Medicaid Services to calculate the costs (in 2020 US dollars) associated with each treatment assuming it was administered a hospital-based (facility) practice. Our calculations included all professional fees including anesthesia and facility fees. The dollars per relative value unit (RVU) conversion factor was \$37.89, the estimated rate for 2020. Reimbursement was adjusted for the geographic modifier for Miami, Florida.

Results: The relative cost per mmHg IOP reduction was highest in year 1 as it included both the surgical cost and cost of anti-glaucoma medications needed postoperatively. Most efficient as SLT (\$66/mmHg at year 1) was substantially lower than all other glaucoma surgical interventions for the first 3 years. The most cost-efficient glaucoma surgery in the first year was trabeculectomy (\$215/mmHg) and least was iStent (\$1420/mmHg). Intermediate cost-efficiency modalities were for CPC \$(446/mmHg) and BGI (\$469/mmHg). The most cost-efficient MIGS procedure was Trabectome (\$505/mmHg) followed by GATT (\$748/mmHg).

Conclusions: There is a wide variation in the costs to lower the IOP and reduce dependence on nonsurgical modalities. While there may well be a role for a more costly modality in individual cases, the high costs of some of the existing therapies should be considered when designing a treatment strategy.

ABSTRACT BODY:

Purpose: Resolvins (Rvs) D3, D4, and D5 are specialized proresolving mediators in inflammation-resolution biosynthesized from the w3 fatty acid docosahexaenoic acid. The purpose of this study was to determine if RvD3, RvD4, or RvD5 interact with rat conjunctival goblet cells and determine the signal transduction pathways utilized to increase intracellular $[Ca^{2+}]_i$ ($[Ca^{2+}]_i$).

Methods: Conjunctiva from male Sprague-Dawley rats was removed and placed in organ culture with RPMI media. Goblet cells were allowed to grow out of the tissue plug. First passage cells were used for all experiments. To measure $[Ca^{2+}]_i$, cells were trypsinized and transferred to 35-mm glass bottom dishes. The cells were incubated at 37°C for 1 hour with the calcium indicator fura2/AM with 250 mM sulfinpyrazone and 8 mM Pluronic acid F127. $[Ca^{2+}]_i$ was measured with a ratio imaging system (InCytIm2; Intracellular Imaging, Cincinnati, OH) using wavelengths of 340 and 380 nm and an emission wavelength of 505 nm. Cells were stimulated with RvD3, RvD4, and RvD5 from 10^{-12} - 10^{-8} M. Inhibitors were added 10-30 minutes prior to stimulation.

Results: RvD3, RvD4, and RvD5 each increased $[Ca^{2+}]_i$ in a concentration dependent manner with peak concentrations of 10^{-9} M for each resolvin. Only RvD5-stimulated increase in $[Ca^{2+}]_i$ was inhibited by BOC2, an inhibitor of the ALX/FPR2 receptor. $[Ca^{2+}]_i$ stimulated by all three of these D-series resolvins was blocked by inhibition of phospholipase (PL) C and D but not A2. Absence of extracellular Ca^{2+} also blocked the increase in $[Ca^{2+}]_i$ stimulated by RvD3, RvD4, and RvD5. Only RvD3-stimulated increase in $[Ca^{2+}]_i$ was blocked by H89, an inhibitor of protein kinase A.

Conclusions: RvD3, RvD4, and RvD5 activate PLC and D, but not A2. Only RvD3 uses cAMP and protein kinase A. Thus RvD3, RvD4, and RvD5 play a role in the physiologic regulation of conjunctival goblet cells.

ABSTRACT BODY:

Purpose: Motivational Interviewing (MI), a type of counseling, has improved medication adherence, health outcomes, and patient-centered outcomes in many chronic diseases. The 7-month MI-based Support, Educate, Empower (SEE) personalized glaucoma coaching program improved medication adherence by 21-percentage points in a sample of non-adherent glaucoma patients. The goal of this study was to assess the impact of the SEE program on patient-centered outcome measures.

Methods: Glaucoma patients (≥ 40 years old, taking ≥ 1 medication) self-reporting poor medication adherence were recruited from the University of Michigan. Patients completed 10 validated surveys both before and after their 7-month coaching program. Five of these surveys measured the participants' skills in managing their glaucoma (Perceived Competence Scale, Glaucoma Knowledge Scale, Glaucoma Medication Self-Efficacy Scale, Goal Setting Scale, Confidence Asking Question Scale). The Treatment Self-Regulation Questionnaire measured participants' motivation for health behavior change. The Healthcare Climate Questionnaire measured the program's support for patient autonomy. Three other scales explored satisfaction with care (Satisfaction with Information Scale), glaucoma related distress (Diabetes Distress Scale adopted for glaucoma), and perceived benefit of treatment (Perceived Benefits Scale). Surveys were scored according to official documentation. Pre- and post-intervention scores were compared using paired t-tests and Wilcoxon signed-rank tests. P-values were adjusted for multiple comparisons using Holm's method.

Results: 39 patients completed the SEE program. Significant positive changes were noted in 8/10 patient centered outcome measures (perceived competence, autonomy support, intrinsic motivation, disease related distress, self-efficacy, satisfaction with information, confidence asking questions, and goal setting). There was no effect on perceived benefits of glaucoma treatment or glaucoma knowledge.

Conclusions: The SEE Program improved a large number of patient-centered outcome measures such as overall glaucoma related distress, motivation to be adherent, and confidence to ask their ophthalmologist questions. These positive changes will hopefully help participants maintain engagement with glaucoma treatment over their lifetime.

ABSTRACT BODY:

Purpose: Physical activity is a central feature of well-being and an essential component of quality of life in older adults, particularly those with vision loss. To optimize physical activity and safety, it is important to understand where persons with visual impairment perform their activities and which activity locations are safe. We performed a prospective cohort study to examine the association of visual field (VF) damage on physical activity away-from-home, per away-from-home excursion, and at home in glaucoma patients.

Methods: We analyzed three years (2013-2015) of data from a well-established cohort of community-dwelling older people with glaucoma (N=229, Table 1). The severity of VF damage was defined as average sensitivity within the integrated VF (IVF). Participants wore accelerometers and GPS trackers for seven days to measure physical activity and characterize activity location. Multivariable negative binomial regressions were used to test whether away-from-home activity per day, activity per away-from-home excursion, and at-home activity per day varied by the severity of VF damage. Covariates included age, race, sex, living arrangement, employment, education, comorbidity, polypharmacy, and cognitive function.

Results: Each 5-dB decrement in IVF sensitivity was associated with a lower amount of away-from-home activity per day [18% less Moderate & Vigorous Physical Activity (MVPA) minutes/day, 16% less active minutes/day (95% CI, 0.75, 0.93) and 17% fewer steps/day (95% CI, 0.74, 0.93)] (Table 2), and physical activity per away-from-home excursion [20% less MVPA minutes/excursion (95% CI, 0.65, 0.98), 19% less active minutes/excursion (95% CI, 0.71, 0.92) and 20% fewer steps/excursion (95% CI, 0.72, 0.90)]. However, worse IVF sensitivity was not associated with measures of at home activity (MVPA minutes/day, active minutes/day, and steps/day), time spent at or away from home, or excursions/week ($p>0.1$ for all).

Conclusions: Restriction of physical activity in more severe glaucoma patients results mostly from activity restriction outside home environment. These findings highlight the importance of maintaining a safe home environment and increasing confidence to perform activity, particularly high-intensity activity, when leaving the home amongst patients with glaucoma. Further research is warranted to define specific environmental features that may improve safety and functionality in visually impaired population.

ABSTRACT BODY:

Purpose: Systemic immunomodulator (SI) use in the acute phase of Stevens-Johnson syndrome/toxic epidermal necrolysis (SJS/TEN) is controversial. Cyclosporine a (CsA) has been of particular recent interest. It is unknown if SIs affect acute ocular disease severity in SJS. Our study investigated the relationship of choice of SI and acute ocular severity (AOS) in SJS. We additionally observed the relationship between use of these regimens and rates of hospital service utilization including but not limited to intensive care unit (ICU) admission, ICU length of stay (LOS), and 30-day readmission.

Methods: We performed a retrospective, observational chart review of all patients in our system with confirmed SJS by biopsy or exam by dermatology. Patients were divided by treatment regimen including: steroids; intravenous immunoglobulin; CsA; combined CsA and steroids; and supportive care. Exclusion criteria included no documentation of the acute episode. Sixty-eight patients and 130 eyes were included. Statistics were performed in R version 4.0.2. The primary outcome was post-SI AOS score. Means with standard deviations are presented for continuous and ordinal variables and frequencies for categorical variables. Generalized estimating equations and Fisher's exact test were used to compare SI therapies on acute ocular disease (reference group was supportive care).

Results: No significant difference in greatest AOS score post-SI administration was seen between treatment groups after controlling for initial disease severity. Significant differences in presence of toxic epidermal necrolysis and ICU admission were noted across treatment groups. Significance did not persist when comparing those receiving any SI combination that included CsA vs no CsA in the aforementioned variables. Additionally, differences in ICU LOS and 30-day readmission rates were not observed.

Conclusions: No relationship was found between the treatment groups and mean AOS scores post-SI administration. Frequency of ICU care was significantly different across groups but not between CsA vs non-CsA groups, suggesting that CsA, versus other SIs, is more readily used across services and in varying degrees of systemic disease severity. SI regimen does not appear to correlate with acute ocular disease outcomes in this cohort. Next steps include studying the timeline and dosage of SI administration in relation to acute and chronic ocular disease in SJS.

ABSTRACT BODY:

Purpose: Nephronophthisis (NPH) is the leading cause of hereditary end-stage kidney disease in children and young adults. Biallelic NPHP1 deletions are the most frequent molecular defect found in NPH patients. Nephrocystin 1, the gene product of NPHP1, is also expressed in photoreceptors where it plays an important role in the intraflagellar transport between the inner and outer segments, but the retinal phenotype has never been investigated in detail. Here, we comprehensively characterized retinal changes in patients with biallelic NPHP1 deletions.

Methods: This cross-sectional, multicenter study included 16 patients with a homozygous deletion of the NPHP1 gene. Subjects underwent ophthalmic examination including best-corrected visual acuity (BCVA) testing and retinal imaging.

Results: Median age at examination was 17 years (range, 6-53 years). Fundoscopy and fundus autofluorescence (AF) imaging showed no obvious abnormalities. However, optical coherence tomography (OCT) imaging revealed a distinct retinal phenotype with mild thinning of the outer nuclear layer, reduced reflectivity of the ellipsoid zone, fading or loss of the interdigitation zone, but a preservation of the retinal pigment epithelium. Median visual acuity was 20/20 (range, 20/80-20/20) with a para-central sensitivity loss on visual field testing. Retina-wide function measured with full-field electroretinography revealed either normal responses or a mild cone-dominant dysfunction. Nine patients were asymptomatic, whereas those with visual symptoms mainly reported reduced night vision as initial vision problem. One patient with more severe retinal degeneration carried an additional heterozygous variant in CEP290.

Conclusions: These data suggest that homozygous NPHP1 gene deletions result in a mild retinal ciliopathy that predominantly affects cones, but with relative sparing of the fovea. The distinct retinal phenotype is visible on OCT and usually remains without obvious correlates on clinical examination and AF imaging ("occult retinopathy"). Despite the predominant cone dysfunction on ERG testing, night vision problems may be an early symptom. The identified additional CEP290 variant in the patient with the more severe retinopathy may indicate a potential role for genetic modifiers, although this requires further investigation.

ABSTRACT BODY:

Purpose: To evaluate the long-term functional and anatomical outcomes of neovascular age-related macular degeneration (nvAMD) eyes treated with intravitreal anti-vascular endothelial growth factors (VEGF) compounds for up to 10 years and to identify associated factors.

Methods: Retrospective evaluation of consecutive nvAMD naïve eyes initially treated with intravitreal bevacizumab and switched to ranibizumab or aflibercept if required using a treat and extend protocol. Data were collected from the electronic medical records including demographics, clinical, and optical coherence tomography findings. Genotyping for the CFH (rs1061170), HTRA1 (rs1200638), and C3 (rs2230199) major risk single nucleotide polymorphisms for AMD were collected.

Results: A total of 206 patients (n=276 eyes) commenced anti-VEGF therapy ≥ 8 years, and 66 (32.0%) patients (n=80 eyes, 29.0%) remained in follow-up ≥ 8 years and were included in this study. The mean number of anti-VEGF injections (\pm SD) was 73.3 ± 28.0 over 10 years. Mean best-corrected visual acuity (BCVA) (LogMAR \pm SD) improved from 0.55 ± 0.53 at baseline to 0.42 ± 0.41 ($p < 0.0005$) at 24 months, but deteriorated to 0.81 ± 0.71 at 8 years ($p < 0.03$) and 1.00 ± 0.73 at 10 years ($p < 0.0005$, compared with baseline). Baseline central point thickness (CPT) and central subfield thickness (CST; microns \pm SD) were 410.9 ± 208.1 and 415.8 ± 162.1 , respectively. Both values decreased to 294.7 ± 135.9 and 323 ± 113.6 ($p < 0.0005$ in each case), respectively, after 3 monthly injections, and remained lower than baseline values until the end of follow-up. BCVA and intraretinal fluid at baseline, macular atrophy and thinning at end of follow-up were associated with the visual outcome after 10 years. Carriers of the CFH and C3 risk alleles had a smaller reduction of CST at follow-up compared with none-carriers. Thinning of CST correlated negatively with the number of CFH/C3 risk alleles borne by a patient. (Pearson rho= -0.246, and -0.608; $p=0.040$, and 0.003 at 8 and 10 years, respectively).

Conclusions: nvAMD patients under anti-VEGF therapy for over 10 years encounter a substantial mean vision loss that is influenced by the presence of IRF at baseline and by atrophy rather than re-thickening of the macula at follow-up. Major complement risk alleles for AMD are associated with a lesser reduction in baseline macula thickness in the long-term.

ABSTRACT BODY:

Purpose: To assess the effect of hypotensive drugs on light absorbance, discoloration, opacification and precipitate formation of IOLs

Methods: In this laboratory study, four types of IOLs (hydrophilic and hydrophobic acrylic) were soaked in solutions containing Brimonidine-tartrate 0.2%, Brimonidine-tartrate/Timolol-maleate 0.2%/0.5%, Dorzolamide 2%, Dorzolamide/Timolol-maleate 2%/0.5%, Latanoprost 0.005% and Timolol-maleate 0.5%. Non-treated IOLs and IOLs soaked in Balanced Salt Solution (BSS) served as controls. All Treated lenses were sealed in glass containers and placed in an oven at 82 degrees Celsius for 120 days (approximating 10 years in 37 degrees according to The Arrhenius equation).

Each IOL underwent four examinations: gross inspection by light microscopy, light absorbance by a photo-spectrometer, Scanning Electron microscopy and an Energy-dispersive X-Ray spectrometry.

Results: A total of 98 acrylic IOLs of 4 different models, were included in the study. 49 hydrophilic and 49 hydrophobic. All BSS-soaked IOLs appeared clear with no significant discoloration or precipitates formation and light absorbance in these lenses was comparable to that of non-soaked, non-heated IOLs ($P>0.05$).

Gross examination revealed brown discoloration of IOLs Soaked in solutions containing Dorzolamide and a yellow discoloration of IOLs soaked in solutions containing Brimonidine. Precipitates of different size, morphology and distribution were seen on hydrophilic and hydrophobic IOLs soaked in solutions containing Latanoprost, Timolol and Brimonidine. Opacification was noted in both hydrophilic and hydrophobic IOLs. Glistening was formed in one IOL model soaks in 6 different solutions, including BSS.

Significant difference in light absorbance was documented between IOLs soaked in Brimonidine/Timolol, Dorzolamide, Dorzolamide/Timolol and latanoprost as compared to control ($P<0.03$).

In most areas of precipitated, spectrometric signatures of Calcium and phosphor was obtained. Brown discolored IOLs contained sulfur.

Conclusions: Interactions between different hypotensive drugs and different IOLs exist in manner of change in light absorbance, discoloration and precipitate formation in-vitro

TITLE: Role of mitochondrial encoded long non-coding RNA in diabetic retinopathy

SESSION TITLE: Mitochondria in ocular diseases

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R. RADHAKRISHNAN, R.A. Kowluru, Kresge Eye Institute, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): RAKESH RADHAKRISHNAN: Commercial Relationship: Code N (No Commercial Relationship) | Renu Kowluru: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the pathogenesis of diabetic retinopathy, mitochondrial DNA (mtDNA) is damaged, compromising the electron transport chain (ETC) system, and accelerating retinal capillary cell death. The proteins, encoded by mtDNA have an important role in the proper functioning of the ETC system, and cytochrome B (CYTB) is one of the 13 mtDNA-encoded genes critical in the functioning of complex III. Diabetes also alters the levels of many nuclear DNA transcribed long non-coding RNAs (LncRNAs; RNAs with more than 200 nucleotides with no open reading frame for translation), and these LncRNAs have been implicated in diabetic retinopathy. However, mtDNA also transcribes three LncRNAs, but their role in diabetic retinopathy remains to be elucidated. Our aim was to investigate the role of mitochondrial encoded LncRNA Cytochrome B (LncCytB) in diabetic retinopathy.

Methods: Human retinal endothelial cells, incubated in 5mM (normal) or 20mM (high) D-glucose were analyzed for LncCytB expression by qRT-PCR and its mitochondrial localization by RNA fluorescence in situ hybridization. The interactions between LncCytB and CYTB were evaluated by Chromatin isolation by RNA purification method. The role of LncCytB in the regulation of CYTB expression was determined in HRECs overexpressing LncCytB using full-length LncCytB, synthesized by T7 promoter based in-vitro transcription.

Results: Compared to normal glucose, high glucose decreased LncCytB transcripts, and also attenuated its levels in the mitochondria. The interactions of LncCytB with CYTB were compromised and the activity of the complex III was reduced. Restoration of LncCytB ameliorated glucose-induced decrease in CYTB.

Conclusions: Decreased interactions of LncCytB-CYTB in hyperglycemic milieu attenuate the processing of mtDNA-encoded CYTB, resulting in its decreased expression, and the ETC system is compromised. Thus, regulation of LncCytB could prevent ETC-mediated self-propagation of the vicious cycle of free radicals, and protect mitochondrial integrity in diabetic retinopathy.

ABSTRACT BODY:

Purpose: This study investigates the impact of anti-VEGF treatment frequency and pattern on long-term VA outcomes in real-world nAMD patients in the U.S..

Methods: A retrospective cohort study was conducted using the de-identified Vestrum Health EHR database. Patients who were newly diagnosed with nAMD between Jan 2015-Mar 2019, ≥ 50 years old, had ≥ 12 -month follow-up, and received ≥ 1 anti-VEGF treatment were included. The primary outcome was change in VA over 48 months. Changes in VA were evaluated across subgroups defined by: baseline VA, first year treatment frequency, and anti-VEGF induction, defined as first 3 injections within 4 months of diagnosis. VA scores were converted from Snellen to ETDRS equivalent letters.

Results: We identified 40,094 patients with newly diagnosed nAMD. Mean age was 80 years and 62.7% were female. The mean baseline VA (SD) was 50.2 (23.9) ETDRS letters; 28% had baseline VA ≤ 35 letters ($\leq 20/200$), 22% had 57-36 letters (20/70-20/200), 29% had 69-58 letters (20/70-20/40), and 22% had ≥ 70 letters ($\geq 20/40$). At 12, 24, 36, and 48 months, patients received an average of 7.7, 6.0, 5.7 and 5.5 injections each year and had a mean VA change from baseline of +4.5, +3.4, +1.7, and +1.1 letters respectively.

VA change was associated with a greater number of injections. Given similar injection frequency, patients with worse baseline VA had larger VA gain compared to those with better baseline VA (Figure 1). Additionally, patients who underwent induction with 3 monthly anti-VEGF doses had higher annual treatment frequency over time and corresponding better short- and long-term visual outcomes (Figure 2).

Conclusions: In the US, based on a large real-world dataset of treatment naive nAMD patients, better short- and long-term VA outcomes are associated with lower baseline VA, higher treatment frequency, and anti-VEGF induction with 3 injections within 4 months of diagnosis.

ABSTRACT BODY:

Purpose: When treating bacterial infections of the eye, knowledge of the antibiotic resistance profile of causative bacteria may aid in selection of the most suitable treatment. Now in its twelfth consecutive year, the ongoing Antibiotic Resistance Monitoring in Ocular microorganisms (ARMOR) study is the only nationwide surveillance study focused exclusively on common ocular pathogens. This interim analysis reports on the antibiotic susceptibility of ocular isolates collected to date in 2020.

Methods: Clinically relevant isolates of *Staphylococcus aureus*, coagulase-negative staphylococci (CoNS), *Streptococcus pneumoniae*, *Pseudomonas aeruginosa*, and *Haemophilus influenzae* cultured from ocular infections were submitted to a central laboratory for in vitro antibiotic susceptibility testing as part of ARMOR. Minimum inhibitory concentrations (MICs) were determined per Clinical and Laboratory Standards Institute broth microdilution methods for up to 16 antibiotics (from 10 drug classes), and isolates were classified as susceptible or resistant based on established interpretative criteria.

Results: A total of 366 isolates from 20 US sites were analyzed. Staphylococci exhibited high levels of in vitro resistance to azithromycin (57-62%), oxacillin/methicillin (36-46%), and ciprofloxacin (25-33%); trimethoprim resistance (28%) was also observed among CoNS. Multidrug resistance (MDR; ≥ 3 antibiotic classes) was common among *S. aureus* (39%) and CoNS isolates (43%), with a substantial proportion of methicillin-resistant isolates exhibiting MDR (78% and 75%, respectively). Although *S. pneumoniae* isolates demonstrated resistance to azithromycin (47%) as well as oral penicillin and tetracycline (both 41%), no resistance to fluoroquinolones was detected. Resistance to polymyxin B and the fluoroquinolones was low (<2%) among *P. aeruginosa*, and no resistance to tested drugs was observed among *H. influenzae* isolates.

Conclusions: Preliminary results from the 2020 ARMOR study indicate continued high levels of in vitro antibiotic resistance among staphylococci, with considerable MDR especially in methicillin-resistant strains. Combined with other clinical information, these surveillance data can help guide the selection of antibiotics for empiric management of ocular infections.

TITLE: A novel, online platform for tracking amblyopia patients: cohort description and initial results

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Le, Case Western Reserve University School of Medicine, Cleveland, Ohio, UNITED STATES|B. Can, A. Peiffer, H. Klein, M. Kohen, F. Orge, Ophthalmology, University Hospitals, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tinh Le: Commercial Relationship: Code N (No Commercial Relationship) | Basak Can: Commercial Relationship: Code N (No Commercial Relationship) | Adam Peiffer: Commercial Relationship: Code N (No Commercial Relationship) | Hayley Klein: Commercial Relationship: Code N (No Commercial Relationship) | Maryo Kohen: Commercial Relationship: Code N (No Commercial Relationship) | Faruk Orge: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Amblyopia is a leading cause of childhood blindness. Although multiple effective treatment methods exist, patient compliance remains a major hurdle to successful outcomes. We assessed the outcomes of patients enrolled in a novel, online amblyopia tracking platform.

Methods: Inside Out Medicine (Seattle, WA) is an online, HIPAA-compliant platform that enhances monitoring of amblyopia patient treatment. The platform let parents create a virtual “log” in which they record their child’s daily treatment (hours patched per day, patches used per day, which eye was patched, etc.) and allows providers to view the logs. The platform also gives instructions for parents to assess and record their child’s near visual acuity (VA). Providers at an urban academic center enrolled eligible patients (amblyopia patients age 1-12 years undergoing occlusion or penalization therapies) by sending an email invitation to parents to create an account on the platform. Parents were instructed to log all amblyopia treatment prescribed by their ophthalmologist/optometrist in the platform. Baseline characteristics, treatment compliance and outcome measures (change in visual acuity) were collected for patients who had presented for a follow up clinic visit at least 60 days after enrollment in the platform.

Results: Since the integration of the program in our clinics on 7/14/20, 65 patients have been enrolled in the platform. The cohort has an average age of 4.95 years (std = 2.55) and is 51% female. For patients whose amblyopia can be graded, 44% have mild amblyopia, 48% have moderate amblyopia, and 10% have severe amblyopia. The right eye is amblyopic in 51% of patients.

Of the 65 enrolled patients, 12 had a follow up visit after at least 60 days of platform enrollment (average 101 days). 7 patients had mild amblyopia, 4 had moderate, and 1 had severe. Average change in visual acuity at first follow up was an improvement of .055 logMAR units (from .300 to .245).

Conclusions: We report the use of a novel, online, HIPAA-compliant platform to provide daily data on patients’ amblyopia treatment compliance. Patients enrolled in the platform for at least 60 days experienced an average VA improvement of .057 logMAR units in the amblyopic eye. This pilot study shows the potential of this online, easy-to-use platform to improve amblyopia patient outcomes by improving compliance monitoring and oversight.

TITLE: Chitosan film adhesive for sutureless corneal surgery

SESSION TITLE: Corneal Stromal Repair and Corneal Biology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Tan, L.J. Foster, S.L. Watson, Corneal Research Group, The University of Sydney Save Sight Institute, Sydney, New South Wales, AUSTRALIA|L.J. Foster, Bio/Polymer Research Group, The University of Alabama in Huntsville, Huntsville, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jackie Tan: Commercial Relationship: Code N (No Commercial Relationship) | Leslie Foster: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Watson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the efficacy of a novel laser activated, thin-film chitosan adhesive technology for sealing penetrating corneal incisions against self-sealed or sutured incisions in an in vivo rabbit model.

Methods: Central penetrating corneal incisions of 2mm were created on the right eyes of 135 albino rabbits. These incisions were closed using either the adhesive technology, 10-0 nylon sutures or left to self-seal (n=45 per group). Wound integrity was quantified by measuring the highest fluid pressure prior to wound leak (burst pressure). At timepoints of up to 14 days post-operatively, 5 rabbits from each group were euthanized and their corneoscleral rim dissected for the burst pressure testing using a modified Barron chamber. Statistical significance was determined at $p < 0.05$.

Results: Average burst pressure from corneal incisions sealed using the chitosan technology were persistently higher than both the suture and self-sealed groups from timepoints 0 to 72 hours ($p < 0.05$). At 3 hours post-operatively, the average burst pressures (\pm standard deviation) were 169.3 (± 100.1), 10.6 (± 6.8) and 5.3 (± 3.8) mmHg, respectively, $p = 0.0023$. At 24 hours, burst pressures were 233.8 (± 83.2), 6.4 (± 2.9), 45.2 (± 16.6) mmHg, respectively, $p = 0.000019$. Burst pressures 72 hours post-operatively were 229 (± 120.1), 12.4 (± 6.6), 36.4 (± 21.6) mmHg, respectively, $p = 0.000696$. After 7 days, burst pressures between all groups no longer showed any statistical difference. The chitosan group recorded an average burst pressure of 307.0 (± 106.0) and 360.0 (± 0.0) mmHg on day 7 and day 14 respectively.

Conclusions: Chitosan adhesive technology can seal full thickness corneal incisions in a living rabbit model, tolerating high burst pressures and accelerating healing.

Commercial Relationships Disclosure (Abstract): Sanjoy Bhattacharya: Commercial Relationship: Code N (No Commercial Relationship) | Genea Edwards: Commercial Relationship: Code N (No Commercial Relationship) | Noel Ziebarth: Commercial Relationship: Code N (No Commercial Relationship) | Yutao Liu: Commercial Relationship: Code N (No Commercial Relationship) | Richard Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine differences in phospholipid profiles, their interconversion enzymes and steady state precursors between human glaucomatous trabecular meshwork and normal controls. To establish whether phospholipid containing vesicles are different in glaucomatous aqueous humor (AH) compared to controls.

Methods: Trabecular meshwork (TM) and AH samples were obtained from human cadaveric donors [control, primary open angle glaucoma (POAG) (each n=24, equal distribution of gender, all Caucasian age 68±5.0 and 69.0± 7.5, respectively)]. The samples were analyzed using a Q-Exactive orbitrap mass spectrometer after chromatography on an Acela 600 HPLC for Lipids after extraction using Bligh and Dyer method. All enzymes in the phospholipid conversion pathway were determined for protein level using Western blot and ELISA, and their activities at 15 minutes interval using established assays. The cadaveric TM and AH were collected under NIH category 4, IRB exempted provisions without identifiers. Extracellular vesicles (EVs) were prepared using established centrifugation and 101Bio P100L isolation kit. The EVs were characterized using nanotracker, electron microscopy (EM), atomic force microscopy (AFM) imaging and dynamic light scattering methods. Steady state pre-phospholipid metabolites entering and exiting interconversion cycle were measured using a stop flow apparatus as well as individual metabolite chase methods. All measurements were performed with samples identities masked to the estimators. Data were subjected to statistical analysis using MetaboAnalyst 4.0/STATA14.2 with recommended settings.

Results: Significant differences in phospholipid composition and their interconversion enzymes were found between control and POAG groups. POAG TM and AH was characterized by significant lower levels of phosphatidylserine (PS) and higher phosphatidylethanolamine (PE) levels. We also found significant up-regulation of phosphatidylserine decarboxylase in POAG TM. POAG AH demonstrated smaller lipid containing EVs compared to normal controls using nanotracker and EM, which was corroborated by other methods.

Conclusions: We found significant differences in phospholipid levels and their interconversion enzymes in glaucoma compared to control eyes. Consistent with these lipid changes, we found decreased size of lipid containing vesicles in the POAG AH.

TITLE: A Spectroscopic Approach to Measuring Meibum Lipid Composition and Conformation in Donors with Sjogren's Syndrome

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.R. Veligandla, J. Swindel, D. Clark, D. Borchman, University of Louisville School of Medicine, Louisville, Kentucky, UNITED STATES|A. Ewum, Chemistry, University of Louisville, Louisville, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sravya Veligandla: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Ewum: Commercial Relationship: Code N (No Commercial Relationship) | Jordan Swindel: Commercial Relationship: Code N (No Commercial Relationship) | Dr. Jeremy Clark: Commercial Relationship: Code N (No Commercial Relationship) | Douglas Borchman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sjogren's syndrome (SS) is a chronic autoimmune rheumatic disease affecting 3 million individuals in the United States. About 80 % of people with SS have dry eye, keratoconjunctivitis sicca. We measured the composition and conformation of meibum in donors with SS and donors without SS or dry eye since meibum lipid has been associated with dry eye and meibomian gland dysfunction.

Methods: Meibum was collected using an ILUX instrument (Alcon, Fort Worth, TX). Infrared spectroscopy was used to measure meibum lipid conformation (structure). ¹H-NMR spectroscopy was used to measure meibum composition.

Results: Meibum was collected from 35 donors without dry eye (Mn) and without SS and eight donors with dry eye and with SS (Mss). The cholesterylester/wax ester ratio was significantly, $P = 0.003$, higher for Mss 0.51 ± 0.02 compared with Mn, 0.70 ± 0.06 . Mss contained significantly, $P = 0.02$, more straight chains, 67 ± 5 %, compared with Mn, 57 ± 1 %. No statistical difference was apparent, $P > 0.05$, between the Anteiso Branched, 20 ± 1 , 15 ± 1 or Iso Branched chains 23 ± 1 , 19 ± 4 of Mn or Mss, respectively. There was no statistical difference, $P > 0.05$, between the eight phase transition parameters measured for Mss or Mn.: Transition Temperature ($^{\circ}\text{C}$), Mn : 30.3 ± 0.4 , Mss: 29.9 ± 0.9 ; Cooperativity, Mn : 7.9 ± 0.4 , Mss: 7.6 ± 0.6 ; Order 36.0°C (% trans), Mn : 35 ± 1 , Mss: 38.4 ± 3.6 ; Order 33.4°C (% trans), Mn : 40 ± 1 , Mss: 43.3 ± 3.7 ; Δ enthalpy (kcal/mol), Mn : 142 ± 6 , Mss : 135 ± 25 ; Δ entropy (kcal.mol/degree), Mn : 0.48 ± 0.02 , Mss: 0.45 ± 0.03 ; Minimum Frequency (cm^{-1}), Mn : 2849.71 ± 0.06 , Mss: 2849.5 ± 0.1 ; Maximum Frequency (cm^{-1}), Mn : 2853.69 ± 0.09 , Mss: 2853.3 ± 0.1 .

Conclusions: In spite of having a higher cholesterylester/wax ester ratio and more straight chains, the compositional differences between Mss and Mn did not affect their phase transition parameters. A higher CE/WE ratio and straight chain composition of Mss compared with Mn, could be a marker for SS and/or contribute to dry eye in patients with SS. Studies are planned to measure the rheology of Mss to test this idea.

TITLE: Determination of the effects of extracellular acidosis on ARPE19 cells using whole transcriptome analysis

SESSION TITLE: Metabolism and protein processing: retina, photoreceptors and RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Jose, W. Yanqun, L. Fan, T. Burks, C. Huang, T. Walshe, Novartis Institutes for BioMedical Research Inc, Cambridge, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sandra Jose: Commercial Relationship(s);Novartis Institute of Biomedical Research :Code E (Employment) | Wang Yanqun: Commercial Relationship(s);Novartis Institute Of Biomedical Research:Code E (Employment) | Lin Fan: Commercial Relationship(s);Novartis Institute of Biomedical Research:Code E (Employment) | Tyler Burks: Commercial Relationship(s);Novartis Institute of Biomedical Research :Code E (Employment) | Chia-Ling Huang: Commercial Relationship(s);Novartis Institute of Biomedical Research :Code E (Employment) | Tony Walshe: Commercial Relationship(s);Novartis Institute of Biomedical Research :Code E (Employment)

ABSTRACT BODY:

Purpose: Metabolic adaptations and perfusion abnormalities lead to extracellular acidosis in atherosclerosis, neurodegeneration, and cancer. We speculate that this also occurs in Age Related Macular Degeneration (AMD) and examined the role of acidosis on ARPE19 cells in culture. We previously observed that extracellular acidosis decreases ARPE19 cell glycolysis, mitochondrial respiration, ATP and NAD/NADH. These data suggest that metabolic/mitochondrial dysfunction could be an important component in AMD pathology. We examined the acute and chronic effects of extracellular acidosis on transcriptional changes in ARPE19 using RNA sequencing.

Methods: Fully confluent 14 day cultures of ARPE19 cells were exposed to pH 7.4 or pH 6.5 for 12, 24 or 48 hours. Total RNA was extracted and analyzed on the Illumina NovaSeq 6000 platform with polyA selection library. The fastq files were aligned to human genome (GRCh38.p10) using STAR 2.4.1a. The transcript abundance was estimated using RSEM 1.2.22. The normalization and differential expression (DE) analysis were performed using edgeR and limma-voom R packages to identify the DE genes between pH 7.4 and pH 6.5 at different time points. The enriched pathways at each time point were obtained using GSEA.

Results: We identified 326, 243 and 138 DE genes (absolute log2 fold change ≥ 1 and adjusted p-value < 0.05) at 12 hours, 24 hours and 48 hours, respectively, demonstrating the highest acidosis-induced gene expression changes occur at the earliest time point. The follow up gene set enrichment analysis showed ARF6 pathway, lysophospholipid pathway and TNF-Alpha signaling via NFkB were significantly altered in ARPE19 cell lines exposed to pH 6.5 at 12hrs (p-value < 0.05). Pathways associated with cell cycles were consistently down-regulated at all three time points.

Conclusions: The results demonstrated that extracellular acidosis reprograms ARPE19 cell gene expression within 12 hours. The gene set enrichment analysis showed that the low pH environment interferes with multiple pathways related to AMD. Further study is required to determine how extracellular acidosis affect those pathways and to validate their potential role in macular degeneration.

TITLE: Effects of demographics on the dilation of preschool children during the eye exam

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Vaughan, T. Dale, D. Herrera, Oregon Elks Children's Eye Clinic, Oregon Health & Science University Casey Eye Institute, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joannah Vaughan: Commercial Relationship: Code N (No Commercial Relationship) | Talitha Dale: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Herrera: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Upon review of 4,722 charts of eye exams performed by Oregon eye doctors over the last decade, analysis revealed that one third of exams were completed without dilation. The goal of this study is to identify any potential demographic bias that may affect the practice of dilation in low-income children ages three to five.¹

1. FitzGerald, Chloë, and Samia Hurst. 'Implicit bias in healthcare professionals: a systematic review.' BMC medical ethics vol. 18,1 19. 1 Mar. 2017, doi:10.1186/s12910-017-0179-8

Methods: In 2017, after IRB permission, chart notes and demographics were collected from vision screening referrals. Results were analyzed to determine if any bias was involved in the usage of cycloplegic drops during the eye exam.

Results: Chart notes were analyzed from 591 Head Start children who went to an eye doctor. Dilation occurred in 65.5% of the eye exams. Chi-square tests revealed that the population size of the child's location did have an impact on dilation. There were no statistically significant differences in the use of cycloplegic drops when looking at age (range between 3, 4, and 5 years-old), ethnicity, gender, or language.

Conclusions: The Oregon Elks Preschool Vision Screening Program found a demographic bias against dilation among children living in a population size less than 50,000. No bias was found regarding age, ethnicity, gender, or language. It is difficult and time consuming to encourage parents to seek eye care for preschool school children who have been referred by a vision screening. More public education is needed to create awareness about the importance of dilation during a pediatric eye exam, especially in rural areas with less access to quality eye care.

TITLE: TNF- α Inhibitors and Risk of Age-related Macular Degeneration in Patients with Rheumatoid Arthritis

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Dugan, H. Sandhu, University of Louisville School of Medicine, Louisville, Kentucky, UNITED STATES|A. Nakamura, Dr. Bing Zhang Department of Statistics, University of Kentucky College of Arts and Sciences, Lexington, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elizabeth Dugan: Commercial Relationship: Code N (No Commercial Relationship) | Aisaku Nakamura: Commercial Relationship: Code N (No Commercial Relationship) | Harpal Sandhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the hazard of age-related macular degeneration (AMD) in rheumatoid arthritis (RA) patients on TNF- α inhibitors to RA patients on methotrexate, the first-line therapy for RA.

Methods: A retrospective cohort study was performed on data from 2010-2015 within a large US commercial insurance database, using a weighted Cox proportional hazards model of three groups: 1) methotrexate alone, 2) TNF- α inhibitor alone, and 3) TNF- α inhibitor and methotrexate. Inclusion criteria were a diagnosis of RA and age ≥ 50 years of age. Exclusion criteria were use of hydroxychloroquine, prior history of inherited retinal degeneration, or a prior diagnosis of AMD within a six-month lead-in time. Covariates included age, sex, and a propensity score consisting of the following: hypertension, smoking (COPD and chronic bronchitis used as surrogates), stroke, uveitis or scleritis, diabetes, coronary artery disease, history of colonoscopy, history of endoscopy, history of GI imaging series, peptic ulcer disease, chronic liver disease, hepatitis C, congestive heart failure, hyperlipidemia, cox-2 inhibitors, renal failure, obesity, osteoporosis and fractures, and intra-articular injections. The end point was any diagnosis of AMD.

Results: Group 1 had 118,562 patients, group 2 had 10,711 patients, and group 3 had 18,657 patients. After controlling for age and sex, there was no significant difference in the hazard ratio in developing AMD between groups 1 and 2 (HR = 1.05, 95% CI 0.89-1.18, $p = 0.39$), or groups 1 and 3 (HR = 0.98, 95% CI 0.92-1.06, $p = 0.66$) or groups 2 and 3 (HR = 0.93, 95% CI 0.84-1.04, $p = 0.20$). A diagnosis of uveitis or scleritis in RA patients was the single largest risk factor for developing AMD (HR = 2.26, 95% CI 1.94-2.626, $p < 0.00001$). Stroke (HR = 1.49, 95% CI 1.35-1.65, $p < 0.00001$) and hypertension (HR = 1.44, 95% CI 1.32-1.57, $p < 0.00001$) were also strong risk factors.

Conclusions: In this sample of patients with RA, immune modulation via TNF- α inhibition did not change the hazard of developing AMD. Interestingly, there was an increased hazard for developing AMD in patients with uveitis or scleritis. This further suggests that an aberrant immune response is implicated in AMD, though therapeutic targets of these pathways remain elusive.

TITLE: Long-term Survival of Cultivated Oral Mucosal Epithelial Cell Sheets in post-COMET Patients

SESSION TITLE: Corneal epithelium and Corneal tissue engineering and regenerative medicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Hsueh, H. Chen, H.D. Ma, Department of Ophthalmology, Chang Gung Memorial Hospital, Taoyuan, TAIWAN|

Commercial Relationships Disclosure (Abstract): Yi-Jen Hsueh: Commercial Relationship: Code N (No Commercial Relationship) | Hung-Chi Chen: Commercial Relationship: Code N (No Commercial Relationship) | Hui-Kang Ma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to verify that collagenase-based spheroidal suspension culture is a promising technique for cultivated oral mucosal epithelial transplantation (COMET).

Methods: Patients with limbal stem cell deficiency who received COMET to promote wound healing were studied retrospectively. Immunoconfocal microscopy was performed on corneal specimens from the patients after COMET, as well on normal corneas, conjunctiva, and oral mucosa for Keratin 3, 4, 13, p63 and p75^{NTR}.

Results: A biopsy taken two years after COMET showed stratified epithelium with small, compact basal epithelial cells. The epithelium was positive for Keratin 4, 13, and 3 in the suprabasal layer but universally negative in the basal layer. Staining for p63 and p75^{NTR} were both positive in the basal layer. The graft remained clear up to post-OP 4 years, and his best corrected vision remained above 20/120.

Conclusions: Both clinical observations and histological examination confirmed the long-term survival of the transplanted OMECs, suggesting that collagenase-based spheroidal suspension culture is a promising technique for COMET.

ABSTRACT BODY:

Purpose: Patients with scleritis may have an associated systemic disease, which is often autoimmune and seldom infectious in origin. The data regarding patient demographics and systemic disease associations for scleritis in the Puerto Rican population is scarce. Herein, we evaluated the demographics, scleritis types, ocular complications, and disease associations in a cohort of patients with scleritis living in Puerto Rico.

Methods: A retrospective review of medical records from January 1990 to July 2020 of 2 private uveitis practices in Puerto Rico was performed. Charts of patients with a diagnosis of scleritis were selected for analysis. Demographic and clinical data from the review of medical records were entered into a new database, and a descriptive statistical analysis was performed. The University of Puerto Rico, Medical Sciences Campus Internal Review Board reviewed and approved this protocol.

Results: A total of 116 eyes of 95 patients with a diagnosis of scleritis were identified. The median age was 54 (range 13-80), 69% were female, and all Hispanics. The disease was unilateral in 77.89% of patients. Diffuse anterior scleritis was present in 73.28%, nodular anterior scleritis in 13.79%, necrotizing scleritis in 6.90%, and posterior scleritis in 6.03% of eyes. Uveitis was present in 16.38%, glaucoma in 13.80%, and keratitis in 6.03% of eyes. The presenting visual acuity was better than 20/50 in 77% of eyes, while 9% had a visual acuity of less than 20/200. An associated autoimmune disease was present in 32.63% of patients (rheumatoid arthritis 15.79%, relapsing polychondritis 4.21%, Sjögren's syndrome 5.33%, sarcoidosis 3.16%, systemic lupus erythematosus 2.17%, and systemic vasculitis 1.05%). An associated infectious disease was present in 6.32% of patients (4.21% syphilis, 1.05% Herpes zoster, and 1.05% Lyme disease).

Conclusions: As in other cohorts, scleritis in Puerto Rico was most common in females and had a median age in the sixth decade. The majority of patients presented with unilateral and diffuse anterior scleritis. Rheumatoid arthritis was the most common autoimmune systemic disease association, while syphilis was the most common infectious cause.

ABSTRACT BODY:

Purpose: Despite universal recommendations for comprehensive eye exams (CEE), uptake has been poor, with as few as 14% of children receiving a CEE in Ontario – Canada, despite coverage through provincial health insurance (PHI). Poor access to or use of vision care services may exacerbate health inequities. We performed a population-based, longitudinal, repeated measures study to test the association between material deprivation and receiving a CEE before age 7 years in Ontario using health administrative d

Methods: We followed 128,091 members of a birth cohort from birth until each child's 7th birthday. Children were included if they were born in Ontario, Canada on or between January 1st and December 31st 2010, and eligible for PHI. Children were excluded if: they became eligible for PHI more than 6 months after birth, were without insurance for more than 6 months during follow up, moved out of the province, did not access the health care system for more than 5 years during follow up, and/or had invalid encoded insurance identification numbers. Also excluded were children who died. Descriptive and logistic regression methods were employed.

Results: Sixty-five percent (82,833/128,091) of children had at least one CEE (56.9% and 70.5% in the most and least deprived neighbourhoods, respectively). Most children had their first CEE at 4 to 5 years of age representing 16.4% (20961/128091) of the cohort. After adjusting for clinical and demographic variables, low material deprivation was associated with a higher odds of receiving an eye exam (AOR 1.43; 95%CI 1.36, 1.51). The association was greatest in the 1st (AOR 1.73; 95%CI 1.55, 1.55) and 4th year of life (AOR 1.67; 95%CI 1.59, 1.59).

Conclusions: Uptake of CEEs is poor, with inequities in care delivery. Universal school-based vision screening could identify children at risk for vision impairment and facilitate the provision of referrals for diagnosis and treatment. Public education on the importance of CEEs for children 1 to 3 years is key.

ABSTRACT BODY:

Purpose: To evaluate the factors associated with the development of ocular candidiasis (OC) and ocular prognosis with echinocandin therapy for candidemia.

Methods: The medical records of 56 consecutive patients with a positive blood culture for *Candida* species between November 2016 and October 2019 were retrospectively reviewed. Information on patient characteristics, isolated *Candida* species, treatment details for candidemia, and ocular findings were extracted to identify factors associated with OC development.

Results: The leading pathogen of candidemia was *Candida albicans* (41.1%). Of 56 patients, 18 (32.1%) were diagnosed with chorioretinitis, categorized as either probable (8 patients) or possible OC (10 patients). There was no case of endophthalmitis with vitritis. The incidence of probable OC was not significantly different between the groups treated with echinocandins and other antifungal drugs (15.2% vs. 11.1%, $p = 1.00$). In all probable OC cases, systemic antifungal therapy was switched from echinocandins to azoles, and no case progressed to endophthalmitis. A multivariate logistic analysis revealed that female sex (adjusted odds ratio [aOR], 8.93; 95% confidence interval [CI], 1.09–72.9) and *C. albicans* (aOR, 23.6; 95% CI, 1.98–281) were independent factors associated with the development of probable OC.

Conclusions: One-seventh of patients with candidemia developed probable OC. Given the evidence of female and *C. albicans* as the factors associated with OC development, careful ophthalmologic management is required especially in candidemia with these factors. Although echinocandins had no correlation with OC development and did not lead to the deterioration of ocular prognosis, further investigation is required.

ABSTRACT BODY:

Purpose: As machine learning (ML) algorithms become more common in the clinical setting, so does the importance of explainable AI. The aim of this study was to explore the use of the What-If Tool (WIT) to help clinicians understand how an ML algorithm makes decisions.

Methods: A supervised deep learning model was trained using Google AutoML Tables to predict visual acuity (VA) in diabetic macular oedema patients receiving anti-VEGF injections. It was trained on a public dataset consisting of 2614 eyes of 1964 patients at a tertiary referral centre in London and optimised for mean absolute error (MAE).

The model was interrogated using the WIT via a jupyter notebook extension. To see how it treated different subgroups, the WIT was used to slice the data by the input features gender and ethnicity. The mean absolute error (MAE) was reported for each of these. To individually explore the data, 10 male patients were chosen at random and had their gender hypothetically changed using the WIT's partial dependence plots. These are able to vary an input and report how a model's prediction changes with it.

Results: The MAE of the model in predicting VA was 8.060 letters. Slicing the data in the WIT by male and female eyes showed that it treated both broadly equally with a MAE of 7.510 and 8.855 respectively. Further slicing by both gender and ethnicity found the largest difference in MAE was between white males (6.888) and white females (10.400).

Partial dependence plots of the randomly chosen points showed a mean change in VA prediction of +0.952 letters when gender changed hypothetically from male to female (range: -8.676 to +10.906). In this sample, changing gender from male to female caused the predicted VA to increase 6 out of 10 times. This was investigated further with a global partial dependence plot, which demonstrated that the average change when changing gender from male to female was -0.57.

Conclusions: Our results show two ways the WIT can scrutinise an ML model. Firstly, the freedom to slice the data by any chosen feature allows us to see deeper than overall performance metrics. Secondly, the use of partial dependence plots to observe the model's behaviour in response to hypothetical scenarios offers a more granular understanding than the basic explainable AI features on the Google Cloud Platform. Overall, the WIT presents a novel method for clinicians to understand how ML algorithms make decisions.

ABSTRACT BODY:

Purpose: Early nutritional status and nutritional source type has been reported to be associated with the prevention of retinopathy of prematurity (ROP) in high-income countries. We sought to determine if nutritional source within the first two weeks of life is associated with the development or regression of ROP in a Latin American cohort.

Methods: Secondary analysis of data from a prospective study of premature infants in La Plata, Argentina, and Guadalajara, Mexico between 2012-2014. Primary outcomes were the associations between the nutritional source in the first 2 weeks of life (predominantly total parental nutrition (TPN) or formula, or exclusive breastmilk) and presence, severity (treatment-requiring), and time to spontaneous regression of ROP or IGF-1 levels (ng/mL), adjusting for gestational age (GA) and birth weight (BW), using multivariable regression and ANOVA.

Results: One-hundred infants were studied, with mean (\pm SD) GA 31.3 (\pm 2.7) weeks, median BW was 1395 g (range 620-2250), and 52% female. Most common nutritional source was predominantly TPN in postnatal weeks 1 (74%) and 2 (45%). Forty-three infants developed ROP, 19 were treated, while 21 children had documented full spontaneous regression at time of discharge. Median time to regression was 5 weeks (range 1-9 weeks). No associations were found between the nutritional source in the first 2 weeks of life and presence, severity, or time to spontaneous ROP regression and vascular maturation. No association was found between mean IGF-1 levels and ROP status by nutritional source.

Conclusions: We did not find an association between sources of nutrition during the 1st two weeks of life and ROP development, severity, or spontaneous ROP regression in this cohort of Latin American infants at risk for ROP.

Hoffman-La Roche, Ltd.:Code E (Employment)

ABSTRACT BODY:

Purpose: Satralizumab, a humanized, monoclonal recycling antibody that targets the interleukin-6 receptor, reduced patients' risk of NMOSD relapse in the double-masked (DM) periods of two randomized, phase 3 clinical trials: SAKuraSky (satralizumab in combination with baseline immunosuppressants; NCT02028884), and SAKuraStar (satralizumab monotherapy; NCT02073279). We assessed the efficacy and safety of satralizumab over a longer period of treatment, using data from the SAKura studies' open-label extension (OLE) periods.

Methods: Patients entering SAKuraSky/Star were randomized to receive satralizumab 120 mg or placebo at Weeks 0, 2, 4, and Q4W thereafter. After completing the DM period or experiencing a relapse, patients could enter the OLE period. Time to first investigator-assessed protocol-defined relapse (PDR) and safety were evaluated in the combined DM+OLE periods, using a pooled population from both studies. Data were analyzed through the clinical cut-off date

(June 2019).

Results: Overall, 179 patients were randomized to treatment (satralizumab n=105; placebo n=74), of whom 166 received ≥ 1 dose of satralizumab in the combined DM+OLE period. The median (range) satralizumab exposure in the DM period was 96.1 (8–224) weeks, and in the combined DM+OLE was 131.9 (13–276) weeks. In the combined DM+OLE, patients originally randomized to satralizumab had a 51% lower risk of investigator-assessed PDR vs those originally randomized to placebo (HR [95% CI] 0.49 [0.31–0.79]; $P=0.002$); the risk reduction was more pronounced in AQP4-IgG seropositive patients (66% risk reduction; HR [95% CI] 0.34 [0.19–0.62]; $P<0.001$). Patients who switched from placebo to satralizumab upon entry into the OLE period were included in the placebo group, which likely reduced the observed treatment difference between satralizumab and placebo compared with the DM period. No patients randomized to satralizumab withdrew from the OLE period due to a relapse, vs four patients who were originally randomized to placebo. Safety profiles in the combined DM+OLE were consistent with those in the DM period (Table). No deaths were reported.

Conclusions: In the DM and OLE periods of the SAKura studies, patients receiving satralizumab had a significantly reduced risk of relapse vs placebo. Satralizumab was well-tolerated and showed a favorable safety profile.

ABSTRACT BODY:

Purpose: Misinformation regarding non-Food and Drug Administration (FDA) sponsored, largely unproven, stem cell therapies (SCTs) for retinal disease may pose significant risks to patients. A survey was administered to patients with retinal disease to ascertain their baseline knowledge of SCTs.

Methods: A prospective survey was administered to patients presenting to a retina clinic for dry age-related macular degeneration (AMD) or a variant of diagnoses requiring anti-VEGF therapy. Before clinical evaluation, patients completed a survey evaluating their knowledge about SCTs for retinal disease. Demographics, visual acuity (VA), and clinical diagnoses were also recorded. Visual impairment was classified in accordance with guidelines defined by the World Health Organization (WHO). Pearson chi-square tests for independence were used for gender and ethnicity comparisons.

Results: There were 58 participants, 31 (53.4%) of whom believed there were FDA-approved and commercially available SCTs for retinal disease (95% CI= 39.9%-66.1%). Thirty-eight (65.5%) patients believed all clinical trials found online were regulated by the FDA (95% CI= 51.9%-77.5%). A chi-square test of independence showed no significant association between patient responses and gender. However, Hispanic patients were more likely than non-Hispanic patients to believe there were current FDA approved SCTs commercially available ($p=0.048$) and to believe that all clinical trials found online are approved by the FDA ($p=0.0006$). Only 9 (15.8%) respondents were aware of risks associated with non-FDA approved SCTs for retinal disease (95% CI=7.3%-27.4%). Twenty-two (37.9%) respondents said they would consider SCT not approved by the FDA (95% CI=25.5%-51.6%).

Conclusions: Confusion exists regarding the federal regulation of SCTs for retinal disease and Hispanic patients may be a population more vulnerable to misinformation regarding these unapproved therapies.

TITLE: Comparing Hypertropia (HT) in Upgaze and Downgaze Does Not Distinguish Congenital From Acquired Superior Oblique Palsy (SOP)

SESSION TITLE: Ocular dysmotility and misalignment: Basic and Clinical studies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.L. Demer, Ophthalmology, University of California Los Angeles, University of California Los Angeles, Los Angeles, CA, US, academic, Los Angeles, California, UNITED STATES|J.L. Demer, Neurology, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joseph Demer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ivanir & Trobe claimed that HT greater in up than downgaze, or equal to it, is characteristic of decompensated congenital & never present in ischemic, traumatic, or tumorous SOP (J. Neuro-Ophthalmol. 37:2017). This claim was tested in SOP confirmed by MRI demonstration of subnormal superior oblique (SO) size.

Methods: Quasi-coronal, surface coil MRI was performed in target-controlled central gaze to identify patients with unilateral SO hypoplasia indicative of SOP. Nine subjects had unequivocal congenital onset (mean age 38 ± 16 yrs, standard deviation, SD); 7 subjects had unequivocal acquired onset (age 47 ± 14 yrs, symptom duration 5.4 ± 4.8 yrs), including 2 with trochlear Schwannoma and 5 with severe head trauma; and 15 subjects had progressive onset unequivocally not congenital (age 52 ± 19 yrs, symptom duration 13 ± 14 yrs).

Results: Results: Maximum SO cross section averaged $8.6 \pm 3.9 \text{ mm}^2$ in congenital & $11.3 \pm 3.5 \text{ mm}^2$ in acquired SOP ($P=0.08$), significantly less than 19 mm^2 identically in both groups contralesionally ($P < 10^{-4}$). Although mean central gaze HT was greater at $20.6 \pm 8.0 \Delta$ in 9 cases of congenital than 22 acquired cases at $11.4 \pm 6.8 \Delta$ ($P=0.002$), HT was $8.4 \pm 16.3 \Delta$ less in up than down gaze in congenital SOP, and $3.7 \pm 11.2 \Delta$ less in acquired SOP. In congenital SOP, 33% of subjects had HT greater in up than downgaze, while in 67% HT was greater in down gaze (by up to 42D). In acquired SOP, HT was greater in up than downgaze, or equal to it in 8 cases (36%, $P=0.87$, χ^2); the similar proportions contradict Ivanir & Trobe's claim. In acquired SOP, HT was greater in up than down gaze in 37%, & greater in down than up gaze in 59% of cases. HT was equal in up & central gazes in 3 acquired and no congenital SOP cases. Trends were similar in unequivocal acquired & progressive acquired (non-congenital) SOP ($P > 0.4$).

Conclusions: HT is not characteristically greater in up than down gaze in congenital SOP proven by SO atrophy on MRI. In fact, average HT is greater in down than up gaze in both acquired & congenital SOP, sometimes strikingly so in the latter. The finding of HT greater in up than downgaze, or equal to it, does not reliably indicate that SOP is congenital.

ABSTRACT BODY:

Purpose: Despite correlation between tear hyperosmolarity and dry eyes (Tomlinson et al. [2006]), no correlation has been found between tear osmolarity and soft-contact-lens (SCL) wear discomfort. This is likely because clinical instruments measure meniscus osmolarity rather than that in the post-lens tear film (PoLTF) where tear interfaces corneal nerve endings. We quantify the time-periodic differences in osmolarities between various tear-compartment during SCL wear.

Methods: Pre-lens tear-film (PrLTF), PoLTF, pre-conjunctival tear-film (PrCjTF) (i.e., the tear film on the bulbar conjunctiva), and meniscus osmolarities are determined based on water and salt conservation balances. The physical model simulates tear-film deposition, black-line formation, interblink period, and eyelid closure following Cerretani and Radke (2014). Lens ion diffusivity (D), ion partition coefficient (k), and thickness are varied to assess the effect of lens properties on various tear-compartment osmolarities. Similarly, tear production and evaporation rates are varied to ascertain the differences in tear osmolarity between normal and dry eyes. All tested parameters are obtained from commercially available SCLs and published studies.

Results: Figure 1 provides various tear-compartment periodic osmolarities during normal eye SCL wear for low and high D s. Increasing lens thickness, decreasing D , and decreasing k all reduce PoLTF osmolarity. However, the effect of k is small for commercially available SCLs. For hypertonic dry eyes, osmolarities of all compartments are elevated depending on the severity of the dry eye. Tested parameters show PoLTF and meniscus osmolarities vary between 303 to 340 mOsM and 310 to 325 mOsM, respectively. Meniscus osmolarity depends on dry-eye conditions and not on lens parameters.

Conclusions: We devised a numerical tool to determine PoLTF osmolarity during SCL wear for the first time. PoLTF osmolarity changes significantly with lens parameters but not the meniscus osmolarity. Tear osmolarity of dry eye is more sensitive to changes in lens parameters than the normal eye. Understanding correlation between SCL wear discomfort and PoLTF osmolarity requires further investigation as the corneal nerves interact with the PoLTF and not with meniscus tear.

ABSTRACT BODY:

Purpose: Glaucoma is characterized by retinal ganglion cell damage, leading to visual field defects and even blindness. Currently, the only established treatment for glaucoma is reduction in intraocular pressure, but new neuroprotective treatment methods are being developed. We have previously shown that Kyoto University Substances (KUSs), which are valosin-containing protein (VCP) modulators, suppress cell death in animal models of glaucoma, retinitis pigmentosa, retinal ischemia, and age-related macular degeneration. The purpose of this study was to elucidate the precise neuroprotective mechanisms of KUSs by focusing on gene expression in mouse with acute retinal ganglion cell damage.

Methods: We administered KUSs orally for 7 days to Thy1-CFP mice, which express cyan fluorescent protein (CFP) in the retinal ganglion cells. Acute retinal ganglion cell damage was induced by an intravitreal injection of N-methyl-D-aspartic acid (NMDA). Four hours after NMDA injection, CFP-expressing retinal ganglion cells were isolated using a fluorescence-activated cell sorter. RNA was purified from the collected retinal ganglion cells and analyzed using next-generation RNA-sequencing to evaluate gene expression profiles. We focused on two genes, endothelin-1 (Edn1) and endothelin receptor type B (Ednrb), whose expression was upregulated by NMDA injection and downregulated by KUS treatments. The mRNA expression levels of the genes in the neural retina were examined by real-time PCR, and protein levels in the neural retina were confirmed by western blotting and immunostaining.

Results: The mRNA expression of both Ednrb and Edn1 was higher in the NMDA-injected group than in the control group ($p < 0.0001$ and $p = 0.005$, respectively). In contrast, mRNA expression of Ednrb in the NMDA-injected-KUS121-treated group and the NMDA-injected-KUS187-treated group did not significantly differ from that of the control group ($p > 0.05$). Expression of EDN1 was significantly higher in the NMDA-injected group than in the control group ($p = 0.007$) as observed in western blot analysis. Immunohistochemical staining showed that EDNRB and EDN1 proteins were strongly expressed in the retinal ganglion cell layer in the NMDA-injected group than in the control group.

Conclusions: These results suggested that KUSs protect retinal ganglion cells by suppressing the upregulated Edn1 and Ednrb expression.

ABSTRACT BODY:

Purpose: The aim is to investigate epidemiological data, risk factors and treatment of childhood glaucoma in Germany. For this purpose, an initial database to register patients diagnosed with different types of childhood glaucoma was established from 2017 until 2019 as part of a prospective clinical cohort study. The intention is to create a national registry for childhood glaucoma in Germany

Methods: Twenty-eight children with different types of childhood glaucoma, who were admitted and treated at the Childhood Glaucoma Center of the University Medical Center Mainz, Germany, were included. Documents and questionnaires for the acquisition and storage of epidemiological and clinical data were developed and checked for feasibility and practicability in the clinical routine. Furthermore, each child and their parents were offered a genetic testing for known genes that cause childhood glaucoma. The test was carried out in cooperation with the Institute of Human Genetics of the University Medical Center in Mainz and was paid for by the statutory health insurance.

Results: The individual documents and questionnaires included: Informed consent form from the parents, medical history form of the child, patient's gestational history questionnaire and examination form of the examination under general anesthesia (EUAF). Primary congenital glaucoma (PCG) and secondary childhood glaucoma (SCG) were revealed in 11 (39.3%) and 17 (60.7%) patients, respectively. The most common cause of SCG was Peters anomaly (41.2%). Bilateral glaucoma was diagnosed in 81.8% (PCG) and 58.8% (SCG) of all patients. In 33.3% of the children mainly these four genes, which are associated with childhood glaucoma, were found: CYP1B1, FOXC1, LTBP2 and TEK.

Conclusions: This pilot study showed good feasibility of data acquisition of glaucoma children and their parents including individually developed documents and questionnaires to provide detailed unique baseline data for a national registry on different types of childhood glaucoma in Germany. In near future, registry data will provide valuable information to identify new risk factors for childhood glaucoma and to evaluate different treatments under real-life condition in Germany

TITLE: Effects of Topical Glycyrrhizin Application on the Normal Ocular Surface

SESSION TITLE: Antimicrobials and Immunomodulators

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.A. McClellan, M. Somayajulu, D. Bessert, A. Pitchaikannu, B. Nguyen, L.D. Hazlett, Ophthalmology, Visual and Anatomical Sciences, Wayne State University School of Medicine, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sharon McClellan: Commercial Relationship: Code N (No Commercial Relationship) | Mallika Somayajulu: Commercial Relationship: Code N (No Commercial Relationship) | Denise Bessert: Commercial Relationship: Code N (No Commercial Relationship) | Ahalya Pitchaikannu: Commercial Relationship: Code N (No Commercial Relationship) | Bao Chau Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Linda Hazlett: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To test whether topical glycyrrhizin (GLY) alters the cytoarchitecture, physiological and/or immunological parameters of the normal mouse cornea and conjunctiva.

Methods: Both normal corneas of C57BL/6 mice were treated topically with GLY (100µg/5µl) or PBS twice daily for 5 days and tested at 0, and/or 3 and 5 days. Slit lamp photography was used to assess bulbar conjunctival hyperemia and fluorescein staining was used to detect epithelial defects. Scanning electron microscopy (SEM) interrogated cell surface morphology, microvillar integrity and cell exfoliation. Phenol treated cotton threads were used to measure tear levels and a Cochet and Bonnet Esthesiometer was used before and after treatment to measure corneal sensitivity. Immunohistochemistry was used to examine corneal nerves (beta tubulin staining) and a phycoerythrin (PE) conjugated anti-langerin monoclonal antibody was used to stain and enumerate langerin positive cells. Intraocular pressure was measured with a tonometer before and after treatment. RT-PCR was used to compare mRNA levels of various TLRs and inflammatory molecules and ELISA assays were employed to compare protein levels of selected toll-like receptors (TLRs), cytokines, and neuropeptides [Substance P (SP) and Vasoactive Intestinal peptide (VIP)].

Results: GLY vs PBS controls showed no evidence of bulbar hyperemia, epithelial defects nor changes in surface cell morphology after 5 days of treatment. However, GLY vs PBS treatment transiently reduced the density of corneal nerves significantly (7%) only at 3 days, yet neither tear production nor corneal sensitivity were changed. No differences in the number of langerin positive cells nor mRNA levels of TLR2, 4, 5 and 9 were affected by GLY vs PBS. In contrast, levels of IL-1β, HMGB1, and TNF-α mRNA were significantly reduced, but protein levels of these molecules, other cytokine and neuropeptides did not differ between groups.

Conclusions: GLY transiently reduced corneal nerve density, but had no other measurable deleterious effect on the ocular surface that would preclude its therapeutic use.

ABSTRACT BODY:

Purpose: Several risk factors have been identified for central retinal artery occlusion (CRAO) in older populations. Its underlying pathophysiology is similar to that of a non-hemorrhagic ischemic cerebrovascular accident and includes a multitude of prothrombotic systemic risk factors. This observational study uses the National Inpatient Sample (NIS) Database to evaluate the systemic and ocular risk factors associated with developing CRAO in the senior population (age > 65 years) with atrial fibrillation and flutter (AFF).

Methods: We conducted a retrospective cross-sectional case-control analysis using the NIS Database, 2002-2014, to evaluate systemic risk factors for CRAO in seniors with AFF. Cases were comprised of inpatients over 65 years of age who were admitted for CRAO and had AFF. The age and gender matched control group included inpatients over 65 years of age with AFF but without CRAO. The ratio of cases to controls was 1:5. Chi square analysis and logistic regression analyses were performed with a Bonferroni correction (alpha significance of 0.0029). An odds ratio was obtained for every significant variable.

Results: We identified 740 weighted cases of AFF with CRAO and 3689 weighted controls of AFF without CRAO. The mean ages of the case and control groups were 79.2 and 79.4 years, respectively ($p=0.452$). Men comprised of 55.6% of the cases and 55% of the controls ($p=0.759$). Systemic comorbidities that significantly ($p<0.0029$) increased the risk of CRAO in these subjects included carotid stenosis ($OR=23.38$), history of stroke ($OR=2.56$), hypertension ($OR=1.80$), and hyperlipidemia ($OR=1.75$). A decreased risk was noted with bleeding diathesis ($OR=0.26$), and diabetes mellitus ($OR=0.54$); also, Hispanic ethnicity had a much lower risk of CRAO compared to Whites ($OR=0.18$).

Conclusions: The risk of CRAO in seniors with AFF increased 24 fold with carotid stenosis. Concurrent medical history of either hyperlipidemia, hypertension, or stroke doubled the risk of CRAO in this population, whereas, having a bleeding diathesis, or uncomplicated diabetes mellitus had a protective effect on developing central retinal artery occlusion.

ABSTRACT BODY:

Purpose: To develop a computational model for predicting contrast thresholds of localized spatial patterns across the visual field based on a model of the eye that includes retinal ganglion cell (RGC) responses, and to apply the model towards evaluating known structure-function relationships in glaucoma.

Methods: Our model is developed by modifying the retina-V1 (RV1) model (Bradley et al., 2014; J. Vis.), which includes a model of parvocellular (P) ganglion cell responses and predicts contrast thresholds of 43 different stimuli in the ModelFest dataset (Watson & Ahumada, 2005; J. Vis.) at the fovea. We extended the RV1 model to include magnocellular (M) ganglion cell responses because the RV1 model in its original form does not predict standard automated perimetry (SAP) thresholds well. In SAP, a stimulus is presented with an abrupt onset and offset suggesting that M cells, which are sensitive to high temporal frequency stimuli, are important for detection performance. M cell parameters in the modified retina-V1 (mRV1) model are estimated by fitting the central 30° of Hermann's hill of vision (HoV) (Hermann et al., 2008; Acta Ophthalmol.). Different types of RGC damage were simulated, including axonal loss and dendritic field (DF) loss, based on the pathophysiology of glaucoma.

Results: The mRV1 model predicts contrast thresholds for both the ModelFest dataset (RMSE = 1.18 dB) and for the central 30° of Hermann's HoV (RMSE = 0.82 dB) well. Without modifying any parameters, simulated RGC damage predicts a well-known but poorly understood structure-function relationships in glaucoma: a large initial decrease in retinal nerve fiber layer (RNFL) thickness is accompanied by only a relatively small sensitivity loss (Hood & Kardon, 2007; Prog. Retin. Eye Res.). Simulated axonal and DF loss predicts the data in Hood & Kardon (2007) better than simulated axonal loss alone (RMSE = 0.23 vs. 0.26 on a linear scale of sensitivity).

Conclusions: The mRV1 model is grounded in the known anatomy and physiology of the eye and predicts SAP thresholds well within the central 30° of visual field. Different types of RGC damage simulated with the mRV1 model may help explain known structure-function relationships in glaucoma that are currently not well understood.

ABSTRACT BODY:

Purpose: To evaluate cornea donor demographics and determine the number of discarded donated corneas and the causes associated with discard in an eye bank in Southern Brazil.

Methods: This retrospective, cross-sectional study analyzed the medical records of all cornea donations between January 2016 and December 2018 at the Londrina University Hospital Eye Bank. Variables analyzed included donor demographics, donor cause of death, enucleation time, endothelial assessment, tissue contamination, quality of the donated cornea and causes of discards.

Results: A total of 1418 donor corneas were identified from 712 donors. Mean age of the donors was 53.54 ± 13.82 years, and 38.2% of the donors were over 60 years old. The main cause of donor death was cardiovascular or neurovascular disease (60.8%), followed by external causes of death (18%). Overall, 739 corneas (52.1%) were discarded. The main causes of discard were positive hepatitis B serology (35.1%), corneal tissue expiry date (28.9%) and corneal tissue contamination (12%). *Acinetobacter baumannii* and coagulase-negative *Staphylococci* were the most frequently isolated bacteria. The discard rate was significantly higher in the over 60 year-old donor age group compared to the 60 year-old and under age group (chi-square: $p < 0.001$). In these groups, 64.4% and 44.5% of the donated corneas were discarded, respectively. Endothelial cell density (ECD) was found to be inversely correlated with the donor age ($r: -0.435$, $p < 0.001$). The ECD average of the discarded corneas was of 2118 ± 452 cells/mm², significantly lower than the average of 2492 ± 382 cells/mm² found in the corneas that were utilized for transplantation ($p < 0.001$). External causes of death had a higher ECD average when compared with cardiovascular or neurovascular diseases, respiratory system diseases and gastrointestinal diseases ($p < 0.001$).

Conclusions: A high corneal discard rate was observed in the present study, with positive serology, tissue expiry date and contamination being the main causes of discard. Discards were significantly more prevalent in older age groups (>60 years), and discarded corneas had lower endothelial cell density. The identification of significant trends in donor demographics could help with a more efficient assessment process of potential cornea donors in eye banks.

ABSTRACT BODY:

Purpose: Vertebrate color vision requires the differential expression of specific cone opsins in separate cone populations. One model for the regulation of the human long and medium wavelength sensitive (LWS/MWS) opsin tandem array suggests an upstream regulatory region interacts with replicated opsin genes at random, resulting in mutually exclusive expression of a specific opsin. However, our prior investigations into the orthologous long wavelength sensitive (*lws1/lws2*) array in zebrafish suggest that thyroid hormone (TH) and retinoic acid serve as trans regulators of this gene array in larvae/juveniles (Mitchell et al., 2015, PLOS Genetics; Mackin et al., 2019, PNAS). This study investigates whether cone opsin expression remains plastic to TH treatment in adult zebrafish, where cone distribution is considered stable.

Methods: Adult zebrafish (both sexes) were treated with NaOH (0.01%, control) or TH (386 nM) for 1 or 5 days (n=3). Left eyes were harvested for qPCR analysis and right eyes for cryosectioning. A set of *lws* reporter transgenic adults (*lws*:PAC(H); *lws1* reported by GFP and *lws2* reported by RFP) were also treated for 5 days with NaOH or TH (n=3). Whole retinas and cryosections were analyzed by confocal imaging.

Results: In adult zebrafish, exogenous TH drastically increased *lws1* expression in both 1 and 5 day-treated groups (p=0.003, 0.0006, respectively) while decreasing *lws2* expression (p=0.002, 0.005). Other phototransduction-related transcripts that were shown to decrease in embryos and juveniles exposed to TH showed a similar response in adults: *gnat2b* (p=0.09, 0.003), *rh2-1* (p=0.05, 5 day treatment). TH treated transgenic *lws* reporter line revealed a clear switch from *lws2* to *lws1* in dorsal retina, consistent with the qPCR data. Whole retinas of transgenic reporters demonstrate an expansion of *lws1*-expressing cones nasally and dorsally as well.

Conclusions: Exogenous TH induced a drastic shift from *lws2* to *lws1* in adult zebrafish, consistent with previous studies of larvae and juveniles. This shift occurs as rapidly as 1 day when exposed to TH, which shows that cones remain highly plastic even into adulthood. Plasticity in spectral sensitivity (to be sensitive to higher wavelengths) in response to TH suggests a role in visual system function well into adulthood.

ABSTRACT BODY:

Purpose: To evaluate the surgical outcomes of XEN gel implant at 12-month follow-up, including post-operative intraocular pressure (IOP), glaucoma medications, rate of needling and secondary surgery intervention for 3 intraoperative MMC concentrations ranges

Methods: Retrospective study of consecutive XEN gel implantation with MMC for treatment of glaucoma. Total MMC amount were divided into 3 ranges: $\leq 20\text{mcg}$ (n = 55), (20-40mcg] (not including 20mcg, n = 177) and $>40\text{mcg}$ (n = 15). The change in intra-ocular pressure and number of glaucoma medications at 12 months were compared among the three MMC groups. The rate of needling and additional surgical interventions were also compared.

Results: The three MMC groups had similar distribution of sex, glaucoma severity, visual acuity, pre-operative IOP, and number of glaucoma medications. There was a difference in the average patient age ($P < 0.01$). XEN implantation was combined with phacoemulsification in 13.5% of patients in the $\leq 20\text{mcg}$ group, 22.7% in the 20-40mcg group, and 33.1% in the $>40\text{mcg}$ group ($P < 0.05$). There were no significant differences in rates of prior tube or trabeculectomy surgeries among the three groups. 50.6% of patients had follow-up at month 12.

At 1 year, the average IOP significantly decreased by $10.8 \pm 8.5\text{mmHg}$ (-38.4%, n=29) for the $\leq 20\text{mcg}$ group, by $7.5 \pm 8.8\text{mmHg}$ (-26.3%, n=92) for the 20-40mcg group, and by $12.8 \pm 11.3\text{mmHg}$ (-55.5%, n=4) in the $>40\text{mcg}$ group. The IOP change was not statistically different among the 3 groups ($P = 0.72$). The average number of medications also decreased in all 3 groups, by -1.4 (-53.2%), -1.6 (-56.5%) and -1.8 (-46.7%), respectively. The rate of needling was 39.5% in the $\leq 20\text{mcg}$ group, 33.1% for the 20-40mcg group, and 22.2% in the $>40\text{mcg}$ group ($P = 0.44$). The rates of secondary surgeries were similar among the three groups, 10.26%, 15.34%, and 16.67%, respectively ($P = 0.69$). Common adverse events included transient hypotony (n=74), choroidal effusion (n=13), bleb leaks (n =10) and hyphema (n =8).

Conclusions: The total amount of MMC used intra-operatively during XEN gel implantation were grouped into 3 ranges: $\leq 20\text{mcg}$, (20-40mcg] and $>40\text{mcg}$. At 1 year, there were no significant difference in post-op IOP change, glaucoma medication, needling rate, and rate of secondary surgeries when comparing among the three MMC groups.

TITLE: Crowding effect in children with and without amblyopia

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Kalnica-Dorosenko, Eye Diseases Clinic, Bernu kliniska universitates slimnica, Riga, Riga, LATVIA|K. Kalnica-Dorosenko, A. Svede, Department of Optometry and Vision Science, Latvijas Universitate Fizikas matematikas un optometrijas fakultate, Riga, LATVIA|

Commercial Relationships Disclosure (Abstract): Kristine Kalnica-Dorosenko: Commercial Relationship: Code N (No Commercial Relationship) | Aiga Svede: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Amblyopia - reduction of visual acuity in one or both eyes, caused by abnormal binocular interaction during the critical period of visual development. One of the most used classifications of amblyopia is related to visual acuity. Amblyopia is most often associated with early onset strabismus, anisometropia or combined (strabismic anisometropic amblyopia). The aim of this study was to evaluate the effect of crowding and age on visual acuity in a sample of young children with and without amblyopia.

Methods: A total of 200 participants (3-9 years old) whose visual acuity was tested monocularly, using the entire open optotype line, isolating one optotype line and separating each optotype separately, participated. The results were analysed in four groups: children with and without amblyopia (younger (3 to 6 years) and older (7 to 9 years)).

Results: In the younger (3 to 6 years) group of children with strabismic and anisometropic amblyopia, the crowding effect was observed ($p < 0.05$) by checking visual acuity (with amblyopic and health eye) isolating the optotype line and showing the optotypes separately, but in the older (7 to 9 years) group the crowding effect was not observed ($p > 0.05$). In the younger (3 to 6 years) and older (7 to 9 years) groups of children without amblyopia, the crowding effect was not observed ($p > 0.05$) by checking visual acuity isolating the optotype line but was observed ($p < 0.05$) by showing the optotypes separately.

Conclusions: Young amblyopic patients up to 7 years old have better visual acuity readings from a single optotype or isolating one optotype line than from entire open optotypes in a row. By demonstrating the optotypes separately, there is a greater risk of overestimating the visual acuity of the amblyopic patient, thereby failing to diagnose amblyopia, and starting therapy in time. This is important because the earlier amblyopia is diagnosed – the better the chance of improving visual acuity.

ABSTRACT BODY:

Purpose: Mesenchymal stem cells (MSCs) are promising therapy to improve vascular repair, yet their role in ischemic retinopathy is not fully understood. The aim of this study is to investigate the impact of modulating the neurotrophin receptor p75^{NTR} on vascular protection of MSCs in an acute model of retinal ischemia-reperfusion (IR).

Methods: WT and p75KO mice were subjected to IR injury by increasing intraocular pressure to 120mmHg for 45 minutes followed by perfusion. Murine GFP-labeled MSCs (100,000cells/eye) were injected intravitreally 2days post-surgery and vascular homing was assessed 1-week later. Acellular capillaries were counted using trypsin digest 10-days post-IR. In vitro, MSC-p75^{NTR} was modulated either genetically using siRNA or pharmacologically using LM11A-31, and conditioned media were co-cultured with human retinal endothelial (HREs) to examine the angiogenic response.

Results: IR significantly increased the number of acellular capillaries (3.2-fold) in WT mice, but not in p75KO compared to sham-controls. GFP-MSCs were successfully engrafted into retinal vasculature and decreased the number of acellular capillaries in all groups, yet IR maintained a 2-fold increase in WT but not in p75KO mice. Silencing p75^{NTR} on GFP-MSC coincided with a higher homing of GFP-MSC to retinal vasculature in WT-IR and normalized number of acellular capillaries to control level when compared to scrambled-GFP-MSC in WT-IR. Silencing p75^{NTR}-MSCs enhanced their secretome including SDF-1, VEGF, and NGF as well as paracrine angiogenic response, where HREs showed enhanced migration (1.4-fold) and tube formation (2-fold) compared to controls. In parallel, modulating MSC-p75^{NTR} using LM11A-31 exerted similar effects on improving the secretome and its paracrine angiogenic effects on HREs. Further, intervention with LM11A-31 significantly improved the decline in visual acuity post-IR-injury.

Conclusions: Silencing p75^{NTR} from MSCs surface potentiates their vascular protective effect in vivo and in vitro. The underlying mechanism can involve, at least in part, increases in SDF-1α NGF and VEGF. LM11A-31, an orally bioavailable p75^{NTR} modulator that exerted vascular and neuro-behavioral protective effects. Thus, a combination of MSCs injection and p75^{NTR} inhibitor can serve as a potential therapeutic strategy to harness greater vascular repair in ischemic retinopathy diseases.

ABSTRACT BODY:

Purpose: To validate a novel deep learning algorithm (DLA) to segment and measure the size of geographic atrophy (GA) in eyes with non-exudative age-related macular degeneration (neAMD) based on the presence of choroidal hyper-transmission defects (HTDs) applicable to both spectral domain (SD-OCT) and swept source (SS-OCT) en face images.

Methods: The DLA for GA segmentation is a deep convolutional neural network modified from U-net where average pooling, rather than max pooling, is used in the encoder stage to tolerate noise and a two-step non-linear transformation employing convolution and residual connections are applied in the skip connections to propagate the encoder features to the corresponding decoder features. Subjects with normal eyes without any evidence of retinal disorders and patients diagnosed with GA secondary to neAMD were enrolled in a prospective OCT study and underwent both SD-OCT and SS-OCT imaging using 6x6 mm scan patterns. The DLA was trained with the OCT images with and without GA accurately annotated by professional graders. For validation, manual gradings were compared to automatic algorithm segmentations to assess the algorithm's classification and segmentation performance.

Results: A total of 160 OCT en face images, including 48/32 SS-OCT images with/without GA, 48/32 SD-OCT images with/without GA, were used to train the DLA algorithm. Another independent series of 80 SD-OCT and SS-OCT en face images made of two balanced sets of 40 eyes (20 with GA, 20 without GA) were used for validation. The DLA achieved a 100% sensitivity and 100% specificity for SD-OCT and a 100% sensitivity and 95% specificity for SS-OCT, respectively. The average Jaccard Index was 0.83 for SD-OCT and 0.80 for SS-OCT. A strong positive correlation was established for the manual and automatic measurements of the GA square root areas for SD-OCT ($R = 0.996$, $P < 0.001$) and SS-OCT ($R = 0.985$, $P < 0.001$). The Bland Altman plots had a bias of -0.01 mm for SD-OCT and 0.05 mm for SS-OCT with no obvious trends.

Conclusions: The DLA had an excellent sensitivity and specificity for identifying and measuring GA in both SD-OCT and SS-OCT images. This algorithm should be useful clinically in providing quantitative measurements of GA and tracking the appearance and enlargement of GA in patients diagnosed with neAMD.

TITLE: Feasibility of fast measurement of macular pigment optical density using a slit-scanning ophthalmoscope

SESSION TITLE: Imaging of posterior segment I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Leahy, A. Covita, Carl Zeiss Meditec Inc, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Conor Leahy: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Angelina Covita: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Objective, non-invasive measurement of the optical density (OD) of human macular pigment (MP) can be performed in vivo using fundus autofluorescence (FAF) imaging. Depending on the protocol used, the exam duration may be lengthened by the need for pupil dilation, repeat image acquisitions, and/or separate calibration for crystalline lens fluorescence. In this study, we investigate the feasibility of quantifying macular pigment optical density (MPOD) using a slit-scanning ophthalmoscope with a single-flash measurement protocol.

Methods: A slit-scanning ophthalmoscope (CLARUSTM 500, ZEISS, Dublin, CA) with prototype software was used to perform non-mydratic measurements of MPOD, derived from pairs of FAF images obtained with blue ($\lambda_{\text{peak}} = 459\text{nm}$, well-absorbed by MP) and green ($\lambda_{\text{peak}} = 520\text{nm}$, much less absorbed) excitation sources. The illumination rapidly alternates between the sources during a single scan, completing in under 0.2 seconds. The image sensor records separately the partial images of stripes of illuminated retina. Retinal autofluorescence appears only within the illuminated stripe, but unwanted crystalline lens fluorescence appears nearly uniformly across the partial image (allowing it to be removed). A fluorescent phantom, incorporating a yellow-colored filter of known OD, was used to test the implementation. MPOD measurements were performed on 5 human subjects.

Results: The manufacturer specified OD for the test phantom is shown in Figure 1A. From the FAF images (Figure 1B-C), the 2-D spatial MPOD profile for the test phantom is derived (Figure 1D). The mean MPOD was within 2.5% of the specified value. For human subjects, we present FAF images and the derived MPOD profiles (an example is shown in Figure 2) for the central 5° around the fovea.

Conclusions: A slit-scanning ophthalmoscope can perform objective FAF measurements of MPOD in a single perceived flash, through non-dilated pupils. This gives encouragement that such a method can be practical for screening, for example for risk of age-related macular degeneration. Validation of such an approach for in vivo use will require careful consideration of confounding effects, such as secondary fluorophores and photobleaching.

ABSTRACT BODY:

Purpose: Controversy currently exists over the underlying pathology in acute posterior multifocal placoid pigment epitheliopathy (APMPPE) and the related condition, relentless placoid chorioretinitis (RPC). We performed a retrospective case series imaging evaluation to reassess the clinical signs and current etiological hypotheses for these conditions.

Methods: Cases were identified from three tertiary uveitis centers in the UK between 2016 and 2020. We defined APMPPE using the following criteria: 1) The appearance of >1 creamy chorioretinal lesion; and 2) Evidence of choriocapillaris hypoperfusion, and; 3) An OCT appearance in keeping with the two described phenotypes. We defined RPC as fulfilling criteria 1-3 but with a clinical course exceeding 60 days and greater than 50 lesions. Qualitative comparative analysis of available multimodal imaging modalities was conducted. Serial imaging afforded the opportunity to analyse preclinical changes in eyes with sequential involvement.

Results: A total 14 patients (9 with bilateral disease) met the diagnostic criteria. 10 patients (17 eyes) had features consistent with APMPPE. 4 patients (6 eyes) had features consistent with RPC. 7/14 patients were female. Median age at presentation was 26.5 years (range, 20-57 years). Changes within the retinal nerve fiber layer precede the occurrence of clinical lesions and associated choriocapillaris hypoperfusion. Optic disc edema occurs proportionally to the extent of retinal lesions, and mirrors the sectoral distribution, suggesting an associated disruption of axoplasmic flow. Areas of choriocapillaris hypoperfusion correspond to zones of separation of the overlying retinal pigment epithelium (RPE) from Bruch's membrane (BM). Transient, hyperreflective foci occur within the outer nuclear layer above the area of RPE/BM separation during acute lesions, and follow the neurons which constitute the Henle's fiber layer orientation. Pathological disruption of retinal layers (following the initial RPE/BM separation) occurs in a descending sequence with ONL/ellipsoid zone disruption preceding the loss of RPE structure.

Conclusions: Our evidence suggests a primary neuronal pathogenesis with a descending progression through the retina, as opposed to a primary disorder of the choriocapillaris.

ABSTRACT BODY:

Purpose: To determine the current clinical characteristics and the trends in treatment for submacular hemorrhage (SMH) in Japan.

Methods: The inclusion criteria were subfoveally involved SMH more than 2 optic discs in area, followed for at least 2 months. One hundred eighty-four (184) eyes of 184 patients (104 men and 80 women) were enrolled from 10 hospitals. The characteristics of SMH were classified by the FLATCAPS classification. Causes, selected treatments, and pre- and post-treatment best-corrected visual acuity (BCVA) were analyzed.

Results: The patients' mean age was 76.1 ± 9.2 . SMH was caused by retinal arterial macroaneurysm (RAM) in 52 eyes (28%), and by age-related macular degeneration (AMD) in 127 eyes (69%): typical age-related macular degeneration in 26%, polypoidal choroidal vasculopathy (PCV) in 73%, and retinal angiomatous proliferation (RAP) in 1%. SMH was observed in more than two retinal layers in 60% of the RAM group and in the subretinal and sub-RPE spaces in 106 eyes (83%) of the AMD group. The mean period between onset and treatment was 10.9 days in all cases, and more cases underwent vitrectomy in the RAM group than in the AMD group ($P < 0.0001$). Subretinal tissue plasminogen activator injection was selected for 49% of the vitrectomy cases. Mean BCVA in the AMD group was significantly better than in the RAM group at baseline, 1 month after treatment, and the final visit ($P > 0.0001$, $P > 0.0026$, $P > 0.0163$).

Conclusions: PCV was about twice as frequent as RAM as the cause of SMH. The RAM group included more cases with vitrectomy than the AMD group and showed poor BCVA.

TITLE: Factors Affecting the Time to Publication in Ophthalmology Journals: A Comprehensive Bibliometric Analysis

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.S. Dhoot, M.M. Popovic, Y. Lee, S. Lee, J.A. Micieli, University of Toronto, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Arjan Dhoot: Commercial Relationship: Code N (No Commercial Relationship) | Marko Popovic: Commercial Relationship(s);Physicians' Services Incorporated Foundation :Code F (Financial Support) | Yerin Lee: Commercial Relationship: Code N (No Commercial Relationship) | Siwoo Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Micieli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Bibliometrics is an understudied topic in ophthalmology. The purpose of this study is to provide comprehensive data on the duration from submission to various stages of the publication process and assess factors influencing time to publication.

Methods: A list of ophthalmology journals was obtained from the 2019 Web of Science Journal Citation Report. For each journal, characteristics such as journal acceptance rate and impact factor were collected. All articles published in 2019 from included journals were extracted and an independent review was conducted to determine dates of article submission, acceptance, electronic and print publication.

Results: In total, 56 journals and 8835 research articles were included. Of these articles, 3591 (40.6%) were open access and 4837 (54.7%) were multi-institutional. In 2019, most publications came from the United States of America (n=1973). For articles that reported relevant data, the median number of days from submission to acceptance was 128 (range across journals: 71-222), acceptance to electronic publication was 30 (range: 2-199) and acceptance to print publication was 146 (range: 27-448). Significant associations were found between the following predictors and a reduced mean number of days from submission to electronic publication: increased journal five-year impact factor (p=0.026), increased immediacy index (p=0.008), increased article influence score (p=0.032), more authors (p=0.028), publishing in a hybrid journal (i.e. both open-access and subscription articles) versus an open-access journal (p=0.021), and a reduced proportion of multi-institutional articles in a journal (p=0.030).

Conclusions: There is a wide variation in the time to acceptance and publication in ophthalmology journals. Authors can expect a shorter time to publication when publishing in high-impact journals. Reducing the time from acceptance to electronic publication for journals is a reasonable first step to improve article exposure and citation volume.

ABSTRACT BODY:

Purpose: Selective laser trabeculoplasty (SLT) may represent a cost-effective treatment for glaucoma care in low-resource regions. To explore this we performed a retrospective chart review to learn about short-term intraocular pressure (IOP) results in the first group of patients in Western Tanzania to receive SLT for chronic primary open angle glaucoma (POAG) or isolated ocular hypertension (OHT) unresponsive to pressure lowering drops.

Methods: Patients at Bugando Medical Center (BMC) in Mwanza, Tanzania who underwent SLT with a Lumenis Selecta II laser over a one-week period and presenting six-weeks later for follow-up were included. Data collected included age, gender, IOP before SLT, central corneal thickness (CCT), energy and number of applications, and IOP within two hours of SLT and six-weeks later. Visual acuity (VA) was obtained before SLT and at the six-week follow-up. IOP was measured using an Icare tonometer (Icare, USA).

Results: A total of 14 eyes of 12 patients (mean age 60.2 years, 83% male) were treated. Mean IOP prior to SLT was 22.1 ± 9.4 mmHg. CCT was <555 μ m in all patients where CCT was measured. All eyes received laser over 360° of the trabecular meshwork at energy levels ranging from 0.7-1.2 mJ per pulse except for one eye treated 180° due to limited patient tolerance. No pressure spikes were observed immediately after treatment. Nine patients (eleven eyes) returned for the six-week follow-up. The mean IOP drop six-weeks post-SLT was 8.5 ± 7.0 mmHg. Five patients (six eyes) had a greater than 30% decrease and three patients (four eyes) had an 11-30% decrease in IOP compared to baseline. The IOP in the fellow eye of five patients six-weeks post-SLT was lower compared to pre-SLT, with a mean IOP drop of 8.0 ± 4.8 mmHg. No patients experienced a decrease in VA at the six-week follow-up.

Conclusions: Selective laser trabeculoplasty of twelve patients with POAG or OHT at BMC resulted in a notable pressure lowering effect in eight of nine patients evaluated at the six-week follow-up. No adverse effects were noted. Results showing one patient who did not have a pressure lowering effect may be attributed to challenges achieving a full treatment of 360°. Our data suggests additional studies of the long-term efficacy of SLT for POAG and OHT in Western Tanzania is warranted in light of the high cost of IOP lowering medication and limited access to specialist care in the region.

ABSTRACT BODY:

Purpose: To identify and understand patterns of progressive thinning in the macular ganglion cell layer (GCL) using spectral domain OCT thickness change maps of the GCL and retinal nerve fiber layer (RNFL).

Methods: 114 glaucoma, glaucoma suspect, and healthy (HC) eyes from 114 individuals had OCT scans and 24-2 and 10-2 visual fields (VFs) as part of a longitudinal, prospective study. Based upon an evaluation of all available OCT and 24-2 and 10-2 VF information, 12 eyes were classified as definite Progressors (P), and 67 as definite non-progressors (NP). OCT thickness change maps of the RNFL and GCL were generated from manually corrected OCT volume scans (30°x25°), by comparing the most recent follow-up to the baseline test (avg. 3.1 yrs apart).

Results: In 6 of the 12 P eyes arcuate shaped regions of progression (Fig. 1A) were visible on GCL, as well as RNFL, thickness change maps. In the other 6 eyes, diffuse regions of progression (Fig. 1B) were visible on GCL, while the RNFL, thickness change maps showed a combination of diffuse and arcuate regions of progression. Healthy controls showed little or no consistent arcuate or diffuse patterns on the RNFL or GCL change maps. (See comparison of maps for HC and P with diffuse changes in Fig. 2.)

Conclusions: Macular progression involves both deep local and shallow widespread thinning in the GCL. Change maps of the RNFL and the GCL can aid in the identification of glaucomatous progression.

ABSTRACT BODY:

Purpose: The effect of the postpartum on diabetic retinopathy (DR) remains unknown. Understanding this can inform whether sight-threatening DR (STDR) is best treated during pregnancy or can be deferred till after delivery. This study explores the prevalence, typical DR course and risk factors for DR progression in the postpartum.

Methods: Subgroup analysis of a prospective longitudinal cohort study of pregnant women with type 1 (T1DM) or type 2 diabetes (T2DM) attending two tertiary maternity hospitals in Melbourne, Australia (Nov 2017 – Sept 2020) who had at minimum one eye examination in pregnancy and one up to 12 months postpartum. DR severity was determined either through grading of 2-field retinal photographs or clinical assessment when fundus photographs were unavailable. Progression was defined as worsening by ≥ 1 step on the Airlie House classification, development of diabetic macula edema (DME) or the need for laser treatment.

Results: This analysis included 87 pregnancies from 86 women; 48 had T1DM and 38 had T2DM (median duration 18.0 and 4.0 years respectively). Mean age was 33.4 years (range 21-47). DR prevalence at ≥ 27 weeks postpartum was 26.3 (CI 16.6, 39.0) per 100 eyes. Between late pregnancy and 12 months postpartum, progression occurred in 20/160 (13%) eyes while 10/160 (6%) regressed. Progression was more common in the latter 6 months postpartum and associated with existing DR at enrolment, T1DM (RR 5.03, CI 1.52-16.70) and duration of diabetes >10 years (RR 3.52, 1.38-8.21). Of the 13 eyes that progressed during pregnancy, 5 (38%) regressed in the postpartum. Regression was seen in 4/5 (80%) eyes that developed new DR in pregnancy, 1/5 (20%) eyes with pre-existing non-proliferative DR and 0/5 (0%) eyes with proliferative DR (PDR). Eyes with DME had good vision (20/40 or better) at the majority of their exams (92%, 49/53), with 53% (9/17) resolving in the postpartum.

Conclusions: The postpartum prevalence of DR was comparable to the non-pregnant diabetic population.

Progression in the postpartum was twice as common as regression, highlighting the need for adequate postpartum

eye screening. In eyes that progressed during pregnancy, most did not regress in the postpartum, especially eyes with PDR. Treatment for PDR thus cannot be delayed in anticipation of resolution post-delivery. However, DME treatment can be safely delayed in most cases.

ABSTRACT BODY:

Purpose: SB11 is a proposed biosimilar to reference ranibizumab, which is currently being reviewed for the marketing authorization, developed for the treatment of ocular diseases. The objective of this study was to assess the structural and functional similarity between SB11 and reference products obtained from United States (US-ranibizumab) and European Union (EU-ranibizumab).

Methods: A comprehensive structural and functional characterization was performed utilizing state-of-the-art analytical methods. Comparisons included the following: primary structure related to amino acid sequence and post-translational modifications; higher order structure; product-related substances and impurities including size and charge variants; and protein concentration. In addition, biological characterization included a series of bioassay such as vascular endothelial growth factor (VEGF)-A binding assay, cell-based VEGF-A neutralization assay, and human umbilical vein endothelial cells (HUVEC) anti-proliferation assay.

Results: The amino acid sequence of SB11 was identical to that of US- and EU-ranibizumab. SB11 was shown to be indistinguishable from the reference products with respect to post-translational modification profiles and higher order structures. Product-related size and charge variants and aggregates were also similar. Functionally, SB11 could not be distinguished from US- and EU-ranibizumab by using a set of bioassays and binding assays covering a broad range of VEGF-related functional activities. The relative binding activity or potencies were calculated relative to the reference standard prepared from one lot of reference product. The binding activity of SB11 representative batches analyzed using VEGF-A binding assay were evaluated as 98% (RSD=2%). The potencies of SB11 representative batches analyzed using HUVEC anti-proliferation and VEGF-A neutralization assay were evaluated as 101% (RSD=5%) and 99% (RSD=4%), respectively.

Conclusions: Based on the comprehensive analytical similarity assessment, SB11 is highly similar to the US- and EU-ranibizumab with respect to structural, physicochemical, and biological properties.

TITLE: Treatment of cystoid macular edema secondary to infectious uveitis with anti-vascular endothelial growth factor agents

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Ogden, University of Louisville School of Medicine, Louisville, Kentucky, UNITED STATES|H. Sandhu, Ophthalmology/Visual Sciences, University of Louisville School of Medicine, Louisville, Kentucky, UNITED STATES|T. Ogden, San Antonio Uniformed Services Health Education Consortium, Fort Sam Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tyler Ogden: Commercial Relationship: Code N (No Commercial Relationship) | Harpal Sandhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intravitreal anti-vascular endothelial growth factor (VEGF) agents have not been well studied in treatment of cystoid macular edema (CME) secondary to infectious uveitis (IU) and may prove to be an effective alternative to steroids without the risk of reactivation of latent infection. The purpose of this retrospective case series was to evaluate anti-VEGF agents as a treatment of CME secondary to IU.

Methods: This retrospective case series included patients treated for CME secondary to inactive IU. Mean change was calculated for central macular thickness (CMT), intraocular pressure (IOP), and best corrected visual acuity (BCVA) between initiation of treatment and final follow up appointments. BCVA was converted into logMAR values for analysis. A paired t test was used to evaluate for statistically significant difference.

Results: 5 eyes of 3 patients were included with underlying diagnoses of syphilitic uveitis in 2 patients (4 eyes) and herpes simplex uveitis in 1 patient (1 eye). The mean treatment course was 11 months with an average of 6 treatments per eye. Mean change in CMT after treatment was -120 μm ($p=0.28$). There was no statistically significant difference in BCVA before and after treatment ($p=0.40$). Mean IOP was 17.4 prior to treatment and 17.2 after treatment ($p=0.86$). Recurrence of uveitis was not observed in any eye during treatment.

Conclusions: Anti-VEGF agents are safe in eyes with inactive IU. Although statistically insignificant in this small series, there was a trend towards improved anatomical outcomes with this treatment.

ABSTRACT BODY:

Purpose: Acquiring good quality images is crucial for disease screening and diagnosis using fundus cameras. A quality indicator after image capture allows recapture of the low-quality ones while the patient is still available. However, running a deep learning image quality algorithm on low-cost fundus cameras can be slow. TensorFlow Lite (TFL) is a deep learning framework designed for inference on the device, also known as edge computing. In this study, we investigated methods to optimize the inference performance using TFL.

Methods: A VGG-16 neural network was trained using fundus images captured with VELARATM 200 (ZEISS, Dublin, CA), a fully automated non-mydriatic fundus camera with a 45 degree field of view centered around the macula. 4574 images, including 3158 good and 1416 bad quality ones were used for training; 597 images, consisting of 353 good and 244 bad quality ones, were used for testing. The grading of the images was performed by a majority vote among 3 subject matter experts. First, the floating-point (FP) TensorFlow model was converted and saved as a tflite file. Then, post-training dynamic range quantization was applied using TFL. The weight of the trained model was quantized into 8-bit integer. To test the accuracy, both the FP and quantized TFL models were evaluated using the same test set. To test the speed, an Android app was built and installed on the fundus camera tablet that comes with a Qualcomm Snapdragon 439 APU.

Results: The sensitivity, specificity and AUC score of the TensorFlow model were 85.7%, 99.2% and 0.976. For FP and quantized TFL models, they were 85.7%, 99.2%, 0.976 and 85.2%, 99.4%, 0.977. 95% confidence intervals and detailed comparison can be found in Figure 1. The sensitivity ($p=0.5$) and specificity ($p=0.5$) are not statistically different after TFL optimization. For inference speed, the FP and quantized TFL models ran at 4808ms and 3008ms per image using the tablet CPU with 1 thread. The inference time reduced to 1847ms and 783ms when using 8 threads. Inference time changed to 1263ms and 1261ms when running on the tablet GPU. For model size, the FP model is 67.3MB and the quantized one is 17.8MB.

Conclusions: In this study, we demonstrated a method to optimize the inference performance of a fundus image quality neural network model for edge computing using TFL.

ABSTRACT BODY:

Purpose: The North American Native (NAN) population has been shown to face significant health disparities in the United States (US) across a spectrum of diseases. However, population-level studies are limited. We performed a retrospective, database analysis of Medicare Fee-for-Service (MFFS) claims to identify disparities in eye health and eye care services between NANs and White Non-Hispanics (WNH) in the US and in the state of Michigan (MI).

Methods: A retrospective analysis from the 2017 100% sample of MFFS claims in the Vision and Eye Health Surveillance System was completed. Mean claims rates in all age groups in all primary diagnoses and selected service categories were extracted. Claims were extracted for categories comprised of individual eye conditions and associated selected eye-care-related services. Logistic regression models were used to obtain age-adjusted claim rates of the cohorts' condition and selected service, and to test for directional patterns between NAN and WNH age-adjusted claims rates for conditions and services to make inferences about possible disparities.

Results: Medicare claims were identified for 177,100 NANs and 24,438,000 WNHs in the US and for 4,500 NANs and 865,400 WNHs in Michigan. Seventeen major categories of eye conditions were paired with their related eye care services (Figure 1). Five eye conditions in the US had significantly higher claims rates for NANs than WNHs, representing potentially higher prevalence in NANs than WNHs. Two of these five conditions, refractive error and diabetic eye diseases, also had significantly higher claim rates among MI NANs. Conversely, these two conditions had lower or on par related services rendered (Figure 2), representing a significant disparity between condition and service claims for NANs versus WNHs for two of the most common eye conditions leading to low vision and blindness.

Conclusions: Refractive error and diabetic eye diseases represent the greatest unmet eye health/care needs for US and MI NANs with MFFS coverage. Because of high Medicare coverage rates among NANs, MFFS claims are useful in examining and understanding disparities in eye health and services in the NAN population in the US.

ABSTRACT BODY:

Purpose: Purpose/Aim: In the United States, high rates of vision impairment and eye disease disproportionately impact those who lack access to eye care, specifically vulnerable populations. The objective of our study was to test instruments, implement protocols, and collect preliminary data for a larger 5-year study, which aims to improve detection of eye diseases and follow-up eye care in vulnerable populations using community health workers and patient navigators.

Methods: Methods: Eligible individuals age 40-and-older were recruited from the Riverstone Senior Center in upper Manhattan, New York City. Participants underwent on-site vision screening (visual acuity, intraocular pressure measurements, and fundus photography). Individuals who failed the vision screening (i.e., visual acuity worse than 20/40 in either eye with correction, 2) IOP 23-29 mmHg, or 3) unreadable fundus images, were scheduled with an on-site optometrist for a non-dilated eye exam, either the same day or within two weeks of initial screening; those with ocular pathologies were referred to an ophthalmologist. All images were read and graded by two study ophthalmologists. Participants were also administered the National Eye Institute Visual Function Questionnaire-9 (NEI-VFQ-9) by community health workers.

Results: Results: Participants (n=42) were predominantly older adults, with a mean age of 70.0 ± 9.8 , female (61.9%), and Hispanic (78.6%). Most individuals (78.6%, n=33) failed vision screening. Of those who failed, 84.8% (n=28) attended the on-site eye exam with the optometrist. Ocular diagnoses: refractive error 13/28 (46.4%), glaucoma/glaucoma suspect 9/28 (32.1%), cataract 7/28 (25.0%), retina abnormalities 6/28 (21.4%); 13 people required eyeglasses. Of the 35 participants who had fundus images taken, 40% (n=14) had a normal image with no significant findings, 37.1% (n=13) had an abnormal image with significant ocular findings, and 22.9% (n=8) had unreadable images. There was 100% agreement between the glaucoma and retinal specialists regarding referral for follow-up eye exam based on the fundus images.

Conclusions: Conclusion: Community-based vision screening using community health workers and optometrist-based eye exams in vulnerable populations may minimize barriers to eye care, improve early detection of eye disease, and patient navigators can link subjects to additional eye care appointments.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of blindness in elderly patients. Genetic mutations in complement and extracellular matrix pathways are associated with AMD risk. Slow dark adaptation (DA) is a key functional defect observed in AMD patients. AMD mouse models do not develop structural hallmarks of clinical disease (e.g., drusen). We investigated whether aged wild type mice (WT) or mice with genetic mutations in complement (Cfh) or extracellular matrix (Efemp1) have slow DA.

Methods: Cfh^{+/-} and Efemp1^{R345W/R345W} mice were generated to induce overactive complement or extracellular matrix defects, respectively. Genetic mouse lines listed above were evaluated and compared to WT littermate controls at 2-18 months of age. C57BL/6J mice were assessed between 2-24 months of age to characterize the natural history of age-related dark adaptation decline. Rod-mediated DA was assessed by electroretinography (ERG) using a two day testing protocol: (i) baseline ERG response in fully dark adapted mice using a 2.7 log scot cd s m⁻² probe flash, (ii) DA ERG response using the same probe flash 4 hours after a photobleach (10 minutes @ ~10,000 lux white light). The DA ERG was compared to the baseline ERG to calculate % recovery after photobleach. Statistics: one-way ANOVA with Dunnett's posttest (3 or more groups) or unpaired t test (2 groups). All error bars are standard error of the mean.

Results: DA recoveries from 24 month old C57BL/6J mice range from normal to severely delayed (mean=68%±8.6, n=14) with 8/14 falling below the 95% confidence interval for 2-4 month old mice (mean=82%±4.6, n=29). Compared to WT littermate controls, Cfh^{+/-} and Efemp1^{R345W/R345W} mice do not have significant DA deficits at 18 and 16 months of age, respectively.

Conclusions: Age-related DA deficits in C57BL/6J mice are highly variable, with a change of -14% at 24 months of age. Aged mice (16-18 months old) with AMD-associated genetic mutations in complement (Cfh^{+/-}) or extracellular matrix (Efemp1^{R345W/R345W}) do not exhibit DA deficits compared to WT littermate controls.

TITLE: IMPACT OF SUBSTRATE FLEXURAL MODULUS AND VERTICAL STABILIZATION ON PHOTORECEPTOR OUTER SEGMENT PHAGOCYTOSIS OF HUMAN IPS-DERIVED RETINAL PIGMENT EPITHELIAL CELLS

SESSION TITLE: Stem cells / gene therapy/ transplantation/ laser/ local therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.H. Tezel, Q. Zeng, Ophthalmology, Columbia University, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tongalp Tezel: Commercial Relationship: Code N (No Commercial Relationship) | Qun Zeng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the impact of flexural modulus and vertical stabilization of the scaffolds on the ability of the human iPS-derived retinal pigment epithelial cells (hiPS-RPE) to phagocytose photoreceptor outer segments.

Methods: RPE cells from five different hiPS-RPE lines and ARPE-19 cells were cultured to confluence on human Bruch's membrane (hBM; flexural modulus: 1.6-2.44 Mpa) explants and tissue culture inserts with a 10 µm-thick transparent polyester (PET; flexural modulus: 2.8-3.5 Gpa) membrane. One week after the confluence, 6.0 mm grafts were cut and transferred to another dish. These circular grafts were either stabilized on a photopolymerizable biogel or left unstabilized within the culture medium. Grafts were maintained within a culture medium for 4 hours in the presence of FITC-labeled human photoreceptor outer segments (10^8 per/ml). At the end of the incubation period, cells were collected after trypsinization. Flow cytometric analyses were carried out to determine the number of DRAQ5-stained viable cells that phagocytosed FITC-labelled human photoreceptor outer segments.

Results: hiPS-RPE exhibited better phagocytosis of photoreceptor outer segments compared to ARPE-19 cells on both substrates regardless of the graft stabilization ($15.6 \pm 4.4\%$ vs $6.8 \pm 2.4\%$ on stabilized hBM, $p=0.004$; $24.1 \pm 5.5\%$ vs $5.8 \pm 2.0\%$ on unstabilized hBM, $p=0.0001$; $56.8 \pm 16.0\%$ vs $5.7 \pm 1.6\%$ on stabilized PET membranes, $p=0.008$ and $78.4 \pm 9.8\%$ vs $29.2 \pm 8.7\%$ on unstabilized PET membranes, $p=1.5 \times 10^{-6}$). Phagocytic ability of the hiPS-RPE cells was better if hBM ($p=0.008$) and PET membrane ($p=4.6 \times 10^{-6}$) were not stabilized. hiPS-RPE demonstrated better phagocytosis on PET membranes compared to hBM regardless of the stabilization of the substrate. ($p<0.001$)

Conclusions: Flexural modulus of the hiPS-RPE graft can modulate the function of the grafted RPE cells. hiPS-RPE cells exhibit better phagocytosis on PET membranes compared to hBM grafts.

ABSTRACT BODY:

Purpose: Social media is a powerful source of ophthalmologic information for the public. Ophthalmology-related content is especially pervasive on Instagram (IG), the most popular photo-sharing platform with over 112 million monthly active users. The objective was to identify top-performing ophthalmology posts on IG and characterize their content and features.

Methods: A 36 term hashtag list was curated composed of common ophthalmic diagnoses and procedures (e.g. #LASIK, #cataract, etc.). Related posts were searched on IG from Sept 1 to Oct 1, 2020. IG uses an engagement-based algorithm to rank posts based on the number of likes and comments, giving high-ranking posts greater reach. The top 9 posts for each term were identified. Posts unrelated to ophthalmology were excluded. Each post was analyzed for engagement level (e.g. total likes), media format (e.g. picture, video), content type (e.g. education, self-promotion, etc.), and the poster's background (e.g. credentials, country, seniority, etc.). Engagement level ratios (ER) for each post were calculated as the number of likes to number of followers per poster account. ANOVA analyses were performed.

Results: This was a cross-sectional epidemiological study where 1,763,898 posts were identified. 324 posts met the inclusion criteria. Most posts were created by ophthalmologists (36.4%), followed by patients (29.0%), and optometrists (20.1%). Overall, ophthalmologists (0.077), optometrists (0.091) and patients (0.087) created posts with similar ER ($p>0.05$). While most content was educational (63%), self-promotional posts (0.182) were the most effective in terms of ER followed by personal experience (0.096) and education (0.081) ($p=0.08$). Photos were the most common media type (84.8%) followed by videos (7.9%) and graphics (7.3%). Curiously, video posts received the highest ER (0.234), followed by graphics (0.102), and photos (0.087) ($p<0.05$). When analyzing the top 100 posts ranked by ER, slit lamp photos were most engaging (0.204), followed by white coat photos (0.175) and photos of ophthalmologists (0.171) ($p<0.05$).

Conclusions: Most ophthalmic content on IG is created by non-ophthalmologists. The performance and reach of each post vary significantly based on factors related to post format and content type. Ophthalmologists have the opportunity to make a larger impact on social media by creating more engaging content, especially in areas related to eye education.

ABSTRACT BODY:

Purpose: Cone photoreceptor transplantation is a potential treatment for macular diseases. The optimal conditions for cone transplantation are poorly understood, partly because of the scarcity of cones in donor mice. To facilitate allogeneic cone photoreceptor transplantation studies in rodents, we aimed to create and characterize a donor mouse model containing a cone-rich retina with a cone-specific enhanced green fluorescent protein (EGFP) reporter.

Methods: We generated OPN1LW-EGFP/NRL^{-/-} mice by crossing NRL^{-/-} and OPN1LW-EGFP mice. We characterized the anatomical phenotype of OPN1LW-EGFP/NRL^{-/-} mice using multimodal confocal scanning laser ophthalmoscopy (cSLO) imaging, immunohistology, and transmission electron microscopy. We evaluated retinal function using electroretinogram (ERG), including 465 and 525 nm chromatic stimuli. Retinal sheets from OPN1LW-EGFP/NRL^{-/-} mice were transplanted subretinally into immunodeficient Rd1 mice.

Results: OPN1LW-EGFP/NRL^{-/-} retinas were enriched with S-opsin⁺ cone photoreceptors in a dorsal-ventral distribution gradient. EGFP reporter expression occurred in L/M- and S-opsin expressing cells. Rosettes formed preferentially in the ventral retina. The outer retina in P35 OPN1LW-EGFP/NRL^{-/-} was thinner than NRL^{-/-} controls. The OPN1LW-EGFP/NRL^{-/-} ERG response amplitudes to 465 nm stimulation were similar to, but to 535 nm stimulation were lower than, NRL^{-/-} controls. Three months after transplantation, there were more S-opsin⁺ than L/M-opsin⁺ outer segments detected in recipients.

Conclusions: OPN1LW-EGFP/NRL^{-/-} retinæ were enriched with S-opsin⁺ cells. Sustained expression of EGFP facilitated the longitudinally tracking of donor cells. Transplanted cone-rich retinal sheet from OPN1LW-EGFP/NRL^{-/-} mice survived and matured into subtype of cone photoreceptors. This novel cone-rich reporter mouse model is a useful tool for the study of cone photoreceptor transplantation as a treatment for macular diseases.

ABSTRACT BODY:

Purpose: To provide a detailed ophthalmic phenotype of two male patients with Bardet-Biedl Syndrome (BBS) due to mutations in the BBS7 gene

Methods: Two brothers ages 26 (Patient 1, P1) and 23 (P2) underwent comprehensive ophthalmic evaluations over a three years. Visual function was assessed with full-field electroretinograms (ffERGs), kinetic and chromatic perimetry, multimodal imaging with spectral domain optical coherence tomography (SD-OCT), fundus autofluorescence (FAF) with short- (SW) and near-infrared (NIR) excitation lights and adaptive optics scanning light ophthalmoscopy (AOSLO).

Results: Both siblings had a history of obesity and postaxial polydactyly; P2 had diagnoses of type 1 Diabetes Mellitus, Addison's disease, high-functioning autism-spectrum disorder and -12D myopia. Visual acuities were better than 20/30. Kinetic fields were moderately constricted. Cone-mediated ffERGs were undetectable, rod ERGs were 60-80% of normal mean. Static perimetry showed severe central cone and rod dysfunction. Foveal to parafoveal hypoautofluorescence, most obvious on NIR-FAF, co-localized with outer segment shortening/loss and outer nuclear layer thinning by SD-OCT, and with reduced photoreceptors densities by AOSLO. A structural-functional dissociation was confirmed for cone- and rod-mediated parameters. Worsening of the abnormalities was documented by SD-OCT and FAF in P2 at 3 years. Gene screening resulted in compound heterozygous mutations in BBS7 (p.Val266Glu:c.797T>A/c.1781_1783delCAT) in both patients.

Conclusions: BBS7-associated retinal degeneration may present as a progressive cone-rod dystrophy pattern, reminiscent of both the murine and non-human primate models of the disease. Predominantly central retinal abnormalities in both cone and rod photoreceptors showed a structural-functional dissociation, an ideal scenario for gene augmentation treatments.

SUBMITTER (NAME ONLY): Landon Rohowetz

TITLE: Corneal abnormalities in the DBA/2J mouse model of glaucoma: DBA/2J-Gpnmb⁺/SjJ as a critical control

SESSION TITLE: Neurodegeneration and neuroprotection

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.J. Rohowetz, S. Riordan, P. Koulen, Ophthalmology, University of Missouri Kansas City Vision Research Center, Kansas City, Missouri, UNITED STATES|P. Koulen, Biomedical Sciences, University of Missouri Kansas City School of Medicine, Kansas City, Missouri, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Landon Rohowetz: Commercial Relationship: Code N (No Commercial Relationship) | Sean Riordan: Commercial Relationship: Code N (No Commercial Relationship) | Peter Koulen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The DBA/2J (D2) mouse strain is widely used as a model for glaucoma. We compared the D2 and DBA/2J-Gpnmb⁺/SjJ (D2G) mouse strains to determine the relative roles of age-related changes in IOP and corneal pathology on visual dysfunction in the D2 mouse model of glaucoma. D2G mice are genetically identical to D2 mice with the exception of a normally functioning Gpnmb gene resulting in a lack of iris pigment dispersion and the absence of IOP elevation and glaucomatous neuropathy.

Methods: IOP, visual acuity (VA) and corneal calcification were studied in D2 and D2G mice. IOP and VA were monitored over a 12-month period using tonometry and behavioral measures of the optomotor reflex. At 6, 9 and 12 months, corneas from each group were examined using confocal microscopy to measure the intensity, thickness and size of calcified regions.

Results: D2 mice developed elevated IOP between 9 (13.53 ± 0.88 mmHg) and 12 months of age (23.53 ± 1.72 mmHg), but D2G mice did not (12.34 ± 0.33 mmHg at 9 and 13.8 ± 0.47 mmHg at 12 months). Corneal calcification was found in 46.4% of D2 eyes and 56.7% of D2G eyes at 6 months ($P = 0.323$), 52.5% and 52.6% at 9 months ($P = 0.991$) and 83.3% and 60.0% at 12 months ($P = 0.1113$). When comparing 9 and 12 month-old mice with calcification, D2 mice demonstrated an increase in calcification thickness ($P = 0.005$) and D2G mice demonstrated increases in calcification intensity ($P = 0.006$) and thickness ($P = 0.036$). At 12 months of age, D2 mice with corneal calcification had greater mean IOP (25.38 ± 1.85 mmHg) than D2 mice without corneal calcification (17.5 ± 2.53 mmHg; $P = 0.048$). No difference in IOP was observed between D2G mice with and without calcification at any age. Calcification thickness correlated positively with IOP ($r = 0.415$, $P = 0.004$) and negatively with visual acuity ($r = -0.451$, $P = 0.014$) in D2 but not D2G mice.

Conclusions: Corneal calcification may affect noninvasive IOP measurements and visual function in D2 mice. While ocular hypertension secondary to iris pigment dispersion causes visual dysfunction, corneal abnormalities, such as corneal calcification, should be considered as potentially confounding factors for the assessment of vision loss in D2 mice.

TITLE: Facedown Positioning Duration for Silicone Oil Tamponade and the Effect on Retinal Re-detachment

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Zubricky, Northeastern Ohio Medical University, Rootstown, Ohio, UNITED STATES|S. Platt, Retina Associates of Cleveland Inc, Beachwood, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ryan Zubricky: Commercial Relationship: Code N (No Commercial Relationship) | Sean Platt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the incidence of retinal redetachments and other complications following pars plana vitrectomy for retinal detachment repair with silicone oil tamponade and the outcome of facedown positioning duration on these endpoints.

Methods: The retrospective study was performed on patients with retinal detachment repair via pars plana vitrectomy with silicone oil tamponade between 2015 and 2020. Surgery was performed by 10 physicians associated with a private retina practice in Cleveland, OH. The independent variable of interest was length of post-operative facedown positioning. Outcome variables were retinal re-detachment, epiretinal membrane (ERM) formation, cataract formation, and other complications.

Results: The study was composed of 227 eyes. The mean age of patients was 62.09 ± 13.65 years with 63% males and 37% female. Of the initial detachments, 27.88% were mac-on and 72.12% were mac-off. Overall, 42 patients had facedown positioning for 1 day, 50 for 3 days, 24 for 5 days, and $99 \geq 7$ days. Redetachment was seen in 45.2% of the 1-day group, 40% of the 3-day group, 41.6% of the 5-day group, and 29.3% of the 7-day group ($p=0.246$). Cataract formation was seen in 64.7% of the 1-day group, 47.8% of the 3-day group, and 74.5% of the 7-day group ($p=0.088$). ERM formation showed no clear trend nor statistical significance ($p=0.523$). Analysis was also performed grouping patients into a ≤ 6 day group and a ≥ 7 -day group. Redetachment was seen in 42.19% of the ≤ 6 -day group and 29.29% of the 7-day group ($p=0.045$). Relative risk for the 7-day group was 0.694. Cataract formation was seen in 51.9% of patients in the ≤ 6 -day group and 74.5% of the 7-day group ($p=0.021$). Relative risk was 1.434. No significant difference was found in ERM formation.

Conclusions: The data suggests a lower rate of retinal redetachment with increasing postoperative facedown positioning time, particularly with 7 days, although the result was not statistically significant. Additionally, there was a suggestive increase of cataract formation in the 7 day group although this also did not meet significance. When comparing patients that positioned ≥ 7 days to all others, significance was achieved. These relationships would be better studied with a larger sample size and a randomized control trial that could further define the associations found here and determine causality.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) may be worsened by pregnancy. Findings from prior studies have been conflicting; many are outdated. Here, we report the prevalence, rate of DR progression and risk factors associated with progression in pregnant women with pre-existing diabetes.

Methods: Prospective longitudinal cohort study of pregnant women with type 1 (T1DM) or type 2 diabetes (T2DM) from two tertiary maternity hospitals in Melbourne, Australia (Nov 2017 - Sept 2019). Eye examinations were scheduled in each trimester and 3-months postpartum. DR severity was graded for each eye from 2-field retinal photographs. At least 2 exams (at early and late pregnancy) were required to evaluate DR change. Progression was defined as worsening by ≥ 1 -step of the Airlie House classification, development of diabetic macular edema (DME), or the need for laser treatment during pregnancy. Sight-threatening (ST) progression was defined as development of proliferative DR (PDR) or DME.

Results: A total of 147 from 191 eligible women (77%) were recruited, with at least one eye exam performed in 130 (88.4%). Mean age was 33.7 years (range 19-47). Sixty-two women (47.7%) had T1DM while 68 had T2DM (median duration 16.5 years and 4 years). DR and STDR prevalence during the study period were 20.8 (CI 16.3-26.1) and 6.6 (CI 4.1-10.4) per 100 eyes, respectively. Among the 144 eyes (72 women) with >1 eye exam, 10/76 (13.2%) and 4/68 (5.9%) from T1DM and T2DM women had DR progression, with an overall progression rate of 9.7%. Six eyes developed new DR. Elevated systolic blood pressure (SBP) (risk ratio 5.07, CI 1.90-13.49) and presence of any DR (RR 10.36, CI 3.14-34.12) in early pregnancy significantly increased the risk of progression. ST progression was observed in 6 eyes (1 developed PDR, 3 developed DME, 2 with treated-PDR required further laser during pregnancy).

Conclusions: The prevalence of DR in pregnant women was similar to the non-pregnant diabetic population in Australia. Nearly 1 in 10 eyes had DR progression between early to late pregnancy, with almost half of these developing STDR. Risk factors for progression included higher SBP in early pregnancy and pre-existing DR at

pregnancy onset. Worryingly, 1 in 5 participants failed to attend any eye exams during pregnancy, highlighting the need to address barriers to eye screening adherence given the significant risk of vision loss from DR in this population.

ABSTRACT BODY:

Purpose: Conventional subjective and objective refractions are examined under visible and near-infrared (NIR) lights, respectively. Diffractive extended depth of focus (EDOF) intraocular lenses (IOLs) utilizing an echelette optics form the far focus with the 1st-order diffraction, and differences between the subjective and objective refractions are clinically addressed. Hence, we evaluated experimentally the lens powers of diffractive bifocal and EDOF IOLs under NIR lights.

Methods: Lens power (D) was measured using a lensmeter (TL-7000, Tomey) that utilized the Hartmann pinhole plate and was modified to accommodate a LED with a peak wavelength of 850 nm. Three pieces of refractive monofocal, refractive (for far) and diffractive (for near) bifocal, and diffractive EDOF IOLs (ZCB00V, ZMB00, and ZXR00V, respectively, Johnson & Johnson Surgical Vision) with labeled powers of 10, 15, and 20D were immersed in water, and the pinhole images were captured with a CMOS camera. Mean distances of 9 pinholes at the center were measured with Image J, and lens powers were calculated with regression results of monofocal IOLs. Power differences from the monofocal IOLs were also obtained for bifocal and EDOF IOLs.

Results: The distances of pinholes were well correlated with the labeled power of monofocal IOLs ($P < 0.001$, $R^2 > 0.999$), and the calibration equation was obtained for water-immersed IOLs. The mean powers for the label of 10, 15, and 20D were 9.89, 14.69, and 19.80D with bifocal IOLs and 10.79, 15.73, and 20.98D with EDOF IOLs, respectively. The mean difference between the bifocal and monofocal IOLs were -0.21D (SD: 0.19D), while the difference between the EDOF and monofocal IOLs was 0.83D (SD: 0.14D).

Conclusions: The powers measured under NIR light were higher than the labeled value of the EDOF IOLs, but such a difference was not found with the bifocal IOLs. The results demonstrated that the lens power of the EDOF IOL increased with longer wavelength light as the 1st-order diffraction of an echelette optics forms the far focus. The difference could reflect the myopic shift in objective refraction from subjective results, as clinically observed.

TITLE: Image Registration for sequential Ocular Multispectral Slices via Heterogeneous Mapping

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Lian, Y. Zheng, Shandong Normal University, Jinan, Shandong, CHINA|J. Lian, School of Intelligent Engineering, Shandong Management University, Jinan, Shandong, CHINA|

Commercial Relationships Disclosure (Abstract): Jian Lian: Commercial Relationship: Code N (No Commercial Relationship) | Yuanjie Zheng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The quality of ocular Multispectral Imaging (MSI) can be spoiled by the relative movement between a sequence of MSI slices due to the inevitable saccadic movements of eyeballs. In clinical practice, this type of misalignment usually leads to ophthalmologists' misinterpretation of the MSI images and renders the corresponding diagnosis error prone. To address the issues caused by the GroupWise misalignment that existed in MSI slices, this study focuses on developing a GroupWise registration instrument for eliminating the misalignment between a set of MSI slices without relying on mutual information or cross-correlation, which is validated to be capable of dealing with the image samples with low resolution.

Methods: 32 sequences of slices were collected with an Annidis RHATH instrument. In total, there are 11 spectral slices captured from 11 discrete monochromatic optical sources. The slices were of the oculus dexter and oculus sinister from 6 patients and 10 healthy subjects in dicom file format (with 16-bit depth and resolution of 2048*2048). First of all, we proposed a novel similarity measure technique by introducing the heterogeneous mapping algorithm, with which the similarity between a group of MSI slices can be represented as their Euclidean distances in one latent space. Furthermore, the scale-invariant feature transform algorithm, an inter-image transformation approach, and alternating minimization were exploited to implement the landmark detection, motion model, and optimization in the registration process, respectively.

Results: The proposed pipeline achieved superior performance over state-of-the-art techniques. The average mean (standard deviation) of the distance between manually delineated points and the transformed ones is 2.9 (1.8). An instance of the MSI slices and the registration results by using the proposed approach are shown in Figure 1.

Conclusions: Transferring the images from varied models into one vector space not only can facilitate the measurement of the difference between sequential images but also can improve the quality of MSI slices and the outcome of the registration algorithms. It is potentially invaluable for the diagnosis and treatment of eye diseases.

TITLE: Validity of Actiwatch and Clouclip Measures of Light Exposure

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.M. Howell, S.J. McCullough, L.A. Doyle, K.J. Saunders, Optometry and Vision Science Research Group, Ulster University, Coleraine, Derry, UNITED KINGDOM|C.M. Howell, M. Murphy, Sport and Exercise Sciences Research Group, Ulster University, Coleraine, Derry, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Colleen Howell: Commercial Relationship: Code N (No Commercial Relationship) | Sara McCullough: Commercial Relationship: Code N (No Commercial Relationship) | Lesley Doyle: Commercial Relationship: Code N (No Commercial Relationship) | Marie Murphy: Commercial Relationship: Code N (No Commercial Relationship) | Kathryn Saunders: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare measures of light exposure obtained with Actiwatch2 (AW) and Clouclip (CC) to 'gold standard' photometer (PHO) measures and evaluate the wearable devices' ability to categorise light into different levels of illumination.

Methods: Illumination was assessed by AW, CC and PHO in a range of lighting conditions and categorised (by PHO) as described in Table 1. Regression plots and Bland/Altman analyses evaluated the relationship between PHO output and the wearable devices. The ability of AW and CC to successfully categorise light into the four categories was examined.

Results: A strong linear relationship was found between light exposure measured by PHO and both AW ($r=0.999$, $p<0.001$) and CC ($r=0.989$, $p<0.001$). However, compared to PHO, both wearable devices underestimated light exposure. The disparity increased with increasing illumination and was greater for AW than CC. Mean differences and limits of agreement in light exposure were; AW vs PHO 430.92 lux (-1397.82 to 2259.66) and CC vs PHO 79.35 lux (-327.98 to 486.68), respectively. Categorisation of illumination level (SCO/MES/IN/OUT) by CC was more accurate than by AW (Figure 1). Adjusted criteria for categorisation of illumination levels by wearables were derived from regression equations (Figure 2).

Conclusions: These data illustrate that both CC and AW devices underestimate light exposure in comparison to 'gold standard' PHO measures, with increasing disparity at higher light levels, especially for AW. For researchers interested in categorising exposure into different levels of illumination, CC more accurately classifies illumination levels than AW in illuminations above SCO levels. Adjusted criteria should be applied to AW and CC data to more closely align with PHO outputs.

ABSTRACT BODY:

Purpose: We first established our original Kyoto Prefectural University of Medicine Glaucoma Registry (KPUM-GR) in 1995, and have continued inputting data since then. The purpose of this study was to analyze the data in the KPUM-GR and investigate the annual trend and seasonal variation of intraocular pressure (IOP) over the past 20 years in Japanese normal tension glaucoma (NTG) patients.

Methods: IOP data was extracted from the KPUM-GR data obtained at the KPUM Hospital and affiliate clinics under the following conditions: 1) 1 data point per patient per month, 2) if bilateral data was available, the right-eye data was used, 3) if measured more than twice within 1 month, the mean IOP data was calculated and used, and 4) if the patient had undergone glaucoma surgery, the postoperative data was excluded, but not excluded if cataract surgery or laser treatment, such as trabeculoplasty, was performed. In order to investigate the trends of IOP throughout the 20-year period, we first calculated the mean IOP from all available data of each month from January 1997 through December 2016. The data was then further divided into 5 groups of 4 consecutive years each (1997-2000, 2000-2004, 2005-2008, 2009-2012, and 2013-2016), and the mean IOP of each month within each group was then calculated. Seasonal variations of IOP over the 20-year period and in the 5 consecutive 4-year groups was then investigated via nonlinear multiple regression analysis.

Results: We ultimately extracted 49,007 independent data points derived from 1,774 Japanese NTG patients (665 males and 1,109 females; mean age: 59.8 ± 14.4 years, mean observation period: 5.6 ± 4.4 years) treated

with/without anti-glaucoma medications over the 20-year period. A continuous decrease of IOP, with seasonal variations, was detected throughout the 20-year period ($p < 0.001$). Annual mean IOP was highest (13.9 ± 2.7 mmHg) in the oldest 4-year group (1997-2000), followed by a gradual decrease in each subsequent group, finally becoming lowest (12.3 ± 2.7 mmHg) in the most recent group (2013-2016) (trend test: $p < 0.001$). The seasonal variations of IOP were clearly detected ($p < 0.001$) in each of the 5 consecutive 4-year groups.

Conclusions: Based on real-world longitudinal data, our findings revealed a continuous decrease and seasonal variations of IOP throughout the 20-year period in Japanese NTG patients.

ABSTRACT BODY:

Purpose: We performed a prospective observational clinical study to differentiate eyes that did and did not develop proliferative vitreoretinopathy (PVR) on the basis of the metabolites and cytokines in human vitreous samples taken at the time of rhegmatogenous retinal detachment (RRD) repair.

Methods: Metabolomic analysis was performed on 66 vitreous samples, obtained at the start of pars plana vitrectomy from patients undergoing surgery for macular hole (n=21) and RRD (n=44), including patients who subsequently developed PVR (n=14) and patients who did not (n=31). One-dimensional ¹H spectra were acquired at 298 °K with 128 scans using a standard Bruker NOESY 1D pulse sequence with pre-saturation water suppression Bruker DRX 600MHz NMR spectrometer equipped with a cryoprobe. Chemical shifts were calibrated with respect to the chemical shift position of the TMSP resonance.

Multiplexed immunoassays with fluorescent microspheres were used to perform cytokine analysis in MH (n= 45); RRD (n= 71) and PVR eyes (n=22). Different disease groups were analysed using both univariate and multivariable approaches.

Results: High levels of 2-hydroxyvalerate, 2-phosphoglycerate, alanine, alloisoleucine, glutamine, histidine, methanol, urea, valine and myo-inositol predicted the development of post-operative PVR. Levels were lower in those eye with RD that did not develop PVR. Creatine was found to be higher in the MH group as compared to RD.

The cytokines IL-1 β and IL-7 were found to be significantly higher in the PVR group compared to the RD group (P=0.02 and 0.03 respectively). IL1ra, IL7, IL8, IL9, IP10 and MIP1b was found to higher in the RD group compared to MH group.

Conclusions: We report, for the first time, vitreous metabolic changes predicting PVR development. Through pathway analysis, increased histidine, glutamine, valine, alanine and isoleucine points to aminoacyl tRNA biosynthesis. High levels are predictive of PVR development. Upregulation is associated with increased protein synthesis required for proliferation of fibrocellular membranes in PVR.

The metabolite results are suggestive of increased glycolysis activity and glutamate signalling, associated with the enhanced cellular migration and proliferation plus excitotoxicity seen in PVR development.

The cytokines detected have a more proliferative than apoptotic profile, supporting the suggestion that the detected metabolic changes relate to cell migration and proliferation.

ABSTRACT BODY:

Purpose: Plasma and cerebrospinal fluid (CSF) levels of protein biomarkers have been associated with Alzheimer's disease (AD). Limited prior studies have suggested amyloid beta 40 (A β 40) and 42 (A β 42) are present in human aqueous, but detection of tau proteins has not been previously reported. We sought to characterize normal concentrations of A β 40, A β 42, and total tau in human aqueous and compare to plasma concentrations and Montreal Cognitive Assessment (MoCA) scores.

Methods: Twenty adults with no history of dementia underwent simultaneous aqueous and plasma sampling and MoCA (blind version) testing at the time of cataract surgery. Aqueous and plasma samples underwent analysis in duplicate using the single-molecule array (SiMoA) SR-X platform (Quanterix[®], Middlesex, MA) to measure A β 40, A β 42, and total tau.

Results: Mean (standard deviation) age was 70.7 (6.6) years. Mean MoCA score was 19.3 (2.5). Two subjects were unable to give plasma. Three of 18 (17%) plasma samples could not be analyzed via SiMoA. Mean measured aqueous concentrations (pg/ml) of A β 40, A β 42, and total tau were 131.0 (67.1), 3.6 (3.6), and 39.2 (41.2) respectively, and corresponding plasma concentrations were 128.5 (57.2), 10.2 (5.7), and 5.6 (3.2). All aqueous samples contained A β 40 and total tau, but only 3/20 (15%) of samples contained detectable A β 42. All analyzed plasma samples (n=15) had detectable A β 40, A β 42, and total tau. Comparisons between first and second runs of aqueous samples demonstrated mean difference of 18% (24%) for A β 40 and 14% (15%) for total tau. There were minimal correlations between A β 40 ($r^2 < 0.01$) and total tau ($r^2 = 0.11$) in aqueous and plasma. Aqueous concentrations of A β 40 and total tau also demonstrated minimal correlation with MoCA scores, $r^2 = 0.07$ and 0.02 respectively or age, $r^2 = 0.01$ and 0.20 respectively.

Conclusions: SiMoA can measure A β 40 and total tau in human aqueous. A β 42 was not detectable in 85% of aqueous samples but was detectable in all plasma samples. In adults without dementia, there is minimal correlation between aqueous and plasma concentrations of A β 40 and total tau. Aqueous concentrations of A β 40 and total tau do not appear to correlate with MoCA scores. Further study in subjects with AD is indicated to determine whether aqueous A β 40 and total tau may differ between AD and controls or correlate with cognitive test scores or CSF protein concentrations.

TITLE: Assessment of retinal microvascular alterations in individuals with amnestic and non-amnestic mild cognitive impairment using optical coherence tomography angiography

SESSION TITLE: OCT Angiography - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Akrobetu, C. Robbins, S.S. Stinnett, S. Soundararajan, A. Liu, K. Johnson, D.S. Grewal, S. Fekrat, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Dennis Akrobetu: Commercial Relationship: Code N (No Commercial Relationship) | Cason Robbins: Commercial Relationship: Code N (No Commercial Relationship) | Sandra Stinnett: Commercial Relationship: Code N (No Commercial Relationship) | Srinath Soundararajan: Commercial Relationship: Code N (No Commercial Relationship) | Andy Liu: Commercial Relationship: Code N (No Commercial Relationship) | Kim Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Dilraj Grewal: Commercial Relationship: Code N (No Commercial Relationship) | Sharon Fekrat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Individuals with mild cognitive impairment (MCI) can be categorized into amnestic and non-amnestic subgroups based on the absence or presence of intact working memory. Patients with amnestic MCI have increased likelihood of progressing to Alzheimer's disease (AD); however, identification of predictive biomarkers distinguishing amnestic and non-amnestic MCI remains ambiguous. This prospective, cross-sectional study utilizes optical coherence tomography angiography (OCT-A) to assess how retinal microvascular density and structure might differ among amnestic and non-amnestic MCI patients.

Methods: One hundred and twelve eyes of 59 amnestic MCI participants, 32 eyes of 17 non-amnestic MCI participants, and 111 eyes of 56 cognitively healthy controls were included in our study. All participants were imaged using the Zeiss Cirrus HD-5000 AngioPlex. OCT-A vessel density (VD) and perfusion density (PD) in Early Treatment Diabetic Retinopathy Study (ETDRS) 3mm and 6mm circles and rings were assessed. Retinal thickness parameters on OCT including retinal nerve fiber layer thickness (RNFL), ganglion cell-inner plexiform layer (GC-IPL), and central subfield thickness (CST) were also analyzed. Generalized estimating equations accounting for correlation between two eyes of the same subject were utilized for statistical analysis.

Results: Assessment of PD in the 3x3mm inner ETDRS ring revealed a significant decrease in amnestic MCI when compared to non-amnestic MCI (0.29 ± 0.03 vs 0.34 ± 0.09 , $p = 0.025$), and was significantly lower in amnestic MCI when compared to healthy controls (0.29 ± 0.03 vs 0.39 ± 0.02 , $p < 0.001$), after adjustment for age and sex. Vessel density, subfoveal choroidal thickness, and other retinal thickness parameters (GC-IPL, RNFL, CST) showed no statistically significant difference among or between diagnostic groups.

Conclusions: After adjusting for age and sex, OCT-A perfusion density significantly differed among controls, non-amnestic MCI, and amnestic MCI. Other retinal parameters did not differ between groups after adjusting for covariates. Non-invasive retinal imaging deserves further study as a potential biomarker for diagnosing and classifying subtypes of MCI.

TITLE: Dexamethasone intravitreal implant as monotherapy for birdshot chorioretinopathy

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Trinh, Ophthalmology, Northwell Health, Great Neck, New York, UNITED STATES|J. Jonisch, Vitreoretinal Consultants, Great Neck, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Minh Trinh: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Jonisch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Birdshot chorioretinopathy (BCR) is an ophthalmic disease not commonly associated with other systemic findings. However, systemic steroids or immunomodulatory therapy (IMT) is often needed to treat acute or chronic BCR, and those have significant morbidity associated with treatment. We present six eyes with BCR undergoing monotherapy with intravitreal dexamethasone implantation 0.7mg (Ozurdex; Allergan, Inc.) to review the efficacy and limitations of this treatment modality.

Methods: A retrospective chart review was performed on patients at our practice with BCR. Eyes receiving Ozurdex monotherapy for the treatment of BCR with a minimum follow-up period of 6 months were included. Eyes which were concurrently receiving systemic steroids or IMT were excluded. Six eyes (3 patients) were included. The main outcome measure was quiescence of disease activity as measured by fluorescein angiogram, optical coherence tomography, ophthalmic exam, and patient symptoms. Secondary outcomes were improvement of best corrected visual acuity. We collected: visual acuity, central macular thickness (CMT), presence of vitritis, presence of retinal vasculitis on fluorescein angiography, intraocular pressure (IOP), and presence of cataract at baseline, 1 month, 3 months, and 6 months after beginning treatment.

Results: All eyes were injected at intervals of 3-6 months if there was clinical evidence of worsening vision, macular edema, vitritis, or retinal vasculitis. All eyes achieved quiescence of disease activity with Ozurdex. The mean LogMar visual acuity was 0.18 ± 0.15 at baseline, 0.16 ± 0.10 at 1 month, 0.16 ± 0.12 at 3 months, and 0.13 ± 0.11 at 6 months (all $p > 0.05$). There was a trend towards improved visual acuity but was not statistically significant. One eye presented with macular edema with a CMT of 409 microns at baseline which improved to 248 microns at 6 months. Two eyes had vitritis and four eyes had retinal vasculitis, all eyes improved with treatment. Four eyes developed elevated IOP after the first injection of Ozurdex, but was successfully managed with topical therapy alone. None of our patients developed cataracts as a consequence of therapy.

Conclusions: Our findings suggest that repeated injections of Ozurdex as monotherapy may be a valuable option in the treatment of BCR and could be used to delay the initiation of IMT. Further studies are warranted to evaluate the utility of local monotherapy with Ozurdex.

TITLE: Comparison of Pre-operative Measured to Post-operative Refractive Astigmatism in Pseudophakes

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Athukorala, N. Kansara, T. O'Rourke, I.U. Scott, S. Pantanelli, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Shavini Athukorala: Commercial Relationship: Code N (No Commercial Relationship) | Neal Kansara: Commercial Relationship: Code N (No Commercial Relationship) | Tara O'Rourke: Commercial Relationship: Code N (No Commercial Relationship) | Ingrid Scott: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s); Carl Zeiss Meditec and Bausch & Lomb: Code C (Consultant); Ziemer Ophthalmics AG: Code F (Financial Support)

ABSTRACT BODY:

Purpose: To evaluate the relationship between various measures of pre-operative keratometric astigmatism and post-operative refractive astigmatism (RA).

Methods: Consecutive eyes evaluated between 11/2018 and 07/2020 underwent pre-operative biometry (IOLMaster 700), tomography/topography (Galilei G4), cataract surgery with implantation of a monofocal intraocular lens, and manifest refraction between 21 and 90 days after surgery. Eyes excluded from the analysis included those with biometry or topography of poor quality (as defined by the device's respective image quality metrics), history of ocular surgery other than laser, corneal disease of any kind, cataract surgery combined with another procedure, intraoperative complications, implantation of a toric or multifocal IOL, missing post-operative manifest refraction, or a best-corrected distance visual acuity worse than 20/40. Post-operative RA was compared to pre-operative astigmatism measured using the following methods: Keratometry (K; IOLMaster), Simulated Keratometry (SimK; Galilei G4), Total Keratometry (TK; IOLMaster), and Total Corneal Power (TCP2; Galilei G4). Difference vectors (DV) were calculated between RA and each of the four pre-operative measures.

Results: One-hundred eighteen eyes met criteria for inclusion in the analysis. The centroid of the DVs for the four measurement methods were 0.26 ± 0.75 D @ 173, 0.52 ± 0.75 D @ 177, 0.08 ± 0.77 @ 151, and 0.30 ± 0.81 D @ 174, respectively. K and TCP2 DVs were not significantly different from one another ($p = 0.58$); all other differences were significant ($p < 0.0001$). The proportion of eyes with DV magnitudes < 0.5 were 36.4%, 23.7%, 41.5%, and 28.8% ($p < 0.0001$), respectively. The proportion of eyes with DV magnitudes < 1.0 D were 85.6%, 67.8%, 83.9%, and 75.4%, respectively ($p < 0.0001$ for all comparisons except K vs. TK [$p = 0.48$]).

Conclusions: Of the pre-operative measurement methods evaluated, TK most closely approximated post-operative RA. The effect of surgically induced astigmatism (SIA) was not evaluated due to the retrospective nature of the study.

ABSTRACT BODY:

Purpose: The rapid spread of coronavirus (COVID-19) has changed the way eye care practitioners provide care. As an early response to the pandemic, the Department of Ophthalmology at the University of Illinois at Chicago created a tele-triage system to screen patients requesting an urgent visit. The aim of this study was to explore demographic and community factors associated with adherence of patients scheduled for recommended urgent eye visits.

Methods: Surveys of all individuals requesting an acute same day in-person visit between April 6, 2020 and June 6, 2020 were reviewed, and medical chart review was completed for patients recommended an urgent visit.

Demographic data and adherence to visit were examined. Using ArcGIS, address was geocoded and census tract level variables were appended from the U.S. Census American Community Survey between 2014 and 2018. COVID-19 related death data during the study period were also included from the Cook County Medical Examiner's Office. Descriptive statistics, t-tests and binary logistic regression were used to compare variables. A p-value of ≤ 0.05 was considered statistically significant. Data was analyzed using SAS Institute Inc. 2018 (SAS 9.4M6, Cary, NC, USA).

Results: A total of 229 patients were recommended an urgent visit. Of 216 patients with matching criteria on chart review, mean age was 46.6 ± 18.6 years. The majority of patients were female (55.6%) and Black or African American (40.3%), and most common insurance was Medicaid (36.6%). 192 patients (88.9%) reported for their scheduled visit. When comparing personal characteristics by adherence to visit, there was no difference based on gender ($p=0.94$), race ($p=0.56$), insurance status ($p=0.28$), nor new versus established status ($p=0.20$). Community level data showed that individuals who did not adhere to their visit more commonly came from neighborhoods with a greater proportion of Blacks or African Americans (59.4% vs. 33.4%; $p=0.03$), greater unemployment rates (17.5% vs. 10.7%; $p<0.01$), and greater cumulative deaths from COVID-19 (56 vs. 31; $p=0.01$).

Conclusions: The findings from this study suggest that, in our patient population, COVID-19 itself disproportionately affects black communities in terms of mortality, but also affects adherence to appointments which, in return, increases gaps in health equity.

SUBMITTER (NAME ONLY): Sean McCafferty

TITLE: Corneal Crosslinking Intracorneal Stress Measured by a Novel and Easily Implemented Differential Tonometry Method

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.J. McCafferty, Ophthalmology, Banner University Medical Center Tuscon, Tucson, Arizona, UNITED STATES|M. Wang, Ophthalmology, Banner University Medical Center South, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sean McCafferty: Commercial Relationship(s);Intuor Technologies:Code I (Personal Financial Interest);Reichert:Code C (Consultant) | Mingwu Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Evaluate corneal changes following corneal crosslinking (CXL) by paired differential tonometry intraocular pressure (IOP) measurements with a Goldmann tonometer (GAT) prism and corneal compensating, correcting applanation tonometry surface (CATS) prism.

Methods: Design: Prospective, controlled, open-label reference device comparison

Methods: IOP was measured on 23 unique eyes undergoing CXL for keratoconus with a GAT using a standard flat GAT prism and a curved corneal error correcting CATS prism before treatment and at 2 weeks, 2 months and 6 months after treatment. Concurrent measurements of central corneal thickness (CCT) and corneal hysteresis (CH) were completed.

Results: Randomized paired IOP measurements with standard GAT and corneal correcting CATS prisms indicated a significant sustained relative increase in the differential IOP between the two prisms after CXL ($p=0.005, 0.015, 0.001$). CH initially decreased at two weeks post-CXL then returned to sustained pre-op levels ($p=0.033, 0.20, 0.20$). CCT progressively decreased following CXL ($p=0.005$).

Conclusions: Differential tonometry between standard GAT and corneal biomechanical compensating CATS prisms demonstrates a simple and sensitive method for measurement of changes in corneal rigidity and corneal stress redistribution. Results suggest that CXL likely re-establishes a more “normal” biomechanical behavior to the keratoconic cornea.

ABSTRACT BODY:

Purpose: Despite being phenotypically normal, the nonaffected side of hemifacial spasm patients (HFS) may have characteristic histopathological findings. This study focuses on objectively evaluating orbicularis oculi muscle (OOM) samples from patients with HFS and control subjects who underwent cosmetic blepharoplasty.

Methods: 21 OOM samples were included in this study. 7 samples from 4 normal control subjects and 7 paired eyelids (7 from the affected and 7 from the nonaffected side) from patients with HFS, virgin of treatment, were evaluated. OOM samples were prepared using Hematoxylin and Eosin (H&E) and Gomori staining. High-resolution slide photos (x400) were obtained. Image parameters were quantitatively analyzed using ImageJ by a blind expert operator. Outcomes were area of each fiber (calculated in H&E staining) and percentage of connective tissue (assessed in Gomori staining). T-student tests and paired-t test were used to compare measurements between groups.

Results: Both the nonaffected side ($13.46 \pm 1.59 \text{ mm}^2$) and the affected side ($12.64 \pm 3.10 \text{ mm}^2$) of HFS patients presented greater fiber size than the control group ($9.03 \pm 1.76 \text{ mm}^2$), $p < 0.01$ and $p = 0.02$, respectively. No statistically significant difference was observed between the paired sides of the patients. The affected HFS-OOM revealed increased connective tissue ($28.76 \pm 8.11\%$) than both the nonaffected ($20.07 \pm 9.04\%$) and control-OOMs ($14.12 \pm 5.38\%$), $p = 0.02$ and $p < 0.01$, respectively. No difference was detected between the control and the nonaffected group. Results presented as mean \pm SD.

Conclusions: There are interesting and significant morphometric differences in the OOM of both nonaffected and clinically affected sides of patients with HFS that may reflect homeostasis disturbances due to the facial movement disorder.

ABSTRACT BODY:

Purpose: The Magnetic Levator Prosthesis (MLP) is a promising non-surgical intervention for severe ptosis that employs magnets placed on the spectacles and on the upper lid. We hypothesized that magnet orientation (Figure 1) would affect Interpalpebral Fissure (IPF) between and within blinks and subject-reported comfort.

Methods: IPF was measured manually using ImageJ from 15s video recording for 5 polarity angles: 0° (poles aligned), 30°, 60°, 90°, and 180° (reverse polarity). Participants reported comfort on a 10-point scale at each rotation position while wearing the MLP. Linear mixed models included rotation position as a fixed effect and also rotation position within subject-eye as random effects (allows subjects to differ from one another).

Results: Eye opening improved for 4 of 5 rotations by 0.9 to 2.5mm ($p<0.001$). Considerable unexplained variance suggested the presence of other factors not included in the model. Comfort rating varied between some rotation positions ($p<0.001$), and higher comfort was strongly associated with more eye opening between blinks ($p<0.001$), but only weakly with closure on the blink ($p=0.05$). Comfort with impeded blink would be expected to worsen with longer wear times.

Conclusions: Our primary hypothesis was confirmed, however, there are remaining factors that affect IPF pattern across rotation angles between subjects that need to be determined. Potential factors for future study include age, physiological differences (brow height and eyelid shape), and the baseline ptosis severity. The MLP's ability to adjust the force on the eyelids is promising for severe ptosis and potentially opens the possibility for complete blink re-animation in total paralysis.

ABSTRACT BODY:

Purpose: To test the hypothesis that dampening intracellular second-messenger signaling by a combination of approved G protein-coupled receptor-targeting drugs provides an effective therapeutic approach against retinal degenerative diseases.

Methods: We investigated a drug combination (TMB) consisting of tamsulosin and metoprolol (alpha- and beta-adrenergic antagonists, G_q - and G_s -coupled, respectively); and bromocriptine (a D2-like dopamine-receptor agonist, G_i -coupled). Longitudinal drug efficacy was tested in four distinct translationally relevant disease models: Pde6 β^{Rd10} , Rho^{P23H}, and Rpe65^{-/-} mice; and Pde6a^{-/-} dogs. The duration of the drug trials ranged from 1-week to 7-months. Drug serum levels were measured by liquid chromatography-mass spectrometry (LC-MS). We primarily used photopic and scotopic electroretinography (ERG) and optical coherence tomography (OCT) to assess drug efficacy during the chronic trials. Immunohistochemistry, Western blotting, bulk and single-cell RNA-sequencing, and proteomics were used to document therapeutic mechanisms, as well as to confirm therapeutic effects at trial termination.

Results: Dietary TMB improved rod and cone function and slowed cone degeneration in Rho^{P23H} and Pde6 β^{Rd10} mouse models of Retinitis Pigmentosa (RP). Drug efficacy was associated with decreased lipid peroxidation preceding the onset of cone degeneration in dark-reared Pde6 β^{Rd10} mice. Dietary TMB improved retinal function and optomotor tracking behavior in Rpe65^{-/-} mouse model of Leber Congenital Amaurosis type 2, but did not halt rod or cone degeneration. Seven-month-long subcutaneous sustained infusion of TMB in Pde6a^{-/-} dog model of RP led to higher cone counts at the end of the trial, and was associated with improved ERG response kinetics during the trial. LC-MS analysis showed that efficacious drug serum levels in the context of blinding diseases were generally at or below the clinically relevant concentration ranges for the drugs' original clinical indications, extrapolated from published literature. Remarkably, monotherapies with the same drugs and dosages did not alleviate disease phenotypes in Pde6 β^{Rd10} or Rpe65^{-/-} mice.

Conclusions: Our results suggest that simultaneous inhibition of G_s - and G_q -coupled receptors and activation of G_i -coupled receptors by a combination of existing drugs is a versatile option to mitigate progressive retinal degeneration caused by distinct etiologies.

ABSTRACT BODY:

Purpose: Inferior Oblique Over Action (IOOA) is commonly associated with congenital esotropia. However, the association of new-onset IOOA with acquired esotropia has not been studied. To explore this further, we analyzed the correlation between lateral rectus recession (LRrc) surgery and the incidence of IOOA.

Methods: A retrospective chart review from January 2010 to December 2011 studied children over two and below 18 years who had lateral rectus recession for exotropia with subsequent post-operative esotropia. Exclusion criteria included patients who had an initial history of esotropia overcorrected by surgery resulting in a consecutive exotropia, patients for whom operative notes were unavailable and magnitude of lateral rectus recession was unknown. Sixty-five patients (116 eyes) met inclusion criteria. Baseline measurements of age, sex, presence of central nervous system pathology, number of surgeries, laterality, and magnitude of recession were tested for association with IOOA. Primary outcome was the relationship between baseline measures and incidence of IOOA.

Results: Included were 116 eyes and 65 patients total. IOOA was observed in 9 eyes of 6 patients (7.8 and 9.2% respectively) and demographics were similar for those with and without IOOA ($p > 0.05$). No statistically significant relationship was found between the incidence of IOOA and laterality ($p = 0.13$), number of surgeries ($p = 0.20$), age at most recent surgical lateral rectus recession ($p = 0.49$), presence of central nervous system pathology ($p = 0.99$), or sex ($p = 0.54$). A statistically significant association was found between magnitude of LRrc and the incidence of post-operative IOOA ($p = 0.005$). The mean distance of recession was 7.3 ± 0.1 mm (mean \pm SEM) for eyes that did not develop IOOA and 8.4 ± 0.4 mm for eyes that did develop IOOA. The odds ratio for the development of IOOA given a one millimeter increase in recession was 1.76 (CI 1.19 - 2.60, $p = 0.005$). This indicates that the odds of IOOA increase 76% for each additional millimeter of recession.

Conclusions: Magnitude of surgical LRrc is positively associated with the incidence of post-operative IOOA in a dose-dependent fashion in children with consecutive esotropia. This finding may help elucidate the etiology of IOOA.

TITLE: Impact of monocular contact lens wear on tear film characteristics

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Basuthkar, N. Keir, Coopervision Inc, Pleasanton, California, UNITED STATES|U. Stahl, L.W. Jones, School of Optometry, Centre for Ocular Research & Education, University of Waterloo, Waterloo, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Subam Basuthkar: Commercial Relationship(s);CooperVision Inc.:Code E (Employment) | Ulrike Stahl: Commercial Relationship: Code N (No Commercial Relationship) | Lyndon Jones: Commercial Relationship: Code N (No Commercial Relationship) | Nancy Keir: Commercial Relationship(s);CooperVision Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: It is well known that presence of a contact lens (CL) on the ocular surface partitions the tear film (TF), disrupting its integrity. However, there is little evidence regarding the impact of one eye on the other, with respect to TF parameters during CL wear. Hence this study was conducted to evaluate the impact of monocular lens wear on TF stability, volume and lipid layer characteristics.

Methods: This was a prospective, randomized, 2-day cross-over study on 15 symptomatic (SYM) and 15 asymptomatic (ASYM) soft CL wearers. On Day 1, no CL was worn on either eye (i.e. no CL wear) and on Day 2, a -0.25DS soft CL (comfilcon A) was worn on one eye only (i.e. monocular CL wear). Assessments of non-invasive tear break up time (NIBUT, seconds), lipid layer thickness (LLT, 0-5 grading; 0=absent, 5=colored fringes) and tear meniscus height (TMH, mm) were conducted in the AM (prior to CL insertion for Day 2) and in the PM, after 8 hours.

Results: The mean age in the SYM and ASYM groups was 31 ± 11.3 yrs (12 females and 3 males), and 37 ± 14.7 yrs (8 females and 7 males), respectively. In the AM: there was no significant difference in TF parameters between eyes or between study days for either group (all $p > 0.05$).

In the PM, after 8 hours: there was no significant difference in TF parameters between eyes on Day 1 (all $p > 0.05$). Day 2 showed significantly lower NIBUT, LLT and TMH in the CL-wearing eye compared to the fellow non-CL wearing eye in both SYM and ASYM groups (all $p < 0.05$).

In the SYM group, the non-CL wearing eye on Day 2 showed longer NIBUT (mean: 7.8 ± 5.9) and better LLT (mean: 3.7 ± 0.2) compared to the same eye on Day 1 (mean NIBUT: 5.0 ± 1.5 ; mean LLT: 3.3 ± 0.7). The difference, however, did not reach statistical significance ($p = 0.07$ for NIBUT and $p = 0.16$ for LLT). TMH was similar between study days ($p = 0.98$).

In the ASYM group, NIBUT, LLT and TMH were similar for the non-CL wearing eye on Day 2 (mean NIBUT: 10.3 ± 6.9 ; LLT: 3.3 ± 1.0 ; TMH: 0.21 ± 0.1) compared to the same eye on Day 1 (mean NIBUT: 10.6 ± 6.6 ; LLT: 3.5 ± 0.9 ; TMH: 0.22 ± 0.1); all $p > 0.05$.

Conclusions: Monocular lens wear resulted in differences between eyes for NIBUT, LLT and TMH, suggesting that these TF parameters are influenced by the interaction of the TF with the CL, but not through an inter-eye interaction. In SYM CL wearers, there was a trend for the non-CL wearing eye to exhibit longer NIBUT and better LLT, potentially to counteract the effects of CL wear in the fellow eye.

ABSTRACT BODY:

Purpose: Non-swelling, biodegradable poly(ethylene glycol)-based oligo-tetra-hydrogels have shown potential as a vitreous substitute with regard to their physical properties. However, for clinical application of this technology, the host response when the material is implanted must be well understood. This study was conducted to investigate in vitro macrophage reactions to oligo-tetra-hydrogels.

Methods: A degradable oligo-tetra-hydrogel, in which the polymers contain hydrolysable bonds, and a non-degradable oligo-tetra-hydrogel were evaluated. Each type of oligo-tetra-hydrogel was incubated in phosphate-buffered saline (PBS) at 45°C for 0, 18, or 25 days. Then, mouse macrophage-like RAW264.7 cells were cultured indirectly with each prepared hydrogel, which was inserted into the culture medium on a porous membrane insert, for 48 h at 37°C. The cells were also cultured in the presence of PBS or lipopolysaccharide as a negative and positive control, respectively. Viability of the RAW264.7 cells was determined by a Cell Counting Kit-8 assay, and their TNF- α production level was quantified by enzyme-linked immunosorbent assay. Student's t-test was used for statistical analysis of the results, and statistical significance was defined as P less than 0.05.

Results: The degradable oligo-tetra-hydrogel became completely degraded in 25 days at 45°C. Thus, RAW264.7 cells were exposed to the degradation products released from the hydrogel. Neither the degradable nor the non-degradable oligo-tetra-hydrogels had any effect on viability of the RAW264.7 cells during the 48-h incubation; relative cell viability of the hydrogel groups did not differ significantly from the control (degradable, P = 0.12; n = 3; non-degradable, P = 0.20; n = 3; Student's t-test). In addition, the level of TNF- α production was not significantly increased by either degradable or non-degradable hydrogels (control = 0.9 ± 0.13 pg/ μ g protein; degradable = 1.2 ± 0.41 pg/ μ g protein, P = 0.32; n = 3; non-degradable = 1.1 ± 0.85 pg/ μ g protein, P = 0.15; n = 3; Student's t-test).

Conclusions: These results show that macrophages were not activated by oligo-tetra-hydrogel degradation products, and they suggest that oligo-tetra-hydrogels are promising candidates for use as a biocompatible artificial vitreous body.

ABSTRACT BODY:

Purpose: Diabetic macular edema (DME) is a multifactorial disease, and best-achievable visual responses to anti-VEGF monotherapy are difficult to achieve and maintain in clinical practice. Dual inhibition of angiopoietin-2 and VEGF-A with faricimab, the first bispecific antibody designed for intraocular use, may synergistically promote vascular stability and improve outcomes in DME. Herein we describe the design and rationale of the phase 3 YOSEMITE and RHINE trials, which assessed the safety, efficacy, and durability of faricimab in patients with DME.

Methods: YOSEMITE (NCT03622580) and RHINE (NCT03622593) are identical, randomized, double-masked, active comparator-controlled, 100-week, phase 3 trials of faricimab in DME. Treatment-naïve or previously anti-VEGF-treated patients with center-involving DME were randomized 1:1:1 to faricimab 6.0 mg every 8 weeks (Q8W) after 6 initial Q4W doses; faricimab 6.0 mg per personalized treatment interval (PTI) after 4 initial Q4W doses; or aflibercept 2.0 mg Q8W after 5 initial Q4W doses. Dosing intervals in the PTI arm were determined by an automated algorithm, and could be reduced or extended by 4-week increments (from Q4W up to Q16W) according to prespecified BCVA and CST criteria at active dosing visits. The PTI algorithm is based on the treat-and-extend concept, and was designed to enable personalized therapy for DME, reduce injection frequency, and potentially optimize real-world outcomes.

Results: Safety and efficacy were assessed Q4W through week 100. To account for differences in time from last treatment and BCVA variability, the primary efficacy endpoint was mean change in BCVA from baseline averaged over weeks 48, 52, and 56. Secondary endpoints included the proportion of patients with ≥ 2 -step ETDRS-DRSS improvement at week 52, change in CST from baseline, and the proportion of patients in the PTI arm receiving Q4W, Q8W, Q12W, or Q16W dosing at 1 year. Safety outcomes included the incidence and severity of ocular and nonocular adverse events.

Conclusions: YOSEMITE and RHINE were designed to evaluate whether dual inhibition of angiopoietin-2 and VEGF-A with faricimab may improve outcomes beyond anti-VEGF monotherapy in patients with DME. The PTI arm will examine the potential for individualized faricimab therapy, tailored according to patient needs, to reduce treatment burden while maintaining efficacy.

ABSTRACT BODY:

Purpose: We previously reported that topical treatment with 1.0% topical dorzolamide was effective in 59.1% patients with cystoid macular edema secondary to retinitis pigmentosa (RP-CME). However, the rate of RP-CME recurrence during follow-up have not been fully characterized. The purpose of this study is to investigate the recurrence rate of RP-CME after an initiation of topical dorzolamide and its risk factors.

Methods: We retrospectively reviewed the data of RP patients who was diagnosed as having RP-CME and treated with topical 1.0% dorzolamide 3 times a day from the electronic medical records. Patients who showed a treatment response to topical 1.0% dorzolamide, defined as the resolution of foveal cysts or >20% reduction of central subfield thickness (CST) from baseline in optical coherence tomography (OCT), were included in this study. The day of treatment initiation was set as the baseline and topical dorzolamide treatment was continued during follow-up. At each follow-up visit, the recurrence of RP-CME (defined as a reappearance of foveal cyst; >20% increase in CST compared to previous visit; or CST exceeding baseline) was evaluated. Risk factors for the recurrence were analyzed by Cox proportional hazards modeling. Kaplan-Meier survival analysis was used to evaluate the time to recurrent RP-CME.

Results: 40 RP-CME patients showed a treatment response to topical 1.0% dorzolamide.

During the mean 3.9-yr follow-up, 21 patients showed recurrent RP-CME. The recurrence rate of RP-CME was 20.2% at 1 year increasing to 46.3% and 57.8% at 3 and 5 years, respectively. High baseline central subfield thickness was significantly associated with recurrent RP-CME (hazard ratio [HR], 1.09 per 10 μ m increase; 95%CI, 1.03–1.14; $p=0.001$).

Conclusions: The recurrence rate of RP-CME increases during the follow-up periods. High baseline CST was a risk factor of recurrent RP-CME.

ABSTRACT BODY:

Purpose: We previously reported that downregulation of TNFRSF10A, a susceptibility gene for age-related macular degeneration (AMD) and central serous chorioretinopathy (CSC), can cause retinal pigment epithelium (RPE) cell death in vitro and Tnfrsf10knockout mice. In this study, we investigated the molecular mechanism of RPE cell death associated with TNFRSF10A downregulation.

Methods: All in vitro experiments were performed using primary fetal human RPE (hRPE) cells. After transfection with siRNA targeting TNFRSF10A, we treated the cells with or without different cell death inhibitors or phorbol 12-myristate 13-acetate (PMA), a PKC activator, and cell viability change were evaluated by Cell Counting Kit-8 and staining with FITC-conjugated annexin V/PI followed by flow cytometric analysis. Realtime RT-PCR was performed to examine the transcriptional levels of cell cycle regulatory proteins in the cells.

Results: Knockdown of TNFRSF10A by siRNA significantly reduced RPE cell viability and increased the percentages of annexin V+/PI- early apoptotic cells ($P<0.0001$). PMA inhibit the cell death induced by TNFRSF10A knockdown, while apoptosis inhibitors, a necroptosis inhibitor, a ferroptosis inhibitor and a pyroptosis inhibitor did not. TNFRSF10A knockdown changed mRNA levels of cell cycle regulatory proteins, downregulation of cyclinA1 ($P<0.05$) and upregulation of p27 ($P<0.005$), which were reversed by PMA treatment.

Conclusions: TNFRSF10A downregulation may contribute to the pathogenesis of AMD and CSC by promoting RPE cell death via PKC pathway.

ABSTRACT BODY:

Purpose: Characterization of clinician-scientists and identification of success predictors may help to develop grant policies that maintain the viability of this career pathway in ophthalmology. The current survey study analyzed responses from a cohort of clinician-scientists in ophthalmology and identified factors associated with successful research funding, income, and career satisfaction.

Methods: A cross-sectional survey study of clinician-scientists in ophthalmology at U.S. academic institutions conducted between April 17 and May 19, 2019. Collected information include 1) demographic data, 2) amount, type, and source of startup funding, first extramural grant, and first R01-equivalent independent grant, 3) starting and current salaries, and 4) Likert-scale measures of career satisfaction. Multivariate regression analyses were used to evaluate factors associated with time to receiving R01-equivalent independent funding, salary, and career satisfaction measures.

Results: 98 clinician-scientists in ophthalmology were surveyed across different ages (mean 48±11 years), research categories, institutional types, geographic regions, and academic ranks. Median startup funding was \$50-99k, and median starting salary was \$150-199k. Most investigators (67%) received their first extramural award from the National Eye Institute mostly through K-award mechanisms (82%). The median time to receiving their first independent grant was 8 years, mostly through an R01 award (70%). Greater institutional startup support ($P = 0.048$) and earlier extramural grant success ($P = 0.035$) were associated with earlier independent funding. Male gender ($P = 0.038$) and MD degree ($P = 0.039$) were associated with higher current salaries, but not starting salaries. Overall career satisfaction increased with career duration ($P = 0.003$), but not with earlier independent funding ($P = 0.533$) or higher income ($P = 0.403$).

Conclusions: Success in research funding by clinician-scientists in ophthalmology may be linked to institutional support and earlier acquisition of extramural grants, but does not impact academic salaries. Nevertheless, career satisfaction among clinician-scientists improves with time, with little impact from research or financial success.

ABSTRACT BODY:

Purpose: To determine if online medical education for ophthalmologists (Opht) could improve their knowledge, competence and confidence to diagnose and treat children with ocular manifestations of nephrotic cystinosis

Methods: Participants completed a 3-item questionnaire plus a confidence assessment before and after watching a 30-minute multispeciality expert roundtable discussion with accompanying slides. A matched pair design was used pre-/post-assessment, with scores compared to assess changes in the proportion of correct responses. A chi-squared test assessed statistical significance at the $P < .05$ level. Launch Jun 18, 2020; data through Aug 8, 2020. Assessment completers: 239

Results: An average of 44% of Opht responses on pre-assessment were correct, increasing to 66% on post-assessment ($p < .001$). The activity significantly increased knowledge of ocular manifestations of nephrotic cystinosis in children, including molecular genetics aspects (pre: 28%, post: 47%, $p < .001$). Diagnostic competence improved, measured in choosing the best diagnostic approach to examine cystine crystal deposition in an applied patient case (pre: 70%, post: 84% $p < .001$). Treatment competence increased for therapy and application choice for the same case, choosing topical cysteamine eye drops over a systemic dose increase, anti-inflammatory or antibiotic topical treatment (pre: 32%, post: 68%, $p < .001$). 54% of Opht had a measurable increase in confidence in their ability to treat ocular manifestations of cystinosis.

Conclusions: Nephrotic cystinosis is a rare inherited disease, diagnosis and specific treatment are frequently delayed with a significant impact on overall prognosis. Corneal cystine deposition is visible by slit lamp biomicroscopy and can lead to photophobia, blepharospasm, superficial punctate keratopathy and recurrent corneal erosions. To deplete deposition additional topical cysteamine treatment is required to reach the avascular cornea. Online medical education in the form of an multispeciality expert roundtable discussion with accompanying slides can significantly improve rare disease knowledge and diagnostic, and therapeutic competence and confidence. Additional education is warranted to shorten time to diagnosis for ocular manifestations of nephrotic cystinosis and share data for emerging therapies.

ABSTRACT BODY:

Purpose: To assess vision and anatomic outcomes in patients with nAMD and the requirement for IVT-AFL treatment more frequently than every 8 weeks (w).

Methods: ARIES (NCT02581891) was a multicenter, randomized, Phase 3b/4 study that compared the efficacy of 2 IVT-AFL T&E regimens over 2 years (Y) in treatment-naïve nAMD patients. Patients were determined as I-I if the study investigator identified need for treatment more frequently than every 8w and if patients had ≥ 1 treatment interval of 4 or 6w after 3 initial monthly doses. This was a post-hoc analysis of patients enrolled in ARIES and statistical analysis is descriptive.

Results: The full analysis set comprised 269 patients (treatment arms combined). Overall, 23.0% (n=62) of patients were determined as I-I; 13.8% (n=37) in Y1 and 9.3% (n=25) in Y2. There were no relevant differences in baseline characteristics between I-I and non-I-I patients. Time from IVT-AFL initiation to the visit where patients were determined I-I varied considerably (range: 16–100w; median: 43.2w). Mean treatment interval was 8.4w before patients were determined as I-I and 6.1w following I-I determination. Mean (SD) best-corrected visual acuity (BCVA) was lower and central retinal thickness (CRT) was higher in I-I patients at the visit when they were determined I-I compared with w16 (BCVA: 61.9 [16.7] vs 65.7 [12.6] letters; CRT: 410.7 [112.3] vs 379.0 [112.6] μm). With treatment more frequent than every 8w, these patients showed BCVA (62.6 [18.7] letters) and CRT (336.8 [101.0] μm) improvements at w104. Improvements in vision from baseline (BL) to w104 were smaller for I-I patients than non-I-I

patients (+2.3 [15.6] vs +5.9 [12.3] letters). Anatomic outcomes at w104 were similar between I-I and non-I-I patients (CRT change from BL: -160.4 [154.0] μm and -167.0 [136.1] μm). Overall, 59.7% of patients achieved treatment intervals of $\geq 8\text{w}$ following I-I determination.

Conclusions: The need for IVT-AFL treatment more frequently than every 8w may arise at various points over the course of nAMD treatment. Up to 1 in 4 patients may require more intensive treatment than every 8w. These patients showed improvements in vision and anatomic outcomes. For most, treatment intervals could be extended to $\geq 8\text{w}$ following I-I determination.

Chan: Commercial Relationship: Code N (No Commercial Relationship) | Vincent Mok: Commercial Relationship: Code N (No Commercial Relationship) | Carol Y. Cheung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The retina is a non-invasive channel for assessing changes in brain microvasculature, which has been implicated in the pathophysiology of Alzheimer's disease (AD). Previous studies revealed significant relationship between clinically diagnosed AD and retinal vasculature. However, clinical diagnosis has limited sensitivity and specificity, and those analyses were conducted from a limited view of the fundus. This cross-sectional study aims to determine changes in vasculature from a larger area of the retina between subjects with Positron Emission Tomography (PET) biomarker-confirmed AD compared to controls.

Methods: Participants were recruited from the community and Cognitive Disorder Clinic of Prince of Wales Hospital, Hong Kong. All subjects received ^{11}C -Pittsburgh compound B (PIB) and ^{18}F -T807 intravenously 35- and 85-minutes before PET scan, respectively. Uptake was quantified by global cortical to cerebellum Standard Uptake Value Ratio (SUVR). Significant amyloid beta ($\text{A}\beta$) burden was defined as increased PIB uptake in regions historically known to have $\text{A}\beta$ deposits in AD patients or $\text{SUVR} \geq 1.42$. Significant tau level was defined as increased ^{18}F -T807 uptake in regions previously known to have tau deposits in AD patients or $\text{SUVR} \geq 1.14$. Retinal imaging was performed with ultra-wide field scanning laser ophthalmoscopy (UWF-SLO). The retinal vasculature was analysed and quantified using semi-automated Singapore I Vessel Assessment (SIVA) software. Independent t-test and multivariable logistic regression analyses were performed to determine cross-sectional relationship of retinal vessel parameters with presence of cerebral $\text{A}\beta$ and Tau, adjusted for age, gender and systolic blood pressure.

Results: Out of the 39 patients, 20 were found to have significant cerebral level of either $\text{A}\beta$ or Tau on PET. Individuals with radiologically confirmed AD (i.e. A+ T+) showed significantly smaller arteriolar fractal dimension (1.32 v 1.38, $p=0.006$), compared with controls (i.e. A- T-). Presence of significant $\text{A}\beta$ and Tau burden was correlated with lower arteriolar fractal dimensions (odds ratio [OR] per SD decrease 0.26 [95% CI 0.09-0.78] $p=0.02$), which was not seen in controls.

Conclusions: Reduction of fractal dimension in retinal arterioles observed in UWF imaging are associated with cerebral PET $\text{A}\beta$ and Tau burden. Our results support that retinal imaging can indicate microvascular alterations related to AD.

TITLE: Examining the Effects of Glaucoma Medications on the Trabecular Outflow Pathway Using Glauconix Bioscience's 3D-HTM™ Tissue Constructs

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Unser, F. Ahmed, H. Afzaal, H. Williams, K.Y. Torrejon, Glauconix Biosciences, Albany, New York, UNITED STATES|H. Afzaal, SUNY Polytechnic Institute, Albany, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrea Unser: Commercial Relationship(s);Glauconix Biosciences:Code E (Employment) | Feryan Ahmed: Commercial Relationship(s);Glauconix Biosciences:Code E (Employment) | Hira Afzaal: Commercial Relationship(s);Glauconix Biosciences:Code E (Employment) | Hunter Williams: Commercial Relationship(s);Glauconix Biosciences:Code E (Employment) | Karen Torrejon: Commercial Relationship(s);Glauconix Biosciences:Code E (Employment)

ABSTRACT BODY:

Purpose: Commonly prescribed glaucoma medications decrease the production of aqueous humor (β -blockers such as timolol) or increase the outflow of aqueous humor (Prostaglandin analogs such as latanoprost and bimatoprost) or both (alpha agonists such as brimonidine). With the exception of bimatoprost, each class of medication focuses mainly on facilitating uveoscleral outflow. This study further explores the effects of these medications on 3D- HTM tissue constructs that mimic the human trabecular outflow pathway, which is responsible for most of the aqueous humor drainage and shown to be affected in glaucoma patients.

Methods: Bioengineered human trabecular meshwork (3D-HTM™) tissue constructs were cultured to confluence, treated with TGFb-2 (5 ng/mL) for 6 days to induce a glaucomatous-like state. These diseased constructs were then exposed to 10mM brimonidine, bimatoprost, timolol, and latanoprost for 3 days. The responsiveness of these molecules under flow was investigated by perfusion studies using a 24-multichannel microfluidic system that constantly monitors pressure across the tissue constructs (N>4 per donor). The “outflow facility” was determined by the ratio of $\Delta(\text{flow rate})/\Delta(\text{pressure})$. An increase in outflow facility is correlated to a decrease in IOP.

Results: Of the four compounds studied, three of them significantly increased outflow facility in the following order: bimatoprost (*P<0.05) < latanoprost (**P<0.01) < timolol (****P<0.0001). Brimonidine did not significantly affect outflow facility in this model.

Conclusions: We report here that commonly prescribed eye drops including bimatoprost, latanoprost and timolol significantly increased outflow facility of glaucomatous 3D-HTM™; thereby indicating an alternative mechanism of action for these compounds through the trabecular meshwork. Further studies are currently ongoing to better understand how these treatments are affecting the trabecular meshwork.

TITLE: Ceria-coated melanin as a novel antioxidant for age-related macular degeneration

SESSION TITLE: AMD: Clinical and translational research I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Kwon, M. Zheng, Z. Han, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yongsu Kwon: Commercial Relationship: Code N (No Commercial Relationship) | Min Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Zongchao Han: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Excessive oxidative stress leads to nonspecific inflammation and is a major cause of pathogenesis of both wet and dry forms of age-related macular degeneration (AMD). Melanin is naturally present in pigmented tissues, such as the retinal pigment epithelium (RPE) in eyes, and has a strong ability to scavenge a broad range of free radicals. By combining melanin with nanoceria to take advantage of nanoceria's auto-regenerative antioxidant property, we have developed a novel nanoceria-coated melanin antioxidant (CCM) which can potentially achieve long-term effects through a single-dose administration and relieve pathological damages for AMD.

Methods: We introduced ceria nanoparticle on the melanin matrix for its auto-regenerative activity and demonstrated the size, shape, charge, and elemental composition through analytic methods, including TEM, DLS, and EDS. We investigated antioxidant and free radical scavenging by using DPPH, Evans blue bleaching, and Amplex red assays. Furthermore, we evaluated the cell cytotoxicity and antioxidative properties of melanin and CCM in vitro using a H_2O_2 -induced oxidative stress in mouse primary RPE cells (mRPE) through various biological experimental techniques.

Results: Melanin and CCM were characterized by different physicochemical techniques. The TEM of melanin was shown uniform nanospheres with an average diameter of ~100 nm. Cerium ions were effectively chelated with catechol groups in melanin matrices and grown to cerium oxide (~5 nm scale), which was clearly shown on the surface of melanin matrix through elemental mapping images. Notably, CCM was explored as highly water stable over 9 months (last time checked) at room temperature. Compared with melanin, CCM showed enhanced antioxidant activities with auto-regenerative properties against the deleterious effects of a broad range of reactive oxygen and nitrogen species (RONS). Furthermore, the cell viability toward the mRPE cells was above 80 % after 48 hours exposure of melanin or CCM, indicating that they are safe and well tolerated.

Conclusions: CCM can protect mRPE cells not only from chemically induced oxidative stress by scavenging a broad range of RONS molecules, but also has the ability to continually scavenge free radicals, owing to the added auto-regenerative property. The newly developed CCM is biocompatible and can be used as a robust antioxidant to attenuate pathological damages in AMD.

TITLE: CD147 contributes to maintain a nonkeratinized squamous epithelium in cornea

SESSION TITLE: Corneal epithelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: P. Argueso, A.M. Woodward, M.N. Feeley, J. Rinaldi, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Pablo Argueso: Commercial Relationship: Code N (No Commercial Relationship) | Ashley Woodward: Commercial Relationship: Code N (No Commercial Relationship) | Marissa Feeley: Commercial Relationship: Code N (No Commercial Relationship) | Jamie Rinaldi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The presence of a non-keratinized stratified squamous epithelium protects organs that are in close contact with the external environment and regularly exposed to physical abrasion. Here we investigated the contribution of CD147 to promoting the differentiation and establishment of barrier function in human corneal epithelial cells.

Methods: CRISPR/Cas9-mediated gene editing was used to produce a human corneal epithelial cell line lacking CD147 expression. Transmission and scanning electron microscopy were used to investigate the ultrastructure of differentiated cell cultures. Protein biosynthesis and localization were determined by immunoblotting and immunofluorescence, respectively. The analysis of genes encoding for tight junction proteins was carried out using a human tight junction PCR array. Epithelial cell permeability was evaluated by transepithelial electrical resistance and rose bengal penetrance.

Results: Cell cultures lacking CD147 change shape and fail to produce a flattened squamous layer on the apical surface. This process is associated with the decreased biosynthesis of MUC16 and involucrin. Expression analysis of genes encoding tight junction proteins indicates that CD147 promotes the physiological expression of occludin and members of the claudin family. Functionally, disruption of CD147 expression leads to increased epithelial cell permeability as evidenced by the decrease in transepithelial electrical resistance and increase in rose bengal flux.

Conclusions: CD147 plays a distinctive role in maintaining the normal differentiation of stratified squamous corneal epithelium under homeostatic conditions.

ABSTRACT BODY:

Purpose: Sleep loss (Stone et al., 2019, doi: 10.1113/JP277779) and alcohol (Tyson et al., 2020, doi: 10.1113/JP280395) have been shown to impair smooth pursuit and its underlying visual motion processing in humans. This study examines the saccadic compensation for this poor pursuit.

Methods: Using an established behavioral ocular-tracking paradigm (Liston & Stone, 2014, doi: 10.1167/14.14.12), we examined the dose-response of ground lost (pursuit deficit integrated across our 300-ms steady-state tracking interval) and ground gained (increased saccadic response harnessed to compensate) across three separate studies – acute low-dose alcohol administration (LDA; n = 16 subjects), acute sleep loss (ASL; n = 12), and chronic sleep restriction (CSR; n = 12). We computed dose-responses as the linear regression slopes of ground lost and gained across treatment dose (% blood alcohol concentration [BAC] or hours awake). For the CSR study, we computed the mean effect for a single dose (5-hours nightly sleep for 1 week).

Results: For LDA, there was significantly increased ground lost ($P < 0.001$) and gained ($P < 0.001$) with increased %BAC. In addition, the dose-responses were not significantly different ($P = 0.35$), indicating effectively complete saccadic compensation due to significant increases in both saccadic rate ($P < 0.05$) and amplitude ($P < 0.001$). For ASL, there was significantly increased ground lost with time awake ($P < 0.01$), however ground gained was significantly lower ($P < 0.001$), indicating, at best, incomplete compensation due to a significant increase in saccadic rate ($P < 0.001$) but not amplitude ($P = 0.10$). With CSR, pursuit was again significantly impaired ($P < 0.05$), with saccadic rate significantly increased ($P < 0.05$) but, surprisingly, amplitude was significantly decreased ($P < 0.05$), effectively eliminating ground gained ($P = 0.90$).

Conclusions: Our analyses show that LDA, ASL, and CSR affect tracking differently, suggesting the involvement of different brain pathways. With LDA, the effect appears largely due to the cortical impairment of visual motion processing with largely healthy brainstem and mid-brain responses (driving effective saccadic compensation). ASL and CSR however appear to affect both cortical and sub-cortical pathways, with at best partial saccadic compensation. Lastly, CSR is associated with an additional compromise due to a maladaptive decrease in saccade amplitude.

ABSTRACT BODY:

Purpose: Due to scarcity of eligible participants, treatment trials for rare inherited retinal diseases often employ the contralateral eye as an internal control. However, for people with Bietti Crystalline Dystrophy (BCD), there is uncertainty as to whether disease extent and course in one eye reflects that in the other. Therefore, we performed an observational clinical study with prospective and retrospective data aimed at evaluating the inter-eye symmetry of anatomical features and functional vision in individuals with BCD, with a focus on the number, area, and distribution of the characteristic retinal crystalline deposits.

Methods: Thirteen Australian and New Zealand participants with confirmed biallelic CYP4V2 mutations and a characteristic BCD fundus appearance underwent comprehensive multimodal clinical examination. Crystals visible on color fundus photography were manually counted and superimposed onto aligned fundus autofluorescence imaging. The distribution of fundus crystals and their phenotypic associations with areas of absent autofluorescence (absent-AF) were then analyzed. Spearman's correlation coefficients (ρ), intraclass correlation coefficients (ICCs), and Bland-Altman plots were used to quantify symmetry of functional and imaging parameters between eyes.

Results: Median participant age was 48 years, interquartile range 40–60 years. Nine (69%) were female, and five (38%) were of East Asian descent. Distance visual acuity ranged from 20/16 to light perception. Crystal density was higher in the foveal region, and decreased in the periphery. The peripapillary region and areas of well-demarcated absent-AF contained few crystals. Inter-eye correlation was high for fundus crystal area ($\rho=1.00$, 95% CI 1.00–1.00; ICC=0.97, 95% CI 0.88–0.99), fundus crystal count ($\rho=0.98$, 95% CI 0.92–1.00; ICC=0.97, 95% CI 0.89–0.99), and absent-AF area ($\rho=0.88$, 95% CI 0.53–0.98; ICC=0.98, 95% CI 0.90–0.99). Average foveal volume was moderately correlated between eyes ($\rho=0.73$, 95% CI 0.18–0.93; ICC=0.85, 95% CI 0.53–0.96). No significant correlation was found for foveal crystal count and area, average or central foveal thickness, best corrected visual acuity, and average macular or central foveal sensitivity.

Conclusions: This study demonstrated strong inter-eye symmetry measured by fundus crystal area, fundus crystal number, and absent-AF area. This data may influence the choice of outcome measures of future therapeutic trials for BCD.

ABSTRACT BODY:

Purpose: Tear film dynamics with soft contact lens (SCL) use remains poorly understood. Herein, we report a novel phenomenon wherein a portion of the silicone hydrogel (SH) SCL causes tears to move from the peripheral area to the center of the posterior SCL surface after an eye blink.

Methods: 100 eyes of 50 regular SH SCL users [Dailies Total 1 (DT1), Alcon and One-Day Acuvue-True-Eye (TE), Johnson & Johnson; 10 men, 40 women; average age, 33.41 years old] were analyzed with Video Placido topography Keratograph 5M (Oculus) and DR-1 α tear interferometer (Kowa, Japan). At visit 1 (v1), measurements were performed for the bare eye and for the eye with SCL in place after 15 min. At visit 2 (v2), which was scheduled 30 \pm 5 days after v1, measurements were performed after the SCL had been in place for a minimum of 5 h.

Results: In TE, thin aqueous layer break (TALB) which is unusual tear film break-up pattern in normal eyes was seen in 87% in v1 and 67% in v2 with DR-1 α . In eyes with TALB, Keratograph 5M detected no tear change in front of the SCL. Furthermore, in 72% of eyes with TALB, the brightness of the Placido ring on Keratograph 5M gradually increased from the periphery toward the center in the absence of tears on the SCL at least 6 seconds after eye blink. This finding captures the phenomenon of tear movement from the edge of SCL toward the center of the posterior SCL surface. In DT1, TALB was seen in 18% in v1 and 12% in v2. In bare eyes, TALB was not observed (0%).

Conclusions: This is the first study on tear film dynamics on the posterior surface of SCLs. Water gradient structure used in DT1 was useful for reducing TALB.

ABSTRACT BODY:

Purpose: Oxidative stress has been implicated in the pathophysiology of glaucoma; however, the biological mechanisms by which oxidative damage causes retinal ganglion cell (RGC) death remain to be elucidated. We previously reported that oxidative DNA damage triggers microglial activation and retinal degeneration via the activation of MutY Homolog (MUTYH), a DNA damage-associated glycosylase, in experimental retinitis pigmentosa. In the present study, we investigate the role of MUTYH in RGC cell death induced by N-methyl-D-aspartate (NMDA).

Methods: Mutyh^{-/-} mice and age-matched wild-type (WT) mice was employed in a model of NMDA-induced retinal excitotoxicity. Eight nM NMDA was intravitreally injected in the mouse eyes. Immunohistochemical analysis was performed using anti-8-hydroxy-deoxyguanosine (8-oxoG) monoclonal antibody (a marker of oxidative DNA damage), anti-Brn3a antibody (a marker of RGC), anti-Iba-1 antibody (a marker of microglia), and anti-ssDNA antibody [a marker of single strand breaks (SSBs)] at 24 hours and 7 days after injection.

Results: Substantial microgliosis and RGC loss were observed in the eyes of NMDA-injected WT mice. In contrast, Mutyh deficiency significantly reduced the density of microglia (P = 0.0152) and attenuated the RGC loss (P = 0.0021). Moreover, 8-oxoG was accumulated within the nucleus of microglia after 24 hours to 7 days and SSBs were developed in WT mice. In contrast, Mutyh deficiency prevented SSBs formation following NMDA-induced oxidative DNA damage.

Conclusions: MUTYH activation associated with oxidative DNA damage accelerates microgliosis and RGC cell death in NMDA-induced retinal excitotoxicity.

ABSTRACT BODY:

Purpose: We conducted a multicenter retrospective study to investigate potential risk factors for recurrence in patients with central serous chorioretinopathy (CSC).

Methods: The study was performed at 8 medical institutions from 2008 to 2020 in Japan on patients who had experienced an active episode of CSC. Exclusion criteria included indications of choroidal neovascularization (CNV), polypoidal choroidal vasculopathy (PCV), and any other ophthalmology related disease. Demographic data and medical history, including age, gender, best corrected visual acuity (BCVA), spherical equivalent, fellow-eye status, history of corticosteroid use or smoking, frequency of recurrence, and treatment choices were noted. In addition, significant differences in central retinal thickness, subfoveal choroidal thickness, chronic manifestation, numbers of leakage points, leakage intensity (intense/subtle), leakage sites in the inner or outer foveal avascular zone (FAZ), and choroidal hyperpermeability were analyzed as between recurrence and non-recurrence groups.

Results: Six hundred forty (640) of 699 patients with CSC (700 eyes; 478 males, 162 females; mean age 52.7 ± 12.1 years) were enrolled by application of the exclusion and inclusion criteria. Among these 640 patients, 323 (50.5%) presented ≥ 1 recurrence. The average time to the first recurrence was 35.8 ± 45.8 months (range 1-360 months), and the mean frequency of recurrence was 1.16 ± 0.50 .

There were no statistically significant differences in age or gender distribution, smoking history, BCVA at baseline and final visit, spherical equivalent, central retinal thickness, leakage site, or subfoveal choroidal thickness between the recurrence and non-recurrence groups. Nevertheless, history of corticosteroid use ($P = 0.0003$), bilateral CSC ($P < 0.0001$), non-therapy ($P < 0.0001$), chronic performance on FAF ($P < 0.0001$), ≥ 2 leakage points ($P = 0.0014$), and subtle fluorescein leakage ($P = 0.0309$) were significantly related to an increased risk of recurrence.

Conclusions: Knowledge of these data and multiple risk factors serving as predictors might aid in early detection or intensive treatment for patients with CSC at high risk of recurrence.

ABSTRACT BODY:

Purpose: To compare the characteristics of central serous chorioretinopathy (CSC) with and without choroidal neovascularization (CNV) at final visit on optical coherence tomography angiography (OCTA) at multiple centers.

Methods: The subjects were 292 eyes of 264 patients (188males, 76 females, 52.0 ± 11.8 years) who were diagnosed with CSC at 6 JCREST participating institutions from 2016 through 2019 and underwent OCTA at the first and final visits. We excluded patients with CNV at first visits. On the basis of clinical assessment by OCTA detection of the presence of CNV at final visit, patients with CSC were divided into two groups (CNV group and non-CNV group).

We examined gender, age, spherical equivalent, best corrected visual acuity (BCVA), subfoveal retinal thickness, choroidal thickness, the presence or absence of recurrence during the course, and whether patients were acute or chronic CSC. Recurrence was defined as the emergence of new subretinal fluid following complete regression of the previous CSC episode. Acute CSC was characterized as the presence of visual symptoms for less than 6 months.

Results: During the three-year follow-up, secondary CNV at final visit was presented in 21 eyes (7.2%) based on the OCTA, whereas 271 eyes (92.8%) in non-CNV group. CNV group appeared worse visual acuity at final visit and older age, which were significantly different from the non-CNV group ($P = 0.002$, $P = 0.033$, respectively). In addition, 13 eyes (61.9%) was regarded as chronic CSC in CNV group, and 104 eyes (38.4%) in non-CNV group with statistical significance ($p = 0.034$). On the other hand, the recurrence rate and recurrence frequency in CNV group were 76.2% and 1.63 ± 0.81 , separately ($P = 0.035$, $P = 0.0018$) which were significantly higher than those in non-CNV group.

Conclusions: CNV appears in 7.2% of CSC patients in long-term follow-up. Patients with CNV secondary to CSC had older mean age, poor visual acuity, higher rates of chronic CSC and recurrence than patients without CNV.

ABSTRACT BODY:

Purpose: Not only ophthalmologists but also non-ophthalmologists often prescribe eye drops for allergic conjunctival diseases (ACDs); however, there are many cases that are treated without sufficient examination and diagnosis of the eyes. We have invented a portable, recordable, and smartphone-attachable slit-lamp device, called the Smart Eye Camera (SEC). The purpose of this study was to compare the diagnostic abilities of ACDs between the SEC and the conventional, non-portable slit-lamp microscope.

Methods: This prospective observational study included thirty-two eyes of 17 Japanese patients (mean age: 21.5±14.8 years; range: 11-51 years; female: 5). The severity of ten objective signs in the palpebral conjunctiva, bulbar conjunctiva, limbus and cornea were scored on a grading scale of 0 to 4 (0 = normal; 1+ = mild; 2+ = moderate; 3+ = severe), respectively. First, two ophthalmologists used the conventional slit-lamp microscope to examine the grade of the ACDs. Second, another ophthalmologist filmed the eyes in video mode by the SEC and two other ophthalmologists evaluated the grades on another day. The correlation and inter-rater reproducibility in total scores of ten objective signs among two devices were determined.

Results: Total scores of clinical signs evaluated by the two approaches showed a strong correlation with statistical significance (both eyes: $r = 0.918$ [95%CI: 0.839 to 0.959; $p < 0.001$]). Inter-rater agreement was substantial (weighted κ value = 0.631 [95%CI: 0.601 to 0.661; $p < 0.001$]).

Conclusions: This study suggests that the SEC is as reliable as the conventional non-portable slit-lamp microscope for evaluating ACDs.

McLaughlin, Illinois College of Optometry, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lydie Tubene: Commercial Relationship: Code N (No Commercial Relationship) | Mallory McLaughlin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Humphrey Visual Field (HVF) testing presents challenges for patients with limited mobility. Virtual reality-based visual field testing could provide a practical and portable alternative for visual field testing. This study examines the agreement between Virtual Field (VF), a virtual reality-based visual field test, and HVF.

Methods: HVF SITA-Fast and VF BOLT Threshold were performed on both eyes of 40 normal subjects (age 23-66), right eye tested first. The test strategies were randomized. Subjects wore surgical masks in accordance with COVID-19 protocol. Outcome measures included mean deviation (MD), test time and visual field index (VFI). Each patient completed a survey about their experience. Eight eyes were excluded due to unreliable results (FL >20%, FP > 15%).

Results: There was not a statistical difference between the right and left eye data on a paired t-test. P-values for HVF were 0.0824, 0.7206, and 0.5663 for MD, VFI and time respectively. P-values for VF were 0.3743, 0.9821, and 0.9872 for MD, VFI and time respectively. The right and left eyes were pooled for analysis.

Average MD values were -0.19 dB for HVF and -2.38 dB for VF. Average VFI values were 99.4% for HVF and 96.2% for VF. Average test times were 176.5 sec for HVF and 194.0 sec for VF. When comparing VF to HVF, VF had mean differences (SD) of -2.18 dB (3.36), -3.2% (7.1) and 17.6 sec (39.7) in MD, VFI and time respectively. 95% CIs [-2.98, -1.40], [-4.89, -1.53], and [8.25, 26.89] respectively. All parameters were level dependent on Bland-Altman analysis with greater bias as the results deviated from normal.

The bias in MD (mean difference \pm SD) was lower for the 29 eyes that did not require trial lenses (-1.0 \pm 2.5 dB) than for the 43 eyes that required trial lenses (-3.1 \pm 4.1 dB). 95% CI [-1.90, -0.04], [-4.33, -1.80] respectively. The difference in bias between the two groups was statistically significant (p=0.0163).

There was a statistically significant difference (p = 0.0011) between subjects who reported some level of fogging on VF (61.6%) compared to the subjects who reported some level of fogging on HVF (19.4%).

Conclusions: VF results did not agree with HVF results. There was more bias between the two tests when a trial lens was required. More subjects experienced fogging of the trial lens on VF than HVF.

ABSTRACT BODY:

Purpose: A neuroprotective effect of glial cell line-derived neurotrophic factor (GDNF) was demonstrated in animal models of glaucoma. It is important to study GDNF content in the human eye and lacrimal fluid for clarification of GDNF role in glaucoma pathogenesis. However, in practice this analysis is impossible except of during surgical interventions. An age-related cataract has relatively weak influence on concentrations of neurotrophic factors. The aim of the study was to measure GDNF levels in the aqueous humor, lacrimal fluid, and blood serum in patients with age-related cataract.

Methods: Forty-seven patients (47 eyes) operated for age-related cataract were examined. Exclusion criteria were any serious ophthalmic or somatic pathology, high refractive errors. Mean age of patients was 74.0 ± 7.4 years (range 57-88 years); there were 17 men and 30 women. Collection of stimulated lacrimal fluid was performed by a pipette on the day preceding surgery; the aqueous humor of the anterior chamber and the blood were sampled during the phacoemulsification of a cataract. The concentration of GDNF was measured in the studied biological media by an enzyme immunoassay using RayBio® Human GDNF ELISA Kit (RayBiotech, USA) on a ChemWell 2910 automatic analyzer (Awareness Technology Inc., USA).

Results: Median (interquartile range) of GDNF concentration was 83 (59–119) pg/mL in aqueous humor, 196 (174–239) pg/mL in serum, and 314 (244–422) pg/mL in lacrimal fluid. In 3 cases, GDNF content in aqueous humor was less than minimum detectable value (4 pg/mL). The concentrations of GDNF in the studied biological media did not show significant correlation with each other. Only correlation of GDNF levels in lacrimal fluid and serum showed Pearson's correlation coefficient r over 0.2 ($r=0.27$, $P=0.07$).

Conclusions: In patients with age-related cataract, the median GDNF concentration in aqueous humor is more than 2 times lower than in blood serum and more than 3.5 times lower than in lacrimal fluid. The concentrations of GDNF in the studied biological media are not correlated with each other. These data could be used for comparison with those of patients with combined glaucoma and age-related cataract.

ABSTRACT BODY:

Purpose: Glaucoma is a heterogeneous group of eye diseases, which result in damage to the optic nerve causing irreversible vision loss. Current treatments for glaucoma focus on lowering intraocular pressure (IOP). However, only one-third to half of glaucoma patients have elevated IOP at the initial stages and disease progression can still occur despite adequate IOP control. Therefore, there is an urgent need to investigate novel therapeutic concepts that complement IOP regulation. We investigated novel compounds that increase cyclic GMP (cGMP) levels in retina by releasing NO and inhibiting PDE5 simultaneously. This dual mode of action may have neuroprotective potential by decreasing IOP and increasing ocular blood flow.

Methods: Candidate compounds were tested in various neuronal and epithelial cell types of the retina. cGMP response profiles were generated for each retinal cell type following compound treatment. In addition, cell viability and phagocytosis of human RPE cells were investigated upon treatment. cGMP levels in retina were determined upon treatment of ex vivo isolated mouse retina with the compounds. For in vivo studies, TOP-V122 (1%) was applied topically using a newly developed formulation in 129S6 mice. To investigate potential physiological effects of the treatment, fundus photography, optical coherence tomography and electroretinography were applied.

Results: Following compound treatment, cGMP levels increased in rMC-1, ARPE-19 and HRPEpiC cells in both time and dose dependent manner. Treatment did not affect the cell viability and phagocytosis of human RPE cells. 3-fold increased cGMP levels were measured in ex vivo isolated mouse retina upon TOP-V122 (1 μ M) treatment. The effect was not dependent on endogenous NO levels in retina, but on the presence of a functional soluble guanylate cyclase. In vivo, multiple topical applications of TOP-V122 (1%) increased cGMP levels in retina compared to the control treatment of the contralateral eye by 65% (27.87 ± 5.30 pmol/mg vs. 16.92 ± 1.67 pmol/mg, n=4, P=0.0076) without affecting retinal function.

Conclusions: Novel compounds targeting PDE5 effectively increase cGMP levels in various retinal cell types and the retina. Repeated dosing did not affect retinal function and structure. The results obtained substantially contribute to understanding the potential use of PDE5 inhibitors specifically designed for retinal neuroprotection and pave the way for future research in this area.

TITLE: Choroidal Thickness in Birdshot Chorioretinitis as Measured by Spectral Domain Optical Coherence Tomography

SESSION TITLE: Imaging of posterior segment I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Yang, Oregon Health & Science University School of Medicine, Portland, Oregon, UNITED STATES|K. Bhavsar, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sen Yang: Commercial Relationship: Code N (No Commercial Relationship) | Kavita Bhavsar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Alterations in choroidal structure may occur in various inflammatory diseases. Spectral-domain OCT (SD-OCT) with enhanced depth imaging (EDI) can better characterize the choroidal structure. This study aims to quantify choroidal thickness from acute to convalescent stage of Birdshot Chorioretinitis (BSCR) utilizing enhanced depth imaging optical coherence tomography (EDI-OCT).

Methods: A retrospective review of 38 eyes in 17 patients with BSCR was conducted and the development of 20 acute and resolution of inflammatory episodes was evaluated. Choroidal thickness was measured from the posterior edge of the retinal pigment epithelium to the choroid/sclera junction at 500- μ m intervals up to 2500- μ m temporal and nasal to the fovea.

Results: The mean age was 59 ± 9 years (range 43-74). All patients self-identified as non-Hispanic Caucasians. 14 out of 17 patients were female (82.4%). The mean flare duration time was 34 weeks (range 7-102). Eighteen (90%) active flare episodes were bilateral. Common clinical exam findings include the presence of vitreous cells in 33 (87%) of 38 eyes and choroidal lesions in all 38 (100%) eyes. The average initial subfoveal choroidal thickness during acute stage BSCR was 280 ± 103 μ m and the average subfoveal choroidal thickness at follow-up examination during convalescent stage was 230 ± 84 μ m, ($p < 0.05$).

Conclusions: We report the novel finding of statistically significant changes in subfoveal choroidal thickness from acute to convalescent stage BSCR as measured by EDI-OCT in a group of 38 eyes. Our results indicate alterations in choroidal thickness occur during active stages of inflammation and may play an important role in the pathophysiology of BSCR.

ABSTRACT BODY:

Purpose: To identify and characterise tear metabolites expression in participants with bacterial keratitis and compare these to expression in healthy controls.

Methods: Twelve tear samples were received from participants with bacterial keratitis (n = 6) at initial presentation and age (case: median age = 59; control: median age = 52; P = 0.44) and sex (case: male:female = 2:4; control: male:female = 3:3; P = 0.70) matched healthy controls (n = 6). Metabolites underwent methanol extraction from the tear samples, chromatographic separation using the Ultimate 3000 System, along with C18 Column, and Mass Spectrometry using QExactive HF. Compound discoverer software v3.1 was used for data analysis. Differential analysis was used to explore fold-change and ratio between cases and controls. The difference in m/z features was adjusted using the Benjamini-Hochberg (B-H) correction for false discovery rate (FDR) with q = 0.05.

Results: Of six cases with bacterial keratitis, two were culture negative and four were culture positive for *S. lugdunensis*, *S. pneumonia*, Multidrug-resistant *S. aureus* or *M. lacunata*. Of 47 metabolites differentially expressed, 25 were upregulated, and 22 were downregulated in the cases compared to controls. Phenylalanyl-lysine (Log_2 fold-change = 11, $P_{\text{adj.}} < 0.0001$) and adenine (Log_2 fold-change = -6.4, $P_{\text{adj.}} < 0.0001$) were the most upregulated or downregulated metabolites in the study, respectively. Purine, tryptophan and amino acid metabolism pathways were primarily observed in tears of participants with bacterial keratitis.

Conclusions: A wide range of tear metabolites was detected in tears of participants with bacterial keratitis. Biologically plausible differences between several metabolite classes such as amino acids, indoles, carbohydrates and nucleosides were observed in tears of participants with bacterial keratitis compared to healthy controls.

Stokholm, OPEN, Odense Universitetshospital, Odense, DENMARK|M. Blaabjerg, Department of Neurology, Odense Universitetshospital, Odense, DENMARK|

Commercial Relationships Disclosure (Abstract): Maria Larsen: Commercial Relationship: Code N (No Commercial Relationship) | Anne Thykjær: Commercial Relationship: Code N (No Commercial Relationship) | Frederik Pedersen: Commercial Relationship: Code N (No Commercial Relationship) | Morten Blaabjerg: Commercial Relationship: Code N (No Commercial Relationship) | Katrine Rubin: Commercial Relationship: Code N (No Commercial Relationship) | Lonny Stokholm: Commercial Relationship: Code N (No Commercial Relationship) | Jakob Grauslund: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Evidence suggests that neurodegeneration is an early event in the pathogenesis of diabetic retinopathy (DR) and, hence, an association between DR and Parkinson's disease (PD) has been proposed. In this nationwide register-based cohort study, we investigated the prevalence and incidence of PD among patients screened for DR in a Danish population-based cohort.

Methods: Cases (n=173.568) above 50 years of age with diabetes included in the Danish Registry of Diabetic Retinopathy (DiaBase) between 2013 and 2018 were matched 1:5 by gender and birth year with a control population without diabetes (n=843.599). The prevalence of PD among cases and controls was compared at index date with an odds ratio (OR). To assess the association between DR and PD, we used a cox proportional hazard model adjusted for age, gender, systemic comorbidity, marital status and medication including insulin, glucose lowering drugs, antihypertensive drugs and cholesterol lowering drugs, to calculate the hazard ratios (HR) with 95% confidence intervals (CI). The study population was followed until earliest registration of PD-event, death, migration or end of follow-up (December 31, 2018), whichever occurred first.

Results: At index date, the prevalence of PD was 0.28% and 0.44% among cases and controls, respectively. Cases with no or any level of DR (level 0-4) were thus less likely to have PD compared to controls (adjusted OR 0.79, 95% CI 0.72-0.88). The multivariate adjusted HR for the association between DR (level 0-4) and PD were 0.88 (0.78-1.00). When looking solely at DR level 0 and 1-4, the adjusted HR were 0.91 (0.79-1.03) and 0.77 (0.56-1.05), respectively.

Conclusions: In a national cohort of more than one million persons, patients with diabetes were 21% less likely to have PD at index compared to a control population without diabetes, and, likewise, there was a general trend towards lower incident PD among cases. This is surprisingly in disagreement with recent published data and accordingly, this nationwide cohort study does not support the suggestion of DR as an independent risk factor for PD.

TITLE: 24-2 visual fields and circumpapillary RNFL thickness accurately predict retrobulbar axons in experimental glaucoma

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.B. Patel, R.S. Harwerth, Vision Sciences, University of Houston, Houston, Texas, UNITED STATES|K. Antwi-Boasiako, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nimesh Patel: Commercial Relationship: Code N (No Commercial Relationship) | Kwame Antwi-Boasiako: Commercial Relationship: Code N (No Commercial Relationship) | Ronald Harwerth: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Visual thresholds and circumpapillary retinal nerve fiber layer (RNFL) thickness both are dependent on the underlying retinal ganglion cell (RGC) content, and are clinically used for the diagnosis and evaluation of progression of optic neuropathies. The purpose of this study was to determine the relationship between endpoint in vivo measures and retrobulbar RGC axonal counts in the non-human primate model of experimental glaucoma.

Methods: Intraocular pressure was elevated by laser scarring the trabecular meshwork in 8 non-human primates. Both experimental and control eyes were monitored with standard automated perimetry (SAP 24-2, full thresholds), and optical coherence tomography (OCT). At varying endpoints, SAP thresholds were converted to RGC counts using the eccentricity dependent non-linear model, accounting for individual differences in retinal scaling. Global RNFL thickness was determined from an elliptical scan path 550 μ m from the Bruch's membrane opening. Post-mortem complete axon counts were determined from thin optic nerve sections imaged with light microscopy using 100X magnification.

Results: The optic nerves of control eyes had an average of 1,309,496 \pm 160,025 axons. RGC estimates from SAP were on average 73,316 less than that established from total retrobulbar axon counts (95% limits of agreement = -365,187, 218,553). The slope of the regression comparing the two RGC counts ($R^2 = 0.89$, slope = 0.96) was not significantly different from 1 ($p = 0.44$). RNFL thickness was linearly related to retrobulbar axon counts ($R^2 = 0.85$, slope = 15322.9 axons/ μ m), and RGC estimates from SAP ($R^2 = 0.92$, slope = 15740 RGCs/ μ m).

Conclusions: Estimates of global retinal ganglion cell counts from visual thresholds are an accurate representation of the retrobulbar axonal count. This relationship is also reflected in objective measures of RNFL thickness, a measure often used as a surrogate of axonal counts.

SUBMITTER (NAME ONLY): Neal Kansara

TITLE: Astigmatism Correction Accuracy with the Barrett and Nittany Toric Calculators

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Kansara, T. O'Rourke, I.U. Scott, S. Pantanelli, Ophthalmology, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|E. Lehman, Biostatistics, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Neal Kansara: Commercial Relationship: Code N (No Commercial Relationship) | Tara O'Rourke: Commercial Relationship: Code N (No Commercial Relationship) | Erik Lehman: Commercial Relationship: Code N (No Commercial Relationship) | Ingrid Scott: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s); Carl Zeiss Meditec: Code C (Consultant); Bausch & Lomb: Code C (Consultant)

ABSTRACT BODY:

Purpose: To compare the accuracy of residual refractive astigmatism (RA) predictions from the novel Nittany Toric Calculator v0.212 (NTC) to those of the Barrett Toric Calculator (BTC) in eyes implanted with a toric intraocular lens (IOL).

Methods: A nomogram was developed that used pre-operative biometry to predict post-operative RA in eyes implanted with a monofocal IOL. This nomogram was combined with the known effective toricities for Alcon Acrysof toric IOLs to create the NTC, which has as inputs pre-operative biometry and outputs residual RA for a given toric IOL implanted at a suggested axis. A separate testing database was assembled, which consisted of consecutive eyes that had toric IOLs implanted between 02/2016 and 02/2019, as recommended by the BTC. The residual RA predictions from the BTC were compared to those from the NTC for the implanted lens. A "remove and replace" method was used to account for differences between the recommended implantation axes of the toric IOL for the BTC and NTC. Outcome measures included the difference vector (DV) magnitude (defined as the vector difference between actual and predicted RA) and proportion of eyes with a DV magnitude <0.5 or <1.0 diopter (D).

Results: The testing database included 82 eyes. The centroid of the DV for all eyes was 0.06 ± 0.50 D x 177 for the BTC and 0.12 ± 0.65 D x 016 for the NTC ($p = 0.49$). Sub-group analysis revealed centroids of 0.02 ± 0.55 D x 008 and 0.23 ± 0.70 D x 011 in eyes with against-the-rule astigmatism ($p = 0.04$), 0.15 ± 0.42 D x 177 and 0.06 ± 0.55 D x 066 in eyes with with-the-rule astigmatism ($p = 0.06$), and 0.07 ± 0.43 D x 104 and 0.04 ± 0.64 D x 062 in eyes with oblique astigmatism ($p = 0.95$) for the BTC and NTC calculators, respectively. The proportion of eyes that had a DV magnitude <0.5 D were 73.2% and 69.5% ($p = 0.513$), while 93.9% and 92.7% had a DV magnitude <1.0 D, respectively ($p = 1.000$).

Conclusions: The current iteration of the NTC performs similar to BTC with respect to most outcome measures. Further refinements of the NTC to incorporate the impact of effective lens position may lead to improvements in prediction accuracy.

TITLE: RvD2 Counter-regulates Histamine-induced $[Ca^{2+}]_i$ Increase and Mucin Secretion by Receptor Specific Protein Kinases in Rat Conjunctival Goblet Cells

SESSION TITLE: Antimicrobials and Immunomodulators

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Yang, R. Hodges, D.A. Dartt, Ophthalmology, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|T.P. Utheim, Faculty of Medicine, University of Oslo, Oslo, NORWAY|N. Botten, T.P. Utheim, Department of Medical Biochemistry, Oslo Universitetssykehus, Oslo, NORWAY|C.N. Serhan, Anesthesia, Brigham and Women's Hospital Center for Experimental Therapeutics and Reperfusion Injury, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Menglu Yang: Commercial Relationship: Code N (No Commercial Relationship) | Nora Botten: Commercial Relationship: Code N (No Commercial Relationship) | Robin Hodges: Commercial Relationship: Code N (No Commercial Relationship) | Tor Utheim: Commercial Relationship: Code N (No Commercial Relationship) | Charles Serhan: Commercial Relationship: Code N (No Commercial Relationship) | Darlene Dartt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: RvD2 is biosynthesized from docosahexaenoic acid (DHA) and was identified in murine self-resolving exudates during the resolution phase of self-limited acute inflammation in vivo. The resolution promoting action of RvD2 was observed in multiple organs and tissues. Histamine is an autacoid produced in the conjunctiva by mast cells in response to an allergen. All four histamine receptor subtypes, H1-4, are present on conjunctival goblet cells and with stimulation increase intracellular $[Ca^{2+}]_i$ ($[Ca^{2+}]_i$) and mucin secretion as a component of allergic conjunctivitis. To determine the molecular mechanism used by RvD2 to terminate the histamine-stimulated allergic response, we investigated the interaction of RvD2 with histamine and its receptors in conjunctival goblet cells.

Methods: Goblet cells were cultured from male rat conjunctiva. Signaling pathways were studied by measuring the $[Ca^{2+}]_i$ responses using fura 2/AM. Mucin secretion was determined using an ELLA.

Results: Thirty-minute treatment with RvD2 (10^{-8} M) significantly blocked the histamine (10^{-5} M) -induced increase in $[Ca^{2+}]_i$ and mucin secretion. Stimulation with an agonist selective for each of the four histamine receptors showed that RvD2 inhibited the $[Ca^{2+}]_i$ increase induced by the activation of H1, H3, or H4 receptors. Blockage of the H1 receptor agonist by RvD2 was reversed by inhibiting β adrenergic receptor kinase (β ARK) and protein kinase A (PKA), but not by inhibiting protein kinase C (PKC). Blockage of the H3 receptor agonist by RvD2 was only reversed by inhibiting PKA. Blockage of the H4 receptor agonist was reversed by inhibiting β ARK and PKC, but not by inhibiting PKA.

Conclusions: RvD2 counter-regulates histamine-induced $[Ca^{2+}]_i$ increase and mucin secretion by phosphorylating and down-regulating H1, H3, and H4 receptors by activating receptor-specific protein kinases.

ABSTRACT BODY:

Purpose: The goal of this study is to compare the outcomes of selected microinvasive glaucoma surgery (MIGS) devices in combination with cataract surgery.

Methods: This is a retrospective chart review of 93 eyes of 79 patients with mild to moderate primary open angle glaucoma (POAG) who underwent a combination of cataract surgery with either iStent inject (n=38), Hydrus microstent (n=24), or Kahook dual blade goniotomy (KDB) (n=31) by one surgeon. Inclusion criteria were no prior surgical intervention for POAG, no laser procedures within 2 years, mild to moderate POAG, and at least 6 months post-op (POM6) follow-up. Statistical analysis was performed using the Kruskal Wallis test.

Results: The percent of intraocular pressure (IOP) reduction at POM6 for iStent inject, Hydrus, and KDB were 10.55%, 4.24%, and 7.74% respectively, but there was no significant difference between the groups ($p=0.75$). There was a significant difference in the number of medications at both pre-op ($p=0.046$) and POM6 ($p=0.03$). The average pre-op number for iStent inject, Hydrus, and KDB were 1.27, 1.67, and 1.81 respectively. At POM6, Hydrus remained at the same average at 1.67 drops, while iStent inject decreased to 0.5 and KDB to 1.29. LogMAR visual acuity improved for all groups by POM6, but there was no significant difference between the groups. 71% of patients identified as Hispanic (Table 1). There were 2 cases of rebound iritis in the iStent inject group, a case of 1 mm hyphema and steroid response in the Hydrus group, and one patient with an IOP spike in the KDB group, all of which were self-limiting.

Conclusions: The MIGS procedures of iStent inject, Hydrus, and Kahook dual blade combined with cataract surgery are safe and effective at lowering IOP, improving visual acuity, and decreasing dependence on drops. However, there was little significant difference found between the groups. Only iStent inject had a significantly lower number of glaucoma medications at both pre-op and POM6. The high percentage of Hispanic patients in this study should be considered when reviewing this data and may be an area of further investigation.

Commercial Relationships Disclosure (Abstract): Jennifer Tingley: Commercial Relationship: Code N (No Commercial Relationship) | Jenna Tauber: Commercial Relationship: Code N (No Commercial Relationship) | Tobin Thuma: Commercial Relationship: Code N (No Commercial Relationship) | Jee-Young Moon: Commercial Relationship: Code N (No Commercial Relationship) | Anne Barmettler: Commercial Relationship(s);Horizon:Code C (Consultant)

ABSTRACT BODY:

Purpose: To examine how the quantity and characteristics of ophthalmology consults at a New York City hospital system changed during the COVID-19 pandemic peak.

Methods: In an IRB approved, HIPAA compliant retrospective, comparative chart review study, ophthalmology (initial, follow-up, and electronic) consult notes from February to May 2019 were compared to those in February to May 2020. Statistical comparisons between 2019 and 2020 were made using T-tests and Fisher's exact tests.

Results: Of 2,215 notes analyzed, 1,374 (62%) were from 2019 and 841 (38%) were from 2020 ($p=0.0002$). Baseline characteristics between groups, including chronic medical conditions, did not differ significantly. In 2019, 41% of patients had a primary hospital diagnosis related to ophthalmology, whereas in 2020 this decreased to 32% ($p=0.002$). In 2019, 7.5% of patients were on ventilators; this increased in 2020 to 10.8% ($p=0.035$). Top reasons for consult requests were stable between years: eye pain/pressure (16.4%, 14.1%, $p=0.79$), trauma (13.1%, 13.7%, $p=1$), and blurry vision (12.9%, 11.2%, $p=0.85$) (Figure 1). After evaluation, the most common diagnoses in 2019 were trauma (14.0%) and glaucoma (10.9%). In 2020, they were trauma (15.2%) and retinopathy of prematurity (11.2%). In 2020, 1.8% of consults were in a newly available format, the e-consult (telephone visit). Within 2020, the number of consults decreased at the end of February (-47.5 %) and in mid-March (-44.1%) (Figure 2). In 2020, 22.5% of all consults were COVID tested and 2.4% of all consults were positive within 2 weeks of in-person evaluation.

Conclusions: These results reflect changes in the activity of the ophthalmology consult service during the peak of the COVID-19 crisis. Consult quantities decreased dramatically in late February and mid-March, which correlate with the timing of the first COVID-19 case in New York State (reported February 29) and the New York State on Pause Program that required all non-essential workers to stay home (ordered March 22). The lower number of ophthalmology consult requests in 2020 may reflect that patients with non-acute eye problems did not seek medical attention and/or primary teams deferred requests.

ABSTRACT BODY:

Purpose: Sorsby fundus dystrophy (SFD) is a rare, autosomal dominant macular dystrophy caused by variants in the Tissue Inhibitor of Metalloproteinase 3 (TIMP3) gene. We identified a novel pathogenic variant in the C-terminal domain of TIMP3 in two unrelated families.

Methods: Clinical imaging included spectral domain optical coherence tomography (SD-OCT), ultra-widefield pseudocolor, autofluorescence and fundus fluorescein angiogram (FFA) imaging, electroretinography (ERGs) and genetic testing.

Results: The 44-year-old proband from pedigree 1, developed nyctalopia and initially presented at the age of 41 with choroidal neovascularization in the left eye, treated with anti-VEGF injections. Her most recent vision was 20/25 OD and 20/60 OS. Ultra-widefield imaging demonstrated multiple discrete areas of nummular peripheral pigmentation and subretinal fibrosis near the fovea in the left eye (Figure 1). FFA showed masking in the areas of pigmentation, staining of deposits in the periphery bilaterally and leakage near the fovea in the left eye. SD-OCT confirmed choroidal neovascularization with development of a juxta foveal sub-retinal pigment epithelium deposit in the left eye. Scotopic ERGs demonstrated a marked reduction in response with standard dark adaptation.

The 64-year-old proband from pedigree 2 developed a sudden drop in central vision with choroidal neovascularization at the age of 39 treated with macular laser, and continued to develop central and peripheral vision loss. His most recent vision was hand motion at 4 feet OD and 20/100 OS. Imaging revealed a foveal scar OD, subretinal deposits and widespread discrete areas of chorioretinal atrophy bilaterally associated with severely reduced photopic and scotopic ERGs (Figure 2). The findings in both patients are consistent with SFD.

Genetic testing in both patients identified a heterozygous missense variant for TIMP3 c.446C>G, p.(Ser149Cys). This variant affects a moderately conserved amino acid at the C-terminal domain of TIMP3, and most of the in silico tools predict the variant as deleterious. To our knowledge, the variant has not been published or reported in the disease related variation databases such as ClinVar or HGMD.

Conclusions: A novel pathogenic variant of TIMP3 was identified in two unrelated families with SFD. To date The HGMD database reports 17 variants in TIMP3 in association with SFD. This expands the spectrum of disease-causing mutations in the TIMP3.

ABSTRACT BODY:

Purpose: Retrotransposons are repetitive DNA sequences constituting more than half of the human or mouse genome that can translocate from one location to another. Retrotransposons were considered as “junk DNA;” however, recent studies suggest that they are involved in many cellular activities, including in neurodegeneration. Optic neuropathies are a group of neurodegenerative diseases caused by damage to retinal ganglion cell (RGC) axons in the optic nerve. Our preliminary data showed that retrotransposons were induced by optic nerve injury in RGCs; here we determine whether retrotransposons play a role in optic neuropathy.

Methods: We performed optic nerve crush (ONC) on the left eyes of 6-8 week old adult mice on day 0, and then isolated RGCs from these animals or from healthy control eyes on day one or day five after ONC. Total RNA was extracted from RGCs and converted to cDNA for qPCR using primers amplifying different classes of retrotransposons, including LINE, SINE, and ERVs.

To inhibit retrotransposon expression in RGCs, we use antiviral drugs stavudine or lamivudine to inhibit their reverse transcription. We performed ONC and intravitreal injection of either drug on day 0 followed by daily intraperitoneal injection of the drug for two weeks. Two days before sacrifice, mice received an intravitreal injection of CTB-555 to anterogradely label RGC axons. Mice were transcardially perfused under deep anesthesia with 4% PFA on day 14. Retinas and optic nerves were further dissected, processed, and examined by fluorescent confocal microscopy.

Results: We found that retrotransposon expression levels were elevated in RGCs after optic nerve injury, especially the LINE family, which increased two- to four-fold after ONC. Inhibition of reverse transcription by antiviral drugs did not promote RGC axon regeneration after optic nerve injury in mice.

Conclusions: Our findings suggest that retrotransposon expression is induced by optic nerve injury in RGCs. Inhibition of retrotransposon reverse transcription by antiviral drugs didn't promote RGC axon regeneration, but may promote neuroprotection. Our future studies will focus on this question, as well as manipulation of retrotransposon expression itself by shRNA knockdown in RGCs.

TITLE: Cholesterol and Cholesterol Bilayer Domains Inhibit the Binding of Alpha-Crystallin with Phospholipid Membranes

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Timsina, N.K. Khadka, L. Mainali, Physics, Boise State University, Boise, Idaho, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Raju Timsina: Commercial Relationship: Code N (No Commercial Relationship) | Nawal Khadka: Commercial Relationship: Code N (No Commercial Relationship) | Laxman Mainali: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The level of α -crystallin decreases in the eye lens cytoplasm, with the corresponding increase in the membrane-bound α -crystallin during cataract progression. Eye lens membrane consists of extremely high cholesterol (Chol) content that favors the formation of cholesterol bilayer domains (CBDs) within the membrane. The function of the high Chol level in the lens membrane is unclear. The purpose of this research is to understand the interaction of α -crystallin with Chol and CBDs in the phospholipid membrane.

Methods: Continuous-wave electron paramagnetic resonance (EPR) spin-labeling method was used to estimate the binding affinity (K_a) of α -crystallin with the Chol/POPC (1-palmitoyl-2-oleoyl-sn-glycero-3-phosphatidylcholine) membranes with varying Chol/POPC mixing ratio from 0 to 1.5. Also, the maximum membrane surface occupied (MSO) by the α -crystallin and the change in the membrane physical property (mobility parameter) after the α -crystallin binding was estimated using the EPR method. The small unilamellar vesicles of Chol/POPC membrane with 1 mol% CSL spin-label were prepared using the rapid solvent exchange method followed by probe-tip sonication. The CSL spin-labels incorporated into the membrane monitor the α -crystallin binding.

Results: The K_a and MSO followed the trends: $K_a(0) > K_a(0.3) > K_a(0.5) > K_a(1) = K_a(1.5)$ and $MSO(0) > MSO(0.3) > MSO(0.5) > MSO(1) = MSO(1.5)$, where numbers in the parenthesis represent the Chol/POPC mixing ratio. For Chol/POPC mixing ratio greater than 1, CBDs form within the membrane. These results indicate that Chol and CBDs inhibit the binding of α -crystallin to the POPC membrane. The profiles of the mobility parameter decrease with an increase in the α -crystallin binding; however, the decrease is pronounced for the lower Chol concentration compared to the high Chol concentration in the membrane. These results represent that membrane becomes more immobilized near the headgroup regions with the increase in α -crystallin binding.

Conclusions: Our results show that the Chol and CBDs inhibit the binding of α -crystallin to the phospholipid membrane, and the membrane physical property alters with α -crystallin binding. These results provide a molecular basis for understanding the functions of Chol and CBDs' in the eye lens membrane in maintaining lens transparency and possibly protecting against cataract formation.

ABSTRACT BODY:

Purpose: To test the hypothesis that early glaucomatous eyes with nasal step defects on 24-2 visual fields (VFs) often have macular damage seen with optical coherence tomography (OCT).[1]

Methods: 216 individuals, including 162 patients with or suspected glaucoma and 54 healthy controls, underwent two baseline 24-2 SITA-Standard VF tests and 9x12mm widefield swept-source OCT scans within 4 weeks. Each hemifield of the 216 eyes was graded for a nasal step based on two definitions: one from the Ocular Hypertension Treatment Study (OHTS) and one we developed that was stricter and more clinically relevant. Figure 1 is a depiction of the minimum (a,c) and maximum (b,d) nasal steps that would satisfy the OHTS (a,b) criteria and our stricter criteria (c,d). Eyes with a nasal step were evaluated for topographical confirmation of the nasal step on OCT retinal nerve fiber layer (RNFL) probability maps. These nasal steps were then evaluated for evidence of macular damage by 2 experts (qualitative approach). For the quantitative approach, a custom R program assessed topographical abnormal structure/function agreement between 24-2 and 10-2 VFs and RNFL and retinal ganglion cell (RGC) probability maps.[2,3]

Results: For the 216 eyes, there were 11 nasal steps with OCT confirmation (10 eyes). 8 of these 11 replicated on the second baseline VF. Notably, 9 of 11 (82%) had macular damage based on the qualitative OCT method, and 1 of the 2 remaining eyes developed macular damage 14 months later (see black arrows in Fig. 2). Based upon the quantitative approach, 7 of the 11 eyes demonstrated abnormal macular structure-function agreement. In general, 8 of the 11 nasal steps were in the superior VF (inferior retina).

Conclusions: Early glaucomatous eyes with nasal step defects on 24-2 VF often have macular damage seen with OCT, as predicted given the prevalence of macular damage in eyes with early glaucoma and the proximity of the disc regions associated with the macular and nasal step regions of the VF.[1] Because of the clinical significance of untreated progressive macular damage, eyes with nasal steps on 24-2 VF should be examined for macular damage on OCT RGC probability maps and/or 10-2 VFs.

ABSTRACT BODY:

Purpose: We previously reported that macular pigment optical density (MPOD) levels decreased during a long follow-up period after clear intraocular lens (IOL) implants surgery presumably due to excessive light exposure (Obana et al. Ophthalmol 2011;118). In the present study, we examined changes in MPOD levels after cataract surgery with yellow-tinted IOL implantation using a different technique to measure MPOD from the previous study.

Methods: This is a prospective, observational study under approval by institutional review board. Subjects were 55 eyes of 35 patients. MPOD levels were measured by a SPECTRALIS OCT (Heidelberg Engineering Inc.) equipped with a dual-wavelength autofluorescence technique on day 4, months 1, 3, and 6, and years 1 and 2 postoperatively. The average optical densities at 0°, 0.5°, 0.9°, and 2° eccentricities (local MPODs) and total MPOD volumes in the area within 9° eccentricity (MPOV) were analyzed.

Results: The mean local MPOD at baseline (on day 4) was 0.79 at 0°, 0.71 at 0.5°, 0.68 at 0.9°, and 0.32 at 2°. The mean MPOV within 1.5° and 9° at baseline was 2950 and 18897, respectively. Local MPOD at 0.9° and 2° and MPOV slightly decreased on month 1 and increased after that. The increase reached statistical significance in local MPOD at 0.5° and 2° and MPOV within 1.5° and 9° on year 2 (Tukey-Kramer test). The change rates of MPOV within 9° on year 2, ((MPOV on year 2 – MPOV on day 4) / MPOV on day 4), were from -0.21 to 1.18 (mean and standard deviation: 1.14±0.28). The MPOV of fifteen eyes increased more than 10% from the initial value, was maintained within 10% in 21 eyes and deteriorated more than 10% in only 3 eyes.

Conclusions: Local MPOD and MPOV tended to slightly decrease at month 1 postoperatively and gradually increase after that, but the increase rates of MPOD levels were small compared to the previous report (Nolan et al. IOVS2009;50). Yellow-tinted IOL that has lower transmittance of blue light might be preferable in the respect of preserving MPOD levels after surgery.

ABSTRACT BODY:

Purpose: It is known that the intraocular pressure (IOP) measurement by the Goldmann applanation tonometer (GAT) tend to fluctuate because of several artifactual factors. This is thought to be mainly influenced by several factors on the observer sides of GAT measurements. In this study, we investigated the fluctuation of IOP by a noncontact tonometer (NCT) and a rebound tonometer (RT) which are considered that the influence of the observer's skill is small.

Methods: The subjects were 37 normal volunteers recruited from the university students. IOP was measured on the subjects by NCT and RT for 5 consecutive days (11:00 to 13:00). Six successive IOP measurements were carried out using CT-1 (Topcon) and Icare PRO (Icare Finland Oy) on the same day. IOP was measured in the first eye (right or left) and then in the fellow eye and IOP was again measured in the first eye and then in the fellow eye. Repeated-measures analysis of variance was used to test differences in IOP between the consecutive measurements (day 1 to 5) or the successive measurements (first to sixth). A P-value < 0.05 was considered statistically significant.

Results: IOP measured by a NCT was significantly higher in both the left and right eye on day1 than on other measurement days (P= 0.000-0.041). IOP measured by RT was significantly higher in both the left and right eye on day1 than that on the other days (P= 0.000-0.030). IOP measured by a NCT were no significant differences in the successive measurements. On the other hand, there were several differences in the successive measurements (e.g. the first IOP measurement was significantly higher than the second to sixth IOP measurements on day 1) with RT measurements.

Conclusions: IOP as measured by a NCT and a RT on day 1 were higher than that on the other day. IOP as measured by a NCT is more stable than that by a RT in the intrasession measurements.

TITLE: Episcleral venous pressure response to brain stem stimulation: effect of topical Lidocaine.

SESSION TITLE: Aqueous humor dynamics and IOP

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Strohmaier, Ophthalmology, Kepler Universitätsklinikum GmbH, Linz, Oberösterreich, AUSTRIA|H.A. Reitsamer, Ophthalmology, Paracelsus Medizinische Privatuniversität, Salzburg, Salzburg, AUSTRIA|J.W. Kiel, Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Clemens Strohmaier: Commercial Relationship: Code N (No Commercial Relationship) | Herbert Reitsamer: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Kiel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Episcleral venous pressure (EVP) is important for steady state intraocular pressure (IOP), as it has to be overcome by aqueous humor in order to leave the eye. It was long assumed to be constant, but recent evidence suggests neuronal control, with a vascular tone through the innervation present. The superior salivatory nucleus in the brainstem could be identified to elicit increases in EVP during electrical stimulation. In the present study the effect of topical anesthesia on the stimulation effect was investigated.

Methods: 8 Sprague Dawley rats were anesthetized, artificially ventilated with CO₂ monitoring and continuous blood pressure monitoring. Intraocular pressure was measured continuously through a cannula in the vitreous body. Episcleral venous pressure was measured by direct cannulation of an episcleral vein via a custom made glass pipette connected to a servonull micropressure system.

Results: Electrical stimulation of the superior salivatory nucleus (10µA, 200 pulses of 1ms duration) increased EVP from 8,51 ± 1,82 mmHg to 10,97 ± 1,93 mmHg (p<0,05). After topical application of topical lidocaine EVP increased from 7,42 ± 1,59 mmHg to 9,77 ± 1,65 mmHg (p<0,05). The EVP response to stimulation before and after lidocaine application was not statistically significantly different (2,45 ± 0,5 vs 2,35 ± 0,49 mmHg, p = 0,69), while the decrease in baseline EVP was (8,51 vs. 7,42 mmHg, p <0,05)

Conclusions: The present data suggest that distinct neuronal mechanisms controlling the episcleral circulation of rats exist. This is in keeping with previous reports of two distinct arterio-venous anastomoses, one in the limbal circulation and one in the conjunctival/episcleral circulation.

ABSTRACT BODY:

Purpose: Currently, there is no presentation biomarker that is significantly correlated with treatment outcome in optic neuritis (ON). Visual fields (VF) reveal global and regional deficits, reflecting visual pathway dysfunction. Archetypal analysis (AA), a form of unsupervised machine learning, has been used in glaucoma to monitor focal VF defects quantitatively. We theorized that AA could detect quantifiable, disease-specific patterns of VF loss that correlate with treatment effect and visual outcome, as well as reveal residual deficits in ON.

Methods: Using the R statistical environment, we performed AA on 3,892 VFs prospectively collected from 456 eyes in the ON Treatment Trial. We decomposed each study eye VF into a weighted sum of its component ATs (total weight=1.0). We defined a minimum AT weight change (7%) distinguishable from normal fluctuations by decomposing VFs of 61 control eyes into ON-specific ATs. To compare outcomes and recovery rates between treatment groups, we created a mathematical model to describe change in AT weight and MD over time.

Results: We used a 10-fold cross-validation model to create 16 ON-specific ATs (Figure 1), which were distinct from control VFs. At presentation, AT2, a severe global dysfunction pattern, had the highest weight (0.33 ± 0.40). Over 6 months, we observed an exponential increase in AT1, a normal AT (Figure 2), and an exponential decrease in AT2 weight. AT1 demonstrated the greatest relative weight increase due to intravenous methylprednisolone (IVMP: 0.57 ± 0.24 ; placebo: 0.51 ± 0.26 ; oral prednisone: 0.49 ± 0.27 , $p=0.01$). Eyes with AT1 weight ≥ 0.19 at baseline (≥ 1 SD above mean) had better visual outcomes for both MD (-1.13 vs. -3.86 dB, $p<0.001$) and AT1 weight (0.68 vs 0.50 $p<0.0001$); however, a treatment benefit for IVMP occurred only for eyes with AT1 weight <0.19 at baseline ($p=0.0115$). Patients receiving IVMP recovered fastest ($p<0.001$). At 6 months, 182/227 eyes with MD >-2.00 dB had at least one abnormal AT.

Conclusions: For the first time, AA reveals specific features of vision loss associated with outcome and treatment effect in ON. AT1 is a quantifiable biomarker of VF function, identifying patients who may benefit most from treatment. AA shows residual deficits in eyes labeled as normal by MD at outcome.

TITLE: Nittany-AK Calculator: A Novel Femtosecond Laser-assisted Keratotomy Nomogram for the Management of Corneal Astigmatism During Cataract Surgery

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Seeger, N. Kansara, A. Sun, A. Longenecker, I.U. Scott, S. Pantanelli, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|B. Ernst, G. Mishra, Schein Ernst Mishra Eye, Harrisburg, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Catherine Seeger: Commercial Relationship: Code N (No Commercial Relationship) | Neal Kansara: Commercial Relationship: Code N (No Commercial Relationship) | Ashley Sun: Commercial Relationship: Code N (No Commercial Relationship) | Amy Longenecker: Commercial Relationship: Code N (No Commercial Relationship) | Brett Ernst: Commercial Relationship: Code N (No Commercial Relationship) | Gautam Mishra: Commercial Relationship: Code N (No Commercial Relationship) | Ingrid Scott: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s); Carl Zeiss Meditec: Code C (Consultant); Bausch & Lomb: Code C (Consultant)

ABSTRACT BODY:

Purpose: This prospective study determined the efficacy of a femtosecond laser-assisted keratotomy (FLAK) nomogram (Nittany-AK calculator) for the correction of astigmatism at the time of cataract surgery.

Methods: This study employed a novel nomogram which considered the posterior and non-keratometric contributions to total ocular astigmatism. The study included consecutive patients who underwent cataract extraction with planned FLAK and insertion of a monofocal intraocular lens by one of two surgeons. Eyes with greater than 0.5D of against the rule (ATR) or oblique astigmatism, or 1.0D of with the rule (WTR) astigmatism were treated in accordance with the nomogram. Biometry and manifest refraction were measured one month post-operatively. Target induced astigmatism (TIA) was compared to corneal and refractive surgically induced astigmatism (SIA). Outcome measures included the correction index (CI), index of success (IOS), and proportion of eyes in which the axis of astigmatism was flipped. A CI of 1.0 indicates that SIA is equal to TIA. An IOS of 0.0 indicates that there is no difference between SIA and TIA. CI and IOS were reported as geometric means for all groups.

Results: A total of 48 eyes from 36 patients have been treated thus far, of which 21 had ATR, 19 had WTR, and 8 had oblique astigmatism. The corneal CI indicated a slight under-correction of both ATR and WTR astigmatism (ATR = 0.93, WTR = 0.86), but the refractive CI revealed an over-correction of WTR (ATR = 1.01, WTR = 1.95). Refractive IOS (ATR = 0.58, WTR = 1.01) indicated greater efficacy of the surgical intervention than the corneal IOS for all groups (ATR = 0.77, WTR = 1.11). More ATR eyes had their axis flipped based upon corneal measurements (ATR = 14.29%, WTR = 21.05%), while more WTR eyes had their axis flipped based upon refractive measurements (ATR = 9.52%, WTR = 47.37%).

Conclusions: The Nittany-AK calculator appeared to be effective at correcting corneal astigmatism at the time of cataract surgery. Ongoing enrollment should translate to further refinements of the calculator and improvements in outcomes.

TITLE: Comparison of retinal characteristics in two rabbit strains

SESSION TITLE: Animal imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.D. Glickman, Ophthalmology, The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, Texas, UNITED STATES|I. Nasonkin, Aivita Biomedical, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Randolph Glickman: Commercial Relationship: Code N (No Commercial Relationship) | Igor Nasonkin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Rabbits have long been used as a large eye model in ophthalmic research because of their relative moderate cost, ease of handling, and relevance to human ocular biology. Moreover, rabbit strains have been developed with different characteristics, such as albinism, variable pigmentation, and body size, to meet specific research needs. In the present study, we compared baseline ocular electrophysiology and biometric parameters between the Dutch Belted (DB) and New Zealand Pigmented (Red) (NZIP) rabbit strains.

Methods: Ocular characteristics were evaluated using fundus photography (Topcon TRC-50X), optical coherence tomography (OCT, Leica/Bioptigen Envisu R2200), and photopic flash and flicker electroretinography (Ocuscience HMsERG handheld tester) to characterize retinal gross morphology, thickness, and visual response, respectively. Three females of each strain were studied, and all animal procedures were carried out with the rabbits anesthetized with isoflurane.

Results: Fundus photography revealed no consistent differences in the gross morphology of the DB and NZP retinas. Photopic flash ERGS did not show significant differences in mean a-wave amplitude (DB: $21.3 \pm 4.7 \mu\text{V}$, NZP: $20.8 \pm 7.5 \mu\text{V}$), b-wave amplitude (DB: $113.9 \pm 20.0 \mu\text{V}$, NZP: $100.5 \pm 25.6 \mu\text{V}$), nor in implicit time (DB: $33.7 \pm 2.7 \text{ mS}$, NZP: $31.8 \pm 2.5 \text{ mS}$); $P > 0.05$ in all comparisons using one-way ANOVA with repeated measures. Photopic flicker mean amplitude did not differ significantly (DB: $49.6 \pm 27.8 \mu\text{V}$, NZP: $44.7 \pm 31.5 \mu\text{V}$, $P = 0.496$, Wilcoxon Rank Sum test). The retinal thickness, measured by OCT, differed significantly between the two strains (DB: $233.6 \pm 14.0 \mu\text{m}$, NZP: $295.7 \pm 15.6 \mu\text{m}$; $P < 0.001$, unpaired t-test).

Conclusions: It is well known that NZP rabbits are larger and heavier compared to DB animals (averaging 3.6 kg vs 1.9 kg, respectively, in our cohorts), and NZP eyes are also larger than DB eyes; however, to our knowledge, the difference in retinal thickness between the two strains has not been reported previously. Because retinal thickness may indicate ocular inflammation and reflect homeostasis, it is an important variable impacting the interpretation of ocular studies. Despite the difference in retinal volume, we did not find strain differences in the photopic ERG responses as reported by others. Although the DB and NZP rabbit strains are both suitable for eye research applications, the potential impact of retinal thickness difference must be considered.

TITLE: Psychological Stress during COVID-19 and Central Serous Chorioretinopathy (CSCR)

SESSION TITLE: Impacts of Covid on patients and practice

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Franklin, A. Wagner, K. Kapoor, Ophthalmology, Wagner and Kapoor Research Institute, Virginia Beach, Virginia, UNITED STATES|M. Franklin, A. Wagner, K. Kapoor, Ophthalmology, Eastern Virginia Medical School, Norfolk, Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mathilde Franklin: Commercial Relationship: Code N (No Commercial Relationship) | Alan Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Kapil Kapoor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Psychological stress is a well-documented risk factor for developing CSCR. Given the unprecedented nature of COVID-19, we wanted to analyze the relationship between the pandemic and CSCR cases in a retrospective, cross-sectional study.

Methods: All newly diagnosed CSCR cases were identified from nine clinics across Hampton Roads, VA (2015—2020). The medical billing system was used to query all CSCR cases, and other causes for retinal exudation were excluded, including inflammation, infiltration, hemorrhage, and choroidal neovascularization. Demographic data and previously reported risk factors were recorded, including recent stressors. CSCR cases and risk factors were compared between the pre-pandemic timeframe (Jan 2015—Feb 2020) and the COVID period (Mar 2020—Sept 2020). Cases were also compared using three-month rolling sums. Categorical variables were analyzed using Chi-square analysis and Fisher's exact test. Continuous variables were analyzed using the Student's t-test.

Results: A total of 247 patients with CSCR were identified with 205 patients in the pre-COVID-19 period and 42 during COVID-19. The total number of CSCR cases per month was analyzed over 69 months (Fig 1). There was an average of 3.61 CSCR cases per month (SD, 2.21; range, 0—10 cases; median, 3 cases). The highest number of cases occurred in May 2020 (10 cases, 99.3 percentile). When comparing the CSCR cases longitudinally (Fig 2), the highest number of cases occurred in 2020 with an average of 6.7 monthly cases. The year 2020 was significantly different from 2015, 2016, 2017, and 2018 ($P < 0.001$). When analyzing the cases using three-month rolling sums, May—July 2020 had the largest number of cases (22 cases, 99.25 percentile), and January—March 2020 had the second-highest total (21 cases, 97.8 percentile). Recent psychological stress was present in 19% of the COVID-era and only 9% of the pre-COVID patients, but was not significantly significant ($P = 0.065$).

Conclusions: The relationship between a worldwide pandemic in the development of CSCR has not been previously reported. While the largest number of monthly cases occurred during the pandemic, there was a relative increase shortly before the designated pandemic start-date. Larger, retrospective studies are warranted to evaluate the significance of these findings.

ABSTRACT BODY:

Purpose: Thyroid eye disease (TED) is a progressive, debilitating and potentially blinding autoimmune disease. Teprotumumab, a novel human monoclonal antibody, reduces orbital soft tissue volume and improves the clinical manifestations of TED, however, the effects on intraocular pressure (IOP) remain uncharacterized. We conducted a retrospective chart review to investigate changes in IOP in patients with TED following teprotumumab treatment.

Methods: A single-center retrospective review of TED patients treated with teprotumumab at the Scheie Eye Institute was conducted. Exclusion criteria included prior surgical treatment for TED and follow-up duration less than 3 weeks. Data was collected on baseline IOP, IOP post-treatment, clinical activity score, proptosis, and treatment duration. IOP was measured using a rebound tonometer in primary gaze. The main outcome measure was change in IOP at week 12 of treatment. Mean differences in IOP following treatment were estimated by modeling the effect of time on IOP using generalized estimating equations. Associations between IOP measurements, proptosis and clinical activity score were established using linear regression that accounted for inter-eye correlation by generalized estimating equations.

Results: 12 TED patients treated with teprotumumab were included. Mean age was 50.8 years (range 34-74); 92% of patients were female (Table 1). Average treatment duration was 13 weeks (range 6-24), average baseline IOP was 19.8 mm Hg (range 13-28) and average baseline clinical activity score was 3.6 (range 0-6). 24 eyes were examined at baseline, 10 at 6 weeks and 20 at 12 weeks. Mean IOP was decreased at 12 weeks of treatment (mean change = -2.8 mm Hg, 95% CI [-4.5 to -1.1], $p = 0.002$; Table 2) compared to baseline. There was no significant correlation between change in IOP and change in clinical activity score or between change in IOP and change in proptosis at 12 weeks ($p = 0.546$ and 0.911 , respectively).

Conclusions: Among patients with TED, teprotumumab treatment was associated with a significant reduction in IOP, likely due to reduced orbital congestion.

ABSTRACT BODY:

Purpose: The presence of a double layer sign (DLS) on structural OCT B-scans is a critical predictor for subclinical choroidal neovascularization (CNV), a stage of non-exudative type 1 macular neovascularization (MNV) before onset of exudation. We sought to develop a 3D CNN to detect DLS of any size using only structural OCT B-scans.

Methods: Eyes with a DLS and eyes with drusen (Dr), to serve as a control, were imaged using 6x6mm swept source OCT angiography (SS-OCTA, PLEX Elite 9000, Carl Zeiss Meditec, Dublin, CA). Each scan pattern consisted of 500 A-scans per B-scan with each B-scan repeated twice at each of 500 B-scan positions along the 6mm y-axis. The OCTA data was used for manual labeling of DLS and Dr; only the structural OCT was used for deep learning.

Results: A total of 232 eyes (196 patients; 173 with DLS and 53 with Dr) were imaged using the SS-OCTA scan pattern. The deep learning model for multi-region segmentation (Figure 1) labels DLS and Dr on a single B-scan image (3D-2D model). We generated dense annotations by integrating manual annotations and predicted segmentation (Figure 2). After refining the labels, we trained a final 3D convolutional model that segments volumetrically (3D-3D model). Finally, eyes with MNV were identified based on en-face projection maps of the predicted masks. Accuracy of final classification was 92.85% (3D-2D model) and 94.28% (3D-3D model). Mean intersection over union (IoU) was DLS: 31.39%, Dr: 12.23% for the 3D-2D model, and DLS: 57.36%, Dr: 25.20% for the 3D-3D model.

Conclusions: Our network can detect DLS from structural B-scans alone by applying an annotation refinement technique for 3D CNN to a dataset with coarse annotations.

TITLE: Effect of Resident Involvement in Ophthalmic Surgery on Patient Outcomes: A Meta-Analysis

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.Y. Cheng, S.I. Beigelman, T. Piawah, A.S. Robinson, USF Health Morsani College of Medicine, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): John Cheng: Commercial Relationship: Code N (No Commercial Relationship) | Steven Beigelman: Commercial Relationship: Code N (No Commercial Relationship) | Tambari Piawah: Commercial Relationship: Code N (No Commercial Relationship) | Avi Robinson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study seeks to determine the effect of resident- versus attending-performed surgeries on patient outcomes in ophthalmic surgery.

Methods: This paper followed Preferred Reporting Items of Systematic Reviews and Meta-Analyses guidelines. Two independent authors searched PubMed, EMBASE, and Cochrane Library from inception to July 2020 to find studies assessing the impact of resident involvement on patient outcomes in ophthalmic cases. All included studies utilized non-overlapping patient populations. 10 patient characteristics were compared between resident and attending arms to investigate participant similarity. 24 outcome variables potentially impacted by resident involvement were compared in this analysis. Study quality was assessed using Newcastle-Ottawa Scale for cohort analysis and given a quality label per Agency for Healthcare Research and Quality standards.

Results: 17 studies were included in this meta-analysis. The highest quality studies were those that employed propensity scoring in their patient analysis. Pooled estimate of only high-quality evidence demonstrated few negative effects of resident involvement. When considering these high-quality studies, the only statistically significant effects observed in the resident-performed arm were longer operative times (mean difference, 12.04 minutes; [95% confidence interval (CI)], [3.91, 20.17]), and increased odds of unplanned return to the OR (odds ratio, 2.58; [95% CI], [1.31, 5.06]), primarily related to nonspecific early postoperative complications in different surgery types with steep learning curves. Analysis of operative time, using propensity scored papers, included 3 studies with 260 patients. Analysis of odds of requiring reoperation, using propensity scored papers, included 4 studies with 342 patients. There was no significant difference between resident- and attending-performed surgeries in 15 other measured postoperative complications in these studies. Significant heterogeneity ($I^2 > 50\%$) was present in 1 of 15 outcomes.

Conclusions: When high-quality studies are considered, resident involvement in ophthalmic surgery has few negative effects on patient success rates and appears safe in carefully selected patients. We recommend future studies on this comparison, given limited sample size of this analysis.

ABSTRACT BODY:

Purpose: To investigate the prevalence of dual sensory impairment (DSI), its associated factors and relationship with health-related quality of life (HR-QoL) in residential care facilities (RCF) in Singapore.

Methods: This was a cross-sectional study of 123 residents aged ≥ 40 years from six RCFs, conducted between 2016 and 2018. DSI was defined as concomitant presenting visual acuity (better-eye) > 0.3 logarithm of the minimum angle of resolution and a pure-tone air conduction threshold (better-ear) > 40 dBHL in any of the four tested frequencies (500, 1000, 2000 and 4000 Hz). HR-QoL was quantified using the EuroQol five-dimension questionnaire. Multivariable Poisson regression was used to determine the associated factors of DSI. Multivariable linear regression was used to determine the association between DSI and HR-QoL adjusted for traditional confounders.

Results: Of the 123 residents (age [mean \pm standard deviation] 75.3 \pm 10.8 years; 56.9% male), 97 (78.9%[95% confidence interval(CI):71.6%, 86.1%]) had DSI, with 89.4% not on follow-up care for their sensory disabilities. In multivariable models, male gender (prevalence ratio(PR) [95%CI]=1.3[1.1, 1.6]), older age (per 10-year increase (1.2[1.1, 1.3]), education ≤ 6 years (1.3[1.1, 1.7]) and the presence of cataract (1.3[1.0, 1.7]) were independently associated with DSI. DSI was in-turn independently associated with a substantial worsening in HR-QoL (β =-0.61; 95%CI: -0.76, -0.45; $p < 0.001$).

Conclusions: DSI affects four in five residential care residents and is substantially associated with reductions in HR-QoL in these residents. Our finding highlights an urgent need for the implementation of routine vision and hearing screening and follow-up care for residents living in these facilities.

ABSTRACT BODY:

Purpose: To assess the incidence and prognostic factors for glaucoma progression within 1-2 years following corneal transplant surgery.

Methods: Retrospective longitudinal analysis of consecutive patients with glaucoma undergoing penetrating keratoplasty (PK), Descemet stripping endothelial keratoplasty (DSEK), DSEK under previous PK, Descemet membrane endothelial keratoplasty (DMEK), or Boston keratoprosthesis I (KPro) implantation from April 2016 to December 2017 at one institution with at least 1 year of follow up. Eyes with retinal and neuro-ophthalmic pathologies were excluded. One eye per patient was included. Glaucoma was defined by a cup to disc ratio (CDR) ≥ 0.6 , CDR asymmetry of >0.2 , history of glaucoma surgery or documented diagnosis of glaucoma and was not based on intraocular pressure (IOP) or use of glaucoma medication alone. Primary outcome measure was to assess for cumulative incidence of glaucoma progression post-transplant, which was defined as CDR progression by ≥ 0.2 or need for glaucoma surgery; and was not based on visual field due to lack of reliable tests for all subjects. Prognostic factors for glaucoma progression were also assessed.

Results: 74 eyes of 74 patients undergoing PK (21), DSEK (26), DSEK under previous PK (10), DMEK (8), KPro (9) with a mean follow-up of 23.9 months (12.3-33.2 months) were analyzed. The incidence of glaucoma progression over first year post surgery was 20.3% overall; by procedure, 14.3% (PK), 27% (DSEK), 0% (DSEK under previous PK), 12.5% (DMEK), and 44.4% (KPro) Figure 1. At 2 years of follow-up, 10.8% of all patients progressed by CDR and 20.3% needed additional glaucoma surgery. Multiple logistic regression showed that KPro surgery, age at surgery, average IOP and average glaucoma medications over follow-up were independently associated with glaucoma progression ($p < 0.03$ for all, Table 1), while gender, ethnicity and additional intra operative anterior or posterior vitrectomy were not ($p > 0.5$ for all).

Conclusions: A significant proportion of glaucoma patients undergoing corneal transplantation show glaucoma progression within 1 year of having surgery. Older patients and patients undergoing KPro implantation are at the highest risk. Average follow-up IOP and glaucoma medications had a marked influence on glaucoma progression and should be carefully managed.

ABSTRACT BODY:

Purpose: Arginase 1 (A1) is the enzyme that hydrolyzes the semi-essential amino acid, arginine, to ornithine and urea. We have previously shown that A1 deletion worsens retinal ischemic injury while intravitreal treatment with a pegylated form of the enzyme (PEG-A1: recombinant human arginase covalently attached to methoxy polyethylene glycol) is protective. In this translational study, we aimed to study the utility of systemic PEG-A1 treatment in mouse models of acute retinal and brain injury.

Methods: Cohorts of WT mice were subjected to retinal ischemia-reperfusion (IR) injury, traumatic optic neuropathy (TON), or brain stroke via middle cerebral artery occlusion (MCAO) and treated with intraperitoneal injections of PEG-A1 or vehicle (PEG only). Drug penetration into the CNS tissues was measured by western blotting for PEG. Neuroprotection was measured in a blinded fashion using NeuN (neuronal marker) immuno-labeling of retina flat-mounts and quantification of brain infarct area using triphenyl tetrazolium chloride (TTC) staining. Furthermore, ex vivo retina explants and in vitro retina neuron cultures were subjected to oxygen-glucose deprivation (OGD) followed by reoxygenation (R) and treatment with PEG-A1.

Results: PEG-A1 given systemically did not cross the intact blood-retina or blood-brain barriers in sham controls but reached the retina and brain tissues after the breakdown of the permeability barriers in all tested models of acute CNS injury. Systemic delivery of PEG-A1 provided statistically significant ($p < 0.05$) neuroprotection after retinal IR injury (increasing neuronal survival to 62% vs 40% in the vehicle group), TON (increasing neuronal survival to 78% vs 62% in the vehicle group), and stroke (reducing infarct size to 34% vs 41% in the vehicle group). PEG-A1 treatment was also neuroprotective in retina explants subjected to OGD/R (73% neuronal survival as compared to 55% in untreated or 48% in PEG only treated explants). PEG-A1 treatment was not effective in promoting survival in retinal neuronal cultures exposed to OGD/R.

Conclusions: Systemic PEG-A1 administration is neuroprotective and provides an excellent route to deliver the drug to the retina and the brain after acute CNS injury.

TITLE: Evaluation of Innovative SSVEP Stimulation Patterns for Neuro-Ophthalmology

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Stock, M. Gerdes, M. Schinle, J. Veloso de Oliveira, L. Hauptmann, L. Martini, W. Stork, Karlsruher Institut für Technologie, Karlsruhe, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure (Abstract): Simon Stock: Commercial Relationship: Code N (No Commercial Relationship) | Marius Gerdes: Commercial Relationship: Code N (No Commercial Relationship) | Markus Schinle: Commercial Relationship: Code N (No Commercial Relationship) | Julia Veloso de Oliveira: Commercial Relationship: Code N (No Commercial Relationship) | Lars Hauptmann: Commercial Relationship: Code N (No Commercial Relationship) | Lucas Martini: Commercial Relationship: Code N (No Commercial Relationship) | Wilhelm Stork: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Steady-State Visually Evoked Potentials (SSVEPs) are the brain's response to periodical optical stimuli. They are great for analyzing and investigating the function of the whole visual system. No conscious patient feedback is required.

We looked at variations of conventional checkerboard patterns to determine how onset/reversal, superimposed noise, or pictures of faces can improve the elicited signals' magnitude. The resulting comparisons may be used to improve existing SSVEP-based procedures using novel types of stimuli.

Methods: Using our custom system, we designed two stimuli sets. Set 1 using checker and faces (7s) and set 2 using dartboard, checker, and faces (6s), both at 7.5Hz. The sets were shown to two groups of 5 participants each (age: 20-30). The resulting reactions to the SSVEP were recorded using an 8-channel EEG (500 Hz) with electrodes positioned on the occiput [P07,O1,Oz,O2,P08,P03,P04,Fz]. The data was analyzed using the Canonical Correlation Analysis (CCA) calculated over the stimulation window using the stimulation frequency and harmonics. Plots represent the mean value of all subjects in the set for the CCA.

Results: Set 1 shows a significant increase in evocation when using pattern onset instead of reversal. Showing faces instead of checkers lead to a slightly increased response. Set 2 indicates that cartoon characters elicit a stronger response than a checker pattern. Through the addition of noise, the response increased at low levels but decreased at higher levels.

Conclusions: SSVEP-based assessment of neuro-visual functions has immense potential in ophthalmology. However, checkerboard stimulations do not necessarily provide the best responses. The addition of low-level noise to the stimuli might improve the generation of SSVEPs in participants. Higher-level stimulation patterns like faces could improve the responses even further.

We suggest that Researchers in Neuro-Ophthalmology consider those or similar stimulation paradigms to improve SSVEP-based objective assessment methods. Especially stimulation with more complex structures like faces could lead to promising results.

ABSTRACT BODY:

Purpose: Methylmalonic aciduria with homocystinuria (cobalamin deficiency cblC type) is a severe but rare disease, caused by mutations in the MMACHC gene. cblC deficiency is multi-symptomatic and often includes ophthalmic manifestations such as macular degeneration, optic nerve pallor and vascular changes that may progress to complete blindness. Cobalamin supplementation can improve some symptoms, but the ocular phenotype remains progressive, suggesting that it might result from a local dysfunction of MMACHC in the retina. Here, we tested the potential ocular consequences of a pan-retinal Mmachc knockout in mice.

Methods: Expression of human MMACHC was tested in the central and peripheral retina and retinal pigment epithelium (RPE) of donor eyes and of mice by real-time PCR. A retina-specific knockout of Mmachc (retina^{ΔMmachc}) was generated using Pax6-Cre mice to delete E3 and E4 of Mmachc in a novel Mmachc^{flox/flox} mouse line. Knockout of Mmachc was confirmed on the genomic level by PCR and on the RNA level by in situ hybridization and real-time PCR. Retinal function was tested by electroretinography, Tissue integrity was investigated by light microscopy and immunofluorescence of tissue sections as well as by fundus imaging, optical coherence tomography and angiography. Metabolites were measured by LC-MS/MS and reversed-phase HPLC.

Results: MMACHC was stably expressed in human retina and RPE up to 91 years of age and in mice from day 1 to 365. In retina^{ΔMmachc} mice, expression of Mmachc was absent in the peripheral retina but was not affected in the central retina or the RPE. The overall reduction of Mmachc expression in the retina of retina^{ΔMmachc} mice was 76±4%. Retinas of knockout mice showed an elevation of cblC-related metabolites including methylmalonic acid (5.6-fold) and homocysteine (1.6-fold) that are known to accumulate also in the serum of patients. However, retinal morphology and function in knockouts was normal up to 1 year of age.

Conclusions: Our data indicate that Mmachc deficiency in the neuronal retina does not lead to ocular impairments in mice. It may be possible, that other supporting cells that do not carry the knockout allele, such as endothelial cells or the RPE, may help to nourish the cells of the retina to compensate them for their lack of Mmachc.

TITLE: Diabetic retinopathy as a marker of prevalent and incident obstructive sleep apnea in type 2 diabetes: results from a national screening program.

SESSION TITLE: DR: Epidemiology and service provision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Grauslund, A.S. Thykjær, M. Rasmussen, Ophthalmology, Odense Universitetshospital, Odense, DENMARK|J. Grauslund, L. Stokholm, K. Rubin, Clinical Research, Syddansk Universitet, Odense, Syddanmark, DENMARK|

Commercial Relationships Disclosure (Abstract): Jakob Grauslund: Commercial Relationship: Code N (No Commercial Relationship) | Lonny Stokholm: Commercial Relationship: Code N (No Commercial Relationship) | Anne Thykjær: Commercial Relationship: Code N (No Commercial Relationship) | Katrine Rubin: Commercial Relationship: Code N (No Commercial Relationship) | Malin Rasmussen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In previous smaller studies, associations have been demonstrated between diabetic retinopathy (DR) and obstructive sleep apnea (OSA), but this has not been tested in national cohorts, and it is not known, if the level of DR acts as an independent predictive marker for OSA. This study aimed to assess the association between DR and OSA, and to evaluate if DR may serve as an independent risk factor of incident OSA.

Methods: As part of the Ocular And Systemic complications In diabetic retinopathy Study (OASIS), we performed a cross-sectional and 5-year longitudinal registry-based cohort study. Data of exposure and outcome as well as systemic morbidity and use of medications were identified in national registers including the Danish Registry of Diabetic Retinopathy (DiaBase), the Danish National Patient Register, the Danish National Prescription Registry, and the Danish Civil Registration System. The index date was defined as the date of the first DR screening registered in DiaBase.

For cases, we included 153,238 patients with type 2 diabetes, who had attended diabetic eye screening and were registered in DiaBase. Each of these were matched by five control persons without diabetes of the same age and gender (n=746,148).

Present and level-specific DR were used as exposures, and main outcomes were crude, age- and sex-adjusted, and multivariable adjusted odds ratio (OR) for prevalent OSA as well as hazard ratio (HR) for 5-year incident OSA.

Results: OSA was present in 5.8% and 2.0% of cases and controls. As compared to persons without diabetes, patients with type 2 diabetes were independently more likely to have prevalent OSA (OR 2.01, 95% CI 1.95-2.08) and to develop OSA within five years (HR 1.55, 95% CI 1.46-1.64). In comparison with cases without DR at the index date, those with DR were less likely to have prevalent (OR 0.57, 95% CI 0.52-0.62) and to develop incident OSA (HR 0.86, 95% CI 0.74-0.99).

Conclusions: In a registry-based national cohort study of 153,238 patients with type 2 diabetes and 746,148 non-diabetes controls, cases had a higher risk of OSA, but the risk of prevalent and 5-year incident OSA were 43% and 14% lower in those with DR, which identifies DR as a marker of reduced risk of OSA.

ABSTRACT BODY:

Purpose: To quantify biomechanical properties in a Col5a1^{+/-} mouse model for classic type Ehlers-Danlos syndrome (EDS) and to compare two different measurement approaches suited for murine corneal mechanical characterization.

Methods: A total of 14 adult eyes, 90 days old, of a Col5a1-haploinsufficient mouse model (Col5a1 het) and 14 eyes of the same age of wild-type littermates (wt) were analyzed by optical coherence elastography (OCE) and 2D stress-strain extensometry. Quasi-static OCE was conducted non-invasively during ambient pressure modulation by -3 mmHg. Corneal displacements were analyzed by phase-difference processing. 2D extensometry measurements consisted of a pre-conditioning cycle, followed by a stress-relaxation test and finally a rupture test.

Results: Compared to wt corneas, Col5a1 het corneas had a thinner corneal thickness (125±11 vs 148±10 mm, p<0.001). Short-term elastic modulus in Col5a1 het corneas was significantly increased in OCT measurements (506±88 vs 430±103 kPa, p=0.023), and the same trend was observed in stress-strain extensometry (30.7±12.1 vs 21.5±5.7 kPa, p=0.057). In contrast, in stress relaxation tests, Col5a1 het corneas experienced a stronger relaxation (55% vs 50%, p=0.010). The two distinct behaviors indicate increased short-term stiffness and reduced long-term stiffness in het corneas.

Conclusions: A reduced expression of collagen V in cornea seems to predominantly affect the viscoelastic properties of the tissue. The results presented here support and rationalize the counterintuitive clinical reported findings, in which even thinner corneas with potential alterations in the structure of collagen manage to maintain a normal topographic pattern.

ABSTRACT BODY:

Purpose: The human cornea has been defined as our “external window” to the visual world that serves as a barrier against the outside environment and as the main refractive lens to focus light into the retina. The histological structure is defined by three layers of cellular elements (epithelium, stroma, endothelium) and two layers of extracellular membranes. Here, we used a combination of single-cell RNA sequencing and in-situ hybridization to characterize the transcriptomic features of different cells and their localization in the human cornea

Methods: Six adult human corneas from healthy donors were processed by sequential tissue digestion and cell sorting. Single-cell suspensions were profiled using 10x Genomics Chromium Single Cell 3' (v2) Gene Expression workflow. Spatial distribution of cell markers was localized by RNA in situ hybridization (RNAscope) in human cornea cross-sections.

Results: Unsupervised clustering of individual cell transcriptomes based on overall gene expression similarity identified 16 transcriptionally distinct clusters within corneal cells, including stromal keratocytes, endothelium, several subtypes of corneal epithelium, and supportive cells in the limbal stem cell niche. Epithelial cells represent the most diverse cell type with eleven sub-clusters. By combining pseudotime bioinformatic analysis and RNAscope we mapped the epithelial cell fate trajectory and location including their initial generation in the limbal region, differentiation, and migration to superficial epithelial layers.

Conclusions: Our study reveals the single-cell map of the adult human cornea and expands the knowledge of the molecularly define cellular subsets of the cornea on a whole genome transcriptional level. This information can be applied to better understand normal corneal biology, serve as a reference to study corneal diseases, and provide potential insights into disease pathology and therapeutics.

TITLE: Differential Corneal Thickness in Pediatric Eyes Implanted with Glaucoma Drainage Devices

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Jabroun, Ophthalmology, Children's National Health System, Washington, District of Columbia, UNITED STATES|A. Elhusseiny, H. Al-Hayouti, Y. El Sayed, Ophthalmology, Abu L Reesh Children's Hospital, Cairo University Faculty of Medicine, Cairo, EGYPT|

Commercial Relationships Disclosure (Abstract): Mireille Jabroun: Commercial Relationship: Code N (No Commercial Relationship) | Abdelrahman Elhusseiny: Commercial Relationship: Code N (No Commercial Relationship) | Huda Al-Hayouti: Commercial Relationship: Code N (No Commercial Relationship) | Yasmine El Sayed: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Children implanted with glaucoma drainage devices are at life-long risk of corneal decompensation. We evaluated the corneal thickness in different quadrants of pediatric eyes implanted with Ahmed glaucoma valve (AGV), as a surrogate indicator of early possible corneal endothelial compromise.

Methods: Corneal thickness in 28 eyes of 23 children (age: 0.8 to 12.8 years; mean: 4.8) successfully implanted with superotemporal AGV was compared to thickness in 63 eyes of 40 glaucomatous children of similar age (0.25 to 13.8 years; mean:3.5) without AGV implantation. Thickness was measured in both groups centrally and in the superotemporal, superonasal, inferotemporal and inferonasal quadrants using ultrasound pachymetry. Measurements were taken at 13.5 ± 8 months post valve implantation and without clinical evidence of tube-cornea touch. The study was conducted at Cairo University Hospitals

Results: The mean corneal thickness was greater in all quadrants in the AGV group, with the central (645 ± 112 vs 590 ± 93 μm ; $P = 0.02$) and superotemporal quadrant (695 ± 90 vs 634 ± 88 μm ; $P < 0.01$) being statistically significant. The superotemporal quadrant was the thickest of all quadrants ($P = < 0.01$) in the AGV but not in the control group. The difference in thickness between the superotemporal and the inferonasal (the furthest away from the tube end) quadrants was significantly higher in the AGV group (38.9 ± 53.3 vs 0.3 ± 35.3 μm ; $P = < 0.01$) indicating a localized subclinical corneal edema likely secondary to the tube implant.

Conclusions: The superotemporal corneal quadrant is significantly the thickest of all quadrants in eyes with a superotemporally implanted Ahmed valve, even in the absence of clinical evidence of tube-cornea touch. Ultrasound pachymetry is a useful tool to monitor for corneal decompensation in children where spectral microscopy is not feasible.

Commercial Relationships Disclosure (Abstract): Sharon Sabapathypillai: Commercial Relationship: Code N (No Commercial Relationship) | Monica Perlmutter: Commercial Relationship: Code N (No Commercial Relationship) | Manik Goel: Commercial Relationship: Code N (No Commercial Relationship) | Bradley Wilson: Commercial Relationship: Code N (No Commercial Relationship) | Mae Gordon: Commercial Relationship: Code N (No Commercial Relationship) | Anjali Bhorade: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the relationship between glaucoma severity and rate of falls, fear of falling, and avoidance of activities at-risk for falls.

Methods: Cross-sectional study. Glaucoma patients (n=138), ages 55-90 years, with mild (n=61), moderate (n=54), and advanced (n=23) glaucoma in the better eye based on Hoddap-Anderson-Parish glaucoma staging system, and age-matched controls (n=50) were recruited from the Eye Clinics at Washington University, St. Louis, MO. Participants completed questionnaires regarding rate of falls, fear of falling, and avoidance of activities at-risk for falls.

Results: Of the glaucoma participants, 36% reported at least one fall in the prior 12 months compared to 20% of controls (adjusted odds ratio [OR], 2.7; 95% CI, 1.18-6.17; p=0.018). Compared to controls, the mild glaucoma group trended towards a higher fall risk (adjusted OR, 2.43; 95% CI, 0.97-6.08; p=0.059) and the advanced group had the highest fall risk (adjusted OR, 7.97; 95% CI, 2.44-26.07; p=0.001). A high fear of falling and high avoidance of activities at-risk for falls relative to controls began at the moderate stage of glaucoma (adjusted OR, 4.66; 95% CI, 1.24-17.49; p=0.023 and adjusted OR, 4.49; 95% CI, 1.34-15.05; p=0.015, respectively).

Conclusions: Patient education, interventions, and appropriate referrals to minimize fall risk should be considered in patients with early glaucoma and continue with advancing disease. Decreasing a patient's rate of falls may decrease their fear of falling and avoidance of at-risk activities. Early reduction of rates of falls, fear of falling, and avoidance of activities at-risk for falls will not only decrease patient morbidity and mortality but also improve patients' emotional and social well-being.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a leading cause of blindness in children, although it is often preventable with accurate and timely diagnosis and treatment. ROP screening guidelines are designed to be highly sensitive to avoid missing cases of treatment-requiring (TR-) ROP; consequently, approximately 80% of exams in a screening population have no or mild disease. Current ROP risk models require multiple predictors and/or exams, and performance often decreases significantly when applied to more diverse populations. We aimed to develop a risk model that could reduce the screening burden without missing cases of TR-ROP by using demographic risk factors and a deep learning-derived vascular severity score (VSS, all of which can be evaluated during a single exam) using a large cohort of North American infants.

Methods: A multi-institutional ROP dataset consisting of retinal fundus images and clinical factors for 852 subjects was collected as part of the Imaging and Informatics in ROP (i-ROP) study. A reference standard ROP diagnosis was provided for each exam. Posterior pole images were assigned a vascular severity score ranging from 1.0 to 9.0. Considering that infants who develop TR-ROP often have increasing VSS prior to the diagnosis of TR-ROP, we developed a risk model based on demographic risk factors and the VSS at 32-33 weeks post-menstrual age. Using all combinations of birth weight, gestational age (GA), and VSS, 7 ElasticNet logistic regression models were tuned via 5-fold cross-validation. The best-performing model was evaluated using the held-out i-ROP test dataset consisting of 121 infants, and an independent dataset of 30 infants screened as part of a telemedicine program in Salem, OR.

Results: The best performing model used GA and VSS, based on the area under the precision-recall curve (Table 1). On each independent test set, the model achieved sensitivity of 100% with a positive predictive value ranging from 12% to 18%, and specificity ranging from 55% to 68% with a negative predictive value of 100% (NPV, Table 2).

Conclusions: This model, with just two predictors which can be collected during a single exam, can identify all subjects who will eventually develop TR-ROP, while correctly ruling out, with 100% NPV, more than half of those who will not.

Commercial Relationships Disclosure (Abstract): Michael James Gilhooley: Commercial Relationship: Code N (No Commercial Relationship) | Moritz Lindner: Commercial Relationship: Code N (No Commercial Relationship) | Steven Hughes: Commercial Relationship: Code N (No Commercial Relationship) | Mark Hankins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Basic levels of visual restoration have been achieved following delivery of light sensitive proteins to the surviving cells of the degenerate retina (optogenetics). Restricting delivery to specific cell populations demonstrates functional advantage over 'non-specific,' high efficiency promotor-based systems but cell specific promoters can often be too large for adeno-associated viral vector (AAV) envelopes. Here we repurposed a compressed promoter complex termed 'L7-6' derived from the L7 (pcp2) promoter to test the hypothesis that it can be used to restrict delivery of a functional optogenetic tool to retinal ON-bipolar cells using AAV in a mouse model.

Methods: At P45, retina-degenerate mice lacking native melanopsin ($Pde^{rd1/rd1} Opn4^{-/-}$) received intravitreal injections of saline or AAV2.2 containing the human melanopsin gene (hOpn4) driven by the L7-6 promotor construct (n=8 per group, 4 male, 4 female). Flat mount immunohistochemistry (IHC) (n=4 per group) and multiple electrode array (MEA) recordings of retinal ganglion cell (RGC) light responses (n=4 per group) were performed on intact retina explants 8 weeks post injection with a range of intensities of light. Comparisons of means were performed by unpaired t-test.

Results: L7-6.hOPN4 treated retinæ demonstrated IHC staining for hOPN4 restricted to $17.75 \pm 3.54\%$ of L7+ bipolar cells in the inner nuclear layer & $1.44 \pm 0.14\%$ of all cells in the GCL (N=4, n=16) compared to $0.00 \pm 0.00\%$ cells in either layer in the saline group ($p < 0.0001$). On MEA, 38 electrodes responded to a 480nm light at 10^{15} photons $cm^{-2} s^{-1}$ in the L7-6.hOPN4 treated (n=0 saline, $p < 0.0001$). A sigmoidal irradiance-response relationship was seen in the treatment group with an EC_{50} of 13.30 ± 0.08 photons $cm^{-2} s^{-1}$.

Conclusions: The L7-6 promotor can be used to deliver a functional melanopsin to retinal ON-bipolar cells using intravitreally delivered AAV vector. This provides a further method to replicate the power of cell-specific melanopsin optogenetics previously demonstrated in transgenic L7.Cre.lox mouse models.

TITLE: Analysis of Longitudinal Antibiotic Susceptibility Trends in Staphylococci: Results from 12 Years of the ARMOR Study

SESSION TITLE: Pathobiology of Ocular Infections

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: P.A. Asbell, Ophthalmology, The University of Tennessee Health Science Center, Memphis, Tennessee, UNITED STATES|C.M. Sanfilippo, H.H. DeCory, Medical Affairs, Bausch and Lomb Rochester, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Penny Asbell: Commercial Relationship(s);Bausch Health US, LLC:Code C (Consultant) | Christine Sanfilippo: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment) | Heleen DeCory: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment)

ABSTRACT BODY:

Purpose: Staphylococci are among the most common causative bacteria in ocular infections, and antibiotic resistance in these pathogens may lead to treatment failure. The Antibiotic Resistance Monitoring in Ocular microorganisms (ARMOR) surveillance study informs on evolving antimicrobial susceptibility patterns in ocular bacterial pathogens. Here, we analyzed in vitro antibiotic resistance among staphylococcal isolates collected from 2009 through 2020 to date in ARMOR for trends over time.

Methods: Each year in ARMOR, *Staphylococcus aureus* and coagulase-negative staphylococci (CoNS) isolated from ocular infections are collected and sent to a central laboratory for species confirmation and susceptibility testing. Minimum inhibitory concentrations (MICs) are determined and interpreted as susceptible/resistant to 16 different antibiotics based on Clinical and Laboratory Standards Institute methods and breakpoints. Data for resistance to various drugs among 2599 *S. aureus* and 2143 CoNS were evaluated here using the Cochran-Armitage test for linear trends in a proportion.

Results: Trend analysis showed a decrease in methicillin resistance (MR) among *S. aureus* (39 to 36%; $P < 0.001$) but no change in MR among CoNS (~50% each year $P = 0.176$). Additional decreasing trends in resistance were noted to azithromycin (62% to 57%), ciprofloxacin (39% to 33%), and tobramycin (24% to 16%) among *S. aureus* ($P < 0.001$ for all), and to ciprofloxacin among CoNS (46% to 26%; $P < 0.001$). In contrast, resistance increased to tetracycline among *S. aureus* (4% to 7%; $P = 0.034$) and to trimethoprim among CoNS (26% to 28%; $P = 0.026$). Multidrug resistance (≥ 3 antibiotic classes) among methicillin-resistant strains remained prevalent in 2020, although no isolates were vancomycin resistant. Besifloxacin retained consistently low MICs, with 2020 MIC₉₀s (1 $\mu\text{g/mL}$ for *S. aureus* and 2 $\mu\text{g/mL}$ for CoNS) up to 128-fold lower than other fluoroquinolones.

Conclusions: Over a 12-year span, staphylococci generally exhibited minimal or no change in in vitro antibiotic resistance. Although a small decrease in MR was observed among *S. aureus* (but not CoNS), the high level of MR in staphylococci warrants attention when selecting empiric antibiotic therapy, particularly with respect to multidrug resistance in these organisms.

ABSTRACT BODY:

Purpose: Calorie restriction reduces the expression of inflammation and increases life span in many organisms. Aged C57BL/6 (B6) lacrimal glands (LGs) have increased inflammation and Th1 infiltration. In this study, we investigate the effects of calorie restriction (CR) or loss of Tnf- α . on the expression of Cathepsin S and markers of inflammation in the LGs of mice during aging.

Methods: B6 mice were used at 2-4, 12, and 24M of age. A separate group of 6M B6 mice received 40% CR or had food ad libitum (AL) for 4M. Young (2-4M) and aged (19-24M) TNF- $\alpha^{-/-}$ were compared to WT mice. LGs were excised and used for histology or gene expression analysis using qPCR. The number of inflammatory foci (>50 cells) was counted under a 10X microscope lens. H&E-stained LGs were scanned, photographed, and image analysis was used to calculate focus score/4mm² and foci area of foci (μm^2). Expression of TNF- α , IL-1 β , IFN- γ , MHC II, IL12, and Ctss was investigated by real-time PCR.

Results: A progressive increase in TNF- α (1.7 and 1.9-fold) and IFN- γ (2.8 and 6.2-fold) was observed in 12 and 24M B6 LGs (P<0.001). Expression of Ctss, MHC II, and IL-12 peaked at 12M (7, 5.8, and 122-fold, respectively, P<0.001) and remained significantly elevated at 24M (3.6, 3.6, and 56-fold, respectively, P<0.001). IL-1 β levels were increased at 24M (2.3-fold, P<0.001). 40% CR significantly decreased TNF- α (46%), IFN- γ (60%), MHC II (64%), Ctss (46%), and IL12 (81%) (all P<0.05) but not IL-1 β mRNAs. Aged TNF- $\alpha^{-/-}$ LGs had a 50% decrease in lymphocytic infiltration compared with aged WT (1 \pm 0.7 vs. 2 \pm 0.8 focus score/4mm², P<0.01) and smaller foci area (47046 \pm 34745 vs. 95730 \pm 49794 μm^2 , P=0.008). A significant increase in TNF- α (3-fold), IFN- γ (9.7-fold), MHC II (10-fold), IL-12 (260-fold), Ctss (7.2-fold), and IL-1 β (3.4-fold) mRNA was observed in aged WT compared with young WT LG (P<0.01). However, IFN- γ (1.3-fold), MHC II (4.4-fold), IL-12 (53-fold), and Ctss (2-fold) mRNA levels were decreased in aged TNF- $\alpha^{-/-}$ compared to WT LGs (P<0.01), but not IL-1 β (1.7 fold).

Conclusions: Taken together, our results indicate that anti-inflammatory therapies (such as CR) or inhibition of TNF- α can ameliorate the age-related increase in cytokine production, and in particular, Ctss, and can decrease LG inflammation. Further studies are needed to evaluate the role of Ctss during aging-related inflammation.

SUBMITTER (NAME ONLY): DaNae Woodard

TITLE: Clinically-Identified C-terminal Mutations in Fibulin-3 are Prone to Misfolding and Destabilization

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Woodard, E. Nakahara, J. Hulleman, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): DaNae Woodard: Commercial Relationship: Code N (No Commercial Relationship) | Emi Nakahara: Commercial Relationship: Code N (No Commercial Relationship) | John Hulleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Distinct mutations in fibulin-3 (F3), a secreted extracellular matrix glycoprotein, have been associated with various ocular diseases including Malattia Leventinese (ML, p.R345W), primary open angle glaucoma (POAG, p.R140W), and age-related macular degeneration (AMD, p.D49A). Previous research has demonstrated that the R345W mutation, which causes ML, appears to lead to protein misfolding and inefficient secretion. However, it is unclear whether other potentially pathogenic or clinically-identified F3 variants reported in the human population also share these features, which we have tested herein.

Methods: Fifteen synonymous and missense mutations located throughout the F3 gene (EFEMP1) were identified using clinical databases. Site-directed mutagenesis was performed to generate the variants. F3 constructs were expressed in HEK293A and ARPE-19 cells and secretion/intracellular F3 levels were monitored by western blotting. Equal expression was confirmed by quantitative PCR.

Results: Of the fifteen new variants, only a single leucine (Leu) to phenylalanine (Phe) mutation at 451 (L451F) in the C-terminal fibulin type domain caused a significant ($p < 0.01$) secretion defect relative to WT F3 ($n \geq 6$). This mutation was found in two unrelated individuals, one with retinal dystrophy and the other with nystagmus. Surprisingly, charged (Arg, Asp), aromatic (Phe, Trp, Tyr), and restrictive (Pro) residues appear to be disfavored at this 451 position, also causing secretion defects ($p < 0.05$). Furthermore, the L451F variant relies heavily on N-linked glycosylation at Asn249 for secretion, consistent with observations made with R345W F3, suggesting that this new variant is also intrinsically unstable.

Conclusions: Secretion defects are not a shared feature of all pathogenic or clinically-identified F3 variants. The previously identified disease-associated D49A (cuticular AMD) and R140W (POAG) F3 variants displayed no signs of misfolding. The novel L451F variant has molecular properties very similar to that of R345W, suggesting that it is likely misfolded, intrinsically unstable, and potentially contributes to ocular disease.

TITLE: Serial treatment of uveitis with intravitreal injections of Methotrexate during the COVID-19 pandemic

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Kovalova, K. Kapoor, Wagner and Kapoor Research Institute, Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Oleksandra Kovalova: Commercial Relationship: Code N (No Commercial Relationship) | Kapil Kapoor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Uveitis is potentially sight-threatening and typically managed with steroids. However, chronic steroid therapy has known systemic and ocular adverse effects. Intravitreal methotrexate (MTX) is a unique option for local treatment that is steroid-sparing, but also immunosuppressive and anti-inflammatory. The purpose of our research is to assess the efficacy of serial intravitreal injections of MTX for uveitis.

Methods: This was a retrospective case series, reviewing three patients with non-infectious uveitis who received a series of intravitreal MTX from February to November 2020. Complete eye exams were performed at baseline and during each follow-up after the initial treatment, with recordings of key outcome measures including cystoid macular edema as measured by foveal thickness, intraocular pressure (IOP), visual acuity (VA), and anterior chamber activity.

Results: Three patients (2 female and 1 male) were diagnosed with panuveitis (33.3%) and posterior uveitis (66.7%) with mean age of 62.3 (59-68). Two patients received a series of three MTX injections (0.04ml of 25mg/ml) at one month intervals followed by one injection every three months thereafter; another patient received intravitreal MTX monthly without interval extension. Patient A formerly took 60 mg oral Prednisone daily, and reduced to 30 mg daily after bridging to local MTX without relapse; patient B received Ozurdex treatment that did not have interval extension but did have reduction in CME. Patient C had reduction in topical steroid therapy. The mean foveal thickness at baseline was 345 (range 248-469) and improved to 316 (range 361-397). Anterior chamber activity improved on average from a baseline of 1+ Cell/Flare to Trace Cell/Flare. The average IOP was in target range between 8-16 mmHg throughout treatment. The average VA improved by one line in the affected eye by the end of the studied treatment courses.

Conclusions: After initiation of intravitreal MTX treatments, all patients achieved measurably decreased clinical signs of inflammation and/or achieved significant reduction in steroid treatment. More research with randomized trials is needed to further elucidate the role of intravitreal MTX as a local steroid-sparing agent for uveitis. It may play an expanded role during the pandemic when systemic immunosuppression is relatively contraindicated and rheumatology support is less achievable.

ABSTRACT BODY:

Purpose: To determine whether RAVO is associated with risk of developing vascular dementia, Alzheimer's disease (AD), or all-cause dementia. Although retinal artery/vein occlusions are ophthalmic complications of systemic vascular pathology and vascular disease is a risk factor for AD and related dementia in older adults, associations between RAVO and dementia risk are unknown.

Methods: Data from Adult Changes in Thought (ACT) study participants were analyzed. This prospective, population-based cohort study recruited older adults (age ≥ 65) who were dementia-free at enrollment and followed them biennially for development of AD, vascular dementia, and all-cause dementia based on research criteria. The diagnosis of dementia and types were made based on consensus conference consideration of all relevant data. RAVO diagnoses were extracted from electronic medical records. Cox-regression survival analyses were stratified by APOE $\epsilon 4$ status (any $\epsilon 4$ versus none) and adjusted for sex, race, education, and smoking history. Secondary analyses controlled for potential confounders including diabetes, hypertension, congestive heart failure, coronary artery disease, transient ischemic attack, carotid endarterectomy, and ophthalmic comorbidities.

Results: On review of 41,216 person-years (4,743 participants), 266 had RAVO. Those with at least one APOE $\epsilon 4$ allele who developed RAVO had > four-fold higher risk for vascular dementia (HR 4.54, 95% CI 1.86, 11.10, $p = 0.001$) than those without RAVO.(Figure) When including other cerebrovascular disease in the model, the risk was three-fold higher (HR 3.06, 95% CI 1.23, 76.2). None of the other conditions evaluated in secondary analyses were found to confound this relationship. This association was not found in people who lacked APOE $\epsilon 4$ alleles (HR 1.03, 95% CI 0.37, 2.80). No significant associations were found between RAVO and AD or all-cause dementia in either APOE group.

Conclusions: Older dementia-free individuals who present with RAVO and carry at least one APOE $\epsilon 4$ allele are at higher risk for developing vascular dementia.

TITLE: Evaluation of unfolding speed and rotational stability of toric intraocular lenses under compression

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Murase, Y. Nakahata, S. Nagasaka, Y. Soda, IOL Development Dept., Eye Care Div.,, Kabushiki Kaisha Nidek, Gamagori, Aichi, JAPAN|I. Ota, Ganka Miyake Byoin, Nagoya, Aichi, JAPAN|

Commercial Relationships Disclosure (Abstract): Kyoko Murase: Commercial Relationship(s);NIDEK Co.,LTD.:Code E (Employment) | Yoshihiro Nakahata: Commercial Relationship(s);NIDEK Co.,LTD.:Code E (Employment) | Shinji Nagasaka: Commercial Relationship(s);NIDEK Co.,LTD.:Code E (Employment) | Yasushi Soda: Commercial Relationship(s);NIDEK Co.,LTD.:Code E (Employment) | Ichiro Ota: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Causes of postoperative misalignment of toric IOLs include intraoperative axial misalignment and lens rotation due to capsular contraction. Hence, toric IOLs that unfold at an appropriate speed are beneficial because they allow intraoperative correction of misalignment and may be rotationally stable postoperatively. This study evaluates the unfolding speed of toric IOLs from various manufacturers and compares the rotation of toric IOLs under compression. Additionally, the fixation stability was clinically assessed in the early postoperative period.

Methods: The following toric IOLs were evaluated: XY1AT5 (HOYA), ZCV300 (Johnson and Johnson Vision), SN6AT5 (Alcon), and NS60YT5 (NIDEK) [20.0 D, three samples each]. The IOLs were held with forceps for 20 seconds at room temperature, and then the time for complete optic unfolding was measured in 20 to 29°C water bath (3°C increments). The position of the haptics were fixed to measure the magnitude of rotation of the optic when the IOLs were compressed from 10.0 mm to 9.0 mm. Additionally, the magnitude of rotation was calculated for a IOL with respect to the planned axis at 1 day, 1 week and 1 month postoperatively.

Results: All lenses unfolded faster at higher temperatures. The smallest difference in unfolding speeds at 20°C and 29°C was 30 seconds with the NS60YT5 IOL and the largest was 76 seconds with the ZCV300 IOL. On compression, the optics of all the lenses rotated. ZCV300 had the greatest magnitude of rotation at 6.5° and the SN6AT5 rotated the least at 5.0°. The planned-versus-actual rotation for NS60YT5 was, 3.0±1.7° at 1 day, 3.2±2.2° at 1 week and 2.4±1.3° at 1 month postoperatively.

Conclusions: Unfolding speed and rotation under compression were evaluated with toric IOLs in vitro. NS60YT5 had the smallest difference in unfolding speed due to temperature. ZCV300 had the largest rotation under compression. The amount of rotation for NS60YT5 from 1 day to 1 month postoperatively was no larger than 5 °.

TITLE: Automatic Measurements of Eye Movements using Video Oculography and Single Shot MultiBox Detector

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Hirota, T. Hayashi, Orthoptics, Teikyo Daigaku, Itabashi-ku, Tokyo, JAPAN|M. Hirota, T. Hayashi, E. Watanabe, Y. Inoue, A. Mizota, Ophthalmology, Teikyo Daigaku, Itabashi-ku, Tokyo, JAPAN|

Commercial Relationships Disclosure (Abstract): Masakazu Hirota: Commercial Relationship: Code N (No Commercial Relationship) | Takao Hayashi: Commercial Relationship: Code N (No Commercial Relationship) | Emiko Watanabe: Commercial Relationship: Code N (No Commercial Relationship) | Yuji Inoue: Commercial Relationship: Code N (No Commercial Relationship) | Atsushi Mizota: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to develop a technique that would combine video oculography (VOG) with single shot multibox detector (SSD) to accurately and quantitatively examine eye movements.

Methods: Eleven healthy volunteers (21.3 ± 0.9 years) participated in this study. Eye movements were recorded during the tracking of the target using a custom-made eye tracker based on EMR-9 (NAC Image Technology Inc.). The subjects were asked to fixate on the nose of the rabbit-like target (visual angle was 0.1°) that was manually moved to a distance of 1 meter by the examiner during the eye movement test. The test produced 500 images from the VOG external camera and these images were divided into 3 groups (300, 100, and 100) for training, verification, and testing. The performance of the SSD was evaluated with 75% average precision (AP_{75}), and the relationship between the location of the fixation target (calculated by the SSD) and the positions of both eyes (recorded by the VOG) was analyzed.

Results: The AP_{75} of the SSD on one class of targets was 97.7%. The horizontal and vertical target locations significantly and positively correlated with the horizontal dominant (horizontal, adjusted $R^2 = 0.984$, $P < 0.001$; vertical, adjusted $R^2 = 0.955$, $P < 0.001$) and nondominant (horizontal, adjusted $R^2 = 0.983$, $P < 0.001$; vertical, adjusted $R^2 = 0.964$, $P < 0.001$) eye positions.

Conclusions: Our findings suggest that using VOG with SSD is suitable to evaluate eye version movements in the standard clinical assessment.

Kim: Commercial Relationship(s);SCAI Therapeutics:Code E (Employment) | Eun Nam Kyoung: Commercial Relationship(s);SCAI Therapeutics:Code E (Employment) | Chae Eun Kim: Commercial Relationship: Code N (No Commercial Relationship) | Jae Wook Yang: Commercial Relationship(s);SCAI Therapeutics:Code C (Consultant) | Kyoung-Hee Kim: Commercial Relationship(s);SCAI Therapeutics:Code E (Employment)

ABSTRACT BODY:

Purpose: Due to a poor solubility of cyclosporine A in water, conventional eyedrops for dry eye syndrome (DES) include surfactants that may cause burning sensation, stinging pain, blurred vision, and eye redness. To develop a patient-friendly eyedrop for DES, we prepared a surfactant-free dispersion of cyclosporine A (D-CsA) and evaluated its efficacies in a murine model.

Methods: D-CsA was prepared as a surfactant-free dispersion in water based on our proprietary technology. DES of 12- to 16-week-old NOD.B10.H2^b mice was induced by daily injections of scopolamine hydrobromide in a low humidity (30~40%) environment for 10 days. Efficacies were evaluated with three eyedrops (Vehicle, 0.05% Restasis, and 0.001% D-CsA) that were bilaterally given 5 µL/eye each twice a day, over 10 treatment days. (n=4 for each group)

Results: When treated with D-CsA, tear production increased more than 4-fold on day 5 already (cf. 10 days required for Restasis) and reached 6.3-fold on day 10. While scores of Restasis in corneal smoothness, fluorescein staining, and epithelial cell detachment, did not or barely changed over 10 days, those of D-CsA were drastically improved by 42.6%, 50.5% and 52.4%, respectively. Their conjunctival efficacies were confirmed to be comparable in goblet cell density and mucin-stained cell density, which increased around 2.2-fold and 2.5-fold, respectively.

Conclusions: We have demonstrated enhanced overall efficacies of D-CsA eyedrop for DES, particularly in tear production, goblet cell density, and corneal recovery. Given the fact that there is no surfactant used in the eyedrop, this demonstration exhibits the true intrinsic efficacies of CsA for DES which have been inevitably veiled in oils and surfactants. We expect that this formulation would provide a pain-free solution to chronic DES patients worldwide.

Commercial Relationships Disclosure (Abstract): George Berrett: Commercial Relationship: Code N (No Commercial Relationship) | Zoe Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Matthias Schmid: Commercial Relationship: Code N (No Commercial Relationship) | Manjusha Narayanan: Commercial Relationship: Code N (No Commercial Relationship) | Francisco Figueiredo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Gonococcal infections are rising in the Western world, as reflected in both the UK where case rates have increased by 90.3% from 2016 to 2019, and the United States, where rates have risen by 63.2% from 2014 to 2018. We suspect a corresponding increase in the incidence of adult gonococcal conjunctivitis (GC), and thus aim to investigate the incidence of the condition in a tertiary hospital in the UK, and further describe its clinical characteristics.

Methods: We report a retrospective, non-comparative, consecutive case series of all adult patients with either confirmed gonococcal growth on culture or positive gonococcal PCR, presenting to the Eye Emergency Department (EED) at the Royal Victoria Infirmary, Newcastle upon Tyne, UK between January 2014 and November 2019. Incidence, demographics and clinical course of these patients are presented, including clinical features, complications and organism sensitivities. Three cases are described further to illustrate the complications of pseudo-pterygia and secondary orbital inflammation.

Results: Of 122,694 EED attendances, 15 patients were included. Incidence increased in the latter years of the period, with 11 cases (73.3%) occurring in 2018-2019. The average patient was 21.3 years old (SD 6.2; range 18-28) and male (73.3%). Of twelve patients with adequate documentation, all presented with unilateral conjunctival injection and purulent discharge. Eight (66.6%) had reduced best corrected visual acuity, of which three (25%) were marked (20/60 or worse). Significant periorbital swelling occurred in eight patients (66.6%), and photophobia, malaise and painful eye movements were seen infrequently. Four patients (26.7%) required admission, including two with features of orbital inflammation. One patient remains under review for severe corneal scarring secondary to a large pseudo-pterygium, but the others recovered fully. Each organism identified was susceptible to ceftriaxone and ciprofloxacin.

Conclusions: Adult gonococcal conjunctivitis is a rare but sight threatening disease most common in young, sexually active males, and its incidence is expected to rise in concert with increasing rates of gonorrhoea internationally, as seen in our series. As such, GC remains an important consideration in adults with unilateral purulent conjunctivitis, who may have reduced visual acuity and periorbital swelling, and thus warrants a low threshold for exploring a sexual history.

ABSTRACT BODY:

Purpose: To develop a consensus nomenclature for reporting optical coherence tomography angiography (OCT-A) findings in the field of retinal vascular diseases.

Methods: Members of the Retina Society, the EURETINA and the Japanese Retina and Vitreous Society choose to participate in responding to an online questionnaire on their preferred terminology for reporting OCT-A findings in retinal vascular diseases. The respondents were divided into two groups based on the number of their publications in OCTA and retinal vascular diseases, including OCTA "experts" group who have five or more publications and the "users" who have less than five publications. Then an expert team of 25 OCTA experts in the field of retinal vascular diseases was formed and Delphi rounds based on the initial results of the survey are being carried out.

Results: The complete responses of 85 retina specialists were included in the analysis. Thirty-one were categorized as "experts". There was a consensus in both groups that OCTA parameters such as foveal avascular zone (FAZ) parameters, areas of nonperfusion and presence of neovascularization (NV) should be implemented in the identification and staging of DR and that OCTA can be applied to differentiate between ischemic vs. non ischemic retinal vein occlusion. Diabetic macular ischemia (DMI) can be also assessed via OCTA. Further, there was consensus that the terminology should differ based on the underlying causes of decreased vascular flow signal. There was disagreement in other areas, such as which terms should be applied to describe decreased OCTA signal from different causes, the definition of widefield OCTA and how to quantify DMI and area of decreased flow signal. These discrepancies form the basis for the upcoming expert Delphi rounds that aim to develop a standardized OCTA nomenclature. First results of the following Delphi rounds will be presented as well.

Conclusions: While there was agreement in some areas, significant differences were found in many areas of OCTA terminology among all respondents, but also between the "expert" and "user" groups. This indicates the need for standardization of the nomenclature among all specialists in the field of retinal vascular diseases.

TITLE: Comparison of intraocular pressure measured with Goldmann applanation tonometry and with Icare tonometry

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Yu, P.G. Soderberg, Neuroscience/Ophthalmology, Uppsala Universitet Medicinska fakulteten, Uppsala, SWEDEN|

Commercial Relationships Disclosure (Abstract): Zhaohua Yu: Commercial Relationship: Code N (No Commercial Relationship) | Per Soderberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of the study was to compare the variation of intraocular pressure (IOP) measured with Goldmann applanation tonometry (GAT) and Icare tonometry, and if the methods were calibrated to each other.

Methods: Totally 20 persons with normal intraocular pressure were included and evenly divided into two groups. The IOPs were measured with GAT in one group and with Icare in another group. With each method, the IOPs were measured at two occasions and at each occasion 3 measurements were performed.

Results: The estimated variance among occasions for IOP with GAT was 7 times lower than the estimated variation with Icare. The estimated variance among measurements was 3 times lower with GAT than with Icare. The 95 % confidence intervals for each method's mean IOPs were 11.9 ± 1.0 mmHg for GAT and 14.2 ± 1.4 mmHg for Icare.

Conclusions: The variation among both measurements and occasions is smaller with GAT than with Icare, and therefore the reliability is different between the two methods. The methods are not calibrated to each other.

ABSTRACT BODY:

Purpose: A subset of mice in our Cfh knockout (Cfh^{-/-}) colony exhibited rapid retinal degeneration, suggesting a spontaneous mutation occurred on mouse chromosome 1 (Chr 1). The retinal phenotype was similar to that in AdipoR1 knockout (AdipoR1^{-/-}) mice, whose gene is located near the Cfh locus on Chr 1. We attempted to determine if a mutation in AdipoR1 occurred on the Cfh^{-/-} background.

Methods: We performed an allele complementation test with a cross between a Cfh^{-/-} mouse with retinal degeneration and an AdipoR1^{-/-} mouse with retinal degeneration. RNA-seq, in situ hybridization, immunohistochemistry and protein analysis were used to profile Cfh^{-/-} and AdipoR1^{-/-} mice.

Results: About 50% of Cfh^{-/-} mice exhibited retinal degeneration. Cfh^{-/-} mice, regardless of retinal phenotype, demonstrated elevated complement activation in the eye compared to littermate controls. All offspring from the complementation test exhibited retinal degeneration, implying that AdipoR1 mutant alleles were responsible for the retinal degeneration. AdipoR1 protein, normally present in the RPE apical microvilli, was notably absent in Cfh^{-/-} mice with retinal degeneration. Cfh^{-/-} mice with normal retinal anatomy expressed AdipoR1 protein and were comparable to littermates[QY1]. AdipoR1 mRNA expression levels were comparable across the colony as measured by RNAscope and RNA-seq. Analysis of AdipoR1 mRNA sequence revealed a transversion at position c.841 C>T in the AdipoR1 gene concordant with mice exhibiting retinal degeneration. Further breeding identified mutant AdipoR1 mRNA in two Cfh^{+/-} mice and one Cfh^{+/+} mice with early onset retinal degeneration, implying a recent cross over on Chr 1. This missense mutation results in a proline to serine conversion (P281S) in the fifth transmembrane domain of AdipoR1 and is predicted to be detrimental to the AdipoR1 protein.

Conclusions: The spontaneous mutation in the AdipoR1 gene results in early onset retinal degeneration in a subset of our Cfh^{-/-} mouse colony. Elevated complement activity in the eye does not appear to affect the course of retinal degeneration, as gene signatures are comparable across all mice with retinal degeneration, regardless of Cfh genotype.

TITLE: Variance and bias of artificial intelligence based denoising and conventional averaging in optical coherence tomography angiography

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.A. Vermeer, L. Smid, Rotterdam Ophthalmic Institute, Rotterdam Eye Hospital, Rotterdam, NETHERLANDS|M.E. Van Velthoven, Rotterdam Eye Hospital, Rotterdam, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Koenraad Vermeer: Commercial Relationship(s);Canon:Code F (Financial Support) | Lisette Smid: Commercial Relationship(s);Canon:Code F (Financial Support) | Mirjam Van Velthoven: Commercial Relationship(s);Canon:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To examine the effect of artificial intelligence (AI) based denoising and conventional averaging on the reproducibility and bias of quantitative measurements, i.e., vessel density (VD) and foveal avascular zone (FAZ), derived from optical coherence tomography angiography (OCT-A) en face images.

Methods: In this retrospective cohort study, the non-pathological fellow eyes of patients with unilateral non-systemic disorders were included. OCT-A scans of two visits were analyzed on a Canon OCT-HS100 workstation. The VD and FAZ were measured on the first single scan (SS), best single scan (BSS), averaged scan (AS), and those scans after AI-denoising (SS-AI, BSS-AI, AS-AI). The reproducibility was calculated as the mean absolute difference (MAD) between the two visits, and the bias as the mean value (MV). A two-factor repeated-measures ANOVA for both the MAD and MV of the FAZ and VD was performed introduced by the factors AI-denoising and averaging.

Results: We analyzed 16 non-pathological eyes of 16 patients (61.9 ± 17.5 years). For VD, the reproducibility of AI-denoised scans (SS-AI, AS-AI) was significantly worse than scans without AI-denoising (SS, AS), but significantly better in BSS-AI than in BSS (Figure 1). AI-denoising also negatively affected the reproducibility of the FAZ measurement (Figure 2). AI-denoising and averaging both introduced a significant bias for the VD; for the FAZ, a significant bias was only introduced by AI-denoising. The marginal effects and results of the pairwise comparisons are presented in Table 1.

Conclusions: AI-denoising negatively affect the reproducibility and introduces a bias for quantitative OCT-A measurements, while the reproducibility of averaged scans was not significantly different from single scans. Only the VD measurement was biased after averaging. When the original single image is of high quality, the AI-denoising technology has a good reproducibility for VD. Otherwise, we recommend using conventional averaging for quantitative comparisons.

Commercial Relationships Disclosure (Abstract): Michael Dong: Commercial Relationship: Code N (No Commercial Relationship) | Rod O'Day: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Hall: Commercial Relationship: Code N (No Commercial Relationship) | Lyndell Lim: Commercial Relationship(s);Allergan:Code F (Financial Support);Bayer:Code F (Financial Support);Novartis R:Code R (Recipient);Novotech:Code C (Consultant);Allergan:Code C (Consultant)

ABSTRACT BODY:

Purpose: Intracameral triamcinolone (TA) is used at the time of uveitic cataract surgery to reduce postoperative inflammatory complications. However, there are currently no studies specifically investigating its use in this setting. We performed a retrospective study to evaluate the safety and efficacy of intracameral TA in reducing postoperative inflammation in uveitic cataract surgery.

Methods: A retrospective cohort study from 2005 to 2020 was conducted by reviewing medical records with a postoperative follow-up period of at least one month, through to 12 months. Consecutive adult patients with uveitis requiring cataract surgery with significant iris manipulation (use of iris hooks or a Malyugin Ring), were included in the study. Cases prior to 2009 where intracameral TA was not used (control group) were compared with cases after 2009 where intracameral TA was administered (study group).

Results: 54 eyes from 46 patients were included in the study group and 19 eyes from 16 patients were included in the control group with a mean follow up of 8.2 months and 9.2 months respectively. Significantly fewer eyes in the study group developed cystic macular edema (CME) during follow-up (22% vs 53%, RR 0.42 (95% CI 0.22 to 0.83), $p=0.020$). At one month, eyes that received intracameral TA had only $\frac{1}{4}$ the risk of having CME compared to the control group (9% vs 35%, RR 0.26, (95% CI 0.10 to 0.75), $p=0.019$). Visual acuity (VA) was not significantly different between the two groups at baseline ($p=0.06$), with the study group achieving a better median VA than the control group at one ($p=0.013$) and three months ($p=0.009$) postoperatively (Figure 1). Mean intraocular pressure (IOP) was lower in the study group at one week ($p=0.004$) and three months postoperatively ($p=0.015$). In the study group there were more cases of IOP-rise ≥ 10 mmHg (50% vs 37%, $p=0.425$) and ≥ 20 mmHg (36% vs 11%, $p=0.210$). There were low rates of other adverse events. Patterns of inflammation control were not significantly different at any time point.

Conclusions: Our findings support the use of intracameral TA as a safe and effective method of reducing postoperative inflammation for uveitic cataract surgery. It appears to be particularly effective for prevention of early CME which may confer a visual acuity benefit.

SUBMITTER (NAME ONLY): Didar Abdulla

TITLE: OZURDEX® (dexamethasone intravitreal implant) vs ILUVIEN® (fluocinolone acetonide intravitreal implant) 0.19 mg in non-infectious posterior uveitis (NIPU)

SESSION TITLE: Stem cells / gene therapy/ transplantation/ laser/ local therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Abdulla, S. Taylor, Ophthalmology, Royal Surrey NHS Foundation Trust, Guildford, Surrey, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Didar Abdulla: Commercial Relationship: Code N (No Commercial Relationship) | Simon Taylor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the effect of switching from Ozurdex to Iluvien in patients with NIPU

Methods: Data were collected retrospectively from medical records and ocular coherence tomography images. We looked at visual acuity (VA), central macular thickness (CMT), intraocular pressure (IOP) and complications three months pre and post treatments with Ozurdex and Iluvien. Patients with NIPU who received both Ozurdex and Iluvien were included. Primary outcomes were control of inflammation as measured by VA and CMT 3 months pre and post treatment, and need for rescue treatment. Secondary outcomes were IOP and complications. Statistical significance was assessed using the student t-test, with a significance level of $p < 0.05$

Results: Fourteen eyes of 8 patients were analysed. Both treatments were equally efficacious in control of inflammation, no significant changes in VA before or after switching from Ozurdex to Iluvien (VA 0.3 to 0.2 logMAR post treatment with Ozurdex vs. 0.1 to 0.2 LogMAR post treatment with Iluvien). Average CMT improved in both groups, 374µm pre Ozurdex, to 317µm 3 months post treatment, and 348µm to 332µm 3 months post Iluvien. A significant rise in IOP was seen in both groups, from 12 ± 3 mmHg to 17 ± 6 mmHg with Ozurdex and 14 ± 4 mmHg to 24 ± 9 mmHg pre and post Iluvien ($p < 0.010$). On average patients reported slower restoration of vision following Iluvien than with previous Ozurdex implants

Conclusions: Our case study shows no significant difference in control of inflammation in NIPU between Ozurdex and Iluvien implants, but a difference in steroid-induced ocular hypertension. Both groups had an increase in median IOP 3 months post treatment, Iluvien causing a more marked pressure rise. Three patients (6 eyes) required treatment in the form of selective laser trabeculoplasty, trabeculectomy and glaucoma drops to reduce IOP 1-3 months post Iluvien implants. Patients also noticed VA didn't improve as quickly with the Iluvien implants. Doctors found the Iluvien injector to be less efficient than the Ozurdex, it was more difficult to use and required more preparation.

Price comparison between the 2 implants is also a factor that needs considering, Iluvien costing £5,500 [ii] and Ozurdex costing £870[iii] per implant. Median requirement for Ozurdex implants for the 3 years prior to switching was 3, equating to a cost of £2,610.

TITLE: Imaging of Presumed Displaced Retinal Ganglion Cells in the Living Human Retina

SESSION TITLE: Advanced imaging technologies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Marte, K. Kurokawa, H. Jung, Y. Liu, M. Bernucci, B. King, D.T. Miller, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mary Marte: Commercial Relationship: Code N (No Commercial Relationship) | Kazuhiro Kurokawa: Commercial Relationship(s);Indiana University:Code P (Patent) | Hae Won Jung: Commercial Relationship: Code N (No Commercial Relationship) | Yan Liu: Commercial Relationship: Code N (No Commercial Relationship) | Marcel Bernucci: Commercial Relationship: Code N (No Commercial Relationship) | Brett King: Commercial Relationship: Code N (No Commercial Relationship) | Donald Miller: Commercial Relationship(s);Indiana University:Code P (Patent)

ABSTRACT BODY:

Purpose: Large somas hypothesized to be displaced retinal ganglion cells (dRGCs) have previously been reported by our group at the inner edge of the inner nuclear layer (INL) of human subjects with adaptive optics optical coherence tomography (AO-OCT). dRGCs have been studied in numerous mammals but have not yet been classified in the human retina. To characterize this cell population, a prospective pilot study was performed obtaining AO-OCT images of the INL in human subjects.

Methods: The right eye from five healthy subjects aged 26.6 ± 1.3 years was imaged. Subjects with retinal pathology or high refractive error were excluded. The Indiana AO-OCT system was utilized to obtain $1.5^\circ \times 1.2^\circ$ volume images at 8 locations: 2° , 3° , 6° , 8° , and 13° temporal and 2° , 3° , and 6° nasal to the fovea, along the horizontal meridian of the retina. ImageJ™ software was used to manually view, count, and measure the en-face area of all large somas at the INL edge. Morphometric biomarkers of soma density, diameter and spatial distribution were measured. Also, AO-OCT images of subjects with glaucomatous arcuate defects were reviewed to assess dRGC presence in the defect.

Results: dRGC soma density was greatest near the fovea and decreased monotonically with increasing retinal eccentricity in all subjects (maximum average of 543.4 cells/mm^2 at 2° nasal; minimum average of 38.0 at 13° temporal). See Fig. 1. This trend is consistent with that of retinal ganglion cells (RGC), except near the fovea where RGC density peaks parafoveally^{1,2} and dRGC density continues to increase as close as 2° from the fovea. Soma size and its standard deviation increased monotonically with increasing retinal eccentricity, from $13.0 \pm 1.4 \text{ mm}$ at 2° temporal to $16.0 \pm 1.5 \text{ mm}$ at 13° temporal. Size and size variation are consistent with that of ganglion cell layer somas at the same retinal eccentricities as reported in the literature ($11.4 \pm 1.8 \text{ mm}$ at $1.5\text{-}3^\circ$ and $13.9 \pm 3.1 \text{ mm}$ at $12\text{-}13.5^\circ$).¹ All glaucoma images showed reduced numbers of dRGCs in the area of the arcuate defect compared to healthy individuals.

Conclusions: We obtained the first morphometric measurements of presumed displaced RGCs in the INL of the living human retina.

ABSTRACT BODY:

Purpose: Ophthalmoscopy is part of the medical curriculum, but the teaching of medical contents is often unsatisfactory because there is no systematic learning of pathologies and their treatment options; instead of that healthy students examine each other. For this reason, we have developed a project to improve teaching at the Medical Faculty of the JWG University of Frankfurt/Main, which offers the opportunity to train ophthalmoscopically using a newly developed online platform (EyesiNet) in addition to simulator training. Defined learning contents are reproducible and made available to everyone equally.

The aim was to test the efficiency of the online platform EyesiNet in combination with the simulation of direct (Eyesi Direct) and indirect (Eyesi Indirect) ophthalmoscopy.

Methods:

At the beginning of the internship and on the last day of the internship, the students worked on cases in Eyesi Direct and Indirect. In the meantime, they were able to deal with the topic in the web-based EyesiNet on a voluntary basis. Results were scored on first and last day and compared to each other

Results:

Eyesi Direct: With $p=0.29$, both groups had the same starting conditions and did not have significantly different results in case processing on the first day of the internship. In the group of non-trainees ($n=54$), a significant improvement in simulator training was observed on the last day of the practical training with $p=0.02$, but with a small effect size of 0.1. Among the trainees ($n=32$), a highly significant improvement with an effect size of 0.3 was observed in the Wilcoxon Matched Pair Test with $p=0.0004$.

Eyesi Indirect: Both groups had no significant difference in the results in the Eyesi Indirect test at the beginning of the training period ($p=0.10$). 32 trainees performed unequivocally (but not significantly) better than 54 non-trainees.

Conclusions: The online platform EyesiNet impressively supports the learning of the most important disease patterns; the skills of direct ophthalmoscopy can be learned much faster than those of indirect ophthalmoscopy; a 3 days period is obviously way too short for the learning process. The online platform EyesiNet substantially accelerates the learning curve in ophthalmology - why not in other subspecialties, too? Home office conditions for sure take extra profit from such a modern tool.

ABSTRACT BODY:

Purpose: We tested whether a stereopure antisense oligonucleotide that selectively targets the P23H mutation in Rhodopsin (RHO) but that spares expression of healthy RHO transcripts can address phenotypes associated with the autosomal dominant form of retinitis pigmentosa (adRP) that is caused by this mutation.

Methods: We applied PRISMTM, Wave's proprietary discovery and drug development platform, to generate stereopure antisense oligonucleotides that selectively target the RHO P23H mutation. We evaluated allele-selective activity of the oligonucleotides against RHO alleles with a luciferase reporter assay in Cos7 cells and in human retinal pigment epithelial (ARPE-19) cells that overexpress RHO. To assess target engagement and efficacy of the oligonucleotides in vivo, we evaluated their activity in mouse and pig models for RHO P23H-induced adRP. Animals received intravitreal (IVT) injections, and eyes were evaluated for RHO P23H expression and expression of rod and cone cell markers by immunohistochemistry.

Results: We demonstrate that stereopure oligonucleotides selectively deplete expression of RHO P23H transcripts in vitro. After a single IVT eye injection of a stereopure oligonucleotide, expression of RHO P23H transcripts are decreased by at least 50% in mouse and pig models for RHO P23H-induced adRP. In the pig model, a single IVT injection led to the retention of rod outer segments and cone pedicles compared with untreated eyes 16-weeks post-injection.

Conclusions: These results confirm that stereopure oligonucleotides can selectively deplete expression of RHO P23H transcripts. These oligonucleotides deplete RHO P23H transcripts in vivo in multiple models and rescue phenotypes associated with adRP. Together, these data suggest stereopure oligonucleotides may provide a viable therapeutic opportunity for addressing RHO P23H-dependent adRP.

TITLE: Influence of perimetric parameters at abnormal points within the central 10 degrees in 24-2 visual field (VF) on the severity of 10-2 VF in early glaucoma.

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Chakravarti, Glaucoma, Eye And Glaucoma Care, Kolkata, West Bengal, INDIA|

Commercial Relationships Disclosure (Abstract): Tutul Chakravarti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Evaluating the influence of perimetric parameters at abnormal points within the central 10 degree in 24-2 VF on the severity of 10-2 VF in early glaucoma (MD < -7dB).

Methods: This cross-sectional study included 54 eyes of 49 early glaucoma patients with central visual field defect (CVFD) on 24-2 VF and related parafoveal scotomas on 10-2 VF. CVFD, a glaucomatous defect with at least 1 abnormal 24-2 VF point, depressed P < 1% in the central 10 degrees (12 points: central-most 4 points and paracentral 8 points) on 3 consecutive tests either on total deviation (TD) or pattern deviation (PD) plot. Based on pattern defects, 10-2 VFs were categorized into 3: arcuate, partial arcuate and minimal defect groups, the arcuate defect being the most severe form. We compared the perimetric parameters differences between 24-2 VFs with central-most VF defects (CMVFD) or paracentral defects and related 10-2 VFs. We assessed the relationship between various perimetric factors at abnormal 24-2 VF points (central 4 and paracentral 8 points) and the severity of 10-2 VF using Pearson's correlation coefficients.

Results: The mean age of the population was 67.6 years and mean 24-2 mean deviation (MD) -3.76dB. On 24-2 VF, 4 (7.4%) eyes had only CMVFDs, 31 (57.4%) had both CMVFDs and paracentral defects and 19 (35.1%) had paracentral defects. On 10-2 VF, 25 (46%) eyes displayed arcuate defect, 11 (20%) partial arcuate and 18 (33%) minimal defect. Arcuate group had worse MD, PSD (pattern standard deviation) than partial arcuate and minimal defect groups (P < .001). High defect depth (> -25dB) and low threshold sensitivity (< 0 to 10dB) at abnormal 24-2 VF points were significantly associated with the presence of arcuate defect on the 10-2 test (P = 0.033; P = 0.002). PSD in arcuate group on the 10-2 test displayed negative correlation with threshold sensitivity (-0.638, P = 0.003) and defect depth [(TD: -0.765, P < .001); (PD: -0.542, P = 0.037)] of abnormal central-most 4 points in 24-2 VF.

Conclusions: High defect depth and low threshold sensitivity at abnormal points within the central-most 4 and/or paracentral 8 points in 24-2 VF are significantly associated with the presence of arcuate defect on 10-2 VF. Clinicians might consider measuring perimetric parameters at abnormal 24-2 VF points within the central 10 degrees to predict the severity and functional impacts of central glaucomatous visual field loss.

ABSTRACT BODY:

Purpose: The current system for pairing medical students to residency programs has been relatively unchanged for half a century. The residency matching algorithms, including SF Match for ophthalmology, are based on Gale-Shapley, a 'stable-marriage' method that favors applicant outcomes. We sought to develop a new matching algorithm (ResOpt) and compared it to Gale-Shapley.

Methods: We obtained anonymized rank lists and match data for applicants and programs in ophthalmology from SF Match between 2011 to 2019. The matches of SF Match and ResOpt were compared in terms of the average rank of matches for both applicants and programs, the percentage of applicants matching to their top choices, and the change in match composition.

Results: For 2011 to 2019, ResOpt always fully matches and avoids the Supplemental Offer and Acceptance Program. In addition, ResOpt consistently matches more applicants to their most preferred programs (Figure 1a). Under ResOpt, 78.7% (3308/4205) of applicants matched their top 3 choices compared to 71.5% (2991/4181) under SF Match. Furthermore, ResOpt achieves better average ranks for both applicants and programs (Figure 1b and 1c), without drastically changing the match composition (Figure 2a). Rank composition analysis (Figure 2b) shows the applicants whose outcomes improve often improve by multiple ranks, while applicants who worsen mostly drop 1 rank.

Conclusions: ResOpt is a credible alternative as a matching algorithm, as it consistently improves matches for most applicants and programs.

ABSTRACT BODY:

Purpose: Understanding the prevalence of myopia in young pediatric patients is crucial to prevent pathological complications such as, retinal detachment, myopic maculopathy, open-angle glaucoma, and cataracts. This study aims to determine the prevalence of myopia in Hispanic children aged 3 to 5-years-old over a 5 year period, 2012 to 2017, with the University of California, Los Angeles (UCLA) Preschool Vision Program (UPVP).

Methods: The UPVP performed visual acuity and undilated refractive screening on 3 to 5-year-old children between 2012 to 2017, and found the majority of the students to be Hispanic. Of these students, 10,903 underwent full cycloplegic examination after failing initial screening criteria. Myopia was defined as a spherical equivalent ≤ -0.5 D in one or both eyes. Prevalence of myopia was compared using Pearson's Chi-squared test and mean spherical equivalent were analyzed using Analysis of Variance (ANOVA).

Results: Across all examined participants, there was significant change in mean spherical equivalent over calendar years, 2012 to 2017 ($p = 0.002$). Of those who were myopic, the severity of myopia, measured by spherical equivalent, also changed significantly from 2012 to 2017 ($p = 0.04$). Additionally, when all participants were stratified by age group, 3 and 4-year-old participants demonstrated a significant increase in prevalence of myopia over time (from 2012 to 2017) ($p < 0.05$). 5-year-old participants demonstrated a positive trend towards increased myopia prevalence ($p = 0.09$). To exclude participants who might have been examined multiple times in the analysis of myopia prevalence over time, first and last calendar years (2012-13 vs 2016-17) were compared. Prevalence of myopia was observed to increase significantly amongst all ages, 3, 4, and 5-years-old, over calendar year ($p < 0.05$).

Conclusions: The severity of myopia is changing, and the prevalence of myopia has increased over time, from 2012 to 2017, in Hispanic pre-school aged children. This information will help in further myopia screening of preschool children to prevent serious pathological complications.

ABSTRACT BODY:

Purpose: The UCLA Preschool Vision Program (UPVP) is a community outreach program that provided free on-site vision screenings and eyeglasses to Los Angeles preschoolers between 2012 – 2017. Here, we investigate the longitudinal visual outcome among those prescribed eyeglasses by UPVP.

Methods: This is a retrospective longitudinal case series. Preschoolers seen twice by UPVP were included. Study eye was designated as the eye with lower BCVA at initial visit. Data including best-corrected distance visual acuity (BCVA), refractive error, and severity of amblyopia were analyzed. Paired statistical analysis was performed using Wilcoxon signed rank and McNemar tests.

Results: 8,866 preschoolers were assessed twice by UPVP. 321 of them had a complete follow-up examination after being prescribed glasses. Mean(\pm standard deviation) BCVA at Visit 1 was 0.24 ± 0.15 (95% CI: 0.23 to 0.26) logMAR, and 10.6% had unilateral amblyopia with mean BCVA of 0.43 ± 0.13 (95% CI: 0.37 to 0.49) logMAR. At 11.5 \pm 2.5 months, 52% of preschoolers wore glasses as prescribed at Visit 1. Follow-up mean BCVA was 0.16 ± 0.12 logMAR (95% CI: 0.15 to 0.18) ($p = 2.2 \times 10^{-16}$). 88% of amblyopic preschoolers improved in BCVA, with mean change of 0.19 ± 0.13 (95% CI: -0.24 to -0.15) logMAR ($p = 2.51 \times 10^{-6}$). BCVA change for glasses compliant amblyopia preschoolers was -0.23 ± 0.12 (95% CI: -0.29 to -0.18) logMAR, while non-compliant group was -0.13 ± 0.11 (95% CI: -0.20 to -0.05) logMAR ($p = 0.025$).

Conclusions: UPVP identified otherwise undetected vision deficiencies, such as amblyopia, and provided timely interventions to improve visual outcome. Compliance to prescribed glasses remains an obstacle to vision care.

ABSTRACT BODY:

Purpose: Wet age-related macular degeneration and diabetic retinopathy are leading causes of blindness with characteristic neovascularization (NV) of the choroid (CNV) or retina (RNV), respectively. This preclinical study explores effects of the investigational drug, risuteganib (RSG), in cell culture and three murine disease models using histology and transcriptomics.

Methods: In photocoagulation-induced CNV model, 1-50 μ g RSG or control peptides were intraocularly injected, followed by measurement of NV area on day 14 (n=4). The rho/VEGF model of subretinal NV was used to examine: i) injection of vehicle, 25 μ g RSG, 10 μ g ranibizumab, or combination of two drugs, followed by NV area measurement on day 7 (n=5), and ii) vascular leakage 1 day after PBS or 25 μ g RSG injection (n=8). In oxygen-induced retinopathy (OIR) RNV model, 0.1-50 μ g of RSG or PBS were injected and NV area was measured on day 5 (n=8). Student's t-test was used except with ANOVA in the rho/VEGF study of NV. Transcriptome changes associated with RNV and 10 μ g RSG injection was measured by RNA-seq. Changes in gene levels were determined by edgeR and enrichment of biological processes/pathways by goseq. RT-CES-based HREC cell adhesion and migration assays were used to test effect of 43-1393 μ M RSG on surfaces coated with vitronectin (VN) or fibronectin (FN) (n=2), statistical test by ANOVA.

Results: In the photocoagulation model, 10 and 25 μ g RSG reduced the area of CNV (p=0.0453, 0.0498). In the rho/VEGF model, RSG (p<0.001) and ranibizumab (p<0.001) both reduced NV area, while combination showed further reduction (p<0.05); RSG reduced vascular leakage by 24% (p=0.017). In OIR, 12.5, 25, and 50 μ g RSG (p=0.0271, 0.0414, 0.0403) reduced NV area. Transcriptome data showed biological processes and pathways related to angiogenesis, inflammation, integrin, cell adhesion and migration were enriched in genes elevated in OIR retina and reduced with RSG. Cell migration on FN was inhibited at low RSG dose (p<0.01), while migration on VN (p<0.01), adhesion on VN (p<0.05) and FN (p<0.01) were inhibited at high RSG dose.

Conclusions: RSG demonstrated anti-NV property, reduced retinal vascular leakage, and inhibited cell adhesion and migration. Transcriptome data suggest important pathological cellular responses are modulated by RSG, with possible therapeutic implication for treatment of human retinal diseases.

ABSTRACT BODY:

Purpose: Hydrogen sulfide (H_2S) releasing compounds and NSAIDs can mitigate cataractogenesis in vitro and in vivo (Zhang et al., Mol Vis, 14:862, 2008; Harding JJ et al., Acta Ophthalmol, 67:518, 1989). However, the role of NSAID- H_2S -releasing hybrid compounds on cataractogenesis has not been elucidated. In the present study, we compared the pharmacological effects of ATB343 (indomethacin & H_2S donor) and ATB337 (diclofenac & H_2S donor) on cataractogenesis in cultured bovine lenses and on lenticular antioxidants concentrations.

Methods: Freshly isolated bovine lenses were cultured in a DMEM buffer solution as follows: Group I: Control (DMEM); Group II: H_2O_2 (10 mM); Groups III-V: ATB343 (10^{-7} M); ATB337 (10^{-7} M); ascorbic acid (AA; 10^{-3} M) in presence and absence of H_2O_2 (10 mM). Lenses were incubated and were qualitatively and quantitatively assessed at 3, 6, 24, 48 and 72 h-time points by photographic captures and measurement of transmittance using a plate reader (Synergy H1 hybrid). Lenticular glutathione (GSH) and superoxide dismutase (SOD) were measured using Cayman Assay Kits.

Results: DMEM-cultured lenses exhibited a time-dependent decrease in transmittance (420nm) and a corresponding loss of lens optical clarity up to 72 h. Unlike ATB343 (10^{-7} M) and the endogenous antioxidant, AA (10 mM) which attenuated time-dependent lens degradation up to 24 h, ATB337 (10^{-7} M) decreased time-dependent transmittance, achieving an inhibition of $34.7 \pm 1.12\%$ ($n=12$; $p<0.01$) after 72 h. H_2O_2 (10 mM) reduced transmittance in a time-dependent manner, attaining an inhibition of $42.0 \pm 1.0\%$ ($n=12$; $p<0.01$) after 72 h. After 48 h, ATB343 (10^{-7} M) and ATB337 (10^{-7} M) enhanced time-dependent GSH depletion by $3.6\% \pm 0.05\%$ ($n=3$; $p<0.05$) and $2.7 \pm 0.5\%$ ($n=3$; $p<0.05$) and H_2O_2 -induced GSH depletion by $12.3 \pm 0.1\%$ ($n=3$; $p<0.01$) and $8.7 \pm 0.4\%$ ($n=3$; $p<0.05$), respectively. However, ATB343 enhanced SOD depletion by $35.3 \pm 2.7\%$ ($n=3$; $p<0.001$) but attenuated H_2O_2 -induced SOD depletion by $56.6 \pm 3.1\%$ ($n=3$; $p<0.001$) ($t=48$ h). Similarly, ATB337 enhanced time-dependent loss in SOD by $48.9 \pm 4.4\%$ ($n=3$; $p<0.001$) but reversed H_2O_2 -induced SOD loss by $31.8 \pm 4.9\%$ ($n=3$; $p<0.001$) ($t=48$ h).

Conclusions: The NSAID- H_2S hybrid compounds, ATB343 and ATB337 can partially protect cultured bovine lenses from cataract formation, presumably via an effect on lenticular SOD concentrations.

ABSTRACT BODY:

Purpose: In the retinal pigment epithelium (RPE), the fluorescence lifetime (FL) of lipofuscin granules, related to their composition, may be a useful biomarker of retinal health. Widefield fluorescence lifetime imaging ophthalmoscopy (FLIO) has been used to investigate RPE changes with age, eccentricity and disease but is limited by low sampling density and artifacts such as lens and macular pigment fluorescence. We improve the resolution and confocality by applying adaptive optics FLIO (AOFLIO), for the first time, to image the RPE mosaic in healthy people.

Methods: To specifically target lipofuscin, a custom-built adaptive optics scanning light ophthalmoscope was used for reflectance and FL imaging in 3 subjects (up to 12 locations across the macula; 30-38 yrs). RPE autofluorescence was excited with 532±10 nm (50 ps pulse width, 80 MHz repetition rate, 15 µW average power) and collected 575-725 nm (1.4-1.7° square field of view, 25 Hz frame rate, ≤60 s exposure). FL data was analyzed using custom and commercial software (Becker & Hickl GmbH). A two-component exponential function $\alpha_1 e^{-t/\tau_1} + \alpha_2 e^{-t/\tau_2}$ was fit to the decay curve at each binned pixel. Mean FL was calculated by $\tau_m = \alpha_1 \tau_1 + \alpha_2 \tau_2$ where τ_n is the FL and α_n is the relative contribution. τ_n and α_n were averaged across each AOFLIO image and compared using Student's t-test.

Results: Across all images, τ_m is 247.3±27.8 ps (ranging from ~200–270 ps, with an outlier at 330 ps); within an image, the average standard deviation of τ_m is 2.8±0.3 ps. α_1 was also consistent with mean 88.7±0.4% (ranging 88.1–89.4%). τ_1 and τ_2 ranged 120–230 and 830–1170 ps, respectively. The measured τ_m is within the range expected for lipofuscin (widefield FLIO long spectral channel attributed to lipofuscin: Dysli et al., 2017; ex vivo: Docchio et al., 1991; Schweitzer et al., 2007; Feldman et al., 2018). AOFLIO measurements taken 8 days apart in one subject showed no significant differences in τ_n and α_n ($p \geq 0.12$). Between two subjects, no significant differences were found in the FLs ($p \geq 0.058$), but α_1 showed a small but significant difference ($s1: 88.6 \pm 1.7\%$, $s2: 88.5 \pm 0.3\%$, $p < 0.001$).

Conclusions: These are the first measurements using AOFLIO to image the human RPE mosaic. Our results suggest AOFLIO will be repeatable within and between young healthy subjects. We expect larger variations with age and disease related to composition and function of the RPE mosaic.

TITLE: Efficacy and Safety of OCS-02 a novel, potent, topical TNF α antibody in acute anterior uveitis (AAU): a phase 2 study

SESSION TITLE: Uveitis: Clinical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Galor, Surgical Services, Miami VA Healthcare System, Miami, Florida, UNITED STATES|A. Galor, Ophthalmology, University of Miami Mary and Edward Norton Library of Ophthalmology, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Anat Galor: Commercial Relationship(s);Novaliq:Code C (Consultant);Dompe:Code C (Consultant);Oculis:Code C (Consultant);Novartis:Code C (Consultant);Oyster Point:Code C (Consultant)

ABSTRACT BODY:

Purpose: Due to the side effects of steroids, there is a medical need for new anti-inflammatory drugs to treat uveitis. Marketed TNF α antagonists are considered effective but are administered systemically. OCS-02 is a potent topical ocular anti-TNF α antibody fragment. This randomized, active-controlled study (ClinicalTrials.gov NCT02482129, registered 6/26/2015, study start 7/17/2015) assessed OCS-02 efficacy and safety in acute anterior uveitis (AAU) patients.

Methods: This was a Phase 2, multicenter, randomized, parallel-group, double-masked, active-controlled study. Dexamethasone was added for masking purposes with no inferential comparison to OCS-02. Patients aged ≥ 18 years with non-infectious AAU and Standardization of Uveitis Nomenclature anterior chamber (AC) cell score of 2+ or 3+ were recruited. Patients were randomized (3:1 ratio) to OCS-02 (60 mg/mL; 8 drops/day for 15 days, then 4 drops/day for 7 days, followed by matching vehicle for last 7 days to maintain masking with active control) or dexamethasone eye drops (8 drops/day for 15 days tapering to 1 drop/day over 14 days). The primary efficacy endpoint was Responder Status at Day 15- at least a two-step decrease in AC Cell Grade relative to baseline. Efficacy was determined if the Bayesian lower limit of the 95% posterior interval of the responder rate was $>30\%$. Safety assessments included adverse events and ophthalmic examination.

Results: Twenty nine patients were treated with OCS-02 and 10 patients with dexamethasone. The Day 15 response rate in the OCS-02 arm was 56%; the lower bound of the 95% credible interval was 40%, i.e. $>30\%$, thus demonstrating efficacy according to prespecified criteria. The proportion of patients with an AC Cell Grade of 0 increased from baseline to Day 29, despite the tapering and discontinuation of OCS-02 at Day 22: 76% had an AC Cell Grade of 0 on at least 1 post-treatment visit. Mean intra-ocular pressure was unchanged in the OCS-02 arm. There were no notable differences in ophthalmic examination results.

Conclusions: Administration of OCS-02, a novel TNF α antibody eye drop, demonstrated efficacy in resolving ocular inflammation in this phase 2 study of patients with AAU. The drug was well tolerated without steroid-type side effects or eye irritation suggesting its potential as a non-steroidal therapy for AAU. Confirmatory clinical studies are planned.

ABSTRACT BODY:

Purpose: The 24-2C test pattern increases sensitivity to central field defects by adding 10 test locations from the 10-2 pattern that are tested at the end of a 24-2 threshold test¹. The purpose of this ongoing, preliminary clinical study was to compare the repeatability of the 10 added test locations in a prototype 24-2C SITA Standard test to legacy SITA tests in normal and glaucomatous eyes.

Methods: Experimental 24-2C SITA Standard (SS-C), as well as 24-2C SITA Faster (SFR-C), 10-2 SITA Standard (SS-10), and 10-2 SITA Fast (SF-10) visual fields (VFs) were acquired on an HFA3 Model 860 perimeter (ZEISS, Dublin, CA) at each of two visits on one eye each for healthy and glaucomatous subjects. 24-2 SITA Standard VFs were extracted from SS-C as a reference for disease severity.

Repeatability was calculated by computing the test-retest standard deviation (TRT-SD) using both visit data for mean deviation (MD) and pattern standard deviation (PSD), as well as individual threshold values at the 10 added test locations.

Results: Mean age was 55.8 (standard deviation, SD: 6.4; range: 44.3 to 69.9) years for 17 healthy eyes and 73.6 (SD: 9.2; range 60.9 to 97.9) years for 16 glaucomatous eyes ($p < 0.001$). Mean 24-2 SITA Standard MD was 0.63 (SD: 1.15; range: -1.14 to 3.04) dB and -6.81 (SD: 6.86; range: -22.61 to 1.85) dB in healthy and glaucomatous eyes ($p < 0.001$), respectively.

TRT-SDs for MD were 0.61, 1.29, 0.52, and 0.49 dB for tests SS-C, SFR-C, SS-10, and SF-10, respectively. TRT-SDs for the 10 added locations were 1.57, 2.28, 1.85, 2.21 dB for tests SS-C, SFR-C, SS-10, and SF-10, respectively (see Table 1). Overall, the repeatability for SS-C MD and thresholds were comparable to their counterparts.

Conclusions: The findings in this preliminary cohort suggest the repeatability of the additional test locations added to 24-2C SITA Standard test is comparable to the repeatability of the same locations in the 24-2C SITA Faster and the 10-2 SITA tests. As a result, a 24-2C SITA Standard test may maintain comparable ability to detect progressive changes in the ten new test locations in the central visual field as compared to the current SITA tests.

TITLE: Visual impairment and 3-year change in cognitive function in the Canadian Longitudinal Study on Aging

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Grant, R. Buhrmann, E.E. Freeman, University of Ottawa, Ottawa, Ontario, CANADA|M. Aubin, M. Kergoat, Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Alyssa Grant: Commercial Relationship: Code N (No Commercial Relationship) | Marie-Josée Aubin: Commercial Relationship: Code N (No Commercial Relationship) | Ralf Buhrmann: Commercial Relationship: Code N (No Commercial Relationship) | Marie-Jeanne Kergoat: Commercial Relationship: Code N (No Commercial Relationship) | Ellen Freeman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our goal was to explore the longitudinal associations between vision-related variables and cognitive test change scores in a community-dwelling sample of older adults and to examine whether sex, education, or hearing loss act as effect modifiers.

Methods: A 3-year prospective cohort study was performed using data from the Canadian Longitudinal Study on Aging consisting of 30,097 individuals aged 45-85 years. Visual impairment (VI) was defined as binocular presenting visual acuity worse than 20/40. Participants were asked if they had ever had a physician diagnosis of age-related macular degeneration (AMD), glaucoma, or cataract. Cognitive change was examined by calculating the difference between baseline and follow-up scores of the Rey Auditory Verbal Learning Test (RAVLT: a test of verbal memory), the Controlled Oral Word Association Test (COWAT: a test of verbal letter fluency), the Animal Naming Test (ANT: a test of verbal category fluency) and the Mental Alternation Test (MAT: a test of processing speed). Multiple linear regression was used and sampling weights were included in all models.

Results: Visual impairment was associated with the 3-year decrease in RAVLT ($\beta=-0.18$, 95% confidence interval (CI)= -0.28, -0.07), RAVLT-Delayed ($\beta=-0.13$, 95% CI= -0.25, -0.02), and ANT ($\beta=-0.95$, 95% CI= -1.44, -0.45) scores after adjusting for age, sex, ethnicity, income, smoking, diabetes, stroke, heart disease, baseline cognitive score, and province. A report of glaucoma was associated with a decrease in 3-year MAT change scores ($\beta=-0.40$, 95% CI -0.77, -0.04). The self-report of AMD or cataract were not associated with 3-year changes in cognitive test scores. No effect modification was detected.

Conclusions: These data indicate that VI and glaucoma are associated with 3-year declines in cognitive test scores. Further research is needed to elucidate the pathways to explain these associations.

ABSTRACT BODY:

Purpose: The PIONEER study evaluates the safety and tolerability of GS030, an investigational optogenetic treatment combining a gene therapy and a light-stimulation medical device in subjects with late-stage non-syndromic retinitis pigmentosa (RP).

Methods: PIONEER is a Phase 1/2a open-label study including three dose-escalation cohorts (5E10, 1.5E11, 5E11 vg/eye) of 3 subjects each, and an extension cohort treated at the highest tolerated dose. Treatment is gene agnostic, and the optogenetic gene therapy encoding channelrhodopsin ChrimsonR-tdTomato (ChRtdT) is administered by intravitreal injection to target preserved retinal ganglion cells (RGCs). While RGCs are normally not light sensitive cells, expression of ChRtdT renders RGCs sensitive to light. After GS030 optogenetic therapy, controlled stimulation of the genetically reengineered retina using a visual interface stimulating goggles encode images of the visual world in real time and project them onto the retina by modulating a tailored light source at a specific wavelength, and mimicking natural visual processing.

Results: As of July 2020, six patients in the first two cohorts and one patient of the third cohort were treated with a single intravitreal injection of optogenetic gene therapy in their worse-seeing eye. Use of the visual interface medical device to stimulate RGCs expressing ChR-tdT was initiated two months after gene therapy injection and showed no safety concerns, before or after injection. Up to 2 years after gene therapy administration, no adverse event led to study discontinuation. The most common adverse events were mild or moderate anterior chamber or vitreous inflammation (4/7 patients) responsive to corticosteroid treatment, and transitory mild sensitivity to light (2/7 patients) that started before the use of light stimulation by the visual interface goggles.

Conclusions: The PIONEER study is the first clinical trial combining a gene therapy and a medical device using an optogenetic approach. The treatment was well tolerated up to two years after gene therapy administration.

TITLE: Aligning patients for fundus image capture – effects of a gameified interface on speed and ease of capture

SESSION TITLE: Multidisciplinary imaging technologies and applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Anderson, A. Bender, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gregory Anderson: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Andre Bender: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Correct alignment of patients' eyes is essential for capturing fundus images, but can be a challenge for inexperienced imaging technicians. Most devices overlay guides on a live view of the eye to show target positions along the x-, y-, and z-axes. These guides rely on mental computations on the part of users to convert colors and arrows to manual adjustments of the device.

This study investigated a new alignment feedback mechanism that uses gamified graphics without live images of the eye to provide feedback that requires fewer mental computations, to assess the impact on alignment times and ease-of-use ratings for imaging technicians.

Methods: Ten participants who are not imaging technicians, and have little to no experience with fundus cameras were asked to capture images on the CLARUS™ 500 (ZEISS, Dublin, CA) using both the commercial user interface (UI) and a modified alignment interface. In each case, participants were asked to capture two widefield (WF) color images of "acceptable" quality (as determined by a study cohort technician with more than 1 year of experience). The average alignment/acquisition times between the two UI conditions were compared using a t-Test. Participants were given 5 minutes of practice before acquiring images with each system, and the order of conditions was reversed for half the participants. Ease-of-Use ratings (5=Very Easy; 1=Very Difficult) were used to quantify perceived ease of use.

Results: Average alignment time to capture two images of acceptable quality was 74.5 seconds (SD=33.8) using the commercial UI, and 49.8 seconds (SD=20.6) using the gameified UI. These show that the gameified UI resulted in significantly faster acquisition times ($T=2.83$, $p<0.05$).

Average Ease-of-Use ratings were 3.1 (SD=1.1) using the commercial UI, and 3.9 (SD=1.0) using the gameified UI. Ease-of-Use ratings between the two UI's were not significantly different. ($T = -1.86$, $p = 0.096$).

Conclusions: An alignment UI design that applies video game elements and neuroergonomic principles to reduce cognitive load during acquisition is shown to speed up acquisition time for new and less-experienced imaging technicians. The practical impact is improved efficiency of fundus imaging workflows.

TITLE: Prevalence of Conjunctival Intraepithelial Neoplasia in Pterygium Specimens

SESSION TITLE: Cornea Trauma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Zhu, M. Weiss, F. Scribbick III, D.A. Johnson, A. Kheirkhah, Department of Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Christopher Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Menachem Weiss: Commercial Relationship: Code N (No Commercial Relationship) | Frank Scribbick III: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Kheirkhah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the prevalence of conjunctival intraepithelial neoplasia (CIN) in pterygium specimens and to determine the possible risk factors for such occurrence.

Methods: This retrospective study included 557 pterygium specimens from patients with a clinical diagnosis of pterygium. None of the patients had clinical signs of CIN. Presence of CIN was evaluated using histopathologic evaluation with hematoxylin and eosin (H&E) and Ki67 staining. In addition, the following clinical data were collected from medical records: age, sex, self-reported race (White, African American, or Asian) and ethnicity (Hispanic versus non-Hispanic), and the involved eye. Logistic regression was performed to determine the possible risk factors for presence of CIN in pterygium specimens.

Results: There were 557 specimens from 557 eyes of 525 patients, which included 333 men and 224 women with a mean age at excision of 53.4 ± 13.1 years. Of all specimens, 95.9% were from patients identified as White, 2.2% from African Americans, and 2% from Asians. Self-identified ethnicity included Hispanic (69.7%) and non-Hispanic (30.3%). Among all specimens, 40 (7.2%) were positive for CIN. Patients with CIN were significantly older (59.2 ± 13.6 years) compared with those without CIN (53.0 ± 13.0 years, $P=0.008$). Furthermore, patients with CIN had a significantly higher percentage of male population (80% vs 58%, $P=0.007$). However, there were no significant differences between those with and without CIN in race and ethnicity. Regression analysis showed that older age ($P=0.01$) and male sex ($P=0.02$) had significant associations with presence of CIN in pterygium specimens.

Conclusions: Pterygium specimens from older male patients are more likely to have CIN. As the treatment and prognosis of these two conditions differ significantly, careful histopathologic evaluation of all pterygium specimens, especially in those with the risk factors, is warranted.

ABSTRACT BODY:

Purpose: Glaucoma is often assessed with optical coherence tomography (OCT) and perimetry to provide clinicians a large number of quantitative parameters that aid in diagnosis. The OCT Early Glaucoma Diagnostic Structural Index (EGDSI), was previously proposed and validated providing a combined structural index for the detection of early glaucoma^{1,2}. In this retrospective clinical study, we compared the sensitivity of EGDSI to individual OCT summary parameters in a cohort with a range of glaucoma severity.

Methods: Retrospective OCT and visual field (VF) data were analyzed from a previous study including 74 eyes of 74 glaucoma subjects, using CIRRUS™ HD-OCT (ZEISS, Dublin, CA) and HFA™ II-i (ZEISS, Dublin, CA)³. At each visit, Optic Disc 200x200 and Macula 200x200 cube scans and SITA Standard 24-2 VFs were acquired. Sixteen OCT summary parameters (Rim Area, Cup-to-Disc area Ratio (CDR), vertical diameter CDR (vCDR), Average and four Quadrant RNFL thicknesses, Average, Minimum, and six Sectoral GCIPL thicknesses) were extracted for comparison and to calculate EGDSI from the last qualified visit data as previously described^{1,2}. A VF mean deviation (MD) cutoff of -4 dB was used to separate early and non-early glaucoma as done previously². Sensitivity at specificities of 95% and 99% were determined for EGDSI and component OCT parameters based on cut-off values from the CIRRUS reference database. McNemar's test was used to compare individual results to the EGDSI.

Results: Mean ± standard deviation (SD) age was 63.6±10.1 (range: 35.7 to 79.6) years. Mean ± SD VF MD was -3.9±4.1 (range: -18.2 to 1.2) dB. Sensitivities for EGDSI were 81.1% and 67.6% for 95% and 99% specificity, respectively (see Table 1). The best individual parameters were: a) GCIPL Minimum (70.3% and 54.1%); b) RNFL Inferior (64.9% 54.1%); and c) Rim Area (56.8% and 36.5%). Comparable sensitivities were seen in the split cohorts, though values for EGDSI and GCIPL Minimum became more comparable in non-early glaucoma (See Table 2).

Conclusions: The combined EGDSI shows improved sensitivity in early glaucoma and comparable sensitivity in non-early glaucoma eyes in this study. As such, EGDSI may be a useful aid for the detection in a clinical range of glaucoma.

ABSTRACT BODY:

Purpose: The visual reconstruction by means of retinal prostheses requires evoking pseudolight sensations (phosphene) by electrical stimulation. However, change in electrode position over time [P. J. Allen, et al. IOVS 2019;60:4983, Y. Terasawa, et al. IOVS 2017;58:4195] makes it difficult to evoke phosphene. In this study, we evaluated whether an electrode array including dorsal protrusions (spike-shaped array; Fig. 1) can reduce the movement of the electrode.

Methods: A control array without dorsal protrusions or a spike-shaped array were implanted in the scleral pocket of rabbits (n = 6). Both arrays had platinum electrodes (diameter; 0.5 mm, height; 0.3 mm). The electrode positions were observed by scanning laser ophthalmoscopy (SLO) images immediately after surgery, and 1 week and 1 month postoperatively. The movement of the electrodes was compared by superimposing the SLO images using the coagulation plaques or black dots around the optic nerve papilla as reference points. All procedures were in accordance with the Association for Research in Vision and Ophthalmology Statement for the Use of Animals in Ophthalmic and Vision Research. This study was approved by the Institutional Animal Care Committee of Nidek Co., Ltd.

Results: SLO imaging showed movement of the device, the control array shifted a mean of 0.20 ± 0.05 mm (n = 4) and the spike-shaped array shifted a mean of 0.12 ± 0.07 mm (n = 6) between the immediate postoperative period and the first postoperative week (p = 0.07, independent t-test). The control array shifted a mean of 0.37 ± 0.06 mm (n = 4) and the spike-shaped array shifted a mean of 0.23 ± 0.10 mm (n = 6) between the first postoperative week and the first postoperative month (p < 0.05, independent t-test).

Conclusions: The spike-shaped array had a smaller movement distance of the electrodes than the control array. It is speculated that the connection between the tissue and the protrusions become stronger with elapsed time after the surgery. These results suggested that using the spike-shaped array was effective as a countermeasure against the shifts in electrode position.

ABSTRACT BODY:

Purpose: To determine whether type 2 diabetes mellitus (T2DM) with and without diabetic retinopathy (DR) are independent risk factors for PCR during cataract surgery while accounting for previous intravitreal injections (IVI).

Methods: A retrospective study was conducted at the Sue Anschutz-Rodgers UCHHealth Eye Center from January 2014 to March 2019. The primary outcome was incidence of PCR during phacoemulsification surgery in patients with T2DM with and without DR, accounting for previous IVI. Univariate and multivariable analysis were utilized to calculate odds ratios (OR) and adjusted odds ratios (AOR).

Results: A total of 10,893 eyes were included. A PCR occurred in 59 (0.5%) of eyes overall: 35 (0.4%) eyes in patients without diabetes, comparatively to 13 (0.7%) eyes with T2DM without DR ($p=0.142$), and 11 (1.8%) eyes with DR ($p<0.0001$).

All groups with previous IVI demonstrated a significant increase in PCR compared to eyes without IVI or T2DM. In the absence of IVI, T2DM without DR was not significant ($p=0.520$), but T2DM with DR had a significantly increased risk of PCR in univariate analysis (OR 3.55, 95% CI: 1.49, 8.50, $p=0.004$) and an increased risk of borderline significance in multivariate analysis (AOR 2.33, 95% CI: 0.98, 5.56, $p=0.056$).

Conclusions: In the absence of IVI, T2DM without DR is not an independent risk factor for PCR. T2DM with DR is likely a risk factor but was of borderline significance due to small sample size. Previous IVI is an independent risk factor for PCR. Consideration of PCR risk should be given during surgical planning for patients with DR and/or previous IVI.

TITLE: Biometric parameters can predict IOP change and IOP spikes after cataract surgery in glaucoma patients

SESSION TITLE: Surgery and Wound Healing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F.G. Sanchez, J. Rees, S.L. Mansberger, Glaucoma research, Legacy Devers Eye Institute at Legacy Good Samaritan Medical Center, Portland, Oregon, UNITED STATES|F.G. Sanchez, S.K. Gardiner, S.L. Mansberger, Glaucoma research, Discoveries In Sight Research Laboratories, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Facundo Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Jack Rees: Commercial Relationship: Code N (No Commercial Relationship) | Stuart Gardiner: Commercial Relationship: Code N (No Commercial Relationship) | Steven Mansberger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We sought to determine whether preoperative anterior segment parameters could predict postoperative day 1 intraocular pressure (IOP) after cataract surgery (CS) in glaucoma patients.

Methods: We used the Lenstar LS 900 Optical Biometer (Haag-Streit, Koeniz, Switzerland) to preoperatively measure axial length (AL), anterior chamber depth [(ACD), i.e. the distance between the posterior surface of the cornea and the anterior surface of the lens], crystalline lens thickness [(LT), i.e. the distance along the optical axis between the two surfaces of the lens], and white-to-white distance [(WTW), i.e. horizontal iris width] in glaucoma eyes scheduled for CS.

We used generalized estimating equations regression to determine the association of these parameters with IOP change from baseline on day 1 after CS, and to derive the odd ratios (OR) for the occurrence of an acute intraocular pressure elevation (IOP spike). We defined a "5 mmHg IOP spike" as a postoperative day 1 IOP \geq 21 mmHg that was also \geq 5 mmHg greater than preoperative IOP, and a "10 mmHg IOP spike" when the elevation was \geq 10 mmHg. All calculations were adjusted for the number of preoperative ocular hypotensive agents.

Results: Table 1 shows baseline characteristics of the eyes included.

The IOP on day 1 (22.2 mmHg, SD 8.4, range 11-54) was significantly higher than preoperatively (16.9 mmHg, 4.69, 7-31; $p=.004$). We found that 38.1% (16/42) of the eyes had a 5 mmHg IOP spike, and 14.3% (6/42) had a 10 mmHg IOP spike.

Patients with shallower ACD had a significantly higher increase in IOP on day 1 (0.64 mmHg per 0.1mm decrease in ACD, $p=.023$) (Fig. 1, top), and a higher risk of 10 mmHg IOP spike (OR 1.22, $p=.013$). Similarly, patients with thicker lens had a higher increase in IOP on day 1 (0.91 mmHg higher per 0.1mm increase in LT, $p=.005$) (Fig. 1, bottom), and were more likely to have a 5 mmHg IOP spike (OR 1.04, $p<.001$) or a 10 mmHg IOP spike (OR 1.19, $p=.053$). Patients with shorter AL were slightly more likely to suffer a 10 mmHg IOP spike (OR 1.04, $p=.046$). Bivariable models showed that AL and LT were significant predictors of a 5 mmHg IOP spike ($p<.001$ and $p=.009$, respectively).

Conclusions: Shallower ACD, shorter AL, and thicker LT were associated with increased risk of IOP spikes on postoperative day 1 in glaucoma patients. This is in contrast to these same parameters being associated with a long-term decrease in postoperative IOP.

TITLE: Field testing of All Aboard, an AI app for helping blind individuals to find bus stops

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Jiang, Z. Ma, A. Singh, A. Bobba, S. Park, S. Pundlik, G. Luo, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eric Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Zhicheng Ma: Commercial Relationship: Code N (No Commercial Relationship) | Abhishek Singh: Commercial Relationship: Code N (No Commercial Relationship) | Akash Bobba: Commercial Relationship: Code N (No Commercial Relationship) | SaengMoung Park: Commercial Relationship: Code N (No Commercial Relationship) | Shrinivas Pundlik: Commercial Relationship: Code N (No Commercial Relationship) | Gang Luo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many blind people take public transportation, especially in metropolitan cities. Due to the lack of pin-point accuracy of conventional geo-location information provided by mobile devices, when navigating to the bus stops, they sometimes may experience the 'last-10-meter' problem, which refers to a gap between the bus stop and the destination announced by the mobile devices. The gap may sometimes be large enough for bus drivers to misunderstand the blind people's intention and not stop the buses for them. This pilot study evaluates an AI solution to address the localization problem.

Methods: We developed a mobile AI app, All Aboard, which detects bus stop signs in the users' vicinity in the images captured by the smartphone camera in real-time. The deep neural network for bus stop sign detection was custom-trained using 5000 to 10000 images collected for a given city. The app guides the users to approach bus stop signs through auditory cues, with pitch coding the distance to the target. In a pilot test, we evaluated the accuracy of localizing bus stops using the All Aboard app versus the Google Map navigation for 20 bus stop locations in the Los Angeles area. 10 bus stops were in the downtown area near high-rises, and the other 10 stops were in suburban areas. The experimenter walked under the guidance of auditory cues given by All Aboard app and Google Maps, respectively, starting from about 25 meters away from each bus stop. The localization error was measured as the distance from the actual bus stop signs to the location where the apps indicated the user arrived at the destinations.

Results: The successful navigation rate with Google Maps was 60% (failed to localize 7 stops in downtown and 1 in suburban), and with All Aboard app was 95% (failed to detect 1 downtown stop). The All Aboard app was able to detect bus stop signs starting from an average distance of 9.7 ± 6.3 (SD) meters. Excluding navigation failures, the localization error with All Aboard app (average \pm SD: 1.1 ± 0.6 meters, max. = 2.2 meters) was significantly lower than Google Maps (7.4 ± 3.8 meters, max. = 13 meters) (paired t-test, $p < 0.001$).

Conclusions: The promising results suggest that the bus stop sign detection app can potentially address the "last-10-meter" problem for blind individuals taking bus transportation.

ABSTRACT BODY:

Purpose: To evaluate differences of structural parameters in patients with open angle glaucoma (OAG), high myopia (M) and both diseases (OAG-M) concurrently.

Methods: 30 patients (22 women, 8 men) were included in the prospective pilot study: 10 patients with OAG (age in years) 54.2 (3.11), 10 patients with OAG-M (51.8 (8.0)) and 10 patients with M (48.2 (5.12)). The study groups did not vary significantly in age ($p=0.07$) or gender ($p=0.84$). Study eyes were chosen randomly. Peripapillary retinal nerve fiber layer (RNFL) thickness, macular ganglion cell complex (GCC), macular and peripapillary vessel density (VD%) were measured using optical coherence tomography (OCT) (swept source, TOPCON DRI Triton). Peripapillary VD was evaluated using ImageJ software (National Institute of Health, Bethesda, Maryland). Kruskal-Wallis test was used to determine the differences in median values between groups with $p<0.05$ considered statistically significant.

Results: The mean spherical equivalent (SE) in OAG was 0.62D (SD 0.53), M -7.2D (1.0), OAG-M -7.75D (3.07). The mean RNFL thickness was 91.7 (17) μm in OAG; 95.1 (6.6) μm in M and 82.7 (17.8) μm in OAG-M groups ($p>0.05$). The RNFL thickness was significantly different between groups in the temporal quadrant ($p=0.023$) with the lowest value found in the OAG group. OAG-M patients had significantly lower GCC thickness 87.6 (10.8) μm , compared to OAG 95.4 (11.34) μm and M 103.1 (3.1) μm patients ($p=0.01$). Significant positive correlations were found between mean RNFL thickness and mean peripapillary VD of the optic nerve head (ONH) ($r=0.532$, $p=0.004$). Higher myopia correlated with decreased RNFL thickness ($r=-0.571$, $p=0.001$). Lower macular GCC thickness positively correlated with thinner optic nerve head (OND) RNFL ($r=0.75$, $p<0.001$).

Conclusions: Peripapillary RNFL and macular GCC thickness were lowest in patients with concurrent OAG and high myopia. Additionally, higher myopia alone was related to a lower RNFL thickness. Specifically designed longitudinal studies are needed to better define and differentiate changes of structural parameters that occur in glaucomatous and myopic disease.

Commercial Relationships Disclosure (Abstract): Saray Tabak: Commercial Relationship: Code N (No Commercial Relationship) | Elie Beit Yannai: Commercial Relationship: Code N (No Commercial Relationship) | Sofia Schreiber Avissar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our purpose was to investigate the effect of physicochemical properties on exosomes interactions with glaucoma eye drops in the context of the pathway by which exosomes enter the target cells.

Methods: Exosomes were isolated by precipitation method and concentrations were determined by Tunable Resistive Pulse Sensing technology. To evaluate the ionic strength (IS) effects on exosomes size and ZP, different PBS buffer strengths, eye drops solutions used for POAG treatment; Alphagan-P®, V-OPTIC®, AZOPT®, Lumigan®, and Travatan®, their active ingredients; Timolol maleate, Brinzolamide or their preservative benzalkonium chloride were analyzed. The size, ZP, and IS of exosomes were measured using NTA and Zeta sizer devices, respectively. The contribution of exosomes interactions to the internalization ratio, regulated by TM cells, was examined at different time points.

Results: Exosomes size and ZP were affected by the IS of the buffer rather than exosomes type. Commercial glaucoma eye drops including β -blocker, α -2-agonist, and prostaglandin analogs, reduced NPCE exosomes ZP. Whereas, exposure of exosomes to carbonic anhydrase inhibitor caused an increase in the ZP. A correlation was found between increased ZP values and increased NPCE exosomes uptake by TM cells. We were able to show that Benzalkonium chloride stands behind this ZP effect and not Timolol or Brinzolamide.

Conclusions: Our findings suggest that exosomes size, surface membrane charge, and IS of the surrounding, have an impact on exosomes:exosomes interactions which affect the uptake of NPCE exosomes by TM cells.

TITLE: Dimension reduction reveals underlying factors of performance within a vision screening battery

SESSION TITLE: Assessing human vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E. Seemiller, E. Palmer, E. O'Keefe, E. Shoda, KBR, Inc., Ohio, UNITED STATES|J. Gaska, M. Winterbottom, Air Force Research Laboratory 711th Human Performance Wing, Wright-Patterson AFB, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eric Seemiller: Commercial Relationship: Code N (No Commercial Relationship) | James Gaska: Commercial Relationship: Code N (No Commercial Relationship) | Marc Winterbottom: Commercial Relationship: Code N (No Commercial Relationship) | Eric Palmer: Commercial Relationship: Code N (No Commercial Relationship) | Eleanor O'Keefe: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Shoda: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vision tests within a screening battery should be quick, easy and independent. Because the early visual system has limited functional architecture, many vision screening tests ultimately provide redundant information. For example, while seeking information about parallel processes such as stereopsis and motion perception, certain test battery results may be muddled by colinear relationships and shared computations. These redundancies potentially make visual screening batteries inefficient and less informative. For career fields requiring extensive medical screening (e.g. commercial pilots/drivers, military aviation, etc.), the duration of the screening may be an important factor. However, by identifying independent factors underlying visual performance, a test battery can be streamlined. The goal of this dimension reduction analysis is to identify such underlying factors in a visual screening paradigm from a large and diverse subject population.

Methods: 192 subjects underwent the Operational Based Vision Assessment Laboratory Automated Vision Testing (AVT) procedure, which included computer-based tests for visual acuity, luminance and cone contrast sensitivity, motion coherence, stereopsis, and binocular oculomotor function. Psychometric thresholds and fusional vergence ranges were collected from each subject. Factor analysis was performed on a total of 14 normalized variables with a promax rotation.

Results: This rotation identified 5 factors that explained 74% of the variance in the dataset. These factors were related to the following: 1) medium and high spatial frequency vision, 2) stereoacuity and horizontal fusional range, 3) color vision, 4) motion perception, and 5) low spatial frequency vision. Variability within individual factor loadings revealed informative trends. For example, while horizontal fusion range was associated with factor 2, vertical fusion range was not well correlated with any factor.

Conclusions: These results suggest that the number of tests within the AVT battery may be reduced to as few as five with a limited loss in information. Furthermore, identifying these underlying factors may have additional utility in predicting performance in naturalistic or operational visual tasks.

ABSTRACT BODY:

Purpose: Intraocular drug delivery faces many challenges including delivery of drugs for extended periods to targeted tissues without adverse systemic effects. Currently, free drug is injected into the vitreous cavity every four to eight weeks with initial overdosing of tissues. In addition, most current therapeutics simply bind pathogenic molecules but do not stop their production. The ability to deliver RNA interference therapeutics intracellularly via a cell receptor specific targeting approach would solve many of the problems of intravitreal therapy.

Methods: We synthesized siRNA carriers consisting of porous silicon nanoparticles that are incorporated into fusogenic liposomes by film hydration to deliver the nanoparticles intracellularly (Fig. 1). The iRGD targeting peptide (CRGDKGPDC), developed to deliver anticancer therapeutics to malignant tumors, was conjugated to the liposome surface and is specific for neovascular epithelium. DL- α -aminoadipic acid (DL-AAA) was used to induce retinal neovascularization (RNV) in rabbits to evaluate the ability of the targeted fusogenic nanoparticles (TFNP) loaded with VEGF siRNA to reduce vascular growth. Normal rabbit eyes were dosed intravitreally with TFNP loaded with 10 μ g VEGF siRNA in a 50 μ L volume. Toxicologic and optical evaluations included slit lamp, fundus, optical coherence tomography, and fluorescein angiography at 2 and 8 weeks.

Results: The vitreous cavity remained clear and all evaluations including histology and electroretinography showed no evidence of toxicity. Fluorescein leakage in the RNV model was absent in eyes treated with VEGF siRNA loaded TFNPs compared to control eyes at 8 weeks (Fig. 2).

Conclusions: TFNPs are a novel and safe vehicle to deliver RNA therapeutics intracellularly. The porous silicon nanoparticles load high quantities of the nucleic acid payload, and the fusogenic lipid coatings enable cell entry while avoiding endocytosis. Targeting of cell-surface receptors expressed more extensively during specific disease allows more accurate targeting of diseased tissues and permits longer acting effects from a single intravitreal injection.

ABSTRACT BODY:

Purpose: To assess correlation between change in central subfield thickness (CST) and change in best-corrected visual acuity (BCVA) in eyes with macular edema due to branch retinal vein occlusion (BRVO) receiving fixed-dosing intravitreal aflibercept injections (IAI) over 52 weeks.

Methods: Post hoc analysis of the VIBRANT clinical trial, in which eyes were randomized to IAI (6 doses every 4 weeks of 2 mg IAI, followed by IAI every 8 weeks) or macular laser photocoagulation at baseline. The relationship between functional (BCVA) and anatomical (CST) outcomes at weeks 12, 24, and 52 was determined using Pearson correlation coefficient.

Results: Of 181 eyes, 91 received IAI and represent the analysis cohort. The percentage of eyes with both BCVA and CST measurements available for analysis at weeks 12, 24, and 52 was 97%, 91%, and 80% of enrolled IAI-assigned eyes. At baseline, the correlation (r) between CST and BCVA was -0.41 (95% CI: -0.56 to -0.22). Correlations (r) between change in CST and change in BCVA from baseline at weeks 12, 24, and 52 were -0.34 (95% CI: -0.51 to -0.14), -0.32 (95% CI: -0.50 to -0.11), and -0.36 (95% CI: -0.54 to -0.14), respectively. In a linear regression analysis of correlation between changes in CST and changes in BCVA at week 52 adjusted for baseline factors (age, perfusion status, time since diagnosis, and baseline BCVA), CST changes accounted for only 23% of the variance in BCVA changes. At 52 weeks, every 100 μ m decrease in CST was associated with a 2.2 letter increase in BCVA (95% CI: -0.2 to 4.5, P = .07).

Conclusions: In eyes treated with fixed-dosing IAI for macular edema from BRVO, the magnitude of the correlation between change in CST and change in BCVA was weak to moderate. For any given change in CST from baseline, there was a broad range of change in BCVA at weeks 12, 24, and 52. While changes in CST may be important in determining the need for repeat anti-VEGF to manage macular edema due to BRVO, these findings do not support using changes in CST to predict visual acuity outcomes.

TITLE: Refinement of optic nerve function and myelination during postnatal wildtype development

SESSION TITLE: Molecular and Structural

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Balraj, R.H. Miller, Anatomy, The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Annika Balraj: Commercial Relationship: Code N (No Commercial Relationship) | Robert Miller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cells generate a pattern of action potentials to communicate visual information. Myelin, an insulating sheath, facilitates signal propagation by wrapping around axons and, when deficient (as observed in patients with optic neuritis), can cause significant visual deficits. However, the relationship between optic nerve function and the extent of myelination is currently unknown.

Methods: We tested if myelination patterns are correlated with changes in optic nerve function during postnatal development using extracellular nerve recordings, immunohistochemistry, western blot, and scanning electron microscopy.

Results: Comparing compound action potentials from C57Bl6 mice across ages 4-12 wks revealed an increase in the number of functional axons and shifts toward more fast-conducting axon populations at 5 and 8 wks ($p < 0.05$, $n=8$). At these ages, nerve assessments suggest increases in myelin and neurofilament protein concentrations ($n=2$) and lower g-ratios ($n > 2$). Increased expression of a mature sodium ion channel (Nav 1.6) at nodes of Ranvier was observed at 6 wks ($p < 0.05$, $n=3$), while axon diameter, axon density, and nodal density remained unchanged across ages.

Conclusions: Changes in the normal optic nerve to favor faster axonal conduction correlate with additional myelin proteins, thicker myelin around axons, and node maturity, suggesting that these properties are critical in the refinement of optic nerve signaling during postnatal maturation.

TITLE: CCR3 inhibition reduces recruitment of peripheral immune cells to the eye in the sodium iodate model of age-related macular degeneration

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Dhande, S. Caryotakis, Y. Lopez, S. Minami, Alkahest Inc, San Carlos, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Onkar Dhande: Commercial Relationship(s);Grifols:Code E (Employment) | Sofia Caryotakis: Commercial Relationship(s);Grifols:Code E (Employment) | Yesenia Lopez: Commercial Relationship(s);Grifols:Code E (Employment) | Sakura Minami: Commercial Relationship(s);Grifols:Code E (Employment)

ABSTRACT BODY:

Purpose: Recent Phase 2a clinical studies were completed with AKST4290, a potent CCR3 inhibitor, in treatment-naïve nAMD and refractory nAMD patients. The majority (83%) of nAMD subjects demonstrated stable or improved best-corrected visual acuity after 6 weeks of AKST4290 treatment. Preclinical studies were subsequently conducted to examine whether the efficacy observed in nAMD patients was in part due to blocking CCR3-mediated retinal homing of damage-promoting immune cells from the periphery which in turn dampens local inflammation and may subsequently modify disease progression.

Methods: The sodium iodate (NaIO₃) model (single iv injection, 20 mg/kg) was used to induce retinal inflammation and degeneration in C57Bl6 mouse eyes. Mice were treated with twice daily oral dose (60 mg/kg) of AKST4290. Flow cytometry was used to examine the immune cell composition in the retinal pigment epithelium (RPE) at 3 days post NaIO₃ injection. The effect of AKST4290 treatment on inflammatory cytokines in the eye was probed using Luminex immunoassays. Nested generalized linear model with pair wise comparison was used for statistical analysis.

Results: NaIO₃ induced a significant increase in number of immune cells in the degenerating RPE (Control vs NaIO₃; monocytes [cell counts, mean±sem]: 74±16 vs 1679±222; neutrophil: 14±3 vs 146±17; CD4 T cells: 33±5 vs 170±26; p<<0.01). AKST4290 treatment significantly reduced immune cell infiltration in NaIO₃ damaged RPE (NaIO₃+4290; monocytes: 1051±153; neutrophil: 82±15; CD4 T cells: 131±29; NaIO₃ vs NaIO₃+4290 p<0.01). Treatment with AKST4290 also significantly reduced NaIO₃ induced increase in chemokines CCL5 (Control vs NaIO₃ vs NaIO₃+4290 (mean±sem (pg/ml): 1.41±0.11 vs 2.05±0.13 vs 1.76±0.13, p<0.05) and CXCL9 (1.8±0.26 vs 5.56±0.67 vs 3.67±0.43, p<0.05).

Conclusions: These data demonstrate that systemic inhibition of CCR3 by AKST4290 reduces the accumulation of peripheral immune cells in the RPE, which is the primary injury site in the NaIO₃ model and in nAMD. This reduction in recruitment of immune cells was associated with a decrease in chemokines in the degenerating RPE. These findings help illustrate the mechanism of action for AKST4290, supporting its observed efficacy as a drug candidate in clinical trials of nAMD patients.

ABSTRACT BODY:

Purpose: AKST4290, a non-brain penetrant inhibitor of CCR3, has undergone Phase 2a clinical studies in treatment-naïve and refractory neovascular age-related macular degeneration (nAMD) patients. The majority of nAMD patients displayed stable or improved best corrected visual acuity (BCVA) after 6 weeks of treatment. The goal of these preclinical studies was to identify potential sites of action by determining the pharmacokinetics and biodistribution of AKST4290 in various ocular compartments.

Methods: Quantitative whole-body autoradiography (QWBA; [^{14}C]-AKST4290) and LC-MS/MS bioanalysis was performed to assess drug levels in the eye. Male and female C57BL/6 mice were used for the QWBA study, and both C57BL/6 and Balb/c male mice were used for LC-MS/MS. For QWBA, [^{14}C]-AKST4290 was administered orally (single dose, 10 mg/kg) and autoradiography was performed at various post-dose time points (15 mins to 12 weeks). AKST4290 levels were quantified by LC-MS/MS in the retinal pigment epithelium (RPE)/choroid and retina at 0.5h, 2h, and 24h post-dose (single oral dose, 30 mg/kg).

Results: QWBA showed maximal levels of AKST4290 derived radioactivity at 24h post-dose in both the whole eye (0.56 $\mu\text{g eq/g}$) and uveal tract (2.61 $\mu\text{g eq/g}$) of male C57BL/6 mice. In comparison, AKST4290 in the uveal tract of female C57BL/6 mice peaked at 48 h (1.37 $\mu\text{g eq/g}$), and both male and female samples showed sustained levels up to 12 weeks (0.18 and 0.0643 $\mu\text{g eq/g}$ respectively) post-dose. Bioanalysis detected high levels of AKST4290 in the RPE/choroid of C57BL/6 mice at 0.5h (mean \pm sem[ng/ml]: 447.8 \pm 143.89), 2h (1087.2 \pm 106.64), and 24h (941.5 \pm 273.09) post-dose. In comparison, levels of AKST4290 in the RPE/choroid of Balb/c were significantly less at 2h (235.6 \pm 27.05, $p=0.0079$, Mann-Whitney). Relatively low levels of AKST4290 were detected in the retina of both strains at the 2h time point (C57BL/6: 460.06 \pm 41.79; Balb/c: 12.98 \pm 1.61).

Conclusions: These data show a preferential accumulation of AKST4290 in the RPE/choroid, the primary site of nAMD pathologies. Moreover, these data show a strong effect of retinal pigmentation on the levels of drug accumulation in the eye. These data support the RPE/choroid as a potential site of AKST4290 action in nAMD and contextualize treatment efficacy observed in clinical trials.

ABSTRACT BODY:

Purpose: Danicopan is an investigational first-in-class small-molecule inhibitor of factor D, an essential enzyme of the complement alternative pathway, which, when dysregulated, is implicated in the pathogenesis of age-related macular degeneration (AMD). We explored, in animal models, delivery of PO danicopan to the posterior segment of the eye for the potential treatment of geographic atrophy (GA), an advanced form of AMD.

Methods: Tissue distribution of drug-related radioactivity was studied following PO administration of [^{14}C]danicopan 20 mg/kg to pigmented Long-Evans (LE) and albino Wistar Han (WH) rats. Danicopan binding to natural and synthetic melanin was determined in vitro. Ocular tissue distribution was studied in pigmented Dutch-Belted (DB) and albino New Zealand White (NZW) rabbits following PO danicopan at 15 and 50 mg/kg BID for up to 15 days.

Results: After PO administration to rats, [^{14}C]danicopan-derived radioactivity was absorbed rapidly and distributed widely to tissues. Radioactivity was present 1–8h and became nonquantifiable 24h post-dose in most tissues. In LE, but not WH rats, radioactivity remained quantifiable in the uvea 672h post-dose ($t_{1/2}=576\text{h}$), suggesting danicopan binding to melanin, which was confirmed in vitro (mean $K_D=8.6\mu\text{M}$). Distribution to ocular tissues was also observed following PO administration of danicopan to rabbits: C_{max} retina:plasma ratios were 0.5–1 in DB and NZW, demonstrating that danicopan crosses the blood–retinal barrier (BRB); AUC choroid/RPE:plasma ratios were 24 and 0.7, respectively, in DB and NZW after single dosing (15 mg/kg), further supporting danicopan binding to melanin; and AUCs increased 7- and 13-fold in choroid/RPE and retina, respectively, after 15-day dosing (15 mg/kg BID) versus single dosing (15 mg/kg) in DB, suggesting that melanin-bound danicopan in choroid/RPE may serve as a drug depot maintaining high concentrations of danicopan in retina. Danicopan was well tolerated and resulted in no toxicity or ophthalmic abnormalities.

Conclusions: PO danicopan crosses the BRB and binds to melanin, leading to high and sustained drug exposure in posterior ocular tissue. These results support clinical investigation of danicopan for the oral treatment of GA.

TITLE: Compensation of OCTA flow index dependence on OCT signal strength

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Camino, Y. Jia, Y. Guo, D. Huang, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Acner Camino: Commercial Relationship(s);Genentech:Code E (Employment) | Yali Jia: Commercial Relationship(s);Optovue:Code F (Financial Support);Optovue:Code P (Patent) | Yukun Guo: Commercial Relationship: Code N (No Commercial Relationship) | David Huang: Commercial Relationship(s);Optovue:Code F (Financial Support);Optovue:Code I (Personal Financial Interest);Optovue:Code P (Patent);Optovue:Code R (Recipient)

ABSTRACT BODY:

Purpose: Optical coherence tomographic angiography (OCTA) images have been used to measure retinal vessel density and quantify the effect of eye diseases on retinal perfusion. Another OCTA parameter, the flow index, has also been investigated. The flow index is the average value of the flow signal in an en face OCTA image. It may be a more sensitive indicator to detect changes in velocity or volumetric flow than vessel density. But, due to its strong dependence on the strength OCT reflectance signal, it is less reliable for disease diagnosis. In this work, we present a compensation method to remove this dependence.

Methods: $3 \times 3 \text{ mm}^2$ macular OCTA scans were acquired by a spectral-domain OCT system (AngioVue). The flow index of the superficial vascular complex (SVC) was defined as the averaged OCTA decorrelation outside the foveal avascular zone (FAZ) - defined as a circle of 0.3-mm radius centered in the fovea - excluding large vessels. Sixty images were acquired from 10 healthy eyes by attenuating the signal strength with neutral density filters (NDF). The decorrelation values of background voxels were set to zero by a thresholding algorithm that accounted for voxel reflectance, which yields a vessel density that is independent of signal strength. Then, capillary flow signal was normalized to the averaged large vessel decorrelation signal of the scan, by compensating the linear dependences of the average large vessel and capillary decorrelation on average OCT reflectance (Fig. 1).

Results: The flow signal compensation was tested on a separate set of nine healthy eyes scanned repeatedly between two and six times under optimal imaging conditions. The dependence of flow index on OCT signal strength (Fig. 2) was reduced after applying the compensation scheme (Pearson's $R = 0.86$, $p < 0.01$ before compensation vs. $R = 0.49$, $p < 0.01$ afterwards). The coefficient of variation on the flow index in the test set was reduced by the compensation scheme from 14.8% to 10.8 %. The repeatability of the flow index, measured as the pooled coefficient of variation per eye was improved from 5.8% before compensation to 4.9% afterwards.

Conclusions: The algorithm successfully reduced the flow index dependence on OCT signal strength and yielded a more repeatable flow index measurement. This metric has potential to describe capillary flow changes in diabetic retinopathy, retinal vein occlusion and glaucoma.

ABSTRACT BODY:

Purpose: To investigate the changes in tear neuromediators and corneal subbasal nerve plexus following small incision lenticule extraction (SMILE).

Methods: Thirty patients were included for tear neuromediator analysis (40 eyes) and corneal nerve analysis using in-vivo confocal microscopy scans (20 eyes). Tear analysis included substance P (SP), calcitonin gene-related peptide (CGRP) and nerve growth factor (NGF) concentrations.

Results: Corneal nerve fiber density (CNFD), corneal nerve fiber length (CNFL), and corneal nerve branch density (CNBD) decreased significantly postoperatively, then gradually increased from 3 months onward, but did not recover to the baseline levels at 12 months. Tear SP and CGRP levels remained stable over 12 months. Tear NGF levels demonstrated a small peak at 1 week, before decreasing significantly compared to preoperative levels at 6 months ($P=0.03$) and 12 months ($P<0.01$). The 1-month reduction in CNFL, tear SP and CGRP concentrations were significantly correlated with the spherical equivalent (SE) corrected ($r=0.71$ for CNFL; $r=-0.33 \sim -0.52$ at different time points for SP and CGRP, respectively, all $P<0.05$). The high myopia group (corrected SE greater than -6.0 diopters), compared to the low-moderate myopia group, had significantly greater decrease in CNFD, and significantly higher tear SP concentrations at 1 week, 1 month and 6 months, as well as significantly higher tear CGRP concentrations at 1 and 6 months.

Conclusions: Our results provide new insight into the neuro-biological responses and their potential implications in corneal nerve damage and recovery after SMILE. High myopic treatment was associated with greater corneal denervation and neuroinflammation.

ABSTRACT BODY:

Purpose: The Bionic Vision Technologies Australia suprachoroidal retinal prosthesis ("bionic eye") has been shown to improve functional vision in patients with late stage retinitis pigmentosa (RP) in a first-generation trial in a laboratory setting. In a subsequent trial of a second-generation device (NCT03406416), we assessed whether patients with late stage RP could increase their performance in real-world functional visual tasks conducted with the prosthesis switched ON compared to OFF.

Methods: The Functional Low-Vision Observer Rated Assessment (FLORA) instrument was administered to three males (aged 39, 47 and 63) and one female (aged 66) before implantation and at 17, 20, 32, 44, 56 and 68 weeks after device fitting. The FLORA contains 13 self-reported and 35 observer-reported items. The ease of which participants completed each functional vision task was assessed with a four-point scale: impossible, difficult, moderate, and easy. The tasks were evaluated in four discrete domains: 'Visual Orientation', 'Visual Mobility', 'Daily Life' and 'Interaction with Others'. The distribution of person-level domain scores has been summarised via mode.

Results: Three participants completed the FLORA up to 68 weeks, with one participant being lost to follow up at 20 weeks for reasons unrelated to the device. For all participants after 17 weeks, the mode ease of task score with the device switched ON was higher or equal to when it was switched OFF (Figure 1). In general, ease of task score increased over time with the device switched ON. Tasks from the 'Visual Orientation' and 'Daily Life' domains were the main contributors to this effect. Qualitative analyses revealed participant-reported improvements in mobility, functional vision, and quality of life with device switched ON.

Conclusions: Participants with late-stage RP implanted with the second-generation suprachoroidal retinal prosthesis demonstrated improved ease of task scores over time with device ON relative to OFF. Improvement of ease of task scores over time with the device ON suggests a learning effect. The device shows potential utility in everyday life, and further research into its real-world use is warranted.

TITLE: Utilizing a Mobile Platform to Obtain Quantitative Measurements of Exophthalmos

SESSION TITLE: Neuro-Ophthalmology and Oculoplastics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Magazin, Ophthalmology, Augusta University Medical College of Georgia, Augusta, Georgia, UNITED STATES|A.A. Tooley, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|A.Q. Tran, Ophthalmology, Manhattan Eye Ear and Throat Institute, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Maja Magazin: Commercial Relationship: Code N (No Commercial Relationship) | Ann Tran: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Tooley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Hertel exophthalmometry has demonstrated limited reproducibility between observers and high variability between instruments of the same design. We conducted a prospective, comparative study to introduce a novel exophthalmometry method utilizing a mobile platform and compare its reliability to Hertel exophthalmometry. We hypothesize that a mobile platform can serve as a simple, socially distanced alternative for obtaining reliable and accurate measurements of globe position.

Methods: Fifty patients (99 eyes) were included for a total of 594 measurements. Healthy individuals from the community and individuals from a routine oculoplastics clinic were included to represent variety within the population. Exophthalmometric measurements were first obtained using a Hertel exophthalmometer by two masked observers. A widely accessible mobile ruler application was then used to obtain measurements through sagittal facial photos by using a credit card as a reference standard in the picture in order to scale measurements. The main outcome was the inter-modality correlation and agreement between Hertel and mobile exophthalmometry, and the intra-observer and inter-observer reliability with repeated mobile measurements.

Results: There was no significant difference between mobile measurements of each eye and those obtained by Hertel exophthalmometry (P-value for right and left eyes 0.726, 0.088). There was a strong linear correlation between Hertel and mobile exophthalmometry with a Pearson Correlation Coefficient of 0.910 and 0.888 for the right and left eyes, respectively ($p < 0.001$, 2-tailed). Bland-Altman plot analysis showed excellent agreement between the two modalities. The mobile platform demonstrated high intra-observer reliability with a Cronbach's alpha of 0.992 and 0.985 for the right and left eyes. An intraclass correlation coefficient of 0.992 (95% CI: 0.987-0.995) for the right eye and 0.986 (95% CI: 0.978-0.991) for the left eye demonstrated excellent reliability between observers.

Conclusions: The strong correlation and agreement between Hertel and mobile measurements suggest that a mobile platform can be a promising new alternative for obtaining reliable and accurate measurements of globe position. This alternative technique may be especially useful in situations where Hertel exophthalmometry may not be available or feasible such as in-patient settings and virtual office visits.

TITLE: Accommodation study 1: Novel physiological changes in anterior segment structures during real-time long-range accommodation

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Pujari, S. Modaboyina, S. Yadav, R. Sihota, P. Sharma, N. Sharma, T. Dada, J. Titiyal, Ophthalmology, All India Institute of Medical Sciences, New Delhi, Delhi, INDIA|

Commercial Relationships Disclosure (Abstract): Amar Pujari: Commercial Relationship: Code N (No Commercial Relationship) | Sujeeth Modaboyina: Commercial Relationship: Code N (No Commercial Relationship) | Suresh Yadav: Commercial Relationship: Code N (No Commercial Relationship) | Ramanjit Sihota: Commercial Relationship: Code N (No Commercial Relationship) | Pradeep Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Namrata Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Tanuj Dada: Commercial Relationship: Code N (No Commercial Relationship) | Jeewan Titiyal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To systematically study anterior segment changes during dynamic, long-range accommodation.

Methods: Design: Prospective, observational study.

Participants: A total of 26 young, healthy, third-decade subjects with less than $\pm 0.5D$ refractive error.

Methods: On swept-source anterior segment optical coherence tomography (CASIA-2, Tomey Corp, Japan), anterior segment structural changes were recorded on accommodation, from baseline (0 diopter) to 8 diopters.

Main outcome measures: Software generated automated changes in corneal thickness and volume, anterior chamber depth and area, iris area and curvature, lens curvature, lens thickness, lens tilt and decentration at each diopter, and qualitative changes in the ciliary body were noted.

Results: Results: 52 eyes of 26 subjects were evaluated, with mean age of 25.92 ± 1.64 years. Each successive dioptric accommodative stimulus from baseline, lead to progressive decremental responses in anterior lens curvature ($p < 0.001$), posterior lens curvature ($p < 0.001$), anterior chamber depth ($p < 0.001$) and anterior chamber area ($p = < 0.05$) with corresponding, incremental responses in lens thickness ($p < 0.001$) noted till 8D. However, the overall and inter-dioptric responses were more significant during the initial phases of stimulation, up to 4D, as compared to later. Likewise, iris (nasal and temporal) curvature ($p < 0.001$) and area ($p < 0.001$) also showed dynamic changes in a coordinated manner. Cornea and anterior chamber width changes were statistically insignificant, even though fluctuations were noted at higher dioptries.

Conclusions: Conclusions: On progressively increasing accommodation, initial significant changes were seen as primarily lenticular, complementary anterior chamber and associated iris changes. Whereas, accommodation at higher diopters showed significantly altered lens position and other complex anterior segment structural changes.

TITLE: Can bacterial cellulose membrane prevent bleb fibrosis in trabeculectomy surgery? An in vivo trabeculectomy study in a rabbit model

SESSION TITLE: Surgery and Wound Healing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Yazgan Akpolat, Ophthalmology, Inonu Universitesi Tip fakultesi, Malatya, TURKEY|I.O. Tekin, Immunology, Zonguldak Bulent Ecevit Universitesi Tip Fakultesi, Zonguldak, Zonguldak, TURKEY|N. Akpolat, Patology, Inonu Universitesi Tip fakultesi, Malatya, TURKEY|

Commercial Relationships Disclosure (Abstract): Serpil Yazgan Akpolat: Commercial Relationship: Code N (No Commercial Relationship) | Ishak Tekin: Commercial Relationship: Code N (No Commercial Relationship) | Nusret Akpolat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the effectiveness of bacterial cellulose membrane (BCM) in preventing fibrosis in a rabbit model trabeculectomy surgery and to investigate the biocompatibility of BCM with eye tissues.

Methods: Twenty-one eyes of 21 adult male rabbits underwent fornix-based trabeculectomy. Standard surgery was applied to the control group (CG, n=7). In addition to the standard process; mitomycin-C (MMC, 0.3 mg/ml) was applied to the sclerotomy area for 3 minutes to MMC group (MMCG, n=7), and in the BCM group (BCMg, n=7), the sclerotomy area was covered with BCM (10x10 mm, ~ 100 µm thick) as a single layer before closing the conjunctiva. BCM was sutured to the sclera from the proximal edges, and the distal edge was extended to the fornix freely. Intraocular pressures (IOP) were measured before surgery (baseline) and on the postoperative 7th, 14th, 28th and 45th days (IOP-POD7, POD14, POD28 and POD45). The rate of decrease in IOP over time were calculated according to the baseline values and expressed as decrease in IOP% (DIOP%)-POD7, DIOP%-POD14, DIOP%-POD28 and DIOP%-POD45. The rabbits were sacrificed on the 45th day. The surgery area was examined histopathologically and immunohistochemically for conjunctival vascularity, fibrosis, inflammation, foreign body reaction and expression of α -smooth muscle actin (α -SMA).

Results: There was no difference between the three groups in terms of baseline IOP and DIOP%-POD7 ($p=0.126$, $p=0.620$, respectively). While DIOP%-POD14, 28 and 45 values were similar between BCM and MMC groups, they were significantly lower in the CG compared to the others ($p < 0.05$). The groups were similar with regard to conjunctival vascularity ($p = 0.122$). Only in the BCMg group, 2 cases had moderate and 5 cases had mild foreign body reaction. There was no difference between CG and MMCG regarding inflammation, but moderate reaction was detected in all cases in the BCMg ($p=0.01$). While fibrosis and α -SMA levels were found to be significantly higher in the CG ($p<0.001$), there was no difference between the MMCG and BCMg.

Conclusions: Bacterial cellulose membrane provided better control of IOP with minimal fibrosis compared to the control. It was also found to have a good biocompatibility with eye tissues. With these features, BCM may be a candidate for use as an adjuvant tissue not only in trabeculectomy but also in other ocular surgeries.

SUBMITTER (NAME ONLY): Masato Matsuo

TITLE: 360-degree gonio-camera-based estimation of peripheral anterior synechiae formed after microhook ab-interno trabeculotomy

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Matsuo, Y. Inomata, N. Kozuki, M. Tanito, Ophthalmology, Shimane University Faculty of Medicine, Izumo, JAPAN|

Commercial Relationships Disclosure (Abstract): Masato Matsuo: Commercial Relationship: Code N (No Commercial Relationship) | Yuina Inomata: Commercial Relationship: Code N (No Commercial Relationship) | Nana Kozuki: Commercial Relationship: Code N (No Commercial Relationship) | Masaki Tanito: Commercial Relationship(s);Inami & Co., Ltd.:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: Postoperative peripheral anterior synechiae (PAS) formation after microhook ab-interno trabeculotomy (μ LOT), a minimally invasive glaucoma surgery (MIGS) procedures is not well studied; however, it could potentially reduce the surgical effectiveness. Additionally, the investigation would contribute to a better understanding of outcomes of trabeculotomy-related surgeries. Therefore, the purpose of the current study was to investigate the characteristics of PAS formation after μ LOT with a 360-degree gonio-camera, gonioscope GS-1 (NIDEK Co., Gamagori, Japan).

Methods: Consecutive one hundred five eyes of 75 subjects with open-angle glaucoma were analyzed; the eyes had undergone μ LOT or combined μ LOT and cataract surgery as an initial glaucoma surgery. Postsurgical PAS formations were evaluated in 16 iridocorneal angle images with the best focus covering 360 degrees in each eye.

Results: Compared to baseline, at 225 ± 226 days postoperatively, the intraocular pressure and number of antiglaucoma medications decreased significantly ($P < 0.01$, respectively). PAS formed in 86% of the eyes. The mean number of iridocorneal angle images in all eyes that exhibited PAS was 4.1 (26%) in the total circumference, 3.1 (39%) within the μ LOT incision, and 1.0 (13%) outside of the μ LOT incision; the rate was significantly higher within the incision than outside of the incision ($P < 0.01$). Moreover, the higher PAS rate in total and that within the incision had the possible association with later postoperative days ($P < 0.01$, respectively); that outside of the incision had the possible associations with μ LOT alone rather than combined surgery, and with shallower preoperative central anterior chamber depth ($P < 0.05$, respectively), which were calculated by the mixed-effect model.

Conclusions: We could have performed the detailed observation of PAS formation after μ LOT with 360-degree gonio-images, and the formation rate was significantly higher within the μ LOT incision. The PAS within and outside of the incision would have different causes.

ABSTRACT BODY:

Purpose: Building robust deep learning-based models requires large quantities of diverse training data. Due to medical data privacy regulations, it is often infeasible to collect sensitive patient data in a centralized data lake. Federated Learning (FL) sidesteps this difficulty by only sharing intermediate model training updates among them. In this study, we will show the effectiveness of FL in comparison to models trained on isolated and centralized data.

Methods: 76,544 OCT B-scans from 598 macular cubes acquired from 598 subjects using CIRRUSTM HD-OCT 5000 (ZEISS, Dublin, CA) were used as the training and test sets (478/120 split at cube level). 40% of B-scans were graded as “abnormal” by at least 1 of 2 retinal specialists.

A real-world scenario was simulated by splitting the training set into 3 originating regions for US (Region A), Europe (Region B), and Asia (Region C). For validation, the global test set consisted of 15,338 B-scans (38% “abnormal”) from the 120 cubes.

A ResNet50 was used to perform binary classification at the B-scan level. To evaluate the FL approach with meaningful baselines, we additionally trained isolated models on the regional data sets and one global model on the complete data set which share the same ANN settings and 50 epochs. All models have been tested on a global test set.

For applying FL, the decentralized ML framework mlx (prenodelabs, Germany, Karlsruhe) was used (see Fig. 1). Each model was trained for one epoch per region locally before centralizing their updated model weights (Δw) for aggregation. This cycled for 100 iterations.

Results: In Table 1, we show the performance (ACC, AUC, and 95% CI in %) of locally best models (selected by best validation score on the global test set) using local training data alone as well as after federated learning.

For Region B and C, a 7.1% relative improvement in accuracy can be observed when the federated model is applied.

Conclusions: Given our experimental results, we can see that FL in a simulated real-world scenario can both ensure a higher level of security and trust between data owners as well as increase the generalizability of the model across regions.

In addition, we observe no difference in the performance of a federated model in comparison to a model that has directly been trained on centralized data. Thus, we show the potential of FL replacing a conventional centralization of data to preserve confidentiality whilst developing robust models.

ABSTRACT BODY:

Purpose: In 2015 the authors were presented with EURETINA European Society of Retina Specialists Innovation Award for their idea to directly place LEDs within the eye during intraocular surgery. Thus better and safer illumination should be reached. The results of their research over the last 4 years is presented. Due to availability of novel LED illumination systems ophthalmologists must consider their impact on patients. Various aspects of LED light when either used as an intraocular light source during surgery or a transscleral illumination system are discussed. Possible hazard of light to the retina and critical parameters will be identified.

Methods: Novel LED illumination concepts have been developed by integration of micro-SMD LED and SM-LED into trocars and diaphanosopes. The physical effects of the LED illumination have been studied by exposing both porcine and human eyes to various light sources.

Results: An anterior to posterior examination revealed a location and pressure dependent transmission of human and porcine sclera. Furthermore pressure dependent direct trans-tissue transmission of eyewall, sclera and vitreous body in the range of 350–1050 nm was confirmed. It was shown that there exists a higher risk of light-induced retinal damage due to increase of intraocular irradiance by endoillumination.

Conclusions: Novel LED based light sources offer a great potential for innovation in the ophthalmic environment. The results of our studies showed that the existing regulations should be reconsidered to further enhance patient safety. Because all our studies have been done in ex vivo settings the next step should be a human in vivo study to determine for surgical purposes relevant data.

TITLE: Persistent Subretinal Fluid in the Comparison of Age-Related Macular Degeneration Treatments Trials (CATT)

SESSION TITLE: AMD: clinical research - biomarkers and outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.Q. Core, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, Pennsylvania, UNITED STATES|M. Pistilli, E. Daniel, M.G. Maguire, G. Ying, Ophthalmology, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jason Core: Commercial Relationship: Code N (No Commercial Relationship) | Maxwell Pistilli: Commercial Relationship: Code N (No Commercial Relationship) | Ebenezer Daniel: Commercial Relationship(s);Novartis:Code C (Consultant) | Maureen Maguire: Commercial Relationship(s);Genentech/Roche:Code C (Consultant) | Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the effect of persistent subretinal fluid (SRF) relative to resolved SRF on long-term visual acuity in eyes treated with ranibizumab or bevacizumab for neovascular age-related macular degeneration (nAMD) in the CATT.

Methods: Secondary analysis of CATT data from eyes with SRF at baseline and were treated pro re nata (PRN) for 2 yrs. OCT imaging was every 4 wks. Treatment was based on signs of active nAMD. Certified readers at the CATT reading center assessed OCT scans for macular presence and foveal thickness of SRF. Persistent SRF at wk 12 was defined as SRF present at wks 4, 8, and 12, while persistent SRF at 1 or 2 yrs was defined as SRF present at $\geq 80\%$ of visits over the 1- or 2-yr period. Mean visual acuity (VA) score and mean VA gain from baseline at 1 or 2 yrs were compared between eyes with vs. without persistent SRF using regression models that adjusted for persistent intraretinal fluid (IRF) and previously reported baseline VA predictors in CATT.

Results: Among 406 eyes with baseline SRF, 26.6% had persistent SRF at wk 12, 23.2% at yr 1, and 19.0% at yr 2. Eyes with vs. without persistent SRF at wk 12 showed similar mean VA score (letters) at yr 1 (68.3 vs. 69.9; $p=0.29$) and yr 2 (69.0 vs. 68.8; $p=0.93$), and similar VA gain at yr 1 (6.1 vs. 7.3; $p=0.30$) and year 2 (6.6 vs. 6.4; $p=0.94$) (Table 1). Yr 1 persistent SRF compared with no persistent SRF was not associated with significantly different mean VA scores at yr 1 (67.6 vs. 70.1; $p=0.12$) and yr 2 (68.5 vs. 69.0; $p=0.77$), or VA gain at yr 1 (5.2 vs. 7.8; $p=0.10$) and yr 2 (6.0 vs. 6.6; $p=0.74$). Yr 2 persistent SRF compared to no persistent SRF was not associated with significantly different mean VA scores at yr 1 (71.4 vs. 70.8; $p=0.71$) and yr 2 (70.0 vs. 69.5; $p=0.80$) or VA gain at yr 1 (7.9 vs. 7.8; $p=0.92$) and yr 2 (6.5 vs. 6.5; $p=0.97$). At yr 1 and earlier timepoints, SRF was absent at the foveal center in nearly half of eyes with yr 1 persistent SRF, and $<200\text{ }\mu\text{m}$ thick among most others (Table 2).

Conclusions: Among eyes with baseline SRF, mean VA in eyes with persistent SRF through 12 wks, 1 yr, or 2 yrs of PRN treatment was similar to eyes in which SRF resolved. Persistent SRF $>200\text{ }\mu\text{m}$ thick at the foveal center was rare.

TITLE: Prednisolone and ketorolac versus ketorolac alone or dropless prophylaxis of macular thickening in cataract surgery

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.H. Erichsen, L.M. Holm, M.F. Jacobsen, L. Kessel, Department of Ophthalmology, Rigshospitalet Glostrup, Glostrup, DENMARK|L.M. Holm, L. Kessel, Department of Clinical Medicine, Kobenhavns Universitet Sundhedsvidenskabelige Fakultet, Copenhagen, DENMARK|J.L. Forman, Section of Biostatistics, Kobenhavns Universitet Institut for Folkesundhedsvidenskab, Copenhagen, DENMARK|

Commercial Relationships Disclosure (Abstract): Jesper Erichsen: Commercial Relationship: Code N (No Commercial Relationship) | Lars Holm: Commercial Relationship: Code N (No Commercial Relationship) | Mads Jacobsen: Commercial Relationship: Code N (No Commercial Relationship) | Julie Forman: Commercial Relationship: Code N (No Commercial Relationship) | Line Kessel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Choice of anti-inflammatory prophylaxis parallel to cataract surgery is contested. We performed a randomized controlled trial to determine if combination of prednisolone- and non-steroidal anti-inflammatory drug (NSAID) eye drops was superior in preventing increased central macular thickness (CMT) following uncomplicated cataract surgery compared with NSAID monotherapy and dropless surgery, and to test if preoperative initiation of eye drop treatment was superior to initiation on the day of surgery.

Methods: Low-risk participants scheduled for cataract removal were randomized to 1 of 5 anti-inflammatory prophylactic regimens; combination of prednisolone- (Pred Forte 1%) and ketorolac (Acular 0.5%) eye drops with or without preoperative initiation (Pred+NSAID-Pre (control) and Pred+NSAID-Post), ketorolac monotherapy with or without preoperative initiation (NSAID-Pre and NSAID-Post) or subtenon depot of dexamethasone (Dropless). Eye drops were administered 3 times per day until 3 weeks after surgery. Primary outcome was CMT 3 months after surgery. Secondary outcomes were intraocular pressure (IOP), visual acuity (VA) and subjective tolerance of treatment. Outcomes were measured at baseline, 3 weeks and 3 months postoperatively.

Results: We included 470 participants, mean age 72.2 (SD 7.0) years, 290 (62%) females – 94 participants in each group. Three months after surgery, CMT was (mean [95%CI]) 250.7 [247.6 ; 253.7] with Pred+NSAID-Pre, 250.7 [247.8 ; 253.7] with Pred+NSAID-Post, 251.3 [248.2 ; 254.4] with NSAID-Pre, 249.2 [246.2 ; 252.3] with NSAID-Post and 255.2 [252.0 ; 258.3] with Dropless. There were no significant differences compared with control and no differences between Pre- and Post-groups, but 56.6% in Dropless group needed additional treatment. NSAID monotherapy- and Dropless groups had significantly lower IOP until 3 weeks after surgery compared with control. There were no significant differences in VA or subjective tolerance at any postoperative time.

Conclusions: Combination of prednisolone and NSAID eye drops was not superior to NSAID monotherapy in preventing central macular thickening, but subtenon depot of dexamethasone was inefficient as a dropless approach. Initiating prophylactic treatment 3 days before surgery was not superior to initiation on the day of surgery. Adding prednisolone to NSAID eye drops resulted in higher IOP during treatment.

TITLE: National Emergency Department Trends for Endogenous Endophthalmitis: An Increasing Public Health Challenge

SESSION TITLE: Endophthalmitis/ trauma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Thangamathesvaran, A. Scott, F. Woreta, M. Breazzano, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Loka Thangamathesvaran: Commercial Relationship: Code N (No Commercial Relationship) | Adrienne Scott: Commercial Relationship: Code N (No Commercial Relationship) | Fasika Woreta: Commercial Relationship: Code N (No Commercial Relationship) | Mark Breazzano: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To use a national database for understanding endogenous endophthalmitis in America and identify risk factors for admission and mortality.

Methods: The National Emergency Department Sample (NEDS) was queried from 2006 to 2017 with details encompassing emergency department (ED) visits: diagnostic codes, procedures, patient demographics, payment sources, total monetary charge, and hospital characteristics. Patients with diagnoses of endophthalmitis and septicemia were required for inclusion using International Classification of Diseases codes for precisely identifying cases of endogenous endophthalmitis, and to characterize patient comorbidities. P value of 0.05 was defined as statistically significant for all analyses.

Results: A total of 6,400 patients with endogenous endophthalmitis were identified. Incidence increased from 0.10 (95% CI: 0.07-0.12) per 100,000 in the American civilian population in 2006 to 0.25 (95% CI: 0.21-0.30) in 2017 ($p<0.05$). Most were female (55.4%), had Medicare (53.5%), were in the first income quartile (29.3%) [top 25% of income bracket], lived in the southern region (40.5%), and presented to a metropolitan teaching hospital (66.6%) ($p<0.05$). There were no seasonal trends in admission. The median ED visit cost increased from \$1,229 (interquartile range [IQR]: \$690-\$1,563) in 2006 to \$2,529 (IQR: \$1,538-\$4,038) in 2017 ($p<0.05$). Mortality increased from 8.6% in 2006 to 13.8% in 2017 ($p=0.94$). On multivariate analysis, factors that predicted admission included older age, and the following comorbidities: pneumonia, endocarditis, renal/urinary tract infection (UTI), and intravenous drug use (IVDU). Factors associated with increased mortality included: human immunodeficiency virus infection (HIV)/immune deficiencies, heart failure, pneumonia, renal/UTI, and hepatic infections/cirrhosis. Patients with diabetes had a decreased odds ratio for mortality.

Conclusions: Endogenous endophthalmitis has increased in incidence throughout America. Factors predicting increased hospitalization include older age, pneumonia, endocarditis, renal/UTI, and IVDU. Factors associated with mortality include HIV/immune deficiencies, heart failure, pneumonia, renal/UTI, and hepatic infections/cirrhosis. Additional exploration of the potential protective effect of diabetes from mortality in this context is needed.

TITLE: Cardiovascular Disease Risk Factors in U.S. Adults with Vision Impairment

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.A. Lundeen, M. Kim, I. Mendez, J. Saaddine, Division of Diabetes Translation, Centers for Disease Control and Prevention, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elizabeth Lundeen: Commercial Relationship: Code N (No Commercial Relationship) | Minchul Kim: Commercial Relationship: Code N (No Commercial Relationship) | Isabel Mendez: Commercial Relationship: Code N (No Commercial Relationship) | Jinan Saaddine: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Adults with vision impairment (VI) have a higher prevalence of cardiovascular disease (CVD) compared to those without VI. However, less is known about whether those with VI have a higher prevalence of CVD risk factors. We describe the relationship between VI and CVD risk factors in US adults.

Methods: We used cross-sectional, nationally representative data from the 2018 National Health Interview Survey of US noninstitutionalized civilians; data are self-reported. The analysis included 23,071 adults aged ≥ 18 years with data on CVD, CVD risk factors, and VI (defined as having trouble seeing, even when wearing glasses or contact lenses). By VI status, we describe the prevalence of CVD, defined as coronary heart disease, angina, myocardial infarction, stroke, or other heart disease. Generalized linear regression models with Poisson distribution and log link were used to generate adjusted prevalence ratios (aPR) for those with VI (reference: no VI) for CVD and seven CVD risk factors: current smoking, physical inactivity, excessive alcohol intake, obesity, hypertension, high cholesterol, and diabetes. Models for each outcome controlled for age, sex, race/ethnicity, education, marital status, employment, income, and health insurance.

Results: Participants' average age was 47.3 years (95% CI: 47.0, 47.7); 51.6% (CI: 50.8, 52.4) were female; 12.9% (CI: 12.3, 13.5) had VI. Crude prevalence of CVD was 26.5% (CI: 24.6, 28.5) in those with VI and 12.1% (CI: 11.6, 12.7) in those without VI (aPR=1.64 [CI: 1.48, 1.76]). Compared to adults without VI, those with VI had a greater number of CVD risk factors (Figure 1) and a higher prevalence for all seven CVD risk factors: current smoking (aPR=1.36 [CI: 1.24, 1.48]), physical inactivity (aPR=1.13 [CI: 1.05, 1.20]), excessive alcohol intake (aPR=1.29 [CI: 1.08, 1.54]), obesity (aPR=1.26 [CI: 1.19, 1.34]), hypertension (aPR=1.24 [CI: 1.18, 1.31]), high cholesterol (aPR=1.17 [CI: 1.11, 1.24]), and diabetes (aPR=1.46 [CI: 1.32, 1.63]).

Conclusions: Adults with VI had a higher prevalence of CVD and CVD risk factors compared to those without VI. Reducing CVD risk in adults with VI requires effective clinical and lifestyle interventions, adapted to accommodate VI-related disability, to aid in the prevention and management of CVD.

ABSTRACT BODY:

Purpose: VEGFA-binding single-chain variable fragment brolucizumab is intravitreally injected to successfully treat retinal diseases associated with deregulated expression of VEGFA, but severe adverse effects, i.e. retinal vasculitis, have been reported. Using the well-established in vitro-model of immortalized bovine REC (iBREC) we studied brolucizumab's effects on unchallenged or VEGFA-exposed iBREC.

Methods: Confluent iBREC were exposed to PBSd or VEGFA₁₆₅ (final concentration: 50ng/ml) for 1d before brolucizumab (Beovu®, final concentration of 1mg/ml reached by intravitreal injection) was added for up to 5d. As a measure of barrier function, we continuously determined the cell index (CI) of iBREC cultivated on gold electrodes. Expression or subcellular localization of tight-junction proteins claudin-1 or claudin-5 or of adhesion proteins VEcadherin or CD9 were assessed. Secretion of VEGFA, IL-6, IL-8 or TNFα by iBREC was determined by ELISA.

Results: VEGFA treatment strongly reduced CI within 12h and persistent for up to 6d accompanied by the loss of claudin-1 and (subtle) changes of claudin-5's and CD9's subcellular localization; VEcadherin was not affected. Beovu reverted these disturbances within 1d, but 5d after its addition, the CI started to decline again although claudin-1 was still strongly expressed. VEGFA was not detected by competitive ELISA in the cell culture supernatant of unchallenged iBREC or those exposed to the growth factor and Beovu, and less VEGFA was then internalized by the cells. None of the inflammatory relevant cytokines studied was detected in the culture supernatant of iBREC at 2h or 30h after Beovu's addition to unchallenged or VEGFA-exposed iBREC. When added to a confluent monolayer formed by iBREC, Beovu induced a transient decline of the CI between 2h and 6h associated with subtle changes of CD9's subcellular localization.

Conclusions: As expected, Beovu strongly counteracts VEGFA-induced dysfunction of the barrier formed by iBREC. However, Beovu might interfere with the adhesion of unchallenged iBREC to the extracellular matrix.

Commercial Relationships Disclosure (Abstract): fangfang lu: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Gross: Commercial Relationship: Code N (No Commercial Relationship) | Lyndsay Leach: Commercial Relationship(s);#9458428:Code P (Patent)

ABSTRACT BODY:

Purpose: Our previous work characterized zebrafish RPE (retina pigment epithelium) regeneration after genetic ablation and has begun to identify molecular and cellular regulators of the regenerative response. mTOR (mechanistic target of rapamycin) signaling has been shown to be activated after tissue injury and to regulate tissue regeneration in multiple contexts; however, whether mTOR signaling is involved in RPE regeneration is unknown. We hypothesized that mTOR signaling was involved in RPE regeneration and sought to identify mechanisms by which mTOR regulates RPE regeneration.

Methods: At 5 days post-fertilization (dpf), rpe65a:nfsB-eGFP larvae were exposed to 10mM metronidazole (MTZ) for 24 hours to ablate the RPE. Larvae were treated with mTOR antagonists (2 μ M rapamycin/0.9 μ M INK 128) or DMSO from 24 hours prior to RPE ablation until 4 days post-injury (dpi). BrdU incorporation and RPE pigment recovery were quantified to assess the effect of mTOR antagonists on RPE regeneration. Immunostaining of phosphorylated 40S ribosomal protein S6 (p-S6), a readout for mTORC1 activity, was performed at 3, 6 and 12 hours post-injury (hpi), and 1- 4dpi timepoints in RPE-ablated and age-matched unablated controls, as well as at 2dpi in larvae treated with mTOR antagonists or DMSO. p-S6 distribution in the RPE was quantified to evaluate mTOR activity during regeneration and to validate drug efficacy. To identify mechanisms by which mTOR modulates RPE regeneration, RNA-seq was performed on eGFP⁺ cells from rapamycin- or DMSO-treated larvae at 2 and 4dpi (n=3). Pathway enrichment analyses (STRING) were performed on groups of significantly differentially expressed genes (DEGs).

Results: Rapamycin and INK 128 treatment significantly decreased BrdU⁺ cells in the RPE (p \leq 0.0001) and impaired central pigment recovery at 4dpi, compared to controls (p \leq 0.0001). Quantification of p-S6 enrichment in the RPE showed significant increases from 6hpi-3dpi with peak expression at 12hpi (p \leq 0.01). p-S6 activity was abrogated in rapamycin/INK128 treated larvae at 2dpi. RNA-Seq results identified a variety of genes that were downregulated in the RPE at 4dpi.

Conclusions: mTOR signaling is required for RPE regeneration after genetic ablation. Putative mTOR targets have been identified and are being experimentally interrogated to determine the mechanisms by which mTOR regulates RPE regeneration.

ABSTRACT BODY:

Purpose: To model the impact of treating severe NPDR with anti-VEGF therapy on PDR progression and blindness compared with delayed treatment.

Methods: A discrete event simulation (DES) model was used to assess the impact of treating patients with severe NPDR (DRSS 47-53) instead of delaying treatment until PDR development. A retrospective cohort of patients with untreated NPDR was identified in the IBM Explorys™ EMR database. Cox multivariable regression was used to model risk of PDR progression. Treatment impact (afibercept and ranibizumab) was estimated based on data from clinical trials (PANORAMA, RISE/RIDE) and averaged by weighted US market share. The DES examined PDR progression rates for a sampled set of 2 million patients scaled to US NPDR disease prevalence over 5 years using age- and gender-adjusted sampling weights, aggregating yearly progression events. Simulated PDR event rates were compared for two simulated cohorts with severe NPDR: untreated (no anti-VEGF treatment until they developed PDR), or treated (clones of the untreated patients modeled to receive early anti-VEGF treatment). Blindness (visual acuity <20/200) rates following PDR progression were obtained from literature. The probability of blindness was applied to all patients who progressed to PDR, and simulated events were compared over 10 years for treated vs untreated cohorts.

Results: A total of 1,174 patients with severe NPDR were identified in the database. The final Cox model included age, gender, baseline DR severity, diabetes control regimen, HbA1c, DME status, and other factors. The simulated cohort included 86,671 severe NPDR patients. Patients with severe NPDR had a 5-year risk of PDR of 37.5% (untreated) and 18.1% (treated); anti-VEGF therapy avoided 16,784 (51.7%) of PDR events for a 19.4% absolute risk reduction. The 10-year risk of blindness was 4.4% (untreated) and 1.9% (treated); treatment was associated with a 57.7% reduction blindness cases for a 2.6% absolute risk reduction.

Conclusions: The DES model suggests that severe NPDR treatment with intravitreal anti-VEGF therapy would significantly decrease PDR progression rates over 5 years and reduce incidence of blindness over 10 years.

ABSTRACT BODY:

Purpose: Data on heritability of anatomic traits in primary angle closure glaucoma (PACG) is sparse. The purpose of this study was to estimate the heritability of ocular biometric and anterior chamber morphologic parameters and to determine predictors of angle closure concordance in South Indian probands with primary angle closure suspect (PACS) or primary angle closure (PAC)/PACG and their siblings.

Methods: We prospectively collected data on a cohort of probands with PACS or PAC/PACG and their full siblings aged ≥ 30 years in South India. All subjects received a standardized ophthalmic examination, A-scan ultrasonography, pachymetry, and anterior segment optical coherence tomography imaging (ASOCT). Heritability was calculated using residual correlation coefficients adjusted for age, sex, and home setting. Concordant sibling pairs were defined as both proband and sibling with PACS or PAC/PACG. Predictors of angle closure concordance among sibling pairs were calculated using multivariable logistic regression models, corrected for collinearity.

Results: 345 sibling pairs participated, including 121 sibling pairs concordant for angle closure and 224 discordant sibling pairs. All anterior chamber parameters were highly heritable ($p < 0.001$ for all), Table 1. Similarly, all iris parameters, axial length, lens thickness (LT), central corneal thickness, anterior lens curvature, lens vault (LV), spherical equivalent, and intraocular pressure were moderately to highly heritable ($p < 0.004$ for all). LV and LT were significantly more heritable among concordant sibling pairs ($p < 0.05$ for both). In contrast, ASOCT angle parameters had statistically insignificant heritability estimates. In multivariable analyses, siblings older than their probands were more likely to be concordant for angle closure (OR=1.05 (95% CI 1.01, 1.09)) and siblings with a deeper anterior chamber depth (ACD) compared to their probands were less likely to be concordant for angle closure (OR=0.74 (95% CI 0.64, 0.86)), Table 2.

Conclusions: Iris, anterior chamber, and lens parameters were significantly heritable while angle parameters were not. LT and LV were significantly more heritable among concordant siblings and may play important roles in the pathogenesis of angle closure disease. Siblings who are older or have a shallower ACD have a greater likelihood of angle closure and may need more careful disease monitoring.

ABSTRACT BODY:

Purpose: Teleophthalmology provides evidence-based diabetic retinopathy screening that is underused even when readily available in primary care clinics. There is an urgent need to increase teleophthalmology use in U.S. primary care clinics. In this study, we describe the development of a tailored implementation program to increase teleophthalmology use (I-SITE) and report outcomes related to primary care provider (PCP) adoption.

Methods: We applied the NIATx Model for healthcare process improvement to develop and test I-SITE in a rural, U.S. multi-payer health system. We hypothesized that teleophthalmology use would be higher among PCPs who did versus those who did not participate in various components of I-SITE. We also surveyed PCPs and clinical staff to identify implementation strategies they perceived to have the greatest impact on increasing teleophthalmology use.

Results: Teleophthalmology use was nearly 5-fold greater among PCPs participating in the I-SITE implementation team (n=3) than other PCPs (n=22, $p < 0.001$). The proportion of all PCPs who elected diabetic eye screening for their performance-based financial incentive increased from 0% (n = 0) at baseline to 56% (n = 14) following I-SITE implementation ($p < 0.001$). PCPs who elected diabetic eye screening as a performance-based financial incentive referred nearly 5 times more patients for teleophthalmology each quarter than those who did not (7.4 vs. 1.5 referrals, respectively, $p = 0.06$). There was a trend towards increased teleophthalmology referrals following audit and feedback presentations at regularly-scheduled staff meetings ($p = 0.16$). PCPs and clinical staff reported the following implementation strategies to have the highest impact on teleophthalmology use: reminders to ask patients about diabetic eye screening during clinic visits, streamlining electronic health record (EHR) documentation, and patient outreach.

Conclusions: I-SITE provides a practical roadmap for tailored integration of teleophthalmology into primary care clinics and increasing teleophthalmology use (<https://hipxchange.org/I-SITE>). Implementation strategies effective for increasing provider adoption of teleophthalmology included enhancing perceived ease of use, participation in implementation, audit and feedback, and performance-based financial incentives.

ABSTRACT BODY:

Purpose: Trichomatous trichiasis (TT) is a severe, blinding consequence of chronic inflammation and scarring in the conjunctiva resulting from trachoma, which is the leading infectious cause of blindness worldwide. Our study evaluated the effectiveness of refresher training (RT), including the “Head Start” approach and live surgery following the WHO recommended procedure for the certification of TT surgeons on the outcomes of upper lid (UL) TT surgery in rural Ethiopia.

Methods: A total of N=283 eyes contributed by 173 patients were included in analysis. Patients were included in the study if they were undergoing UL TT surgery in at least one eye by one of the participating surgeons. Patients were split into two cohorts: Cohort 1 (C1) was comprised of patients enrolled prior to the RT, and Cohort 2 (C2) included those enrolled after the RT. Data were collected at 3 time points: baseline, 6-month, and 12-month follow-up. Surgical outcomes were recorded throughout follow-up using multiple response forms. The main outcome of interest was development of post-operation TT (POTT), which was defined as: presence of at least one UL lash touching the eye; and/or epilation; and/or repeat surgery. A series of multivariate generalized estimating equations (GEEs) were fit to model POTT against all potential covariates of interest, including demographic factors and clinical measurements. Odds ratios (ORs) and 95% CIs were calculated.

Results: Within C1, 37/128 eyes (28.91%) developed POTT while within C2, 22/133 eyes (16.54%) developed POTT ($p=0.03$). In the fully saturated GEE model, only the cohort covariate was significant at the $\alpha=0.05$ significance level ($p=0.03$) after adjusting for all other covariates. After performing stepwise model selection using the quasiliikelihood under the independence model criterion (QIC), our final model included cohort as the singular chosen covariate. The corresponding OR for an eye being in C2 relative to C1 was 0.41 (95% CI: 0.19, 0.86).

Conclusions: Our results indicate a substantial reduction in the odds of developing POTT for eyes receiving treatment after initiating RT including the “Head Start” approach followed by live surgery training as compared to eyes receiving treatment prior to the RT. This observation implies a significant potential benefit of the program’s effectiveness, even with experienced surgeons, and suggests comprehensive RT may be a valuable strategy to improve surgical outcomes.

Commercial Relationships Disclosure (Abstract): K V Chalam: Commercial Relationship: Code N (No Commercial Relationship) | Ravi Murthy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the protein profile of vitreous fluid from human subjects undergoing vitreoretinal surgery with or without pre-existing posterior vitreous detachment (PVD) with quantitative proteomics

Methods: In this study, protein profile of 2 cohorts of patients (pre-existing PVD vs. without PVD) undergoing vitreoretinal surgery was analyzed with quantitative proteomics to identify novel markers that may be involved in vivo induction of a PVD. Vitreous humor specimens were collected before initiation of vitrectomy. Presence of PVD was confirmed with ultrasonography prior to surgery. Five biological replicates (500 ul) were included for both control and disease groups. The protein was centrifuged at 15,000rpm, 4°C for 30 min assays were performed using a BCA® Protein Assay. iTRAQ labeling was performed with iTRAQ Reagents 8-plex kit.

After strong cation exchange, tryptic peptides were separated with a LC Packing C18 Pep Map HPLC column. Hybrid quadrupole-TOF QSTAR Elite MS/MS system was used for data acquisition. The MS/MS data were processed by a thorough search against the Uniprot human database (2,464,346 entries) with ProteinPilot v.4.2 software. The cutoff score was set to 1.3 (a confidence level of 95%), and the false discovery rate (FDR) was estimated with search against concatenated databases containing both forward and reverse sequences. Functional analysis of proteins was done with GO annotation (q-value ≤ 0.05). Protein with at least three spectra and fold change >1.2 or <0.8 ($p < 0.05$) was considered for significant differential expression.

Results: A total of 446 proteins were identified. 72 proteins overlapped with at least three peptides. Nine proteins were differentially expressed between two groups (8 up regulated and 1 down regulated in PVD). Filensin (15.75x), serotransferrin (11.9x) and cathepsin D (10.95) were overwhelmingly expressed ($p < 0.001$) in PVD

Conclusions: Our study provides comprehensive protein listing in vitreous humor samples in PVD. Filensin and Cathepsin D were identified as candidate proteins involved in induction of PVD. Further studies using microplex arrays to quantify protein levels in vitreous samples are required

TITLE: C-Reactive Protein (CRP) in Pediatric Orbital Cellulitis

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.W. Orban, D. Freeman, H. Hahn, R. Trivedi, A. Eiseman, Ophthalmology, Medical University of South Carolina, Charleston, South Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Molly Orban: Commercial Relationship: Code N (No Commercial Relationship) | Dylan Freeman: Commercial Relationship: Code N (No Commercial Relationship) | Hallie Hahn: Commercial Relationship: Code N (No Commercial Relationship) | Rupal Trivedi: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Eiseman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: C-Reactive Protein (CRP) levels have been shown to have prognostic value in pediatric bacterial infections, including orbital cellulitis. However, it is unclear how frequently CRP levels are utilized for diagnostic evaluation and management. The purpose of this study is to determine how frequently CRP levels were obtained and to evaluate for any correlation of CRP levels with presenting signs and symptoms, radiographic findings, or prognosis.

Methods: We performed a retrospective chart review of all cases of orbital cellulitis in patients age 1 – 18 years old in a large, tertiary-care academic institution from January 2008 to January 2018 to measure the frequency CRP levels were obtained. We explored the relationship between CRP levels and signs and symptoms at presentation, clinical prognosis (length of stay), and demographic data. Lastly, we examined how the CRP level changed throughout admission. Information recorded included laterality, association with sinusitis, sex, race, age, time of year during presentation, treatment course, laboratory values throughout the hospital course, and major complications including abscess, operations, etc. Patients were excluded if the final diagnosis was not orbital cellulitis or if insufficient data was available in the patient chart. SPSS statistical analysis software was used to perform statistical testing. Categorical variables were compared with chi squared tests (Fisher's exact tests). Categorical data were compared with continuous data with independent samples t-tests.

Results: 54 patients were included in the study, 15 who had a CRP level measured during admission and 39 who did not. CRP was elevated in 9/15 (60%) of patients at the time of diagnosis. CRP elevation at the time of diagnosis was not found to correlate with sex ($p=0.136$), race ($p=0.732$), length of stay ($p=0.494$), whether steroids were administered during admission ($p=0.791$), whether sinus symptoms were present at admission ($p=0.815$), or whether an abscess was present on imaging ($p=0.906$). There was insufficient data to determine trends in CRP levels as treatment course progressed.

Conclusions: CRP level was not routinely ordered in our pediatric population presenting with orbital cellulitis and was not often used prognostically. Our study had significant data limitations, mostly driven by the small sample size. Further studies should evaluate the diagnostic and prognostic utility of CRP in pediatric orbital cellulitis.

TITLE: A2Ar-dependent anti-uveitic Treg cells home to the eye to suppress uveitis

SESSION TITLE: Innate and Adaptive Immune Cells in Humans and Animal Models of Immune Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D.J. Lee, T. McDonald, K. Peters, Ophthalmology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|D.J. Lee, Microbiology and Immunology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Darren Lee: Commercial Relationship: Code N (No Commercial Relationship) | Trisha McDonald: Commercial Relationship: Code N (No Commercial Relationship) | Kayleigh Peters: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Experimental autoimmune uveitis (EAU) is used to gain a better understanding of human autoimmune uveitis. EAU-resolution is in part due to emergence of ocular antigen specific regulatory T cells (Tregs) found in the spleen of EAU-resolved mice. Multiple FoxP3⁺CD25⁺CD4⁺ Treg subsets in EAU-resolved mice (post-EAU Tregs) are PD-1⁺ (PD-1 Treg) or TIGIT⁺ (TIGIT Treg). The adenosine 2A receptor (A2Ar) is required for ocular Tregs at EAU-onset, but A2Ar^{-/-} mice still recover from EAU. This suggests each Treg subset may function through different mechanisms. One such mechanism is where the Tregs home to suppress disease, CCR6 homes to tissue, CCR7 to lymph. We asked where post-EAU Tregs home, and the chemokine receptors (CCR) required for each Treg subset to suppress disease.

Methods: CCR expression was determined on post-EAU Tregs by NanoString. Then the influence of the identified CCRs on EAU and Treg suppression was determined by transferring specific CCR⁺ post-EAU T cells, and TIGIT or PD-1 Tregs from CCR6^{-/-} or CCR7^{-/-} mice to recipient EAU mice. Homing to the eye and secondary lymphoid tissue by post-EAU Tregs was also monitored in recipient mice. Peripheral blood mononuclear cells from uveitis patients and healthy volunteers were A2Ar-stimulated, and assayed for CCR6 and CCR7 expression in each Treg subset.

Results: Post-EAU Tregs had transcript and protein for CCR6 and CCR7, homed to the eye, and lymphoid tissue, and CCR6⁺ and CCR7⁺ post-EAU Tregs suppressed EAU. Elimination of CCR6-CCL20 signaling in CCR6^{-/-} and CCL20^{-/-} mice delayed resolution, but CCR7^{-/-} mice had similar disease as WT mice, and more Tregs were in post-EAU CCR7^{-/-} mice compared to CCR6^{-/-} mice. CCR7 was not necessary for EAU suppression by PD-1 or TIGIT Tregs. Whereas, CCR6 was necessary for PD-1, but not TIGIT Treg EAU suppression. A2Ar^{-/-} mice had fewer CCR6 and CCR7 post-EAU Tregs compared to WT mice. A2Ar-induction of PD-1⁺ CCR6⁺ Tregs was reduced in uveitis patients (n=20) compared to healthy volunteers (n=19), but was not significantly different for TIGIT⁺CCR6⁺, PD-1⁺CCR7⁺, or TIGIT⁺CCR7⁺ Treg subsets.

Conclusions: This work indicates that different Treg subsets that may function during different phases of disease, have different homing requirements to suppress disease. Importantly, induction of the tissue homing Tregs in uveitis patients may be impaired. Therefore, a defect in Treg homing capacity may contribute to autoimmune uveitis.

TITLE: Visual Acuity Outcomes in a Randomized Trial of Clinically Derived Refractions and Objectively Derived Wavefront Metric Optimized Refractions in Adults with Down Syndrome

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H.A. Anderson, The Ohio State University College of Optometry, Columbus, Ohio, UNITED STATES|J.S. Benoit, J.D. Marsack, R.E. Manny, K.D. Fern, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Heather Anderson: Commercial Relationship: Code N (No Commercial Relationship) | Julia Benoit: Commercial Relationship: Code N (No Commercial Relationship) | Jason Marsack: Commercial Relationship: Code N (No Commercial Relationship) | Ruth Manny: Commercial Relationship: Code N (No Commercial Relationship) | Karen Fern: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Determining refractive corrections for individuals with Down syndrome (DS) is challenging due to the presence of elevated refractive error, optical aberrations, and cognitive impairment. This randomized clinical trial evaluated performance of spectacle corrections determined using clinical techniques versus objective refractions derived from wavefront aberration measures.

Methods: Thirty adults with DS received a comprehensive eye examination during which clinical refraction was determined by a single expert examiner experienced in examination of individuals with special needs using techniques appropriate for this population. To determine objective refractions, dilated wavefront aberration measures were obtained and processed post-visit to identify refractions based on the optimization of each of two image quality metrics: pupil fraction tessellated (PFSt) and visual Strehl ratio in the spatial domain (VSX). The three refractions were dispensed in random order in an identical spectacle frame selected by the participant. The primary outcome measure, binocular visual acuity, was obtained after 2 months of wear for each prescription type by a masked examiner administering a distance logMAR acuity test. To compare treatment types, mean acuity was compared using a 2-sided Type 3 F-test of the treatment effect in a linear mixed-effect regression model, where the final model included fixed-effects for treatment, period (1, 2, or 3), and first order carryover effects.

Results: The two-month estimated least square means in binocular visual acuity (logMAR) was 0.34 (95% CI: 0.25, 0.39) for clinical refraction, 0.31 (0.25, 0.36) for PFSt, and 0.33 (0.27, 0.38) for VSX. No statistically significant treatment effect was observed ($F=1.10$, $p=0.34$).

Conclusions: Objective refractions derived from wavefront aberration measures resulted in acuity similar to expert clinician derived refractions, suggesting the objective method may be a suitable alternative for patients with DS. Further study with younger patients is warranted to determine if improvements in acuity may be obtained when objective refractions are dispensed to patients with greater neural plasticity and less likelihood of long-standing amblyopia.

TITLE: OCT segmentation errors of Minimum Rim Width (MRW) and Retinal Nerve Fiber Layer Thickness (RNFLT) in glaucoma subjects

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Rees, F.G. Sanchez, S.L. Mansberger, Research, Legacy Devers Eye Institute at Legacy Good Samaritan Medical Center, Portland, Oregon, UNITED STATES|J. Rees, F.G. Sanchez, H. Yang, S.K. Gardiner, S.L. Mansberger, Devers Eye Institute, Legacy Research Institute, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jack Rees: Commercial Relationship: Code N (No Commercial Relationship) | Facundo Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Hongli Yang: Commercial Relationship: Code N (No Commercial Relationship) | Stuart Gardiner: Commercial Relationship: Code N (No Commercial Relationship) | Steven Mansberger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We were interested in whether differences exist in manual segmentation (MS) vs automatic segmentation (AS) of optical coherence tomography (OCT) in the Bruch's Membrane Opening–Minimum Rim Width (BMO-MRW) and Retinal Nerve Fiber Layer Thickness (RNFLT) in glaucoma eyes, and whether differences occur more frequently in the same clock-hour sectors.

Methods: We used spectral-domain OCT (Heidelberg Engineering, Heidelberg, Germany) to obtain BMO-MRW measurements in 24 radial Optic Nerve Head (ONH) B-scans, and RNFLT measurements in peripapillary circle scans (12 degrees) from 2 different timepoints in glaucoma eyes.

We obtained AS with the Heidelberg Eye Explorer Software. The software marked the position of the internal limiting membrane (ILM) and the BMO to calculate the MRW, and the ILM and posterior boundary of the RNFL. We then used custom software to perform manual corrections of the same parameters.

'Machine error' was the MRW or RNFLT AS value subtracted from the MS value. We calculated the proportional error by dividing the mean absolute error (AE) by the median MS value. To test whether errors occurred more often in any sector, we fit the AE per clock hour using a mixed effects model(R).

Results: We included the MRW and RNFLT scans from 162 glaucoma eyes (162 subjects) at 2 timepoints 4.28 years (SD 0.48, range 2.5-5.1) apart. Average age was 70.24 (10.21, 42-91), and 94 (58.02%) were female.

Mean MRW (SD, range) with AS and MS was 253.0µm (89.2, 22.6-523.4) and 249.8µm (90.1, 11.5-534.5), respectively; and RNFLT was 85.37µm (32.8, 8.6-208.2) with AS and 86.88µm (34.1, 8.6-208.2) with MS.

The mean AE for MRW was 11.36µm (16.4, 0-166.6), and for RNFLT was 3.35µm (4.6, 0-83.2). MRW showed a larger proportional AE than RNFLT (4.49% versus 4.13%, respectively, p=.004).

The AE in the superior sector of the MRW tended to be larger, although not significant (p=.075). RNFLT did not show sectors with larger errors (p>.1 for all). We found no evidence for errors happening in the same sectors between techniques (p=.79).

Conclusions: The error with AS is small and proportionally larger in MRW than RNFLT. The error in MRW tends to be larger in the superior sector. There is no evidence of sectorial correlation between the errors of MRW and RNFLT, suggesting no common source of error. This higher variability may decrease the ability to detect progression with MRW as compared to RNFLT.

ABSTRACT BODY:

Purpose: Stimulation via temporally interfering (TI) electric fields is attracting attention as a means of activating neural tissues distant from the stimulation electrodes. This stimulation strategy can be advantageous to suprachroidal retinal prosthesis in which stimulation electrodes are relatively distant from the target neurons of retina. The purpose of this study is to establish methods of direct measurements and visualization of the electric field generated when retina is stimulated using TI.

Methods: A phantom eye was constructed from a custom-made dish (dia.=24 mm). We placed 25 silver electrodes (dia.=0.5 mm) along the inside wall of the annular chamber at 6 mm from the bottom (Fig. 1). Sinusoidal waves of 1.4 mA amplitude were applied to the two selected electrodes. The frequencies of sinusoidal waves were 2 kHz for the first electrode and 2.05 kHz for the second, respectively. The electric field was recorded using two pairs of PTFE insulated platinum-iridium wires (dia.= 0.05mm), each pair making a 0.35 mm- spaced dipole electrode and aligned orthogonally to each other at the tip. These recording electrodes were connected to an oscilloscope via differential probe.

Results: The interference of two sinusoidal electric fields was successfully observed as shown in Fig.2. Phases of envelopes were 180 degrees different between X component and Y component, which was consistent with the theoretical prediction.

Conclusions: We successfully visualized the envelope waveform generated by TI. Our future work will include a qualitative and quantitative comparison of results from measurements and numerical calculation.

ABSTRACT BODY:

Purpose: A novel augmented reality mobile application for glaucoma education named EyeCU previously validated in an Asian population was adapted for our South Bronx population. We performed a prospective study to evaluate the impact of EyeCU on patient knowledge and to assess patient perceptions of this technology.

Methods: Thirty-one participants > 18 years old with a diagnosis of glaucoma on medical therapy for at least 4 months used EyeCU on a hospital-owned tablet during their clinic visit. Exclusion criteria included those with a non-glaucomatous optic neuropathy, visual acuity of 20/100 or worse in both eyes, visual field defects impairing fixation in both eyes, inability to use a tablet and inability to understand English or Spanish. Participant characteristic data was collected, and pre- and post-intervention National Eye Health Education Program Eye-Q tests were administered. Self-reported understanding was evaluated and a 5-point Likert scale (1 being “not at all” and 5 being “extremely likely”) assessed application acceptance. Fisher’s exact test, Mann-Whitney test and two-tailed Student’s t-test were used.

Results: The median test score was 70% for pre- and post-intervention groups ($p=0.84$). The three worst pre-intervention questions were “eye pain is often a symptom of glaucoma” (52% correct), “glaucoma is caused by increased eye pressure” (3% correct) and “a complete glaucoma exam consists only of measuring eye pressure” (42% correct). The pre-intervention median test score was 70% and 60% in those preferring English and Spanish respectively ($p=0.002$). The post-intervention mean test score was 72% and 61% in those preferring English and Spanish respectively ($p=0.02$). Those preferring English had higher educational attainment than their Spanish counterparts ($p=0.002$). 97% of participants reported improved understanding of glaucoma and the purpose of eye drops. The mean score for willingness to use this technology for health education and to recommend this technology to others was 4.2 and 4.4 respectively.

Conclusions: The current version of EyeCU did not demonstrate a statistically significant improvement in objective glaucoma knowledge. However, there was a high level of acceptance of the technology and subjective reporting of improved knowledge. Efficacy may be improved through targeted modifications of the application based on knowledge gaps and discrepancies between English and Spanish speakers.

ABSTRACT BODY:

Purpose: Aqueous humor outflow facility was compared preoperatively and postoperatively to elucidate the mechanism of intraocular pressure (IOP) reduction by microhook ab interno trabeculotomy (μ LOT), a minimally invasive glaucoma surgery.

Methods: Fifty-one eyes of 37 subjects (mean age, 67.2 ± 11.8 years) were included in the study. The outflow facility coefficient (C) was estimated by pneumatonography ((Model 30 Classic, Reichert Technologies, Depew, NY, USA). Using the paired t-test, the IOP, number of medications, and C value were compared between pre- and post-operatively of μ LOT. Possible correlations between the C value and IOP or number of medications were assessed by using linear regression analysis. To adjust for biases derived from the inclusion of both eyes of a patient and differences in background, the pre- and post-operative C values were compared using a mixed-effects regression model.

Results: Compared to the preoperative IOP of 18.2 mmHg and number of medications of 2.8, the postoperative IOP of 13.5 mmHg and medications of 2.3 decreased significantly by 26% ($p < 0.0001$) and 18% ($p < 0.0001$), respectively. Compared to the preoperative C value of 0.27 μ l/min/mmHg, the postoperative C value of 0.51 μ l/min/mmHg increased significantly by 47% ($p < 0.0001$). By linear regression analysis, higher IOP was associated with lower C values (estimate, -0.01/mmHg, $p = 0.0107$), while number of medications was not associated with the C value (estimate, -0.04/medication, $p = 0.1739$). By mixed-effects regression analysis, the postoperative measurement (estimate, 0.11/preoperative measurement, $p < 0.0001$) was associated with higher C value, while age, sex, μ LOT procedure, IOP, and number of medications were not.

Conclusions: After μ LOT, significant increase of outflow facility was observed. The results provide the evidence that increased conventional outflow by elimination of the outflow resistance at the trabecular meshwork is the main mechanism of IOP reduction after μ LOT.

ABSTRACT BODY:

Purpose: B-scans from optical coherence tomography (OCT) cube scans are commonly reviewed during clinical evaluation of the macula. A deep learning algorithm was previously trained to predict if a given B-scan might be flagged “of interest” based on ground truth labels from retinal specialists in healthy and eyes with retinal pathology or disease¹. In this preliminary study, the performance of a B-scan of interest tool was compared to a clinical assessment of OCT cube data in healthy and glaucomatous eyes.

Methods: A B-scan of interest algorithm was previously trained and tested on 76,544 B-scans (598 subjects) and 25,600 B-scans (200 subjects), respectively². Retrospective OCT data were analyzed from an ongoing visual field (VF) study including 19 eyes of 19 patients in both healthy and glaucoma groups, using CIRRUS™ 5000 HD-OCT (ZEISS, Dublin, CA) and HFA3 (ZEISS, Dublin, CA). At each visit, a qualified Macula 512x128 cube scan was used for inference. Mean Deviation (MD) of a SITA Standard 24-2 VF was used to indicate disease severity. A trained grader reviewed each cube and assessed if either a) <10% or b) ≥10% of total B-scans of interest should be flagged.

Results: Mean age was 56.4 (standard deviation, SD: 7.7; range: 44.3 to 73.1) years and 73.4 (SD: 9.5; range 60.6 to 97.9) years for healthy and glaucomatous eyes (p<0.001). Mean VF MD was 0.66 (SD: 0.91; range: -0.62 to 2.62) dB and -6.39 (SD: 6.67; range: -23.16 to 1.63) dB in healthy and glaucomatous eyes (p<0.001). Observed grader and algorithm agreement (95% confidence interval) was 100.0 (82.4,100.0)% and 79.0 (54.4, 94.0)% in healthy and glaucomatous eyes (see Fig 1). B-scans from the four disagreement cases included the presence of unusual retinal curvature (two cases), unusual contrast in the vitreous, and general false positives with inference scores near the algorithm cut-off (see Fig 2).

Conclusions: The findings in this study suggest excellent agreement in healthy eyes and reasonable agreement in glaucomatous eyes for detecting the presence of pathologies typically associated with retinal disease. As a result, a B-scan of interest tool may be a useful workflow aid to identify retinal disease co-morbidities in glaucomatous eyes.

TITLE: Impact of myopia control spectacle lenses with aspherical lenslets on peripheral vision

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Gao, E. Lim, A. Yang, B. Drobe, R&D AMERA, Essilor International, Singapore, SINGAPORE|

Commercial Relationships Disclosure (Abstract): Yi Gao: Commercial Relationship(s);Essilor:Code E (Employment) | Ee Woon Lim: Commercial Relationship(s);Essilor:Code E (Employment) | Adeline Yang: Commercial Relationship(s);Essilor:Code E (Employment) | Bjorn Drobe: Commercial Relationship(s);Essilor:Code E (Employment)

ABSTRACT BODY:

Purpose: New spectacle lenses with concentric rings of contiguous aspherical lenslets have shown promising effects for myopia control. The purpose of the study was to evaluate peripheral visual performance through these lenses using psychophysical tasks.

Methods: Two types of experimental lenses were used - spectacle lenses with highly aspherical lenslets (HAL) and spectacle lenses with slightly aspherical lenslets (SAL) arranged in concentric rings in both lenses. A standard plano single vision lens was used as a control. We tested three visual functions consisting of motion detection (phase-shifting gabor), coherent motion direction discrimination (random dot kinematogram), and useful field of view (UFOV™, Posit Science®, United States). Each function was tested on a sample of 10 adults (mean age: 30.5, 26.3, 33.7 years, age range 20-37, 19-49, 26-49 years, for the three functions respectively). All subjects had normal or corrected-to-normal vision and all tests were done monocularly using their dominant eyes.

Results: No significant difference between the test lenses and control was found in any test. Specifically, the motion detection threshold was not affected by the lens in any quadrant of the visual field (one-way ANOVA, $p > 0.7$). For global motion direction discrimination, a two-way ANOVA found no significant effect of the lens ($p = 0.87$) on the coherence threshold in any direction. In the useful field of view test, one-way ANOVAs showed no significant effect of the lens on visual detection in the whole visual field ($p > 0.5$).

Conclusions: Myopia control lenses with concentric rings of contiguous aspherical lenslets (HAL and SAL) did not significantly impact peripheral visual functions including motion detection, coherent motion direction discrimination, and useful field of view, compared to single vision lenses.

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) is the most common subtype of glaucoma worldwide. We evaluate the cost-effectiveness of polygenic risk score (PRS) profiling as a screening tool for POAG.

Methods: We used a Markov cohort model to evaluate the cost-effectiveness of implementing polygenic risk profiling as a new POAG-screening approach in the UK and Australia. Six health states were included in this model: death, early, mild, moderate, severe, and healthy individuals. The evaluation was conducted from the healthcare payer's perspective. We used the best available published data to calculate prevalence, transition probabilities, utility and other parameters for each health state and age group. The study followed the Consolidated Health Economic Evaluation Reporting Standards checklist. Our main outcome measure was the incremental cost-effectiveness ratio (ICER) and secondary outcomes were years of blindness avoided per person and a 'Blindness ICER'. We did one-way and two-way deterministic and probabilistic sensitivity analyses to reflect the uncertainty around predicting ICERs.

Results: Our proposed genetic screening programme for POAG in Australia is predicted to result in ICER of AU\$34,252 (95% CI AU\$21,324-95,497) and would avoid 1 year of blindness at ICER of AU\$13,359 (95% CI: AU\$8,143-37,448). In the UK, this screening is predicted to result in ICER of £24,783 (13,373-66,960) and would avoid 1 year of blindness at ICER of £10,095 (95%CI: £5,513-27,656). Using the willingness to pay thresholds of \$54,808 and £30,000, the proposed screening model is 79.2% likely to be cost-effective in Australia and is 60.2% likely to be cost-effective in the UK, respectively.

Conclusions: Although the level of willingness to pay for Australian Government is uncertain, and the ICER range for the UK is broad, we showed a clear target strategy for early detection and prevention of advanced POAG in these developed countries.

ABSTRACT BODY:

Purpose: Research suggests that time spend on near-work is potentially an environmental risk factor for myopia. Although current technologies attempt to quantify near-work objectively (e.g. Clouclip, Glasson Technology Co. Ltd., Hangzhou, China), they simply estimate a general gaze direction (without measuring eye-movements) and just record an object distance within a limited field of view.

We aim to develop a device that can accurately quantify durations and distances to objects that the eyes are focusing on.

Methods: Head-mounted eye-trackers combining high-speed eye-observing cameras with a worldview camera (Figure 1 A) to map eye-versions onto worldview images to determine gaze coordinates in 2D. Using a time-of-flight camera (3D camera) as the worldview camera allows measurement of spatial information from the subject's field of view including the distance to the object the subject is looking at. To combine 2D gaze coordinates with the 3D point cloud data we developed a PicoFlexx depth plugin for Pupil Labs' eye-tracking software (Figure 1 B).

Results: Scene data was recorded as point cloud with 5 Hz (Figure 1 B). For precise time-matching of gaze directions and point cloud data, gaze was calculated from both eye-videos with 240 Hz. This method provides more than 90% high quality data with angular precision of +/- 3 degrees over extended periods.

Conclusions: The novel device is capable of quantifying direction and distances to objects that the subject is looking at during natural viewing conditions. Therefore, we can measure the time spend on and the distance to the accommodative and vergence stimuli the eyes are exposed to. This provides an additional objective facilitative function in myopia research for assessing factors such as near-work.

ABSTRACT BODY:

Purpose: A significant proportion of subjects with autosomal recessively inherited retinitis pigmentosa (arRP) and Usher syndrome type 2 (USH2) lacks a genetic diagnosis, subsequent prognosis and possibilities for future therapy. The USH2A gene is the most frequently mutated gene in USH2 and also prevalent in individuals with arRP. As such, USH2A is an important target for genetic screening. The aim of this study is 1) to screen genetically unexplained USH2 and arRP cases in which already one pathogenic USH2A variant was identified using targeted analyses and 2) to include genetically unexplained cases in our future whole genome sequencing effort.

Methods: Eleven unscreened or partially prescreened arRP cases with one previously detected USH2A variant and 29 USH2 cases were included for Molecular Inversion Probe (MIP)-based sequencing of USH2A coding regions, surrounding regions and published deep-intronic variants. After identification of pathogenic coding variants, data was prioritized based on four splice site prediction tools and the deep learning-based tool SpliceAI (Jaganathan et al. 2019). Wild-type and mutant minigene constructs were generated and transfected in Human Embryonic Kidney cells. Transcriptional analysis was performed to determine the splicing effects.

Results: Forty cases were assessed through MIPs. Four unique copy number variants and 107 rare (<1% in gnomAD) unique single nucleotide variants were identified. In 30 cases two (likely) pathogenic variants were identified and in three cases variants of unknown significance were found. One synonymous splice variant and one cryptic acceptor splice site variant that were absent or very rare (<0.001%) in gnomAD were identified. Subsequent minigene splice assays revealed partial exon skipping or no effect on splicing, respectively.

Conclusions: We identified five novel pathogenic variants and have shown the effect on splicing of one known synonymous USH2A variant. This analysis confirms that this MIPs approach is cost-effective. Through this study, genetic diagnoses were completed for at least 30 patients. Six of the unexplained cases will be included for WGS to explore the noncoding regions for pathogenic variants.

ABSTRACT BODY:

Purpose: Oculo-facio-cardio-dental (OFCD) syndrome is an extremely rare X-linked dominant disorder that is lethal in men. It is associated with congenital cataract, microphthalmia, and systemic complications including facial dysmorphic features, congenital heart disease, and tooth abnormalities. OFCD syndrome is caused by variants in BCOR. We performed a retrospective observational clinical study to assess the long-term clinical course of Japanese OFCD patients with BCOR variants.

Methods: We clinically examined and collected blood samples from four OFCD patients from two families who had been visiting our hospitals for a long time. To identify the causative variants, whole-exome sequencing (WES) was performed to identify the candidate variants, which were confirmed by Sanger sequencing.

Results: Case 1: A 12-year-old girl with a sporadic case, had congenital cataracts and microphthalmia immediately after birth. At 2 months of age, a lensectomy was performed on both eyes. Subsequently, she developed secondary glaucoma and was treated surgically several times; this included a tube shunt surgery in her right eye. She also had a broad nasal bridge, an atrial septal defect (which was surgically treated), and teeth dysplasia (radiculomegalies with prolonged dental roots). She had a de novo nonsense variant [c.4438C>T:p.(Arg1480*)] in BCOR.

Cases 2–4: A 16-year-old girl, a 46-year-old mother, and a 73-year-old grandmother, had congenital cataracts and microphthalmias. The girl underwent lensectomy in the right eye, and the grandmother had pseudophakia in her left eye. Nystagmus was observed in each patient. All patients had broad nasal bridges and elongated faces. The youngest had a heart murmur when she was a toddler. The girl had a cleft palate and the mother had teeth dysplasia. The girl and the mother had a toe malformation. They had a novel frameshift variant [c.717_729del:p.(Asn240Phefs*22)].

Conclusions: We reported the clinical features of four Japanese OFCD syndrome patients with BCOR variants. WES was useful for a precise diagnosis. Congenital cataracts and microphthalmia were common in all cases. Facial, cardiac, and dental abnormalities varied in severity. In some cases, skeletal abnormalities were observed. It is vital to obtain additional information on Japanese OFCD syndrome patients. The data from this study provides further insight into OFCD syndrome and may be useful for formulating an accurate diagnosis.

TITLE: Distribution and growth pattern of *Pseudomonas aeruginosa* bacteria in the corneal stroma during corneal infection

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Elsahn, I. Lewis, M. Stephens, H. Dua, I. Mohammed, University of Nottingham, Nottingham, Nottinghamshire, UNITED KINGDOM|A. Elsahn, Ophthalmology, Alexandria University, Alexandria, EGYPT|

Commercial Relationships Disclosure (Abstract): Ahmad Elsahn: Commercial Relationship: Code N (No Commercial Relationship) | Isobel Lewis: Commercial Relationship: Code N (No Commercial Relationship) | Megan Stephens: Commercial Relationship: Code N (No Commercial Relationship) | Harminder Dua: Commercial Relationship: Code N (No Commercial Relationship) | Imran Mohammed: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the behaviour of *Pseudomonas aeruginosa* bacteria inside the corneal stroma after corneal infection in human microbial keratitis

Methods: Human whole donor corneas obtained from the eye bank were used in this project. Bacterial suspensions of GFP expressing PAO-1L or mCherry expressing *P. aeruginosa* PAO-1L with a fluorescence-based biosensors of c-di-GMP were prepared to a concentration of 10^7 cfu/ml. Two methods of infection were used. In the intrastromal injection method, 50 microlitres of bacterial suspension was injected into the middle of the corneal stroma from the endothelial using a 30G hypodermic needle. In the transepithelial method, the superficial epithelial layers were removed by a Kimwipe, 3 epithelial scores were made. An 8.75 mm corneal trephine was placed on the cornea creating a well. Fifty microlitres of bacterial suspension were placed inside the well. The corneas were incubated in medium for 24 to 72h and examined under a Laser Confocal Fluorescence Microscope (CFLM)

Results: In the intrastromal model, mCherry-expressing PAO-1L bacteria were observed to grow locally at the site of injection. The levels of c-di-GMP initially increased steadily, indicating the increase of bacterial association. Towards the end of the 72h period, bacterial growth rate and the levels of c-di-GMP increased rapidly, and bacterial spread was observed in the corneal stroma. In the transepithelial model, GFP expressing POA-1L bacteria formed large colonies on the corneal surface that penetrated deeper into the cornea with time

Conclusions: We have established an ex-vivo models of bacterial keratitis and demonstrated that *P. aeruginosa* can grow over the corneal surface and within the corneal stroma after an initial phase of slow growth

ABSTRACT BODY:

Purpose: As cataract surgery is nowadays considered a refractive surgery, new formulas are continually being developed in order to achieve optimal refractive outcomes after the surgery. This study compares newer IOL power formulas, Kane and Hill-RBF V 2.0, to other formulas for different axial lengths.

Methods: This retrospective study included 406 eyes of 406 patients who underwent cataract surgery. Eyes with previous refractive surgery, associated corneal or anterior segment abnormalities, or intraoperative complications were excluded. Biometry was performed using IOL-Master 700. Predicted refraction from 7 formulas (Hill-RBF V 2.0, Kane, Barrett Universal II, Haigis, Hoffer-Q, Holladay 2, and SRK/T) was compared to postoperative refraction at 1-3 months for different axial lengths: <22.5 mm (short), 22.5-25.5 mm (medium), and >25.5 mm (long). Post-hoc analyses and Bonferroni correction were applied for multiple comparisons.

Results: Overall and within short and medium eyes, all formulas had similar percentages of eyes within ± 0.5 D of the target refraction (Table 1). In long eyes, however, the percentages within ± 0.5 D were significantly higher for Barrett Universal II and Kane formulas (both 72%) compared to those for Hoffer-Q and Holladay 2 formulas (both 52%) ($P=0.004$). Mean numerical error (MNE) and mean absolute error (MAE) were similar for all formulas overall as well as within medium and long eyes. However, within short eyes, MNE was significantly lower for Barrett Universal II (0.27 ± 0.38 D) and Haigis (0.28 ± 0.42 D) compared to Holladay 2 (-0.06 ± 0.41 D) ($P=0.021$ and $P=0.014$, respectively).

Conclusions: The accuracy of newer IOL formulas may depend on the axial length. For long eyes, Kane and Barrett Universal II performed better than Hill-RBF V 2.0 and other formulas studied. For short and medium eyes, Kane and Hill-RBF V 2.0 had an accuracy similar to other formulas.

Hoffmann-La Roche Ltd.:Code E (Employment)

ABSTRACT BODY:

Purpose: Faricimab, a bispecific antibody (ab) currently in phase (Ph) 3 trials, targets both angiopoietin-2 (Ang-2) and VEGF-A, key drivers of vascular instability, and demonstrated improvement in BCVA and sustained efficacy vs anti-VEGF monotherapy in Ph2 clinical trials of diabetic macular edema (DME) and neovascular AMD (nAMD). We present new preclinical data from 2 CNV mouse models showing that dual Ang-2/VEGF-A blockade significantly reduces fibrosis vs anti-VEGF monotherapy.

Methods: 7-week (W)-old JR5558 mice developing bilateral spontaneous neovascular fibrotic lesions were treated intraperitoneally (ip) with mouse cross-reactive tool abs against Ang-2, VEGF-A, or both (bispecific anti-VEGF-A/Ang-2 ab), and IgG (control). Fibronectin (FN) immunostaining was performed on retinal pigment epithelium (RPE)/choroid flat mounts to assess fibrosis at 1 (PT1), 3 (PT2), and 5 (PT3) W post treatment. Fluorophore-labeled collagen hybridizing peptides (CHPs) were used to detect collagen remodeling in active fibrotic lesions. Effect of Ang-2/VEGF-A blockade on subretinal fibrosis was analyzed in a laser-induced CNV mouse model by treating 10–12W-old wild-type mice ip with tool abs directly after and at 1W post laser injury. FN- and CHP-positive (+) areas were analyzed 3W post laser injury.

Results: There was significant reduction in FN+ area in the RPE/choroid of JR5558 mice with the bispecific ab (38%, $P<0.01$) and anti-Ang-2 (41%, $P<0.001$) vs IgG at PT1; effect of anti-VEGF-A alone was not significant. Only dual Ang-2/VEGF-A inhibition maintained significant reduction at PT2 (47%, $P<0.01$) and PT3 (54%, $P<0.05$). Dual inhibition significantly prevented collagen remodeling, as shown by reduced CHP in RPE/choroid lesions at PT2 (66%, $P<0.01$). Anti-VEGF-A or anti-Ang-2 alone showed no significant effect. In the laser-induced CNV mouse model, dual inhibition significantly reduced both FN+ (47%, $P<0.05$) and CHP+ (39%, $P<0.01$) areas at 3W; blocking VEGF-A or Ang-2 alone had no significant effect.

Conclusions: We present preclinical data from 2 independent CNV mouse models suggesting sustained prevention of scarring with dual Ang-2/VEGF-A pathway inhibition. Our findings support the hypotheses that Ang-2 and VEGF-A drive subretinal fibrosis. Future studies are underway to determine how dual Ang-2/VEGF-A inhibition limits subretinal scarring.

Sohn, H.S. Khalaf, J.R. Gallagher, D.A. Johnson, A. Kheirkhah, Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Noah Hodson: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Jeong-Hyeon Sohn: Commercial Relationship: Code N (No Commercial Relationship) | Hamzah Khalaf: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Gallagher: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Kheirkhah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although research indicates proliferative diabetic retinopathy (PDR) itself is associated with changes in ocular surface parameters, it is still not clear whether panretinal photocoagulation (PRP) further affects these parameters. This study evaluated the effects of PRP, a commonly used treatment for PDR, on the ocular surface and tear film parameters.

Methods: In this prospective study, PRP was performed on 44 eyes of 37 patients with PDR. Patients with previous PRP, vitreoretinal surgery, recent use of contact lens, or cataract surgery within 3 months were excluded. The following were measured before and at 1 and 3 months after PRP: Ocular Surface Disease Index (OSDI) questionnaire, tear breakup time (TBUT), corneal fluorescein staining, conjunctival lissamine green staining, and Schirmer test with anesthesia. Wilcoxon signed-rank test was performed to determine changes in tear film and ocular parameters after PRP.

Results: This study included 19 men and 18 women, with a mean age of 53.6 ± 10.3 years. TBUT decreased from a pre-PRP value of 6.9 ± 2.4 s to 5.5 ± 2.7 s after 1 month ($P=0.02$) which subsequently increased to 7.0 ± 2.7 s at 3-month visit ($P=0.03$) and which was not different from the pre-PRP value ($P=0.93$) (Figure 1). There were no significant changes in other ocular surface or tear film parameters after PRP.

Conclusions: In patients with PDR, PRP causes transient instability of the tear film with values returning to the baseline at 3 months. Such tear film changes can transiently worsen the preexisting dry eye disease in patients with PDR.

TITLE: Use of a Shack-Hartmann wavefront sensor to characterize the scattering properties of soft contact lenses

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Chen, Johnson and Johnson Vision, Jacksonville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Minghan Chen: Commercial Relationship(s); Johnson and Johnson Vision: Code E (Employment)

ABSTRACT BODY:

Purpose: Soft contact lenses (CL), with manufactured cosmetic patterns, not only correct patient's refractive error but also offer different forms of ocular cosmetic enhancement by changing the eye appearance. Various decorative designs with different colors are typically integrated around the peripheral region of the CL optical zone (OZ). When light passes through these regions, diffraction and scattering can be generated and degrade the retinal image contrast. Thus, it is essential to develop an instrument and associated methodology to quantitatively characterize the CL optical scattering properties and understand the on-eye performance of cosmetic patterns.

Methods: A benchtop Shack-Hartmann wavefront sensor (Lumetrics, Inc., NY) was installed with additional imaging optics. The collimated laser light (635nm) was made to pass through the CL and focused by a lenslet array into foci captured by a CCD camera. The ratio of the optical intensity within Airy disc versus the total intensity of the individual lenslet element was computed, and the averaged ratio of the lenslet within the measured pupil was defined as forward-scattering-ratio (FSR). The background signal (system without any sample) and nine lens samples (3 lenses for each brand), including Johnson & Johnson 1-DAY ACUVUE DEFINE with LACREON Fresh Green color (Fresh), 1-DAY ACUVUE® MOIST (Moist) lenses, and a lab-made hazy lens, were measured three times for each lens and the FSR were analyzed respectively. The ratio, defined as normalized forward scattering (NFS), between individual sample FSR versus the background FSR value, was utilized as the metric to characterize the magnitude of sample scattering. The higher the NFS value, the less CL scattering.

Results: Within the measured 6-mm pupil, on average, the NFS value for Fresh, Moist, and the hazy lens was 0.9918 ± 0.0028 , 0.9907 ± 0.0026 , and 0.9475 ± 0.0071 , respectively. Thus, both Fresh and Moist showed much less scattering than the hazy lens. There was no statistically significant difference between Fresh and Moist lenses. However, a significant difference was observed between the hazy lens versus Fresh ($p=0.0012$) and Moist ($p=0.0013$), respectively.

Conclusions: Within a 6-mm pupil, the Fresh lens does not generate stronger scattering comparing with the Moist lens, and thus its optical performance does not degrade by scattering.

ABSTRACT BODY:

Purpose: Quantify accommodative movements of intravitreal structures/fluid in the monkey eye to determine if they are related to accommodative amplitude and presbyopia.

Methods: In eyes of 11 rhesus monkeys (aged 8-22 yrs), maximum accommodative responses were induced by central electrical stimulation of the Edinger-Westphal (E-W) nucleus. Ultrasound biomicroscopy (UBM; 50, 20 MHz) images were collected in the region of the lens, ciliary body and over the entire extent of the globe.

Results: During accommodation, the anterior hyaloid bowed backward by 0.26 ± 0.02 mm [mean \pm s.e.m.] ($p = 0.001$; $n=8$), the central vitreous moved posteriorly by 0.27 ± 0.05 mm ($p = 0.001$; $n=7$), while the peripheral lacunae (cistern) tips move forward by 0.42 ± 0.09 mm ($p = 0.002$; $n=8$), and inward (centripetally) by 0.14 ± 0.02 mm ($p = 0.001$; $n=8$). Accommodative central vitreous posterior movement was significantly related to accommodative amplitude; the more the central vitreous moved posteriorly during accommodation, the higher the accommodative amplitude (32.9 ± 9.64 diopters/mm; $p = 0.019$; $n=7$), and these movements declined significantly with increasing age (-0.0185 ± 0.0062 mm/yr; $p = 0.031$; $n=7$). In addition, the accommodative forward movement of the peripheral lacunae (cistern) tips increased with increasing accommodative amplitude; the greater the forward movement of the cistern tip the higher the accommodative amplitude (16.95 ± 6.52 D/mm; $p = 0.047$; $n=8$) and these movements tended to decline with age (-0.024 ± 0.011 mm/yr; $p = 0.08$; $n=8$). Accommodative backward bowing of the anterior hyaloid and centripetal movement of the cistern tip were not significantly related to accommodative amplitude and did not decline significantly with age.

Conclusions: There are statistically significant accommodative movements of various intravitreal structures. The posterior central vitreous movement and the forward movement of the cistern tip are related to accommodative amplitude and decline with age, and may be related to the mechanism of accommodation, presbyopia and perhaps glaucoma. These findings may also inform on the mechanism of accommodation and presbyopia, and the function of accommodating IOLs.

ABSTRACT BODY:

Purpose: A new femtosecond laser aiming for tissue-bridge-free corneal refractive surgery has been developed. The scanning system creates a fast scanline as the cutting “blade”, then moves it to draw any 3D incision shape. The LASIK flap creation consists of three basic cutting shapes: a pocket cut for minimizing the undesired opaque-bubble-layer (OBL), a bed cut consisting of a ring annulus cut and a series of rectangular cuts, and a side cut. To design a robust flap cut, we hypothesize that the laser beam must not be blocked by the laser-tissue-interaction induced gas bubbles in any section of the cutting process.

Methods: Both ex vivo porcine eyes (N = 89) and invivo rabbit eyes (N = 110) were used in the flap experiments. To exacerbate bubble generation, we used higher-than-necessary laser pulse energy or dextran-immersed porcine eyes or both in some of the experiments. Since the flap pocket is a proven mitigation for OBL, which occurs frequently in flap creation for human but rarely in the animal tissue, we simply adopt it in the flap cut design. The R&D laser software allowed us to select and specify the different cut elements and apply them at different time orders. The flap lift dynamics was assessed on a scale of 1-4 (1 = no lift, 2 = moderate adhesion, 3 = minimal adhesion, 4 = no adhesion) by the subject matter expert (SME).

Results: First, the bed cut must be done before the side cut. If the side cut is done prior to the bed cut, the gas bubble generated during the bed cut can migrate through the side cut to the interface between the patient interface glass window and the cornea surface, causing uncut tissue island in the bed cut. Second, to minimize the gas bubble induced tissue adhesion, the side cut must be done in multiple layers. Third, the bed cut must double pass any location in the flap bed to minimize the tissue adhesion.

Conclusions: The results are consistent with our hypothesis. We arrived the final flap cut design with pocket cut → double-pass bed cut → multilayered side cut. The pocket is to minimize the OBL. The double-pass bed cut is to minimize tissue adhesion in the bed, and it is performed before the side cut to avoid uncut tissue island. The multilayered side cut minimizes the tissue adhesion induced by gas bubble interference with the laser focus during the side cut. All flaps created with the final flap cut design have achieved SME score 3-4 robustly.

TITLE: Designing a quality monitoring system for low-resource ophthalmology clinics using Bayesian analysis

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Massa, P. Misra, Z. Elkin, Department of Ophthalmology, New York University School of Medicine, New York, New York, UNITED STATES|Y. Lu, R. Anthopolos, Department of Population Health, New York University School of Medicine, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Scott Massa: Commercial Relationship: Code N (No Commercial Relationship) | Ying Lu: Commercial Relationship: Code N (No Commercial Relationship) | Poonam Misra: Commercial Relationship: Code N (No Commercial Relationship) | Rebecca Anthopolos: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Elkin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ophthalmology clinics with minimal statistical analytics capabilities may struggle to implement a quality monitoring system to evaluate patient outcomes. We performed a quality improvement study by designing a quality monitoring system for a low-resource ophthalmology clinic that would use small samples to estimate outcomes for larger patient populations.

Methods: We evaluated the proportion of primary open-angle glaucoma (POAG) patients who were treated “successfully” according to American Academy of Ophthalmology Preferred Practice Patterns (PPPs). We analyzed 100 patients seen in the clinic over 3 months in 2019 as the input for our Bayesian analysis. We also created a standardized note template for use by clinicians in the electronic medical record (EMR) for POAG patient visits to facilitate monitoring of treatment successes without requiring clinical expertise. We evaluated adherence to clinician template use in POAG patient notes on the weekly day of glaucoma patient visits over 9 weeks in 2020.

Results: Using Bayesian analysis based on our initial data, we created tables that allow for quality monitoring of future 3 month intervals using parameters from smaller samples. Using a small sample of 30 patients, we were able to determine that there was a 100% probability that the clinic as a whole was not achieving the pre-defined target percentage of 80% of POAG patients successfully treated, as defined by the PPPs. Regarding adherence to use of the note template for POAG patients, the median proportion of patients for which the template was used on a single clinic day was 27%, with a maximum of 53% and a minimum of 11%.

Conclusions: Based on the input parameters of the number of patients in the sample, the number of treatment successes in that sample, and the target proportion of successfully treated patients, a small sample Bayesian analysis can be used for quality monitoring of patient outcomes for larger patient populations in low-resource clinical settings. Future work includes creation of an open-access database of tables derived from Bayesian analysis for use as a reference by other low-resource clinics in quality monitoring efforts.

TITLE: Recovery of corneal threshold and symptoms in symptomatic contact lens wearers

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Situ, C. Begley, School Of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|T. Simpson, School Of Optometry and Vision Science, University of Waterloo, Waterloo, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Ping Situ: Commercial Relationship(s);CooperVision:Code F (Financial Support) | Trefford Simpson: Commercial Relationship(s);CooperVision:Code F (Financial Support) | Carolyn Begley: Commercial Relationship(s);CooperVision:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To investigate the changes in symptoms and corneal thresholds to cooling stimuli in a group of symptomatic contact lens (CL) wearers when habitual CL wear is first ceased (washout phase) and then restarted (re-challenge phase) for 3-month periods, in an attempt to understand the neural mechanisms underlying CL discomfort.

Methods: Twenty-four symptomatic soft CL wearers (based on Contact Lens Dry Eye Questionnaire-8 (CLDEQ-8) scores and comfortable wearing time) completed the study. Corneal detection thresholds to cooling stimuli (approximately 22°C) were estimated by a modified Belmonte esthesiometer at study entry while still using habitual CLs (BL) and repeated at each month over the 3-month of washout (M1, M2, M3) and 3-month re-challenge phase (M4, M5, M6). The CLDEQ-8 was administered at BL, M4, M5 and M6. Repeated measures ANOVA and post-hoc tests with Bonferroni adjustment were used for data analysis.

Results: There was a significant difference in detection threshold between study visits ($p < 0.001$), with the threshold increasing gradually (become less sensitive) during no-CL lens wearing washout and then decreasing during the re-challenge phase (Figure 1). The cooling threshold at BL was significantly different than M2, M3, M4 and M6 (all $p \leq 0.035$), but not M1 ($p = 0.082$) and M5 ($p = 0.188$). The CLDEQ-8 was significantly different between visits ($p < 0.001$), with CLDEQ-8 scores for M4, M5 and M6 all significantly lower compared to baseline (all $p < 0.001$) but similar to score during the re-challenge phase (all $p \geq 0.941$) as shown in Figure 2.

Conclusions: The study demonstrated that corneal sensitivity to cooling stimuli decreased while symptoms improved following a no-CL washout in a group of symptomatic CL wearers. Sensitivity tended to increase again after restarting CL wear. These results suggest that sensory function contributes to CL discomfort and point to the complex role that corneal sensory processing plays in the group of symptomatic CL wearers.

ABSTRACT BODY:

Purpose: Matriptase, a cell surface serine protease, is critical for function of several epithelia. Matriptase null mice die 1-2 days after birth due to decreased epidermal barrier function. Hypomorphic mice (low matriptase) have a mild transient epidermal barrier defect in pups but have a normal lifespan allowing studies of functionality in adults. Our purpose is to determine the effects of matriptase gene deletion on the eye and lacrimal gland in adult mice.

Methods: C57BL/6J-Matriptase hypomorphic and littermate control mice at 4-6, 11-12 and 13.5 months of age were sacrificed and eyes and lacrimal glands removed, fixed, embedded in epon-araldite and sectioned. Corneal epithelial thickness (cross sections through the pupil) was measured at 15 points across the central cornea. Corneal epithelial sheets were processed from both groups and Langerhans cells (dendritic cells) stained with a Langerin specific PE conjugated primary antibody. Eyes also were examined by slit lamp, and scanning EM. Mice also were infected with *Pseudomonas aeruginosa* and their response to infection scored for disease, and photographed using a slit lamp.

Results: Measuring corneal thickness revealed that matriptase hypomorphic mice of 6 months of age had a significantly thicker corneal epithelium when compared with control mice. Similar measurements of older mice showed no differences between the two groups. Photographs taken with a slit lamp did not reveal any noticeable differences in corneal or ocular surface morphology between mice at any age. However, scanning EM showed differences in corneal surface morphology and irregularities in structure in the 4-6 month vs older aged hypomorphic vs control mice. Hypomorphic vs control mice of younger age also had a two-fold increase in Langerin positive cells in the peripheral cornea; and, lacrimal glands differed from controls in that glands exhibited patches of abnormal vacuolated acinar cells and the presence of an inflammatory infiltrate. Infected mice responded similarly to eye infection, but only hypomorphic mice exhibited swollen facial features and ruffled fur.

Conclusions: In young vs older mice with low levels of matriptase we observed: a significant increase in corneal thickness, irregular surface cells, increased Langerhans cells, lacrimal gland abnormalities, and a worsened response to *P. aeruginosa* infection.

TITLE: Refractive outcomes using "Barrett True K Formula" for intraocular lens calculation in patients with radiated keratotomy

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Sanchez, K. Zuniga, A.K. Escalona Brito, E. Chavez-Mondragon, Anterior Segment, Instituto de Oftalmologia Fundacion Conde de Valenciana IAP, Mexico City, Mexico City, MEXICO|

Commercial Relationships Disclosure (Abstract): Alejandra Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Karla Zuniga: Commercial Relationship: Code N (No Commercial Relationship) | Ana Escalona Brito: Commercial Relationship: Code N (No Commercial Relationship) | Eduardo Chavez-Mondragon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess reliability of intraocular lens (IOL) calculation using "Barrett True K" in patients with radiated keratotomy (RK).

Methods: Prospective, observational. Conducted in the Anterior Segment department of the Ophtalmology Institute "Fundacion Conde de Valenciana". Patients with RK and cataract diagnosis were included between September 2017 to October 2019. IOL calculation was carried out using "Barrett True K" with a -0.50 target of spheric equivalent (SE). The dioptric power of the implanted IOL was the closest suggested by Barrett True K. Refraction was obtained 1 month posterior to surgery. IOL Prediction Error (IOL PE) was calculated subtracting the power indicated by Barret True K to the implanted lens power and then the refractive predictive error (RPE) was calculated assuming that 1 diopter (D) of IOL PE corresponded to 0.7 D in aerial lenses.

Results: 24 eyes were included . 77.8% were women, the rest men with a 14.3%. Median age was 60.4 years. 57.1% were right eyes and 42.9% left. Average axial length was 24.19 ± 1.61 . The median of radiated cuts was 8.5. The median flattest keratometry was 34.9 ± 3.9 , and the steepest was 36.4 ± 3.33 . The median D of the lens implanted was 20.575. The month after the surgery a median residual ametropy of 0.7 D and ± 1.02 D of SE were found. Best corrected visual acuity was 0.21 LogMAR. The median IOL PE was calculated of $0.30 \pm .17$ and the median RPE was of $0.21 \pm .12$. 42% of the eyes had a RPE of ± 0.50 D and 58% a RPE de ± 1.00 D. 64.3% had a residual SE ≤ 0.50 D.

Conclusions: Barret True K was precise in predicting a refractive error of ± 1.00 D in approximately 65% of the eyes, it proved to be effective in 9 out of 14 cases.

Commercial Relationships Disclosure (Abstract): Nimra Ghani: Commercial Relationship: Code N (No Commercial Relationship) | Jahnvi Bansal: Commercial Relationship: Code N (No Commercial Relationship) | Abhishek Naidu: Commercial Relationship: Code N (No Commercial Relationship) | Khurram Chaudhary: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study analyzes postoperative changes in the position of the Argus II Retinal Prosthesis's electrode array over a two-year period. It specifically assesses the presence or absence of linear implant movement and/or angular rotation around the axis of the implant tack over time, and evaluates any correlation that such movement had with postoperative visual function tests.

Methods: This is a single center, single surgeon cohort study that enrolled five patients with implantation of Argus II Retinal Prosthesis at Stony Brook University Hospital. Fundoscopy was performed at each postoperative follow up visit at month 1 (M1), month 3 (M3), month 6 (M6), month 12 (M12), and month 24 (M24). Visual function data (Direction of Motion (DOM) and Square Localization (SL)) from each visit was extracted from the Argus II Retinal Prosthesis Post Approval Study. Fundoscopy images were extracted and analyzed via NIH ImageJ. Data analysis was completed using IBM SPSS.

Results: The angle of the implant with respect to the horizontal (Δ) showed a statistically significant increase from both M1 to M6 and M1 to M24 (paired t-test, $p < 0.05$). The optic disc-tack-surgical handle angle (β) showed a significant increase from both M1 to M12 and M1 to M24 (paired t-test, $p < 0.05$). The linear distance from the optic disc to the surgical handle on the implant (AB) significantly increased between M1 and M12 (paired t-test, $p < 0.05$). There were significant negative correlations between length AB and SL ($r = -0.582$, $p < 0.01$) and DOM ($r = -0.0753$, $p < 0.01$), between angle β and SL ($r = -0.725$, $p < 0.01$) and DOM ($r = -0.459$, $p < 0.05$), and between angle Δ and SL ($r = -0.615$, $p < 0.01$). Based on multivariate regression analysis, angle β , angle Δ , and length AB were significant predictors of SL outcome ($p < 0.000$) and angle β , angle Δ , length AB, and length AC were significant predictors of DOM outcome ($p < 0.01$).

Conclusions: This study demonstrates that there is both statistically significant linear implant movement and angular rotation around the axis of the implant tack over time and that this movement had negative effects on visual function outcomes. It is important, moving forward, to take this into consideration when designing retinal implants, so that the implant's efficacy is not affected by such anatomic changes.

TITLE: Evaluation of a UNet Convolutional Neural Network (CNN) for Automatic Measurements of Ellipsoid Zone (EZ) Area and Photoreceptor Outer Segment (POS) Volume in X-Linked Retinitis Pigmentosa (xLRP)

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Wang, A. Cao, D.G. Birch, Retina Foundation of the Southwest, Dallas, Texas, UNITED STATES|Y. Wang, D.G. Birch, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yi-Zhong Wang: Commercial Relationship: Code N (No Commercial Relationship) | Ashley Cao: Commercial Relationship: Code N (No Commercial Relationship) | David Birch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Manual segmentation of OCT volume scans is time-consuming and costly. CNN models may provide new tools to facilitate this task. Previously we reported that a UNet was effective and efficient for segmenting retinal layers of SD-OCT B-scan images of patients with RP (Wang et al., ARVO 2020). Here we evaluated this model for automatic measurements of EZ area and POS volume from volume scans in xLRP.

Methods: UNet was implemented in MATLAB and trained with 480 midline B-scan images obtained from 220 patients with RP and 20 control subjects. The test included 38 high-speed 9mm 31-line macular volume scans from a separate group of 38 patients with xLRP. All volume scans showed a POS transition zone within the scan window. The Spectralis segmentation of volume scans was corrected manually for EZ and apex RPE to serve as a reference. UNet was used for segmentation of B-scan images in a volume scan to obtain EZ and RPE boundary lines that defined POS. The 3-D POS map was reconstructed by interpolating the discrete 2-D POS layers from 31 B-scans over the grid of scan area. EZ area was measured by multiplying the area of a single grid pixel by the number of pixels having measurable POS. The POS volume was the sum of the products of the grid pixel area and the POS length at the pixel. Bland-Altman and correlation analyses were conducted to compare EZ area and POS volume measured by UNet to the reference.

Results: For EZ area (range: 0.17 to 27.8 mm²), Bland-Altman analysis revealed a mean±SE difference of -1.55±0.25 mm² and CoR of 2.98 mm² between UNet and the reference. EZ area estimated by UNet was highly correlated with the reference (r=0.98; slope=0.85). For POS volume (range: 0.002 to 0.65 mm³), Bland-Altman analysis showed a close agreement between UNet and the reference (mean±SE difference of 0.0004±0.004 mm³ and CoR of 0.05 mm³). POS volume measured by UNet was also highly correlated with the reference (r=0.99; slope = 1.05).

Conclusions: While both EZ area and POS volume determined by UNet had a similar correlation with the reference, UNet tended to underestimate EZ area but had a closer agreement with the reference in measuring POS volume. The deep machine learning method may provide an effective tool for studying the relationship between disease progression and POS volume and EZ area changes in RP.

ABSTRACT BODY:

Purpose: A new generation femtosecond laser is currently in development for corneal lenticule extraction for refractive surgery. Combined with iris registration and corneal mark registration, the new femtosecond laser will be used to perform a wavefront-guided lenticule treatment on a surgical eye. The goal of this paper is to evaluate iris registration on the new femtosecond laser system.

Methods: 33 paired eye images from 33 subjects were collected in a clinical study of the new femtosecond laser. Each paired images included one eye image captured by a diagnostic device (iDesign Wavefront Studio system, Johnson & Johnson Vision, Inc) when the subject was in a seated position, and an image of the same eye captured on the laser system before applanation at 40mm from the patient interface when the subject was in the supine position. The diagnostic eye images were imaged under the infrared illumination of 780 nm and 940 nm wavelength, while the laser eye images were imaged under the infrared illumination of 835 nm wavelength. An image processing software was used to evaluate the image processing quality and iris registration with the 33 paired eye images. The identified matched blocks in the unwrapped iris images from each paired images should be 21 or better for a successful iris registration capture.

Results: On average, the detected pupil diameter from the 33 diagnostic eye images was 6.444 ± 0.968 mm, (range from 4.176 mm to 8.088 mm), and the iris diameter was 12.383 ± 0.3222 mm (range from 11.784 mm to 13.019 mm). The pupil boundary and outer iris boundary in all 33 laser eye images were detected correctly. On average, the detected pupil diameter from the 33 laser eye images was 5.043 ± 0.981 mm (range from 2.719 mm to 7.130 mm), and the iris diameter 12.144 ± 0.316 mm (range from 11.265 mm to 12.648 mm). The average cyclotorsion angle detected in the 33 paired eye images was $0.62 \pm 2.53^\circ$ (range from -3.52° to 6.13°), and the matching blocks identified in each paired diagnostic eye image and laser eye image were all above the 21. The capture rate of iris registration between the diagnostic device and the new femtosecond laser system achieved 100%.

Conclusions: Pupil boundary and outer iris boundary were detected correctly in the 33 eye images from the new femtosecond laser. The infrared eye images captured on the new femtosecond laser are adequate for iris registration with human eyes.

ABSTRACT BODY:

Purpose: Faricimab, currently in phase 3 trials, is the first bispecific antibody for intraocular use. It independently binds and neutralizes both angiopoietin-2 (Ang-2) and VEGF-A, key drivers of vascular instability (vascular leakage, neovascularization [NV], and inflammation). Faricimab demonstrated sustained efficacy compared with anti-VEGF monotherapy in the phase 2 clinical trial for neovascular AMD. This abstract presents new preclinical data on the anti-inflammatory effect of targeting Ang-2 and supporting the vessel stabilization potential of Ang-2 inhibition in a mouse model of spontaneous choroidal NV (sCNV) in the context of observed phase 2 clinical data.

Methods: 7-week-old JR5558 mice developing bilateral spontaneous neovascular lesions were treated intraperitoneally with mouse cross-reactive tool antibodies against VEGF-A, Ang-2, or both (bispecific anti-VEGF-A/Ang-2 antibody), and IgG as controls. Subretinal macrophage infiltration, detected by Iba1 immunostaining, was evaluated ex vivo by flat-mounted retinal pigment epithelium (RPE)/choroid histology at 1, 3, and 5 weeks post treatment to assess immediate and long-term effects on the number of inflammatory cells around lesions.

Results: Treatment with the bispecific anti-VEGF-A/Ang-2 antibody significantly reduced the number of Iba1-positive macrophages around lesions on flat-mounted RPE/choroid histology by 23% and 38% ($P < 0.05$) vs IgG control at 1 and 3 weeks post treatment, respectively. The effect of VEGF-A or Ang-2 inhibition alone was not significant. At 5 weeks post treatment, only anti-Ang-2- and anti-VEGF-A/Ang-2-treated mice showed significant reduction in the number of Iba1-positive macrophages by 53% and 49% ($P < 0.0001$), respectively, vs IgG control. Anti-VEGF-A treatment alone did not prevent subretinal infiltration of Iba1-positive immune cells.

Conclusions: Preclinical experiments further elucidated the potential role of Ang-2 inhibition alone and in combination with anti-VEGF in reducing inflammation in the retina, and demonstrated that the prolonged anti-inflammatory effect was driven by Ang-2 neutralization. In a mouse model of sCNV, dual Ang-2/VEGF-A inhibition was superior to VEGF-A monotherapy in causing sustained prevention of subretinal macrophage infiltration around lesions on RPE/choroid, supporting the results of the phase 2 clinical trial.

ABSTRACT BODY:

Purpose: To assess correlation between change in best-corrected visual acuity (BCVA) and change in central subfield thickness (CST) for diabetic macular edema receiving fixed-dosing intravitreal aflibercept injection (IAI) over 100 weeks.

Methods: Post hoc analysis of VISTA and VIVID wherein eyes were randomized to IAI 2 mg q 4 weeks (2q4) or IAI 2 mg q8 weeks after 5 initial monthly doses (2q8). The relationship between change in functional (BCVA) and change in anatomical (CST) outcomes at early (week 12) and later (week 52, and 100) visits was determined using Pearson correlation.

Results: Of 872 eyes, 290 were treated with 2q4 and 286 with 2q8. Percentage of eyes with BCVA and CST measurements available for analysis at weeks 12, 52, and 100 was 95%, 86%, and 74% in the 2q4 arm; and 97%, 85%, and 71% in the 2q8 arm. At baseline, the correlation (r) between CST and BCVA was -0.45 (95% CI: -0.53, -0.35) and -0.47 (95% CI: -0.55, -0.37) in the 2q4 and 2q8 arms. Change in CST and change in BCVA at weeks 12, 52, and 100 had r values of -0.39 (95% CI: -0.49, -0.29), -0.27 (95% CI: -0.38, -0.15), and -0.30 (95% CI: -0.41, -0.17) in the 2q4 arm and -0.28 (95% CI: -0.39, -0.17), -0.29 (95% CI: -0.41, -0.17), and -0.33 (95% CI: -0.44, -0.20) in the 2q8 arm. Linear regression analysis of correlation between changes in CST and changes in BCVA at week 100, adjusted for relevant factors showed CST changes accounted for 17% of variance in BCVA changes; every 100 µm decrease in CST was associated with a 1.2 letter increase in BCVA (P = .001).

Conclusions: Correlations between change in CST and change in BCVA following 2q4 or 2q8 fixed-dosing regimens of IAI for DME were modest. For any given change in CST from baseline, there was a broad range of change in BCVA from baseline at follow-up. These findings are consistent with a PRN regimen in the DRCR Retina Network Protocol T and suggest change in CST may be important in determining the need to withhold, continue, or resume anti-VEGF therapy for DME, but is a poor surrogate for predicting visual acuity outcome, even with fixed-dosing treatment regimens.

TITLE: Unique MIGS Combining Goniotomy and Direct Viscodilation of the Collector Channels in Eyes with Peripheral Laser Iridotomies

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Burk, J.E. Gilmore, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|L.L. Gilmore, Dallas Eye and Ear, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Linda Burk: Commercial Relationship: Code N (No Commercial Relationship) | Jane Gilmore: Commercial Relationship: Code N (No Commercial Relationship) | Linda Gilmore: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose was to evaluate Dual Blade Goniotomy and Direct Viscodilation of the collector channels in eyes with previous peripheral iridotomies for narrow angle glaucoma. Could the "clean the gutter and power wash the downspout" procedure effectively open the once aggravated trabecular meshwork?

Methods: After standard cataract surgery, 32 eyes had 180 degrees of trabecular meshwork removed with the Kahook Dual Blade exposing the ostium of the collector channels allowing direct visco-dilation of the collector channels. Viscoelastic was injected into the collector channels as the cannula was snugly held perpendicularly against the outer wall and dragged through the opened Schlemm's canal. Viscoelastic was used to break any anterior synechiae.

Results: 53% were African American. 72% were women. The average age was 68 years. 41% had moderate or advanced glaucoma. 51% were diabetics. 28% were on anticoagulants. Before surgery, the IOP was 22.4 mmHG (SD+/- 7.7) on 1.4 drops. At 3 months, the IOP was 15 mmHG (SD+/- 4/1) on 0.3 eye drops. IOPs were 16.1 mmHG (SD+/- 4.7) on 0.4 eye drops (1yr), 14.3mm HG (SD+/- 3.5) on 0.7 eye drops, and 14.7 mmHG (SD+/- 4.7) on 0.5 eye drops. Eye drops were eliminated in 74% (1yr), 53% (2yr), and 64% (3yr). A blush of blood was seen over the trabecular meshwork was common in the angle but was gone in two weeks. Avascular fibrosis was seen in several eyes and removed with the Dual Blade when the trabecular meshwork had been identified.

Conclusions: Narrow angles previously treated with laser iridotomies can be successfully treated with the Goniotomy-Visco-dilation-Cataract Surgery technique. This "clean the gutter and powerwash the downspouts' approach demonstrates that the once aggravated trabecular meshwork can be rejuvenated, improving IOP control and reducing the amount of drops required.

ABSTRACT BODY:

Purpose: The usefulness of optical coherence tomography angiography (OCTA) in clinical practice is heavily influenced by the scan resolution. Angio 3x3 mm scans provide best commercially available scan resolution, however, due to its limited field of view (FOV), it is commonly complemented with an Angio 6x6 mm scan with a lower resolution. In this study we compare the image quality of a traditional Angio 3x3 mm scan with a High Definition (HD) 6x6 mm Angio scan.

Methods: A modified PLEX® Elite 9000 (ZEISS, Dublin, CA) was used to image 10 subjects (5 healthy and 5 diseased eyes) with the following protocol:

Pattern 1: 3x3 mm FOV consisting of 300 A-lines/B-scan and 300 B-scans acquired at 100kHz with 4 repetitions for angiography processing.

Pattern 2: 6x6 mm FOV consisting of 600 A-lines/B-scan and 600 B-scans acquired at 200kHz with 3 repetitions for angiography processing. HD 6x6 mm OCTA volumes are generated by processing clusters of three B-scan repetitions each for a shorter acquisition time, and the processing algorithm has been modified to enhance sensitivity to lower blood flow velocity.

An experienced grader compared quality and details of two scan patterns by grading the en-face slabs on a scale of 1-5 in a blind study. 6x6 mm images for every subject were cropped to a 3x3 mm FOV before comparison.

Results: As expected from the fact that the same sampling resolution was used in both patterns, HD 6x6 mm en-face views of the retinal slabs reveal comparable details and similar quality as seen in 3x3 mm scans (Figure 1). However, HD 6x6 mm scans also provide a larger FOV (Figure 1c), which is often necessary to visualize the extent of vascular lesions, for example in patients with macular neovascularization (MNV). Figure 2 shows the outer retina to choriocapillaris (ORCC) slab. Although both patterns provide the same resolution, the extent of MNV is only fully captured in the HD 6x6 mm en face projection.

Conclusions: We demonstrated that HD 6x6 mm scans provide a larger FOV while maintaining the same quality and detail as Angio 3x3 mm scans, and thus might be a suitable replacement for the Angio 3x3 mm scan in clinical practice.

ABSTRACT BODY:

Purpose: The major route of infection of SARS-CoV-2 is supposed to be the respiratory way. Thus, mouth-nose masks are requested to prevent the viral transmission. The aim of the present study was to investigate, if wearing a mouth-nose mask impaired visual field function in normal eyes.

Methods: 30 healthy eyes of 30 subjects were recruited. Visual field function was tested by white-on-white perimetry (OCTOPUS 900; 90°). Sensitivity thresholds were analysed in 14 defined test points (P1-P14, inferior visual field) under 3 different test conditions while wearing a nose-mouth mask: (I) position 1: 1.5cm under the lower eyelid, nose clip not used; (II) position 2: 1.5cm under the lower eyelid, nose clip correctly positioned; (III) position 3: 0.5 cm under the lower eyelid, nose clip correctly positioned. All data were compared to sensitivity thresholds without wearing a nose-mouth mask (reference). Mean D was calculated as difference between each test condition and reference, respectively. The study was approved by the local ethics committee and was done in accordance with the tenets of the Declaration of Helsinki. Informed consent was obtained from each participant.

Results: Mean sensitivity was not significantly different between all three test conditions (26.6 ± 2.4 dB (I); 28.3 ± 2.4 dB (II); 27.8 ± 2.2 dB (III) and reference (28.5 ± 2.4 dB), respectively. Subgroup analysis for test points P1-P14 yielded significantly different sensitivity thresholds between test condition (I) and reference at test point P3 – P12 ($p \leq 0.005$). Sensitivity thresholds at test point P7 were significantly different between test condition (II) and (III) compared to reference ($p < 0.001$), respectively. Mean D increased while wearing a mask at P7 in test condition (II) < (III) < (I) (-8.3 ± 7.3 dB; -11.3 ± 9.5 dB; -20.1 ± 7.6 dB).

Conclusions: Visual field function was significantly impaired inferior-nasal while wearing a nose-mouth mask in normal eyes, especially if the nose clip was not used correctly.

ABSTRACT BODY:

Purpose: To determine the inter-reader agreement for structural features related to incomplete and complete retinal pigment epithelium and outer retinal atrophy (iRORA and cRORA respectively) in age-related macular degeneration (AMD).

Methods: Following formal training (reviewing literature, performing a pre-test twice and undergoing a web-based tutorial), readers qualitatively assessed 60 optical coherence tomography (OCT) B-scans from 60 eyes with AMD for nine individual features associated with early atrophy and performed seven different annotations to quantify the spatial extent of OCT features within regions-of-interests. Cases were selected to depict the entire spectrum of findings that may be observed in dry AMD eyes with and without atrophy. Inter-reader agreement based on kappa coefficients (κ) and smallest real difference (SRD) was assessed.

Results: Slight to substantial inter-reader agreement was observed for assessment of individual features associated with atrophy ($\kappa=0.19-0.70$), with lowest and highest agreement being for outer nuclear layer thinning and inner nuclear layer (INL) subsidence, respectively. The lowest SRD for horizontal annotations was observed for the zone of choroidal hypertransmission ($\pm 190.8\mu\text{m}$). Using the qualitative and quantitative gradings to derive atrophic features, there was moderate agreement for a two-category classification of the presence or absence of at least iRORA ($\kappa=0.53$), and substantial agreement for the presence or absence of cRORA ($\kappa=0.62$). There was moderate agreement for a three-category classification of no atrophy, iRORA and cRORA ($\kappa=0.52$). Exploratory analyses suggested a significantly higher level of agreement for a three-category classification using (i) no atrophy, (ii) presence of INL and outer plexiform layer subsidence, or a hyporeflective wedge-shaped band as a less severe atrophic grade and (iii) the latter plus an additional requirement of choroidal hypertransmission $\geq 250\mu\text{m}$ for a more severe atrophic grade ($\kappa=0.68$; $P=0.004$).

Conclusions: While current definitions of iRORA and cRORA allow for a consistent and robust assessment of early atrophy, a refined combination of individual features improved inter-reader agreement. This evaluation represents an important step towards a more detailed classification system for atrophic AMD and helps to inform the design and analysis of future early interventional clinical trials in AMD.

ABSTRACT BODY:

Purpose: Registration of longitudinal OCT data is important for measuring the changes of retinal thicknesses over time. The registration based on OCT en face images becomes difficult when the OCT data is generated by a low-cost OCT system due to low contrast in the data. Here we propose to use the macular thickness and principal curvatures as alternative maps to provide sufficient number of landmarks for registration.

Methods: To obtain well distributed landmarks across the OCT field of view of two maps for robust registration, the macular thickness and corresponding principal curvature maps were used, where landmark correspondences were extracted from all three maps of each scan. Then, a subset of landmark correspondences with high confidence were selected using an exhaustive search method to compute the rigid transformation. Figure 1 shows an example of the thickness map registration. The mean registration error along with the number of landmarks between the landmark matches after registration were calculated for each pair of OCT volumes.

Results: Figure 2 shows the statistics for the registration error and landmark distribution for 243 pairs of OCT volumes of disease eyes acquired using a low-cost OCT prototype system (ZEISS, Dublin, CA). The mean and standard deviation of registration error in x, y and radial direction $\sqrt{x^2+y^2}$ are smaller than 70 and 15 microns respectively, which is acceptable for macular thickness analysis. The average number of landmarks used for registration is relatively high for computing three parameters of rigid transformation.

Conclusions: A registration method based on macular thickness and curvature maps has been explored in this study. We showed that this algorithm performed well for data acquired from low-cost OCT devices.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) angiography scans can be acquired at different scan rates. With faster scan rates becoming more prevalent, clinicians are expecting the most common OCT metrics to be available regardless of the rate at which these scans are acquired. The purpose of this study is to compare measurements of retinal pigment epithelium (RPE) elevation obtained on a swept-source OCT instrument at two different scan rates: 100 kHz and 200 kHz.

Methods: In this study, 25 dry AMD eyes were imaged on the swept-source OCT, PLEX[®] Elite 9000 (ZEISS, Dublin, CA) using 6×6 mm angiography scans. The acquisition consisted of 3 repeated scans at 200 kHz and 1 single scan at 100 kHz. The RPE elevations were computed over 3 mm and 5 mm circular areas and volumes centered on the fovea. The RPE elevation values from the scans acquired at both scan rates were plotted against each other. Linear regression was applied to the data to determine the R-squared value. The Bland-Altman analysis was used to determine the mean offset in RPE elevation measurements between the two scan rates. Paired t-tests were also calculated.

Results: The correlation plots (figures 1 and 2) show very good correlations ($R^2 > 0.98$) in area and volume of RPE elevation between 100 kHz and 200 kHz scan rate. The p-values from a paired t-test were all well above 0.05 (p = 0.47 and p = 0.73 for the area of RPE elevation computed over 3 mm² and 5 mm² circles respectively; p = 0.17 and p = 0.36 for the volume of RPE elevation computed over 3 mm³ and 5 mm³ circles respectively) indicating no statistical difference in measurement difference between the 2 scan rates.

Conclusions: Based on these results, there is very good agreement in the RPE elevation measurements between 100 kHz and 200 kHz scan rate. Therefore, the current RPE elevation measurements obtained at 100 kHz are also applicable at 200 kHz.

ABSTRACT BODY:

Purpose: Intraocular pressure (IOP) is a mechanical oscillation with unknown physiological significance. TRPV4 (transient receptor potential isoform 4) channels partially mediate the trabecular meshwork (TM) response strain, shear, swelling and pressure. Their response to sustained stimulation is associated with stochastic regenerative $[Ca^{2+}]_{TM}$ spikes. The goal was to elucidate the cellular mechanisms that underlie this process.

Methods: Primary human TM cells were stimulated with the selective TRPV4 agonist GSK1016790A (GSK101). $[Ca^{2+}]_i$, $[Na^+]_i$ and transmembrane currents measured with optical imaging and patch clamp in the presence/absence of pharmacological modulators. mRNA and protein levels were determined with qPCR, Western blot and spatial expression determined with antibody labeling. Cells were transfected with GFP probes, shRNAs and exposed to modulators of plasma membrane and intracellular Ca^{2+} signaling pathways.

Results: Sustained TRPV4 activation triggered Ca^{2+} oscillations with periodicity of ~0.2 – 1 Hz, sustained depolarization and increase in $[Na^+]_i$. The oscillations were insensitive to blockers of Orai channels, voltage-operated Ca^{2+} and Na^+ channels but could be mimicked with inhibition of Ca^{2+} sequestration into ER stores. Inhibition of mitochondrial Ca^{2+} signaling and suppression of TRPM4, a Ca^{2+} -activated Na^+ channel blocked the oscillations. However, pharmacological inhibition of TRPM4 had no effect on trabecular outflow and genetic ablation did not affect IOP.

Conclusions: These results show that activation of pressure transducing ion channels in TM cells triggers amplitude- and time-dependent Ca^{2+} fluctuations that are regulated by steady-state $[Ca^{2+}]_i$ and activation history. The fluctuations require continual interactions between multiple plasma membrane TRP channels, endoplasmic reticulum and mitochondrial calcium sequestration/release mechanisms. TM calcium homeostasis, therefore, is a sophisticated, multi-pathway process that time-dependently coordinates molecular activity of plasma membrane, cytosolic and store compartments.

Commercial Relationships Disclosure (Abstract): Sophie Kubach: Commercial Relationship(s);Carl Zeiss Meditec, Inc:Code E (Employment) | Luis De Sisternes: Commercial Relationship(s);Carl Zeiss Meditec, Inc:Code E (Employment) | Jean-Francois Korobelnik: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Bonnin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Widefield optical coherence tomography angiography (OCTA) has the potential to improve the detection of peripheral retinal lesions in diabetic retinopathy (DR) that might otherwise be missed using conventional OCTA scans. Widefield OCTA can be obtained by combining multiple cube scans taken at different locations. In this study we assessed a new volumetric montage protocol designed to cover an area of 24 mm (Horizontal) x 15 mm (Vertical) for the identification of peripheral vascular lesions.

Methods: Ten eyes with diabetic retinopathy were imaged on PLEX® Elite 9000 swept-source OCT (ZEISS, Dublin, CA) by acquiring a central 15x15 mm angio scan of 17 um resolution followed by two lateral 15x15 mm angio scans at nasal and temporal fixations of same resolution as the central scan. The two lateral 15x15 mm angio scans were registered together such as to produce a volumetric 24 mm (H) x 15 mm (V) x 6mm (D) angio scan. The retinal slab from the resulting volumetric montage was compared to the retinal slab from the central single 15x15 mm scan to identify the extent of vascular lesion in the periphery.

Results: Figure 1 and Figure 2 show the retinal slabs and central B-scans from the volumetric montage protocol and from central 15x15 mm angio scan respectively. Out of 10 eyes with diabetic retinopathy, 8 were found to have lesions beyond the central 15x15 mm FOV. In addition, the quality of the montage, especially over the overlapping area of the 2 scans was preserved with no noticeable artifact. The sampling resolution of the montage protocol of 17 um was found to be adequate to identify the type of lesions: ischemic area, microaneurysm, vessels tortuosity were commonly reported. Some of these lesions were also visible on the structural B-scan with flow signal overlaid.

Conclusions: With a FOV of 24 mm (H) x 15 mm (V) and a sampling resolution of 17 um, the proposed volumetric montage protocol expands the imaging capability of OCTA for the detection and classification of vascular peripheral lesions.

ABSTRACT BODY:

Purpose: Most reports on Alport syndrome (AS) have focused on the posterior pole, while the retinal periphery has remained largely unexplored. Newer diagnostic modalities utilizing optical coherence tomography angiography (OCTA) and fundus photography have allowed for widefield (WF) and ultra-widefield (UWF) imaging of the retina. We performed a cross-sectional clinical study correlating the retinal findings on WF and UWF imaging with the clinical characteristics of our cohort of AS patients.

Methods: Demographics, past medical and ophthalmic history were collected at the inclusion visit. All patients underwent UWF color fundus photography and fundus autofluorescence (FAF), WF OCTA, and spectral-domain OCT (SD-OCT). Clinical associations were quantitatively explored with Pearson's correlation tests and chi-squared tests for quantitative and qualitative variables, respectively.

Results: Forty-two eyes of 21 patients (11 males, 55%; mean age 36.6 ± 12.9 years) with AS were included. Female carriers were older at time of inclusion (mean age 46 ± 15 years). Dot maculopathy was more frequent in male patients with X-linked AS; macular dots corresponded to inner limiting membrane (ILM) granularity on SD-OCT. Thirteen eyes (34%) had a consistent pattern of peripheral hypoautofluorescent ring on UWF-FAF. En-face OCT revealed multiple areas of retinal nerve fiber layer (RNFL) dehiscence in the macula, overlapping with temporal vascular lacunae seen on OCTA. Twenty eyes (52%) had absent RNFL raphe temporally. Mid-peripheral SD-OCT scans revealed a splintered and/or multi-lamellated ILM in 8 eyes (19%), which was likely progressive.

Conclusions: WF and UWF imaging allowed for the detection of new findings in AS patients. Most of the features are presumably congenital but some may be progressive and may share similar features to the renal pathology identified in this rare disorder.

ABSTRACT BODY:

Purpose: Although radiation retinopathy is a well-recognized entity, preventive measures have not been defined. We aimed to study how a novel agent, JP4-039, may prevent acute radiation toxicity in the mouse retina by stabilizing mitochondria and preventing apoptosis after irradiation.

Methods: Forty-five BALB/c mice were sorted into three groups of 15 mice each. Anesthesia was then performed on all mice with 2% isoflurane. Mice in Groups 1 and 2 received a 32-gauge/10 microliter intravitreal injection of either 40 nanogram JP4-039 (n=5 per group) or 30% cyclodextrin (control; n=5 per group). The remaining 5 mice in either group did not receive an intravitreal injection. Group 3 mice (n=15) all received an injection of BODIPY-labeled JP4-039. Thirty minutes after injection and further anesthesia with Nembutal, all mice in Groups 1 and 2 were irradiated with a dose of 18 Gy via 6 MV photon beam (Varian TrueBeamTM STx linear accelerator), while Group 3 mice remained without irradiation. All mice were then sacrificed and enucleated according to the following sequence: Group 1 and Group 2 underwent TUNEL assay 24 hours after irradiation to determine rate of apoptosis, or flow cytometry 120 hours after irradiation in order to detect retinal migration of inflammatory cells. Group 3 underwent fluorescent microscopy at 0, 15, 30, and 60 minutes after injection only, in order to determine retinal uptake of intravitreal JP4-039.

Results: Eyes treated with JP4-039 prior to irradiation had lower levels of retinal apoptosis ($35.8 \pm 2.5\%$) compared to controls ($49.0 \pm 2.7\%$; $p=0.0066$), as well as reduced migration of apoptotic N1 cells ($30.7 \pm 11.7\%$) compared to controls ($77.7 \pm 5.3\%$; $p=0.0105$). Retinal uptake of intravitreal JP4-039 was detected in the mouse retina 15, 30, and 60 minutes after injection.

Conclusions: Intravitreal injection of the novel antioxidant, JP4-039, reduces the effects of acute radiation toxicity in the mouse retina.

Commercial Relationships Disclosure (Abstract): Meenakshi Kurup: Commercial Relationship: Code N (No Commercial Relationship) | Jared Ching: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Yu-Wai-Man: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Leber Hereditary Optic Neuropathy (LHON) is a mitochondrial optic neuropathy characterised by bilateral subacute central visual loss. The visual prognosis is poor. The majority of patients achieve visual acuities worse than 20/200. Anxiety and depression can compound the loss of visual function in LHON patients, exerting further detrimental effects on quality of life (QoL).

The aims of this study were to:

1. Assess vision-related QoL using the validated Visual Function Index-14 (VF-14) and National Eye Institute Visual Function Questionnaire-25 (VFQ-25).
2. Screen for anxiety and depression using the Hospital Anxiety and Depression Scale (HADS).

Methods: A standardised telephone interview, which included the VF14, VFQ25 and HADS, was conducted on 50 affected LHON patients and 28 unaffected LHON carriers.

Results: The mean VF-14 and VFQ-25 scores (\pm standard deviation (SD)) were significantly lower in affected patients compared with unaffected carriers (VF-14: 29.4 ± 24.0 vs 98.6 ± 2.51 , $p < 0.001$; VFQ-25: 48.3 ± 19.8 vs 92.9 ± 4.23 , $p < 0.001$). 54% of LHON patients were found to be anxious based on the HADS-Anxiety (HADS-A) score and 28% of LHON patients were depressed based on the HADS-Depression (HADS-D) score. The mean HADS-A (7.48 ± 3.9) and HADS-D (5.72 ± 4.13) scores for LHON patients were greater than the general population scores of 6.14 ± 3.76 and 3.68 ± 3.07 , respectively. The mean HADS-D score for LHON patients was significantly greater compared with unaffected carriers (3.68 ± 3.06 , $p = 0.024$). In affected patients, the duration of disease correlated moderately with VF-14 and VFQ-25 scores (both $r = 0.49$, $p < 0.001$), as well as the HADS-D score ($r = -0.41$, $p = 0.003$).

Conclusions: Vision-related QoL is significantly reduced in LHON patients who also have higher levels of depressive symptoms compared to unaffected carriers. Vision-related QoL and depressive symptoms correlate with disease duration, suggesting that both may improve as patients adapt to chronic disability. HADS-A and HADS-D scores of LHON patients are higher compared to the general population, highlighting their increased risk of anxiety and depression. Addressing mental health concerns and promoting enabling skills and strategies that overcome role limitations may improve QoL and mood in LHON patients.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is the most common cause of retinal detachment (RD) repair failure. The impact of primary (preoperative) PVR on the occurrence of multiple surgical failures has not been studied in detail. We aimed to characterize the association between primary PVR and multiple failures of RD repair using a nationwide healthcare claims database.

Methods: We selected cases of initial RD repair from the IBM® MarketScan® Commercial Claims and Encounters Database (2010-2017). Cases were categorized by the absence (P0 group) or presence (P1 group) of primary PVR. We defined surgical failure as the occurrence of a subsequent RD repair procedure with concurrent PVR. The frequency of surgical failures and the inter-surgical intervals (ISI) were compared between the groups. Kaplan-Meier analysis was used to estimate the probability of surgical failures in each group over time. Hazard ratios (HR) were adjusted for age, sex, and procedure.

Results: A total of 27,137 cases of initial RD repair were included, with 24,500 (90.3%) in P0 and 2,637 (9.7%) in P1. The median age of patients was 56 years. The frequency (%) of one, two, three, or four surgical failures in P0 vs. P1 was 1.88 vs. 10.24 ($p<0.001$), 0.26 vs. 2.50 ($p<0.001$), 0.07 vs. 0.64 ($p<0.001$), and 0.03 vs. 0.08 ($p=0.272$), respectively. The median ISI between the initial repair and the first failure was 70 days in P0 and 59 days in P1 ($p=0.021$). The cumulative probability of the first failure at 60 months was 2.8% in P0 and 16.3% in P1 ($p<0.001$). Subsequently, the cumulative probability of a second failure at 60 months was 19.2% in P0 and 29.6% in P1 ($p=0.002$). The risk of the first failure was higher in P1 than in P0 (HR: 6.02, 95% confidence interval (CI): 5.24-6.92, $p<0.001$). The risk of the second failure was also higher in P1 than in P0 (HR: 1.67, CI: 1.23-2.28, $p=0.001$). There was no difference in the risk of the third failure between the groups (HR: 0.76, CI: 0.41-1.40, $p=0.372$).

Conclusions: RD cases with primary PVR were >6 times more likely to undergo repeat surgery than those without. Primary PVR may increase the risk of requiring multiple RD repair surgeries. Healthcare claims analysis may be a useful tool to study population-based estimates of the incidence and recurrence pattern of RD repair failure.

TITLE: Evaluation of machine learning algorithms for prediction of trabeculectomy outcomes

SESSION TITLE: Data science, machine learning, and artificial intelligence

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.A. Zanabli, West Virginia University School of Medicine, Morgantown, West Virginia, UNITED STATES|H. UI Banna, West Virginia University, Morgantown, West Virginia, UNITED STATES|B. McMillan, M. Lehmann, S. Gupta, J.R. Palko, West Virginia University Eye Institute, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ahmed Zanabli: Commercial Relationship: Code N (No Commercial Relationship) | Hasan UI Banna: Commercial Relationship: Code N (No Commercial Relationship) | Brian McMillan: Commercial Relationship: Code N (No Commercial Relationship) | Maria Lehmann: Commercial Relationship: Code N (No Commercial Relationship) | Sumeet Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Joel Palko: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To utilize pre-operative patient features obtained from electronic medical records to assess the accuracy of machine learning (ML) algorithms to predict trabeculectomy outcomes.

Methods: Demographic, ocular and systemic health data resulting in 40 features from 220 consecutive trabeculectomy operations on 175 patients were input into four machine learning algorithms. The primary outcome classification was surgical failure at 1 year, defined as IOP > 21 or <5 at two consecutive visits after 3 months, less than a 20% IOP reduction, or a need for reoperation for glaucoma. Eyes that had not failed by the above criteria and were not receiving supplemental medical therapy to lower IOP were considered a complete success and the remaining eyes considered failures. Up-sampling was carried out to equalize the frequency of the underrepresented class. Random forest (RF), artificial neural network (ANN), logistic regression (LR) and support vector machine (SVM) algorithms were evaluated using accuracy, sensitivity, specificity and area under the curve (AUC) metrics with 10-fold nested cross-validation. The model with the best performance was further optimized using recursive feature elimination and hyper-parameter tuning. The data set was divided using 60% training/validation and 40% testing for evaluation of the final optimized model. The features most influencing the accuracy of each algorithm were identified using mean decrease in accuracy (MDA).

Results: 123 (55.90%) of the operations were classified as surgical failures and 97 (44.10%) as complete successes. The accuracy and AUC were highest in the RF algorithm, followed by SVM, LR and ANN as seen in Table 1. The accuracy and AUC of the final optimized RF model were 0.65 and 0.70, respectively. The most influential features on the accuracy of the final RF model are shown in Fig 1.

Conclusions: To our knowledge, this is the first study to leverage the use of machine learning algorithms to predict trabeculectomy outcomes. The four ML algorithms performed similarly, with the RF algorithm providing moderately higher accuracy and AUC. Future work will focus on combining trabeculectomy outcomes from other institutions to increase sample size and provide more generalized predictive algorithms.

ABSTRACT BODY:

Purpose: There is only little knowledge existing about the refractive change over the course of a lifetime, particularly in adulthood. Therefore, the aim of this study was to examine the 5-year change in refractive error in phakic eyes and its risk factors in the retrospective population-based Gutenberg Health Study, representing a German general population.

Methods: The Gutenberg Health Study is a German population-based cohort study including 15,010 participants aged 35-74 years at baseline examination (2007-2012). After 5 years, a follow-up examination was carried out (82% participation). At both examinations, objective refraction was measured. Phakic eyes at follow-up examination were included in this analysis. 5-year change of spherical equivalent was computed and age- and sex-stratified analysed. Linear regression analysis was conducted analysing potential risk factors, namely sex, age spherical equivalent, intraocular pressure, cardiovascular parameters (HbA1c, HDL-cholesterol, LDL-cholesterol, triglycerides, body-mass index, physical activity, smoking) as well as level of education and occupation.

Results: 10,156 subjects were included. An age-related shift of refractive error was identified, namely -0.07 D for age 35-44 years, 0.20 D for 45-54, 0.19 D for 55-64, and -0.03 D for age 65-74 years. Smokers had a hyperopic shift ($B=0.03$; $p=0.02$), while higher intraocular pressure ($B=-0.006$ per mmHg; $p<0.001$) and female sex ($B=-0.04$; $p<0.001$) were linked with a myopic shift. Education, occupation and other cardiovascular parameters were not associated with change in refractive error.

Conclusions: The Gutenberg Health Study demonstrates a U-like shift in refractive error with a myopic change at younger and older age and a hyperopic shift at age 43 to 70 years. Smoking is associated with a hyperopic shift whereas a higher IOP is associated with a myopic shift. Educational level and occupation were not linked to a change in refractive error at age 35 to 74 years.

ABSTRACT BODY:

Purpose: While prognosis and risk of progression is crucial in developing precise therapeutic strategy in treatment-naive neovascular age-related macular degeneration (nAMD) patients, limited predictive tools are available. We proposed a novel deep convolutional neural network (CNN) that enables feature extraction through image and non-image data integration to seize imperative information and achieve highly accurate outcome prediction.

Methods: A total of 698 evaluable nAMD patients who received intravitreal injection of anti-vascular endothelial growth factor (anti-VEGF) were analyzed. The Heterogeneous Data Fusion Net (HDF-Net) was designed to predict VA outcome in 12th months after anti-VEGF treatment. A set of baseline optical coherence tomography (OCT) image and non-image demographic features were employed as input data and the 12th-month VA as target data to train, validate, and test the HDF-Net. Accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve (AUC) were evaluated.

Results: Of all evaluable patients, 163 patients had at least 2-line VA improvement, and 535 failed to achieve VA improvement (≥ 2 line). This newly designed HDF-Net was trained to perform 12-month VA forecast and demonstrated an AUC of 0.989 (95% CI, 0.970-0.999), accuracy of 0.936 (95% confidence interval [CI], 0.889-0.964), sensitivity of 0.933 (95% CI, 0.841-0.974), and specificity of 0.938 (95% CI, 0.877-0.969). The HDF-Net demonstrated superior performance to the classic AlexNet (AUC of 0.936 (95% CI, 0.894-0.978), accuracy of 0.895 (95% CI, 0.841-0.933), sensitivity of 0.824 (95% CI, 0.716-0.896), and specificity of 0.942 (95% CI, 0.880-0.973)). In the attention heatmap, focused locations that contributed most to decision making by HDF-Net showed validity and corresponded well to clinically relevant features within OCT images.

Conclusions: By simulating the real-world clinical decision process with mixed baseline information from OCT images and non-image data, HDF-Net demonstrated promising performance in predicting individualized treatment outcome. The results highlight the potential of deep learning to simultaneously process a broad range of clinical data to weigh and leverage the complete information of the patient. This novel approach is an important step toward personalized therapeutic strategy for nAMD.

ABSTRACT BODY:

Purpose: To evaluate the relationship between eye diseases-diabetic retinopathy (DR), age-related macular degeneration (AMD), and glaucoma-and the development of Alzheimer's disease and related dementia (ADRD) and the extent to which these might be explained by poor glycemic control and retinal microvascular disease burden.

Methods: The Adult Changes in Thought (ACT) is a 25-year-old ongoing longitudinal study of dementia-free adults aged >65 followed for the development of ADRD. Among participants with diabetes, we used information from the electronic health record and ACT study visits to ascertain time-varying exposures of DR, AMD, and/or glaucoma at study entry or during follow-up and how established these conditions were (onset <5 vs ≥5 yrs ago). Using estimated glomerular filtration (eGFR) as a marker for retinal microvascular disease burden, we also computed time-varying estimates of mean level, trajectory, and variability of eGFR, as well as mean blood glucose (BG), using fasting/random glucose and HbA1C. We fit Cox models to estimate the relationship between each eye disease and risk of ADRD after adjusting for eGFR, BG, sex, education, >1APOE ε4, race, and smoking. The potential modifying effect of BG and eGFR were assessed by changes in the magnitude of each association from adjusted models.

Results: Over 3342.4 person-years of follow-up among 526 ACT participants with diabetes, 131(25%) developed dementia including 98 (19%) who developed AD. A total of 85,439 eGFR and 72,960 GB measures were available for analysis. DR was associated with the development of both AD and dementia (the association was similar in magnitude to APOE ε4). (Figure) The hazard ratios (HR) for established DR vs. no DR and established AMD vs. no AMD changed very little after adjustment for eGFR and BG (from 1.65 [p=0.04] to 1.67 [p=0.03] for DR), (from 1.66 [p=0.07] to 1.74 [p=0.045]). There was no association between glaucoma and either outcome.

Conclusions: An association between diabetic retinopathy and the development of Alzheimer's and dementia in people with diabetes did not appear to be explained by markers of glycemic control and microvascular disease.

TITLE: Combination of split fixation and hypertensive phase is associated with vision loss in Latino and Black patients following Ahmed Glaucoma Valve surgery

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Tan, S.X. Chen, SUNY Downstate Health Sciences University College of Medicine, New York, New York, UNITED STATES|N.M. Radcliffe, Ophthalmology, New York Eye and Ear Infirmary of Mount Sinai, New York, New York, UNITED STATES|N.M. Radcliffe, The New York Eye Surgery Center, The Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nicholas Tan: Commercial Relationship: Code N (No Commercial Relationship) | Shannon Chen: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Radcliffe: Commercial Relationship(s);New World Medical:Code C (Consultant)

ABSTRACT BODY:

Purpose: Few studies have explored reasons for vision loss after Ahmed Glaucoma Valve (AGV) insertion, especially among minorities. We hypothesized that in a Latino and Black population, eyes with both preoperative split fixation and a postoperative hypertensive phase (SFHP) were more likely to lose visual acuity (VA) 1 year after AGV surgery.

Methods: We reviewed charts of eyes followed for 12 months from Latino or Black patients who received standalone or combined AGV surgery (with phacoemulsification and/or cyclodestructive lasers). We excluded eyes with previous tube shunts and eyes missing visual field data or Snellen VA. A single surgeon conducted all procedures in the Bronx, NY from 2014-2019. Split fixation (SF) described <10 dB sensitivity in any of the four paracentral quadrants of the Humphrey 24-2 visual field. Hypertensive phase (HP) was defined as an IOP reading > 21 mmHg within the first 3 postop months after reduction of IOP to less than 22 in the first week, without tube malfunction. We used logistic regression to test the effect of SFHP on VA loss of two lines or more by 12 months. We considered 8 covariates: SF alone, HP alone, preop IOP, age, sex, race, diabetes, and systemic hypertension. Sterling IRB deemed this study to be exempt.

Results: Of 241 eyes from 186 patients, VA loss of 2+ lines occurred in 52 (21.6%). Univariate regression revealed that SFHP eyes were 5.96 times more likely (95% CI=3.06-11.79; $p<0.0001$) to experience this outcome. Of the 8 covariates, only preop IOP and HP alone modified the odds ratio by $>10\%$ when added. HP increased the OR by 53.3%, while preop IOP decreased the OR by 10.6%. In the model including SFHP, SF alone, HP alone, and preop IOP, SFHP eyes were 7.99 times more likely to have lost 2+ lines by 1 year (95% CI=2.92-25.95; $p=0.0001$).

Conclusions: SFHP moderately to greatly increased the odds of vision loss after AGV surgery in Latino and Black patients. HP alone and preop IOP were true confounders. In theory, SF may signify a severe glaucoma with fragile retinal nerve fibers, enabling a postoperative IOP spike to extinguish central vision. The confounding effect suggests that a hypertensive phase may even harm eyes without SF. Our findings indicate that prospective studies on controlling HP in severe glaucoma to protect vision may be warranted.

TITLE:

Introduction of a new silicone hydrogel contact lens with surface modification of MPC polymer

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Wu, C. Shi, V. Sharma, D. Cantu-Crouch, R&D, Alcon Laboratories Inc, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): James Wu: Commercial Relationship(s);Alcon:Code E (Employment) | Charlie Shi: Commercial Relationship(s);Alcon:Code E (Employment) | Vinay Sharma: Commercial Relationship(s);Alcon:Code E (Employment) | David Cantu-Crouch: Commercial Relationship(s);Alcon:Code E (Employment)

ABSTRACT BODY:

Purpose: A new silicone hydrogel (SiHy) material with surface modification of a cross-linkable bioinspired 2-methacryloyloxyethyl phosphorylcholine (MPC) polymer was developed for outstanding ocular performance. The purpose of this study was to characterize the lens in fully hydrated conditions for its unique surface structure and properties, which are expected to contribute to the enhanced on-eye comfort and tear film stability of this novel contact lens.

Methods:

The surface structure of MPC polymer gel layer was imaged using a combination of environmental scanning electron microscopy (ESEM) and atomic force microscopy (AFM). The surface softness and lubricity of this new SiHy vs. comfilcon A, senofilcon A, and senofilcon C contact lenses were characterized via AFM nanoindentation and tribometer, respectively. All analyses were conducted in either 100% relative humidity or aqueous solutions to maintain lenses at hydrated state, mimicking on-eye conditions.

Results: A distinctive layer of hydrated MPC polymer was clearly visible on the top of the base material of the new SiHy lens under ESEM. MPC surface gel was further confirmed by both AFM phase image and ESEM image of the new SiHy lens cross-section. AFM nanoindentation testing showed the new SiHy lens surface was approximately 5 times softer than the surface of comfilcon A, senofilcon A, and senofilcon C lenses (~400nm vs. ~80nm of indentation depth under the eyelid contact pressure). The coefficient of friction of the new SiHy lens was also at least 5 times lower than that of comfilcon A, senofilcon A, and senofilcon C lenses.

Conclusions: A novel biomimetic MPC surface-modified SiHy contact lens was characterized for its surface structure and surface properties. The results indicate that the new SiHy lens has the exceptional characteristics of super-hydrophilicity, ultra-softness, and superior lubricity, which may enhance tear film stability and provide mechanical properties similar to ocular tissue, and is expected to achieve outstanding on-eye performance.

ABSTRACT BODY:

Purpose: Significant variability exists in the monitoring of acute posterior vitreous detachments (PVD) across ophthalmologists. This retrospective analysis hypothesizes that certain factors are associated with greater incidence of complications. It also examined the rate of delayed complications up to 6 months after initial presentation.

Methods: A case-control study of 9,635 eyes with symptoms for no more than 4 weeks prior to diagnosis were followed. Those eyes with a history of diabetic retinopathy, vitrectomy, retinal detachment, or panretinal photocoagulation were excluded. Cases were reviewed from the Vestrum database and included data from 65 retina practices and 316 individual physicians. Average age was 63 years old. Outcome measures included rate of development of vitreous hemorrhage, retinal detachment, or retinal tear at initial presentation, 3 months, and 6 months following initial presentation. Statistical analysis was done using a two-tailed t-test.

Results: Of 9,635 eyes, 12.2% (1,172 eyes) had retinal tears and 3.1% (299 eyes) had detachments at initial presentation. By 6 month follow-up, 3.1% (295 eyes) developed retinal tears and 1.1% (104 eyes) developed detachments. Among those with a tear, 61% occurred within one month after presentation, 28.5% within 1-3 months, and 10.5% within 3-6 months. Among those with a detachment, 48% occurred in the first month, 35.6% within 1-3 months, and 16.3% within 3-6 months. Men were more likely to have a detachment at presentation (57% vs. 43%, $p=0.025$) and within 6 months of presentation (67% vs 33%, $p<0.0006$). Phakic eyes compared to pseudophakic eyes were more likely to develop retinal breaks at presentation (44% vs. 16%, $p<0.00001$) and within 6 months of presentation (39% vs. 18%, $p<0.00001$). They were also more likely to have a detachment at initial presentation (37% vs. 25%, $p=0.011$). Peripheral retinal degeneration also correlated with increased retinal detachments at initial presentation (62% vs. 38%, $p<0.00006$).

Conclusions: Male sex, phakic eyes, and peripheral retinal degeneration were associated with increased incidence of complications after acute PVD, specifically retinal detachments. Several complications were also noted up to 6 months following initial presentation warranting appropriate counseling and consideration for repeat examination even up to 6 months after initial presentation.

ABSTRACT BODY:

Purpose: In the US, incarcerated persons are three times more likely to report vision impairment (VI) compared to the general population. However, there is a paucity of studies that examine VI and criminal justice involvement (CJI). The purpose of this study was to investigate the prevalence and predictors of VI among National Survey on Drug Use and Health (NSDUH) respondents with a CJI history.

Methods: This study was a retrospective cross-sectional analysis. Using 2015-2018 NSDUH data, we compared sociodemographic and health characteristics, stratified by CJI history. We labeled respondents as having a CJI history if they had ever been arrested or had a history of parole or probation in the past year. We used logistic regression to investigate the association between VI and CJI history. Among those with a CJI history, we identified variables associated with VI.

Results: The total study sample consisted of 226,632 respondents, representative of 270,745,251 people in the US. A weighted total of 2,431,106 (0.91%) people reported VI and CJI. VI was more prevalent in the CJI group (2,451,071 [5.8%]) compared to those with no CJI (9,532,920 [4.2%], $p < 0.001$). The VI and CJI cohort was 62.9% male, with racial distributions 57.8% white, 19.6% Black, 15.5% Hispanic, and 1.1% Asian (Table 1). Those with VI and CJI were more likely to be ages 50-64, have lower education, have less employment, earn $\leq \$20,000$, and have Medicaid. High blood pressure was the most common chronic condition. Physical impairment was the most common co-disability. Nearly half of the VI and CJI cohort reported to have a fair/poor health status. In multivariable analysis, controlling for sociodemographic and health factors, CJI history was associated with a 20% increased risk of VI (OR 1.2, CI 1.1-1.2, $p < 0.01$). Among those with CJI, significant predictors of VI were female gender, lower income, not having private insurance, recent arrest, diabetes, heart condition, hearing, cognitive, and physical impairment (all $p < 0.05$).

Conclusions: There is a higher prevalence of VI among individuals with CJI compared to those with no CJI. Predictors of VI among those with a CJI history include female gender, lower income, insurance type, recent arrest, select chronic conditions and disabilities. Further research exploring the etiologies of VI among formerly incarcerated persons would help to elucidate these findings and guide allocation of resources.

ABSTRACT BODY:

Purpose: Depression is a common and serious medical condition more prevalent in dry eye disease (DED) patients than the general population. To further elucidate the relationship between depression and DED, we performed a secondary longitudinal analysis to assess the association of the severity of DED symptoms and signs with depression in participants of the multi-center Dry Eye Assessment and Management (DREAM) Study.

Methods: Ocular Surface Disease Index (OSDI) and the Brief Ocular Discomfort Index (BODI) were administered at baseline, 6 and 12 months. Clinical signs of DED were evaluated in each eye by corneal fluorescein staining, tear break-up time, Schirmer's test, conjunctival lissamine green staining, meibomian gland abnormality, and tear osmolality. Patients scoring ≤ 42 on the Mental Component Summary (MCS) of the Medical Outcomes Study 36-Item Short Form Health Survey (SF-36) were considered positive for depression based on the SF-36 user manual guidelines. We compared the score of DED symptoms, signs, and composite severity score of signs between patients with and without depression using generalized linear models adjusted for age, gender, race, time, and longitudinal observations per person. Effect sizes ($[\text{mean difference}]/[\text{SD}]$) were calculated to assess the magnitude of their associations.

Results: Among 535 patients with moderate to severe DED, 15.7% had depression at baseline, 17.3% at 6 months and 13.2% at 12 months. When baseline, 6 and 12 months data were combined, patients with depression had worse DED symptoms ($P < 0.001$), ocular discomfort ($P < 0.001$), composite severity score of DED signs ($P = 0.006$), and corneal staining scores ($P = 0.02$) compared to patients without depression (Table 1). The effect size for the OSDI (0.45) and BODI (0.46) were larger than for the composite severity score of signs (0.21) (Table 1). Lower MCS scores (i.e., higher likelihood of depression) were significantly correlated with higher OSDI score (i.e., worse DED symptoms) at baseline (Spearman $\rho = -0.09$, $P = 0.03$), 6 months ($\rho = -0.20$, $P < 0.001$) and 12 months ($\rho = -0.21$, $P < 0.001$).

Conclusions: DED symptoms and signs were worse in moderate to severe DED patients screening positive for depression. However, depression was more strongly associated with severity of the symptoms than clinical signs of DED, which may relate to the discordance between symptoms and signs of DED.

ABSTRACT BODY:

Purpose: Neurotrophic keratopathy (NK) is a rare disease leading to impaired corneal sensation and function. This cross-sectional study measured the utility values of NK in an effort to better understand the impact of this disease on patients.

Methods: Patients with a clinical diagnosis of NK were recruited from an urban ophthalmology clinic. Utility was assessed with the time trade off (TTO) and standard reference gamble (SRG) methods; the anchor points were defined as 0 being death and 1 being perfect health (ph) or perfect eye function (pf). Visual acuity, comorbidities, and responses to the 25-question Vision Function Questionnaire (VFQ-25) were also collected.

Mean, standard deviation, and 95% confidence interval were calculated for each measure of utility and compared to an anchor of 1.0 using a one sample t-test. Simple linear regressions were used to predict the relationship between utility values of NK and variables investigated in this study.

Results: A total of 24 patients (mean age 66.5 ± 14.8 years; 12 males, 12 females) were recruited for this study. The utility values for NK ranged from 0.69 to 0.86 depending on the TTO/SRG method and pf/ph anchor points (Table 1). Patients were willing to trade approximately 3 years of an additional 10-year life expectancy in return for perfect eye function or health. Subcategories of VFQ related to activity limitation (role difficulty and dependence) were found to be significantly associated with NK utility (Table 2). Utility values for NK were not significantly associated with age, gender, comorbidities, visual acuity, or severity of NK disease.

Conclusions: Our study found that NK has a significant impact on quality of life measured as health utility. The TTO utility values for patients with NK are similar to those with a hand amputation (0.70). Utility values for NK appear to be directly related to the functional loss from the disease rather than the degree of vision loss. Participants who felt limited in what they could accomplish, required more help, or felt a loss of control due to their ocular condition reported lower utility. As treatment options for NK are expanding and increasing in efficacy, this study can provide a foundation for future cost-effectiveness analyses on the various treatments for NK.

TITLE: Maturation of hand-eye coordination in typically developing children and adolescents

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Niechwiej-Szwedo, S. Wu, Kinesiology, University of Waterloo, Waterloo, Ontario, CANADA|L. Christian, Optometry and Vision Science, University of Waterloo Faculty of Science, Waterloo, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Ewa Niechwiej-Szwedo: Commercial Relationship: Code N (No Commercial Relationship) | Susana Wu: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Christian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Spatial and temporal coordination between eye and hand movements is essential for the performance of most daily activities. Studies with adults demonstrate a highly stereotypical coordination pattern during reaching and grasping tasks. Specifically, eye movements precede the hand by ~100 ms, and the eyes fixate on the object during a manipulation task. To date, the developmental profile of hand-eye coordination has not been examined in children. The purpose of this study was to characterize age-related changes in temporal hand-eye coordination in typically developing children.

Methods: Children (n=28, age=9.0±0.6yrs) and adolescents (n=29; age=12.3±1.3yrs) were assessed during the performance of a bead threading task, which requires precision grasping and placement. A group of adults (n=12, age=22±2.2yrs) were also tested. Eye and hand movements were recorded concurrently using the Eyelink 2 eye tracker and the Optotrak motion capture system. Temporal hand-eye coordination was assessed by calculating the latency of the motor responses for the primary movement of the eyes and hand towards the bead, and the secondary movements towards the needle, as well as the duration of eye fixation when grasping and placing the bead on the needle.

Results: Statistical analysis revealed significant differences between the groups of children, adolescents, and adults for all measures (p<0.05). When reaching for the bead, the eye-hand latency difference was longer in children (174±16ms) compared to adolescents (134±10ms) and adults (117±8ms). Similarly, the fixation duration during grasping was longer in children (243±21ms) compared to adolescents (146±16ms) and adults (165±17ms). There was also a longer delay between the eye and hand movements when reaching towards the needle in children (38±11ms) compared to adolescents (7±11ms) and adults (12±15ms). Fixation duration on the needle while placing the bead was longer in children (657±31ms) and adolescents (497±24ms) compared to adults (336±28ms).

Conclusions: Temporal hand-eye coordination pattern for a precision grasping and placement task becomes more efficient during adolescence in typically developing children with normal vision. Further investigation is required to determine the impact of decorrelated binocular vision on the development of hand-eye coordination profile.

ABSTRACT BODY:

Purpose: Adult retinal stem cells (RSCs) give rise to all retinal cell types. Clonal RSC progeny treated with taurine/retinoic acid (T+RA) produce 95% rod progeny, while coco (BMP/Wnt/TGF β triple-inhibitor) induces 60% cones. We hypothesized that cone lineage-specific progenitors, specified using exogenous factors, display unique transcriptome signatures that can identify stage-specific molecular markers. No markers exist for these lineage-specific progenitors and literature is divided on their existence in vivo.

Methods: Adult RSCs were isolated from mouse and human donor eyes, while neural retinal progenitor cells (RPCs) were isolated from the embryonic mouse retina. We used single cell/well sorting to isolate individual progenitor clones.

Results: Embryonic RPCs (E14) show similar rod differentiation in T+RA (>95%) compared to adult RSCs and increased cone differentiation in coco (>90%). Coco permitted differentiation from single non-pigmented RSC progeny to >95% cone-only clones, while single pigmented RSC progeny were unable to produce any cones. Constant coco exposure causes E12, E14 and E19 RPCs to adopt a cone-restricted fate. We compared gene expression between RSC-derived and endogenous cones with RNAseq, and profiled the transcriptome throughout rod and cone differentiation from embryonic RPCs. Principal component analysis showed a distinct progression of rod and cone lineages. Pathway analysis showed clustering of stem cell-derived and endogenous cones, as well as candidate progenitor markers. SOX15 may be a unique marker of a cone restricted progenitor; its expression follows other factors that bias photoreceptor differentiation, including OTX2 and OLIG2. SOX15 is expressed in early proliferating RPCs in vivo, and persists in some early-born post-mitotic cells, but not photoreceptors. SOX15 knockdown reduced colony formation from E14 RPCs, but not E19 RPCs or adult RSCs. After 4-6 weeks of coco, 60% of human RSC progeny differentiated into cones; both the time-course and efficiency is similar to mouse RSC progeny.

Conclusions: Exogenous signals instruct early lineage decisions in fate-restricted retinal progenitors, and we identify potentially new markers. SOX15 may promote cone differentiation by prolonging or promoting proliferation of early RPCs, or by inhibiting factors that specify alternative, late-born, cell fates and promoting a default cone differentiation.

ABSTRACT BODY:

Purpose: To investigate the associations between intraocular pressure (IOP) and ocular geometry.

Methods: The Gutenberg Health Study is a population-based cohort study in Mainz, Germany including 15,010 subjects at age 35 to 74 years at baseline examination. Study participants underwent a comprehensive ophthalmologic examination including non-contact tonometry (NT 2000™, Nidek Co., Japan), objective refraction, optical biometry (LenStar, Haag-Streit, Bern, Switzerland) and Scheimpflug imaging (Pentacam, Oculus, Wetzlar, Germany) of the anterior segment at the first 5-year follow-up examination (in the year 2012-2017). Anterior chamber angle width was analyzed on Scheimpflug images using proprietary software. Multivariable linear regression analyses with generalized estimating equations were carried out to determine associations of IOP and geometric parameter, namely central corneal thickness (CCT), corneal curvature, anterior chamber depth, lens thickness and posterior segment length with adjustment for age and sex. In an additional model, anterior chamber angle width was also included.

Results: 13,280 phakic eyes of 6,640 participants (mean age 57.3 ± 10.2 years, 49.1% female) were included in this cross-sectional analysis. No included eye showed angle closure on Scheimpflug imaging. Mean IOP was 14.84 ± 2.92 mmHg in right eyes and 14.91 ± 2.93 mmHg in left eyes. IOP increased with higher CCT ($B=0.042$ per μm ; 95%CI: 0.040-0.044), longer posterior segment length ($B=0.20$ per mm; 95%CI: 0.14-0.25), higher age ($B=0.20$ per 10 years; 95%CI: 0.13-0.26) (all $p<0.001$), thicker crystalline lens ($B=0.25$ per mm; 95%CI: 0.08-0.42; $p=0.003$) and female sex ($B=0.12$; 95%CI: 0.00-0.24; $p=0.05$), while anterior chamber depth and corneal curvature was not associated. IOP increased with a narrower anterior chamber angle in univariate analysis ($B=-0.02$ per degree; 95%CI: -0.03 - -0.01; $p<0.001$), but not in multivariable analysis ($p=0.34$).

Conclusions: IOP measurement is related to the individual ocular geometry. Thus, those ocular parameters should be taken into consideration when clinically interpreting non-contact tonometric data. In eyes with an open anterior chamber angle, there is no correlation between anterior chamber angle width and IOP level in our multivariable model.

ABSTRACT BODY:

Purpose:

Patients receive intraocular anti-VEG-F injections for multiple retinal vascular diseases. While vision threatening side effects are rare, many patients will note some level of discomfort after an injection. A common practice for many retina specialists is to recommend that the patient call the office if he or she has significant discomfort. It is our experience that patients will with some frequency come in for their next injection stating that they had significant discomfort after the injection but did not call the office. The purpose of our study is to determine whether patients will use post-injection eye drops if made available to them for mild to moderate discomfort.

Methods:

Prior to the intraocular injection patients were given a handout with five options: 1. No discomfort - no drops necessary. 2. Mild discomfort - artificial tear drops as needed. 3. Mild to moderate discomfort - topical nonsteroidal eye drops (acular) every 4 hours as needed for one day. 4. Moderate discomfort - topical steroid eye drops (pred forte 1%) every 4 hours as needed for one day. 5. Severe discomfort - call office immediately. Patients were then anesthetized with topical anesthetic drops and tetracaine gel. Betadine was applied to the conjunctiva and lid twice. The anti-VEG-F injection was performed 2-5 minutes later via the pars plana. Topical antibiotic drops and IOP lowering drops were applied. The patient was discharged home. A follow-up phone call was made the next day.

Results:

125 consecutive anti-VEG-F injection patients were included in the study. 94 patients responded to the follow-up questionnaire the day after the injection. 31 patients used an eye drop on the day of the injection (33.0%). Of the patients that used eye drops, 6 (19.4%) used artificial tears, 9 (29%) used acular, and 16 (51.6%) used pred forte. All patients stopped the eye drop after the follow-up phone call.

Conclusions: The study confirms that a significant number of patients undergoing anti-VEG-F injections in an office setting will develop mild to moderate discomfort the day of the injection. We recommend counseling the patient about possible discomfort and making topical drops including lubricating drops, nonsteroidal, and steroid drops available on a short term basis following injections. This will increase patient satisfaction and lessen the number of post-injection phone calls regarding mild to moderate discomfort.

TITLE: The Effect of Small Incision Phacoemulsification on Intraocular Pressure in Patients with Primary Open Angle Glaucoma

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Rahmatnejad, F.J. Gross, P.B. Wu, Ophthalmology, Eastern Virginia Medical School, Norfolk, Virginia, UNITED STATES|R. Chaganty, Mathematics and Statistics, Old Dominion University, Norfolk, Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kamran Rahmatnejad: Commercial Relationship: Code N (No Commercial Relationship) | Fredric Gross: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Wu: Commercial Relationship: Code N (No Commercial Relationship) | Rao Chaganty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the effect of small incision phacoemulsification on intraocular pressure (IOP) of patients with primary open angle glaucoma (POAG)

Methods: We retrospectively reviewed the charts of 353 patients who had small incision phacoemulsification cataract surgery between 2017 and 2018 and identified patients who had a diagnosis of POAG for further analysis. All procedures were performed by the same surgeon using the same technique. Patients with complicated cataract surgery or a history of incisional glaucoma surgery were excluded from the analysis. The study population is composed of 30 eyes from 26 patients who had stable glaucoma treated with medication, laser, or a combination of both prior to cataract surgery.

We defined preoperative IOP as the average of up to 3 IOP measurements in the 18 months period prior to cataract surgery and postoperative IOP as the average of up to 3 postoperative IOP measurements 2 to 18 months after surgery. Age, race, sex, eye laterality, number of pre-operative and post-operative glaucoma medications, and history of glaucoma laser were recorded for all patients.

Results: The age mean +/- standard deviation (SD) was 71.53 +/- 9.13 years. The patients were mostly male (63.33%) with a small predominance of Caucasians compared to African Americans (56.67% vs. 43.33%). Right and left eyes were equally distributed (50%) and 70% of the patients had a history of glaucoma laser treatment. After confirming the normality assumption, paired t-test was performed for the difference between preoperative and postoperative data. The IOP (mean +/- SD) was decreased from 15.17 +/- 2.77 mmHg preoperatively to 14.00 +/- 2.40 mmHg postoperatively ($p < 0.001$). Twenty-one patients had an IOP reduction (range 1-5 mmHg), one patient's IOP remained unchanged, and 8 patients had an increase in IOP (range 1-2 mmHg). The number of IOP-lowering eye drops decreased from 0.73 to 0.67 which was not statistically significant.

Conclusions: In this study, uncomplicated small-incision phacoemulsification resulted in a small but statistically significant reduction in IOP on average in patients with POAG. Interestingly, some patients experienced small increases in IOP after surgery. Further studies are needed to evaluate clinical parameters that could explain this observation.

TITLE: Impact of Duration of Exposure to Residual Intraretinal Fluid on Visual Function Outcomes in Neovascular Age-Related Macular Degeneration

SESSION TITLE: AMD: clinical research - biomarkers and outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R.P. Singh, Center for Ophthalmic Bioinformatics, Cole Eye Institute, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|R.P. Singh, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rishi Singh: Commercial Relationship(s);Genentech:Code C (Consultant);Regeneron:Code C (Consultant);Novartis:Code C (Consultant);Zeiss:Code C (Consultant);Bausch and Lomb:Code C (Consultant);Apellis:Code F (Financial Support);Graybug:Code F (Financial Support);Aerie:Code F (Financial Support)

ABSTRACT BODY:

Purpose: This analysis assessed the impact of duration of exposure to residual intraretinal fluid (IRF) on visual function outcomes in eyes with neovascular age-related macular degeneration (nAMD) treated with anti-VEGFs in the VIEW 1 and 2 trials.

Methods: This post hoc analysis included patients that received either ranibizumab 0.5 mg q4 weeks (Rq4) or intravitreal aflibercept injection 2 mg q4 weeks (IAI 2q4) or q8 weeks after 3 monthly doses (IAI 2q8) in VIEW 1 and 2. Duration of IRF from baseline through week 52 was evaluated as quartiles in both pooled treatment groups (Q1: ≤ 2 weeks, n=581; Q2: 3– ≤ 8 weeks, n=411; Q3: 9– ≤ 18 weeks, n=389; Q4: > 18 weeks, n=423) and within each treatment group (Rq4, n=588; IAI 2q4, n=612; IAI 2q8, n=604). Visual function outcomes assessed included best corrected visual acuity (BCVA) and Visual Function Questionnaire 25 (VFQ-25) near activities and driving subscale scores.

Results: In the pooled analysis of treatment groups, mean BCVA gains from baseline at week 52 for Q1–Q4 were 10.9, 10.1, 9.4, and 6.6 ($P < 0.0001$, Q4 vs Q1) letters, respectively. The corresponding proportions of patients with a ≥ 5 letters gain at week 52 were 71.4%, 72.0%, 72.6%, and 59.9% ($P < 0.05$, Q4 vs Q1), and for those with a ≥ 5 letters loss at week 52 were 10.0%, 9.7%, 11.2%, and 16.5% ($P < 0.05$, Q4 vs Q1), respectively. The mean change from baseline in the VFQ-25 near activities subscale score in Q1–Q4, respectively, were 9.7, 8.3, 7.2, and 5.3 ($P < 0.001$, Q4 vs Q1) points, and for the driving subscale score were 3.0, 1.6, 2.4, and -2.4 ($P < 0.01$, Q4 vs Q1) points. In the quartile analysis within each treatment group, the mean BCVA gains for Q1–Q4 were 11.0, 11.1, 9.3, and 5.8 ($P < 0.05$, Q4 vs Q1) letters for Rq4; 10.7, 9.7, 9.2, and 7.7 letters for IAI 2q4; and 11.3, 11.2, 8.6, and 6.3 ($P < 0.05$, Q4 vs Q1) letters for IAI 2q8, respectively.

Conclusions: In this analysis of patients treated with intravitreal aflibercept and ranibizumab in VIEW 1 and 2, longer duration of exposure to residual IRF was associated with lower visual acuity gain and worse vision-related quality of life outcomes.

ABSTRACT BODY:

Purpose: The purpose of this study was to compare the performance of 7 IOL power prediction formulas in axial myopes.

Methods: Retrospective consecutive case series of eyes with axial length (AL) greater than 25.0 mm that underwent cataract extraction with implantation of a monofocal IOL (Akreos AO60, Bausch & Lomb) between January 2016 and October 2018 by a single surgeon. Eyes were excluded if they had history of surgery or trauma, inflammatory conditions, intraoperative complication, cataract surgery combined with another procedure, or a postoperative best-corrected visual acuity worse than 20/40. Residual refractive error for each eye was predicted for the implanted IOL using 7 formulas (Holladay1 [H1], Linear Wang-Koch adjusted Holladay1 [I-WKH1], SRK/T, Barrett II Universal [BU-II], Hill-RBF v3.0, EVO, and Kane). The same nominal A-constant (118.4) was used in all formulas. Prediction error was calculated as the difference between the actual and predicted spherical equivalent (SE). Mean prediction errors (MPEs) and absolute errors (MAEs) were compared using a Friedman with Dunn post-test. Comparison of proportions was done using a Cochran Q test with McNemar's post-test.

Results: Among the 200 study eyes, the MPE was 0.36 ± 0.51 , 0.00 ± 0.53 , 0.22 ± 0.52 , 0.11 ± 0.46 , 0.23 ± 0.48 , 0.09 ± 0.47 , and 0.13 ± 0.47 D for H1, I-WKH1, SRK/T, BU-II, Hill-RBF, EVO, and Kane, respectively ($p < 0.0001$). The MAEs were 0.48 ± 0.40 , 0.39 ± 0.36 , 0.41 ± 0.38 , 0.35 ± 0.33 , 0.40 ± 0.35 , 0.35 ± 0.32 , and 0.36 ± 0.32 D, respectively ($p < 0.0001$). The proportion of eyes within 0.5 D of predicted SE was 60.5%, 71%, 68%, 76%, 70.5%, 76.5%, and 74%, respectively, with BU-II and EVO each performing better than H1, I-WKH1, SRK/T, and Hill-RBF ($p < 0.0001$). EVO ($p < 0.0001$), but not BU-II ($p = 0.49$) performed better than Kane with regards to this metric. There was no significant difference between BU-II and EVO regarding proportion of eyes within 0.25, 0.5, 0.75, or 1.0 D of predicted SE. Hyperopic prediction errors occurred in 82%, 49%, 71.5%, 61.5%, 73%, 61%, and 66.5% of eyes, respectively ($p < 0.0001$), with SRK/T being similar to Hill-RBF ($p = 1.0$) and BU-II being similar to EVO ($p = 1.0$).

Conclusions: The I-WKH1 improves outcomes over H1. Modern formulas (BU-II, EVO, Hill-RBF, and Kane) outperform older ones (H1 and SRK/T). An AL adjustment or modern formula should be used when performing IOL power calculations in axial myopes.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) affects a sizeable group of the population, leading to blindness, which can be reduced with proper monitoring and treatment. As the disease progresses from non-proliferative diabetic retinopathy (NPDR) to PDR, diabetic macular edema (DME) may occur at any stage. It was proven the increase of vascular endothelium growth factors (VEGFs) levels with disease stage, from NPDR to PDR, while DME appears to be independent of VEGF levels. This fact may lead ophthalmologists to opt for different initial treatments depending if patients are in an inflammatory or angiogenic stage. This study aimed to compare VEGF-A and VEGF-B levels with disease severity and the presence of DME and correlate VEGF levels with central retinal thickness (CRT) and macular volume (MV).

Methods: Vitreous samples were collected from 41 DR patients undergoing vitrectomy. VEGF-A and B were quantified by ELISA. Optical coherence tomography (OCT) was evaluated for CRT and MV.

Results: Forty-one patients with DR, 61% (n=25) male, with a mean age of 67.9 ± 10.0 (mean \pm standard deviation). Mean vitreous VEGF-B levels were 18.13 ± 22.10 pg/mL for NPDR and 115.70 ± 278.42 pg/mL for PDR, with a statistically significant difference ($p=0.004$) showing higher values for PDR patients. VEGF-B was increased in DME (120.47 ± 288.97 pg/mL) in comparison with non-DME (24.38 ± 20.44 pg/mL), however, the difference was not statistically significant ($p=0.204$). Vitreous VEGF-A was significantly increased in PDR in comparison with NPDR, (576.88 ± 681.15 vs 39.11 ± 71.13 pg/mL, $p=0.019$, respectively). DME patients showed higher values of VEGF-A than non-DME, despite not statistically significant (456.10 ± 651.84 vs 83.21 ± 80.30 pg/mL, $p=0.371$, respectively). The correlation of NPDR with VEGF-B, CRT, and MV was not statistically significant, ($r_{sp}=0.636$, $p>0.05$), while was statistically significant in PDR ($r_{sp}=0.590$, $p=0.008$). The correlation of NPDR with VEGF-A, CRT, and MV was $r_{sp}=-0.975$, $p=0.005$ and with PDR was $r_{sp}=0.590$, $p=0.008$.

Conclusions: VEGF-A and B are increased in vitreous of DR patients and values increase with disease stage, while the absence of relation of VEGF-A and B with DME suggests VEGF levels may not be increased in all patients with DME. The strong correlations showed a simultaneous increase of VEGF levels with anatomical parameters.

ABSTRACT BODY:

Purpose: Emerging evidence suggests that low macular pigment levels—modifiable through dietary intake of the carotenoids (lutein and zeaxanthin)—may be a novel risk factor for glaucoma. We evaluated whether macular pigment levels are associated with manifest primary open-angle glaucoma (POAG) within a longitudinal cohort of older women from the Carotenoids in Age-Related Eye Disease Study (CAREDS).

Methods: The CAREDS2 follow-up study (2016-2019) included 685 participants. Macular pigment optical density (MPOD) was measured at both CAREDS baseline (2001-2004) and CAREDS2 using customized heterochromatic flicker photometry at 0.5° from foveal center. Manifest POAG status at CAREDS2 was adjudicated by 2 glaucoma specialists (YL, CT) masked to MPOD in 1258 eyes (630 participants) based on abstracted medical records, intraocular pressure, visual fields, stereo disc photos, and peripapillary retinal nerve fiber layer optical coherence tomography. Associations between MPOD and manifest POAG were investigated utilizing age-adjusted logistic models in the: (1) full sample and (2) 'worst' eyes based on severity of visual field loss. We conducted additional sensitivity analyses among the subset of eyes with stable MPOD over 15 years (± 0.20 optical density units).

Results: Manifest POAG was present in 79 eyes (51 participants). Women in the lowest quartile of baseline MPOD (quartile 1) were significantly more likely to have manifest POAG than those in quartiles 2-4. In the full sample ($n=1258$ eyes), odds ratios (OR(95%CI)) for manifest POAG were 0.49(0.25-0.93), 0.63(0.32-1.26), and 0.53(0.24-1.20) for MPOD quartiles 2-4 vs. quartile 1, respectively ($p=0.04$). The association was stronger in the subsample of eyes with stable MPOD over 15 years ($n=242$ eyes, $p=0.001$). Analyses of the 'worst' eye ($n=630$ eyes) resulted in ORs of 0.51(0.23-1.15), 0.72(0.34-1.52), and 0.43(0.18-0.99) for quartiles 2-4 vs. quartile 1, respectively ($p=0.06$); with a stronger association in the subset of 'worst' eyes with stable MPOD ($n=242$, $p=0.003$).

Conclusions: This is the first study to identify an inverse association between MPOD and manifest POAG in a longitudinal cohort of older women. Further studies are warranted to confirm whether low macular pigment levels may be a novel modifiable glaucoma risk factor and support the development of low-cost, dietary interventions for glaucoma prevention.

TITLE: Clinical trial versus real-world outcomes with anti-VEGF therapy for branch and central retinal vein occlusion

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.J. Danzig, Rand Eye Institute, Deerfield Beach, Florida, UNITED STATES|S. Blotner, V. Steffen, Z. Haskova, Genentech Inc, South San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Carl Danzig: Commercial Relationship(s);Genentech, Inc.:Code C (Consultant);Novartis:Code C (Consultant);Regeneron:Code C (Consultant) | Steven Blotner: Commercial Relationship(s);Genentech, Inc.:Code E (Employment) | Verena Steffen: Commercial Relationship(s);Genentech, Inc.:Code E (Employment) | Zdenka Haskova: Commercial Relationship(s);Genentech, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Landmark trials of anti-VEGF treatment for macular edema due to branch (BRVO) and central retinal vein occlusion (CRVO) show that clinically significant vision gains are achievable with frequent initial injections, monthly monitoring, and timely re-treatment; however, this is burdensome and not feasible in clinical practice. This study assessed the impact of anti-VEGF injections and monitoring frequency on BCVA outcomes in patients with BRVO and CRVO.

Methods: This was a cross-trial comparison between controlled clinical trials, long-term extension (LTE) trials, and real-world studies of anti-VEGF therapy in patients with macular edema due to BRVO or CRVO. Published data were used to compare average 12-month injection frequencies and BCVA outcomes achieved with fixed, as-needed, treat-and-extend, and real-world anti-VEGF treatment regimens; and with monthly or less-frequent monitoring visits.

Results: Analyses included 7 controlled clinical trials (2 BRVO, 5 CRVO; all with monthly monitoring), 4 LTE trials (2 BRVO/CRVO, 2 CRVO; most with less-than-monthly monitoring), and 2 real-world studies (both BRVO/CRVO; monitored per investigator discretion). Patients with BRVO in clinical trials received 8.5–9.0 injections over 12 months versus 1.6–4.9 injections in LTE trials and real-world studies. In clinical trials, mean BCVA change over 12 months was 17.1–18.3 letters versus –0.7 to –2.1 letters in LTE trials with less-frequent visits. Mean BCVA change over 12 months in real-world BRVO studies was only 7.7–13.1 letters. Patients with CRVO in clinical trials received 7.8–11.8 injections over 12 months versus 1.5–5.1 injections in LTE trials and real-world studies. Patients with CRVO in clinical trials gained 10.7–21.9 letters over 12 months. However, these gains were not maintained in LTE trials (–7.6 to 0.2 letters), nor achieved in real-world studies (4.1–7.1 letters).

Conclusions: In real-world studies, patients with BRVO or CRVO were monitored less frequently, received fewer anti-VEGF injections, and did not achieve the BCVA gains seen in clinical trials. Likewise, patients who achieved vision gains in clinical trials on average experienced BCVA loss with fewer follow-up visits in LTE trials. These data highlight the need for new strategies that extend the durability of treatment to reduce treatment burden and need for frequent monitoring, and to improve real-world vision outcomes.

ABSTRACT BODY:

Purpose: The iExaminer allows the user to utilize the view from the PanOptic and an instructor to coach the user on relevant findings. This study assesses the role of the iExaminer as a teaching and diagnostic tool for medical students compare to the PanOptic alone.

Methods: Prospective cross-over study of medical students performing direct ophthalmoscopy on patients after a didactic session at a single academic center in 2018. Students used the PanOptic and the PanOptic with iExaminer and were blinded to the correct diagnoses. For control, students were shown images taken with the iExaminer. Students documented their findings and level of confidence in making diagnoses in each scenario. A paired t-test was used to compare end points between all three groups.

Results: This study enrolled 81 second-year medical students, and a total of 4 glaucoma patients were examined. Mean percentage of correct findings was 63% for the exams with the PanOptic, which was more than the 60% found with the PanOptic with iExaminer ($p=0.03$) and 53% with the control iExaminer image ($p<0.01$). More confidence was reported with the PanOptic with iExaminer than with the PanOptic, with mean confidence scoring at 2.43 and 2.04 on a five-point scale, respectively ($p=0.02$).

Conclusions: The iExaminer is a useful teaching tool and confidence booster for medical students with instructor help as opposed to a diagnostic device in the hands of an inexperienced user. Relatively low absolute scoring with the iExaminer image alone suggests baseline ophthalmic knowledge as the limiting performance factor. This study emphasizes the need for practice in correctly identifying findings in patients and using the equipment. Higher confidence with the PanOptic with iExaminer may increase the likelihood of students practicing direct ophthalmoscopy outside the confines of our session. Further studies looking into sequential workshops for students will hopefully show improvement in their exams.

TITLE: Robust registration using multiple OCT/OCTA en face images in advanced disease cases

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Bagherinia, M.K. Durbin, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Homayoun Bagherinia: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Mary Durbin: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Robust registration of longitudinal data is required to measure the changes of OCT/OCTA slabs and retinal thicknesses over time. The pathological changes in the retina from one visit to another makes the registration of two OCT/OCTA slabs a challenging task. This abstract proposes a robust registration method that utilizes multiple slabs.

Methods: The OCT registration consists of aligning the corresponding keypoints in a pair of images. The well distributed keypoints matches were ensured by extracting the keypoints from OCT/OCTA slabs at different depth. OCT images were generated from 1) superficial and deep retinal layer, 2) RPE and 3) choroidal slabs. OCTA images were generated from 1) superficial (SRL), 2) deep capillary plexus and 3) RPE and choriocapillaris slabs. An exhaustive search method was used to fit best rigid transformation to a subset of matched keypoints. 15, 25, and 5 pairs of OCT volumes over 6x6 mm using CIRRUSTM HD-OCT 5000 (ZEISS, Dublin, CA), PLEX[®] Elite 9000 SS-OCT (ZEISS, Dublin, CA), and CIRRUSTM HD-OCT 5000 with AngioPlex[®] OCT Angiography (ZEISS, Dublin, CA) were used with eye diseases such as diabetic retinopathy and age-related macular degeneration. The performance of 5 registration methods were measured using keypoints extracted from 1) RPE, 2) all 3 OCT, 3) SRL, 4) all 3 OCTA and 5) all OCT and OCTA images. The nonparametric statistics of the RMSE of the matched keypoints along with the number and keypoints image area coverage for each pair of OCT volumes were reported for all 5 methods.

Results: Fig 1 shows examples using multiple slabs for registration. Fig 2 shows the box plots for RMSE of the matched keypoints, the number and keypoints image area coverage for 5 registration methods. The number and the keypoints area coverage increase significantly when multiple OCT/OCTA slabs were used for keypoints extraction, which is important for robust image registration with small RMSE. The RMSE using multiple slabs shows tighter distribution with a median value around 10 μ m indicating robustness and higher success rate. This may meet the accuracy requirement of OCT registration with A-scan spacing of 12 to 20 μ m.

Conclusions: We introduced a novel registration approach based on matched keypoints extraction from multiple slabs. We showed that using multiple slabs outperforms using a single slab for registration which is essential for measuring changes in longitudinal data.

TITLE: Percentile Charts for Normal Axial Length Changes in Chinese Schoolchildren with Stable Emmetropia

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Wong, A. Yang, B. Drobe, Essilor International, SINGAPORE|Y. Yuan, Y. Ding, Y. Ye, H. Chen, J. Bao, Wenzhou Medical University, Wenzhou, Zhejiang, CHINA|Y. Wong, Y. Yuan, Y. Ding, Y. Ye, A. Yang, B. Drobe, H. Chen, J. Bao, Wenzhou Medical University-Essilor International Research Centre, Wenzhou Medical University, CHINA|

Commercial Relationships Disclosure (Abstract): Yee Ling Wong: Commercial Relationship(s);Essilor International, Singapore:Code E (Employment) | Yimin Yuan: Commercial Relationship: Code N (No Commercial Relationship) | Yang Ding: Commercial Relationship: Code N (No Commercial Relationship) | Yingying Ye: Commercial Relationship: Code N (No Commercial Relationship) | Adeline Yang: Commercial Relationship(s);Essilor International, Singapore:Code E (Employment) | Bjorn Drobe: Commercial Relationship(s);Essilor International, Singapore:Code E (Employment) | Hao Chen: Commercial Relationship: Code N (No Commercial Relationship) | Jinhua Bao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the normal growth pattern of axial length (AL) with age in a cohort of schoolchildren with stable emmetropia.

Methods: Stable emmetropia was defined as spherical equivalent (measured by subjective refraction) > -0.5 D and $\leq +0.75$ D in the right eye for 2 consecutive annual visits. A total of 700 schoolchildren with stable emmetropia enrolled in the Wenzhou Medical University-Essilor Progression and Onset of Myopia (WEPrOM) prospective cohort study, aged between 7 to 9 years with at least 2 years of follow-up between 2014 to 2018, were analysed. Ocular biometry, including AL measurements, was performed.

Results: A logistic function model was used to describe the changes in axial length with age, and a chart for AL changes versus age was plotted in percentiles (2.5th, 5th, 25th, 50th, 75th, 95th, and 97.5th; Figure). For children with stable emmetropia, the predicted change in AL in the next year was 0.22 (interquartile range [IQR; 25th to 75th percentile], 0.2-0.32) for children aged 7-9 years, 0.21 (0.13-0.3) for aged 10 years, 0.18 (0.08-0.27) for aged 11 years, and 0.12 (0.03-0.2) for aged 12 years. The lines with the predicted change in AL in the next year decreased gradually with age, till they plateaued nearing the age of 15 years, indicating that eyes of children with stable emmetropes continue to have AL growth till late adolescence.

Conclusions: Normal AL growth of approximately 0.2 mm/year (50th percentile) occurs among stable emmetropic Chinese schoolchildren aged 7-11 years. Percentile growth curves of changes in AL among stable emmetropes may be useful for clinicians to assess the effectiveness of myopia control interventions in slowing down axial elongation of myopic patients to that of a normal emmetrope.

ABSTRACT BODY:

Purpose: To evaluate the impact on central distance visual acuity (VA) and contrast sensitivity (CS) in children of three different spectacle lens designs with lenslets used for myopia control while looking through the peripheral zones containing the lenslets.

Methods: Distance VA and CS were measured using Freiburg Visual Acuity and Contrast Test (FrACT) and CSV-1000 (Vector Vision Corp, USA), respectively. For each test, four spectacle lens designs were evaluated in random order: standard single vision lens (SVL) as a control, spectacle lens with concentric rings of highly aspherical lenslets (HAL), spectacle lens with concentric rings of slightly aspherical lenslets (SAL) and spectacle lens with honeycomb configuration of spherical lenslets (HC). To ensure vision through the lenslets zones, zones without lenslets were patched. 50 myopic children (mean age 12.7 ± 1.7 years, range 10 to 15 years, mean spherical equivalent refraction (SER) 3.22 ± 1.57 D, range -6.50 to -0.38 D) participated in the VA test; 36 myopic children (mean age 13.2 ± 1.2 years, range 10 to 16 years, mean SER 3.20 ± 1.67 D, range -7.25 to -0.75 D) participated in the CS test. All tests were done monocularly on the right eye with corrected-to-normal vision.

Results: Compared to SVL, VA through the lenslet zones of HAL, SAL and HC decreased significantly by 0.07 ± 0.09 , 0.06 ± 0.09 , 0.09 ± 0.07 LogMAR, respectively (all $p < 0.01$). Decrease in VA was similar in HAL and SAL ($p > 0.9$) while significantly larger in HC compared to HAL ($p = 0.02$) and to SAL ($p = 0.03$). VA changes induced by lenslets showed no significant correlation with SER (all $p > 0.05$), but had a weak positive association with age for SAL ($r = 0.36$, $p = 0.01$) and HC ($r = 0.31$, $p = 0.03$), but not for HAL ($p = 0.3$). The lenslet structures did not affect CS at low spatial frequency (3 cycles per degree (cpd), $p = 0.8$). At mid to high spatial frequencies (6 to 18 cpd), CS was significantly reduced by HAL and HL (all $p < 0.05$), but not SAL ($p > 0.05$) compared to SVL. At high spatial frequencies (12 to 18 cpd) both SAL and HAL reduced CS significantly less than HC (all $p < 0.01$).

Conclusions: When looking through the lenslet structures, short-term visual performance was minimally reduced by spectacle lenses with lenslets compared to SVL. Concentric rings of aspherical lenslets had significantly lower impact on both VA and CS than honeycomb configuration of spherical lenslets.

ABSTRACT BODY:

Purpose: Choroidal thinning is usually associated with myopia progressing. This study aimed to assess changes in choroidal thickness (ChT) in Chinese children wearing two new types of myopia control spectacle lenses with concentric rings of contiguous aspherical lenslets over a period of one year.

Methods: Within a randomized, controlled, double-masked clinical trial, 160 children (age 8 to 13 years, myopia between -0.75 D and -4.75 D) wore either spectacle lenses with highly aspherical lenslets (HAL), slightly aspherical lenslets (SAL) or single-vision lenses (SVL). We acquired ChT from central 6 mm radial OCT scans (Topcon Triton) at the baseline, 6 months, and 12 months. The changes from the baseline were compared between groups at foveal locations according to the Early Treatment Diabetic Retinopathy Study (ETDRS) areas.

Results: After one year, the ChT decreased at all regions in the SVL group by up to $-10.29 \pm 20.11 \mu\text{m}$ in the central fovea. This trend was significantly less pronounced in all regions in the SAL group ($p < 0.05$) that showed a maximal thinning of $-2.94 \pm 21.78 \mu\text{m}$ also in the central fovea. Most remarkably, the HAL group exhibited an increase in choroidal thickness in all regions by up to $18.24 \pm 18.22 \mu\text{m}$ in the superior regions and this effect was significantly different from both SVL and SAL ($p < 0.05$).

Conclusions: We observed the expected choroidal thinning associated with myopia progression in the SVL group. Wearing SAL lenses reduced this effect and wearing HAL lenses reversed this effect. These results are in agreement with the superior myopia control effect of the HAL lenses.

TITLE: Effect of Preoperative Anterior Chamber Depth and Intraocular Lens Power on Postoperative Pseudophakic Accommodation Following Monofocal Phacoemulsification Cataract Surgery

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Joseph, J. Eikenberry, D.K. Wallace, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sophia Joseph: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Eikenberry: Commercial Relationship: Code N (No Commercial Relationship) | David Wallace: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Following phacoemulsification cataract surgery with a monofocal intraocular lens, patients generally experience good visual acuity at distance but have varying degrees of accommodative ability. We performed a prospective clinical study to test the hypothesis that preoperative anterior chamber depth (ACD) and/or implanted intraocular lens (IOL) power influence postoperative accommodative ability.

Methods: We enrolled fifteen adult patients (one eye each) who had undergone uncomplicated phacoemulsification cataract surgery more than one month prior by a single surgeon. Eligibility criteria included in-the-bag intraocular lens placement, surgery not requiring mechanical pupil stretching, and postoperative best-corrected distance visual acuity of 20/25 or better. We measured each patient's near visual acuity with only distance correction in place at 40 centimeters. We then measured amplitude of accommodation by placing a 2.5D lens over the distance correction and asking the patient to read a 20/30 near chart line. The chart was moved forward until blurred and back until clear to establish the near point. This was repeated 10 times and the average near point was used to determine the accommodative amplitude. The preoperative anterior chamber depth as measured by the IOL Master 700 as well as the IOL power implanted was obtained from the patient's medical record. Multiple linear regression analysis was used to determine if ACD and/or IOL power were associated with pseudophakic patients' accommodative ability.

Results: Postoperative accommodative ability was associated with larger ACD ($p=0.004$) but was not associated with IOL power ($p = 0.918$). For every 1 mm increase in ACD, there was a 2.63 D increase in accommodation.

Conclusions: Larger preoperative ACD predicts better postoperative accommodative ability in our pseudophakic patients. Larger ACD has been shown to correlate with younger age, and it is possible that younger pseudophakic patients retain more accommodation. Additionally, larger ACD has been shown to correlate with larger corneal diameter, and perhaps the larger cornea has more multifocality. These data could potentially be used to inform preoperative decision making when choosing between monofocal and multifocal lenses.

ABSTRACT BODY:

Purpose: To investigate the impact of the instillation timing of carteolol hydrochloride/latanoprost combination ophthalmic solution (LCFC) , in the morning or at night, in patients with glaucoma on the diurnal variations of IOP and on the circulatory system, comparing with timolol/latanoprost combination ophthalmic solution (LTFC) as a control.

Methods: Twenty-two eyes of 22 patients with POAG or OH on monotherapy with a prostaglandin ophthalmic solution were included. They were randomly assigned to either a group of switching from LCFC to LTFC or a group of switching from LTFC to LCFC. Both drugs were administered at 8 p.m. every night for 2 months each.

At the start of evaluation, the diurnal variation in IOP, vital signs (pulse rate, blood pressure), fluorescein corneal staining test and ophthalmological subjective symptoms at 2 months after the start of administration of each ophthalmic solution were evaluated. The adverse events during the evaluation period were also surveyed.

Results: The diurnal variation in IOP at 2 months after the start of evaluation period showed a similar transition in the LCFC group and the LTFC group, with a maximum value of 16.21 mmHg and 16.55 mmHg at a.m. 4:00 and a minimum value of 13.06 mmHg and 12.42 mmHg at p.m. 4:00, respectively. There were no differences in the range of the diurnal variation and the changes from the start of evaluation.

For the diurnal variation in pulse rate at 2 months after the start of evaluation period, there were significant differences in the changes from the start of evaluation, i.e., -0.8 and -4.3 at 22:00, -2.6 and -7.0 at 2:00, -3.1 and -7.1 at 4:00, and -3.7 and -8.0 at 6:00 in the LCFC group and the LTFC group, respectively.

No adverse events with a causal relationship with the treatment occurred in the both groups.

Conclusions: The IOP-lowering effect was equivalent in the diurnal variation of IOP at 2 months after the start of the administration in the LCFC group and the LTFC group. The transitional changes were similar, showing the maximum IOP at a.m. 4:00. For the diurnal variation at 2 months after the start of the administration, the pulse rate is less affected in the LCFC group, and the safety of night instillation was shown.

ABSTRACT BODY:

Purpose: Some ocular diseases can affect eye shape and size, hence, high-resolution imaging with whole eye optical coherence tomography (OCT) may be necessary to examine these pathological changes. Here we report a prototype OCT that allows measurement of the whole eye and axial length (AL) measurement.

Methods: We used a swept-source OCT with vertical cavity surface emitting laser (VCSEL) with 1060 nm center wavelength and a modifiable wavelength sweep frequency (WSF). In vivo imaging was performed on healthy patients. Low-speed and high-speed WSF allow low-resolution or high-resolution imaging. The anterior segment and fundus can be captured in one shot in low-speed mode (Fig. 1A). This image was registered as a reference image to construct the whole eye image. In high-speed mode, anterior segment and fundus OCT image capture were performed separately. The whole eye OCT image was constructed by registration of the image captured at high-speed mode with the reference image from the low-speed mode. AL was the distance between the corneal vertex and fovea based on the low-speed OCT image. AL measurements were compared to those from a commercially available optical biometer (AL-Scan; NIDEK).

Results: Figure 1B present a reference OCT image in low-speed mode and Figure 1C presents the whole eye OCT image. The optical design precluded imaging of the area around the equator and ora serrata. The axial length was 25.56 mm with the prototype OCT and 25.34 mm with the AL-Scan.

Conclusions: A prototype OCT was developed that allows whole eye OCT imaging and axial length measurement, to simultaneously assess the fundus to the equator and the anterior segment in a single device. We confirmed similar measurement capability of the prototype and the AL-Scan. Incorporation of this prototype into clinical practice may decrease diagnostic workup time and increase patient turnover and patient comfort.

ABSTRACT BODY:

Purpose: To investigate the association between various macular layer thicknesses and superficial vessel density measurements and both axial length (AL) and glaucoma severity to improve glaucoma detection in highly myopic eyes.

Methods: 248 glaucoma patients (401 eyes) with AL measurements and macular optical coherence tomography (OCT) imaging were stratified into three axial myopia groups of no- (146 eyes), mild- (208 eyes) and high-axial myopia (AL > 26mm) (47 eyes). Ganglion cell inner plexiform layer (GCIPL) thickness, macular retinal nerve fiber layer (mRNFL) thickness, ganglion cell complex (GCC) thickness and the macular superficial vessel density (sVD) were measured with the built-in software and macular choroidal thickness (mCT) was assessed using deep learning strategies for each axial myopia group. Univariate and age- and VFMD-adjusted models were assessed to evaluate the association between structural measures and AL and VFMD.

Results: Thinner global GCIPL and GCC were not associated with AL ($p < 0.350$) but were significantly associated with visual field mean deviation (VFMD) ($R^2 = 35.1$; and $R^2 = 33.4$; respectively $p < 0.001$). Thicker mRNFL showed a weak association with larger AL ($R^2 = 3.4$; $p = 0.001$) and a positive association with VFMD (global $R^2 = 20.5$; $p < 0.001$). Lower sVD was moderately associated with worse VFMD ($R^2 = 31.8$; $p < 0.001$) and weakly associated with larger AL ($R^2 = 2.3$; $p = 0.016$). Thinner MCT was not associated with VFMD ($P = 0.262$) but was associated with larger AL ($R^2 = 17.3$; $p < 0.001$).

Conclusions: Thinner GCIPL and GCC were associated with more severe glaucoma and were not associated with AL suggesting that these measurements might be useful for glaucoma detection in myopic eyes.

ABSTRACT BODY:

Purpose: Australian optometrists manage glaucoma in shared care agreements with ophthalmologists. Optometrists gained access to the Pharmaceutical Benefits Scheme (PBS) for glaucoma drugs in 2008. PBS data was explored to determine the extent of optometrists' role in glaucoma management and compare prescribing patterns of optometrists and medical practitioners over time.

Methods: PBS data were retrieved from 2009 to 2019 for topical glaucoma drugs. The number of scripts dispensed per year for each glaucoma drug and drug classes (α -agonists, β -blockers, carbonic anhydrase inhibitors (CAI), miotics, prostaglandins (PGA) and fixed combinations (FC)), and preservative free (PF) were determined. The proportion of optometrists' scripts was calculated as a proxy measure for shared care uptake. Percent change over time, relative proportions of drug classes and most prescribed drug within each class were calculated for each professional group.

Results: The number of glaucoma scripts dispensed per year (mean 3.70M, IQR 3.43 – 3.84M) has been stable since 2009 despite population ageing with the number of scripts prescribed per person (65y/>) ranging from 1.23 in 2009 to 0.86 in 2019. The proportion of optometrists' scripts to total scripts has increased (0.04% in 2009 to 2.61% in 2019) but appears to be plateauing. Optometrists' (OP) largest increases were for PGA (924 to 238,936) and FC (338 to 146,556). Medical practitioners' (MP) scripts for miotics (-51.1%), β -blockers (-45.8%), PGA (-27.3%) have decreased, FC (55.8%) and CAI (17.5%) have increased, while α -agonists remained stable. PF use has increased since first introduced in 2013 accounting for 7.5% of scripts. Relative proportions of drug classes in 2019 were similar for both professions: PGA (OP 47%, MP 41%), FC (OP 35% , MP 39%), and others (OP 18.3%, MP 20.0%) The most frequently prescribed drugs in each class were the same for both professions.

Conclusions: Optometrists prescribed a small but increasing proportion of glaucoma scripts indicating slow uptake of shared care agreements. Both professions exhibit similar prescribing patterns. The reduced number of scripts per person, decreased PGA and β -blockers, and increased FC prescribing by medical practitioners may reflect changes in glaucoma treatment paradigms. Opportunity exists for more optometrists to engage in glaucoma management via shared care agreements to assist with increased future demand.

ABSTRACT BODY:

Purpose: A better understanding of the association between policy intervention promoting outdoor activities and the changes in the prevalence of myopia among preschoolers is critical for improvement of preventive strategies against myopia during early childhood. This study aimed to report the prevalence of preschool myopia and its secular trend after implementing a policy intervention promoting outdoor activities in a Taiwan preschool population.

Methods: The repeated countywide population-based, cross-sectional surveys were based on the Yilan Myopia Prevention and Vision Improvement Program (YMVIP) which has been conducted since August 2014. Myopia prevention strategies, such as increasing outdoor exercises (2 hours/weekday), have been promoted in all kindergartens in Yilan County, and school-based eye examinations, including cycloplegic autorefraction, and caregiver-administered questionnaires have been performed annually for all preschoolers aged 5-6 years.

Results: Among 20,419 kindergarteners aged 5-6 years in 6 school-year cohorts from 2014 through 2019, a total of 18,621 (9,715 [52.2%] boys) were finally included for analysis. The prevalence of myopia (spherical equivalent $\leq -0.5D$ in either eye) among preschoolers aged 5-6 years declined continuously from 15.4% (95% confidence interval [CI], 14.1%-16.6%) in the 2014 cohort which was not yet exposed to the YMVIP before eye examinations to 8.4% (95% CI, 7.4%-9.4%) in the 2016 cohort which had been exposed to the YMVIP for up to 2 years and remained relatively stable in the subsequent cohorts with 2-year YMVIP exposure (8.5% [95% CI, 7.6%-9.5%] in 2017, 10.0% [95% CI, 9.0%-11.0%] in 2018, and 9.1% [95% CI, 8.1%-10.1%] in 2019). Multivariable logistic regression analysis showed a significant and dose-response association between the duration of exposure to preventive strategy and the prevalence of myopia (one-year YMVIP exposure: odds ratio [OR], 0.86; 95% CI, 0.75-0.999; two-year YMVIP exposure: OR, 0.55; 95% CI, 0.49-0.61) after controlling other myopiogenic factors.

Conclusions: This population-based evidence showed high prevalence of preschool myopia and an L-shaped decline after introducing strategies to promote outdoor activities in kindergartens.

ABSTRACT BODY:

Purpose: Intravitreal injections of anti-vascular endothelial growth factor is traditionally administered by physicians and represents a considerable workload on ophthalmology departments. To optimize the available resources, we developed a training program for nurses with the aim to inject equally as efficient and safe as physicians. In a randomized controlled trial (RCT) we showed nurses to be non-inferior to physicians.

In this qualitative study we aimed to evaluate if the nurses were confident and in control having participated in the training program, and if the nurses were satisfied with the training program and the new task.

Methods: During 2014-2018, twelve registered nurses were trained in a tertiary clinic covering about 300.000 inhabitants in Central Norway. Work experience ranged from two to thirty-one years. All nurses were interviewed with a semi structured interview guide, either individually (n=7) or in a focus group (n=5). We analyzed the interviews using Granheim and Lundemans qualitative content analysis.

Results: Twelve sub-themes clustered in four main themes 1) responsibility and safety, 2) motivation and respect, 3) collaboration and 4) organization. The nurses felt confident and in control when administering injections but experienced moments of insecurity. The new task gave the nurses a sense of achievement, mastering a task that is not part of their usual training. Improvement of patient's lives were mentioned as a positive effect. A greater level of responsibility gave the nurses pride in their profession. They were satisfied with the training program but had suggestions that could improve the efficiency of the training.

Conclusions: Our study showed that the nurses trained were satisfied with the training and learning a new task led to higher self-esteem and gained respect. They had several suggestions on how the training could be improved, which should be considered before recommending it to other departments.

ABSTRACT BODY:

Purpose: Telehealth consultations will be increasingly used to assess eye patients during the COVID-19 pandemic. An audit was performed at a major quaternary referral centre for Ophthalmology in Sydney, Australia. This study assesses the outcomes of teleconsultation in an acute ophthalmic clinic setting.

Methods: 242 patients with an Acute Ophthalmic Service clinic appointment at the Sydney Hospital & Sydney Eye Hospital between 19th March 2020 and 9th April 2020 inclusive were included in this study. These patients were separated into two study groups - 162 patients attended their pre-arranged appointment, whereas 80 patients had their appointment changed to a telehealth consultation.

A final year Ophthalmology Registrar performed an online medical records review of all patients and selected 80 patients for teleconsultation, following which re-presentation rate and reason for re-presentation was collected each month for five months for the two patient populations.

The primary outcome measure was the rate of re-presentation and reason for re-presentation to the Eye Emergency Department.

Results: There were no significant differences in the number of re-presentations after each month during the five months ($P = 0.166, 0.113, 0.139, 0.266$ and 0.390 at each month). There were also no significant differences in the reason for re-presentation after each month during the five months ($P = 0.999, 0.999, 0.872, 0.663$ and 0.517 at each month).

Conclusions: There were similar short-term outcomes between the two study groups suggesting that telehealth is a viable alternative for the provision of acute care to appropriately selected patients.

ABSTRACT BODY:

Purpose: Selective laser trabeculoplasty (SLT) is a procedure increasingly used as first-line therapy to reduce intraocular pressure (IOP) in patients with ocular hypertension (OHT) or glaucoma. This subgroup analysis evaluated corneal endothelial cell loss (CECL) associated with SLT treatment in a randomized, phase 3 study.

Methods: A 52-week, randomized, phase 3, paired-eye comparison study (NCT02636946) evaluated bimatoprost implant compared with SLT in patients with open-angle glaucoma or OHT whose IOP was inadequately managed with topical medication for reasons other than medication efficacy. SLT was performed on Day 1 using single-burst mode and a standard fixed 400 µm spot size with ~100 contiguous, non-overlapping spots delivered 360° in the angle; power began at ~0.6 mJ and was titrated between ~0.4 and ~1.2 mJ as needed. Patients were randomized to treatment with implant or SLT in the worse eye; contralateral eyes received the alternate treatment. Corneal endothelial cell density (CECD) was assessed as a safety parameter at multiple time points throughout the study with a Konan CellChek noncontact specular microscope present at each site. The imaging technician was qualified by an experienced reading center (Cornea Image Analysis Reading Center [CIARC], Case Western Reserve University) commonly used for registration studies. CECD was quantified by the reading center. All available data from the primary database lock, when the last enrolled patient completed the Week 24 visit, were analyzed.

Results: Mean (SD) CECD in SLT-treated eyes (n=141) was 2487 (311) cells/mm² at baseline and decreased during the study; at Week 24 the mean (SD) CECD was 2422 (329) cells/mm². Among all SLT-treated eyes, 9.9% (14/141) had ≥10% corneal endothelial cell loss (CECL), 5.7% (8/141) had ≥15% CECL, and 3.5% (5/141) had ≥20% CECL during a mean (SD) follow-up of 317 (83) days.

Conclusions: Previous open-label studies with 1 month follow-up have generally reported transient corneal changes and reduction in CECD after SLT with limited follow up. Results of this phase 3 study suggest that persistent CECL may be a previously unrecognized side effect of SLT that becomes evident with longer follow-up.

TITLE: Surface softness comparison of select contact lenses by nanoindentation

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Oyler, B. Tucker, Vision Care, Alcon Laboratories Inc, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Paul Oyler: Commercial Relationship(s);Alcon Laboratories, LLC:Code E (Employment) | Bob Tucker: Commercial Relationship(s);Alcon Laboratories, LLC:Code E (Employment)

ABSTRACT BODY:

Purpose: The objective of the study was to determine surface softness differences between a new contact lens material with biologically inspired water gradient surface and five other contact lens types using nanoindentation and to assess any in-vitro to ex-vivo softness differences among the lenses.

Methods: In-vitro: Contact lenses made from a new contact lens material (NCLM) (5 lenses) and 5 other comparator lenses (samfilcon A, comfilcon A, senofilcon C, senofilcon A, and fanfilcon A; n=6 each) were removed from their packaging and placed in PBS/0.1% Pluronic F-127 testing solution for 30 minutes. All tested lenses were then mounted on a steel ball for nanoindentation using an Optics 11 Piuma nanoindentation system. In order to determine the surface softness the depth required for the probe to apply 5 kPa of pressure to the lenses was calculated.

Ex-vivo: NCLM lenses (n=6) were worn by patients daily and disinfected in OPTI-FREE® RepleniSH® nightly during the 30-day clinical trial. These lenses were tested using the same method as above and compared to the in-vitro NCLM from the same manufacturing lot as well as the 5 comparator lens types (Figure 1).

Results: In-Vitro: NCLM lenses were found to have a significantly greater ($p<.05$) depth to reach 5 kPa (490 ± 72 nm) than the other 5 lens types tested (68 ± 35 nm, 83 ± 39 nm, 79 ± 36 nm, 82 ± 58 and 64 ± 31 for samfilcon A, comfilcon A, senofilcon C, senofilcon A, and fanfilcon A, respectively).

Ex-vivo: Clinically worn NCLM lenses had comparable depth (518 ± 89 nm) to in-vitro controls.

Conclusions: The in-vitro surface softness characterized by nanoindentation of the NCLM lenses showed they were significantly softer than samfilcon A, comfilcon A, senofilcon C, senofilcon A, or fanfilcon A lenses. The surface softness of the ex-vivo NCLM did not decrease after being worn on-eye, which indicates the integrity of the water gradient surface was maintained throughout daily wear for 30 days. Surface softness may provide good correlation with lubricity, which could indicate greater comfort during lens wear.

Commercial Relationships Disclosure (Abstract): Sriganesh Ramachandra Rao: Commercial Relationship: Code N (No Commercial Relationship) | Steven Pittler: Commercial Relationship: Code N (No Commercial Relationship) | Steven Fliesler: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the requirement for dehydrolipoyl diphosphate synthase (Dhdds) gene expression in the early development of photoreceptor and bipolar cells.

Methods: Dhdds was ablated in rod and cone photoreceptor and bipolar cells by crossing Dhdds^{flx/flx} mice to CRX (cone-rod homeobox) promoter-driven Cre recombinase transgenic mice, to initiate Dhdds knockout (KO) at E12.5 days. Dhdds^{flx/flx} CRX-Cre⁺ (KO) and Dhdds^{flx/flx} CRX-Cre⁻ (control) mice were selected by PCR for the presence of the loxP-modified Dhdds allele and CRX-Cre transgene. Cre recombinase expression and activity were tested by crossing CRX-Cre mice with ZsGreen reporter mice. Western blot (WB) analysis was performed, ±PNGase-F treatment, on retinas from PN 4-wk old KO and control mice, probing with 1D4 Mab to assess opsin N-glycosylation status. Eyes from PN 3-4-wk old KO and control mice were subjected to TUNEL labeling and immunohistochemistry (IHC), using cell type-specific antibodies, or probed with fluor-conjugated lectins (Con-A, PNA) or Cholera toxin-B (CTx). Retina whole mounts were probed with PNA to assess cone density. ERG analysis was performed on control and KO mice at PN 4-5 wk (N=3/group). Statistical analysis: Student's t-test, P<0.05.

Results: ZsGreen reporter analysis demonstrated Cre recombinase activity in rods, cones, and bipolar cells, as well as patchy expression in Mueller glia. ERG analysis showed extinguished scotopic and photopic a- and b-waves in KO mice at PN 4-wk. Relative to controls, IHC of PN 4-wk KO retinas revealed significant (>90%) loss of cones and bipolar cells, shortened rod outer segments, and gliosis; TUNEL+ cells were observed only in the ONL, with a cone-rod degeneration pattern. CTx binding revealed aberrant ganglioside GM1 accumulation in KO retinas; however, no overt protein N-glycosylation defects were evident by WB or Con-A staining.

Conclusions: Despite initiation of Dhdds ablation at E12.5 days in progenitors of photoreceptor and bipolar cells, retinal degeneration (not dysplasia) was observed. These findings suggest the presence of a long-lived, progenitor-derived dolichol pool that persists even after differentiation of photoreceptors and bipolar cells has occurred and after de novo synthesis has ceased in those cells. This may explain the absence of obvious glycosylation defects in other Dhdds mutant mouse models of RP59.

TITLE: Water gradient wettability and durability of a new monthly replacement contact lens

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Varde, B. Tucker, Alcon Laboratories Inc, Johns Creek, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Pushkar Varde: Commercial Relationship(s);Alcon Inc:Code E (Employment) | Bob Tucker: Commercial Relationship(s);Alcon Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: A new contact lens material (NCLM) was designed with a unique phosphoryl choline water gradient surface. This work evaluates the durability and wettability of this water gradient surface after 30 days of on-eye daily wear use.

Methods: The NCLM (n=5) were worn on a daily wear regimen for 30 days that included nightly manual cleaning (rubbing) and disinfection in OPTI-FREE[®] RepleniSH[®]. The control group was out of pack (OOP) lenses (n=5). The lenses were pre-soaked in PBS for 16 hrs and then tested with the Interfacial Dewetting and Drainage Optical Platform (iDDrOP) wettability measurement (Bhamla, 2015), which provides quantitative in vitro surface material property analysis without interference from packaging solution, tears, or patient variation. A video of the lens dewetting in PBS allows objective water break-up time (WBUT) to be collected. The same lenses were then stained using Sudan Black to assess the loss of the gradient surface coating. Staining was analyzed using a custom software that generates a percent stain metric.

Results: The WBUT for ex vivo lenses (21 ± 5.62 sec) was comparable to the OOP control lenses (27 ± 3.28 sec) even after 30 days of on-eye daily wear, The ex vivo lenses demonstrate significantly higher WBUT compared to the OOP WBUT for other inherently wettable CL: comfilcon A: 6 ± 2 sec, senofilcon A: 9 ± 3 sec, samfilcon A: 15 ± 5 sec, and senofilcon C: 14 ± 4 sec (Fig 1). The staining metric on either group of lenses was less than 1% (ex vivo: $0.12 \pm 0.09\%$ vs OOP: $0.43 \pm 0.65\%$) indicating uniform coverage of the hydrophilic water gradient coating. However, for competitor lenses, the staining metric was higher than 10%.

Conclusions: The surface coating durability of ex vivo CL for a new 30-day wear lens product was comparable to OOP lenses, and the surface wettability was superior to the OOP properties of other inherently wettable CL even after 30 days of on-eye wear. Moreover, the biologically inspired water gradient coating maintains uniform coverage on the lens even after 30 days of daily wear.

Commercial Relationships Disclosure (Abstract): Tom Lawler: Commercial Relationship: Code N (No Commercial Relationship) | Zhe Liu: Commercial Relationship: Code N (No Commercial Relationship) | Marine Nalbandyan: Commercial Relationship: Code N (No Commercial Relationship) | Yao Liu: Commercial Relationship: Code N (No Commercial Relationship) | Billy Hammond: Commercial Relationship: Code N (No Commercial Relationship) | Robert Wallace: Commercial Relationship: Code N (No Commercial Relationship) | Julie Mares: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Carotenoids lutein and zeaxanthin (L/Z) accumulate in the macula to form macular pigment, which may be neuroprotective and preserve vision. L/Z supplements increase macular pigment density (MPOD) and improve vision in trials of younger/middle-aged adults, but less is known of their long-term effects in older adults (age 70-100). Using data from the Carotenoids in Age-Related Eye Disease Study (CAREDS), a cohort study of postmenopausal women, we examined associations between L/Z supplement use and MPOD over 15 years, best-corrected visual acuity (BCVA) and contrast sensitivity (CS).

Methods: We used linear models and generalized estimating equations to evaluate relationships between L/Z use, MPOD, BCVA, and luminance CS. The main exposure was self-reported L/Z supplement use ≥ 1 mg/day (≥ 1 month) assessed via questionnaire prior to CAREDS2. The primary outcome was 15-year MPOD change. MPOD was measured at 0.5° from foveal center using heterochromatic flicker photometry at CAREDS and CAREDS2. Other outcomes included BCVA and luminance CS measured at CAREDS2 using Snellen and Pelli-Robson charts, respectively, in eyes without ocular pathology (assessed at CAREDS2 visits) or self-reported diabetes to mitigate confounding.

Results: Of 2,005 women enrolled in CAREDS baseline (2001-2004), 487 participated in CAREDS2 visits (2016-2019). For those with complete data (n=417), L/Z supplement use was reported by 76 (18.2%). L/Z use was more common in women with advanced AMD (68.3%). L/Z use was associated with larger increases in MPOD over 15 years (0.22 ± 0.03 optical density units (ODU) vs. 0.12 ± 0.01 (mean \pm SE), $p < .001$). However, a linear dose-response (up to 20+ mg/day) was not observed. MPOD change was maximal in those consuming 10-19.9 mg/day (0.29 ± 0.04 ODU). In eyes without pathology (n=414), L/Z use was not associated with BCVA (83.3 ± 1.1 letters vs. 82.8 ± 0.4 (20/25), $p = .65$), but was associated with greater CS (12.3 ± 0.2 triplets vs. 11.8 ± 0.1 , $p = .006$).

Conclusions: In this cohort of older women, L/Z use was associated with a greater increase in MPOD over 15 years and greater CS (in eyes without pathology), consistent with clinical trials in younger and middle-aged adults. Greater CS related to L/Z use may help maintain quality of life in older adults.

TITLE:

Using Fixed-Force Goldmann Applanation Tonometry to measure the Ocular Pulse Amplitude

SESSION TITLE: Clinical Studies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.C. Wen, Ophthalmology, Duke University, Durham, North Carolina, UNITED STATES|T. Spaide, Y. Wu, A.Y. Lee, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joanne Wen: Commercial Relationship: Code N (No Commercial Relationship) | Theodore Spaide: Commercial Relationship: Code N (No Commercial Relationship) | Yue Wu: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Lee: Commercial Relationship(s);US Food and Drug Administration:Code E (Employment);Santen:Code F (Financial Support);Carl Zeiss Meditec:Code F (Financial Support);Novartis:Code F (Financial Support);Microsoft:Code F (Financial Support);NVIDIA:Code F (Financial Support);Genentech:Code C (Consultant);Verana Health:Code C (Consultant);Topcon:Code R (Recipient)

ABSTRACT BODY:

Purpose: The role of the ocular pulse amplitude (OPA), which is the difference in measured IOP during the diastolic and systolic cardiac cycle, in glaucoma pathogenesis is under-studied due to the limited methods for measuring OPA. We present a novel method for measuring OPA using standard ophthalmic equipment and fixed-force Goldmann Applanation Tonometry (GAT).

Methods: The methods for automated fixed-force GAT have been previously described.¹ Briefly, an iPod Touch clamped to the ocular of a standard slit lamp microscope (Fig A) recorded the applanation mires (Fig B) created with the GAT set at a fixed force. IOP values from each frame of the video were calculated from the mire diameters (Fig C) and plotted over time (Fig D). In this post hoc analysis, we analyzed previously collected videos used for validation of the automated GAT method. The right eyes of subjects diagnosed as POAG or glaucoma suspect (GS) were included. The OPA was calculated by measuring the difference in IOP between the upper and lower IOP measurements in each cycle and taking the mean of these differences. The OPA of POAG eyes were compared to GS eyes.

Results: 41 POAG eyes and 20 GS eyes were included. Mean age (67.5 ± 8.2 vs 66.5 ± 13.5 years), IOP (14.5 ± 4.8 vs 16.9 ± 4.6 mmHg) and CCT (535 ± 39 vs 550 ± 32 μ m) for POAG vs GS eyes did not differ significantly ($p=0.71$, 0.08 , 0.13 , respectively). OPA was found to be decreased in POAG eyes (1.18 ± 0.7 mmHg) compared with GS eyes (1.62 ± 0.94 mmHg) ($p=0.05$, t-test). A significant correlation between OPA and IOP was found ($r=0.62$, $p<0.0001$) while no significant correlation was found between OPA and CCT ($r=0.14$, $p=0.30$) and OPA and age ($r=-0.01$, $p=0.91$).

Conclusions:

Preliminary measurements of OPA using automated fixed force GAT are promising. This method is easily incorporated into standard ophthalmic equipment and may become a tool to improve our understanding of the role of OPA in ocular disease.

ABSTRACT BODY:

Purpose: Emerging research identifies elevated oxidative stress as central to the pathogenesis of many degenerative retinal diseases, such as dry age-related macular degeneration and retinitis pigmentosa. Treatment options for these diseases are limited, resulting in visual loss affecting millions of patients worldwide. In the present study, we investigated the cytotoxicity of hydrogen peroxide (H_2O_2) and protection by an investigational drug, risuteganib (RSG), in cultured human RPE (ARPE-19) and Müller (MIO-M1) cells.

Methods: ARPE-19 (n=3) and MIO-M1 (n=8-9) cells were treated according to the following five regimes: (1) untreated control for 36 h, (2) RSG treatment for 36 h, (3) untreated for 24 h, then H_2O_2 for 12 h, (4) RSG pre-treatment for 24 h, then H_2O_2 for 12 h, and (5) RSG for 24 h, then RSG and H_2O_2 co-treatment for 12 h. 400 μ M RSG and 100 μ M H_2O_2 were used. After exposure, cells were incubated for 48 h in fresh media before cell viability was measured by Trypan Blue dye exclusion assay. Statistical analysis was by Student's t-test. Control, H_2O_2 , and [RSG pre-treatment + H_2O_2] samples (n=6) were analyzed by RNA-seq for whole transcriptome gene expression. Differentially expressed genes were determined using edgeR and over-represented biological processes/pathways using goseq.

Results: H_2O_2 treatment significantly reduced cell viability by 27.7% (p=0.023) and 20.5% (p<0.0001) in ARPE-19 and MIO-M1 cells, respectively. Cell viability was significantly rescued by RSG pre-treatment (30.3%, p=0.015; 7.7%, p=0.0454) and RSG co-treatment (26.3%, p=0.027; 10.4%, p=0.0046) in ARPE-19 and MIO-M1 cells, respectively. RNA-seq showed H_2O_2 exposure regulated genes in the angiogenesis, immune system, cell adhesion/migration, cell proliferation/death, and metabolic processes. Biological pathway analysis showed integrin cell surface interaction was significantly regulated by H_2O_2 . RSG effectively reversed the harmful effects of H_2O_2 treatment across many of the biological processes and pathways.

Conclusions: H_2O_2 induced significant cytotoxicity that was mitigated by RSG. Expression data showed H_2O_2 regulated genes across many disease-relevant processes and pathways, whereas RSG treatment lessened these effects. Our results suggest RSG may be effective in reducing oxidative stress-induced toxicity in retinal cells with relevance to human diseases.

ABSTRACT BODY:

Purpose: To evaluate the efficacy and safety of combined cataract extraction (CE) and either excisional goniotomy performed with Kahook Dual Blade (KDB), iStent or iStent inject trabecular bypass implantation in patients with mild to moderate open-angle glaucoma and visually significant cataract.

Methods: A retrospective analysis was performed on 55 eyes of 51 adults with mild to moderate open-angle glaucoma treated with one or more intraocular pressure (IOP)-lowering medications who underwent combined CE and iStent, iStent inject or KDB. Inclusion criteria included no previous glaucoma surgeries and one year of postoperative follow up. Data included best-corrected visual acuity (BCVA), IOP, IOP lowering medications, and adverse events (AE) collected through 12 months postop. The primary outcome variables were IOP reduction and reduction in number of IOP lowering medications.

Results: 35 iStent eyes, 7 iStent inject eyes and 13 KDB eyes were included in the study. Mean preoperative IOP was 19.15 ± 5.29 mmHg on a mean number of 1.67 medications. At 12 months postoperative, mean IOP decreased 3.70 ± 4.50 mmHg ($p < 0.001$) in iStent group, 6.64 ± 2.38 mmHg ($p < 0.001$) in the iStent inject group and 3.59 ± 3.84 mmHg ($p = 0.082$) in KDB group. Mean number of medications decreased 1.06 ± 0.32 ($p < 0.001$) in iStent group, 1.25 ± 0.96 ($p < 0.001$) in the iStent inject group and 0.57 ± 0.60 ($p = 0.061$) in KDB group. A favorable safety profile included no intraoperative AE, and BCVA of 20/40 or better in 96% of eyes at 12 months.

Conclusions: iStent and iStent inject with CE led to statistically significant and clinically meaningful reductions in IOP and glaucoma medication burden at 12 months, adding to existing literature that these implants are safe and effective add-on procedures for cataract surgeons to incorporate into practice. KDB did not show statistically significant reductions, which may be due to inherent technique variability. iStent and iStent inject allow anterior segment surgeons to offer, in a single low-risk procedure, increased visual potential by removing the cataract and improved quality of life by decreasing dependence of eye drops, maintaining long term IOP control and slowing the progression of glaucoma. Prospective large-scale studies would help further elucidate the role of these MIGS procedures with CE.

TITLE: Surface characterization of a new contact lens water gradient using fluorescent staining

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Lang, B. Tucker, R&D, Alcon Laboratories Inc, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Weihong Lang: Commercial Relationship: Code N (No Commercial Relationship) | Bob Tucker: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

A fluorescently labelled C-reactive protein (CRP) was used to characterize a new contact lens material (NCLM) with a water gradient surface containing embedded phosphoryl choline (PC) groups. The uniformity and functionality of these groups were verified before and after 30 days of daily wear.

Methods: PC polymers with unique biocompatibility may inhibit nonspecific protein deposition. With strong affinity binding to PC groups, CRP was used to identify these groups.

Each new contact lenses material (NCLM) with the PC containing water gradient surface was treated with Alexa 488 labelled CRP. The treated lenses were rinsed in DI water and set on glass slide for fluorescent microscope study. Full view of lenses were collected to evaluate surface coating integrity. The same treated lenses were also cross sectioned and imaged to verify coating layer uniformity. This process was repeated using NCLM after worn for 30 days of daily wear and use of OPTI-FREE® RepleniSH®.

NCLM lenses were treated with Pyrenebutyric acid (PBA) for staining the silicone bulk, followed by Alexa 488-CRP staining. Each lens was cryosectioned and microscope images collected on both CRP and PBA channels for dual fluorescent stains.

Results: Top view new contact lenses material showed uniform coverage of the PC-containing water gradient layer. After 30 days of daily wear, the contact lens material still shows good coating layer uniformity, shown in Figure 1. In cross-section, the CRP-stained layer was visibly distinct from the PBA stained hydrophobic silicone section of the lens shown in figure 2.

Conclusions: The in vitro and ex vivo fluorescent staining technique showed evidence of a stable PC containing water gradient layer on the NCLM. After 30 days of daily wear, excellent coating uniformity remained, indicating the integrity of the water gradient structure despite on eye wear, exposure to OPTI-FREE® RepleniSH® and daily insertion, handling, rubbing, and removal.

ABSTRACT BODY:

Purpose: The All of Us Research Program is a nationwide prospective cohort study. As the only alpha phase demonstration project related to ophthalmology, our aims were to (1) externally validate a previously published model predicting need for surgery among individuals with glaucoma, (2) develop new models using All of Us data, and (3) share insights regarding the use of this data for ophthalmic research.

Methods: Electronic health record data were extracted for 1231 adult participants in All of Us diagnosed with primary-open angle glaucoma. We compared a previously published single-center cohort and the All of Us cohort with respect to demographics and need for glaucoma surgery. The performance of the single-center model was evaluated on All of Us data, based on area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity. All of Us data were then used to train new models using multivariable logistic regression (LR), artificial neural networks (ANN), and random forests (RF). These were cross-validated on All of Us data. Performance was evaluated based on AUC, accuracy, precision, and recall.

Results: The mean (standard deviation) age of the All of Us cohort was 69.1 (10.5) years, with 57.3% women and 33.5% Black or African American, both significantly exceeding representation in the single-center cohort ($p=0.04$ and $p<0.001$, respectively). Of 1231 participants, 286 (23.2%) needed glaucoma surgery. When applying the single-center model to All of Us data, accuracy was 0.69, and AUC was 0.49, indicating that the model was not generalizable to All of Us data. Using All of Us data to train new models resulted in superior performance: AUCs ranged from 0.80 (LR) to 0.99 (RF). Blood pressure (BP) had the highest relative importance for driving predictions in RF models.

Conclusions: Models trained with national All of Us data achieved superior performance compared to using single-center data. The relationship between BP and glaucoma warrants ongoing investigation. Novel big-data sources such as All of Us offer numerous opportunities for ophthalmic research.

ABSTRACT BODY:

Purpose: Children with juvenile idiopathic arthritis (JIA) aged 7 and younger are at a greatest risk for uveitis. The impact of JIA-associated uveitis (JIA-U) on quality of life (QOL) and visual function of young children is not well characterized. We administered questionnaires in a cross-sectional study to compare visual function and QOL of children ages 2 to 7 with JIA and JIA-U.

Methods: Three validated questionnaires were administered to parents of 51 children, ages 2-7, diagnosed with JIA alone or JIA-U during their regular clinic visits at Cincinnati Children's Hospital Medical Center and Emory University. The Children's Visual Function Questionnaire (CVFQ) measures visual function from 0-1 with general health, general vision, competence, personality, family impact, and treatment subscales. The Pediatric Quality of Life Inventory (PedsQL) measures overall QOL from 0-100 with total, physical (e.g. sports), and psychosocial subscales. The Childhood Health Assessment Questionnaire (CHAQ) measures physical function (e.g. activities of daily living) from 0-3. Higher scores indicate better function and QOL in the CVFQ and PedsQL, respectively, but worse function in the CHAQ. Group differences were tested using the Student's T-Test.

Results: Of 51 children, 38 had JIA alone and 13 had JIA-U (Table 1). They were predominantly white (92%), non-Hispanic (96%), and female (84.%). Oligoarticular was the most common JIA subtype (33%), ANA was positive in 65%, and mean age at JIA diagnosis was 2.4 years (SD 0.99). There were no significant differences in the demographic or clinical characteristics of the groups.

CVFQ general vision and family impact subscales were significantly worse among children with JIA-U compared to those with JIA alone (0.83 vs. 0.93, $p=0.013$; and 0.83 vs 0.93, $p=0.004$, respectively). The CHAQ score was worse for children with JIA alone compared to JIA-U (0.38 vs 0.00, $p=0.009$). There were no significant differences in PedsQL scores.

Conclusions: Young children with JIA-U have worse visual function and impose a larger family burden, but have comparatively less physical limitation with activities of daily living than children with JIA alone. Emotional and labor-intensive burdens on families may be related to social interactions, appointments, and uncertainty of prognosis. Further studies are needed to characterize the impact of uveitis in young children with JIA.

TITLE: Oral APX3330 treatment reduces L-CNV lesions in preclinical mouse model and confirms Phase 2 DR/DME clinical dose with sufficient distribution to human retina using PBPK modeling

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Lachi Silva, R.E. Stratford, S.K. Quinney, T.W. Corson, M.R. Kelley, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|N. Lambert-Cheatham, Michigan State University, East Lansing, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Larissa Lachi Silva: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Lambert-Cheatham: Commercial Relationship: Code N (No Commercial Relationship) | Robert Stratford: Commercial Relationship: Code N (No Commercial Relationship) | Sara Quinney: Commercial Relationship: Code N (No Commercial Relationship) | Timothy Corson: Commercial Relationship(s);Indiana University School of Medicine:Code P (Patent);NIH:Code F (Financial Support) | Mark Kelley: Commercial Relationship(s);Indiana University School of Medicine:Code P (Patent);Apexian Pharmaceutical:Code C (Consultant);Ocuphire Pharma:Code C (Consultant);NIH/NEI/NCI:Code F (Financial Support)

ABSTRACT BODY:

Purpose: APX3330 is a small molecule inhibitor of Ref-1, a target involved in key vascular and inflammatory ocular disease processes including diabetic retinopathy (DR), diabetic macular edema (DME) and wetAMD. The purpose was to determine the efficacy of oral administration of APX3330 to reduce lesion size in a laser-induced choroidal neovascularization (L-CNV) mouse model and to develop a physiological-based pharmacokinetic (PBPK) model for retinal delivery of APX3330 to confirm dosing for a Phase 2 trial.

Methods: Following laser treatment, mice received twice daily gavages of 25 or 50 mg/kg APX3330 or vehicle for 14 days. Optical coherence tomography (OCT), fundoscopy, and 3-dimensional quantification of agglutinin stained CNV were performed. The Ocular Compartmental Absorption and Transit (OCAT™) model within GastroPlus 9.6 was used to build a mechanistic compartmental model accounting for APX3330 systemic absorption and retinal distribution in the human eye. ADMET Predictor™ 9.5 was used to model systemic distribution and clearance using physicochemical and biopharmaceutical properties. PBPK simulation results for single oral doses of APX3330 (60, 180, and 240 mg) were compared to plasma concentrations observed in multiple Phase 1 clinical trials. Simulations for retinal exposure using 480 and 600 mg total daily doses across different dosing regimens were also performed.

Results: At both 25 and 50 mg/kg doses, APX3330 reduced size of L-CNV lesions by >50%. No obvious signs of ocular toxicity were observed during treatment. PBPK model predictions matched reported human plasma concentrations of APX3330 after oral administration and demonstrated predictive capability of the developed model. Predicted retinal exposures were 13.5; 12.3; 15.4; 16.5 and 20.7 ug*h/mL after 200 mg TID, 240 mg BID, 300 mg BID, 480 mg QD and 600 mg QD, respectively.

Conclusions: Oral administration of APX3330 safely and effectively reduced neovascularization in an L-CNV preclinical model. The PBPK model resulted in important insights into delivery of orally administered APX3330 to the human retina with predicted human retina levels significantly higher than observed and required for efficacy in preclinical studies. These findings confirm the 600 mg dose BID for APX3330 in a planned DR/DME Phase 2 trial.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has significantly impacted surgical resident education. We sought to assess the impact of COVID-19 on ophthalmology resident training and wellness at the University of Washington through observing changes in volume of overnight on-call consults, resident clinics, and resident surgical cases, in addition to studying changes in sleep, activity, and resident wellness survey results.

Methods: A retrospective cohort study of ophthalmology residents at the University of Washington comparing clinical volumes, sleep and activity data recorded by a wrist actigrapher, and wellness surveys during a “pre-COVID” period from February 1st, 2020 to March 15 to the period of initial COVID response (“COVID period”) from March 16 to May 1st, 2020.

Results: The initial response to the COVID-19 pandemic resulted in a 64% decrease in resident clinic volume, 64% decrease in resident-surgical cases, and 50% decrease in on-call consult volume, see figure 1. The fraction of consults involving an open globe injury increased more than four-fold. Resident depersonalization as measured by Maslach Burnout Inventory decreased during the pandemic ($p=0.038$), see figure 2. Most residents experienced decrease emotional exhaustion and increased anxiety during the pandemic. There was no statistically significant change in recorded sleep or activity among residents before and during the pandemic.

Conclusions: The initial response to the COVID-19 pandemic at the University of Washington resulted in a large decrease in clinical, surgical, and on call volumes with mixed effect on ophthalmology resident well-being.

ABSTRACT BODY:

Purpose: To develop a normative model of the macular ganglion cell-inner plexiform layer (GCIPL) and evaluate its accuracy in prediction of visual field (VF) defects in patients with glaucoma.

Methods: Macular OCTs were acquired for 493 healthy and 37 glaucoma participants using the Spectralis OCT. GCIPL measurements from the healthy cohort were used to develop a normative model incorporating hierarchical cluster analysis, to identify locations with similar structural properties under considerations of normal variations in optic disc tilt position and aging characteristics. Glaucoma participants underwent 10-2 and 30-2 VFs using the Humphrey Field Analyzer, and GCIPL locations were binarized to VF-normal and VF-defective based on a pattern deviation cut-off of <2% for the corresponding VF location. Receiver operator characteristic (ROC) analyses based on the normative model were conducted to generate GCIPL cut-off values per cluster using Youden's criterion. Global and cluster-specific accuracy of the model was assessed by applying derived GCIPL cut-offs to individual locations and comparing areas under the ROC curves (AUROCs) respectively.

Results: The normative model resulted in 10 quasi-concentric clusters (Figure 1A) that largely co-locate despite various fovea to optic disc tilts, reflecting robust classification. The model demonstrated moderate global sensitivity and specificity in predicting VF defects from GCIPL thicknesses, at 0.75 and 0.76 respectively. AUROCs were significantly different between clusters ($P < 0.0001$, Welch's ANOVA), with central clusters demonstrating higher accuracy than peripheral clusters ($P = 0.009-0.04$, Figure 1B).

Conclusions: Normative models applying cluster analysis principles can predict VF defects from macular GCIPL measurements with moderate accuracy. However, spatial variability in peripheral macular locations were associated with poorer accuracies, suggesting that OCT alone may be insufficient to holistically predict macular function.

ABSTRACT BODY:

Purpose: Canada does not have published data on the incidence of visual impairment. Our goal was to determine the 3-year incidence of visual impairment (VI) in Canada and its risk factors.

Methods: Data from 23,973 adults taking part in the Canadian Longitudinal Study on Aging Comprehensive Cohort baseline and 3-year follow-up exams were included in this prospective 3-year cohort study. Inclusion criteria included being 45 to 85 years of age, community-dwelling, and living near one of the 11 data collection sites across 7 Canadian provinces. Presenting binocular visual acuity was measured using the Early Treatment of Diabetic Retinopathy Study chart. VI incidence was defined as the development at follow-up of visual acuity worse than 20/40 in those with acuity better than or equal to 20/40 at baseline. Logistic regression was used to account for the complex survey design.

Results: 3.99% (95% Confidence Interval (CI) 3.75, 4.25) of Canadian adults developed VI over a 3-year period. There was a high degree of variability in the incidence rates between Canadian provinces with a low of 1.42% in Manitoba and a high of 7.33% in Nova Scotia. Uncorrected refractive error was the leading cause. Risk factors for incident VI included older age (odds ratio (OR)=1.07, 95% CI 1.06, 1.07), Black race (OR=2.64, 95% CI 1.36, 5.14), lower household income (OR=1.73 for those making less than \$20,000 per year, 95% CI 1.24, 2.40), current smoking (OR=1.78, 95% CI 1.37, 2.32), and province.

Conclusions: Incidence of visual impairment is common in older Canadian adults, varies markedly between provinces, and is largely due to treatable causes. Risk factors for VI suggest sub-groups that may benefit from interventions to improve access to eye care.

ABSTRACT BODY:

Purpose: Rearing under high-intensity illumination produces a hyperopic shift in chicks and inhibits the development of form-deprivation myopia in chicks and primates. Recent studies also show that time spent outdoors is protective against the development of myopia in children. In this study, we examined the effects of 120 minutes of exposure to 500 and 1000 lux of bright illumination on axial length and choroidal thickness (ChT) in young adult participants.

Methods: Fifteen participants (mean age, 21.60 ± 2.16 years) with a mean refraction of -0.30 ± 0.39 D were exposed to 500 ($142 \mu\text{W}/\text{cm}^2$) and 1000 ($284 \mu\text{W}/\text{cm}^2$) lux of illumination for 120 minutes in a dark room on two different days, using a pair of custom-made light-emitting glasses. On each day, a series of ocular measurements were performed in the left eye before the light exposure (0 minutes), at 30, 60 and 120 minutes of light exposure, and 30 minutes after light offset to measure recovery. All ocular measurements were repeated on a third measurement day without any light stimulus in darkness (~ 5 lux). Axial length was measured using the Lenstar optical biometer and the changes in the subfoveal ChT were measured using the Cirrus 5000 optical coherence tomographer. Measurements are reported as mean \pm standard error mean and statistical comparisons were made using two-way ANOVA.

Results: Axial length increased significantly across all time points in darkness. Exposure to 500 and 1000 lux of continuous illumination resulted in a gradual and significant reduction in axial length at 30, 60, and 120 compared to darkness (change in axial length at 60 minutes: darkness, $+0.014 \pm 0.003$ mm; 500 lux, -0.007 ± 0.002 mm; 1000 lux -0.010 ± 0.004 mm, $p < 0.001$). Exposure to 500 and 1000 lux of illumination caused a significant thickening of the choroid (change in ChT at 60 minutes: darkness, -0.011 ± 0.006 mm; 500 lux, $+0.006 \pm 0.003$ mm; 1000 lux $+0.008 \pm 0.004$ mm, $p = 0.025$). None of the ocular changes were significantly different between the 500 and 1000 lux illumination levels ($p > 0.05$). All ocular changes recovered to normal within 30 minutes of light offset.

Conclusions: Our results show that exposure to mild- or moderate-intensity illumination can induce a significant reduction in axial length and thickening of the choroid in young subjects. Similar to animal models, these changes were found to be sensitive to the duration of light exposure.

SUBMITTER (NAME ONLY): Jack Phu

TITLE: Static automated perimetry using a new head-mounted virtual reality platform, Virtual Field, compared with the Humphrey Field Analyzer in glaucoma and optic nerve disease

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Phu, M. Kalloniatis, University of New South Wales, UNSW Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Jack Phu: Commercial Relationship(s);Virtual Field:Code F (Financial Support) | Michael Kalloniatis: Commercial Relationship(s);Virtual Field:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To compare the visual field outputs obtained using Virtual Field against the Humphrey Field Analyzer (HFA) in subjects with glaucoma or optic nerve head disease, and to determine its potential deployment as a portable, low-cost alternative for perimetric testing.

Methods: One eye (the eye with more severe disease) from 43 subjects with open angle glaucoma or optic nerve disease underwent testing using both Virtual Field and the HFA. Both devices presented Goldmann size III stimuli in the 24-2 test grid arrangement. Virtual Field uses a screen with a background luminance of 0.218 cd.m^{-2} , whereas the HFA uses a projection system with a background luminance of 10 cd.m^{-2} . All patients undertook three tests on each device in random order. We compared conventional global indices (mean deviation [MD], pattern standard deviation [PSD], "cluster" criterion pass/fail, Glaucoma Hemifield Test [GHT]), pointwise sensitivity and probability scores, and the overall number of defects found using each device, after averaging all indices across all three tests.

Results: MD and PSD were correlated between both devices (Fig 1). There were differences in the individual decibel values reported by each device due to the differences in background luminance and hence retinal adaptation. Bland-Altman analysis revealed a bias of 6.1 dB, with 95% limits of agreement between -1.8 to 14.0 dB, with the HFA results returning higher readings. 10 (23%) subjects showed more defects on the HFA, 3 (7%) had more defects on Virtual Field, and the others had no differences between devices. On average, the HFA identified 3 more defects on the pattern deviation map compared to Virtual Field. Using a combinatory criterion of PSD ($>2\text{dB}$), GHT (outside normal limits) and "cluster" cut-offs, there were no significant differences between devices in identifying the presence of disease (6 cases identified by only Virtual Field, 1 only by the HFA, 31 by both, and 5 by neither).

Conclusions: Virtual Field is a head-mounted perimeter that produces functionally indistinguishable results to the HFA, offering a low-cost, portable alternative to specialised clinic-based perimetry devices.

ABSTRACT BODY:

Purpose: The objective of this project was to describe the demographics and characteristics of ocular injuries among infants ages 0 to 12 months using data documented by the National Electronic Injury Surveillance System (NEISS) database from 2009 to 2019.

Methods: The NEISS Database was used to identify cases of ocular injury among the infant population (0-12 months) between 2009 to 2019. The NEISS Database is a collection of data regarding consumer product-related injuries in the United States derived from a representative probability sample of hospital emergency departments (ED) in the U.S. and its territories. The patient population was divided into three age subgroups (1-4 months, 5-8 months, 9-12 months), and statistical analysis was performed using IBM SPSS 23.

Results: In total, 21,013 cases of ocular injury in the infant population (0-12 months) were identified. Among infant ocular injuries, males (55%), the 9-12 months age group (54.9%), and Whites (45.3%) accounted for the plurality of cases by gender, age group, and race, respectively. Temporally, the plurality of injuries occurred on Sunday (17.4%) and in July (11.0%) with regard to day of the week and month of the year for all cases of ocular injury. The most common diagnosis in cases of infant ocular injury over the study time period was contusion, accounting for 45.8% of cases, which was nearly three times more common than the second most common diagnosis of dermatitis/conjunctivitis (16.6%). The vast majority of infant ocular injuries occurred at home (71.0%), and the three most commonly involved consumer products among the cases of ocular injury were detergents and chemicals (26.1%), toys (12.9%), and home furniture (10.9%). When stratifying ocular injuries by age, toys (12.9%) were the most commonly involved consumer product in the 1-4 months age group, while detergents and chemicals were the most commonly involved product in the 5-8 months and 9-12 months age groups. By gender, detergents and chemicals were the most common consumer product involved in ocular injury in both boys (23.6%) and girls (29.2%).

Conclusions: In the infant population studied (ages 0-12 months) in the ED, between 2009-2019, ocular injuries occurred most commonly in males, in the oldest age subgroup of 9-12 months, in Whites, and in July. The most common diagnosis for ocular injury was contusion, and the most commonly associated consumer product was detergents and chemicals.

TITLE: Vitrectomy for vitreous hemorrhage in infants with retinopathy of prematurity: clinical characteristics and anatomic outcomes

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Liao, T. Xu, G.B. Hubbard, P. Rao, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Albert Liao: Commercial Relationship: Code N (No Commercial Relationship) | Tan Xu: Commercial Relationship: Code N (No Commercial Relationship) | G Hubbard: Commercial Relationship: Code N (No Commercial Relationship) | Prethy Rao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a sight-threatening illness due to abnormal development of retinal vasculature in premature infants. While non-clearing vitreous hemorrhage (NCVH) in ROP patients is associated with progression to late-stage disease, controversy exists regarding the management, surgical timing, and outcomes of these cases. We performed a retrospective, observational clinical study to evaluate patient characteristics, anatomical outcomes, and visual outcomes in infants with ROP who underwent pars plana vitrectomy (PPV) for NCVH.

Methods: This is a single institution, retrospective chart review of ROP infants who underwent PPV for NCVH from November 1st, 1998 to April 30th, 2019. Data collected included postmenstrual age (PMA) at time of NCVH diagnosis, ROP status at time of VH, previous treatments, time between diagnosis of NCVH and PPV, intraoperative findings, and anatomic outcomes.

Results: Seven eyes of 7 patients were included (table 1). Median (range) gestational age was 25.0 (23.0-27.0) weeks. Median birth weight was 652.0 grams (445.0-822.0). PMA at the time of NCVH diagnosis was 37.6 weeks (31.0-45.3). At the last preoperative visit, all eyes were noted to have attached retinas by clinical exam. The median time to PPV from diagnosis of NCVH was 37.0 days (5.0-45.0). Median post-menstrual age (PMA) at PPV was 40.8 (36.3-47.0) weeks. The overall median time from NCVH diagnosis to PPV was 37.0 days (5.0-45.0). Intraoperatively, 3 of 7 eyes (42.9%) were noted to be detached. Median time from NCVH diagnosis to PPV was 42.0 days (5.0-45.0) in eyes with retinal detachments (RD) versus 29.0 days (20.0-37.0) in eyes without RDs. Five of 7 (71.4%) eyes remained attached at the last follow up. Of the 4 eyes with documented visual acuity upon follow-up, 2 eyes exhibited fixation behavior and 2 eyes did not exhibit fixation behavior. The median follow up time was 27.0 months (1.0-152.0).

Conclusions: NCVH in ROP requiring PPV is rare. These eyes may be at higher risk for developing a RD, particularly if there is an extended duration of time between VH diagnosis and PPV. The visual prognosis for these patients remains poor despite surgical intervention.

ABSTRACT BODY:

Purpose: To evaluate the feasibility of anterior segment optical coherence tomography (AS-OCT) for the measurement of anterior chamber (AC) cells in children with uveitis and to evaluate different AS-OCT acquisition modes for measuring AC cells.

Methods: We prospectively enrolled children younger than 18 years of age with histories of uveitis involving the anterior chamber and healthy children without histories of uveitis or intraocular surgery as controls. All children underwent a comprehensive eye examination and grading of AC cell using the Standardization of Uveitis Nomenclature (SUN) grading system. All were imaged using the Optovue Avanti RTVue XR AS-OCT. Each underwent AS-OCT scans using two acquisition modes: a single cross-sectional line scan and 8 cross-sectional line scans in an asterisk formation. Two independent, masked graders manually counted cells (represented by hyperreflective foci in AS-OCT images). Rater agreement was assessed using intraclass correlation (ICC).

Results: We evaluated 59 eyes of 30 children with histories of uveitis (mean age 12.1 years, range 3-17 years; 19 [63%] females) and 40 eyes of 20 control children (mean age 10.9 years, range 4-17 years; 9 [45%] females). Of 59 eyes with uveitis, 32 (54%) had Grade 0 cell; 12 (20.3%) had 0.5+ cell; 5 (8.5%) had 1+ cell; 8 (13.6%) had 2+ cell; and 2 (3.4%) had 3+ cell on clinical examination. For line scans, mean OCT cell counts for each grade were: Grade 0, 0.17 (range 0-5); 0.5+, 0.88 (0-3); 1+, 2.9 (0-7); 2+, 9.7 (0-25); and 3+, 25.8 (17-35). For asterisk formation scans, mean OCT cell counts for each grade were: Grade 0, 0.11 (range, 0-4); 0.5+, 0.49 (0-3); 1+, 1.4 (0-6); 2+, 5.5 (0-18); and 3+, 22.0 (12-31). ICC of graders for line and asterisk formation scans were 0.87 and 0.90, respectively, with no significant difference between acquisition modes (95% confidence interval -0.04 to 0.14). No eyes of control children had cells on AS-OCT images.

Conclusions: Quantification of AC cell in children with uveitis is feasible with AS-OCT and has excellent reliability between different graders. Given the similarity in cell counts between line and asterisk formation scans, AS-OCT line scans may be a more suitable option given the relative speed of image acquisition compared to asterisk formation scans, especially in children.

ABSTRACT BODY:

Purpose: To investigate the myopia control efficacy of two new designs of spectacle lenses with concentric rings of contiguous aspherical lenslets in a 2-year clinical trial.

Methods: One hundred and seventy Chinese children (aged 8 to 13 years old, myopia between -0.75D and -4.75D) with myopia were randomly assigned to wear one of the three spectacle lenses: spectacle lenses with highly aspherical lenslets (HAL), spectacle lenses with slightly aspherical lenslets (SAL), or control single-vision lenses (SVL) for 2 years. Spherical equivalent of cycloplegic autorefraction (SER) and axial length (AL) were measured on a six-monthly basis. Wearing time was assessed using a questionnaire at each visit.

Results: A total of 157 children completed the 2-year study, of which, 54, 53, and 50 were in the HAL group, SAL group, and SVL group, respectively. After 2 years, the mean SER and AL (\pm SEM) of the SVL control group increased by -1.46 ± 0.60 D and 0.69 ± 0.26 mm, respectively. Compared with SVL, spectacle lenses with aspherical lenslets significantly slowed myopia progression (HAL, -0.66 ± 0.08 D, difference 0.80 D; SAL, -1.04 ± 0.06 D, difference 0.42 D) and axial elongation (HAL, 0.34 ± 0.03 mm, difference 0.35 mm; SAL, 0.51 ± 0.03 mm, difference 0.18 mm; all $p < 0.001$). In children who wore their lenses every day for at least 12 hours per day, the reduction in SER and AL, compared to SVL group, was greater at 0.99 D ($p < 0.001$) and 0.41 mm ($p = 0.03$) for HAL ($n = 32$) and at 0.57 D ($p = 0.04$) and 0.26 mm ($p = 0.02$) for SAL ($n = 28$), respectively.

Conclusions: Spectacle lenses with aspherical lenslets were effective in slowing myopia progression and axial elongation in children over a two-year period, compared with SVL. Myopia control efficacy was higher in children who wore their lenses full-time (≥ 12 hours/day) and spectacle lenses with highly aspherical lenslets.

ABSTRACT BODY:

Purpose: Targeting the melanocortin system, which plays a key role in promoting resolution of the inflammatory process, may be protective against ocular disease. The studies presented here investigated the effects of 2 melanocortin receptor pan-agonists, PL8331 and PL9654, delivered by intravitreal (IVT) injection in mouse models of retinopathy.

Methods: In Study 1, mice received 40-mg/kg intraperitoneal streptozotocin once daily for 7 days to induce hyperglycemia. They were then left untreated or were given uniocular 1- μ l IVT injections of 3.3 μ M PL8331 at 1, 4, 8, 12, and 16 weeks following hyperglycemia induction. At 17 weeks, retinas were evaluated for retinal ganglion cell (RGC) density and vascular endothelial growth factor (VEGF) concentration.

In Study 2, mice received 5 uniocular laser burns to the retina to induce choroidal neovascularization. They then received 1 of 6 IVT treatments immediately after laser burn and again on Day 15: vehicle, anti-VEGF antibody, 10 or 100 μ M PL8331, or 10 or 100 μ M PL9654. Fundus fluorescein angiography and immunohistochemistry were used to quantify the extent of leakage, neovascularization, and fibrosis.

Results: In Study 1, RGC density was significantly reduced and VEGF concentrations were significantly increased in hyperglycemic mice versus normal glycemic controls ($P \leq 0.05$ and $P < 0.005$, respectively), but there were no statistically significant differences in RGC density or VEGF concentration between retinas of hyperglycemic mice treated with PL8331 and healthy control retinas. In Study 2, the extent of leakage, neovascularization, and fibrosis were significantly reduced ($P < 0.05$) in mice treated with anti-VEGF antibody or either dose of PL8331 or PL9654 compared with vehicle.

Conclusions: IVT delivery of the melanocortin agonists PL8331 and PL9654 significantly reduced several markers of retinal damage in mouse models of eye injury, supporting the continued development of PL8331 and PL9654 for the treatment of ocular disease.

ABSTRACT BODY:

Purpose: Controversy exists as to the exact autoimmune pathophysiology of Stevens-Johnson syndrome/toxic epidermal necrolysis (SJS/TEN). Because atopy is a common immune disorder, we conducted a retrospective, observational chart review to determine the incidence of components of the atopic triad (AT; atopic dermatitis, asthma, or allergic rhinitis) in patients with history of SJS/TEN and then examined if a difference exists in acute ocular outcomes in SJS/TEN patients who have AT vs those who don't have AT.

Methods: Patients with history of any of the AT constituents were identified using the Research Patient Data Registry of Mass General Brigham (MGB). A combined search was then run to identify all SJS/TEN patients within this group. Diagnosis of SJS/TEN was confirmed by biopsy report or exam by dermatology or burn service as documented in the medical record. Chart review was done to confirm clinical diagnosis of the atopic conditions and that they were documented as occurring prior to the diagnosis of SJS. The primary outcome was the worst acute ocular severity (AOS) score reached during the acute SJS hospitalization. All statistics were performed in R version 4.0.2. Means with standard deviations are presented for ordinal variables.

Results: Twenty-three unique patients with atopic conditions and confirmed history of SJS/TEN were included. Four patients had a history of atopic dermatitis, 10 of allergic rhinitis, and 18 of asthma.* One hundred seventy seven SJS/TEN patients without history of any atopic conditions were included as controls. One hundred fifty-five of these patients had AOS scores available for analysis. Worse mean AOS score was seen in those with any component of the AT vs controls ($p=0.01542$). The prevalence of atopy in this SJS population exceeded that in the general MGB population ($P < .0001$).

*Total number of unique patients is fewer than the sum of the groups as several patients had more than one atopic condition.

Conclusions: In this study, there was worse acute SJS-induced ocular disease in those with a history of atopy compared to those without. A history of atopy may exist at a higher-than-expected rate in SJS/TEN. The underlying mechanisms to explain these associations are not known. Plausible contributory factors may include baseline immune dysregulation, increased inflammatory markers, and an IgE mediated component of disease onset or exacerbation in SJS/TEN.

ABSTRACT BODY:

Purpose: Assessment of regional visual field (VF) changes typically requires qualitative, subjective analysis by a clinician. A type of unsupervised machine learning known as archetypal analysis (AA) identifies objective, quantitative patterns of VF loss in glaucoma. We investigated the use of AA to quantify and monitor disease-specific VF defects in idiopathic intracranial hypertension (IIH).

Methods: We performed AA within the R statistical environment on 2,862 VFs prospectively collected from 165 participants in the IIH Treatment Trial. We decomposed each study eye VF into a weighted mixture of the ATs (total weight =1.0). We decomposed VFs from 61 control eyes according to the IIH ATs to define a minimum AT weight change of 9% as clinically relevant. We developed an AT score based on the cumulative changes in weights for all ATs, which showed recovery, decline or no change in visual function from baseline.

Results: Using a 10-fold cross-validation model, we identified 14 IIH-specific archetypes that were distinguishable from controls (Figure 1). AT scores correlated strongly with change in MD ($R^2=0.80$, $p<0.001$). Mean AT scores distinguished treatment failures from non-treatment failures ($p<0.001$). The treatment benefit of acetazolamide was best reflected in the relative weight of AT2 (a near-normal AT) at trial outcome (0.27, 95% confidence interval (CI): 0.24-0.30 for acetazolamide, vs. 0.21, 95%CI: 0.18-0.24 for placebo, $p=0.007$). Study eyes with AT2 weight $\geq 44\%$ (≥ 1 SD above mean) at baseline had a better visual outcome based on AT2 weight at 6 months ($p<0.001$); however, a significant treatment effect for acetazolamide was only demonstrable among eyes with AT2 weight $<44\%$ at baseline ($p=0.034$; Figure 2). In addition, AA revealed residual VF defects in 70 eyes deemed normal ($MD \geq -2.00$) at 6 months, which frequently included enlarged blind spots, step, and arcuate defects.

Conclusions: AA quantifies changes in regional IIH-specific VF defects over time, thus increasing the utility of VF analysis. AT2 weight at baseline identifies patients who may respond best to treatment, suggesting that AA can provide prognostic value. Further, AA uncovers residual defects not otherwise revealed by global VF indices, such as MD.

TITLE: A smart vitrector equipped by a fiber-based OCT sensor mitigates simulated iatrogenic retinal injuries during vitrectomy in pigs

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Boutopoulos, A. Abid, F. Rezende, R. Duval, Universite de Montreal, Montreal, Quebec, CANADA|F. Rezende, R. Duval, Hopital Maisonneuve-Rosemont, Montreal, Quebec, CANADA|C. Boutopoulos, A. Abid, Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Christos Boutopoulos: Commercial Relationship(s);United States Provisional Patent Application No. 63/109,040,:Code P (Patent) | Alexandre Abid: Commercial Relationship(s);United States Provisional Patent Application No. 63/109,040,:Code P (Patent) | Flavio Rezende: Commercial Relationship(s);United States Provisional Patent Application No. 63/109,040,:Code P (Patent) | Renaud Duval: Commercial Relationship(s);United States Provisional Patent Application No. 63/109,040,:Code P (Patent)

ABSTRACT BODY:

Purpose: The occurrence of iatrogenic retinal breaks (IRB) in pars plana vitrectomy (PPV) is a complication that compromises the overall efficacy of the surgery. A subset of IRB occurs when the retina (rather than the vitreous gel) is cut accidentally by the vitrector. We hypothesise the a smart vitrector, equipped by a fiber-based optical coherence tomography (OCT) sensor, can detect intraoperatively the onset of IRB and activate promptly a PPV machine response to prevent them. We developed such a system and performed PPV on pigs to validate it.

Methods: We fabricated the smart vitrectors by attaching a miniaturised fiber-based OCT sensor (125 µm in diameter) on commercial vitrectors (25G). The OCT sensor was appropriately positioned to detect undesirable retina displacement towards the vitrector orifice (i.e., IRB onset). The smart vitrector was connected to a commercial vitrectomy machine as in standard PPV. We used a customized OCT machine and a built-in algorithm to process the intraoperative signal. The system response time to an IRB onset was measured and compared to that of the average surgeon. Finally, two surgeons validated its ability to prevent simulated IRB (i.e., vitrector manipulations aiming to “bite” attached or detached retina) by performing PPV in 2 two pigs. Note that the system requires no signal interpretation by the surgeons.

Results: We found that the response time of the system (28.9 ± 6.5 ms) is 12-times faster compared to that reported for intraocular maneuvers performed by surgeons ($p < 0.0001$). We show that an additional 2-times improvement can be attained with minor technical modifications that require proprietary access to the vitrectomy machine that was used. Ex-vivo validation (porcine eyes) showed that the system prevents 78.95% (15/19) (95% CI: 54.43 – 93.95) of simulated IRB, while in-vivo validation showed that the system prevents or mitigates 70.37% (38/54) (95% CI: 56.39 – 82.02) of simulated IRB.

Conclusions: Our results are consisted with the hypothesis that an OCT – sensor attached to the vitrector can prevent IRB by providing intraoperative feedback to the PPV machine. Importantly, the use of the smart vitrector with its safety mechanism requires no modifications of the established PPV procedure. It can mitigate a significant proportion of IRB and thus improve the overall efficacy of the surgery.

ABSTRACT BODY:

Purpose: Retinal defocus maps can provide clinically relevant information for diagnosis and monitoring of disease. We investigated a novel construction of defocus maps of the retina using novel analyses of slit-scanning ophthalmoscopy data.

Methods: The CLARUSTM 700 (ZEISS, Dublin, CA) slit-scanning ophthalmoscope projects broad stripes onto the retina and records images of stripe illuminations. Using prototype software this stripe scanning was done with strongly overlapping stripes (1-pixel step) which can be converted into digital structured illumination using sinusoidal weighted sums. Sinusoidal illumination has the special property of staying a sine wave under defocus with changing amplitude. This amplitude change is a direct measure of optical defocus and can be analyzed to produce high-res. retinal defocus map, especially when different frequencies of illumination are used. We demonstrate the validity of the method on test-object and real eye data.

Results: Defocus maps generated from the sinusoidal illumination show both the optical defocus due to the optics, and the aberrations of the eye and retinal height of structures. The sine-amplitudes as a function of frequency represent the illumination modulation transfer function and a width-analysis generates a retinal defocus map. The defocus map of a ridged test-object (Fig.1) clearly shows the different height features (e.g. ridges and plateaus), and the defocus map of a human eye (Fig. 2) shows features with expected retinal elevations (e.g. vessels, fovea, optic nerve). Quantitative analysis of defocus as height is difficult as it is not clear at which depth the light is reflected.

Conclusions: Overlapping stripe illumination provides an information rich dataset which can be analyzed in many different ways. Here we showed that conversion into structured illumination allows the direct analysis of the illumination defocus, which is a direct measure of the optical properties of the eye and the retinal height profile. This analysis could enhance the detection of retinal elevations with clinical significance, including tumors, retinal detachments, or staphylomas.

ABSTRACT BODY:

Purpose: Given the role of chronic inflammation in the pathogenesis of age-related macular degeneration (AMD), montelukast might have a potential protective impact on the development of neovascular AMD (nAMD) through an anti-inflammatory effect including its selective antagonism for cysteinyl leukotriene receptor 1 (CysLTR1). The proposed case-control study aimed to evaluate the association of oral montelukast with reduced odds of nAMD development.

Methods: The index study was conducted using Institutional Cohort Finder tool, and included 1913 patients who were diagnosed as nAMD (ICD: H35.32 and 362.52) and visited the Byers Eye Institute at Stanford from 1991 to 2020, and 1913 age- and gender- matched control subjects without nAMD. The subjects were assessed for the presence of nAMD risk factors (e.g. smoking history, Caucasian race, hypertension, hyperlipidemia) and for the use of specific medications (e.g. oral montelukast, nasal or oral cromolyn [mast cell stabilizer], oral steroids, oral NSAIDs, oral H1-antihistamines). Then, the odds ratio (OR) calculations using multivariable conditional logistic regression analyses were performed in order to assess the effect of oral montelukast use on reducing the odds of nAMD development, adjusting for possible risk factors.

Results: A total of 47 (2.5%) nAMD cases were identified to have a history of oral montelukast use prior to nAMD diagnosis, compared to 84 (4.4%) controls (crude OR: 0.54, P=0.0001). In the multivariable analysis, montelukast usage was significantly associated with reduced odds of nAMD (adjusted OR: 0.57, P=0.004). On the other hand, Caucasian race (adjusted OR 1.52, P<0.0001), history of smoking (adjusted OR: 1.91, P<0.0001), and NSAIDs use (adjusted OR: 0.75, P=0.005) were found to have significant relationship with increased odds of nAMD.

Conclusions: The study results suggested that oral montelukast consumption is linked to reduced odds of nAMD development. Future prospective cohort studies is needed to validate these findings.

TITLE: Identification of cis-regulatory elements that allow for AAV-based Müller glial-specific labeling and manipulation in the retina

SESSION TITLE: Animal imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Lin, C. Chan, M. Wu, A. Davis, S. Wang, Ophthalmology, Stanford University School of Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Cheng-Hui Lin: Commercial Relationship: Code N (No Commercial Relationship) | Candace Chan: Commercial Relationship: Code N (No Commercial Relationship) | Man-Ru Wu: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Davis: Commercial Relationship: Code N (No Commercial Relationship) | Sui Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Müller glial cells (MG), the major type of glia in the retina, provide structural and functional support to retinal neurons, and play important roles in a variety of retinal diseases. Recent advances in cell reprogramming also suggest that regeneration of desired neurons from MG in mammalian retina may offer promising cues for retina diseases. To study the function of MG and stimulate their regeneration, developing the molecular tools that allow for easy access of MG in vivo in mammalian retina are of fundamental importance. Adeno-associated viruses (AAVs)-based tools that can specifically label MG have been developed. However, there are critical limitations. First, the commonly used GFAP promoter often responds to disease insults in MG, leading to uneven expression under control and diseases conditions. Second, AAVs that can direct gene manipulation via the Cre-LoxP system in MG are not available. The goal of this study is to overcome these limitations, and develop engineered AAVs that allow for MG-specific labeling and manipulation in mammalian retina.

Methods: We first searched for cis-regulatory elements (CREs) that could drive MG-specific expression and were unresponsive to disease insults. We then integrated these CRMs into AAV vectors to drive EGFP or Cre/CreER expression, and tested their specificity in vivo in mice. The neurotoxin NMDA was used to investigate whether these CRMs respond to injuries. We compared the specificity of the identified CRMs with the published GFAP promoter in this study.

Results: We identified multiple novel CRMs that can direct expression specifically in MG in vivo in mice. When integrated into AAVs, one of these CRMs, namely MG1, was able to drive MG-specific expression, and its activity was not affected in the presence of NMDA. In addition, the AAV-MG1-CreER virus can activate the tdTomato reporter gene specifically in MG in a tamoxifen and Cre-dependent manner in Ai9 mice. More importantly, the MG1 CRM was only 93bp, which does not impact the packaging capacity, allowing for additional genes in AAVs.

Conclusions: We identified novel MG-specific cis-regulatory elements, and developed novel AAV tools that can specifically label and manipulate MG in an injury-independent manner in vivo. These tools can significantly benefit the study of MG function and regeneration in mammalian retina.

ABSTRACT BODY:

Purpose: We have found that glaucomatous perimetric defects can show good agreement with structural defects, and that an elongated sinusoidal stimulus can be oriented based on structural defects to identify scotomas. Here we extend this finding, by testing angioscotomas in healthy eyes.

Methods: Right eyes of healthy adults were tested with a DLO (Digital Light Ophthalmoscope, Aeon Imaging, Bloomington IN) which gathered fundus images during stimulus presentation to allow registration of eye movements. The first stimulus was the size III perimetric stimulus (circle at top in Figure 1). Thresholds were measured at 247 locations in a 13 x 19, 0.5°-interval grid from 11° to 17° horizontally, and -3° to +6° vertically. A ZEST algorithm used 6 trials to estimate contrast threshold at each location. The fundus images were used to infer retinal stimulus location on each trial. Three custom stimuli were developed, each being the first derivative of a Gaussian (D1) times an orthogonal Gaussian: "Small" had peak spatial frequency of 1.0 cycle/deg (cpd) and orthogonal standard deviation (SD) = 1°; "Medium", had peak 1.0 cpd and SD = 2°; "Large" had peak 0.25 cpd and SD = 4°. Each D1 stimulus was used to measure contrast threshold at 33 locations in an 11x3, 0.5°-interval grid from 11° to 16° horizontally and 4° to 5° vertically, chosen on the basis of size III results and anatomical information.

Results: Findings for one participant are shown; the same pattern was observed for the other participants. When the size III stimulus had Weber contrast > 200% it was seen unless it fell on the optic disc, a region between the disc and the vasculature, or on larger vessels (Fig. 1, bottom). When maximum likelihood estimation was used to estimate contrast sensitivity for local regions, an angioscotoma was seen with an orientation near -45° (Fig. 2, top). The D1 stimuli were therefore oriented at -45°, and results were plotted as "defect depth" (Fig. 2, bottom). Locations in color have contrast sensitivity below the mean contrast sensitivity for that retinal region. All three stimuli revealed a scotoma.

Conclusions: We confirmed our prior finding that oriented sinusoidal stimuli can be effective for identifying mild scotomas, and extended it to larger stimuli. The use of oriented stimuli holds promise for structure-guided perimetry, and results are consistent with our models of cortical pooling.

ABSTRACT BODY:

Purpose: Inherited retinal disorders (IRD) are challenging to diagnose because of genetic heterogeneity and overlapping phenotypes. Genetic testing helps determine the underlying molecular pathophysiology, confirms the clinical diagnosis, estimates the risk of recurrence, and determines possible eligibility for future gene-based therapies. We report a case of a patient with two previously unreported mutations in KCNV2, a gene strongly linked to CDSRR.

Methods: Ocular assessment was done, which included visual acuity assessment, slitlamp, and dilated fundus examination. Magnetic resonance imaging, full-field electroretinography (ffERG), and optical coherence tomography were done. Whole blood was obtained, DNA extracted, and genetic testing was performed through the My Retina Tracker Program of Blueprint Genetics, which screened 285 genes for disease-causing mutations implicated in IRDs.

Results: An 8-year old Chamorro female presented with congenital nystagmus, high myopia progression, and preferential right gaze since infancy. Medical and family histories were unremarkable. Ocular exam showed BCVA of 20/200, myopic fundus, and thin macula in both eyes. ffERG was consistent with cone dystrophy. Neurologic workup was unremarkable. The IRD gene panel test showed the patient was compound heterozygous for two nonsense mutations in KCNV2: c.153T>A, p.(Tyr51*) and c.625G>T, p.(Glu209*). Tyr51* is absent in the Genome Aggregation Database control population cohort while one individual is heterozygous for Glu209*.

Conclusions: To our knowledge, this study is the first to identify these two nonsense mutations in KCNV2 in a patient with CDSRR. Both mutations are predicted to lead to loss of normal protein function either through protein truncation or nonsense mediated decay. KCNV2 encodes the voltage-gated potassium channel subunit Kv8.2. Deficiency of Kv8.2 can influence the photoreceptor membrane potential and is thought to cause the visual symptoms of patients. Identifying these novel mutations highlights the value of genetic testing, especially in underrepresented minorities such as Asia Pacific Islanders, as these guided the clinical management and anticipation of disease progression.

TITLE: Joint ILM and RPE segmentation confidence map improves macular thickness analysis for low-cost OCT

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Zacks, H. Bagherinia, C. Leahy, T. Shagam, S. Bello, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gabrielle Zacks: Commercial Relationship(s);Carl Zeiss Meditec Inc:Code E (Employment) | Homayoun Bagherinia: Commercial Relationship(s);Carl Zeiss Meditec Inc:Code E (Employment) | Conor Leahy: Commercial Relationship(s);Carl Zeiss Meditec Inc:Code E (Employment) | Taylor Shagam: Commercial Relationship(s);Carl Zeiss Meditec Inc:Code E (Employment) | Simon Bello: Commercial Relationship(s);Carl Zeiss Meditec Inc:Code E (Employment)

ABSTRACT BODY:

Purpose: The robustness of macular thickness analysis (MTA) depends on the performance of the inner limiting membrane (ILM) and retinal pigment epithelium (RPE) segmentation. With a low-cost OCT, multiple scans are acquired to increase the probability of a successful MTA. This abstract proposes a method to generate a joint ILM/RPE segmentation confidence map to automatically select the most reliable scans for analysis.

Methods: A low-cost OCT prototype system (ZEISS, Dublin, CA) and a CIRRUSTM HD-OCT 5000 (ZEISS, Dublin, CA) imaged 43 patients (70 eyes) with pathologies, including age-related macular degeneration. On the low-cost device, each eye was imaged 2-3 times using a 5.78x7 mm OCT volume capturing 512 A-scans/B-scan and 128 B-scans with 2.77 mm of depth. A 6x6 mm scan with the same density was also captured on CIRRUS.

The ILM and RPE layers were segmented in all images acquired with the low-cost device. A confidence map for each layer was generated from the processed image at each segmentation point. The algorithm was trained using maps data classified as high or low confidence, using a threshold to generate likelihood functions for Bayesian inference. The joint segmentation confidence maps (JSCM) of each set of OCT volumes were created by a posterior probability using the likelihood functions (Fig 1a). The ETDRS grid has 3 concentric circles of 0.5, 1.5, and 2.89 mm radius placed at the fovea center (Fig 1b). The confidence index for a scan was calculated by averaging the JSCM over the full grid.

From 215 scans on the low-cost device and JSCM, 70 high and 70 low-confidence scan MTAs of the same eyes (no scan overlap) were compared to 70 baseline CIRRUS MTAs of the same eyes.

Results: Table 1 shows the correlation and Bland-Altman agreement for each ETDRS subfield between the low-cost OCT and CIRRUS MTA. There was a dramatic improvement when high confidence scans were used vs. low confidence scans.

Conclusions: We demonstrated a joint ILM/RPE segmentation confidence method that shows the best scans for MTA. Multiple scans of the same eye can be acquired to increase the probability of acquiring a high confidence scan. Improved MTA in a low-cost device is important for detection and management of retinal diseases.

ABSTRACT BODY:

Purpose: To characterize the prevalence and progression of macular edema in minimal to moderate non-proliferative diabetic retinopathy (DR) using measurements of tissue optical reflectivity (OCT-Leakage).

Methods: Seventy-four eyes from 74 diabetic DR type 2 patients were imaged annually during a 3-year follow up with the CIRRUS™ HD-OCT 5000 with AngioPlex (Zeiss, Dublin, CA) using the “Angiography 6mmx6mm” protocol. Forty healthy eyes from 40 control volunteers were also imaged on a single visit.

OCT-A structural data was segmented using an in-house segmentation algorithm. OCT-Leakage, an algorithm to detect sites of low optical reflectivity (LOR) was applied to the full retina and to each retinal layer. Extracellular fluid was measured by the LOR area ratio, which stands for the fraction of the number of A-scans with LOR and the total number of A-scans, within the considered area. DRCR.net standards were used to identify eyes with subclinical (SCME) and clinical macular edema (central involved macular edema - CIME).

Results: The 74 eyes from 74 patients were classified using the ETDRS severity scale, Grade 10 to 20 (n=23), 35 (n=31) and 43 to 47 (n=20).

CIME was found in the first visit in 8.7% of eyes in ETDRS group 10-20, 9.7% of eyes in ETDRS group 35 and 15.0% of eyes in ETDRS group 43-47. In the eyes with increased central retinal thickness (CRT), the inner nuclear layer (INL) is the layer showing most frequent increase in thickness (52.9%). In the eyes with CIME at baseline, there is a strong correlation between the INL OCT-Leakage LOR (LOR-INL) and CRT value differences from V01 to V04 (Spearman rho=0.73, p-value=0.03). The changes in CRT and LOR-INL occur in parallel and are characterized by frequent fluctuations. The variations observed in the LOR-INL showed a much wider range well demonstrated by the standard deviation of the measurements of the average value (The Table).

Conclusions: Eyes from diabetic patients in the initial stages of DR with different ETDRS retinopathy grading shows similar prevalence of macular edema, showing that it increases only moderately with severity of the retinopathy. OCT-Leakage measurements of INL correlate with the presence of CIME and its evolution over a series of 4 visits during a 3-year period of follow up, showing that its course is characterized by frequent fluctuations.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) has always been considered a microvascular disease, but it has been suggested that neurodegeneration also plays a key role in this complex pathology. In the context of a 5-year prospective longitudinal study, we evaluated the progression of DR neurodegenerative events and its correlation with microvascular events and disease severity progression.

Methods: 142 patients with type 2 diabetes (T2D) and mild NPDR (ETDRS grades 20 or 35) were followed in a 5-year longitudinal study. Ophthalmological examinations were performed at baseline, 6-months and annually. Optical coherence tomography (OCT) was performed to evaluate average thickness of the ganglion cell layer (GCL). An aged-matched population of 58 healthy individuals was evaluated with OCT as a control for layer segmentation. ETDRS and severity progression was assessed in T2D individuals by grading of 7-fields CFP performed at the initial and last visits. Microaneurysm turnover (MAT) was evaluated using the RetMarkerDR.

Results: At baseline GCL thickness ($80.06 \pm 7.71 \mu\text{m}$) in T2D individuals was significantly reduced when compared to controls ($82.67 \pm 5.46 \mu\text{m}$, $p=0.0201$), indicating the presence of neurodegenerative changes since in the initial stages of retinopathy (ETDRS 20 and 35). Ganglion cell layer average thickness remained stable through the 5-year period in T2D individuals, showing no significant associations with baseline ETDRS, severity progression or MAT (Table 1).

Conclusions: Neurodegeneration, represented by GCL thinning, is present since the initial stages of non-proliferative DR, however it does not progress significantly over a 5-year period and is independent of the microvascular alterations (considering MAT), ETDRS grade and DR severity progression.

ABSTRACT BODY:

Purpose: Analysis of inter-reader reliability of structural biomarkers for intermediate age-related macular degeneration (iAMD) based on the observational European multi-center study MACUSTAR (ClinicalTrials.gov: NCT03349801).

Methods: For the analysis of the inter-reader repeatability of discrete features (measured by Cohen's kappa), double gradings of maximum drusen size, presence of pigment epithelium detachment (PED), reticular pseudodrusen (RPD) and vitelliform lesions were performed by two independent readers. The overlap (Dice similarity coefficient [DSC]) of retinal multilayer segmentation was compared between readers as well as readers and a deep-learning (DL) based segmentation model. Mixed-effects models were fitted to data from each retinal layer with the DSC as dependent variable and patient as random intercept term to compare the different pairings (R1-vs.-R2; R1-vs.-DL; R2-vs.-DL), which were included as independent variable.

Results: For the discrete parameters (based on 168 study eyes) almost perfect agreement was obtained for the presence of PED (Cohen's kappa = 0.87 [0.69–1.00]), while agreement for presence of RPD (0.75 [0.63–0.87]) and vitelliform lesions (0.65 [0.39–0.91]) was substantial and moderate, respectively. For multilayer segmentation, the inter-reader-overlaps (R1-vs.-R2) were comparable between the retinal-nerve fiber layer (RNFL) (DSC estimate [95% CI] of 0.85 [0.80–0.90]), the outer nuclear layer (ONL) (0.82 [0.69–0.94]), the inner photoreceptor segments (IS) (0.78 [0.67–0.90]) and the retinal-pigment-epithelium-drusen complex upper segment (RPEDC-upper) (0.64 [0.52–0.77]) and lower segment (RPEDC-lower) (0.76 [0.66–0.85]). For nearly all retinal layers the reader-DL-segmentation-overlap was overall similar to the inter-reader-overlap ($p>0.05$). Only the R2-vs.-DL-overlap for the inner plexiform layer (IPL) (+0.03 [0.00–0.06], $p=0.04$), the RPEDC-upper (+0.07 [0.03–0.11], $p=0.002$) and the RPEDC-lower

segment appear to be minimally worse than the inter-reader-overlap.

Conclusions: Qualitative and quantitative imaging biomarkers exhibited moderate to perfect agreement among readers. Fully-automated DL-based image segmentation provides comparable results in terms of retinal multilayer segmentation. Analysis of inter-reader variability will be important to establish robust structural endpoints for future interventional clinical trials in iAMD eyes.

TITLE: Emmetropic, but not myopic human eyes distinguish positive defocus from calculated blur

SESSION TITLE: Effects of Light Intensity and Blur on Refractive Development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Swiatczak, F. Schaeffel, Institute of Molecular and Clinical Ophthalmology Basel (IOB), Basel, SWITZERLAND | F. Schaeffel, Eberhard Karls Universitat Tübingen, Tübingen, Baden-Württemberg, GERMANY |

Commercial Relationships Disclosure (Abstract): Barbara Swiatczak: Commercial Relationship: Code N (No Commercial Relationship) | Frank Schaeffel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is well established that defocus blur imposed by positive lenses induces hyperopia development while blur imposed by diffusers induces deprivation myopia. While it is known that such ocular growth changes are controlled by the retina, it is unclear whether the retina can distinguish between both conditions when the magnitude of blur is matched. We have studied this question in young human subjects.

Methods: Ten emmetropic (average refractions 0.0 ± 0.3 D) and ten myopic (-2.7 ± 0.9 D) young subjects (average age: 24 ± 4 years) watched a movie on a large screen (65") at 2 m distance. The movie was presented either unfiltered ("control"), or with calculated low-pass filtering equivalent to a defocus of 2.5 D, or with real optical defocus of +2.5D that was imposed by +3D spectacle lenses in both eyes. Before and after 30 minutes of movie watching, axial length was measured using low coherence interferometry (Lenstar LS-900 with autopositioning system). Spatial filtering movies was done in real-time by software written in Visual C++. Defocus was simulated by convolving each pixel with a blur circle that was calculated for 2.5D of defocus, using the average pupil size of the subjects (6.5 ± 0.7 mm).

Results: Watching unfiltered movies ("control") caused no changes in axial length. In emmetropes, watching movies with calculated defocus caused axial eye elongation ($+9.8 \pm 7.6 \mu\text{m}$) while watching movies with real positive defocus caused shorter eyes ($-8.8 \pm 9.2 \mu\text{m}$; difference between both $p < 0.0001$). Also in myopes, calculated defocus caused longer eyes ($+8.4 \pm 9.0 \mu\text{m}$) compared to control ($-3.0 \pm 8.3 \mu\text{m}$, $p = 0.001$). Strikingly, myopic eyes responded differently to positive defocus since they became also longer ($+9.1 \pm 11.2 \mu\text{m}$, $p = 0.02$, compared to control). The difference in responses to positive defocus between emmetropic and myopic subjects was highly significant ($p = 0.001$).

Conclusions: Two conclusions emerge: (1) in emmetropic human subjects, the retina appears to be able to distinguish between real positive defocus and calculated defocus even when the modulation transfer function was matched, (2) in myopic eyes, the retina apparently no longer distinguishes between both conditions since the eyes became longer in both cases. These results suggest that the retina in a myopic eye has reduced ability to detect positive defocus and restrain axial growth.

ABSTRACT BODY:

Purpose: Impact of baseline retinal NP and leakage on rates of CI-DME and/or VTC (PDR/anterior segment neovascularization) was assessed in patients receiving intravitreal aflibercept injections (IAI) or sham injections through 100 weeks in PANORAMA.

Methods: This post hoc analysis included patients with moderately severe to severe NPDR (Diabetic Retinopathy Severity Scale [DRSS] 47–53) without baseline DME who received IAI 2 mg q16 weeks (N=135) or q8 weeks (PRN dosing in year 2; N=134) (both after initial loading doses) or sham (N=133). IAI groups were combined. Baseline NP (mm^2) was analyzed in 4 groups: G1: ≤ 0 , n=201; G2: $>0\text{--}\leq 0.24$, n=52; G3: $>0.24\text{--}\leq 0.66$, n=53; G4: >0.66 , n=51. Baseline leakage area (mm^2) was analyzed by quartile: Q1: ≤ 10.20 , n=98; Q2: $>10.20\text{--}\leq 19.76$, n=97; Q3: $>19.76\text{--}\leq 30.41$, n=97; Q4: >30.41 , n=97.

Results: Proportions of patients who developed CI-DME/VTC across increasing baseline NP or leakage groups increased with sham but were similar with IAI (Figures 1, 2). Risk of developing CI-DME/VTC increased with baseline NP area (per 1 mm^2 increase) with sham, hazard ratio (HR): 1.32 (95% confidence interval [CI]: 1.06, 1.64; P=0.0125) but not with IAI, 1.06 (0.88, 1.27; P=0.5669). Results were similar for impact of baseline NP on risk of CI-DME alone, HR (95% CI): 1.32 (1.04, 1.67) with sham and 0.95 (0.68, 1.33) with IAI; and VTC alone, 1.44 (1.08, 1.92) with sham and 1.10 (0.89, 1.38) with IAI. Similarly, risk of CI-DME/VTC increased with baseline leakage area (per 1 mm^2 increase) with sham, HR 1.05 (95% CI: 1.02, 1.07; P<0.0001) but not IAI, 1.03 (1.00, 1.05; P=0.0550). The HR (95% CI) for impact of baseline leakage on risk of CI-DME alone was 1.02 (0.99, 1.05) with sham and 1.03 (1.00, 1.07) with IAI; and for VTC alone was 1.08 (1.04, 1.12) with sham and 1.00 (0.96, 1.04) with IAI. Sham but not IAI was associated with a lower proportion of patients with ≥ 2 -step DRSS improvement and higher proportion with ≥ 2 -step DRSS worsening with increasing baseline NP and leakage areas, although the trend was not significant for baseline NP.

Conclusions: Increasing baseline retinal NP and leakage areas were associated with increased rates of CI-DME/VTC in the sham group. This association was not observed in the IAI-treated group.

ABSTRACT BODY:

Purpose: As the prevalence of trachoma declines in districts worldwide, standardizing graders for surveys to document elimination becomes increasingly expensive. The use of photographs to train graders may play a role. The purpose of this observational study is to develop an Image Capture and Processing System (ICAPS) that will permit hands free image acquisition of the tarsal conjunctiva. This device will allow a single person to evert the eyelid and then take, store and upload photographs to a virtual Reading Center for grading. This can potentially eliminate the need for expensive grader standardization currently used in trachoma prevalence studies.

Methods: This study was conducted as part of the Chamwino, Tanzania district survey. The ICAPS was integrated with the WHO Tropical Data system to examine 1305 children ages 1-9 years for trachomatous inflammation – follicular (TF). Three trachoma graders were trained for the survey over one day with technical training and field training components. The ICAPS comprised of Samsung's Gear VR headset and Galaxy S8 smart phone.

Results: The ICAPS system has proved successful in being able to scan and assign bar codes to images, achieve focus on the everted eyelid, and capture images with sufficient magnification. It permits the use of augmented reality features to save and delete images and maintain a reasonable battery life. Grading of the ICAPS images compared to the field grades at the child level yielded a kappa agreement score of 0.53 but a similar proportion of children with TF (Field: 5.2%, ICAPS: 5%). The lower agreement was due to difficulties in grading follicles in the images taken in the field. This may be resolved with a newer system that can quickly take higher quality images. For 199 children, there were ungradable images for at least one eye (15%) and more ungradable images occurred in younger children ages 1-3 (18.5%) than older children ages 4-9 (4.3%). The percent of ungradable images remained consistent over the course of the study.

Conclusions: More training and ability to certify trainers is needed to reduce the percentage of ungradable images. Better understanding of the causes of disagreement in graded images and field grades is necessary before ICAPS can replace field graders. Newer phone-cameras can potentially improve image quality for more accurate follicle assessment.

ABSTRACT BODY:

Purpose: Astrocytes are stellate-shaped glia that support optic nerve head (ONH) axons with numerous actin-rich processes. With intraocular pressure (IOP) elevation in animal models, ONH astrocytes retract their processes. Here, we determined if Rho kinase inhibition with fasudil promotes stellation in cultured primary ONH astrocytes.

Methods: Adult rat ONH astrocytes were collected and validated as previously described. Cultures of passages 10-15 were seeded at 25,000 cells/cm². After 24h, cells were treated with fasudil (0, 1, 5, 10, 25, 50, and 100µM) for an additional 24h. Cells were fixed in 4% paraformaldehyde solution, labeled for actin and nuclei, and imaged using confocal microscopy. MTT uptake and LDH release assays were performed to determine any cytotoxic effects from fasudil. Cell shape and Sholl-like analyses (5-170µm radii circles from the cell center) were used to determine cell area and perimeter, cell circularity (graded on a scale of 0-1, where 1 represents a circle), and mean/maximum process lengths, respectively, via Adobe Photoshop. Data were analyzed using ANOVA statistical analysis (n=53±14 cells/group) and presented as mean ± SEM.

Results: Control astrocytes were non-stellate in shape. Mean cell area and cell viability remained unchanged with 1-100µM fasudil treatment. With increasing fasudil concentration, cells became more stellate in shape. Mean cell perimeter increased with fasudil treatment (significant at fasudil concentrations ≥50µM: 377.9±14.3µm in experimental vs. 293.4±12.0 in controls; p=0.001). Mean cell circularity decreased with fasudil treatment (significant at fasudil concentrations ≥10µM: 0.24±0.01 in experimental vs. 0.31±0.01 in controls; p=0.001). In Sholl-like analyses, mean astrocyte process number of intersections at various radii increased with fasudil treatment (most intersections at 25µm from the cell center; significant at fasudil concentrations ≥50µM: 3.7±0.2 in experimental vs. 3.0±0.1 in controls; p=0.03). Mean maximum cell process length increased with increasing fasudil concentrations (by up to 1.4x in experimental vs. control cells; linear regression slope=3.5, r²=0.63, p<0.0001).

Conclusions: Rho kinase inhibition promotes stellation in cultured ONH astrocytes, mirroring astrocyte morphology described in ONH tissue. Rho kinase inhibition in vivo may maintain astrocyte stellate morphology in the setting of elevated IOP.

ABSTRACT BODY:

Purpose: To compare the efficacy and safety of 2 IVT-AFL dosing regimens, T&E and q8, for patients with nAMD beyond Year (Y) 1 of treatment.

Methods: AZURE (NCT02540954) was a randomized, multicenter study. All patients completed $\geq 1Y$ of IVT-AFL treatment prior to enrollment. Patients were randomized 1:1 to fixed q8 (2mg IVT-AFL every 8 weeks [w]) or T&E dosing (IVT-AFL $\geq 8w$ [no upper limit] per functional/anatomic criteria). Primary endpoint was mean change in best-corrected visual acuity (BCVA) from baseline (BL) to w52. Key secondary endpoint was proportion of patients losing < 15 letters.

Results: The full analysis set comprised 332 patients ($n=167$ [q8] and $n=165$ [T&E]). Mean (standard deviation) BCVA at IVT-AFL treatment initiation (1Y prior to study BL) was 60.9 (9.9; q8) and 59.4 (10.5; T&E) letters. At study BL, mean age was 74.7 (7.0; q8) and 76.2 (8.3; T&E) and mean BCVA was 70.1 (10.9; q8) and 69.0 (12.1; T&E) letters. At w52, mean BCVA change from BL was -0.5 (8.4; q8) and -0.3 (7.5; T&E) letters. Least-squares mean difference (95% CI) vs q8 dosing was 0.22 (-1.51 ; 1.96). Compared with q8 dosing, T&E achieved a non-inferior change in mean BCVA at w52 (pre-specified margin of 5 letters; $P<0.0001$). At w76, mean BCVA change from BL was -0.9 (10.4; q8)

and -1.5 (10.9; T&E) letters. From BL to w52, 94.0% (q8) and 95.2% (T&E) of patients maintained vision (<15-letter loss). Mean central retinal thickness change from BL was -33.4 μ m (47.1; q8) and -24.4 μ m (55.2; T&E) at w52, and -37.8 μ m (51.1; q8) and -21.7 μ m (57.0; T&E) at w76. Mean number of IVT-AFL injections was 6.8 (0.8; q8) and 6.0 (1.0; T&E) at w52, and 9.6 (1.4; q8) and 8.0 (1.8; T&E) at w76. Ocular treatment-emergent adverse events in the study eye were similar for q8 (48.8%) and T&E (45.5%) dosing regimens.

Conclusions: In patients who previously received ≥ 1 Y of IVT-AFL treatment for nAMD, T&E dosing achieved similar functional outcomes as q8 dosing. Functional and anatomic improvements achieved during Y1 were maintained in Y2 and Y3 of IVT-AFL treatment with both regimens. Of the 2 regimens, T&E required fewer injections. No new safety signals were identified, which is consistent with prior studies.

ABSTRACT BODY:

Purpose: To determine whether the lens acts as a circadian clock that controls the rhythmic expression of genes involved in glutathione (GSH) redox regulation

Methods: Western blotting and immunohistochemistry were used to confirm the expression of circadian clock core proteins (BMAL1 & CLOCK) in rat lenses. Reverse transcription-quantitative PCR (RT- qPCR) was performed on RNA extracted from rat lenses collected every 4 hours over a 24-hour period to determine if there were cyclic differences in the expression of clock component genes (Bmal1, Clock, Per and Cry) and GSH related redox genes involved in GSH synthesis and regeneration.

Results: Western blotting for circadian clock proteins from lens homogenates revealed bands consistent with the predicted molecular weights for BMAL1 and CLOCK. Immunohistochemistry revealed labelling for BMAL1 and CLOCK in the epithelium and fibre cells in the outer cortex. RT-qPCR revealed fluctuations for both the clock component genes and redox genes over a 24-hour period suggestive that the lens may utilize circadian time keeping mechanisms to regulate GSH homeostasis

Conclusions: Collectively, these findings reveal that the lens contains the core molecular components of the circadian clock, and that fluctuations in the expression of clock component genes and GSH related genes occurs during the day/night cycle. This implies that the lens may act as a circadian clock that controls the rhythmic expression of genes involved in GSH homeostasis to provide protection against UV insults. Since circadian rhythms are altered with advancing age, this implies that disruption of the circadian regulation of redox balance may be an initiating factor in age related lens cataract.

ABSTRACT BODY:

Purpose: Successful contact lens designs are predicated on the accurate identification of the limbus. Custom scleral lens designs can now be fabricated using 3D ocular surface maps from scanning and impression-based methods. Utilizing 3D topography maps, an objective method of defining the limbus was developed.

Methods: Thirty impression-based 3D topography maps were selected based on ocular conditions that do not affect the limbal region.

Subjective Detection: An expert clinician identified at least 5 points on the topography map using the EyePrint Designer (EPD) software to represent the limbal margin. Visual selection of points was guided by known anatomical features such as expected curvature change and limbus size.

Objective Detection: A custom algorithm in MATLAB detects changes in 3D ocular surface profile at the limbal region. An initial estimate of candidate limbal points represent locations with large gradient magnitudes. An adaptive varying threshold is applied since the gradient magnitude of the limbus is not constant across all meridians. Candidate points away from the probable limbal region are rejected. Further testing for outliers using Random Sample Consensus (RANSAC) is done to remove points that do not fit an elliptical profile. The detected limbal points tend not to be planar, resulting in a best fit hyperbolic paraboloid shape.

Comparison: Limbal parameters from subjective and objective methods collected using the EPD software were compared. All objective limbus designs were reviewed by another expert clinician. Lens designs with >75% similarity of the limbal region between the two methods were clinically acceptable.

Results: Limbal parameters were reported as: major diameter, minor diameter, and axis of major diameter. The average difference between the two methods were 0.16mm, 0.07mm, and 1.92 degrees, respectively. The median difference between the two methods were 0.05mm, 0.03mm, and 2.95 degrees, respectively. Review of objectively determined limbal points found 80% of designs to be clinically acceptable.

Conclusions: This objective method of identifying the limbus may be an effective way of guiding novice contact lens designers to create custom scleral lenses. Further investigation of irregular ocular surfaces is necessary to address the broader ocular demographic who wear scleral lenses.

TITLE: Multi-modal Geographic Atrophy Lesion Growth Rate Prediction using Deep Learning

SESSION TITLE: AMD imaging - GA

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Q. Yang, N. Anegondi, V. Steffen, C. Rabe, D. Ferrara, S.S. Gao, Genentech Inc, South San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Qi Yang: Commercial Relationship(s);Genentech:Code E (Employment) | Neha Anegondi: Commercial Relationship(s);Genentech:Code E (Employment) | Verena Steffen: Commercial Relationship(s);Genentech:Code E (Employment) | Christina Rabe: Commercial Relationship(s);Genentech:Code E (Employment) | Daniela Ferrara: Commercial Relationship(s);Genentech:Code E (Employment) | Simon Gao: Commercial Relationship(s);Genentech:Code E (Employment)

ABSTRACT BODY:

Purpose: To predict geographic atrophy (GA) lesion growth rate from fundus autofluorescence (FAF) and spectral-domain optical coherence tomography (OCT) using a multi-modal multi-task deep learning approach.

Methods: This study was performed retrospectively on study eyes of patients with bilateral GA enrolled in the lampalizumab clinical trials. The macular Spectralis (Heidelberg Engineering, Inc. Heidelberg, Germany) OCT volumes of 496x1024x49 voxels and macular 30 degree FAF images of 768x768 pixels from baseline visits were used to predict baseline GA lesion area and annualized GA growth rate. For OCT volumes, each B-scan was flattened along Bruch's membrane (BM) and three en-face maps averaged over full, sub-BM and above-BM depths were combined as a three-channel input. The growth rate (mm^2/year) of GA lesion area (mm^2 , measured from FAF images by an independent reading center and graded by two readers and an adjudicator if necessary) was estimated as the slope from a linear regression model fitted for each individual patient using all available visits. The datasets from 1279 patients were divided into 80% training and 20% test datasets. Further, the training data were randomly divided into 5 cross-validation (CV) folds. Three multi-task convolutional neural network (CNN) models were trained to simultaneously predict GA lesion area and GA growth rate: OCT only, FAF only and multi-modal (OCT and FAF). The performance was evaluated by calculating the in-sample coefficient of determination (R^2) defined as the square of Pearson correlation coefficient (r) between true and predicted GA area and growth rate.

Results: Table 1 shows the CV and test set performance of the three multi-task CNN models: OCT only, FAF only and multi-modal input. The multi-modal model had the best CV performance with mean R^2 of 0.92 and 0.46 for GA lesion area and GA growth rate predictions, respectively. On the test set, the same model showed R^2 of 0.94 for GA lesion area prediction and 0.56 for GA growth rate prediction.

Conclusions:

These findings show the feasibility of using baseline FAF and/or OCT images to predict individual GA growth rate with a multi-task deep learning approach and that a multi-modal approach could improve performance. This work can potentially be useful for clinical trial adjustment, stratification and/or enrichment. Meanwhile, further validation in additional datasets is needed to confirm robust performance.

TITLE: Studying Visual Disability in a Nationally-Representative Panel Study of Older Adults

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Kolli, L. De Lott, M. Hu, Y. Zhou, J.R. Ehrlich, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ajay Kolli: Commercial Relationship: Code N (No Commercial Relationship) | Lindsey De Lott: Commercial Relationship: Code N (No Commercial Relationship) | Mengyao Hu: Commercial Relationship: Code N (No Commercial Relationship) | Yunshu Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Ehrlich: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Self-reported visual disability (SRVD) is an important indicator of the perceived impact of vision on an individual's life. The National Health and Aging Trends Study (NHATS) is an ongoing, nationally-representative panel study of late-life disability. Using survey items with binary response options, we sought to develop an ordinal indicator of SRVD in NHATS in order to improve measurement precision and facilitate future studies of disability trajectories related to vision in older adults.

Methods: Sociodemographic factors, medical comorbidities, SRVD, functional activity scores (mobility, self-care, household activity), and a subjective well-being scale were assessed in NHATS. Participants were asked questions (yes/no) to assess vision: blindness; sight adequate to recognize someone across the street; sight adequate to read newspaper print; use of glasses or corrective lenses; and use of any low vision aid (LVA). We categorized participants into one of six ordinal groups: 1) Blind; 2) Near and distance SRVD without use of LVA; 3) Near and distance SRVD with LVA; 4) Near or distance SRVD without LVA; 5) Near or distance SRVD with LVA; or 6) No SRVD. Multivariable Poisson regression models were used to assess convergent validity of the SRVD scale with functional activity (household, self-care, mobility) and subjective wellbeing scores.

Results: 7061 Individuals, age 65 years or older were included in this analysis. Weighted percentages of individuals in each of the six ordinal SRVD categories, and weighted mean functional activity and wellbeing scores by vision category are shown in Table 1. In models adjusted for sociodemographic and medical comorbidities, worse SRVD was significantly associated with lower scores for mobility ($p<0.0001$), self-care ($p<0.0001$), household activity ($p<0.0001$), and subjective wellbeing ($p<0.0001$) (Figure 1).

Conclusions: More severe SRVD on this novel scale was associated with worse scores for mobility, self-care, household activities, and subjective wellbeing among aging adults. This scale provides a new tool to capture the range of impacts that poor vision may have on the lives of older adults in a nationally-representative cohort. Use of this scale may facilitate analyses of the impact of SRVD on late-life disability trajectories.

ABSTRACT BODY:

Purpose: To investigate the effect of proteasome inhibition in neovascularization induced by limbal stem cell deficiency (LSCD). By understanding the molecular mechanisms that control neovascularization, it may be possible to design therapeutic strategies to selectively prevent or halt pathologic vascular growth. The anti-angiogenic thrombospondin-1 (TSP-1) has been shown to be a natural inhibitor of neovascularization. An increase in TSP-1 expression might decrease corneal vascularization in case of LSCD

Methods: Rabbits with experimentally induced LSCD were used to quantify the expression of TSP-1. Cultured Autologous Oral Mucosal Epithelial Cell Sheets (CAOMECS) was grafted back to reconstruct corneal epithelium. Using immunofluorescent staining, the levels of TSP-1 were compared between control, diseased and CAOMECS treated corneas. In addition, oral mucosal epithelial cells were cultured and treated with proteasome inhibitor to analyze TSP-1 levels. Treated cells were analyzed for the expression levels of (TSP-1) and its downstream signaling involved in angiogenesis.

Results: The immunofluorescent staining of normal healthy ocular surface showed that TSP-1 was expressed in corneal epithelial cells, and had a much lower expression in conjunctival epithelial cells. The limbal cells did not express TSP-1. In the LSCD diseased ocular surface, TSP-1 expression was greatly decreased in cornea epithelial cells. Conjunctival and goblet cells were present on the corneal surface. CAOMECS-grafted corneas greatly expressed TSP-1, in comparison to LSCD-disease corneas, but to a much lower extent compared to the healthy corneas. In an attempt to stimulate TSP-1 expression, cultured oral mucosal epithelial cells were treated with proteasome inhibitor. Results showed that treatment with proteasome inhibitor lead to an increase in the expression levels of TSP-1.

Conclusions: TSP-1 expression may be activated in CAOMECS tissue prior to grafting back onto cornea to reconstruct the ocular surface, and maintaining corneal avascularity in case of LSCD.

TITLE: Comparison of ocular biometric parameters between Hispanic and non-Hispanic ethnicities

SESSION TITLE: Cornea Trauma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B.C. Lam, C. Zhu, F. Jing, C.C. Jiang, N.M. Hodson, Ophthalmology, The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, Texas, UNITED STATES|M. Weiss, D.A. Johnson, A. Kheirkhah, Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Brandon Lam: Commercial Relationship: Code N (No Commercial Relationship) | Menachem Weiss: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Frank Jing: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Noah Hodson: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Kheirkhah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare ocular biometric parameters between Hispanic and non-Hispanic white populations among adult patients undergoing cataract surgery.

Methods: This retrospective study included 433 adult patients who underwent surgery for senile cataract. Only patients with self-reported ethnicities of Hispanic and non-Hispanic white were included. We excluded those with a history of anterior segment surgeries or abnormalities. The following parameters as measured by the IOLMaster 700 (Carl Zeiss Meditec, Jena, Germany) were compared between Hispanic and non-Hispanic patients: mean keratometry, corneal astigmatism, anterior chamber depth, lens thickness, vitreous length, axial length, white-to-white diameter, and emmetropic intraocular lens power. Average of both eyes of each patient was used for analysis.

Results: There were 219 Hispanic and 214 non-Hispanic patients with a mean age of 70.1 ± 7.7 years (range, 50 to 88 years), and 66.7% were females. Although sex distribution was similar between the two groups, Hispanic patients had a lower age compared to non-Hispanics (69.3 ± 8.3 vs 70.9 ± 6.9 years, $P=0.02$). In biometric values, anterior chamber depth was significantly lower in Hispanics (3.067 ± 0.403 mm) than in non-Hispanics (3.159 ± 0.367 mm, $P=0.013$). Such statistically significant difference persisted even after adjustment for age ($P=0.004$). No other significant differences were found in other ocular parameters measured. Hispanics had a higher percentage of corneal with-the-rule astigmatism (29.7% vs 26.2%) and a lower percentage of corneal against-the-rule astigmatism (23.7% vs 28.0%); however, the difference was not statistically significant.

Conclusions: Anterior chamber depth is significantly lower in Hispanics compared with non-Hispanics. Such ethnic difference should be considered when performing cataract and corneal surgeries as it may be associated with a higher risk of corneal endothelial injury.

TITLE: Airborne particulate matter topical exposure triggers ocular hypertension

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Lei, L. Li, X. Sun, Eye and ENT Hospital of Fudan University, CHINA|J. Zhou, Shanghai Key Laboratory of Meteorology and health, CHINA|

Commercial Relationships Disclosure (Abstract): Yuan Lei: Commercial Relationship: Code N (No Commercial Relationship) | Liping Li: Commercial Relationship: Code N (No Commercial Relationship) | Ji Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Xinghuai Sun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Over 90% of the global population is exposed to air pollution. Latest epidemiological studies have found that particulate matter (PM), especially PM_{2.5} (aerodynamic diameter $\leq 2.5 \mu\text{m}$), is associated with glaucoma. However, it is controversial as the association is linked to intraocular pressure elevation or retinal damage. This study aims to determine how PM_{2.5} affects IOP and the underlying molecular mechanism involved.

Methods: Atmospheric PM_{2.5} samples were obtained from May 2016 to Dec 2018 in Lanzhou, China. PM_{2.5} suspension was given as topical eyedrops (1 mg/mL) to the right mouse eyes (C57BL/6, male, 6 weeks old, n=10) 3 times a day for 104 days, the contralateral left eyes serving as the control. Human trabecular meshwork (HTM) cells (three cell lines) were subjected to various PM_{2.5} concentrations (25 - 400 mg/mL) for 48 hours. Cell viability, ROS production, NLRP3/caspase-1, IL-1 β , and GSDMD expression was measured by western blot or ELISA. HTM cells were pre-treated with N-acetyl-L-cysteine (NAC, 3 mM) for 2 hours before cultured with PM_{2.5} (100 ug/mL) for 48 hours.

Results: In mouse eyes exposed to PM_{2.5}, IOP elevation was steadily significant from day 30 compared with the controls (n = 10; P < 0.05). Western blot analysis showed that PM_{2.5} increased the expressions of NLRP3 inflammasome mediated pyroptosis pathway (NLRP3/caspase 1/IL-1 β /GSDMD) in the mouse cornea and outflow tissues (NLRP3, n = 3, caspase-1, n = 4, IL-1 β , n = 3, GSDMD n = 4, p < 0.05). Cell experiments showed that PM_{2.5} exposure elevated ROS levels (n = 3, p < 0.05), decreased cell viability (n = 5, p < 0.05) and encouraged cell contraction in HTM cells (n = 3, p < 0.05). Antioxidant NAC improved HTM cell viability (n = 5, p < 0.05), inhibited the activation of the NLRP3 inflammasome axis (n = 3, p < 0.05) and HTM cell contraction (n = 3, p < 0.05).

Conclusions: This study provides novel evidence that PM_{2.5} has a direct toxic effect on intraocular tissues and may contribute to the initiation and development of ocular hypertension. This occurs as a result of increased oxidative stress and the subsequent induction of the NLRP3 inflammasome mediated pyroptosis signaling pathway in trabecular meshwork cells.

TITLE: Predicting High Impact Ophthalmology Articles Using Machine Learning and Natural Language Processing

SESSION TITLE: Data science, machine learning, and artificial intelligence

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Karandikar, Occidental College, Los Angeles, California, UNITED STATES|S.Y. Wang, Stanford University, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yash Karandikar: Commercial Relationship: Code N (No Commercial Relationship) | Sophia Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to understand characteristics of top-cited ophthalmology articles by building machine learning predictive models to predict top-cited ophthalmology articles based on bibliometric and natural language processing features. We also investigated which were the most important features for predicting a top-cited ophthalmology article. We also evaluated model performance on the subset of glaucoma-related articles.

Methods: Ophthalmology papers published between January 2000 to June 2020 and their metadata were downloaded from Scopus, including publication year, titles, abstracts, journal, number of authors, page-range, funding source, and author and index keywords. Text of titles and abstracts were lowercased and tokenized (split into constituent words) and individual key words were represented as one-hot vectors for inputs into models. Gradient boosted machine (GBM) predictive models were created to identify whether or not each paper would be in the top 25th percentile of citations. The model was evaluated on a held-out test set on F1 score and areas under the receiver operating curve (AUROC) and precision-recall curves (AUPRC). The model was also evaluated on a subset of glaucoma-related articles, which had glaucoma-related keywords. Relative importance of features in the GBM model was determined to find the most predictive features.

Results: The gradient boosting machine model had an AUROC of 0.846, an AUPRC of 0.531, and an F1 score of 0.206 for all ophthalmology papers, and a similar performance on the glaucoma subset (AUROC 0.885). The most influential predictive factors were standard bibliometric variables, namely publication year (133.209), paper length (74.064), and author count (31.152). Between the tokenized and scored keywords, the most influential were the index keyword study, with a relative influence of 29.882; ophthalmology, 22.177; and RNA, 19.345.

Conclusions: This study found that natural language processing, especially with algorithmic scoring of specific keywords, is a useful tool to predict citation count in addition to standard bibliometric variables. This study also found that the most effective variables for predicting citation count are bibliometric variables, followed by certain index keywords.

TITLE: Subciliary Rotating Sutures Combined with Modified Hotz Procedure for Correction of Congenital Lower Eyelid Entropion

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Khuu, Washington State University Elson S Floyd College of Medicine, Spokane, Washington, UNITED STATES|K. Michels, Northwest Eyelid and Orbital Specialists, Spokane, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Thomas Khuu: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Michels: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report and evaluate the use of combined subciliary rotating sutures with modified Hotz procedure for repair of lower eyelid congenital entropion.

Methods: A retrospective chart review was conducted of all patients who underwent lower eyelid congenital entropion repair by a single surgeon (K.M.) using subciliary rotating sutures combined with a modified Hotz procedure between 2016 and 2020. Study variables included patient demographics, follow-up period, postoperative complications, and need for further intervention. In brief, a skin incision was made at the lower lid crease and dissection was carried superiorly to separate the anterior lamella from the tarsus. Any overriding orbicularis oculi muscle was removed inferior to the incision. Horizontal mattress sutures were passed starting inferior to the lash line, through the anterior lamella and inferior border of the tarsus, then reversed in the same direction as entry to rotate the lid margin. The lid crease was then reformed in the manner of the Hotz procedure.

Results: Twelve patients (19 eyelids) met the study inclusion criteria. The mean patient age was 7.1 ± 6.1 (range 0.2–22) years. Nine of the patients were female (75%) and 3 were male (25%). The distribution of eyelids was 8 right (58%) and 11 left (42%). The mean follow-up time was 19.5 ± 15 (range 2.5–45) months. There were 2 cases (11%) of entropion recurrence in 2 patients (17%) following initial repair, one which recurred after a patient underwent craniosynostosis surgery and another which recurred in a patient with pediatric thyroid eye disease. Repeat entropion surgical repair using the same technique was performed in these two cases for which no recurrence was noted during the follow-up period. Overall, the described entropion repair technique was successful and without recurrence in 17 cases (89%) in 10 patients (83%). There were no cases of ectropion, lid retraction, or other complications.

Conclusions: Subciliary rotating sutures combined with modified Hotz procedure is effective for correction of congenital lower eyelid entropion. The technique does not manipulate the posterior layer of the lower eyelid retractors which may reduce the risk of lower eyelid retraction and overcorrection in particular cases. It is also useful for when retractor reinsertion may not yield adequate improvement.

ABSTRACT BODY:

Purpose: We previously reported ROCK inhibitor, Ripasudil could inhibit epithelial to mesenchymal transition of retinal pigment epithelium (RPE). The purpose of this study was to investigate the inhibitory effects of liposome-encapsulated Ripasudil (Lipo-Ripa) on an animal model of proliferative vitreoretinopathy (PVR).

Methods: PVR was induced in the eyes of Dutch rabbits as previously reported. After PVR induction, we performed single vitreous injection of BSS (control), Ripasudil (Ripa) and Lipo-Ripa in each group. We collected the vitreous fluid at 6 h, 24 h and 48 h after injection and measured the concentration of Ripasudil. PVR progression was observed by fundus camera and the stage was graded.

Results: Vitreous concentration of Ripasudil was significantly higher (4-32 times) in Lipo-Ripa group compared to Ripa group over time. In Ripa group, PVR progression was significantly suppressed on day 7 and 14 compared to control group ($p<0.05$). In Lipo-Ripa group, PVR progression was significantly suppressed on day 7, 14, 21 and 28 ($p<0.05$).

Conclusions: Lipo-Ripa could efficiently suppress PVR progression by its prolonged residency in the vitreous.

ABSTRACT BODY:

Purpose: To assess the impact of slab selection on the correlation between choriocapillaris (CC) flow deficits percentage (FD%) in eyes with geographic atrophy (GA) and the yearly enlargement rate (yER) of GA.

Methods: In this retrospective study, spectral domain optical coherence tomography (SD-OCT) and SD-OCT angiography (OCTA) images acquired on the Cirrus HD-OCT device (Carl Zeiss Meditec, Dublin, CA) were collected from patients with GA. Each patient underwent a 6x6 mm OCTA scan at baseline and two 6x6 mm structural SD-OCT volume scans, one at baseline and one after a minimum of 12 months. The edge of the GA lesion was delineated on the en face OCT fundus image and the yER was calculated after square root transformation. OCTA images were generated from three 10 µm thick slabs 11, 21 and 31 µm posterior to the RPE-fit line. A grid composed of 100 µm wide concentric rings was created around the GA on the compensated OCTA CC image and the FD% was calculated. FD% from each ring was correlated with the yER of GA. This was repeated for OCTA images from the different slab positions.

Results: Twenty-nine eyes of 22 patients were included in the study. For the 11-21 µm slab, the FD% was not significantly correlated with the yER for any of the evaluated rings. For the 21-31 and 31-41 µm slab, the FD% in the first five rings (from 0 to 500 µm from the border of GA) was significantly correlated with the yER. In all slab locations, there was no statistically significant correlation between the yER and CC FD% beyond 500 µm from the GA lesion.

Conclusions: Slab selection for quantification of CC FD% may have a significant impact on quantitative results and the correlation with other parameters of interest in eyes with GA.

TITLE: Substance P/Neurokinin-1 receptor pathway blockade alleviates epithelial stem cell deficiency

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.M. Lasagni Vitar, P. Fonteyne, P. Rama, G. Ferrari, Eye Repair Lab, IRCCS Ospedale San Raffaele, Milano, Lombardia, ITALY]

Commercial Relationships Disclosure (Abstract): Romina Lasagni Vitar: Commercial Relationship: Code N (No Commercial Relationship) | Philippe Fonteyne: Commercial Relationship: Code N (No Commercial Relationship) | Paolo Rama: Commercial Relationship(s);Ospedale San Raffaele:Code P (Patent) | Giulio Ferrari: Commercial Relationship(s);Ospedale San Raffaele:Code P (Patent)

ABSTRACT BODY:

Purpose: To evaluate the role of substance P (SP)/neurokinin-1 receptor (NK1R) pathway in corneal epithelium wound healing in a pre-clinical model of stem cell deficiency (SCD).

Methods: Eight-week-old C57BL6/N (WT) and B6.Cg-Tac1tm1Bbm/J (TAC1-KO) male mice underwent complete corneal disepithelization, including the limbus. Animals were followed-up for 14 days, corneal epithelial wound closure and transparency were assessed by biomicroscopy. To test the effect of NK1R blockade, WT mice received 0.1 or 1 mg/mL NK1R antagonist Fosaprepitant solution topically for 16 days after disepithelization (FOSA 0.1 and FOSA 1). After animal sacrifice, the number of goblet and conjunctival cells infiltrating the cornea was quantified with Periodic Acid Schiff and cytokeratin-8 and 19 stainings, respectively. Cytokeratin-12 was employed as a marker of corneal epithelial cells. The number of stem cells was quantified with p63 and BrdU co-staining.

Results: TAC1-KO mice showed a significant increase in epithelial wound healing rate ($p<0.001$) and corneal transparency ($p<0.001$) up to 14 days after disepithelization, compared to WT. Similarly, FOSA 1 mice showed a significant improvement in wound closure rate and transparency starting from day five when compared to WT mice ($p<0.05$), while FOSA 0.1 group did not show any improvement. TAC1-KO and FOSA 1 mice showed reduced number of infiltrating goblet and conjunctival cells ($p<0.05$) and increased number of corneal epithelial stem cells ($p<0.01$).

Conclusions: These results suggest that excessive expression of SP is associated with SCD and results in conjunctival infiltration and exhaustion of residual stem cells, supporting the hypothesis that blockade of neurokinin-1 receptor could be used as an adjuvant treatment in SCD.

TITLE: Improving OCT B-Scan classification feature attribution maps with adversarial training

SESSION TITLE: Machine learning I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Spier, Carl Zeiss AG, Oberkochen, Baden-Württemberg, GERMANY|G. Ghazaei, A. Urich, E. Hoeck, Carl Zeiss AG, Munich, Bayern, GERMANY|G.C. Lee, N. Manivannan, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nathalia Spier: Commercial Relationship(s);Carl ZeissAG:Code E (Employment) | Ghazal Ghazaei: Commercial Relationship(s);Carl ZeissAG:Code E (Employment) | Alexander Urich: Commercial Relationship(s);Carl ZeissAG:Code E (Employment) | Eva Hoeck: Commercial Relationship(s);Carl ZeissAG:Code E (Employment) | Gary Lee: Commercial Relationship(s);Carl ZeissMeditec:Code E (Employment) | Niranchana Manivannan: Commercial Relationship(s);Carl ZeissMeditec:Code E (Employment)

ABSTRACT BODY:

Purpose: Feature attribution methods provide insight into the decision-making process of convolutional neural networks by highlighting pixels that strongly influence the classification decision. Training a network using adversarial examples causes it to emphasize the most relevant image features, resulting in more focused feature maps in comparison to conventional training. In this study, we investigated if an adversarially trained network produces more robust feature maps for an OCT B-scan classifier.

Methods: 61,058 B-scans from 478 independent eyes were used for training an Xception network both conventionally and with adversarial attacks for a binary classification task (i.e. B-scan is either normal or abnormal). A B-scan is considered “abnormal” if it was graded by at least one (of two) retina specialist to contain one of the pathologies shown in Table 1. The performance of each network was evaluated on a hold-out test set containing 15,338 B-scans of 120 eyes. The percentage of samples where pathology is present/absent for training and test set was, respectively, 41%/59% and 38%/62%. All B-scans were acquired with CIRRUSTM HD-OCT 4000 or CIRRUSTM HD-OCT 5000 devices (ZEISS, Dublin, CA).

Five different feature attribution methods – Grad-CAM, SmoothGrad2, VarGrad2, Integrated Gradients, and Vanilla Gradients – were used to generate feature maps indicating how much each feature in the model contributed to the predictions. The maps were qualitatively compared for the two types of training regimes.

Results: In all feature attribution methods except Grad-CAM, the model trained with adversarial examples displays clearer and more focused feature maps, as shown in Figure 1. However, the gains in feature attribution map interpretability come at the cost of a small loss in model performance. The conventionally trained model obtained an accuracy of 96.14% and AUC of 0.992, while the adversarially trained model obtained an accuracy of 94.74% and AUC of 0.989.

Conclusions: The results consistently show that when using feature attribution maps for model interpretability, one can obtain enhanced feature attribution maps by adversarially training the models

ABSTRACT BODY:

Purpose: There is agreement on pathological loss rate of nerve fiber layer (NFL) in the optic nerve head (ONH) in glaucomatous individuals, as well as non-pathological due to aging. Morphometric measures of the NFL allow for assessment of the loss rate. Previous studies of non-glaucomatous individuals have reported a normal loss rate ranging from -1 to -2 $\mu\text{m}/\text{year}$. So far, a fully automatic method has never been used in studies for morphometrical measurement of the NFL.

Our clinical experimental study was performed with the use of an in-house developed AI-algorithm for automatical annotation and measurement of the NFL waist along the ONH, to investigate whether there is an age-related NFL loss rate in non-glaucomatous subjects.

Methods: Altogether 16 non-glaucomatous individuals were enrolled and equally stratified according to sex and age in four age groups of [30 39], [40 49], [50 59], [60 69] years. Three left-eye volumes were obtained from each participant. In each volume 500 annotations of the central limit of pigmental epithelium and their shortest distances to the inner limit of the retina were detected by the AI algorithm. The average distance was calculated in each volume. Then, all three volumes were averaged for each subject.

ANOVA and simple linear regression analysis were performed to evaluate the obtained data.

Results: Automatic measurement of one volume took approximately 1 minute. The 95% CI for the mean in age groups of [30 39], [40 49], [50 59], [60 69] years were estimated as 376.0 ± 33.5 , 292.3 ± 51.4 , 364.6 ± 61.6 and $344.3 \pm 49.9 \mu\text{m}$.

Variation among volumes and subjects was $7.7 \mu\text{m}^2$ (d.f.= 32) and $2758 \mu\text{m}^2$ (d.f.= 12) respectively. In a linear regression graph a negative trend was found, equivalent to a NFL loss of $-2.43 \mu\text{m}/\text{year}$.

Conclusions: Our automatical algorithm successfully annotated and computed the NFL waist thickness and produced results in line with current research, although general conclusions about normal loss rate in the population are difficult to draw due to our small sample size.

A fully automated approach to track changes in NFL thickness over time for glaucoma follow-up is possible.

Comparison of loss rate in the glaucomatous and non-glaucomatous population enables new glaucoma follow-up method to detect pathological changes earlier than current clinical perimetry.

ABSTRACT BODY:

Purpose: Conventional dendritic cells (cDC) are critical for initiating T helper-1(Th1) alloimmunity post-corneal transplantation; however, the differential roles and molecular mechanisms of migratory CD103⁺ cDC and CD11b⁺ Ag-presenting cells (APC) subsets in Th1 alloimmunity have not been completely investigated. Herein, we examined the function of CD103⁺ DC in regulating CD11b⁺ APC-mediated anti-allograft Th1 immunity

Methods: High risk (HR) and low risk (LR) allogeneic corneal transplantation were performed using C57BL/6 mice as donors and BALB/c as hosts. On days 1,3,4,7,and 14 post-transplantation, CD103⁺CD11c⁺ DC, B220⁻CD11b⁺MHC-II^{high} APC, CD4⁺CD25⁺FoxP3⁺ regulatory T cells (Treg), and CD4⁺IFN-g⁺ (Th1) cells, were assessed by flow cytometry in graft recipient mice. On day 14, CD103⁺ DC of LR graft recipients and CD11b⁺ APC of HR graft recipients were FACS-sorted, incubated, and assessed for production of IL-10 and IL-12 by ELISA. CD11b⁺ APC were co-cultured with syngeneic CD103⁺ DC, syngeneic and CD4⁺CD25⁻ T cells, and allogeneic corneal lysate. Anti-IL10R blocking antibody was added, and IL-12 and IFN-g were measured by ELISA in supernatants

Results: CD103⁺ DC frequencies were significantly higher in LR setting compared to HR (p<0.001). CD11b⁺MHC-II^{high} APC frequencies were found significantly augmented in the HR setting compared to LR (p<0.001). Functional Treg (measured by FoxP3 expression) were found significantly higher in LR vs. HR (p<0.01), but no significant change in Treg-frequencies was observed. Th1 cell frequencies were significantly increased in HR vs. LR (p<0.001). IL-10 production was significantly reduced (p<0.001) and IL-12 significantly increased (p<0.001) by CD11b⁺ APC compared to CD103⁺ DC. The presence of CD103⁺ DC with CD11b APC led to a significant reduction in IL-12 secretion by CD11b⁺ APC (p<0.001) and modulation of allosensitization measured by IFN-g production by Th1 cells compared to CD11b⁺ DC alone (p<0.001). Blocking IL-10R, abrogated the modulatory effect of CD103⁺ DC on CD11b⁺ APC

Conclusions: These results provide novel insights into the distinct roles of migratory DC subsets in the regulation of Th1 immunity. Additionally, they show that CD103⁺ DC are critical for regulating Th1 immunity following corneal transplantation

ABSTRACT BODY:

Purpose: To compare glaucoma specialists' evaluation of progression of glaucoma using optic disc photos and OCT, according to the intra- and inter-rater reproducibility of each technique, agreement between techniques, and ability of each technique to detect visual field (VF) progression.

Methods: We collected monoscopic disc photos, OCT reports (minimum rim width and retinal nerve fiber layer scans) and 24-2 VF tests from glaucoma subjects and healthy controls followed in longitudinal observational cohorts. Subjects with a baseline disc photo and OCT (taken on the same day) and a follow-up disc photo and OCT with at least 3 years of follow-up were included. Five glaucoma specialists evaluated the disc photos and OCT reports, ranking the likelihood of glaucoma progression as follows: definitely no progression, likely no progression, likely progression, definitely progression, corresponding to scores 1-4, respectively (Fig 1). Eight subjects were duplicated to determine intra-rater reproducibility and another 8 subjects were duplicated and presented in reverse order to estimate false positive (FP) progression detection. The controls were used to provide another estimate of FP and excluded from other analyses. VF glaucoma progression was defined as a classification of 'possible' or 'likely' on Guided Progression Analysis software, using VFs between the baseline and follow-up examinations. Reproducibility analyses were conducted with intraclass correlation (ICC). Average scores given by examiners were compared with Wilcoxon test. Accuracy to detect VF progression was explored using area under receiver operating characteristics curve (AUC).

Results: We included 72 glaucoma and 7 control subjects. Intra-rater reproducibility was higher for OCT than disc photos (mean ICC= 0.82 vs. 0.55). Intra-rater agreement between disc photos and OCT was poor (mean ICC= 0.23). Inter-rater agreement between the 5 examiners was moderate for OCT and poor for disc photos (ICC= 0.62 vs. 0.37). The mean score for inverted order images was higher in photos than OCT (2.1 vs. 1.6, $p=0.07$), which could suggest greater FP in photos than OCT. However, the mean score in controls was the same (1.6) with both techniques. The techniques had a comparable AUC (Fig 2).

Conclusions: OCT evaluations had higher intra and inter-rater agreement than evaluations of optic disc photos. Both techniques had similarly low detection of VF progression.

ABSTRACT BODY:

Purpose: Several studies suggest that statins have anti-inflammatory effect besides their cholesterol-lowering effect, and therefore may be beneficial for dry eye disease (DED). Data on the association between oral statin use and severity of DED is limited. We examine the association between statin use and severity of DED symptoms and signs among participants in the DREAM[®] study, a randomized multi-center clinical trial to evaluate the effect of omega-3 fatty acid supplements for the treatment of dry eye.

Methods: Self-reported oral statin use and daily dosage were collected at baseline. Statin use was further classified as low-intensity, moderate-intensity, and high-intensity according to American College of Cardiology guidelines. At baseline, 6 and 12 months, DED symptoms were evaluated using the Ocular Surface Disease Index (OSDI), DED signs in each eye were tear break up time (TBUT), Schirmer's test, corneal fluorescein staining, conjunctival lissamine green staining, and Meibomian gland dysfunction (MGD). Generalized linear models adjusted for age, gender, race, time and inter-eye correlation were used to compare the score on OSDI, scores of DED signs and a composite score of DED signs between statin users and non-users, and among users of different statin intensities.

Results: Among 535 participants with moderate to severe DED, 129 (24.1%) were statin users, with 15 (2.8%) low-intensity, 77 (14.6%) moderate-intensity and 31 (5.9%) high-intensity statin use. Statin users were significantly older than non-users (mean [SD] age 64.7 [9.4] vs. 55.9 [13.5], $p<0.001$). When data from baseline, 6 and 12 months were combined, statin use at baseline was not associated with severity of dry eye symptoms or signs (Figure 1, all adjusted $p\geq 0.09$). Higher intensity statin use was associated with lower MGD (Figure 2, adjusted trend $p=0.049$); although the mean score for non-users was similar to the mean score for moderate intensity users.

Conclusions: Among participants with moderate to severe DED, statin use was not associated with severity of dry eye symptoms and signs. Use of higher intensity statin was associated with lower MGD. Further analysis is needed to identify whether there is a specific type of MGD associated with intensity of statin use.

ABSTRACT BODY:

Purpose: Infectious and non-infectious uveitis (NIU) are significant causes of vision loss. Several studies have reported an association between NIU and low Vitamin D levels. However, a causal relationship between low Vitamin D level and NIU has not been established. We employed Mendelian randomization (MR) to investigate a possible causal association between Vitamin D levels and NIU.

Methods: Cases and controls were identified from the Massachusetts General Brigham Biobank. NIU cases were found by diagnostic codes and verified with an electronic medical record review. Controls were identified by the absence of uveitis diagnostic codes. Systemic diseases associated with NIU and diseases associated with Vitamin D metabolism were recorded for cases and controls. Genome-wide genotyping was performed on all patients using the Illumina Multi-Ethnic Global Array followed by imputation based on the European Haplotype Reference Consortium Panel. Then, 25-hydroxy Vitamin D (25OHD) candidate instruments (genetic variants) were selected from the summary statistics of a large genome-wide association study for Vitamin D level. Two-sample MR was performed where the causal effect was evaluated by the random-effects inverse-variance weighted (IVW) method. Individual 25OHD loci were evaluated for association with NIU.

Results: 375 cases and 4,167 controls were identified. 75 genetic variants were used in the primary MR analysis. We found a suggestive association of genetically decreased 25OHD with increased NIU risk (OR=2.17, 95%CI=0.99-4.73, P=.05; Fig. 1). Other MR methods and the leave-one-out analysis yielded consistent results. Excluding variants in the vitamin D binding gene (GC) showed a significant association (OR=2.40, 95%CI =1.06-5.46, P=.04; Fig. 1). In analyzing individual loci, genetically decreased 25OHD was associated with increased NIU risk using 6 variants within the CYP2R1 locus ($r^2 < .01$ and > 1 kb apart) (OR=7.09, 95%CI =2.76-18.25, $P=4.8 \times 10^{-5}$; Fig. 2). We identified no heterogeneity of effects or outlying genetic variants in the primary MR or individual locus analyses.

Conclusions: Our findings support a causal association between low Vitamin D levels and higher risk of NIU. This provides further support for a clinical study of Vitamin D supplementation as an adjunct intervention for preventing NIU recurrences or inducing remission.

TITLE: Effects of reading with different letter size and contrast polarity on short term changes of axial length

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Schaeffel, B. Swiatczak, Institute of molecular and clinical Ophthalmology Basel (IOB), Basel, SWITZERLAND|F. Schaeffel, Ophthalmic Research Institute, University of Tübingen, Tübingen, GERMANY|

Commercial Relationships Disclosure (Abstract): Frank Schaeffel: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Swiatczak: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Animal studies have shown that selective stimulation of ON and OFF pathways in the retina can induce bi-directional changes in the eye growth. Recently, it has also been found that choroidal thickness increases in young human subjects when they read text with inverted contrast but decreases when they read normal text. The effect was assumed to be associated with asymmetrical stimulation of ON vs OFF pathways but the receptive field sizes were not studied.

Methods: Ten young adult subjects (average age: 23 ± 1 year) with a mean refraction of -0.7 ± 1.9 D (range: $+1.7$ to -4.2 D) read text from a large screen (65") in the dark room at 2 m distance. Four kinds of texts were tested: (1) small standard text (black letters on bright background, 0.8 cm height), (2) like 1 but contrast inverted, (3) large standard text (2 cm height), (4) like 3, but contrast inverted. The visual angle for a large text was similar as for newspaper letters read at 40 cm distance. All displays were matched in brightness (40 cd/m^2) and were presented to the subjects for 30 min on two separate days (one day small text, other day large text). Changes in axial length were measured using low coherence interferometry with autopotitioning system (Lenstar LS-900) before and after reading.

Results: Averaged over all subjects, the small text did not cause any significant changes in axial length after 30 minutes of reading (standard text $+0.6 \pm 7.7 \mu\text{m}$ and inverted text $-3.9 \pm 10.6 \mu\text{m}$, n.s.). However, large text with inverted contrast induced significant axial shortening of the eye, compared to standard large text ($-11.7 \pm 8.5 \mu\text{m}$ vs. $-1.6 \pm 5.9 \mu\text{m}$, $p=0.015$). Also in myopes the large inverted text caused significant axial shortening despite the small sample size ($n=3$, $-16.3 \pm 9.6 \mu\text{m}$ vs. $0.8 \pm 5.8 \mu\text{m}$, $p=0.05$).

Conclusions: As previously described for choroidal thickness, we find that reading text with inverted contrast induces significant shortening of the eyeball. However, in this study this only worked when the visual angle of the text height was about 0.6 deg but not when it was only 0.2 degrees.

TITLE: Comparing Refractive Accuracy of Cataract Surgery Using Multiple Keratometric Platforms

SESSION TITLE: Anterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Ahmed, Ophthalmology, Washington University in St Louis, St Louis, Missouri, UNITED STATES | S. Naing, P. Dickinson, Ophthalmology, Wake Forest University, Winston-Salem, North Carolina, UNITED STATES |

Commercial Relationships Disclosure (Abstract): Kamran Ahmed: Commercial Relationship: Code N (No Commercial Relationship) | Su Naing: Commercial Relationship: Code N (No Commercial Relationship) | Paul Dickinson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We compare accuracy of spherical equivalent prediction in patients undergoing cataract surgery using keratometric values from the manual keratometer, IOL Master 500 and 700, and Pentacam. Our null hypothesis is that there is no difference in predicted spherical equivalent accuracy when comparing different keratometry platforms.

Methods: This study was an ongoing retrospective case series of all eyes undergoing cataract surgery by a single surgeon from 2019 to 2020 at Wake Forest University. Preoperative, biometric, intraoperative, and post-operative data were collected including keratometry measurements from each platform, predicted spherical equivalent based on the Barrett Universal II formula, and post-operative manifest refraction. All manual keratometry measurements were performed by the surgeon.

Results: 133 eyes met inclusion criteria for the study. Average best-corrected visual acuity improved from 20/50 (0.40 logMAR) pre-operatively to 20/22 (0.04 logMAR) post-operatively. Average spherical equivalent was -0.83 D pre-operatively and -0.31 post-operatively. There was no significant difference in prediction error: -0.05 D for the IOL Master 700, -0.05 D for the IOL Master 500, -0.10 D for the manual keratometer, and -0.19 D for the Pentacam ($p = 0.17$). There was also no significant difference in percentage of cases within 0.5 D of predicted spherical equivalent: 72% IOL Master 700, 87% IOL Master 500, 73% manual keratometer, and 73% Pentacam ($p = 0.65$).

Conclusions: There was no significant difference in keratometry measurements and accurate prediction of spherical equivalent after cataract surgery across the four platforms. This can reduce time and expense in obtaining multiple keratometry measurements unless there is suspicion for unreliability. Refractive accuracy of this study is similar to what is reported in the literature. IOL Master prediction tends toward more myopia and accuracy which is likely due to the smaller keratometric ring diameter measuring the steeper central cornea. Reaching 100% refractive accuracy will involve improved prediction of effective lens position, incorporating direct measurements of posterior corneal power, and post-operative refraction modification.

TITLE: Imaging the zonules using OCT with folded obliquely-aligned optics

SESSION TITLE: Anterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Bumstead, S. Kubach, A. Carpenter, T. Callan, K. Arianta, Y. Wang, S. Bello, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|S.T. Zhao, University of Alberta, Edmonton, Alberta, CANADA|

Commercial Relationships Disclosure (Abstract): Jonathan Bumstead: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Sophie Kubach: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Amanda Carpenter: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Thomas Callan: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Kabir Arianta: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Yingjian Wang: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Simon Bello: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Si Xi Zhao: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code C (Consultant)

ABSTRACT BODY:

Purpose: The zonules are the suspensory ligaments that connect the ciliary body to the crystalline lens and are critical for transferring force to the lens during accommodation. Because the zonules are positioned behind the iris, they are difficult to image using slit lamps and optical coherence tomography (OCT) and are therefore usually visualized using a gonioscope that contacts the patient's eye. Here we present a folded optical system that redirects the OCT scanning beam for imaging the zonules without contacting the patient.

Methods: An add-on lens was designed to redirect the scanning beam from a PLEX[®] Elite 9000 (ZEISS, Dublin, CA) swept-source OCT system to image the zonules. The add-on system maintains the same working distance and avoids the center of the field-of-view, so the iris viewer and internal fixation target of the OCT system can be used as the patient maintains central fixation. The design consists of several lenses and mirrors folded to redirect obliquely-scanned light at an angle of 70° into the patient pupil (Figure 1). Due to the non-uniform optical path length over the scan, the B-scans were transformed to more closely reflect the anatomical structure of the zonules.

Results: B-scans of the zonules were imaged in one volunteer (Figure 1d). Our design was capable of imaging the zonules over an 8.5° field-of-view with approximately 27.5µm 1/e² beam diameter at the zonules. In comparison to previous studies, the subject does not need to tilt the head or rotate the eye, which simplifies alignment.

Conclusions: Our proposed imaging system has the potential to improve assessment of whether an intraocular lens is viable for a patient by simplifying imaging of the zonules using OCT. Future designs will aim to increase imaging coverage to include the full circumference of the crystalline lens.

TITLE: Patient fixation analysis in a combined OCT and fundus imaging system.

SESSION TITLE: OCT - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Nair, H. Bagherinia, P. Sha, A. Fard, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aditya Nair: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Homayoun Bagherinia: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Patricia Sha: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Ali Fard: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: The quality of fixation achieved can greatly improve the OCT image acquisition by reducing eye motion. The patient fixation analysis serves as a measure of feedback during and after acquisition. This assessment can then be used during or after the scan to remind the patient to fixate better. In this work we demonstrate that meticulous patient fixation analysis can improve the acquisition workflow.

Methods: The motion of the eye is determined by calculating movement of the retina in the infrared-reflectance (IR) fundus image that appears in a sequence. IR images are acquired by using an IR fundus imager which is a separate sub-system from the OCT. This motion can either be horizontal (x) or vertical (y) direction along with some minor rotation. IR tracking prototype software of the CLARUSTM 500 (Zeiss, Dublin, CA) computes the tracking parameters of x and y eye motion relative to a fixation position. We analyzed the overall eye motion during an OCT image acquisition using these tracking parameters. Each eye was scanned using 3 different motion levels: good fixation, systematic eye movement, and random eye movement. The mean and standard deviation of the eye motion were reported for each motion level and each scan.

Results: Around 500 CLARUS IR images per scan (768x624 pixels over 11.52x9.36 mm² at the frame rate of 50Hz) of 15 eyes were captured with induced eye motion. Figure 1 shows the x and y eye motion relative to the initial fixation for three subjects with different induced eye motion. Figure 2 shows the statistics of eye motion for each scan of the 15 subjects. The mean value indicates the overall fixation offset from the initial fixation position. The standard deviation indicates a measure of overall eye motion within an acquisition. Scans containing systematic or random eye movement show significantly greater mean and standard deviation compared to good fixation, which is used as an indicator for poor fixation.

Conclusions: We track the retina and perform fixation analysis to highlight its use as feedback for the operator or the patient by providing informative messages during or after acquisition for reduced motion in OCT images, which is important for subsequent data processing.

SUBMITTER (NAME ONLY): Ying Wang

TITLE: Refraction vs. Keratometry Comparisons After Wavefront-Guided LASIK and Wavefront-Guided Photorefractive Keratectomy

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Wang, C. McKinnon, S. Kasthurirangan, Johnson and Johnson Medical Devices, New Brunswick, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ying Wang: Commercial Relationship(s);Johnson and Johnson:Code E (Employment) | Cheryl McKinnon: Commercial Relationship(s);Johnson & Johnson:Code E (Employment) | Sanjeev Kasthurirangan: Commercial Relationship(s);Johnson & Johnson:Code E (Employment)

ABSTRACT BODY:

Purpose: To compare the changes in refractive error and keratometry (K) in wavefront guided (WFG) LASIK and WFG photorefractive keratectomy (PRK) for correction of myopic refractive errors.

Methods: A retrospective analysis of 334 eyes (170 patients) with manifest refractive spherical equivalent (MRSE) of $-6.21 \text{ D} \pm 2.78 \text{ D}$ (range: -12.13 D to -1.25 D) who underwent WFG Lasik, and 334 eyes (167 patients) with MRSE of $-4.08 \text{ D} \pm 1.97 \text{ D}$ (range: -8.75 D to -0.63 D) who underwent WFG PRK was performed. Outcome measures were changes in keratometry measurements taken with a full gradient corneal topographer and corresponding refractive changes compared preoperatively and at 6 months postoperatively. A correlation analysis was performed to determine the relationship between changes in refractive error (ΔSE) and changes in keratometry (ΔK). Ratio ($\Delta\text{K}/\Delta\text{SE}$) of change in keratometry (ΔK) to change in refractive error (ΔSE) was calculated and compared.

Results: A strong negative correlation (LASIK: $r = -0.897$ (ΔSE vs ΔK), and PRK: $r = -0.903$ (ΔSE vs ΔK), $p < 0.0001$ for both) was seen between the change in refraction and change in average K for both. The mean ratio for ΔK and ΔSE was -0.78 ± 0.28 for LASIK and -1.03 ± 0.52 for PRK. A larger ratio ($\Delta\text{K}/\Delta\text{SE}$) for the WFG PRK compared to the WFG LASIK (ratio difference of 0.25 with 95% CI of (0.19, 0.31), $p < 0.0001$) was found. WFG PRK required more corneal flattening for a given change in refractive error when compared to WFG LASIK. The accuracy of intended versus achieved MRSE outcomes at 6 months indicate good accuracy of treatment per MRSE outcomes (LASIK, slope: 0.99, $r = 0.988$, $p < 0.001$ and PRK, slope: 1.04, $r = 0.975$, $p < 0.001$).

Conclusions: The refractive outcomes after both LASIK and PRK were comparable with good predictability at correcting myopia. However, WFG LASIK measurements showed a smaller amount of corneal flattening for a given degree of myopic refractive correction compared to WFG PRK.

TITLE: Trachoma and facial cleanliness are associated with environmental factors and hygiene behaviors in Tanzania

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Chen, B. Munoz, M. Wolle, H. Mkocha, S.K. West, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Xinyi Chen: Commercial Relationship: Code N (No Commercial Relationship) | Beatriz Munoz: Commercial Relationship: Code N (No Commercial Relationship) | Meraf Wolle: Commercial Relationship: Code N (No Commercial Relationship) | Harran Mkocha: Commercial Relationship: Code N (No Commercial Relationship) | Sheila West: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Facial cleanliness and environmental improvement are parts of the SAFE strategy to eliminate trachoma, but the impact of environmental factors on children's facial cleanliness and trachoma have not been extensively explored, especially when disease burden is low. We performed a cross-sectional clinical study to identify environmental factors affecting children's facial cleanliness and trachoma in Kongwa, Tanzania, where the overall prevalence of trachoma was 7% but varied between villages.

Methods: A standardized survey was carried out to observe characteristics of household environment and hygiene behaviors in a random selection of 1,798 households in 92 villages. Children aged 0-5 in these households were examined for facial cleanliness. In 50 randomly-selected villages, children aged 1-9 were randomly selected and examined for trachoma.

Results: Time spent on obtaining water was generally short and not correlated with clean faces. In a multivariate model adjusting for child age and household wealth, children were more likely to have clean faces if the yard was clean, if the household had an improved latrine, if the household had greater water storage capacity, and if there were clothes drying around the house. Based on our findings, we constructed a cleanliness index which was a summary score of the following markers: clean yard, washing clothes, improved latrine, ≥ 1 child in the household having clean faces. When the community prevalence of trachoma was $<5\%$, more than 50% of household in the community had a score of 2 or higher. If the trachoma prevalence was more than 10%, less than 50% of households had a score of 2 or higher. An ordinal logistic regression predicting category of trachoma prevalence (0-5%, 5-9.9%, $\geq 10\%$) found that a 0.5 unit increase in the community average clean index score was associated with a 2.3 increase in the odds of dropping trachoma prevalence by one category.

Conclusions: A household cleanliness index that increases with increasing number of cleanliness factors was significantly correlated with decreased community prevalence of trachoma, suggesting that a multi-pronged approach to improve household cleanliness is valuable for trachoma elimination.

ABSTRACT BODY:

Purpose: The kinetics of antigen-presenting cells (APCs) vary depending on their resident tissues and the manner of sensitization. We investigated the long-term kinetics of APCs in Balb/c mouse models of corneal quiescent or potent sterile inflammation and allosensitization using corneal partial trephination, syngeneic, and allogeneic corneal transplantation.

Methods: Balb/c mice were assigned into 4 groups: control, corneal partial trephination (PT), 2.5 mm-to-2.0 mm syngeneic (Syn) and C57BL/6 to Balb/c allogeneic corneal transplantation (Allo). The serial changes in CD11b⁺CD11c⁺MHCII^{hi}, CD11b⁺CD11c⁺MHCII^{hi}, and CD11b⁺CD11c⁻MHCII^{hi}, and CD69^{hi} or interferon gamma (IFN γ)^{hi} effector T cell subsets were evaluated in the ocular surface, draining lymph nodes (dLNs), and spleen for over 4 weeks.

Results: In PT, CD11b⁻CD11c⁺MHCII^{hi} and CD11b⁺CD11c⁺MHCII^{hi} subsets increased until 4 weeks with increases in ocular IFN γ ^{hi} T cells. In Syn, ocular CD11b⁺CD11c⁺MHCII^{hi} and CD11b⁺CD11c⁻MHCII^{hi} cells increased until 4 weeks with an increase in ocular CD69^{hi} T cells. However, in Allo, the ocular and lymph nodal CD11b⁺CD11c⁺MHCII^{hi} and CD11b⁺CD11c⁻MHCII^{hi} cells and ocular CD11b⁺CD11c⁻MHCII^{hi} cells significantly increased until 4 weeks and primed both the ocular and lymph nodal IFN γ ^{hi} and CD69^{hi} T cell subsets. Ocular CD11b⁺CD11c⁺MHCII^{hi} subset appears to be a major population that becomes mature MHCII^{hi} APCs, regardless of the inflammation type.

Conclusions: This indicates that allosensitization activates the corneal CD11b⁻CD11c⁺MHCII^{hi}, CD11b⁺CD11c⁺MHCII^{hi} and CD11b⁺CD11c⁻MHCII^{hi} cells leading nodal maturation of CD11b⁻CD11c⁺MHCII^{hi} and CD11b⁺CD11c⁺MHCII^{hi} subsets to interact with nodal T cells, whereas sterile inflammation seems to induce ocular T cell interaction independently of the nodal activation of APCs.

ABSTRACT BODY:

Purpose: One of the most common causes of vision loss after retinal surgery is the formation of scar tissue on, in or under the retina, which can result in proliferative vitreoretinopathy (PVR). The current standard practice involves surgical removal of scar tissue, which carries intrinsic risk. Even if PVR is successfully treated by surgery, vision impairment could still result, and hence there is an urgent need to find alternative non-surgical solutions for PVR prevention.

Methods: Thermogelling polymer, composed of poly(ethylene glycol) (PEG), poly(propylene glycol) (PPG) and poly(ϵ -caprolactone) (PCL), referred to as poly(CEP), was synthesized. A surgically induced rabbit model of PVR was used to validate poly(CEP)'s efficacy in preventing PVR, in comparison to Sulfur Hexafluoride (SF_6). The polymer-cell interactions and the effect on scarring were further investigated in an in vitro model of PVR using human embryonic stem cell-derived retinal pigment epithelial (ES-RPE) cells. Cellular assays to study poly(CEP)'s effects on hyper-proliferation and increased migratory capacity of RPE cells, were conducted. Poly(CEP) internalization was observed using flow cytometry. Key epithelial-mesenchymal transition (EMT) markers were analyzed at both mRNA and protein level.

Results: Poly(CEP) prevented fibrosis, scarring and tractional retinal detachment in the rabbit model of PVR, in addition to acting as an effective vitreous tamponade. Poly(CEP) at 1wt%, in its micellar form and in a concentration-dependent manner, completely inhibited the formation of contractile fibrocellular membranes in the in vitro model of PVR. Furthermore, at the same concentration of 1wt%, poly(CEP) showed the highest suppression of proliferation and migration of RPE cells. Poly(CEP) exerted this anti-scarring property after internalization and through the modulation of EMT-related transcription factor genes.

Conclusions: In this work, we show that a thermogelling polymer prevents retinal scarring in a pre-clinical rabbit model of PVR. This is mediated via a polymer-induced impairment of EMT, which results in suppression of RPE cell proliferation and migration. This is the first report wherein a synthetic polymeric material, without the use of any small molecule therapeutics, is shown to inhibit EMT and prevent retinal scarring. This study highlights the potential of the next generation of nanomedicine whereby small molecule drugs are no longer required.

TITLE: Efficacy of elastic Breath-O Correct orthokeratology on myopia control in a 1-year study period

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Wong, K. Choi, H.H. Chan, C.T. Lam, School of Optometry, The Hong Kong Polytechnic University, Kowloon, HONG KONG|H.H. Chan, C.T. Lam, Centre for Eye and Vision Research Limited, Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): Tsz King Wong: Commercial Relationship: Code N (No Commercial Relationship) | Kai Yip Choi: Commercial Relationship: Code N (No Commercial Relationship) | Henry Chan: Commercial Relationship: Code N (No Commercial Relationship) | Chuen Lam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study is to evaluate the myopia reduction effect and myopia control efficacy of the novel elastic Breath-O Correct orthokeratology (OK) lenses.

Methods: A total of 85 subjects aged 9 to 12 years with spherical equivalent refraction (SER) between -1.00D and -4.00D were recruited, then randomly assigned into OK (n=49) or spectacle control (n=36) groups. Breath-O Correct lenses were prescribed in OK group with routinely scheduled aftercares. Corneal topography, SER, unaided and best-corrected visual acuity in LogMAR (BCVA), anterior chamber depth (ACD), and axial length (AL) were measured at baseline and 1-year visit. For the control group, update of spectacles was indicated if there was a 0.50D difference in spherical or cylindrical power by subjective refraction in a 6-month follow-up.

Results: Seventy-one subjects (OK: 42, Control: 29 Age 9.46 ± 1.32 years) completed the 1-year study. Seven OK subjects withdrew due to poor visual quality, inconvenient lens care, and COVID-19 pandemic. Seven control subjects withdrew due to fast myopia progression and COVID-19 pandemic. In OK group, the 1-year simulated flat and steep K decreased significantly (Flat K: -1.57 ± 0.95 D; Steep K: -1.59 ± 1.07 D; $p < 0.001$) with a mean unaided visual acuity of 0.09 ± 0.13 . The mean dry subjective SER in control and OK groups were -2.92 ± 1.32 D and -0.07 ± 0.66 D ($p < 0.001$) respectively without significant difference in BCVA (Control: 0.01 ± 0.04 , OK: 0.00 ± 0.05 ; $p > 0.05$). The mean AL elongation was significantly different between two groups (Control: 0.35 ± 0.2 mm, OK: 0.14 ± 0.17 mm, $p < 0.001$). A significant ACD elongation was also noted in control group but absent in OK group (Control: 0.073 ± 0.096 mm, $p < 0.001$; OK: -0.054 ± 0.326 mm $p > 0.05$). RM-ANOVA with post-hoc Bonferroni correction revealed significant interaction between OK treatment and the rate of myopia progression in 1 year ($p < 0.001$).

Conclusions: The novel elastic Breath-O Correct OK lens effectively retarded AL elongation, and hence, myopia progression in school-aged children without compromising BCVA and with maintenance of good unaided daytime vision.

ABSTRACT BODY:

Purpose: We hypothesize that patients with type 1 diabetes (T1D) may have abnormal retinal vascular responses before diabetic retinopathy (DR) is clinically evident. Optical coherence tomography angiography (OCTA) was used to dynamically assess the retinal microvasculature of diabetic patients with no clinically visible retinopathy.

Methods: Controlled non-randomized interventional study. The studied population included 48 eyes of 24 T1D patients and 24 demographically similar healthy volunteers. A commercial OCTA device (AngioVue®) was used and two tests were applied: (i) the hypoxia challenge test (HCT) and (ii) the handgrip test, in order to induce a vasodilatory or vasoconstrictive response, respectively. The HCT is a standardized test that creates a mild hypoxic environment equivalent to a flight cabin. The handgrip test (i.e. isometric exercise) induces a sympathetic autonomic response. Changes in the parafoveal superficial and deep capillary plexuses in both tests were compared in each group. Systemic cardiovascular responses were also comparatively evaluated.

Results: In the control cohort, the median parafoveal superficial and deep plexuses' vessel density increased during hypoxia ($F_{1,23}=15.69$, $p<0.001$ and $F_{1,23}=16.26$, $p<0.001$, respectively). In the T1D group, this physiological response was not observed in neither the superficial, nor the deep retinal plexuses. Isometric exercise elicited a significant decrease in vessel density in both superficial and deep plexuses in the control group ($F_{1,23}=27.37$, $p<0.0001$ and $F_{1,23}=27.90$, $p<0.0001$, respectively). In the T1D group, this response was noted only in the deep plexus ($F_{1,23}=11.04$, $p<0.01$).

Conclusions: Our work suggests there is an early impairment of the physiologic retinal vascular response in patients with T1D without clinical diabetic retinopathy.

TITLE: Modulating ocular surface pain through Neurokinin-1 receptor blockade

SESSION TITLE: Corneal disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: G. Ferrari, R.M. Lasagni Vitar, P. Fonteyne, P. Rama, Eye Repair Lab, IRCCS Ospedale San Raffaele, Milano, Lombardia, ITALY]

Commercial Relationships Disclosure (Abstract): Giulio Ferrari: Commercial Relationship(s); Ospedale San Raffaele: Code P (Patent) | Romina Lasagni Vitar: Commercial Relationship: Code N (No Commercial Relationship) | Philippe Fonteyne: Commercial Relationship: Code N (No Commercial Relationship) | Paolo Rama: Commercial Relationship(s); Ospedale San Raffaele: Code P (Patent)

ABSTRACT BODY:

Purpose: The aim was to test the role of Substance P and its receptor Neurokinin 1 (NK1R) on ocular surface pain.

Methods: 8-week-old C57BL6/N (WT) and B6.Cg-Tac1tm1Bbm/J (TAC1-KO) male mice were used. 5 M NaCl was topically applied on the cornea, followed by topical application of NK1R antagonist Fosaprepitant 2, 10, 50 mg/mL; 4 mg/mL Oxybuprocaine chloride, or 0.1% Diclofenac. The eye-wiping test was used to quantify ocular surface pain. Substance P (SP) content was quantified in the tear fluid and trigeminal ganglia (TG), and TAC1 mRNA was assessed in the cornea. Corneas were immunostained for β 3-tubulin and NK1R to image peripheral nerves.

Results: TAC1-KO mice or a single dose of 10 or 50 mg/mL Fosaprepitant applied topically to WT displayed a significant reduction of nociception ($p < 0.001$) compared to vehicle, while 2 mg/mL Fosaprepitant induced corneal analgesia when it was administered for 10 days, ($p < 0.05$). Diclofenac or Oxybuprocaine reduced corneal nociception when compared to vehicle or Fosaprepitant ($p < 0.05$). Fosaprepitant or Oxybuprocaine treated groups showed lower SP content in tear secretions and TG ($p < 0.05$), and reduction in TAC1 mRNA ($p < 0.05$) in the cornea. Co-localization of NK1R and β 3-tubulin was detected in mouse corneas.

Conclusions: Topical administration of the NK1R antagonist Fosaprepitant effectively reduces ocular surface pain, SP release in the tear fluid and TG. Fosaprepitant repurposing shows promise for the treatment of ocular pain.

ABSTRACT BODY:

Purpose: Diagnostic delay in identifying intracranial pressure (ICP) elevation may lead to permanent visual impairment or profound neurological disability. Invasive, poorly tolerated methods currently used have associated clinical risk. Optical Coherence Tomography (OCT) and retinal infrared (IR) video offer a non-invasive, non-contact imaging method. Absence of spontaneous venous pulsation (SVP) on IR video alongside OCT optic nerve head (ONH) swelling raises suspicion of elevated ICP.

However, OCT is typically table-top mounted, installed in primary eye care centres or hospital ophthalmology departments and is inaccessible in acute or high dependency care settings. We aim to establish the feasibility of OCT, OCT-Angiography (OCTa) and IR video as a bedside investigation for acutely unwell hospital inpatients including intensive care.

Methods: The Heidelberg Flex™ imaging system is a flexible and mobile ophthalmic imaging solution with a highly capable imaging head mounted on a flexible arm on a wheel-based structure. One individual using a foot pedal took images in healthy control and conscious hospital inpatients laying supine. Three individuals were needed to image unconscious patients. One individual held patients' heads still and lids open, one operated the computer interface and one operated the imaging head. Due to the flexibility of the mobile imaging head, it was possible to capture ONH imaging independent on patient fixation, a significant advantage in unconscious patients. Hypromellose 0.3% eye drops were used prior to imaging for unconscious patients. No mydriatic drops were used.

Results: OCT and OCTa box scans plus IR en-face video centred on the ONH were acquired from both eyes for all conscious study patients. OCT videos, positioned to intersect a main branch of the retinal vein, were also captured. OCTa was not possible on unconscious patients due to poor fixation and lack of patient blink. OCT video failed to identify SVP possibly due to the fact that several images are averaged to produce each frame. However, SVP was clearly detectable on IR en-face video.

Conclusions: The Heidelberg Flex™ imaging system presents a useful method to non-invasively confirm normal ICP in acutely unwell hospital inpatients, including intensive care patients. En-face IR video is more effective than OCT video in identifying SVP and thus normal ICP.

ABSTRACT BODY:

Purpose: The role of IL6-family cytokines, potent activators of the STAT3 pathway, on angiogenesis and in vascular retinal disease is controversial. Despite STAT3 as a shared signaling pathway, some IL-6 family members like oncostatin M (OSM) seem to be proangiogenic, others like ciliary neurotrophic factor (CNTF) appear to inhibit retinal angiogenesis.

This study tries to explain those differences and the role of STAT3 in retinal angiogenesis by comparing the effect of cytokine-induced activation and knock-down in vascular endothelial cells.

Methods: Angiogenic responses of human umbilical vein cells in response to VEGF, OSM or CNTF treatment were assessed by spheroid sprouting- and migration assays. Cytokine-dependent signaling was evaluated by western blot and metabolic alterations by extracellular flux. A STAT3 knock-down was established using siRNA. Transcriptomic shifts were assessed by RNA sequencing.

Results: OSM elicits proangiogenic responses on top of VEGF-induced cell sprouting ($\Delta = +31\%$, $p < 0.05$) and migration ($\Delta = +29.2\%$, $p < 0.05$) whereas CNTF has antiangiogenic effects on sprouting ($\Delta = -21.9\%$, $p < 0.05$) and a small influence on migration ($\Delta = +6.1\%$, $p < 0.05$). Both cytokines activate STAT3 while OSM also signals through ERK and AKT. Furthermore, OSM phosphorylates STAT3 at serine 727 and shifts cells to an active metabolic state by increasing mitochondrial performance. RNA-Seq revealed a transcriptomic shift favoring migration in response to OSM but not CNTF treatment. STAT3 knock-down reduced VEGF-induced cell sprouting ($\Delta = -39\%$, $p < 0.05$) by affecting the cytoskeleton assembly. Interestingly, STAT3 knock-down changed CNTF's antiangiogenic effect to a proangiogenic response ($\Delta = +77.8\%$, $p < 0.05$) while enhancing OSM's proangiogenic drive ($\Delta = +369.9\%$, $p < 0.05$). No other pathways showed compensatory upregulation on protein level. RNA-Seq analysis determined a clear shift to a state of proliferation and migration in OSM-stimulated knock-down cells.

Conclusions: The divergent angiogenic properties of OSM and CNTF can be explained by individual differences in signaling, influence on metabolism and transcriptomic shifts. The shared STAT3 pathway seems to be essential to keep proangiogenic responses in check. In conclusion, this study sheds light on IL6-family endothelial cell interaction and reveals a novel perspective on the role of STAT3 in angiogenesis.

TITLE: OKN-onset is influenced by the contrast level of a visual stimulus

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Essig, Y. Sauer, S. Wahl, Institute for Ophthalmic Research, Tübingen, GERMANY|S. Wahl, Carl Zeiss Vision International GmbH, Aalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Peter Essig: Commercial Relationship: Code N (No Commercial Relationship) | Yannick Sauer: Commercial Relationship: Code N (No Commercial Relationship) | Siegfried Wahl: Commercial Relationship(s); Carl Zeiss Vision International GmbH: Code E (Employment); Carl Zeiss Vision International GmbH: Code F (Financial Support)

ABSTRACT BODY:

Purpose: Search for an objective approach to measure contrast sensitivity has already been commenced, while the use of eye movements showed a potential solution. The current study aimed to search for the onset time of the optokinetic nystagmus (OKN) quick-phase (QP) in respect to various contrast levels over a range of spatial frequencies (SF) of a moving grating. A trend in timing of the first-OKN-QP for different parameters of a visual stimulus may give a theoretical implementation in the stimulus-presentation-time optimization.

Methods: To stimulate the OKN response, a 3 seconds sequences of horizontally moving bars with a velocity of 2.5 °/sec, of selected spatial frequencies (SF=1,2,3,4 cpd) and a contrast range C=0.1-58 %, with 22 log-steps in between, were used, whereas the contrast levels were uniformly distributed over 184 trials. Furthermore, as the clinical approach for measuring contrast sensitivity was followed (monocular stimulation), an infra-red filter was installed in front of the left eye of all seven subjects with normal vision. Extracting the OKN events was performed first using a velocity-based algorithm for saccadic (OKN-QP) detection, in continuation with directional and velocity analysis of the slow-phase of OKN (OKN-SP) between two detected OKN-QPs. Next, the search for time of the first OKN-QP after stimulus onset was performed just in trials in which at least two OKN events were detected, requesting a robust response to given parameters of the visual stimulus. On top of that, the found times were clustered with respect to the stimulus parameters (SF, C) for all subjects and the mean time was calculated within a 7.5 % contrast windows.

Results: The application of Spearman's correlation, showed a robust propensity of decreasing the mean first-OKN-QP time with increasing contrast level for all four used SFs ($R_{all}^2 > 0.76$), while the effect of SF was shown as not significant ($p=0.1$; $\chi^2=6.27$). In all SFs combined, the first-OKN-QP time was found to be 361 ± 12 ms for the highest contrast level (C = 58%), whereas it changed towards 525 ± 32 ms for the lowest contrast level (C=0.1 %).

Conclusions: In conclusion, this study showed an influence of contrast level on the time of OKN onset, hence this study discloses a possible methodological approach of improving the time efficiency of contrast sensitivity testing using the OKN reflexes, by adjusting the presentation time of a visual stimulus of particular parameters.

TITLE: Deep learning based best focus image detection in automated gonioscopy

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Zandonà, L. Cappellari, NIDEK Technologies Srl, Albignasego, Padova, ITALY|

Commercial Relationships Disclosure (Abstract): Alessandro Zandonà: Commercial Relationship(s);NIDEK Technologies Srl:Code E (Employment) | Lorenzo Cappellari: Commercial Relationship(s);NIDEK Technologies Srl:Code E (Employment)

ABSTRACT BODY:

Purpose: NIDEK GS-1 (NIDEK CO., LTD Japan) provides a 360° view of the iridocorneal angle by acquiring multiple images on different focus planes over the whole angle depth. The device also provides a feature-based algorithm (FB) to automatically detect the images with the best focused Target Region (TR), i.e. the trabecular meshwork or, in case of angle closure, the iridocorneal interface. In this work, we developed a deep learning based algorithm (DLB) to improve the detection accuracy of the images with the best focused TR (henceforth best focus shots).

Methods: The algorithm includes two steps: first, the extraction of a ROI centered at the TR (not part of this work), then the processing of image pairs by a Siamese Convolutional Neural Network (SCNN) that predicts the probability that one shot has a more focused TR than the other. The SCNN is coupled with a concatenation and a fully-connected layer with a softmax activation function, and optimizes a categorical cross entropy loss. The SCNN is trained inside a Cross-Validation (CV) on 288 stacks of 17 images each, and a Bayesian optimization is performed over the CV folds to tune the SCNN hyperparameters. To test the predictive performance of our solution, both DLB and FB algorithms are run on 96 image stacks that were not considered for training, and the results are compared with the manually identified best focus shots. In detail, the performance is assessed by computing the distance between predicted and actual best focus shots.

Results: DLB achieves better mean performance over the stacks with respect to FB, being both mean and median distance between predicted and actual best focus shots smaller (Tab. 1, Fig. 1). Moreover, DLB's smaller standard deviation suggests a more stable performance over the stacks than FB (Tab. 1).

Conclusions: Our algorithm has the potential to improve the detection of shots with the best focused TR; consequently, our solution increases the automation of the examination, making it more accessible to non-expert personnel, and providing an exam quality that is less operator dependent.

ABSTRACT BODY:

Purpose: NIDEK GS-1 (NIDEK CO., LTD. Japan) captures 360° exams of the iridocorneal angle. The angle is split into 16 sectors each acquired on 17 focal planes. Incorrect alignment conditions, patients' movements during exam acquisition, difficulty in keeping the eye open may degrade the quality of acquired images possibly preventing a correct pathology assessment. The aim of this work is to use Deep Neural Networks (DNNs) for assigning a quality index to GS-1 images.

Methods: A total of 1835 images (RGB, 1280x960) taken from healthy and pathologic eyes were used. For each image a 224x224 ROI centered on the most relevant part of the angle (trabecular meshwork or irido-corneal interface for closed angles) was considered as input to the DNN. The dataset was manually split into two classes: "good" and "bad". The former enclosed all images whose ROI was not saturated and rich of details, whereas the latter contained the remaining images (see examples in Fig 1). Since good and bad classes were unbalanced (1-to-10 ratio), 5 partially overlapping ROIs for good images and 1 ROI for bad images were considered, respectively. Transfer Learning was chosen in place of training a DNN from scratch. Hence, a pretrained network was chosen and partially retrained for the new quality-index task, with the advantage of reducing training time and computational requirements. For this study, the VGG16 and Xception DNNs trained on ImageNet were considered. The input dataset was divided into training, validation, and test sets having 70%, 20%, and 10% of images, respectively.

Results: The Xception-based DNN gave the best results with ~95% accuracy and fast convergence (<15 epochs). The quality index has been assessed both on the test set and by visually comparing the best-quality image with the best-focus image in a focus sequence (see Fig 2).

Conclusions: Transfer learning based on off-the-shelf DNNs can be successfully used for giving a quality index to GS-1 images. The proposed algorithm could reduce the time spent by clinicians for selecting the best images on which to perform the clinical assessment and could be also used for automatically retaking the examination if an insufficient quality is detected improving the effectiveness of the device.

ABSTRACT BODY:

Purpose: The Phase 3 HAWK (NCT02307682) and HARRIER (NCT02434328) studies evaluated the efficacy and safety of brotacizumab (Bro) versus aflibercept (Afl) in previously untreated patients with neovascular age-related macular degeneration. All patients received three monthly loading injections, then brotacizumab was injected q12w unless disease activity (DA) was identified resulting in permanent adjustment to q8w, while aflibercept was dosed q8w throughout the study, as per label at study initiation. Due to the study design, Bro patients adjusted to a q8w regimen at the end of the matched loading phase at Week 16 owing to DA could not subsequently extend to a q12w interval. The aim of this post-hoc analysis is to assess subsequent DA in patients with DA at Week 16 to determine the potential for interval extensions during the first year of treatment if the protocol had allowed it.

Methods: In Year 1 of HAWK and HARRIER, disease activity assessments (DAA) were conducted at Weeks 16, 20, 32, and 44 in both studies for all Bro and Afl patients regardless of whether DA was detected at earlier visits or not; presence of DA was determined at the discretion of the masked investigator. This post-hoc analysis evaluated the absence of DA, and thus potential for interval extension, in the matched cohort of Bro and Afl patients with DA at Week 16 using pooled data from the Bro 6 mg arms and Afl arms of both studies. Absence of DA at two consecutive DAA was considered a surrogate for stable disease control.

Results: At the first DAA at Week 16, more Bro vs Afl patients had no DA (77.0% [n=540/701] vs 67.5% [n=470/696]). Within the subgroup of patients with DA at Week 16, more Bro than Afl patients had absence of DA at each subsequent DAA in Year 1 (Fig 1). Furthermore, a higher proportion of Bro vs Afl patients had DA absence at two consecutive DAA (Week 20/32: Bro=56.8%, Afl=45.2%; Week 32/44: Bro=66.9%, Afl=51.2%).

Conclusions: Conclusions: In HAWK and HARRIER, more Bro- vs Afl-treated patients with DA at Week 16 had no DA at subsequent assessments from as early as Week 20, including at consecutive DAAs. These findings indicated a higher potential for treatment interval extension and robust and stable disease control with Bro within the first year of treatment.

ABSTRACT BODY:

Purpose: RETIPROGRAM is a registered clinical decision support system program for diabetic retinopathy (DR) screening. The algorithym calculates the risk of developing DR in the next years attending to medical variables. The initial results were already shown previously in ARVO 2020. Currently the aim is not only to show its accuracy as much as its prediction capability, detecting future DR in short term in patients without DR.

Methods: The program was developed since a statistical analysis was based on fuzzy random forest methodology, assessing different medical variables.

The sample included 98873 of diabetes mellitus type 2 population. The medical variables registered were age, gender, diabetes mellitus duration, arterial hypertension, HbA1, glomerular filtration rate, microalbuminuria and body mass index. Attending to these variables it is calculated an estimated risk and it is suggested a date for the next control.

Results: To validate the results consistency the risk percentage were compared with the presence of DR in the retinography.

The test sensibility was 60.36%, specificity 78,61% and 19644 were considered false positive. The false positive group images were reviewed after two years and it was shown that 11.949 had already DR. The progression rate in the false positive group was 60,82% in two years.

The initial sensitivity and specificity values were good enough, but if they are corrected according the results after two years, the sensitivity (84,20%) and specificity (90,37%) values would be even better.

False positive group, is commonly considered as a test error, but in this case, analyzing it carefully it would report some added test value, the capability of prediction in absence of DR in the retinography.

Conclusions: In general, and also in DR, screening models efficacy means its capability to detect pathologies in early stages and their risk of progression. Currently all patient without DR in the retinography are usually considered into low risk group, ignoring their medical risk and they would be misdiagnosed. On other hand, an isolated retinography offers an accurate information about the current patient status but it has to be completed with medical factors related with the progression risk (RETIPROGRAM).

In our opinion RETIPROGRAM offers a predictive value of DR progression in short term and completes the retinographies information, offering a more personalized and accurate acting plan.

TITLE: A double-pass fundus reflection model for efficient single retinal image enhancement

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Zhang, Universiteit Maastricht Faculty of Health Medicine and Life Sciences, Maastricht, Limburg, NETHERLANDS|W. Carroll, T. Berendschot, Maastricht Universitair Medisch Centrum+, Maastricht, Limburg, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Shuhe Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Webers Carroll: Commercial Relationship: Code N (No Commercial Relationship) | Tos TJM Berendschot: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: High contrast is a prerequisite for fundus images to be used for successful diagnosis in clinical practice. Current contrast enhancement models show promising results, but they have not been optimized for retinal images, due to the ignorance of specific double-pass fundus reflection feature. In this study, we propose the double-pass fundus reflection (DPFR) model and test the hypothesis that the DPFR model can be more efficient and simpler for retinal image enhancement than previous methods.

Methods: The DPFR model is derived according to the light propagation in a fundus camera. Based on the model, the dark-channel prior de-hazing is applied twice to a raw retinal image to correct the uneven illumination, and reduce the straylight effect of the image. Then we convert the de-hazed image into CIE-Lab color space to apply the Contrast Limited Adaptive Histogram Equalization to its L channel, resulting in the final enhanced image. We compared the performance of the DPFR model with two state-of-art methods including the Luminosity and Contrast Adjustment (LCA) and Pixel Color Amplification (PCA). All methods are applied to the data from four public databases, namely the DRIVE-, the STARE-, the DiaRet- and the Cataract database. Both visual and objective assessments are shown. For objective assessments, we use the multiscale image contrast, C_{RAMM} , and the color difference between raw images to evaluate enhancement performance.

Results: Figure 1 shows that the DPFR model effectively balances the uneven illumination, and improved the clarity of retinal images since structures like blood vessels that were hidden behind the cataract in the raw image could be observed after enhancement. Table 1 shows the mean value of C_{RAMM} and color differences of raw and enhanced images from the four separate databases for the LCA, PCA, and DPFR methods, respectively. We found significant differences between the three methods (all $P < 0.001$). Although the PCA resulted in higher C_{RAMM} than other methods, it has worse color preservation (larger color difference value), as can be seen in Fig. 1, which makes this method less suitable for clinical use.

Conclusions: The DPFR model enables efficient illumination correction, contrast improvement, and color preservation. It on average enhances image contrast by two-fold, while the color differences are less than 10%, and show better performance compared to existing methods.

ABSTRACT BODY:

Purpose: X-linked cone dysfunction has been shown to cause variable structural and functional disruption of the long (L) and/or middle (M) wavelength-sensitive cone mosaic. Although the condition is considered to be isolated to L and M cones, the effect, or lack thereof, on rod density has not yet been confirmed. Adaptive optics scanning light ophthalmoscopy (AOSLO) enables in vivo visualization of the photoreceptor mosaic. Here we quantify the density of rods – derived from the density recovery profile (DRP) – and cones within the macula in patients who do not have normal L or M opsin, and thereby present with symptoms of blue cone monochromacy.

Methods: Eight patients (aged 16 to 51 years) with quantifiable parafoveal AOSLO images were selected for analysis. All patients had genetically confirmed mutations affecting both L/M opsin genes: four had the Cys203Arg missense mutation, three had abnormal exon-3 haplotypes (two with LVVVA; one with MIAVA + LIAVA), and one had a deletion of the locus control region (LCR). Where possible, rods and cones were counted (using confocal and split-detection AOSLO images respectively) in 1° increments from 3° to 10° along the temporal meridian.

Results: Although the overall mean (SD; n) cone density (cones/mm²) was reduced from normal, ranging from 6,446 (5,817; 4) at 3° to 1,750 (636; 2) at 10°, there were differences between the genotypes, with Cys203Arg trending towards lower cone density (Fig 1). Mean (SD; n) cone-corrected DRP-derived estimates of rod density (rods/mm²) ranged from 54,383 (28,276; 5) at 4° to 81,810 (1,4621; 3) at 9°, although, again, there were genotype differences, with Cys203Arg trending towards higher rod density (Fig 2).

Conclusions: Understanding the cone and rod topography within the macula is crucial for assessing the potential impact and monitoring efficacy of future therapeutic efforts in X-linked cone dysfunction. Our data suggest that, in patients who lack expression of normal L and M opsin genes, rod density and/or distribution across the retina may be affected by genotype.

ABSTRACT BODY:

Purpose: Presentation of the 52-week results from KITE and KESTREL, two prospective pivotal Phase III studies evaluating the efficacy and safety of brolucizumab (BRO) versus aflibercept (AFL) for the treatment of patients with visual impairment due to diabetic macular edema (DME).

Methods: KITE (NCT03481660) and KESTREL (NCT03481634) are 2-year, ongoing, double-masked, randomized, active-controlled, multicenter studies. Adults (≥ 18 years of age) with type 1 or type 2 diabetes mellitus, visual impairment due to DME with a BCVA score between 78 to 23 ETDRS letters, and DME involving the center of the macula with a central subfield thickness (CSFT) $\geq 320\mu\text{m}$ on SD-OCT in the study eye at screening were included. In KITE, patients were randomized 1:1 to BRO 6mg or AFL 2mg; in KESTREL, the randomization was 1:1:1 to BRO 3mg, BRO 6mg and AFL 2mg. Patients in the BRO groups received 5 loading doses every 6 weeks (q6w) followed by q12w dosing in the first year, with an option to adjust to q8w at predefined disease activity assessment visits. The AFL group received 5 loading doses monthly followed by fixed q8w dosing. The primary endpoint was the change from baseline in BCVA at Week 52; secondary endpoints included the proportion of BRO patients maintained at q12w dosing up to Week 52 and the change from baseline in CST. Results from the KITE study only are included here, results from the KESTREL study (estimated primary completion, December 2020) will be available to present at congress.

Results: In KITE, the primary objective was met with BRO 6mg non-inferior to AFL 2mg in the change from baseline in BCVA at Week 52. More than 50% of BRO 6mg patients were maintained on a q12w dosing interval through Week 52, following the loading phase. BRO 6mg showed superior improvements versus AFL 2mg in the change from baseline in CST over the period of Week 40 through Week 52. BRO 6mg demonstrated an overall well-tolerated safety profile that was comparable to AFL 2mg; in addition, the rate of intraocular inflammation was equivalent between BRO 6mg and AFL 2mg.

Conclusions: Results from the KITE study show that brolucizumab offers the potential for robust vision gains and superior anatomical outcomes with q12w treatment intervals in more than 50% of patients with DME. The data from KESTREL are expected later this year.

ABSTRACT BODY:

Purpose: Myo/Nog cells express MyoD, Bai1 and the bone morphogenic protein inhibitor Noggin. They are critical for normal embryonic development, including eye morphogenesis. In adults, they respond to stress and injury. Depletion of Myo/Nog cells in the mouse retina was associated with increased photoreceptor cell death, while their addition to the vitreous preserved function and reduced cell death following light damage in the rat. Here we examine the behavior of endogenous and exogenous Myo/Nog cells in response to increased intraocular pressure (IOP) in a mouse model of glaucoma.

Methods: Glaucoma was induced in the right eye of each animal by impeding the outflow of the aqueous humor with microbeads injected into the anterior cavity of C57BL/6J mice (D0). IOP was measured periodically from D0 to D32. Seven days after insertion of microbeads, three of four groups received bilateral AC injections of PBS, unsorted brain cells or Myo/Nog cells isolated from the brain with the G8 monoclonal antibody and prelabeled with a fluorescent dye. The fourth group received no follow up injections. Eyes were collected at D32, and immunofluorescence localization of exogenous and endogenous G8+ cells was performed.

Results: Myo/Nog cells injected into the anterior chamber were tracked to areas of stress, such as the trabecular meshwork, the ciliary body and the canal of Schlemm. The highest concentration of Myo/Nog cells were found in the cornea and retinal ganglion cell layer. H&E staining showed a statistical deficit in living retinal ganglion cells within the RGC layer of the glaucomous eye compared to the non-glaucomous eye among the PBS and mixed population treatment groups, and no statistical loss of cells within the glaucomous eye compared to the non-glaucomous in the exogenous Myo/Nog treatment group.

Conclusions: Myo/Nog cells increase in number in response to elevated IOP and are concentrated in areas of stress in the eye. Endogenous Myo/Nog cells were increased around the optic nerve and periphery of the retina compared to normal retinas. Myo/Nog cells injected into the anterior chamber showed evidence of integration into tissues that are affected by impaired aqueous humor outflow and migrate to areas of increased endogenous Myo/Nog concentration within the eye. Injection of exogenous Myo/Nog cells also showed preservation of retinal ganglion cells in glaucomous eyes.

ABSTRACT BODY:

Purpose: RPD are currently considered a high-risk feature for progression in early age-related macular degeneration. We thus sought to train a deep learning model to reliably segment RPD on B-scans in order to automatically detect and quantify the extent of these lesions.

Methods: 478 B-scan images with visible RPD from 29 participants with bilateral large drusen were used. An expert assigned each pixel a binary classification of RPD or normal. Using Dice coefficient loss, a U-Net was trained on randomly sampled regions of 359 B-scans of 20 participants. The network was then validated on the 119 B-scans of the remaining 9 participants. Sensitivity to training patch size and the number of scans used for training was investigated.

Results: The model segmentation (Figure 1) achieved a Dice of 0.67 and 0.8 on the validation and training sets, respectively. Horizontal flipping and rotation imparted no appreciable gain on the Dice. Training patch widths were varied from 32 pixels to the full size 1024 pixels (Figure 2A), resulting in the decrease of the Dice for the 32 pixel case, which is attributed to a higher fraction of lesion segments being cut off for this patch width. A patch width of 256 pixels was selected for training thereafter. For the data subtraction study (Figure 2B), the number of scans in the training set were varied from 359 down to 1 scan. With a training set of 1 B-scan the Dice was 0.48.

Conclusions: A U-Net was successfully trained to segment RPD lesions achieving a Dice of 0.67. Our results suggest that patch width should be chosen to avoid cutting off most lesions. The data subtraction study suggests that the dataset is uniform enough for the network to learn a general set of features from a single B-scan. Our preliminary findings demonstrate promise for developing a reliable method for detecting and quantifying RPD.

ABSTRACT BODY:

Purpose: The biocompatibility of intravitreal bevacizumab has been established over the past two decades for the safe and effective treatment of retinal neovascular diseases. The topical application of bevacizumab, however, for the treatment of corneal neovascularization raises concerns due to its potential corneal cytotoxicity. In this in vitro, experimental study, we evaluated the cytotoxic effects of bevacizumab on the viability and metabolism of human corneal epithelial cells (HCEpCs) and human corneal endothelial cells (HCEncs), as well as human retinal pigment epithelial cells (ARPE-19) for comparison.

Methods: Cell lines of HCEpCs, HCEncs and ARPE-19 were exposed to clinically relevant concentrations of bevacizumab (0.313-5.00 mg/ml). The ApoTox-Glo Triplex Assay was used to assess cell viability, cytotoxicity and apoptosis and the Mitochondrial ToxGlo Assay was used to assess cell membrane integrity and ATP levels of the three cell types after a 24-hr. treatment period.

Results: Across all three cell types, we observed similar results of a decrease in cell viability at 5.00 mg/ml ($p < 0.05$) and an increase in cytotoxicity at 5.00 mg/ml ($p < 0.05$), while apoptotic activity remained unchanged ($p > 0.05$), which is a profile consistent with cells undergoing primary necrosis at high concentrations. Additionally, cell membrane integrity was compromised at 5.00 mg/ml ($p < 0.05$), while no decrease in ATP levels were observed ($p > 0.05$). This indicates no interference with mitochondrial oxidative phosphorylation in ATP production and thus, the cells were able to maintain normal metabolic levels at high concentrations.

Conclusions: HCEpCs, HCEncs and ARPE-19 experience a decrease in viability and undergo primary necrosis when exposed to bevacizumab at concentration of 5.00 mg/ml, however they are able to maintain normal metabolism and mitochondrial function at high concentrations used for the treatment of corneal neovascularization.

ABSTRACT BODY:

Purpose: Binocular summation of briefly-presented, central and peripheral, spatially-distributed stimuli has been investigated in numerous studies with emphasis on stimulus size, location in the visual field and state of background adaptation. This study examined the binocular threshold summation of cone- and rod-specific, flickering stimuli as a function of stimulus size and retinal location.

Methods: Flicker modulation thresholds (FMT's) were measured under monocular and binocular viewing conditions in 13 subjects with normal vision (mean age:23±3yrs, best-corrected visual acuity $\leq 0.0\log\text{MAR}$, stereoacuity $\leq 40\text{arc sec}$ and normal trichromatic colour vision). Rapid flicker thresholds were measured using the Flicker-Plus test (City Occupational Ltd., London) for 5 different target sizes (7, 15, 30, 45 and 60arc min) in central vision (0°) and at an eccentricity of 5° in each quadrant using a 5-alternative forced-choice psychophysical technique. The temporal frequency, duration, luminance and chromaticity of the flickering stimuli was optimized to favour either cone- or rod-photoreceptors. The ratio of the subject's monocular FMT (measured in the best eye) and the corresponding binocular threshold was used to quantify binocular summation.

Results: Monocular FMT's decreased monotonically with target size for both cone- and rod-optimized stimuli ($p<0.001$). Not surprising, the extreme percentage FMTs corresponded to the smallest (7') and the largest (60') stimuli with $m\pm s$ values of: 9.69 ± 1.06 and 2.35 ± 0.20 (for cones) and 20.92 ± 2.50 and 4.45 ± 0.50 (for rods). Binocular FMT's followed the same trend for all viewing conditions but were smaller than their monocular counterparts ($p<0.001$). The mean summation ratios was 1.28 ± 0.49 for cones and 1.41 ± 0.35 for rods. There was no indication of significant changes in binocular summation with either target size ($p<0.12$) or retinal location ($p=0.67$).

Conclusions: Detection thresholds for luminance-modulated flicker exhibit large binocular summation with both cone- and rod-enhanced stimuli. Although both monocular and binocular FMTs show large, systematic variation with target size and retinal location, the binocular summation ratio remains largely invariant of these parameters.

ABSTRACT BODY:

Purpose: The role of the transcription coactivator YAP has been studied during eye development but its implication in ocular homeostasis and diseases is much less documented. YAP is expressed by several ocular cell types including the non-pigmented cells of the ciliary body (CB) as well as Müller glial cells (MGs) of the neuroretina. Here, we assessed whether postnatal Yap deletion in these two cell types could affect eye homeostasis during aging.

Methods: Specific Yap deletion in CB and MGs was induced in a conditional mouse model (Yap cKO) at P10. The phenotype was investigated by western-blot, immunohistochemistry, and RNA-sequencing (RNA-seq). Blood defects were identified by fluorescein angiography. Optic nerve degeneration was assessed by optical coherence tomography. Intraocular pressure (IOP) was recorded by a rebound tonometer. Imaging of the CB in healthy and uveitic human patients was performed by ultrasound biomicroscopy.

Results: At two months, Yap cKO eyes exhibited distended ciliary processes and blood leakage from the iris. Anterior uveitis became chronic with age resulting in collapse of the CB as observed in human patients. At nine months, the CB was dysfunctional as inferred by pathway analysis of RNA-seq data showing deregulation of genes belonging to the GO group "symporter activity" that encode regulators of aqueous humor composition. In line with this, IOP was increased in aged female mice whereas males had a trend towards hypotony. Since such a phenotype is highly reminiscent of glaucoma, we assessed whether Yap cKO mice exhibited other hallmarks of the disease, focusing on the neuroretina. At two months, MGs-derived glutamine synthetase – the key enzyme in the regulation of glutamate metabolism – was downregulated. By six months of age, MGs gliosis and microglial cell activation were evident. Finally, nine-month-old Yap cKO retinas harbored signs of blood defects, disturbed glutamate metabolism, reduced number of retinal ganglion cells, and excavation of the optic nerve head.

Conclusions: Altogether, these results show that Yap deletion in both the CB and MGs causes chronic anterior uveitis followed by secondary glaucoma. This highlights a novel and unsuspected function of YAP in homeostasis maintenance of both the neuroretina and the anterior chamber which may open new avenues towards a better understanding of glaucoma etiology.

TITLE: Risk factors for neovascularization after central retinal artery occlusion

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Lo, M. Chen, Taipei Veterans General Hospital Department of Ophthalmology, Taipei, TAIWAN|M. Chen, National Yang-Ming University School of Medicine, Taipei, TAIWAN|

Commercial Relationships Disclosure (Abstract): Kang-Jung Lo: Commercial Relationship: Code N (No Commercial Relationship) | Mei-Ju Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Central retinal artery occlusion (CRAO) is a rare disease with prevalence about 1/100,000, not to mention the ocular neovascularization (NV) after CRAO was only account for 10-20%. With such a low occurrence rate, most related articles were published in case reports or case series. In recent four decades, only few articles mentioned about the risk factors that associate with this scenario. As a prestigious tertiary referring center in Taiwan, we possessed much cases of ocular NV after CRAO. Hence, in this article, we try to find the risk factors in patients with ocular NV after CRAO in recent fifteen years in our hospital.

Methods: We reviewed medical records of all patients who visited Taipei Veterans General Hospital from January 2006 to May 2020 and enrolled patients with a diagnosis of acute CRAO. All charts were further reviewed for the occurrence of ocular NV and the period between CRAO and ocular NV. In addition, systemic conditions, first visit ocular conditions, age and gender were all recorded for analysis. The mean and standard deviation of continuous variable parameters were analyzed using the Student t test, and the hazard ratio (HR) and their 95% confidence intervals (95% CIs) of risk factors in two cohorts (with or without ocular NV after CRAO) were analyzed by using the Cox proportional hazards regression model.

Results: Eighty-seven eyes were eligible for this study. Among them, 13 patients were found ocular NV after CRAO while 74 patients were found no ocular NV after CRAO. The percentage of hypertension, diabetes mellitus, history of stroke, chronic kidney disease (CKD) and age at first visit were found higher in patients with ocular NV after CRAO than patients without ocular NV after CRAO. Moreover, most CKD patients in ocular NV group were found underwent dialysis. After multivariate Cox regression analysis, CKD (HR:9.27, 95% CI: 1.87-46.05) and patient has glaucoma (HR:7.52, 95% CI: 1.14-49.46) were considered as risk factors in patients with ocular NV after CRAO.

Conclusions: In this study, we found CKD and patient has glaucoma were two risk factors in patients who have ocular NV after CRAO, especially in patients who underwent dialysis. The unstable hemodynamic condition during dialysis was thought to be the main contributor. Therefore, it is important to strictly control of hemodynamic variation during dialysis and receive at least annual fundoscopic exam in patients underwent dialysis.

TITLE: Comparison of best corrected visual acuity estimated with a digital chart and the ETDRS chart

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Raeme, P.G. Soderberg, Z. Yu, neuroscience/ophthalmology, Uppsala Universitet, Uppsala, SWEDEN|

Commercial Relationships Disclosure (Abstract): Faisal Raeme: Commercial Relationship: Code N (No Commercial Relationship) | Per Soderberg: Commercial Relationship: Code N (No Commercial Relationship) | Zhaohua Yu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the best corrected visual acuity (BCVA) estimated with a digital visual acuity chart, the AxAnlvls system, and with the ETDRS chart at different visual acuity classes.

Methods: Total 26 subjects ≥ 55 years were divided into 4 visual acuity classes of [1.0 0.8], [0.7 0.5], [0.4 0.2] and [0.1 -0.1] logMAR. The BCVA of each subject was measured with both the ETDRS chart and the AxAnlvls system on two separate occasions. The examination time, spherical error, cylindrical error and axis angle were recorded.

Results: The estimated 95% CI for the mean BCVA difference between two charts (AxAnlvls – ETDRS) was -0.03 \pm 0.03 logMAR. No systematic difference between the charts was found (Test statistic = 2.60, $F_{1,16,0.95} = 4.49$), and there was no statistically significant difference between the charts depending on visual acuity class (Test statistic = 0.67, $F_{3,8,0.95} = 3.24$). The examination time for the AxAnlvls system was 40s shorter than that for the ETDRS chart.

Conclusions: The findings that no significant difference between the two charts, and no significant difference between the charts depending on visual acuity class indicate the AxAnlvls system can be an alternative of the ETDRS chart. This digital system has shorter testing time compared to the ETDRS chart

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has necessitated a global paradigm shift regarding healthcare delivery, replacing the traditional in-office visit with a virtual platform, in order to limit viral exposure and spread. The purpose of this study is to evaluate agreement between the diagnosis and management of common eye diseases seen in virtual eye care visits versus traditional in-office visits.

Methods: This is a retrospective chart review of patients who presented to a single center for a video televisit between March and June 2020. Agreement was based on a qualitative comparison between the documented primary diagnosis and treatment plan at the first synchronous video visit and first subsequent in-office visit.

Results: During the NY State Lockdown, a single-center practice saw 779 distinct patients virtually. The most common diagnostic categories were Lids/Adnexa (29%), Cornea (18%), and Glaucoma (16%). Of these, 425 (55%) were subsequently seen at an in-office visit. When comparing the primary diagnosis at the two visits, a similar diagnostic code was maintained for 354 patients (83%). There were no known significant adverse outcomes for any patient seen virtually.

Medication changes were made at 268 (34%) video visits. These were guided by symptoms and external exams, although a minority were prophylactic or part of post-operative care. The new treatment plan was maintained for the same diagnosis at 50% of the subsequent in-office visits. Overall, there was an escalation of care for 131 patients (31%), a de-escalation of care for 32 patients (7.5%), and no change in management for 257 patients (60.1%) at the follow-up traditional office visit. Glaucoma patients were the most likely to require additional management (either drops or procedural intervention) when seen in the office.

Conclusions: Based on the results of this study, teleophthalmology provides a safe, feasible, and fairly accurate means of providing routine outpatient eye care.[1] There was an agreement in diagnoses between the virtual and traditional visit in 83% of patients and management plans remained unchanged for at least 60% of patients. Particularly given the importance of the ophthalmic exam, there are limitations to this model of care resulting in missed diagnoses or escalations of care. Addressing these limitations will require further investigation. 1. Tan et al., J Telemed Telecare, 2017.

ABSTRACT BODY:

Purpose: To investigate the five-year cumulative incidence and progression of myopic maculopathy in the general population in Germany and to analyze potential risk factors.

Methods: The Gutenberg Health Study (GHS) is a population-based cohort study, including 15,010 participants aged 35 to 74 years at baseline. Myopic maculopathy incidence and progression was assessed by grading of fundus photographs according to a recent international photographic classification system (META-PM), in phakic eyes with spherical equivalent $\leq -6D$ (baseline). 509 eyes of 334 participants (mean age 50.4 ± 9.2 years; median: $-7.25D$ myopic refractive error) without myopic maculopathy at baseline and 34 eyes of 27 subjects (mean age 56.7 ± 9.1 years; median $-9D$ myopic refractive error) with myopic maculopathy met the conditions and had gradable fundus photographs at baseline and five-year follow-up. Multivariable logistic regression analysis was used to assess risk factors for progression of myopic maculopathy.

Results: 5-year cumulative incidence of myopic maculopathy was 0.3% (95%CI: 0.02-1.92%; n=1). Progression occurred in 17 of 34 eyes (50%) with prior myopic maculopathy over 5 years with 4 changes in category. The most common types of progression were enlargement of chorioretinal and patchy atrophy; a new pathology was present in 8 eyes. Higher IOP (OR=1.62, 95%CI: 1.03-2.53, p=0.035) was associated with progression of myopia, while female gender (OR=5.54, 95%CI: 0.93-32.92, p=0.060) and higher myopic refractive error (OR=1.62 per diopter, 95%CI: 0.99-1.49, p=0.063) showed a tendency towards progression.

Conclusions: Incidence of myopic maculopathy is rare in highly myopic eyes in the general population in Germany at age 35 to 74 years. Progression of eyes with myopic maculopathy in the German population occurred in 50% of prior diseased highly myopic eyes. These population-based five-year follow-up data on incidence and progression of myopic maculopathy are the first in Europe.

ABSTRACT BODY:

Purpose: Since the surgical approach for progressive symptomatic retinal detachment complicating degenerative retinoschisis (PSRDCR) is controversial, the purpose of this study is to identify factors important for selecting the appropriate surgical intervention. We present the outcomes following surgical intervention for PSRDCR via pars plana vitrectomy (PPV), scleral buckle (SB), or combined PPV/SB in a retrospective case series of 18 phakic eyes.

Methods: Patient records from Jan 1, 2008-Dec 31, 2019 were reviewed. Charts with retinal detachment (RD) surgeries were identified using billing codes, and those with PSRDCR were included following manual screening. Charts with diagnoses other than degenerative retinoschisis or less than 6 months of follow-up following primary RD repair were excluded. Data regarding demographics, surgical approach, post-operative complications, and anatomic/functional outcomes were collected from patient records.

Results: Of the 4973 charts reviewed, 36 eyes (0.7%) had retinoschisis with RD. Eighteen eyes of 17 patients met inclusion criteria. The median age was 54 years (range 18 to 74). All eyes were phakic and 10/18 presented with cataracts. 10/18 eyes had outer layer breaks (OLBs), 17/18 had inner layer breaks (ILBs), and 9/18 had a concurrent ILB and OLB. The single surgery anatomic success (SSAS) rate and final anatomical success rate were 66% (12/18) and 100% (18/18) respectively. Eyes treated with PPV/SB had the highest SSAS rate at 75% (9/12), while PPV and SB had SSAS rates of 66% (2/3) and 33% (1/3), respectively.

Conclusions: The SSAS rate in this series is lower than for uncomplicated rhegmatogenous RD. The low SSAS rate may be caused by poor visualization of ILBs, especially with cataract, and the inability to remove peripheral vitreous leading to vitreous base contraction with resultant vitreoretinal traction. Due to low sample size, statistical conclusions regarding optimal surgical technique are not possible. However, a combination of PPV to enhance visualization of ILBs, and SB to mitigate vitreous base contraction should be considered for extensive PSRDCR. We further postulate that in eyes with concurrent cataract, combining phacoemulsification and IOL placement with RD repair may improve visualization of ILBs and allow the removal of peripheral vitreous.

ABSTRACT BODY:

Purpose: The ABCD progression display (Pentacam, Oculus GmbH, Wetzlar, Germany) monitors progression in corneal ectasia and reports statistically significant changes by displaying one-sided 80% and 95% confidence intervals (CI) of each measured parameter. The parameters are anterior (A) and posterior (B) radii of curvature taken from a 3.0 mm optical zone centered on the thinnest point and thinnest pachymetry reading (C). The current system does not display CI after corneal cross-linking (CXL), as measurement noise of this population has not been established. Our prior study on noise post-CXL showed large CI in eyes with less than a year follow-up period. This study aimed to measure noise of post-CXL eyes after a year or longer and provide CI for this group.

Methods: Patients from ELZA Institute (Zurich, Switzerland) and Homburg Keratoconus Center (Homburg, Germany) with a minimum of 12 months post-CXL were enrolled. Three separate Pentacam measurements were taken for each eye, removing the patient from the Pentacam device between each measurement. A minimum 7.5 mm of coverage and an acceptable quality score were required. Pooled variance, standard deviations (SD), and one-sided CI were computed. Site specific and time specific comparisons were made using nonparametric statistics.

Results: 60 eyes (38 Zurich, 22 Homburg) of patients aged 29.5 ± 12.3 (range 11-62) were enrolled. Patients were 26.1 ± 19.3 months (range 12-28 Zurich, 16-115 Homburg) post-CXL. The values of A, B, and C parameters and their respective noise measured as SD were all comparable between sites. A subgroup analysis of eyes from Homburg comparing 16-35 months to 38-115 months post-CXL showed no difference in SD. Spearman's Rho demonstrated no correlation between time post-CXL and SD in all parameters. The 80% CI of A, B, and C parameters were 0.0283, 0.0492, and 3.682, respectively. The 95% CI were 0.0553, 0.0962, and 7.196, respectively.

Conclusions: Measurement noise of each parameter on the ABCD progression display was analyzed in eyes post-CXL with at least 12-month follow-up period. Noise, after 12 months post-operatively, was not correlated with time post-CXL in this group. CI of each measured parameter were computed as above and will be incorporated into the next iteration of the Belin ABCD progression display.

ABSTRACT BODY:

Purpose: Flavoprotein fluorescence (FPF) imaging has emerged as a technology to better understand retinal metabolism. There is no disseminated, standardized method of grading these images. The purpose of this study was to apply a novel Likert-based grading scale to an existing image database to test its ability to select for high quality images, reduce variability in scores, and improve intergrader reliability.

Methods: 3664 images and their associated flavoprotein fluorescence (FPF) and heterogeneity score (CW) were automatically generated by Ocumet® Image Analysis software at the time of patient presentation. The images had been analyzed by a combination of graders on a three point Likert scale without a rubric. Three independent, blinded graders were trained on appropriate use of a novel, five point novel grading rubric. A database was populated with the images and graders completed the images. Intergrader reliability was assessed by Fleiss Kappa metric.

Results: Fleiss Kappa metric for the novel grading scale was 0.584, indicating moderate agreement. Of the mismatches occurring in the old grading scale roughly 33.3% were between adequate/inadequate images (highest/lowest category). Of all mismatches occurring in the new grading scale only 11.7% occurred between Grade A and B images and Grade C,D, F images (highest/lowest categories). With only 2.4% occurring in Grade A images. When applied to Diabetes Mellitus and Age-related Macular Degeneration the new model reduced the variability in FPF and CW images classified as grade A or B. The greatest variance in FPF and CW occurred in images classified as Grade D or F. The total number of usable images decreased from 62.3% to 11.7%.

Conclusions: The Likert-based grading scale enhanced selection of high-quality images, reduced score variability, and improved inter-grader reliability. It has promise for future applications in similar settings.

ABSTRACT BODY:

Purpose: Oxidative stress and subsequent damage to retinal mitochondria is thought to play a key role in the pathogenesis of several retinal diseases including age-related macular degeneration (AMD). When oxidized, retinal mitochondrial flavoproteins auto-fluoresce green light when excited by a particular wavelength of blue light. This emitted flavoprotein fluorescence (FPF) can be measured and used as a quantifiable marker for oxidative damage-induced mitochondrial dysfunction. This study aims to assess FPF in a sample of AMD patients grouped by stage of disease progression.

Methods: This study was a retrospective chart review of patients diagnosed with early, intermediate, or advanced non-exudative AMD or neovascular AMD between 2012-2019 based on AREDS criteria. The comparison group included retinal images from healthy age-matched controls. Patients with comorbid glaucoma, ocular hypertension, concomitant retinopathy or uveitis, history of retinal detachment, history of cataract surgery, retinal surgery within three months, fluorescein angiogram prior to imaging, or pseudophakic lens were excluded. For each patient image, FPF score (i.e., intensity) and curve width (i.e., heterogeneity) were recorded using the OcuMet Beacon (OcuSciences, Ann Arbor, MI).

Results: The final analysis included 369 images. The multivariable regression included early, intermediate, and advanced non-exudative AMD and neovascular AMD as well as age, smoking status, gender, ethnicity, and eye location. Intermediate and advanced non-exudative AMD and neovascular AMD were significant predictors of increased FPF score intensity (13.86, CI 8.46–19.25, $p < 0.001$; 30.85, CI 17.86–43.83, $p < 0.001$; 17.79, CI 11.91–23.67, $p < 0.001$ respectively), but early non-exudative AMD was not (-3.83, CI -12.82–5.16, $p = 0.40$). Early, intermediate, and advanced non-exudative AMD and neovascular AMD were significant predictors of increased FPF score heterogeneity (0.39, CI 0.17–0.60, $p < 0.001$; 0.43, CI 0.31–0.56, $p < 0.001$; 0.83, CI 0.52–1.13, $p < 0.001$; 0.69, CI 0.55–0.83, $p < 0.001$, respectively)

Conclusions: Non-exudative and neovascular age-related macular degeneration are associated with increased retinal mitochondrial oxidative stress as evidenced by increased intensity and heterogeneity of flavoprotein fluorescence in patients with this disease.

Commercial Relationships Disclosure (Abstract): Masahiko Ayaki: Commercial Relationship: Code N (No Commercial Relationship) | keiichi miyasaka: Commercial Relationship(s);Echo Electricity Co., Ltd.:Code E (Employment) | hiroshi otake: Commercial Relationship: Code N (No Commercial Relationship) | aya o'hira: Commercial Relationship: Code N (No Commercial Relationship) | Mico Arai: Commercial Relationship: Code N (No Commercial Relationship) | tsutomu sakai: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the association of the strip meniscometry (SM) tear meniscus volume measurement with dry eye-related signs and symptoms in over 2000 sample case series.

Methods: This cross-sectional study enrolled 2234 consecutive outpatients and we used dry eye symptomatology and related ocular surface examinations including the Schirmer Test (ST), fluorescein tear film break-up time (BUT), corneal fluorescein vital staining (FLUO), and SM. The cut-off of SM was estimated using ROC analysis. The subjective symptoms consisted of binarized seven items: dryness, fatigue, photophobia, pain, irritation, blurring, and lacrimation. The clinical signs were also binarized by the cut-off in each test. The entire presence of signs and symptoms were then analyzed using Hayashi's quantification theory type III to depict their mutual similarities.

Results: The mean age of subjects was 59.3 ± 17.3 yrs. The mean values were 13.6 ± 9.6 mm for ST, 3.1 ± 2.1 s for BUT, 0.40 ± 0.66 for FLUO, and 2.4 ± 2.7 mm for SM. ST had a weak negative correlation with age ($r = -0.152$, $p < 0.01$), whereas BUT and SM did not. All pairs among ST, BUT and SM had significant correlations; the highest value was found in the BUT-SM pair ($r = 0.238$, $p < 0.01$). On the basis of the large-scale sample size ($n = 1162$), a cut-off length of SM was newly suggested as 2.5 mm (AUC = 0.618) in reference to former 4.5 mm. The quantification type III analysis elucidated the high similarity among the presence of signs by SM, BUT and FLUO, while that by ST appeared to be isolated from the other signs. Three symptoms (pain, irritation and dryness) had a distinct similarity.

Conclusions: SM results with the cut-off = 2.5 mm could be a useful clinical indicator for initial screening of dry eye.

TITLE: Anti-VEGF Therapy and Elevated Intraocular Pressure: A Race-Based Analysis

SESSION TITLE: Blood flow/ Ischemia/reperfusion/Aqueous humor dynamics/IOP

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Nasser, A. Michael, V. Chen, Z. Zhang, Ophthalmology, Tulane University, New Orleans, Louisiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Taj Nasser: Commercial Relationship: Code N (No Commercial Relationship) | Abenet Michael: Commercial Relationship: Code N (No Commercial Relationship) | Victor Chen: Commercial Relationship: Code N (No Commercial Relationship) | Ze Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Since the advent of anti-VEGF therapy, many reports of associated elevated intraocular pressure (IOP) have come to light. It is known that race has an important role in patient care where African American (AA) patients are at higher risk of reaching adverse glaucomatous endpoints more frequently. However, the literature lacks race-based studies regarding anti-VEGF therapy and incidence of elevated IOP. The aim of this study is to compare the incidence of elevated IOP following anti-VEGF therapy between AA and Caucasian patients as well as evaluate for possible risk factors.

Methods: This is a retrospective study of adult patients treated with intravitreal Bevacizumab injections (IVI) at two tertiary referral centers and two Veteran Affairs clinics over the past decade. Subjects were included if they were >18 y.o. with a minimum of two years of follow up after the first IVI. Exclusion criteria were current or history of intravitreal steroid or topical steroid therapy and neovascular glaucoma. Subjects were categorized into three groups: group 1 were subjects receiving IVI with no previous diagnosis of ocular hypertension (OHTN) or glaucoma, group 2 were subjects receiving IVI with pre-existing diagnosis of OHTN/glaucoma, and the control group were subjects who did not receive IVI. Data collected included race, age, gender, indication of IVI, elevation of IOP above baseline ($\geq 20\%$, $\geq 21\text{mmHg}$, $\geq 25\text{mmHg}$), months until first IOP elevation, and phakic status.

Results: There was a statistically significant association between incidence of IOP elevation and IVI whereby our study showed that after about 5 IVI, patients were found to have a higher incidence of elevated IOP. There was no statistical significance between Caucasian and AA subjects receiving IVI. The elevated IOP occurred at an average of about 6-7 months following the first IVI in both groups. Furthermore, we found that there was no statistically significant difference based on indication for IVI, phakic status, gender or age.

Conclusions: This study confirmed that there is a statistically significant relationship between anti-VEGF therapy and incidence of elevated IOP. We found that this relationship was not significant based on history of glaucoma/OHTN, race, indication, gender, age, and phakic status. These results further reinforce the importance of monitoring the IOP of patients receiving anti-VEGF therapy and contribute to patient-centered care.

TITLE: Incremental Economic Burden of Depression in Ophthalmic Patients

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Alsaloum, C. Rasendran, School of Medicine, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|R.P. Singh, K. Talcott, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|Y. Imran, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Peter Alsaloum: Commercial Relationship: Code N (No Commercial Relationship) | Chandruganesh Rasendran: Commercial Relationship: Code N (No Commercial Relationship) | Yahya Imran: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Talcott: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The total economic burden of ophthalmic pathologies is rising exponentially. In addition, there is a correlation between the development of depression in patients with vision problems; yet, little is known about the additional economic stress of depression placed on these co-morbid patients. A retrospective cross-sectional analysis was performed to analyze the incremental economic burden of depression on adults with ophthalmic conditions in the United States.

Methods: Adults with at least one outpatient ophthalmology visit were identified by ICD-9-CM codes within the Medical Expenditure Panel Survey (MEPS, 2007-2015). These patients were stratified based on the presence of concurrent depression. A multivariate two-part regression model was used to compare economic burden, healthcare utilization, and expenditures between ophthalmic patients with and without depression.

Results: Ophthalmic patients diagnosed with depression (n=2474) had a mean expenditure of \$15,385.48±731.38 while ophthalmic patients without depression (n=7944) had a mean expenditure of \$11,744.26±350.98. Patients with depression were more likely to be female, white, and lower-income (p<0.001). These patients faced \$2,564.25 (p<0.001) in incremental economic expenditures due to depression, resulting in an additional \$4.52 billion annually when extrapolating nationally. These patients also had higher expenditures for inpatient (p=0.002) and prescription medications (p<0.001) (Table 1).

Conclusions: The increase in inpatient and medication expenditures were the major drivers of high healthcare utilization seen in ophthalmic patients with depression. However, there was no difference in outpatient expenditures, suggesting possible inadequate outpatient management of depression in these patients with increased reliance on inpatient care. Alternatively, these patients may have confounding systemic diseases that require inpatient hospitalization and eye-related exams. The presence of a bidirectional relationship between ophthalmic and psychiatric conditions and the demonstrated financial burden for patients with both, displays the need for ophthalmologists to be more cognizant of the financial burdens of depression among their patients.

ABSTRACT BODY:

Purpose: To determine the incidence of uveitis in the US for new and established patients in the IRIS Registry.

Methods: IRIS® Registry patients receiving eye care prior to and during the 2017 period of interest (POI) were included. Cases of uveitis and their anatomic location were identified and subdivided using ICD-10 codes: anterior uveitis (AU), intermediate uveitis (IU), posterior uveitis (PU), panuveitis (PanU), scleritis, retinal vasculitis (RV), and “mixed” (scleritis + any intraocular inflammation). New patients were those not previously registered in IRIS who presented with a uveitis diagnosis during the POI. Established patients were defined as the cohort seen prior to 2016 with ≥1 year of follow-up who received a new diagnosis of uveitis in 2017. To exclude postoperative uveitis, patients who had an intraocular procedure in or 90 days before 2017 were excluded. Cumulative incidence rate and demographic factors were analyzed.

Results: Among established patients, the cumulative uveitis incidence rate during the POI was 112.84 per 100,000 person-years, with incident cases being most common in the 7th and 8th decades of life (DOL).(Table) Among new patients, the percentage of patients who presented with a uveitis diagnosis was highest in the working-age population, with a peak percentage of 0.63% in the 4th DOL. Black or African-American patients had the highest incidence among established patients and also the highest percentage of uveitis among new patients.(Table) The baseline age distribution of both established and new patients diagnosed with IU was wider than the rest of the uveitis categories and patients without a diagnosis of uveitis.(Figure)

Conclusions: The incidence of uveitis within the IRIS dataset is comparable to that reported in other population-based studies. Among established patients, uveitis incidence was highest in the 7th and 8th DOL. Among new patients, the working-age population was predominantly affected. Black or African-Americans were disproportionately affected by uveitis, compared to other races.

ABSTRACT BODY:

Purpose: To evaluate the relationship between choriocapillaris (CC) flow deficits (FD) and structural optical coherence tomography (OCT) biomarkers, and the progression of intermediate age-related macular degeneration (iAMD) to complete retinal pigment epithelial and outer retinal atrophy (cRORA) or macular neovascularization (MNV).

Methods: Multicenter retrospective analysis of consecutive patients with iAMD. Odds ratios for IHRF, hDC, SDDs, and high drusen volume, fellow eye with late AMD, duration of follow-up, peripheral and central CC FD estimated from logistic regression.

Results: 30 iAMD eyes from 30 patients were enrolled into each group. Among eyes which progressed to cRORA, there was a significantly higher proportion of eyes with IHRF, hDC and high drusen volume. The CC FD was greater in the peripheral sectors of the macula of eyes which progressed to cRORA compared to the other two groups ($P < 0.0001$). The central CC FD was also significantly impaired in eyes that progressed to cRORA or MNV compared to those that did not progress ($P = 0.001$ and $P = 0.02$, respectively). CC FD in the peripheral macula was significantly and independently associated with the development of cRORA, while CC FD in the center was significantly and independently associated with the development of MNV.

Conclusions: While the CC is diffusely impaired throughout the macula in iAMD eyes that progress to cRORA, it is relatively spared in the more peripheral macula among eyes which progress to MNV. These differential findings may have implications for the pathophysiology of the different late stage manifestations of AMD.

TITLE: Examining the Necessity of Day-1 Postoperative Review After Pars Plana Vitrectomy: A Meta-Analysis

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.R. Bheemidi, V.D. Roan, Case Western Reserve University School of Medicine, Cleveland, Ohio, UNITED STATES|J. Muste, R.P. Singh, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Abhinav Bheemidi: Commercial Relationship: Code N (No Commercial Relationship) | Vivian Roan: Commercial Relationship: Code N (No Commercial Relationship) | Justin Muste: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship(s);Alcon/Novartis:Code C (Consultant);Genentech/Roche:Code C (Consultant);Zeiss:Code C (Consultant);Bausch + Lomb:Code C (Consultant);Regeneron Pharmaceuticals, Inc.:Code C (Consultant);Apellis:Code F (Financial Support);Graybug:Code F (Financial Support)

ABSTRACT BODY:

Purpose: The current standard of care following retina surgery, particularly pars plana vitrectomy (PPV), is an in-person evaluation conducted on postoperative day 1 (POD1). Given the inherent difficulty of patients with visual disability attending POD1 visits and the safety concerns raised during the COVID-19 pandemic, a critical examination of this standard of care is needed. This study is a meta-analysis that aims to evaluate the necessity of the POD1 review following PPV.

Methods: The analysis included available literature documenting medical and surgical interventions performed on POD1 review following PPV. 2262 patients across 14 eligible studies were included in the analysis. A meta-analysis of proportions was conducted using a binomial-normal model to analyze datasets consisting of all interventions, medical interventions, and surgical interventions. The primary outcome measured was the proportion of patients requiring an intervention on POD1. Heterogeneity and publication bias analyses were performed. Statistical analyses were performed using R (version 3.5.1).

Results: Of the 80 references identified as being of potential relevance, 14 studies met all eligibility criteria. POD1 reviews of 2262 patients were analyzed to yield an intervention rate estimate of 4.7% [95% CI 3.0-13.9]. The proportion of patients requiring medical interventions (4.1% [95% CI 1.4-11.6]) was significantly greater than that of surgical interventions (0.7% [95% CI 0.3-1.3]). Elevated intraocular pressure was the most frequent POD1 complication, accounting for 77.0% and 40.0% of medical and surgical interventions respectively. The heterogeneity analysis revealed significant inter-study variation, with I^2 values of 97.93%, 97.80%, and 20.99% for the all intervention, medical intervention and surgical intervention datasets respectively. Attempts to integrate the different indications for surgery into this analysis were unsuccessful due to variability in reporting of indications and interventions.

Conclusions: Given the wide confidence interval of the estimated intervention rate, variability in postoperative practices, and range of interventions performed, the POD1 review cannot be discarded. Future analyses could identify clinical characteristics associated with patients at a higher risk of requiring POD1 intervention.

TITLE: JR5558 transgenic mice are a reliable model to investigate subretinal fibrosis

SESSION TITLE: Models to study retinal degeneration and remodeling

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Seyed-Razavi, S. Lee, J. Fan, W. Shen, M.C. Gillies, Ophthalmology, The University of Sydney Save Sight Institute, Sydney, New South Wales, AUSTRALIA

Commercial Relationships Disclosure (Abstract): Yashar Seyed-Razavi: Commercial Relationship: Code N (No Commercial Relationship) | So-Ra Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jiawen Fan: Commercial Relationship: Code N (No Commercial Relationship) | Weiyong Shen: Commercial Relationship: Code N (No Commercial Relationship) | Mark Gillies: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The development of subretinal fibrosis is a major and untreatable cause of poor outcomes in eyes with neovascular (n)AMD. JR5558 transgenic mice develop subretinal neovascularization along with subretinal hyperreflective lesions similar to areas of subretinal fibrosis seen in eyes with nAMD. This project aims to characterise JR5558 mice as a model to study subretinal fibrosis.

Methods: Colour fundus photographs (CFP) and optical coherence tomography (OCT, Phoenix Micron IV) were utilised to non-invasively track hyperreflective lesions and subretinal fibrosis from 4 weeks in JR5558 transgenic mice. The number and area of lesions in CFP was quantified in ImageJ. Fluorescein angiography was performed to investigate vascular leak. Immunohistochemistry (IHC) of retinal sections was performed with antibodies against α SMA, GFAP and CD31. Protein expression in the neural retina was assessed by Western blot and compared to age-matched controls. Data presented as mean \pm sem with one-way ANOVA performed to compare the data.

Results: Analysis of CFP revealed subretinal lesions expand between 4 and 8 weeks (0.32 ± 0.20 vs $0.41\pm0.23\text{mm}^2$, $p=0.0005$), becoming established in size and location around 12 weeks ($0.38\pm0.49\text{mm}^2$, vs. 4wks $p=0.06$; vs. 8wks $p=0.55$). The number of lesions increased in 60% of animals between 4-8 weeks (15.2 ± 1.5 vs. 16.6 ± 1.1 , $p=0.68$) and remained static at 12 weeks (16.8 , $p=0.99$). Analysis of OCT images revealed alterations in the layers of the neural retina and underlying subretinal lesions. Retinal sections confirmed alterations in the neural retina layers and revealed Muller-glia (GFAP⁺) penetrate through the photoreceptor layer, becoming an integral part of the lesions at 8 weeks. Analysis of neural retina protein expression revealed a significant increase in fibronectin (4wk: $386\pm54\%$; 8wk: $357\pm24\%$, both $p<0.001$) at the early timepoints, while CTGF (20wks: $161\pm7\%$, $p<0.001$), MMP2 (12wks: $159\pm15\%$, $p<0.01$; 20wks: $150\pm15\%$, $p=0.014$) and α SMA (12wks: $188\pm33\%$, $p=0.02$; 20wks: $226\pm24\%$, $p=0.002$) significantly increased later. Increased GFAP expression (8wk: $247\pm30\%$, $p<0.001$; 12wk: $180\pm6\%$, $p=0.01$) confirmed the IHC results.

Conclusions: Our study provides evidence that naturally occurring subretinal lesions in JR5558 mice have a fibrotic component that grows reliably and predictably between 4-8 weeks, making these mice a good model to further study the mechanisms of subretinal fibrosis and how it may be prevented.

TITLE: Safety and Efficacy of Topical, Transzonular, and Intracanalicular Corticosteroids for the Prevention of Postoperative Inflammation after Cataract Surgery

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Lu, T. O'Rourke, I.U. Scott, S. Pantanelli, Penn State Eye Center, Pennsylvania, UNITED STATES|M. Rizk, Penn State College of Medicine, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amy Lu: Commercial Relationship(s);Ocular Therapeutix:Code F (Financial Support) | Monica Rizk: Commercial Relationship(s);Ocular Therapeutix:Code F (Financial Support) | Tara O'Rourke: Commercial Relationship: Code N (No Commercial Relationship) | Ingrid Scott: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s);Ocular Therapeutix:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To compare the safety and efficacy of topical prednisolone, transzonular triamcinolone-moxifloxacin, and intra-canalicular dexamethasone ophthalmic insert for the prevention of post-operative inflammation after cataract surgery.

Methods: Retrospective consecutive case series. Patients undergoing phacoemulsification cataract surgery received topical prednisolone acetate (Jan 2018-Dec 2019), transzonular triamcinolone-moxifloxacin (Tri-Moxi, ImprimisRx)(Nov 2016-Jan 2018), and intracanalicular dexamethasone (Dextenza, Ocular Therapeutix)(Dec 2019-Nov 2020). Patients with a history of glaucoma suspect, glaucoma, intraocular pressure (IOP) elevation, or uveitis were excluded. Primary endpoints were proportion of eyes with breakthrough inflammation requiring escalation of anti-inflammatory therapy and proportion of eyes with IOP increase ≥ 10 mmHg at 4-8 weeks follow-up. Secondary endpoints included post-operative visual acuity (VA) and intra-operative complications. The Kruskal-Wallis test was used to compare between groups of data. Data were reported as mean \pm standard error. Statistical significance was assumed at $p < 0.05$.

Results: Of 161 study eyes, 59 eyes from 35 patients received drops, 54 eyes from 33 patients received transzonular injection, and 48 eyes from 30 patients received the intracanalicular insert. Three (5.1%), 9 (16.7%), and 4 (8.3%) eyes from each group, respectively, developed symptomatic rebound inflammation ($p=0.11$). IOP increase ≥ 10 mmHg from baseline was measured in 0 (0.0%), 1 (1.9%) and 1 (2.1%) eye, respectively ($p=0.55$). Mean baseline VA in logMAR was 0.33 ± 0.04 , 0.33 ± 0.04 , and 0.27 ± 0.03 , respectively ($p=0.34$). Mean logMAR VA at the 4-8 week post-operative visit was 0.13 ± 0.03 , 0.18 ± 0.04 , and 0.10 ± 0.02 , respectively ($p=0.17$). Two eyes in the drops group did not receive drops as prescribed due to poor compliance. One eye in the injection group was not successfully injected with drug and was placed on topical drops. Three eyes in the dexamethasone insert group that developed rebound inflammation did so due to extrusion of the inserts.

Conclusions: "Dropless cataract surgery" may yield similar rates of breakthrough inflammation and IOP elevation as topical drops. Whereas drops are susceptible to non-compliance, transzonular and intracanalicular corticosteroids rely on delivery and sustained presence of the dispensed agent.

ABSTRACT BODY:

Purpose: To investigate the relationship between the initial retinal electrophysiological response and axial elongation (AE) in children with and without prescription of Breath-O Correct orthokeratology (OK) lenses.

Methods: Eighty-five subjects aged 9 to 12 years with spherical equivalent refraction (SER) between -1.00D and -4.00D were recruited and randomly assigned into OK (n=49) or spectacle control (n=36) groups. Breath-O Correct lenses were prescribed in OK group with routinely scheduled aftercare. Retinal electrophysiological responses were measured by global flash multifocal electroretinogram (mfERG) in 49% contrast at baseline before any intervention. Responses from the 61 hexagons were averaged into 5 concentric rings to investigate the localized responses at different retinal eccentricities. Axial length measurements were performed at baseline and one-year to monitor refractive changes. Spearman's correlation with Bonferroni correction was used to assess the relationship between mfERG and AE.

Results: Seventy-one subjects completed this one-year study (Control: 29, OK: 42). The baseline SER for control and OK group were -2.49D and -2.97D (t-test, $p>0.05$), respectively. The mean AE in OK group was significantly lower than the control group (Control: $0.35\pm0.2\text{mm}$, OK: $0.14\pm0.17\text{mm}$, $p<0.01$). In OK group, no significant correlation was noted between AE and the initial mfERG responses ($p>0.05$). In contrast, for the control group, the AE was negatively correlated with baseline Ring 1 induced component amplitude ($\rho=-0.484$, $p<0.01$, representing the central inner retinal response) and Ring 3 direct component amplitude ($\rho=-0.488$, $p<0.01$, representing the para-central outer retinal response), respectively.

Conclusions: Without OK intervention, weaker retinal response was associated with faster myopic progression. However, this risk factor did not predispose faster AE under the effect of Breath-O Correct OK intervention. It indicates that the OK intervention is suitable for children with different myopia progression rates.

TITLE: Changes in Optical Coherence Tomography Angiography metrics over 24 hours in healthy adults

SESSION TITLE: OCT Angiography - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Lal, D. Alonso-Caneiro, S.A. Read, B. Tran, C. Van Bui, D. Tang, J.T. Fiedler, S. Ho, A. Carkeet, School of Optometry, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA

Commercial Relationships Disclosure (Abstract): Barsha Lal: Commercial Relationship: Code N (No Commercial Relationship) | David Alonso-Caneiro: Commercial Relationship: Code N (No Commercial Relationship) | Scott Read: Commercial Relationship: Code N (No Commercial Relationship) | Binh Tran: Commercial Relationship: Code N (No Commercial Relationship) | Cong Van Bui: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Tang: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Fiedler: Commercial Relationship: Code N (No Commercial Relationship) | Steven Ho: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Carkeet: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diurnal variations have been observed in a range of posterior eye structures, yet the pattern of diurnal variation in retinal vasculature over 24 hours has not been established. We performed a prospective observational study to explore the magnitude and pattern of diurnal variation in retinal vasculature over 24 hours using optical coherence tomography angiography (OCT-A) among healthy myopes and non-myopes.

Methods: Healthy young adult participants (n=44, 23.2±4.1 years (range:18-35)) underwent measurements every 4h for 24h starting at 9 AM. AngioPlex OCT-A macula images were captured to determine a range of retinal vascular metrics including foveal avascular zone (FAZ) metrics (area, perimeter, and circularity) as well as the vessel, and perfusion density in the 3mm ETDRS central, and inner subfields. Blood pressure, intraocular pressure (IOP) and axial length were also assessed. Acrophase and amplitude of diurnal variation for each measurement were calculated and compared between 24 myopes and 20 non-myopes.

Results: Vessel and perfusion density showed significant variations over 24h (ANOVA, p<0.05) whereas none of the FAZ metrics changed significantly (ANOVA, p>0.05). Central vessel and perfusion density had their minima phase at 4:48 AM ± 4.44h and 5:45 AM ± 4.14h respectively, with a diurnal amplitude of 1.09±0.65 mm⁻¹ and 1.95±1.25 %. The inner vessel and perfusion density peaked around 5 PM. Myopes and non-Myopes showed different 24h variation patterns for inner vessel density (Figure 1) and perfusion density (with a significant time of day and refractive groups interaction; p=0.04 for both) but not in the central subfield. The myopes and non-myopes had minima at 4:35 AM and 6:06 AM, respectively however, the amplitude of daily variations was not significantly different (p>0.05) between them. The minimum pulse pressure was also in the morning (5:56 AM). Axial length and IOP both demonstrated an acrophase in the afternoon at 2:24 PM and 12:22 PM respectively.

Conclusions: This study, for the first time, demonstrates that significant diurnal variation exists in OCT-A metrics of macular retinal vasculature when evaluated over a full 24h duration while the FAZ does not exhibit any significant variations

SUBMITTER (NAME ONLY): Michael Offutt

TITLE: Success of Micropulse Cyclophotocoagulation following Tube Shunt Surgery

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.E. Offutt, B. Moody, A. Kheirkhah, C. Waldman, Ophthalmology, The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Offutt: Commercial Relationship: Code N (No Commercial Relationship) | Braedon Moody: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Kheirkhah: Commercial Relationship: Code N (No Commercial Relationship) | Corey Waldman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the outcomes of micropulse cyclophotocoagulation (MP-CPC) in patients with and without a history of tube shunt surgery.

Methods: This is a retrospective chart review of patients who underwent MP-CPC from May 2017 to December 2020, comparing those with and without a history of tube shunt surgery. The treatment group is referred to as the tube-group and the control group is referred to as the non-tube group. All forms of glaucoma were included, and the patients were followed for at least 12 months. Success (S) was defined by an intraocular pressure (IOP) of 8-18mmHg, requiring fewer drops than before MP-CPC, vision greater than no light perception (NLP), and requiring no further intervention. If any alternative procedural (i.e. repeat MP-CPC) or surgical intervention was required to control IOP, this would qualify as a failure.

Results: The tube group (n=21) had an average age of 57.62 ± 10.53 , male preponderance (52.4%), and neovascular glaucoma the most common glaucoma diagnosis. 57.1% of the tube group was phakic. This contrasts to the non-tube group (n=41) with average age of 59.68 ± 15.7 , female preponderance (53.7%), and primary open angle glaucoma the most common diagnosis (46.3%). Pre-op IOP for the tube group was 28.29 ± 7.68 with the number of pre-op topical glaucoma medications 3.90 ± 0.525 ; pre-op IOP for the non-tube group was 30.46 ± 10.68 with the number of topical glaucoma medications 3.29 ± 0.74 ($P=0.37$). Principal data suggests greater success in the tube group than the non-tube group at six months of follow up (IOP of 14.6 versus 15.67; $P=0.024$). In addition, at 3-, 6-, and 12- month follow ups, there were statistically significant decreases in IOP and the number of medications used for the tube group – 13.5mmHg with 2.67 topical drops, 14.6mmHg with 2.67 topical drops, and 12.33mmHg with 2.50 topical drops. For the 3-, 6-, and 12- month follow ups, the success rate, as defined above, was 33% & 17%, 43% & 14%, and 33% & 7% for the tube group and the non-tube group, respectively. The most common complication was hypotony (as defined by ≤ 7 mmHg) occurring four times in each group.

Conclusions: This data suggests that MP-CPC is more effective in patients with previous tube shunt surgery compared to those without while maintaining a good safety profile.

ABSTRACT BODY:

Purpose: The success of our prototype clinical trial (NCT01603576) of a suprachoroidal retinal prosthesis led us to develop a 44 channel fully implantable device with a transcutaneous receiver stimulator system, with the aim of providing visual information to profoundly visually impaired patients, allowing them to utilise this device at home.

Methods: Four patients (P1, P2, P3 and P4) with end-stage rod - cone dystrophy and perception of light visual acuity were implanted with a 44 channel electrode array in the suprachoroidal space during 2018 (NCT03406416). After recovery they commenced stimulation of the device in the psychophysics laboratory.

Post operative follow-up included clinical examination, fundus photography and optical coherence tomography (OCT) to assess surgical recovery and impact on the eye.

OCT imaging was used to track the retinotopic location of the leading edge of the implant. The translation and rotation of the array relative to baseline (1 week post-implantation) was calculated at 108 weeks post-implantation.

Primary outcome measure was safety as assessed by device related serious adverse events (SAEs), secondary measure efficacy as assessed by tests of visual function and functional vision.

Results: The surgical procedures were uncomplicated. At the completion of surgery, impedance testing showed in all electrodes were functional in all patients. Post operative recovery was uneventful . Fundus imaging and OCT imaging confirmed the position of the devices under the macula and the absence of retinal trauma.

No device related serious adverse events occurred during the two years of the study.

OCT imaging showed some minor movement of the device for all four patients. P3 had the most significant movement with 15 degrees of rotation at 108 weeks compared to baseline, however no functional changes were noted.

Translational movement was minimal in all patients.

Conclusions: A 44 channel retinal prosthesis can be safely implanted in the suprachoroidal space, with no serious adverse events, device related or not, recorded for 4 patients. Over twenty four months of post operative follow-up

clinical findings, fundus photography and OCT imaging confirm safety and stability of the suprachoroidal approach with only slight movement on OCT imaging, which is usually rotational. The devices were functional for the 24 months of the study and continue to be used in the home environment.

TITLE: Occurrence of Second Primary Malignancy (SPM) in Lacrimal Squamous Cell Neoplasms (LSCN): A Surveillance, Epidemiology, and End Results (SEER) Analysis

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Hussain, Texas Tech University Health Sciences Center El Paso Paul L Foster School of Medicine, El Paso, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zain Hussain: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As diagnostic and therapeutic advances continue to enhance longevity in patients with lacrimal squamous cell neoplasms (LSCN), comparative second primary malignancies (SPM) are showcasing increasing relevance in long-term management. Current market analysis demonstrates lack of SPM characterization in LSCN. This retrospective cohort analysis evaluates SPMs and latency periods in patients with LSCN.

Methods: The Surveillance, Epidemiology, and End Results (SEER) Program acted as provision for cases of first primary LSCN from 2000 to 2015. Standardized incidence ratios (SIR), excess absolute risk (EAR), were extracted, computed, and analyzed via multiple outcome analysis within the SEER software. Strict utilization of index records was performed. 95% confidence intervals (CI) are provided with statistical significance achieved at $p < 0.05$.

Results: Extraction of 132 patients diagnosed with LSCN revealed mean(\pm SD) age of 62.20 (\pm 12.52) years with distribution of sex as 41.66% (55) female and 58.34% (77) male. Within the sub-cohort of patients afflicted with SPM, mean age upon diagnosis of SPM is 61.08 years. Relative to the US general population, patients diagnosed with LSCN demonstrated significantly increased risk for SPM on multiple fronts. Cumulative SPM (SIR 5.63, CI 3.22 – 9.15, EAR 256.52), ocular & orbital SPM (SIR 7205.07, CI 3294.62 – 13677.47, EAR 175.42), and non-epithelial skin SPM (SIR 193.34, CI 39.87 – 565.02, EAR 58.18) showcased statistically significant increases in overall SPM occurrence at 5- and 10-years post-LSCN diagnosis.

Conclusions: In contrast to the US general population, diagnosis of LSCN entails heightened propensity for development of second primary malignancy, including ocular, orbital, and non-epithelial skin cancers. Diagnostic and therapeutic advancements pertaining to LSCN prolong quality and longevity of patient life, thereby emphasizing the need for long-term risk management via real-time reconnaissance of malignancy-related signs and symptoms.

ABSTRACT BODY:

Purpose: Electroretinography (ERG) is an important clinical tool for evaluating retinal integrity and the physiology of retinal circuits involved in visual processing. Recent studies show that ERGs elicited by heterochromatic modulation stimuli (HF-ERG) can reflect the activity of cone opponent and luminance pathways at 12 and 36 Hz respectively. The aim of this study was to evaluate cone opponent and luminance reflecting ERGs in patients with onset dry age-related macular degeneration (AMD) stages using a 20° diameter stimulus in the center of the retina (target) and compare the results to those elicited by the full field (FF) stimuli.

Methods: Twenty seven patients with early stage AMD, recruited from the Prevent Senior Institute, and 18 age-matched healthy volunteers participated in this study. Flicker ERGs were recorded from one randomly chosen dilated eye. A heterochromatic flicker stimulus for ERG-HF was generated by a Ganzfeld apparatus using the RETIport system (Roland Consult, Germany). This controlled the modulation of red and green LEDs with average luminance of 100 cd.m⁻² each. The contrasts in red (R) and green (G) LEDs were varied while keeping the total contrast (R+G) constant. The fraction of red modulation (R/(R+G)) was varied between 0 (green modulation only) and 1 (red modulation only).

Results: ERGs measured in AMD patients displayed similar amplitudes and phases to FF and targeted stimuli at 12Hz and 36Hz frequencies compared to those measured in the control group. The amplitudes to R/(R+G)=0 stimuli at 12 Hz were higher for target than for FF stimuli in both the control and dry AMD groups. Conversely, the target stimuli resulted in smaller responses compared to FF stimuli at 36Hz.

Conclusions: The HF-ERGs suggest that there are no alterations in post-receptoral processes in early stages of dry AMD. The larger amplitudes to target stimuli R/(R+G)=0 stimuli at 12 Hz may be caused by rod stimulation through stray light. Because, targeted stimuli elicited large responses at 12 Hz, their use could be an alternative, non-invasive method to study the cone opponency in other types of macular diseases compared to FF ERGs.

TITLE: Morphology and cell density of the corneal endothelium of healthy Japanese eyes

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Ono, Y. Mori, R. Nejima, T. Iwasaki, K. Miyata, Ophthalmology, Miyata Eye Hospital, JAPAN|T. Ono, Ophthalmology, the University of Tokyo, Tokyo, JAPAN|

Commercial Relationships Disclosure (Abstract): Takashi Ono: Commercial Relationship: Code N (No Commercial Relationship) | Yosai Mori: Commercial Relationship: Code N (No Commercial Relationship) | Ryohei Nejima: Commercial Relationship: Code N (No Commercial Relationship) | Takuya Iwasaki: Commercial Relationship: Code N (No Commercial Relationship) | Kazunori Miyata: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The density and morphology of corneal endothelial cells are important factors for endothelial function and the maintenance of corneal clarity. Although they reportedly differ among populations, only a few previous studies have examined them in ophthalmologically healthy young patients. Therefore, we aimed to examine the density and morphology of corneal endothelial cells in healthy Japanese.

Methods: This observational study included eyes without ophthalmologic diseases other than refractive errors examined at the Miyata Eye Hospital between 1996 and 2015. The eyes with a previous history of ophthalmologic diseases or contact lens wear were excluded. Medical records of patient age, corneal endothelial cell density (ECD), coefficient of variation (CV), the appearance rate of hexagonal cells (6A), and cell area were retrospectively reviewed. The corneal endothelium data were obtained using non-contact specular microscopy.

Results: We included 16842 eyes of 8421 patients in the study (mean age, 19.6±8.7 years): 6668 eyes of 3334 male patients and 10174 eyes of 5087 female patients. The mean ECD of patients aged 1-10, 11-20, 21-30, 31-40, 41-50, 51-60, 61-70 years was 3312.0±319.1, 3168.0 ± 284.0, 3032.8±285.9, 2891.1±284.9, 2815.8±294.6, 2741.2±278.3, and 2771.3±297.9 cells/mm², respectively. The relationship between ECD and age was expressed as $Y = -12.63 X + 3364.53$ ($R^2 = 0.359$, $p < 0.001$). The relationship between CV and age was expressed as $Y = 0.158 X + 24.50$ ($R^2 = 0.267$, $p < 0.001$). The relationship between 6A and age was expressed as $Y = -0.31 X + 72.08$ ($R^2 = 0.232$, $p < 0.001$). The relationship between endothelial cell area and age was expressed as $Y = 1.45 X + 295.97$ ($R^2 = 0.387$, $p < 0.001$). The reduction in ECD per year was significantly higher in patients younger than 21 years than in those aged 21 years or older (-19.4 cells/mm²/year and -10.1 cells/mm²/year, $p < 0.001$).

Conclusions: ECD, 6A, CV, and cell area are significantly related to age. Because the reduction in ECD per year is significantly higher in patients younger than 21 years than in those who are older, it is important to monitor corneal endothelial cells in young patients.

TITLE: Association between retinal thickness and retinal fluid volumes measured by deep learning in the HAWK & HARRIER trials

SESSION TITLE: Machine learning I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Pawloff, H. Bogunovic, U. Schmidt-Erfurth, Medizinische Universitat Wien, Wien, Wien, AUSTRIA|Z. Mulyukov, D. Lorand, Novartis AG, Basel, Basel-Stadt, SWITZERLAND|

Commercial Relationships Disclosure (Abstract): Maximilian Pawloff: Commercial Relationship: Code N (No Commercial Relationship) | Hrvoje Bogunovic: Commercial Relationship: Code N (No Commercial Relationship) | Zufar Mulyukov: Commercial Relationship(s);Novartis AG:Code E (Employment) | Daniel Lorand: Commercial Relationship(s);Novartis AG:Code E (Employment) | Ursula Schmidt-Erfurth: Commercial Relationship(s);Boehringer Ingelheim:Code C (Consultant);Genentech:Code C (Consultant);Novartis:Code C (Consultant);Kodiak:Code C (Consultant);Roche:Code C (Consultant);Heidelberg Engineering:Code C (Consultant)

ABSTRACT BODY:

Purpose: To investigate whether central subfield retinal thickness (CSFT) values correlate with exudative activity of patients undergoing treatment with anti-VEGF substances (Brolucizumab and Aflibercept). Fluid measurements i.e. intraretinal fluid (IRF) and subretinal fluid (SRF) were obtained by deep learning based on spectral-domain optical coherence tomography (SD-OCT) scans.

Methods: We utilized a previously validated, fully automated deep learning approach based on convolutional neural networks to detect and quantify macular fluid in SD-OCT volumes (Cirrus, Spectralis, Topcon) from patients gathered from multicenter studies HAWK (1078) & HARRIER (739) with neovascular age-related macular disease. Volumes (nl) for IRF and SRF were measured at baseline and monthly under anti-VEGF therapy in the central mm. The dataset was analyzed using descriptive statistics. We summarized the association between fluid volumes and CSFT measured from ILM to outer retinal pigment epithelium (RPE) boundaries, using the Pearson's r correlation coefficient.

Results: 41,906 SD-OCT volume scans underwent fluid volume analysis using deep learning. Detection level AUC values for IRF in the central millimeter were 0.849 in HAWK and 0.933 in HARRIER. For SRF, AUC values were 0.874 for HAWK and 0.871 for HARRIER. In HAWK, IRF volumes showed only a moderate association with CSFT at baseline ($r=0.54$) and an even weaker correlation between CSFT and IRF under therapy ($r=0.44$). Correlation of SRF and CSFT was very weak at baseline ($r=0.29$) and did not increase much under therapy ($r=0.38$). Consistently, in HARRIER, IRF volumes had a moderate correlation of $r=0.62$ with CSFT at baseline. Under therapy, association of CSFT and IRF was weak ($r=0.34$). Correlation between SRF and CSFT was very weak at baseline ($r=0.22$) and increased only marginally under therapy ($r=0.45$).

Conclusions: In patients with nAMD, CSFT does not adequately represent exudative activity and IRF and SRF volumes are more clinically relevant particularly during therapy. Due to the limited correlation of CSFT with retinal fluid, our findings do not support the use of CSFT as the main anatomical measure for treatment guidance and disease management. In contrast quantitative deep learning methods allow for a precise determination of fluid volumes and may be used as an optimal clinical decision support tool in anti-VEGF therapy in patients with nAMD.

TITLE: Semantic segmentation of gonioscopic images exploiting adaptive ROI localization and uncertainty estimation

SESSION TITLE: Anterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Peroni, E. Trucco, VAMPIRE Project, Computing, School of Science and Engineering, University of Dundee, Dundee, UNITED KINGDOM|M. Campigotto, A. Paviotti, NIDEK Technologies Srl., Albignasego, ITALY|

Commercial Relationships Disclosure (Abstract): Andrea Peroni: Commercial Relationship(s);NIDEK Technologies Srl.:Code F (Financial Support);NIDEK Technologies Srl.:Code P (Patent) | Mauro Campigotto: Commercial Relationship(s);NIDEK Technologies Srl.:Code E (Employment);NIDEK Technologies Srl.:Code P (Patent) | Anna Paviotti: Commercial Relationship(s);NIDEK Technologies Srl.:Code E (Employment);NIDEK Technologies Srl.:Code P (Patent) | Emanuele Trucco: Commercial Relationship(s);NIDEK Technologies Srl.:Code F (Financial Support);NIDEK Technologies Srl.:Code P (Patent)

ABSTRACT BODY:

Purpose: To develop a semantic segmentation algorithm highlighting anatomical structures of interest in digital gonioscopic images acquired by a semi-automatic ophthalmic device, and to overcome ground truth limitations (e.g. missing or incomplete target annotations) by adaptive identification of the most informative region of interest (ROI) in the data and estimation of spatial prediction uncertainty.

Methods: In gonioscopic acquisitions, only the central part of each image is well illuminated, and the focus varies according to the selected focal plane; therefore, only part of the image can be reliably annotated. A dataset of 274 irido-corneal sector images have been annotated by four experienced ophthalmologists and used to train (202), validate (41) and test (31) a custom Dense-Unet from scratch. The network is trained to achieve two simultaneous, complementary aims: exploiting the ground truths to maximise the segmentation accuracy within the annotated region of the images, and learning to evaluate the informative value of local regions based mainly on sharpness and lightness, locating a ROI. The ROI is then used to filter out uncertain segmentation outputs. Moreover, the use of drop-out during inference makes it possible to generate multiple predictions, enabling us to estimate uncertainty via the pixel-wise variance of the predicted probabilities.

Results: With a test set representative for relevant clinical cases and un-correlated with the training and validation ones we obtain an overall pixel-wise classification accuracy above 90% within the annotated area of the ground truth data. The automatic ROI identification can locate the most informative region in every test image and the uncertainty estimation proves to effectively highlight most of the un-correctly predicted image pixel sub-sets.

Conclusions: The proposed system can maximise the information learnt from ground truth annotations and combine it with an effective ROI localization to provide an accurate segmentation of irido-corneal angle layers. Uncertainty estimation can help for a better interpretation of model predictions and may act as an important support in clinical applications.

TITLE: Refractive ametropia induced by contact lenses changes OCT-A macular indices

SESSION TITLE: Advances in Retinal Imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Carkeet, B. Lal, S.A. Read, D. Alonso-Caneiro, School of Optometry and Vision Science, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA

Commercial Relationships Disclosure (Abstract): Andrew Carkeet: Commercial Relationship: Code N (No Commercial Relationship) | Barsha Lal: Commercial Relationship: Code N (No Commercial Relationship) | Scott Read: Commercial Relationship: Code N (No Commercial Relationship) | David Alonso-Caneiro: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is unclear how Optical Coherence Tomography Angiography (OCT-A) indices are influenced by refractive ametropia. This research used spherical contact lenses to vary refractive ametropia in healthy young participants and assessed whether OCTA indices changed in a way that could be predicted by changes in retinal image transverse magnification (TM).

Methods: 11 participants (mean age 26 ± 5 years, 5M:6F) took part in the study. For each participant, spherical soft contact lenses (-6D to +6D in 2D steps) were used to vary spherical refractive error. This varies anterior surface power, but leaves axial length unchanged. For each condition, OCT-A measurements of macular vasculature were made using a Zeiss HD-OCT 5000 OCT-A imaging system and the following indices generated: foveal avascular zone (FAZ) area, perimeter, circularity and vessel density and perfusion density, for the central 1mm zone. Optical modelling was also used to calculate TM based on biometry and autorefraction. TM of en face images was also empirically measured for each condition.

Results: Empirical TM measures matched theoretical calculations, (regression slopes: mean 1.02, 95% CI 0.74 to 1.30). Without magnification correction, contact lens power had a significant effect on all OCT-A indices assessed (F6,60 from 2.39 to 8.51, $p < 0.05$), and all OCT-A indices showed linear relationships with induced refractive ametropia that were significantly different from zero (magnitude $t(10) > 3.79-7.93$, $p < 0.05$). Corrected for TM, FAZ area (Fig 1) showed no relationship with induced refractive error ($t(10) = 1.13$, $p = 0.28$). FAZ perimeter and vessel density showed reduced but still significant relationships with refractive error even after correction for TM ($t(10) > 2.77$, $p < 0.02$).

Conclusions: This study is the first to demonstrate that refractive spherical ametropia affects OCT-A indices to an extent that may be clinically significant, with changes of up to 12%. Simple correction for transverse magnification can reduce but not fully compensate for the effect of refraction on most OCT-A indices tested. TM changes may also change perfusion density and vessel density measurements, by including different vessel beds in calculations as magnification changes.

ABSTRACT BODY:

Purpose: To assess the relationship between baseline factors and DME resolution in patients randomized to IAI or laser control in VISTA/VIVID.

Methods: Of 862 patients in VISTA/VIVID full analysis set, this analysis included 558 patients treated with IAI 2 mg (given either q4 weeks or q8 weeks after 5 monthly doses) and 274 patients treated with laser control; 30 patients with baseline central subfield thickness (CST) <290 µm were excluded. Effect of baseline factors (age, gender, race, ethnicity, diabetes type and duration, HbA1c, hypertension, hyperlipidemia, smoking status, CST, best-corrected visual acuity [BCVA], and DRSS) on time to first DME resolution (CST <290 µm) was assessed in univariate and multivariate models and was further evaluated by Kaplan–Meier method based on tertiles of baseline factors.

Results: IAI patients had a 2.5-fold higher rate of DME resolution, with median (95% confidence interval [CI]) time of 33.0 (28.1, 40.0) weeks vs not achieved with laser. Based on multivariate analysis of baseline factors, lower DME resolution rate was associated with thicker CST (HR [95% CI] per 100 µm CST increase: 0.79 [0.72, 0.86]) and better BCVA (HR [95% CI] per 5 letters increase: 0.87 [0.83, 0.92]) in the IAI group. Based on Kaplan–Meier analysis, in the IAI group, tertiles of increasing CST (T1: ≤419, T2: 419–541, T3: >541 µm) were associated with significantly longer median time to DME resolution (20.1, 39.1, and 49.1 weeks for T1–T3, respectively; P≤0.0001 for T2 and T3 vs T1) and lower cumulative incidence of the event (HR of 0.6, and 0.6 for T2 and T3 vs T1, respectively, P<0.001 for T2 and T3 vs T1). In the IAI group, tertiles of increasing BCVA (T1: ≤57, T2: 57–66, T3: >66) were also associated with relatively longer median time to DME resolution (28.4, 31.7, and 44.1 weeks for T1–T3, respectively; P<0.05 for T3 vs T1) and lower cumulative incidence of events (HR of 0.9, 0.8 for T2 and T3 vs T1, respectively; P<0.05 for T3 vs T1).

Conclusions: Thicker CST and better BCVA in the IAI group were baseline factors associated with longer time to and lower rate of DME resolution in VISTA and VIVID. These findings may inform physicians and patients regarding expectations of DME therapy.

ABSTRACT BODY:

Purpose: Corneal surgeries such as penetrating keratoplasty (PKP) can result in significant postoperative refractive errors that are difficult to assess intraoperatively with the current standard of care. Microscope-Integrated OCT (MIOCT) has the potential to characterize corneal astigmatism intraoperatively to help improve post PKP refractive outcomes. Here, we report accurate detection of astigmatism magnitude and axis in software-generated and 3D-printed phantom corneas.

Methods: Software phantoms were designed using MATLAB to simulate the corneal surface with astigmatism from 0 – 6 diopters (D). Plastic, 3D-printed phantom corneas were designed with astigmatism from 0 – 6 D. Four phantoms in each group have astigmatism with steep axis at 180°, and two have astigmatism with steep axis at 0° to evaluate anisotropy in imaging direction. Printed phantoms were imaged with MIOCT. After manually segmenting the first frame as a pilot, each subsequent Bscan in the volume was automatically segmented to identify the epithelial surface. Segmentations were fit to a 6th order Zernike function and corrected for system-specific distortions. Astigmatism magnitudes and axes were calculated according to ANSI standards for all phantoms.

Results: Topography maps are shown for software (Figure 1) and 3D-printed (Figure 2) phantoms. For software phantoms, the mean absolute difference between calculated and reference astigmatism magnitude and axis was 0.012 D and 0 degrees, respectively, for phantoms with steep axis at 90° and was 0.016 D and 0 degrees, respectively, for phantoms with steep axis at 0°. For printed phantoms, the mean absolute difference between calculated and reference astigmatism magnitude and axis was 0.26 D and 2.7 degrees, respectively, for phantoms with steep axis at 90° and was 0.25 D and 8.1 degrees, respectively, for phantoms with steep axis at 0°.

Conclusions: We used the MIOCT-based corneal topography system on software and 3D-printed corneal phantoms to calculate astigmatism magnitude and axis. The system calculates astigmatism magnitude within approximately 0.25 D and detects axis within 10 degrees. This system has potential for intraoperative astigmatism assessment during procedures such as PKP.

ABSTRACT BODY:

Purpose: The purpose of this study was to identify the mechanism by which a novel selective soluble guanylate cyclase activator (ID-65-CW69) lowers intraocular pressure (IOP) and alters aqueous humor dynamics in monkeys with unilateral laser induced glaucoma.

Methods: Fifteen female cynomolgus monkeys with unilateral laser-induced glaucoma were dosed with one 30 μ l drop of ID-65-CW69 or its vehicle to the cornea of both eyes at 6:00 PM the day before the measurement day in a masked crossover fashion. Intraocular pressures (mmHg) were measured by pneumatonometry at 6:00 PM (IOP1), just before dosing; and again at 10:00 AM (IOP2) and noon (IOP3) the following day. Other measurements were aqueous flow (Fa, μ l/min) by fluorophotometry, outflow facility (C, μ l/min/mmHg) by fluorophotometry (C) and uveoscleral outflow (Fu, μ l/min) by mathematical calculation.

Results: The hypertensive eyes showed a significant decrease in IOP to the level of the normotensive eyes. Results in the hypertensive eyes are summarized in the Table. Values are Means \pm SD. Drug treatments and corresponding vehicle treatments were compared by two-tailed paired t-tests (p). No significant changes were found in the normotensive eyes.

Conclusions: ID-65-CW69 reduced IOP in hypertensive eyes by increasing uveoscleral outflow by over two-fold. Outflow facility increased but this did not reach significance. The drug did not significantly lower IOP in the normotensive eyes.

ABSTRACT BODY:

Purpose:

Significant barriers to OCT automated diagnosis include need for expert-labeled training data and long computing times required by state-of-the-art algorithms. We explore a student-teacher framework for training LWMs with fewer parameters leveraging unlabeled images to perform fast automated detection of abnormal B-scans.

Methods:

The dataset consisted of 76,396 expertly labeled B-scans from 598 patients (45,698 normal and 30,698 abnormal) and 478,588 unlabeled B-scans from 3,148 patients, acquired using a CIRRUS™ HD-OCT 5000 (ZEISS, Dublin, CA). B-scans were labeled abnormal if intraretinal/subretinal fluid; disruption of inner retinal layers, IS/OS, or vitreoretinal interface; or RPE atrophy/elevation were present. A ResNet50 “teacher” model and 27 “student” DL networks from 4 LWM families (SqueezeNet, SqueezeNext, MobileNet, and ShuffleNet) were trained to identify abnormal B-scans. The labeled dataset was split by patients into 80% training and 20% validation. Average inference time on a NVIDIA P100 and best validation accuracy over epochs were reported. The unlabeled B-scans were artificially labeled using the teacher network (Figure 2A) and then combined with the labeled B-scans to retrain the LWMs from random initialization.

Results: Figure 1 presents the accuracy versus inference-time tradeoff for all models. ResNet50 achieves 96.1% validation accuracy and the LWM range from 83.2% to 95.0%. The best performing LWM, a SqueezeNet model with residual connections (SRN.1), is 4.13 times faster than ResNet50 (0.109s vs. 0.452s). Figure 2 shows student-teacher training results, revealing that all models benefit from increasing training set by including unlabeled B-scans. SRN.1 again obtains the highest validation accuracy (96.3%), narrowly exceeding the teacher network.

Conclusions: We demonstrate the effectiveness of a student-teacher framework for training fast LWMs for automated abnormal B-scan detection leveraging unlabeled, routinely-available data.

ABSTRACT BODY:

Purpose: Although part of periocular normal flora, coagulase-negative staphylococci (CNS) are frequent opportunistic pathogens after ocular surgery that cause endophthalmitis. CNS is generally not identified to the species level from eye cultures, but some species may be more common than others. The goal of the current study was to evaluate three methods of species level identification (Biolog GEN III, API Staph Ident, DNA sequencing) of CNS isolated from cases of endophthalmitis and determine whether they are in agreement with their identification of staphylococcal species that cause endophthalmitis.

Methods: We compared the identifications of 47 isolates of CNS from endophthalmitis from the Charles T. Campbell Ophthalmic Microbiology Laboratory using Biolog GEN III Microplates, (phenotypic substrate system) (Hayward, CA), API Staph IDENT (biochemical system) (bioMerieux, USA), and DNA sequencing of the *sodA* gene. Sample preparation followed the standardized procedures for each test.

Results: The identification of CNS to the species level were identical for Biolog and DNA sequencing except for 1 isolate. Of the 47 isolates for Biolog, 42 were *Staphylococcus epidermidis*, 3 were *Staphylococcus lugdunensis*, 1 was *Staphylococcus hominis*, and 1 was *Staphylococcus haemolyticus*. For DNA sequencing, 43 isolates were *S. epidermidis*, 2 were *S. lugdunensis*, 1 was *S. hominis*, and 1 was *S. haemolyticus*. Species identification differed for API Staph IDENT by 6 isolates compared to DNA sequencing and by 5 isolates compared to Biolog. Of the 47 isolates, 40 were *S. epidermidis*, 2 were *S. lugdunensis*, 2 were *S. hominis*, 1 was *Staphylococcus capitis*, 1 was *S. haemolyticus*, and 1 was *Staphylococcus aureus* (a possible weak producer of protein B?).

Conclusions: CNS identification to the species level by all three methods indicated that *S. epidermidis* is the predominant species of CNS isolated from cases of endophthalmitis. Identification of CNS from keratitis, conjunctivitis, and blepharitis may indicate different distributions of CNS species.

ABSTRACT BODY:

Purpose: To evaluate the central prosthetic vision with the photovoltaic subretinal implant activated by augmented-reality glasses and simultaneous perception of the natural peripheral vision in patients with geographic atrophy.

Methods: Five patients with visual acuity $\leq 20/400$ due to geographic atrophy of at least 3 optic discs diameters and no foveal vision have been implanted with a wireless photovoltaic chip (PRIMA, Pixium Vision) of 2x2mm in size, 30 μ m in thickness, containing 378 pixels of 100 μ m in width. Each pixel in the implant converts pulsed near-infrared light (880nm) projected from video glasses into electric current to stimulate the nearby neurons in the inner nuclear layer of the retina. Prosthetic acuity was assessed using electronic magnification of 1, 2, 4 and 8. Simultaneous perception of central prosthetic and peripheral natural vision was evaluated under room lighting.

Results: In all patients, chip implanted under the macula remains stable and functional, with a follow-up extending now up to 3 years. No decrease in natural eccentric visual acuity was observed in any of the study eyes. All 5 patients perceive white-yellow patterns with adjustable brightness, in retinotopically correct locations within previous scotomata. All 4 patients with subretinal placement of the chip achieved acuity without zoom in the range of 20/438 – 20/564, corresponding to the average of 1.17 ± 0.13 implant pixels. With electronic magnification of up to a factor of 8, patients demonstrated acuity in the range of 20/63-20/98. Under room lighting, patients could simultaneously use prosthetic central vision and the remaining peripheral vision in the operated eye and in the fellow eye.

Conclusions: Wireless chip PRIMA implanted under the atrophic macula in patients with geographic atrophy remains stable and functional during the 2-3 years of follow-up. The implant provides central visual perception with acuity close to the single pixel size of the photovoltaic array. Augmented reality glasses enable simultaneous perception of the central prosthetic and natural peripheral vision under room lighting, while electronic zoom provides significantly higher resolution.

ABSTRACT BODY:

Purpose: Glaucoma results in retinal ganglion cells (RGC) loss and is commonly assessed from structural changes detected by optical coherence tomography (OCT) and functional changes detected by perimetry. Progression analyses are available for both types of data to indicate when change exceeds test-retest variability and have been shown to have acceptable specificity. A structure-function RGC index (RGCI) provides a combined model to monitor progression instead of isolated structure or functional metrics¹. In this short-term, multi-visit clinical study, we investigated the specificity of several progression methods based on RGCI.

Methods: Visual field (VF) and OCT data were acquired from 74 eyes of 74 glaucoma subjects at 5 repeat visits within 4 months, using HFA™ II-i (ZEISS, Dublin, CA) and CIRRUS™ HD-OCT (ZEISS, Dublin, CA). At each visit, SITA Standard 24-2 VFs and Optic Disc 200x200 and Macula 200x200 cube scans were acquired.

RGCI progression was flagged and specificities calculated for two sets of methods. One set used results of linear regression (trend), assuming a visit interval of 0.5 years: a) reg_nonzero – significant non-zero slope; b) reg_less_cross, reg_less_long – slopes significant and less than previously reported cross-sectional and longitudinal rates, respectively^{1,2}; and c) reg_less_zero_confirm – slope significant and negative at final two visits (confirmation). The second set was patterned on change from baseline (event) based OCT GPA analyses using RGCI variability previously reported³: a) cfb_possible – “Possible” or “Likely” progression at final visit and b) cfb_likely – “Likely” progression at final visit.

Results: Mean age was 63.6 (SD: 10.1; range: 35.7 to 79.6) years. Mean MD was -3.9 (SD: 4.1; range: -18.2 to 1.2) dB. Specificities were 93.2% for reg_nonzero, 98.6% for reg_less_cross, reg_less_long, reg_less_zero_confirm, cfb_possible, and 100% for cfb_likely (see Table 1).

Conclusions: The combined RGCI shows excellent specificity in a short-term, multi-visit study design in a glaucoma population where no progression, only random fluctuation, is expected. As such, the RGCI may be a reasonable parameter for monitoring glaucomatous progression for both event-based and trend-based progression analyses.

ABSTRACT BODY:

Purpose: Rhegmatogenous Retinal Detachment (RRD) is a serious ocular condition that carries risk for vision loss. However, there remains a paucity of information on the impact of demographics on RRD repair outcomes. The purpose of this retrospective chart review is to characterize how RRD repair outcomes differ between racial groups.

Methods: Data was collected from electronic medical records of adult patients who underwent an RRD repair at Cole Eye Institute from 2012 to 2020. Patients were excluded if they had previous penetrating trauma to the presenting eye, previous posterior intraocular segment surgery to presenting eye, or less than 90 days of follow-up after surgery. Demographic differences were characterized. Univariate and multivariate logistic regression was used to compare retinal reattachment rate and macula-off status at diagnosis by race.

Results: Preliminary results are that 1012 patients underwent surgical RRD repair. Mean age of the patients was 63.8 years. 61.0% of the patients were male and 39.0% were female. 86.8% were white, 10.1% were black, 1.1% Asian and 2.1% other race. 95.1% of all patients, 95.6% of white patients, and 92.2% of black patients had successful retinal reattachment at 90 days following the procedure ($p=0.162$). Of patients who underwent one surgery, black patients had higher odds of repeat retinal detachment than white patients (OR 3.13, $p=0.020$, $n=805$), controlling for age, gender, and smoking status. Black patients also had higher odds of macula-off status at the time of diagnosis than white patients (OR 1.51, $p=0.079$, $n=952$). Current smokers have higher odds of macula-off status than non-smokers (OR 2.39, $p=0.001$, $n=952$).

Conclusions: Black patients have higher odds of their retina detaching after RRD repair when compared to white patients. There is also a trend for black patients to have relatively higher odds of macula-off detachment at presentation, however this is not statistically significant. This suggests that black patients may have both more severe presentation at diagnosis and worse outcomes of RRD surgical repair than white patients. Further studies are needed to determine factors that may mediate this association.

ABSTRACT BODY:

Purpose: Diabetic macular ischemia (DMI) is a vision-threatening and common complication of diabetic retinopathy (DR) that can lead to irreversible vision loss. At present, there is no approved treatment to prevent either the onset or progression of DMI. We are conducting a non-randomized, open-label, single rising dose/multiple rising dose study (NCT04424290) to investigate the safety and tolerability of intravitreal BI-X, an ischemia modulator agent.

Methods: Patients with DR treated with pan-retinal photocoagulation and evidence of DMI are eligible for inclusion. DMI was defined as any degree of disruption in retinal vascularity within the superficial and/or deep retinal plexus, imaged with optical coherence tomography angiography. A total of 6 patients have been enrolled into two dosing cohorts (0.5 mg and 1.0 mg of BI-X, n=3 per cohort) to date, with a future cohort at 2.5 mg (n=6) planned. Patients received a single intravitreal dose of BI-X. The primary endpoint is the number of dose-limiting events, with secondary endpoints being the number of drug-related adverse events (AEs) and number of ocular AEs.

Results: The mean age of the 6 patients was 62.8 (standard deviation ± 10.7) years, 4 were female. No drug-related AEs or dose-limiting events were reported in either cohort, but 2 procedure related AEs were reported in the 0.5 mg cohort. One patient with glaucoma experienced a temporary increase in intraocular pressure (IOP), from 19 mmHg at baseline to 44 mmHg after injection. The patient was treated with topical anti-glaucoma therapies, after which IOP reduced to 35 mmHg; the patient reported no pain or discomfort. At follow up visits on days 4 and 8, IOP was 27 mmHg and 22 mmHg, respectively. A second patient had a subconjunctival hemorrhage that resolved without sequelae.

Conclusions: Single doses of BI-X were well-tolerated by patients with DMI, with no dose-limiting events, no SAEs and no drug related AEs reported to date. A single-masked, randomized, multiple rising dose study is planned to further examine the efficacy of BI-X in patients with DMI.

ABSTRACT BODY:

Purpose: Stevens-Johnson Syndrome (SJS) is a severe hypersensitivity reaction affecting skin and mucous membranes with potentially debilitating ocular sequelae. Acute ocular severity (AOS) may correlate with long-term ocular outcomes. AOS can progress rapidly and early ophthalmology consultation (OC) is of paramount importance. We performed a retrospective, observational chart review to clarify the relationship of AOS and initiation of ophthalmologic care.

Methods: All patients with history of SJS in our hospital system were considered. Included patients had documented confirmed SJS diagnosis by biopsy or clinical exam by dermatology or burn service. 127 patients were included. The outcome measures included frequency of OC in the acute phase, AOS score at initial OC, and length of time in days to first OC. AOS score was compared between those seen within 1 day of admission and those seen after 1 day. Statistics were performed in R version 4.0.2. Means with standard deviations are presented for ordinal variables.

Results: 85 (66.9%) patients were seen by ophthalmology within 1 day, 26 (20.5%) were seen after 1 day, and 16 (12.6%) were not seen. Those seen occurred at a mean of 1.47 days after admission. Greater AOS scores were present in those seen within 1 day of admission compared to those seen after 1 day ($p = 0.003$). Worse systemic disease was seen in those patients seen within 1 day versus after 1 day. 23% of eyes in patients seen after 1 day of admission went on to develop chronic disease complications.

Conclusions: Most patients with SJS were seen by ophthalmology during the early acute phase. More severe eye disease was noted in those seen within 1 day of admission. As the workup of SJS is complex, often requires biopsy, and therefore increases time to diagnosis, this finding suggests more significant acute ocular and/or systemic disease may prompt more expedient ophthalmologic care when SJS is suspected. However, those not seen within 1 day of admission still have significant chronic complications. While large improvements have been made in the practice of OC for SJS, we suggest that all patients suspected of having SJS/TEN be examined by ophthalmology as early as possible as ocular disease can rapidly progress and even initially mild cases can have chronic complications.

TITLE: Vogt-Koyanagi-Harada disease (VKHD) after systemic treatment discontinuation

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Silveira Souto, R.F. Missaka, M.M. Lavezzo, P.F. Nóbrega, M.K. Oyamada, C.E. Hirata, J.H. Yamamoto, Ophthalmology, Universidade de Sao Paulo, Sao Paulo, São Paulo, BRAZIL|V.M. Sakata, Ophthalmology, Universidade Federal do Parana, Curitiba, PR, BRAZIL|

Commercial Relationships Disclosure (Abstract): Fernanda Maria Silveira Souto: Commercial Relationship: Code N (No Commercial Relationship) | Ruy Missaka: Commercial Relationship: Code N (No Commercial Relationship) | Marcelo Lavezzo: Commercial Relationship: Code N (No Commercial Relationship) | Priscilla Nóbrega: Commercial Relationship: Code N (No Commercial Relationship) | Viviane Sakata: Commercial Relationship: Code N (No Commercial Relationship) | Maria Oyamada: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Hirata: Commercial Relationship: Code N (No Commercial Relationship) | Joyce Yamamoto: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the clinical course of VKHD after systemic treatment discontinuation

Methods: Retrospective study with 11 patients (22 eyes) with VKHD after systemic treatment discontinuation for at least 12mo. All patients were followed from acute disease onset with systematic clinical and imaging evaluation (indocyanine green and fluorescein angiographies and enhanced depth imaging optical coherence tomography (Spectralis HRA+OCT)). All patients were treated with methylprednisolone pulse therapy followed by oral prednisone (1mg/kg/day) with slow tapering; 5 patients also received non-steroidal immunosuppressive therapy. Presence/fluctuation of clinical sign of inflammation (anterior chamber cells (ACC)); optic disc (OD) or perivascular leakage, dark dots (DD), subfoveal choroidal thickness (CT) increase $\geq 30\%$ (subclinical inflammation); and complications were analyzed during treatment period (TP) and post-treatment period (PTP). Criteria for treatment discontinuation were no anterior uveitis relapse, stable subclinical inflammatory signs and stable full-field electroretinogram (ffERG) parameters for at least 12mo. Binary ocular data were analyzed by descriptive statistics and generalized estimated equations. This study was approved by the Institutional Ethics Committee and followed the Helsinki declaration

Results: Mean disease duration at TP and PTP was 37.6 ± 15.8 mo (range 12-59mo) and 33.6 ± 21.3 mo (range 12-87mo), respectively. At the last TP visit, visual acuity (VA) was 0.1 ± 0.2 logMAR; no eyes had ACC; DD were present in all eyes (mean score 5.3 ± 0.9), while OD leakage was observed in 2 eyes (1 patient). During PTP, 1 patient (2 eyes) had transitional ACC, but none had systemic treatment restarted. All evaluated parameters (events/year and at last visit) improved in PTP, with statistical significance only for DD score fluctuation ($p=0.004$). ffERG parameters remained stable on PTP despite some subclinical inflammatory signs were still present. Table 1 describes TP and PTP data.

Conclusions: This is a pioneer description of VKHD course after systemic treatment discontinuation. After a systematic follow-up, criteria used for treatment discontinuation seems adequate. Subclinical inflammation tends to ameliorate during PTP. Further studies with longer follow-up are needed to better understand subclinical inflammation signs in VKHD after treatment discontinuation and to detect risk factors for late recurrence.

ABSTRACT BODY:

Purpose: Smoking tobacco is a known risk factor for many eye diseases. However, the association between electronic cigarettes (e-cigarettes), which contain nicotine (a by-product of tobacco), and eye diseases is not fully known. The purpose of this study was to use the Behavioral Risk Factor Surveillance System (BRFSS) to study the association between e-cigarette smoking and visual impairment.

Methods: A population-based, cross-sectional study was performed using data from 2016-2018 BRFSS surveys. BRFSS is a nationwide telephone survey that interviews U.S. adults ages 18+ about health behaviors. E-cigarette use for tobacco was assessed by the questions: "Have you ever used an e-cigarette or other electronic vaping product, even just one time, in your entire life?" and "Do you now use e-cigarettes or other electronic vaping products every day, some days, or not at all?". Visual impairment was defined as: "Are you blind or do you have serious difficulty seeing, even when wearing glasses?". Logistic regression was performed to assess the association between e-cigarette use and visual impairment, while controlling for the covariates of age, sex, race/ethnicity, marital status, education, employment status, family income, heavy alcohol use, BMI, physical activity, and mental health. Cigarette smoking was not included because it was highly correlated with e-cigarette use. All analyses were performed by incorporating sampling design and weights according to the BRFSS analytic guidelines.

Results: The study included 1,173,646 total individuals. 6.2% of current e-cigarette smokers and 5.8% of former e-cigarette smokers stated they were visually impaired, as opposed to only 4.7% of never e-cigarette smokers. These are weighted percentages which BRFSS uses to more accurately represent the total population from the survey. The odds ratio of visual impairment in current e-Cigarette smokers compared to never smokers was 1.37 (95% CI, 1.14-1.64) adjusted, and 1.36 (95% CI, 1.15-1.61) unadjusted. The odds ratio of visual impairment in former e-Cigarette smokers compared to never smokers was 1.21 (95% CI, 1.09-1.35) adjusted, and 1.20 (95% CI, 1.09-1.31) unadjusted.

Conclusions: E-cigarette smoking was associated with visual impairment in the BRFSS survey. Given the strong association between tobacco smoking and other behaviors like alcohol use, a future study is needed to determine the independent risk of e-cigarette smoking on visual impairment.

ABSTRACT BODY:

Purpose: To identify clinical and anatomic factors associated with vision loss in the eyes with treatment-naïve diabetic macular edema (DME) and good initial visual acuity (VA).

Methods: Retrospective cohort study following the long-term natural history of eyes with untreated center-involving DME and baseline VA $\geq 20/25$ seen at the University of California, Davis Eye Center between March 2007 to March 2018. We collected clinical characteristics including diabetes type, hemoglobin A1c, presence of visual symptoms, VA, and diabetic retinopathy (DR) severity; and spectral domain-optical coherence tomography (SD-OCT) biomarkers including central subfield thickness, intraretinal cyst size, intraretinal hyperreflective foci, disorganization of the retinal inner layers (DRIL), and outer retinal layer disruptions, to determine factors associated with vision loss as defined by the DRCR Protocol V study as the threshold for initiating aflibercept therapy.

Results: 76 eyes (67 patients) with untreated DME and mean baseline VA of logMAR 0.05 ± 0.05 (Snellen 20/22) was followed for an average of 4.3 ± 3.2 years, with a median time to vision loss of 335.5 days (11 months). Older age (hazard ratio (HR) 1.027/year, $P = 0.04$) and eyes with severe non-proliferative DR (HR 2.42, $P = 0.01$) or proliferative DR (HR 3.79, $P < 0.001$) showed a higher risk of vision loss, while no SD-OCT biomarker showed a significant association.

Conclusions: In eyes with DME and good initial vision, older patients or those with worse DR severity should be monitored more closely for prompt treatment initiation when vision loss occurs.

ABSTRACT BODY:

Purpose: Intracameral implants providing sustained release of drug to lower intraocular pressure (IOP) have the potential to bypass the ocular surface and manage IOP in glaucoma without use of daily eye drops. To facilitate the development of intracameral drug implants for lowering IOP, we developed a dog model to determine optimal drug release rates in the intracameral space.

Methods: Female normotensive Beagle dogs were used (n=5-8 per treatment). Under general anesthesia, an Alzet osmotic microinfusion pump was surgically placed subcutaneously in the back of the neck of each dog, with a cannula opening into the intracameral space of the right eye; the main body of the cannula was sutured to the sclera. Patency of the cannula was confirmed with fluorescein (Figure). After recovery from surgery, a solution of prostaglandin/prostamide analog at varying concentrations was delivered continuously into the intracameral space at 2.5 μ L/hr for 10 to 15 days. Aqueous humor samples were collected to determine drug concentration. IOP was measured in awake animals with a TonoVet rebound tonometer.

Results: Infusion of bimatoprost, bimatoprost acid, or latanoprost acid lowered IOP; infusion of latanoprost did not affect IOP. The IOP lowering during bimatoprost infusion was relatively steady and sustained. When the infused bimatoprost dose was increased to two higher doses, the magnitude of IOP lowering was similar, ranging from -32.9% to -34.3% at steady state with no clear dose-dependency. The aqueous humor bimatoprost concentration increased with increasing bimatoprost dose; bimatoprost acid was detected only at the highest dose. These results suggest that the lowest dose would represent a good target release rate when developing an intracameral bimatoprost drug implant. Ophthalmic observations were as expected with the surgical procedure, and no adverse findings were attributed to the tested drugs.

Conclusions: This dog model can be used to effectively screen IOP-lowering drugs as candidates for intracameral sustained-release platforms. Use of this model system to determine an optimal release rate and initial target dose to be used for in vivo testing of a sustained-release drug delivery device can accelerate intracameral implant drug development.

ABSTRACT BODY:

Purpose: Diabetic retinopathy remains a major cause of vision loss worldwide. Mineralocorticoid receptor (MR) is expressed in the retina and its antagonism has anti-inflammatory and anti-angiogenic effects. While MR pathway overactivation is recognized in the pathogenesis of diabetic nephropathy, its role in diabetic retinopathy is unknown. We aimed to evaluate the effect of intravitreal MR antagonist spironolactone in the retina of type2 diabetic Goto-Kakizaki (GK) rat and to establish the link between MR overactivation and diabetic retinopathy.

Methods: Young (3-4 months) and old (≥ 1 year) GK rats were injected intravitreally with PLGA microspheres controlled releasing spironolactone or non-loaded microspheres. Age and gender matched Wistar rats were used as control. One month later, retinal morphology, immunofluorescence of ion (Kir4.1) and water channels (AQP4) and microglia/macrophages (IBA-1), gene expression of inflammatory factors were analyzed. In old rats, we also assessed the effect of spironolactone on retinal vascular permeability and a transcriptomic analysis was performed to identify spironolactone-regulated genes and pathways in the diabetic retina. Human ocular media and retina have been used to confirm the relevance.

Results: The sustained local delivery of spironolactone decreased the early and late features of diabetic retinopathy such as retinal inflammation, vascular leakage and retinal edema in diabetic GK rats. The transcriptomic signature of the retina of old diabetic rats treated with spironolactone highlighted the regulation of genes encoding proteins known to intervene in vascular permeability and retinal edema such as Vldlr, Sesn2, Adcyap1, Dusp8, Pten, Slc7a1, Tjp1, Dlg1 and Sema7a. In human diabetic retina, MR expression was enhanced and cortisol was the preferential ligand binding to MR. Lipocalin 2 and galectin 3, two known MR target molecules increased in GK rat retina, were also enhanced in human diabetic retina.

Conclusions: Sustained intravitreal delivery of spironolactone reduces early inflammation and late retinal edema and vascular permeability in the retina of diabetic GK rats, suggesting involvement of MR pathway overactivation in the pathogenesis of diabetic retinopathy. Increase in MR expression, and in its ligand and target molecules in human diabetic retina further confirms the hypothesis.

ABSTRACT BODY:

Purpose: Pegcetacoplan (APL-2) is a C3 therapy targeting complement overactivation driving geographic atrophy (GA) progression. Neovascular age-related macular degeneration (nAMD) can coexist with GA. APL-203 was designed as an 18-month, Phase 1b/2, multicenter, open-label study evaluating the safety of monthly intravitreal (IVT) APL-2 for 12 months in patients with nAMD receiving anti-VEGF, with an additional 6 months of follow up.

Methods: Patients age ≥ 60 years with nAMD and BCVA of ≥ 24 ETDRS letters (20/320 Snellen equivalent) in the study eye were enrolled. Eyes had received ≥ 6 months of IVT anti-VEGF therapy (at ≤ 8 -week intervals for the most recent 2 injections). At screening, response to anti-VEGF was confirmed by reduction in macular fluid or thickness on optical coherence tomography (OCT). The primary endpoint was the incidence and severity of ocular and systemic treatment-emergent adverse events (TEAEs). APL-2 was administered ≥ 30 minutes apart from anti-VEGF.

Results: 17 patients (mean 77.2 years; 58.8% men; 94.1% white) received ≥ 1 dose of APL-2. Mean baseline VA in study eyes was 69.5 EDTRS letters. The majority of TEAEs were either mild or moderate. Common ocular TEAEs included increased intraocular pressure (IOP), uveitis, and conjunctival hemorrhage. Mean IOP was generally unchanged, and no deaths occurred. Two TEAEs of mild ocular hypertension were controlled with IOP-lowering drugs. Decline in BCVA (≥ 15 letters) in the study eye was observed in 8 patients; 6 fully recovered. In the other 2 patients, BCVA loss at the last study visit was deemed related to an ocular AE (unrelated to APL-2) or nAMD progression. During the study, patients remained on monthly anti-VEGF therapy. All patients had received a lyophilized APL-2 formulation for up to 7 months with no events of intraocular inflammation (IOI). A liquid formulation was introduced mid-study in 4 patients who then developed events of mild to severe IOI. All these events were transient, without long-term sequelae, and likely caused by a low-level impurity in the active pharmaceutical ingredient of the liquid formulation. The study was subsequently terminated early because sufficient data were collected for the sponsor's objectives.

Conclusions: Administration of APL-2 in combination with anti-VEGF therapy in patients with nAMD appears to be safe and well tolerated.

ABSTRACT BODY:

Purpose: The 24-2 visual field test has limited ability to detect change in the center of the visual field (VF). One approach to detecting change is to apply the change limits estimated from the central points in repeated 24-2 scans to 10-2 scans. In this study we use short-term reproducibility data to determine the specificity of using the 24-2 inner zone change limits from the HFA guided progression analysis (GPA) to detect change in the 10-2 VF.

Methods: VFs were acquired from 74 eyes of 74 glaucoma subjects at 5 repeat visits within 4 months, using HFA™ II-i (ZEISS, Dublin, CA). At each visit, SITA Standard 10-2 and 24-2 VFs were acquired. Because the repeated visits occurred over a short period of time, any change observed in this data would by definition be a false positive. In HFA, GPA change limits in the 24-2 field depend on location as well as baseline mean deviation (MD), and baseline pattern deviation (PD). For this study, we substituted 10-2 MD for the 24-2 MD. We plotted the correlation between the MDs to confirm that this was reasonable.

As in HFA GPA the first two scans in the series were averaged to create a baseline. The first and second follow-ups were compared to the baseline for each test point and the differences compared to the change limits used for the central portion of the 24-2 in the commercial version of GPA. False positive rates (FPR) with 95% confidence intervals (CI) were pooled for all 74 patients and all 68 test points in the 10-2 for both follow-ups. Specificity was defined as $1 - \text{FPR}$. GPA was not performed on test locations where the MD or PD are too poor(censoring), which would be denoted as "out of range" or "X" on the report and in the analyses. FPR was calculated two ways: pooling all points, and pooling only points not marked "X".

Results: Mean age was 63.6 (35.7 to 79.6) years. Mean MD was -3.9 (-18.2 to 1.2) dB. Correlation of 24-2 MD with 10-2 MD showed an R^2 of 0.67, a slope of 0.89 and an offset of 0.19, so it is reasonable to substitute the MD from 10-2 to determine change limits. FPR was 0.47 (CI: 0.43 to 0.52) considering all 10064 pooled points and 0.51 (CI: 0.46 to 0.55) considering 9380 pooled valid points, consistent with specificity of ~95%.

Conclusions: Specificity was ~95% for detecting progression in 10-2 fields using limits established in the central portion of the 24-2, indicating that a simple GPA for 10-2 can be created using existing data.

ABSTRACT BODY:

Purpose: The currently most comprehensive genome-wide association study (GWAS) for age-related macular degeneration (AMD) identified disease associations for 52 independent genetic variants at 34 genomic loci. Collectively, the AMD-associated loci are enriched for genes contributing to a number of shared cellular processes. Of note, most current approaches focus on single loci and their influence on AMD pathogenesis without considering epistatic interactions. Here, we present a novel approach to investigate combined effects of apparently independent GWAS variants associated with AMD.

Methods: The influence of genetic variants on genome-wide gene expression was analyzed in harmonized post-mortem liver tissue (n = 588; Strunz et al. Sci Rep. 8:5865, 2018). Multiple combinations of AMD-associated genetic variants were used to generate genetic risk scores (GRS) and gene expression in liver was compared between the respective low and high-risk groups.

Results: We determined 26 genes (eGenes) with a significantly altered expression in high-risk vs. low-risk combinations. Seven of these, namely LIPC, CFHR1, CFHR4, CFHR3, PILRA, PILRB, and TSPAN10 were previously reported to be regulated by single AMD-associated variants in expression quantitative trait locus (eQTL) studies. Nineteen eGenes represent exciting new candidates for AMD etiology. Among the novel candidates, BRCA1 and ASNS show the highest effect sizes (ESs), whereby a high genetic risk for AMD is correlated with a downregulation of BRCA1 (ES = -1.18, SE = 0.21, Q-Value = 1.55×10^{-7}), and an upregulation of ASNS (ES = 1.17, SE = 0.20, Q-Value = 9.36×10^{-8}).

Conclusions: Here we present a novel method combining GRS and eQTL mapping to investigate joint effects of seemingly independent genetic variants on gene expression. We replicated earlier eQTL findings, and report 19 novel genes to correlate with the genetic risk to develop AMD. All genes were exclusively identified by jointly analyzing several AMD-associated variants, which is in-line with the theory that the signals underlying GWAS associations contribute to shared biological mechanisms.

ABSTRACT BODY:

Purpose: Cystoid macular edema (CME) is a common complication in retinitis pigmentosa (RP) and Leber congenital amaurosis (LCA) patients, with a reported prevalence of 11-50% in adults. However, CME prevalence in the pediatric RP population has not been addressed. The aim of our study was to assess the prevalence of CME in pediatric RP/LCA patients detected by optical coherence tomography (OCT).

Methods: Medical records of children up to age 18 with a diagnosis of RP/LCA were reviewed retrospectively; only those who performed an OCT scan were included in the study. Diagnosis was based on history of poor vision since birth, nyctalopia, visual field constriction, characteristic fundus findings on clinical examination or electroretinogram (ERG), and/or genetic testing. OCT images were reviewed and assessed for macular cystic changes. Patients with more than one hyporeflective cystic macular space with well-defined boundaries were included.

Results: Of the 51 children (age 4-18 years, mean 10.8±4.0) diagnosed with RP, 16 had CME (31.3%) diagnosed by OCT, 14/16 (87.5%) had bilateral CME and 2 patients (12.5%) had unilateral CME. Among children with CME, 8 had an identified causative gene; among them 7/8 (87.5%) were inherited in an autosomal recessive fashion and 3/8 (37.5%) children had biallelic CRB1 mutations. CME was treated in 11/16 children and 4/11 had some improvement; 1/4 had improved vision (one line gain in vision for distance and near) and 3/4 had reduced central foveal thickness with stable vision.

Conclusions: Our results show that as many as one-third of children with RP/LCA will manifest cystic changes on OCT, comparable to the reported prevalence of CME in adults. Since clinical suspicion of cystic retinal lesions is challenging in children, it is necessary to screen these children by OCT to exclude the presence of CME. Early treatment of CME may potentially lead to better visual outcome. Additional long-term research is needed to assess recommended treatment and its efficacy on CME in pediatric RP/LCA patients.

ABSTRACT BODY:

Purpose: Correcting aphakia in pediatric eyes that lack capsular support can be a challenge. Reports addressing this issue in children with Marfan Syndrome or the FBN1 mutation have been few. Here we compare safety and efficacy outcomes for 4 different approaches: 1. An iris-enclaved anterior chamber IOL (Artisan-Ophtec, AO IOL); 2. An angle-supported anterior chamber intraocular lens (AC IOL); 3. A trans-scleral sutured IOL (TSS-IOL); and 4. Aphakic (Aph) managed only with spectacles/contact lenses.

Methods: Outcomes were collated for correction of aphakia in 38 patients (68 eyes) with a history of lensectomy-vitreectomy and complete capsulectomy for ectopia lentis. 17 children (30 eyes) were implanted with an AO IOL; 10 (16 eyes) with an ACIOL; 9 (17 eyes) with a TSS-IOL; and 8 (15 eyes) remained Aph. Average follow up was: 3.8 yrs (range 0.5-10 yrs) for the AO IOL group; 5.5 yrs (0.25-15) for AC IOL; 9.6 years (5-15) for TSS-IOL; and 4.9 years (0.5-13) for Aph.

Results: At last follow-up visit, CDVA was better than pre-implantation VA in 90% of AO IOL eyes, 87% of AC IOL eyes and 47% of TSS-IOL eyes. 73% of Aph eyes had a CDVA of ≤ 0.18 logMAR (20/30). Major complications encountered in follow-up were least with the AO IOL and most with the TSS-IOL approach. Complications for each approach were: AO IOL eyes, ocular hypertension (OHT) (10%, 3/30 eyes) and haptic dislocation (3.3%, 1/30); Aph eyes, OHT (13.3%, 3/15) and retinal detachment (6.7%, 1/15); and AC IOL eyes, angle closure (20%, 3/15), OHT (6.7%, 1/15), vitreous hemorrhage (6.7%, 1/15), and retinal detachment (6.7%, 1/15). TSS-IOL complications were more prevalent: haptic suture breakage necessitating re-suturing or explantation (65%, 11/17), iris capture, (24%, 4/17), and retinal detachment (41%, 7/17). Endothelial cell density tended to be lower in TSS-IOL and higher in Aph eyes. Likewise, corneal thickness tended to be lower in Aph and higher in TSS-IOL eyes.

Conclusions: The pediatric eyes with the best longer-term outcomes appear to be those implanted with the AO IOL or those that remain aphakic. TSS-IOL implantation was associated with more complications. On-going follow-up will help clarify CDVA outcomes and the state of corneal health.

ABSTRACT BODY:

Purpose: Retinal neurons spend most of their energy to support the transmembrane movement of ions. Light-induced electrical activity is associated with a redistribution of ions, which affects the energy demand and results in a change in metabolism. Light-induced metabolic changes are expected to be different in distal and proximal retina due to differences in the light responses of different retinal cells. Extracellular K^+ concentration ($[K^+]_o$) is a reliable indicator of local electrophysiological activity, and the purpose of this work was to compare $[K^+]_o$ changes evoked by steady and flickering light in distal and proximal retina.

Methods: Intraretinal recordings were made from isolated mouse (C57Bl/6J) retinæ. Diffuse steady and flickering (1 and 10 Hz) light of scotopic and photopic intensities was applied in both dark- and light-adapted conditions. Double-barreled K^+ -selective microelectrodes were used to record $[K^+]_o$. Simultaneously recorded local ERGs assisted in verification of the electrode position.

Results: In the distal retina, photoreceptor hyperpolarization led to suppression of ion transfer, a decrease in $[K^+]_o$ by 0.3-0.5 mM, reduced energy demand, and, as previously shown in vivo, decreased metabolism. Flickering light had the same effect on $[K^+]_o$ in the distal retina as steady light of equivalent intensity. The conductance and voltage changes in photoreceptor neurons are cell-specific, but the overall effect of steady light in the proximal retina is excitation, which was reflected in a $[K^+]_o$ increase there (maximally 0.2 mM). In steady light the $[K^+]_o$ increase lasts only 1-2 seconds, but a sustained $[K^+]_o$ increase was evoked by flickering light. A squarewave low frequency (1 Hz) flicker of photopic intensity produced the largest increases in $[K^+]_o$.

Conclusions: Judging by measurements of $[K^+]_o$, steady illumination decreased energy metabolism in the distal retina, but not in the proximal retina (except for the first few seconds). Flickering light evoked the same decrease in the distal retina, but also evokes a sustained $[K^+]_o$ increase in the proximal retina, suggesting an increase of metabolic demand there, especially at 1 Hz, when neurons of both on- and off-pathways appear to contribute maximally. This proximal retinal metabolic response to flicker underlies the increase in blood flow during flicker that constitutes neurovascular coupling.

TITLE: Comparison of Pressure-Volume Ratios in Diabetic vs. Normal Eyes

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.L. Huang, M.P. Ohr, Ophthalmology, The Ohio State University, Columbus, Ohio, UNITED STATES|A. Mahmoud, C.J. Roberts, Ophthalmology and Biomedical Engineering, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tiffany Huang: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Ohr: Commercial Relationship(s);Alimera:Code C (Consultant);Alimera:Code I (Personal Financial Interest) | Ashraf Mahmoud: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Roberts: Commercial Relationship(s);Oculus Optikgeräte GmbH:Code C (Consultant);Ziemer Ophthalmic Systems AG:Code C (Consultant);Optimo Medical:Code C (Consultant)

ABSTRACT BODY:

Purpose: To date, little is known regarding the biomechanical response of the eye to diabetes or the relationship of such changes to clinical retinopathy. In this study, we use static pressure-volume (PV) ratios as a surrogate for ocular rigidity and compare it among subjects with diabetic retinopathy (DR), diabetes without retinopathy (DIA), and controls (NL).

Methods: A total of 240 subjects (475 eyes) were analyzed; 150 NL (n=297 eyes), 45 DIA (n=90 eyes), and 45 DR (n=88 eyes). Intraocular pressure (IOP) was obtained using corneal compensated IOP from Ocular Response Analyzer, Goldmann applanation tonometry, PASCAL dynamic contour tonometer, and Corvis ST. Anterior chamber volume (ACV) was measured using the Pentacam. Four PV ratios were calculated using the IOP obtained from the different methodologies over ACV. PV was correlated to two stiffness parameters (SP) calculated as load over displacement, from undeformed state to first applanation for cornea (SP-A1), and from applanation to highest concavity for sclera (SP-HC) using regression analysis. ANCOVA was performed to compare PV between groups with pachymetry and age as covariates. Significance threshold was $p < 0.05$.

Results: PV ratios were significantly greater in DR compared to DIA and NL using all 4 methods of measuring IOP, with no difference between DIA and NL. For SP-HC, DR was significantly stiffer compared to DIA (< 0.0001) and NL (< 0.0001), with no difference between DIA and NL ($p = 0.19$). No relationship was observed for SP-A1 among the 3 groups. PV ratio had stronger correlation to SP-HC ($R^2 = 0.39$, $p < 0.0001$) than SP-A1 ($R^2 = 0.15$, $p = 0.0002$), with the strongest relationship noted in DR group.

Conclusions: In this report, we used PV ratios as a surrogate for ocular rigidity. Our results showed greater PV ratios in DR than both DIA and NL. Furthermore, there is high correlation between PV ratio and the scleral stiffness parameter. Clinically, the scleral stiffness parameter can be thought of as the entire posterior ocular shell, encompassing structures beyond the sclera including the retina, choroid, and supporting vasculature and connective tissue. Our results suggest eyes with DR have stiffer posterior ocular shell and we are currently investigating potential mechanisms.

TITLE: Dose uniformity of loteprednol etabonate (submicron) ophthalmic gel 0.38% compared with prednisolone acetate ophthalmic suspension 1.0%

SESSION TITLE: Cornea, cytokines, anti-inflammatory

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z.T. Marlowe, M.J. Coffey, Pharmaceutical Product Development, Bausch + Lomb, Rochester, New York, UNITED STATES|M.E. Cavet, Medical Affairs, Bausch + Lomb, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zora Marlowe: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment) | Megan Cavet: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment) | Martin Coffey: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment)

ABSTRACT BODY:

Purpose: Dose uniformity can be challenging with ophthalmic suspensions since drug particles may settle over time and patients often fail to adequately shake the bottle prior to instillation. Loteprednol etabonate (submicron) ophthalmic gel 0.38% (LE gel 0.38%) is a polycarbophil-based formulation that is a semi-solid at rest to prevent drug particle settling. This study compared dose uniformity of LE gel 0.38% and prednisolone acetate (PA) 1% suspensions under shaken and unshaken simulated in-use conditions.

Methods: One set of 5 mL bottles of LE gel 0.38% and branded and generic PA suspensions was shaken for 5 seconds immediately prior to drop expression at simulated dosing time points over two weeks, whilst a second set of bottles was not shaken prior to drop expression. The dispensing time points followed product label recommendations: LE gel 0.38% was dispensed three times daily (7 AM, 12 PM, and 10 PM, \pm 1 h), while PA suspensions were dispensed four times daily (7 AM, 12 PM, 5 PM and 10 PM, \pm 1 h). The first and last daily dispensed drops were collected and drug concentrations analyzed by high pressure liquid chromatography. Data were expressed as mean \pm SD percent of the declared (labeled) concentration for each drug.

Results: Dispensed drops of LE gel 0.38% showed consistent on-target mean drug concentrations over 2 weeks of dosing whether expressed from shaken ($103.2 \pm 1.3\%$) or unshaken ($103.3 \pm 1.5\%$) bottles. In contrast, while mean drug concentrations for both branded and generic PA suspensions were on-target over 2 weeks of dosing following expression from shaken bottles ($102.2 \pm 1.39\%$ and $98.3 \pm 2.87\%$, respectively), they were highly variable over the two weeks when dispensed from unshaken bottles ($89.2 \pm 18.59\%$ and $78.3 \pm 13.47\%$, respectively). Drug concentrations of dispensed PA drops from unshaken bottles were lowest at the start of the study and were outside of 90-110% of the declared concentration for the majority of dispensed drops over the 2 weeks.

Conclusions: Drops of LE gel 0.38% delivered the declared concentration of LE under both shaken and unshaken simulated in-use conditions whereas drops of PA 1% suspensions were on-target when shaken, but highly variable when the bottles were not shaken. LE gel 0.38% is expected to provide consistent dosing and therefore consistent efficacy over the entire 2 week dosing regimen regardless of shaking.

ABSTRACT BODY:

Purpose: Time spent in outdoor activities is decreased due to home confinement for the Covid-19 epidemic. Concerns have been raised about whether it may have worsened the burden of myopia due to substantially decreased time spent outdoors and increased screen time at home. The purpose of this study is to investigate the refractive change and prevalence of myopia for school-aged children during the Covid-19 home confinement.

Methods: In this school-based cross-sectional study in 10 elementary schools in Feicheng, China, and a total of 123,535 children aged 6 to 13 years were screened during 6 consecutive years (2015-2020). The Non-cycloplegic photorefractive was examined by Spot photoscreener. The Spherical Equivalent Refraction (SER) was recorded for each child and the prevalence of myopia for each age group in each year was calculated. The mean SER and prevalence of myopia were compared between the year of 2020 (after home confinement) and the previous 5 years for each age group.

Results: A total of 194,904 test results (389,808 eyes) from 123,535 children were included in the analysis. A substantial myopic shift (around -0.3D) was found in the 2020 school-based photoscreenings when compared with previous years (2015-2019) for younger school-aged children aged 6 (-0.32D), 7 (-0.28D), and 8 years (-0.29D). The prevalence of myopia in the 2020 photoscreenings was much higher than the highest prevalence of myopia within years of 2015-2019 for children at age of 6 (21.5% vs 5.7%), 7 (26.2% vs 16.2%), and 8 (37.2% vs 27.7%). The differences in SER and prevalence of myopia between 2020 and previous years were minimal in children aged 9-13 years.

Conclusions: Covid-19 home confinement was associated with a significant myopic shift for younger children (aged 6-8 years) according to the 2020 school-based photoscreenings. Younger children's refractive status may be more sensitive to environmental changes than older ages, given they are in a critical period for the development of myopia.

TITLE: A two-step model of PVL and ROP

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Song, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|W. Song, G. Hoppe, D. Hanna, J.E. Sears, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Weilin Song: Commercial Relationship: Code N (No Commercial Relationship) | George Hoppe: Commercial Relationship: Code N (No Commercial Relationship) | Demiana Hanna: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Sears: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although both the retina and the brain are central nervous system tissues, pathology of each created by preterm birth is ascribed different etiologies. Retinopathy of prematurity (ROP) is created by a two-step mechanism of oxygen induced retinovascular growth attenuation and vasoobliteration (phase 1) followed by ischemic hypoxia and pathological angiogenesis (phase 2). However, the current hypothesis of the etiology of periventricular leukomalacia (PVL) relies on hypoxic ischemia alone that drives inflammation and hypomyelination. We have noted a similar metabolic response of brain cortical astrocytes and retinal Müller cells during hyperoxia, which stimulated the idea that the pathogenesis of PVL may resemble the two-step origin of ROP. In this study, we have developed a murine PVL model to correlate retinal and brain pathology using phase 1 hyperoxia and phase 2 relative hypoxia.

Methods: C57BL/6J pups and their nursing dam were placed into 80% oxygen from P4-P8, control pups from the same litter were placed with a second nursing dam. Dams were switched every 24 hours. Brains and retinas were dissected at P8 and P11. Brain tissue was processed for immunofluorescence staining (MBP, lectin, GFAP, Caspase 3) and western blots (CD31, HIF-1a). Retinal vasculature was revealed by lectin staining. Immunofluorescent images of brain and retina were analyzed with ImageJ and AngioTool. Statistical analysis was performed by comparing means using Student's t-test.

Results: Mice in the hyperoxia group demonstrated hypomyelination and increased apoptosis in periventricular zones at P8 and P11. Astrocytes demonstrated decreased GFAP expression at P8 compared to normoxic controls but increased expression at P11, consistent with PVL. Hyperoxic mice also had decreased cerebral capillary density on the roof of the lateral ventricles with decreased CD31 and HIF-1a expression. Retinal vasculature contemporaneously revealed vaso-obliteration at P8.

Conclusions: A two-step model of PVL using hyperoxia followed by relative hypoxia results in hypomyelination, decreased cerebral capillary density, and downregulation of HIF-1a. These findings support the hypothesis that hyperoxia results in dysregulation of periventricular vasculature development and hypomyelination and provides an experimental correlate of PVL.

ABSTRACT BODY:

Purpose: Use of topical corticosteroids (CSs) to treat ocular inflammation may be limited by CS class-associated adverse events (AEs) including intraocular pressure (IOP) increase, glaucoma, cataracts, delayed healing, and infections. Loteprednol etabonate (LE) is a topical ophthalmic CS which undergoes rapid metabolism following exertion of its anti-inflammatory effect and therefore has a low propensity for eliciting AEs. A next generation LE formulation (LE SM gel 0.38%) with reduced (submicron-sized) drug particles and improved ocular penetration was introduced in early 2019. We report on occurrence of ocular CS class-associated AEs for this and other LE ophthalmic formulations.

Methods: The Bausch + Lomb pharmacovigilance (PV) AE database system (ARISGlobal[®]) was queried for all CS class-associated AEs (spontaneous, study, literature) reported in the US for LE ophthalmic formulations since development and launch of the first LE suspensions in the late 1990s through September 2020. The following formulations were included in the analysis: LE 0.5% and 0.2% suspensions, LE 0.5% and tobramycin 0.3% suspension, LE 0.5% ointment, LE 0.5% gel, and LE SM 0.38% gel. Throughout the reporting period, AEs were entered into the PV database using preferred MedDRA terms.

Results: Corticosteroid-associated AEs for LE SM 0.38% gel were infrequent, with 8 reports of IOP increase, 2 reports of cataract, and 1 reported eye infection. Across all LE formulations, there were a total of 19 reports of cataract, 131 reports of IOP increase, 19 reports of glaucoma or ocular hypertension, 8 reports of impaired healing, and 56 reports of ocular infections. Most AEs were categorized as non-serious, with the exception of several reports of glaucoma and cataract. During this reporting period, nearly 67 million units were shipped for these products in the US.

Conclusions: Corticosteroid class-associated AEs were reported infrequently in the PV AE database for all LE formulations, including for the recently introduced LE SM 0.38% gel formulation, suggestive of a very low incidence rate for these AEs with LE treatment. Data limitations include possible underreporting of AEs due to the voluntary nature of the reporting and uncertainty as to whether the AE was causally related to LE treatment.

ABSTRACT BODY:

Purpose: Posterior Polymorphous Corneal Dystrophy (PPCD) is associated with a dysregulated cell state, induced by mutations that alter the levels of epithelial mesenchymal transition (EMT)-regulating transcription factors ZEB1, GRHL2 or OVOL2. Here we investigate the transcriptomic signature of dysregulation in PPCD type 1 (PPCD1) corneal endothelial cells (CECs) to identify biomarkers of the disease mechanism as potential therapeutic targets.

Methods: We cultured primary CECs from five individuals affected with PPCD1 and seven controls. All PPCD1 individuals were confirmed to harbour the same regulatory mutation in the OVOL2 promoter (NM_021220:c.-370T>C), previously hypothesised to lead to ectopic expression of OVOL2 within the corneal endothelium. Total RNA was extracted from each primary culture using NucleoSpin RNA XS isolation kit (Macherey Nagel). We enriched mRNA using oligo(dT) beads and paired-end Illumina RNA sequencing was performed using a stranded library preparation. Transcriptomic analysis was performed using DESeq2, rMATS and IsoformSwitchAnalyzeR programs to investigate differential gene expression and splicing events in PPCD1 CECs compared to control CECs.

Results: Utilizing the EMT Gene Database, 279 EMT-associated genes were found to be highly dysregulated (false discovery rate (FDR) corrected p-value <.05; Log-2 fold change > 1) in PPCD1 including CDH1, OVOL2, GRHL2, GATA6, members of the mir200 family, numerous keratins, and the epithelial splice regulator ESRP1. Alternative splicing was further identified for ESRP1 targets, CD44 and FGFR2.

Conclusions: Our study confirms the aberrant upregulation of OVOL2 in PPCD1 and suggests that EMT-associated genes and pathways are significantly disrupted in PPCD1 CECs. Our data suggests that overexpression of the epithelial cell type-specific splicing regulator, ESRP1, induces aberrant splicing of CD44 and FGFR2. We hypothesise that this mechanism contributes to the 'epithelialisation' of the corneal endothelium observed in PPCD1 and may act as a target for future therapeutic interventions.

TITLE: Optic disc drusen prevalence in the retinitis pigmentosa population

SESSION TITLE: Retinitis pigmentosa/ retinal prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Russell, C. Fraser, J.R. Grigg, Sydney Hospital and Sydney Eye Hospital, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Nicholas Russell: Commercial Relationship: Code N (No Commercial Relationship) | Clare Fraser: Commercial Relationship: Code N (No Commercial Relationship) | John Grigg: Commercial Relationship(s);Novartis:Code C (Consultant)

ABSTRACT BODY:

Purpose: Optic disc drusen (ODD) are acellular benign deposits originally reported to occur in 0.3-0.5% of the normal population. More modern studies of the normal population involving histopathology and improved imaging put the prevalence of ODD at 1.8-2.4%. ODD are understood to be associated with retinitis pigmentosa (RP) and the prevalence of ODD in individuals with RP is reported to range from 3-80%. The higher rates within this range however, of 80% (4/5 individuals) and 38% (9/24 individuals), were identified in small populations with the less common RP subtype of preserved para-arteriole RPE and more recent population studies have shown rates of 2.95-3.6%. Usher's syndrome is also associated with elevated rates of ODD ranging from 7.6-35% depending on the subtype of Usher's syndrome. Visible ODD may be identified on fundoscopic examination, whereas ultrasonography, OCT or autofluorescence may assist in identifying buried ODD. This retrospective study was undertaken to further investigate the prevalence of ODD using imaging techniques in an RP population.

Methods: A database of electrophysiologically confirmed RP patients (N=195) was retrospectively examined and fundus photography, autofluorescence and OCT images were assessed in each patient for signs of ODD. Two clinicians examined fundus photographs for changes consistent with ODD. Genetic testing results were not available for all patients but were included when possible.

Results: The prevalence of ODD was 3.1% (N=6) with 2 patients having bilateral ODD. Three of these cases were X-linked with an identified RPGR gene and three cases did not have genetic testing completed. A total of 11 patients with confirmed Usher's syndrome and 4 patients with suspected Usher's syndrome were examined with no patients demonstrating ODD. No individuals in this population had preserved para-arteriole RPE RP.

Conclusions: Our results are consistent with the lower range of reported ODD prevalence. These results are more in keeping with the normal population prevalence of ODD within an RP population. The variation in results may be explained by particular subtypes of RP having stronger genetic associations with ODD. The link with RPGR is worth further investigation.

ABSTRACT BODY:

Purpose: Pupil dilation is often performed before patients undergo dark adapted perimetry testing. We tested the hypothesis that the mean of the average sensitivity differs based on dilation status in individuals without retinal pathology.

Methods: 15 healthy adults (9 female) ages 23-63 without retinal pathology underwent a 45-minute dark adaptation period followed by sequential undilated and dilated two color perimetry testing of the left eye. 14 (8 female) ages 23-63 of these adults also underwent repeat undilated testing using the same protocol on a separate day to evaluate intervisit variability. A modified Octopus 900 perimeter utilizing size III Goldman targets with a 500nm (blue) or 650nm (red) filter were used. The mean differences in average sensitivity were compared using two-sided paired t-tests.

Results: The average sensitivity to the red stimulus was 26.68dB (SD: 2.43dB) under undilated conditions and 27.31dB (SD: 1.79dB) under dilated conditions. The mean difference in the average sensitivity between the undilated and dilated conditions using the red stimulus was -0.63dB (SD: 1.40dB; 95% CI: [-1.40dB, 0.14dB]; $p = 0.102$). The average sensitivity to the blue stimulus was 41.84dB (0.87dB) for the undilated condition and 41.75dB (SD: 1.00) for the dilated condition. The mean difference in the average sensitivity between the undilated and dilated conditions using the blue stimulus was 0.09dB (SD: 0.57dB; 95% CI: [-0.23dB, 0.40dB]; $p = 0.557$). The mean difference in the average sensitivity between the initial and subsequent undilated test using the red stimulus and blue stimulus was -0.63dB (SD: 1.01dB; 95%CI: [-1.22db, -0.05dB]; $p = 0.036$) and -0.14dB (SD: 0.66dB; 95%CI: [-0.52dB, 0.24dB]; $p = 0.451$) respectively.

Conclusions: These findings show no statistically significant difference in the mean of the average sensitivity to red or blue stimuli under scotopic conditions based on dilation status. The intervisit variability was similar to that observed between the same day undilated and dilated conditions. Finally, the absolute value of the 95%CI's for all mean differences was <1.5dB were suggesting that dilation may not have a clinically meaningful effect on the average sensitivity to red or blue stimuli under scotopic conditions in patients without retinal pathology.

TITLE: MMP9 differentially regulates proteins involved in actin polymerization and cell migration during EMT of lens epithelial cells

SESSION TITLE: Posterior Capsular Opacification and Fibrosis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. Liu, A. Taiyab, J.A. West-Mays, Pathology and Molecular Medicine, McMaster University Faculty of Health Sciences, Hamilton, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Zi Zhen (Ginny) Liu: Commercial Relationship: Code N (No Commercial Relationship) | Aftab Taiyab: Commercial Relationship: Code N (No Commercial Relationship) | Judith West-Mays: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Posterior capsular opacification and anterior subcapsular cataract are attributed to transforming growth factor- β (TGF β) induced epithelial-to-mesenchymal transition (EMT) of lens epithelial cells (LECs). Previous studies from our lab have identified matrix metalloproteinase-9 (MMP9) as a potential regulator of cytoskeletal reorganization during EMT of LECs. Here, we studied the effect of MMP9 inhibition on TGF β activation of proteins involved in actin reorganization and cell migration.

Methods: A NanoString gene expression analysis was performed on LEC explants from 1.5-2 month-old wild-type (WT) mice, transgenic mice overexpressing TGF β in the lens (TG^{tg}) or TG^{tg} mice on a MMP9 knockout background (TG^{tg}:MMP9KO). A cytoskeletal protein array was conducted using similar samples as above. For validation, rat LEC explants were obtained from 17-19 days old Wistar rat pups, and a novel MMP9-specific inhibitor, JNJ0966, was used. These explants were either treated with <5% dimethyl sulfoxide (Rat^D), 6ng TGF β (Rat^{TG}), 20 μ M JNJ0966 (Rat^{JNJ}) for 48 hrs or pretreated with 20 μ M JNJ0966 for 2 hours followed by 6ng TGF β for 48 hours (Rat^{TG:JNJ}). Immunofluorescence and Western Blot analyses were performed using antibodies specific to proteins identified from the protein array and imaged for analysis.

Results: Gene expression analyses revealed significant decreases in alpha-smooth muscle actin (α SMA)(p<0.01) and F-actin formation (p<0.01) in TG^{tg}:MMP9KO LECs when compared to TG^{tg} LECs. Furthermore, the protein array identified fold changes of 0.41 for cortactin, 0.93 for phosphorylated lim-kinase 1 (LIMK1) and 0.64 for phosphorylated focal adhesion kinase (FAK) in TG^{tg}:MMP9KO LECs when compared to TG^{tg} LECs. Rat^{TG:JNJ} explants showed cortical staining of E-cadherin and minimal staining of α SMA polymerization when compared to Rat^{TG} explants. Immunofluorescence and Western Blot analyses further revealed a marked decrease in phosphorylated FAK (Y397) and LIMK1 (T508) in Rat^{TG:JNJ} explants when compared to Rat^{TG} explants.

Conclusions: The protein array and its validation indicate that MMP9 deficiency results in lowered levels of activated LIMK1 and FAK, proteins known to be involved in TGF β -induced actin polymerization and cell migration. Further analyses should be performed to understand the mechanism by which MMP9 regulates the activity of these proteins during TGF β -induced EMT.

TITLE: Inducing dry eye disease using a custom engineered desiccation system: impact on the ocular surface including keratin-14-positive limbal epithelial stem cells

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Di Girolamo, R. Zhang, E. Pandzic, M. Park, D. Wakefield, Medical Sciences, University of New South Wales Faculty of Medicine, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Nick Di Girolamo: Commercial Relationship: Code N (No Commercial Relationship) | Richard Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Elvis Pandzic: Commercial Relationship: Code N (No Commercial Relationship) | Mijeong Park: Commercial Relationship: Code N (No Commercial Relationship) | Denis Wakefield: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dry eye disease (DED) is characterized by loss of tear-film stability. Currently, desiccation stress (DS) is the predominant means for inducing DED in mice, however its effect on limbal epithelial stem cells (LESCs) has been overlooked. This study aimed to establish a DS model of DED using our in-house system to investigate the impact on the ocular surface including LESCs.

Methods: A mouse transporter unit was customized to generate a dehumidified environment in an isolated room. C57BL/6j mice were exposed to mild DS or remained untreated (UT) in our vivarium for 10 consecutive days (n=28/group). Clinical assessments included phenol red tear-thread, fluorescein staining and optical coherence tomography (OCT). Histopathology and immunofluorescence was used to evaluate tissue architecture, goblet cell (GC) status, lacrimal gland (LG) inflammation and ocular surface phenotype. Whole flat-mounted corneas were immunostained for K14, imaged by confocal microscopy and analyzed to investigate the effect of DS on LESCs.

Results: Modifications made to the animal transporter unit resulted in decreased relative humidity (RH) in cages ($43.5 \pm 4.79\%$) compared to those in the vivarium ($53.9 \pm 1.8\%$, $p=0.0243$). Under these conditions, tear production was suppressed whilst corneal permeability and corneal irregularity significantly increased. H&E staining indicated that basal corneal epithelia were stressed and increased desquamation. However, no major change in corneal thickness was detected using OCT. DS-exposed mice had reduced GC density (41.0 ± 5.10 GC/mm vs 46.9 ± 3.88 GC/mm, $p=0.0482$) and their LGs had elevated $CD4^{+}$ T-cells compared to controls. DS also elicited $K14^{+}$ epithelial cell displacement, as indicated by increased normalized fluorescence signal distanced 50-100 μm radially inwards from the limbus [$0.63 \pm 0.053\%$ (DS) vs $0.54 \pm 0.060\%$ (UT), $p=0.0317$].

Conclusions: Mild DS applied to C57BL/6 mice using a customized system generated features of DED. Following DS, ocular surface epithelial cell health decreased and LESCs appeared stressed. This suggests that downstream effects of DS on corneal homeostasis are present. The method used to induce DED in this study enables a chronic model to be developed which more closely resembles the clinical situation.

ABSTRACT BODY:

Purpose: High visual acuity in prosthetic vision requires effective stimulation by small pixels with little crosstalk. However, due to shallow penetration of the field with planar bipolar pixels, retinal stimulation threshold exceeds the safe charge injection limit with pixels under 40µm. To bypass such limitation, we developed arrays with deep-penetrating field and investigated their stimulation threshold and acuity in vivo.

Methods: The 1.5mm-wide hexagonal arrays of monopolar photovoltaic pixels of 20 or 40µm in size, having a common return electrode at the edge, were produced with and without 25µm tall walls surrounding each pixel. To reduce the crosstalk, the nearby pixels were converted into transient local returns by spatiotemporal modulation of their conductivity. Following subretinal implantation in rats with degenerate retina (RCS), visually evoked potentials (VEP) were recorded in response to pulsed NIR (880 nm) activation of the implants. The full-field stimulation threshold was measured with 10ms pulses at 2Hz, while acuity was measured using gratings alternating at 2Hz, under 4ms stimulation applied either at 64Hz or multiplexed into 4 sub-frames at 256Hz.

Results: The full-field stimulation threshold was $0.057 \pm 0.029 \text{ mW/mm}^2$, corresponding to a current density of 0.092 mA/mm^2 on the active electrodes, independent of pixel size and presence of the walls. This is nearly 30 times lower than that with bipolar pixels of 40µm in size. On the day of implantation, VEP amplitude typically exceeds 100µV, but it dropped to tens of µV one week later, and gradually recovered back to the initial level within 8 weeks post-op. Grating acuity matched the pixel size in 40µm arrays.

Conclusions: Photovoltaic prostheses with nearly-vertical electric field in the retina demonstrated stimulation thresholds independent of pixel size, and much lower than those with bipolar pixels. Using optical spatiotemporal modulation of the photodiode conductivity, any subset of pixels can be converted into transient local returns, thereby providing field confinement necessary for high resolution. Presence of the vertical walls did not negatively affect the retinal excitability, paving the way to honeycomb implants with local returns. Resolution of 40µm corresponds to acuity of 20/160, exceeding the threshold of legal blindness in US. Acuity studies with 20µm pixels are in progress.

ABSTRACT BODY:

Purpose: We aimed to identify candidate Mendelian ciliopathy genes relevant to childhood blindness syndromes by enriching all single gene homozygote or heterozygote knockout mouse strains produced by the International Mouse Phenotyping Consortium (IMPC) with abnormal ocular phenotypes with multiple abnormal phenotypes commonly found in human ciliopathy syndromes.

Methods: We enriched the set of knocked out genes with abnormal ocular phenotypes with the genes of knockout strains with concomitant abnormalities in renal function, renal morphology, reproductive tract function, and reproductive tract morphology. The resulting set of enriched genes were then analyzed for predicted protein-protein interactions with known cilia proteins resulting in a list of "candidate ciliopathy genes". We then assessed these genes for novel association with disease by systematic literature review. From this analysis, thirty-two ciliopathy candidates were predicted to interact with known ciliopathy genes, either directly or through a secondary intermediate protein.

Results: Seven of the 32 genes have been previously identified as ciliopathy genes in non-human vertebrates, and one of these has been shown to function in human cilia. Therefore, we identified 31 novel human ciliopathy genes and 25 novel vertebrate genes with predicted roles in ciliary pathobiology. Representative histological and morphological evidence of phenotypes consistent with ciliopathies are presented from several of these ciliopathy candidates; Abi2, Wdr62, Ap4e1, Dync1li1, and Prkab1.

Conclusions: Here we present targeted deletions of 32 candidate ciliopathy genes identified by phenotyping of knockout mice, predictive bioinformatic analysis, and systematic literature review. These putative ciliopathy genes may be responsible for human syndromes including childhood blindness. Furthermore, these knockout strains are available to serve as models to test novel pre-clinical preventative or therapeutic strategies.

ABSTRACT BODY:

Purpose: The growing need for cost-effective, accessible ophthalmic care has led to an interest in telemedicine. The capabilities of telemedicine for diagnosis and triage of emergent eye complaints warrants investigation. This study assesses the utility of a tele-ophthalmology program to diagnose and triage common ophthalmic complaints presenting to an ophthalmic emergency room.

Methods: Prospective, observational study of 258 eyes of 129 patients presenting to the Massachusetts Eye and Ear Infirmary Emergency Ward (MEE EW) completed a questionnaire to gather chief complaint, history of present illness, and medical history. Anterior segment photographs with and without fluorescein dye were collected via iPhone 5C camera and posterior segment photos by a Canon non-mydratic fundus camera. Ophthalmic vital signs were collected by MEE EW physicians. All information was reviewed remotely by three MEE physicians; a diagnosis and urgency designation was recorded. Remote findings were compared to in-person clinical findings, which were treated as the gold standard. Primary outcomes included sensitivity and specificity of triage status and diagnostic accuracy via virtual examination of patients with common ophthalmic complaints: eye pain, eye redness, blurry vision, eyelid complaint. The study was not powered for subgroup analysis.

Results: 129 patients were recruited, of which 69 (53.50%) were female with mean age 56 (range 23-96). Sensitivities and specificities for telemedical triage were as follows: eye pain (n=56; sens: 0.58, CI [0.41, 0.74]; spec: 0.91, CI [0.80, 1]), eye redness (n=54; 0.68, CI [0.50, 0.86]; 0.93, CI [0.84, 1]), blurry vision (n=68; 0.73, CI [0.60, 0.86]; 0.91, CI [0.80, 1]), and eyelid complaints (n=42; 0.67, CI [0.43, 0.91]; 0.96, CI [0.89, 1]). The remote diagnostic accuracies, as stratified by chief complaint, were eye pain (27/56; 48.21%), eye redness: (32/54; 59.26%), blurry vision: (30/68; 44.11%), eyelid (24/42; 57.14%).

Conclusions: Telemedical examination of emergent ophthalmic complaints consisting of a patient questionnaire, anterior segment and fundus photos, and ophthalmic vital signs, may be able to reliably triage eye disease based on presenting complaint. Further research is needed to evaluate the diagnostic accuracy of ophthalmic telemedicine for specific ophthalmic conditions in larger pilot studies of patients with emergent eye complaints.

ABSTRACT BODY:

Purpose: Data from the phase 2 BOULEVARD trial and preclinical models suggest that dual inhibition of the angiopoietin-2 and VEGF-A pathways with faricimab, the first bispecific antibody designed for intraocular use, may reduce inflammation and vascular leakage, promote vascular stability, and improve outcomes beyond anti-VEGF monotherapy for DME. The phase 3 YOSEMITE and RHINE trials were designed to compare the efficacy, durability, and safety of faricimab with aflibercept in patients with DME.

Methods: YOSEMITE (NCT03622580) and RHINE (NCT03622593) are identical, randomized, double-masked, active comparator-controlled, 100-week, phase 3 trials of faricimab in treatment-naïve and previously anti-VEGF-treated patients with center-involving DME. Patients were randomized 1:1:1 to faricimab 6.0 mg every 8 weeks (Q8W) after 6 initial Q4W doses; faricimab 6.0 mg per personalized treatment interval (PTI) after 4 initial Q4W doses; or aflibercept 2.0 mg Q8W after 5 initial Q4W doses. The PTI algorithm is a protocol-driven regimen based on the treat-and-extend concept, using prespecified BCVA and CST criteria to adjust treatment intervals at active dosing visits. Noninferiority, followed by superiority in treatment-naïve patients and then the overall population, was assessed separately for each

faricimab arm against aflibercept. The primary efficacy endpoint was mean change in BCVA from baseline averaged over weeks 48, 52, and 56. A key secondary endpoint was the proportion of patients with ≥ 2 -step ETDRS-DRSS improvement from baseline; other endpoints included the proportion of patients gaining ≥ 15 ETDRS letters from baseline, change in CST from baseline, and the proportion of patients in the PTI arm on Q4W, Q8W, Q12W, or Q16W dosing at 1 year. Safety was assessed by the incidence and severity of ocular and nonocular adverse events.

Results: In BOULEVARD, faricimab Q4W demonstrated superior vision gains and greater improvements in diabetic retinopathy severity at week 24, and showed potential for extended durability in a 16-week off-treatment observation period, when compared with ranibizumab Q4W. YOSEMITE and RHINE are ongoing trials, with year 1 results to be presented at the meeting.

Conclusions: YOSEMITE and RHINE evaluate the efficacy, durability, and safety of faricimab Q8W or per PTI, a protocol-driven regimen based on treat-and-extend, in patients with DME.

ABSTRACT BODY:

Purpose: Corneal neovascularization (CNV) is a major cause of blindness worldwide. Topical steroids are widely used to treat CNV, but the results are highly variable. Glucocorticoids act through binding to both glucocorticoid (GR) and mineralocorticoid receptors (MR). MR overactivation contributes to retinal and choroidal neovascularization, and endothelial MR invalidation reduces CNV in mice. We thus aimed to evaluate the pharmacological effects of MR antagonism in CNV.

Methods: CNV was induced in one eye of Lewis rats by a 360° circumference total corneal de-epithelialization and limbal scratching. Rats were injected subcutaneously with MR antagonist (MRA) spironolactone 25mg/kg/day or vehicle for 14 days. Corneal morphology and thickness were assessed in vivo at day 3, 7 and 14 using Micron III optical coherence tomography (OCT). Corneal re-epithelialization was evaluated by fluorescein staining under slit lamp at day 3 and 7. Fluorescein (FA) and indocyanine green angiographies (ICG) were performed at day 14 to evaluate the surface of CNV. Rats were sacrificed at day 16 and eyes removed for immunostaining of ED1, IBA1 and GSI-B4. Peripheral cornea and tissues adjacent to limbus were also dissected at day 3 and day 7 for quantitative PCR and transcriptomic analysis. A more specific MRA eplerenone (200mg/kg/day in chew for 14 days) was also used to confirm the effect of MR antagonism.

Results: Spironolactone significantly reduced the CNV and corneal thickness compared to vehicle. There is no difference in corneal re-epithelialization between spironolactone and vehicle. Spironolactone reduced infiltration of ED1 and IBA1 positive inflammatory cells and decreased the isolectin-positive neovascular surface in the cornea. The transcriptomic signatures showed 212 differentially expressed genes (26 up-regulated and 186 down-regulated) involved in corneal wound healing and differentiation, infectious responses, inflammatory and immune responses, myogenesis and hypoxia. The qPCR showed an up-regulation of GR in spironolactone treated group tilting the GR/MR balance in favor of GR pathway. Eplerenone confirmed the anti-angiogenic effect of MRA.

Conclusions: MRA is anti-angiogenic, anti-inflammatory, and anti-edematous in rat CNV. The potential additive effect of MRA and glucocorticoids on CNV will be further tested.

ABSTRACT BODY:

Purpose: To determine the risk factors for center-involving diabetic macular edema (ciDME) and increased central subfield thickness (CST) assessed by optical coherence tomography (OCT) in South Indian patients with type 2 diabetes (T2D).

Methods: For this cross-sectional analysis, patients with T2D were recruited prospectively at Sankara Nethralaya Main Hospital in Chennai, South India. Both eyes of each patient were imaged with color fundus photographs (Daytona Plus Panoramic Ophthalmoscope – P200T, Optos), which were graded for presence or absence of clinically significant macular edema (CSME), and structural OCT (Cirrus HD-OCT, Model 5000). Exclusion criteria included having significant ocular disease that prevented obtaining gradable images. Demographic and clinical data were recorded. Blood was drawn for lipid, hemoglobin A1c, and genetic testing, and a urine sample was taken to measure albuminuria. CSTs were recorded from OCT retinal thickness maps of both eyes, and only the eye with the higher CST for each patient was used for analyses. ciDME was defined as being present if CST was $\geq 290 \mu\text{m}$ in women and CST was $\geq 305 \mu\text{m}$ in men. Scans demonstrating other macular pathology that could influence CST such as epiretinal membrane were excluded. Multivariate analyses were done using stepwise logistic regression to assess the effect of covariates on ciDME and CST.

Results: Of participants with gradable OCT scans (N=483), 88 had ciDME and 395 had no ciDME. The concordance between OCT assessment of ciDME and fundus photograph assessment of CSME was 89.6%. In multivariate regression with imputation, participants with ciDME were more likely to be younger, men, have a longer duration of diabetes, lower triglycerides and have albuminuria ($p < 0.028$ for all comparisons). Examining CST as a continuous outcome in multivariate regression, it was found that a higher CST was associated with male sex ($p = 1.22 \times 10^{-5}$) and albuminuria ($p = 1.09 \times 10^{-3}$).

Conclusions: OCT analysis quantitates and refines risk factors for DME, and validates observations from previous studies that have assessed DME by fundus photography alone. By clearly assessing the demographic and clinical risk factors for DME, it will be possible to better identify genes associated with the disease through ongoing genetic analyses of the collected DNA samples from these patients.

ABSTRACT BODY:

Purpose: PRPF31-associated retinopathy (RP11, OMIM: #600138) is a common form of autosomal dominant retinitis pigmentosa (adRP). RP11 exhibits extreme variation in phenotype, ranging from non-penetrance to severe early-onset RP. Herein, we report four patterns of RP11 natural history in seven unrelated families in a prospective cohort study.

Methods: Patients underwent complete ophthalmic examination, 10-2 microperimetry (MAIA), spectral-domain optical coherence tomography and fundus autofluorescence imaging at baseline and every 6 months thereafter. Main outcome measures included age of onset of symptoms, best-corrected visual acuity (BCVA), microperimetry mean sensitivity (MS), residual ellipsoid (EZ) span and hyperautofluorescent ring (HAR) area. Genotyping was performed using targeted next-generation sequencing and Sanger sequencing.

Results: PRPF31 mutation was found in 14 members. The four patterns of disease phenotype are: (A) childhood onset with rapid progression (Figure 1A), (B) adult-onset with rapid progression (Figure 1B), (C) adult-onset with slow progression (Figure 1C) and, (D) non-penetrance (Figure 1D). Patients in group A (n=4) revealed no or barely detectable EZ with a BCVA of 20/50 or worse and MS less than 2 dB by age 50 years (n=2) or counting fingers by age 80 years (n=2). Patients in group B (n=4) presented with EZ span reduced to 4000 μ m by age 17 (n=1), 3000 μ m by age 29 (n=1) and 1500 μ m by early 60s (n=2). Group C (n=4) revealed either a mild asymptomatic phenotype (normal MS and large EZ and HAR) at age 18 (n=1) or residual EZ span greater than 3500 μ m and MS 8–19 dB by age 34–63 (n=3). Two unaffected patients were assigned to group D. Two families revealed combinations of phenotypes across and within generations. All detected mutations are predicted to lead to a loss of PRPF31 function.

Conclusions: Our findings suggest disease expression may be related to the level of wild-type PRPF31 allele expression rather than the type of the mutation. Further in vitro studies correlating wild-type PRPF31 allele expression level with clinical manifestation are necessary.

ABSTRACT BODY:

Purpose: There is a growing subset of age-related macular degeneration patients that do not successfully respond to a monthly monotherapy treatment of anti-vascular endothelial growth factor (VEGF). Recent studies suggest that this subset may respond to a combination therapy of corticosteroid and anti-VEGF. The current combination therapy is administered in separate injections where anti-VEGF injections are repeated monthly/bimonthly. Recently, we developed a single drug delivery system that can release dexamethasone (DEX) and aflibercept (AFL) simultaneously. This study was to determine the treatment efficacy of DEX and AFL released from a single drug delivery system (DDS) in a choroidal neovascularization (CNV) rodent model.

Methods: AFL and DEX were encapsulated into poly(lactic-co-glycolic acid) particles that were embedded into a single thermoresponsive hydrogel DDS. CNV lesions were created by laser photocoagulation (50um, 0.5W) in Long-Evans rats. Animals were randomly assigned into: control (no treatment), blank-DDS (5ul, no drugs), bolus AFL intravitreal (IVT) injections (5ul, 10ug, bimonthly), AFL-DDS (5ul, 1.5ug), AFL+DEX-DDS (5ul, 1.5ug, 20ug, respectively), and DEX-DDS (5ul, 20ug). At week 0 (14 days after the laser induction), treatment was administered. Fluorescein angiography (FA) was obtained at weeks 0, 2, 6, 10, 14, 18 and 22. Multi-Otsu Thresholding was used to quantify lesion area to determine treatment efficacy.

Results: Before the treatment, FA confirmed that CNV lesions were fully developed. At week 14, increases in lesion size were seen in control($10\pm 8\%$), while slight decreases were seen in blank-DDS($-1\pm 8\%$), bolus AFL injections($-3\pm 7\%$), and DEX-DDS($-5\pm 5\%$), and larger decreases were seen in AFL-DDS($-21\pm 5\%$), and AFL+DEX-DDS($-33\pm 5\%$). At week 22, decreases were seen in bolus AFL injections($-11\pm 7\%$), DEX-DDS($-12\pm 7\%$), AFL-DDS($-33\pm 4\%$), and AFL+DEX-DDS ($-30\pm 7\%$), and increases were seen in control($2\pm 8\%$) and blank DDS($4\pm 10\%$).

Conclusions: The combination treatment of AFL and DEX released from a single DDS delivered a lower amount of overall aflibercept compared to bolus injection, with improved treatment efficacy. [MOU1] The study suggests that a combination treatment may be a viable alternative for non-responsive patients.

ABSTRACT BODY:

Purpose: The PDS is an innovative, investigational, intraocular drug delivery system with the potential to reduce treatment burden in patients with retinovascular diseases. The PDS implant is a permanent, indwelling device designed to continuously deliver a customized formulation of ranibizumab. The PDS refill needle consists of a dual cannula system that allows for simultaneous exchange of implant contents with fresh drug. The characterization of ranibizumab release and refill-exchange efficiency of the PDS is reported here.

Methods: The ranibizumab release rate, active release rate, and retained ranibizumab within the implant over time were measured in vitro with various starting concentrations of ranibizumab. In the ongoing phase 3 Archway trial (NCT03677934) for neovascular AMD, PDS 100 mg/mL with fixed Q24W refill-exchanges was compared with intravitreal ranibizumab 0.5 mg Q4W.

Results: The PDS includes a surgically placed, permanent implant and ancillary devices for implant insertion, initial fill, and in-clinic refill-exchange procedures. The PDS implant was designed to be biocompatible; durable; transparent to facilitate visualization of ranibizumab within the implant; have a self-sealing, refillable septum; not interfere with the patient's field of vision; and be implanted in the superotemporal quadrant. In in vitro studies, ~73% of ranibizumab 100 mg/mL was released from the implant over 6 months after initial implant insertion and after ~450 days, levels were below the lower quantification limit. The average active release rate (SD) at 6 months was 3.95 (0.17), 3.99 (0.13), 3.85 (0.15), and 4.00 (0.17) µg/day at initial fill, first, second, and third refills, respectively, demonstrating reproducibility from implant to implant and between multiple refill-exchanges of the same implant. Changing initial ranibizumab concentration from 10 to 100 mg/mL increased starting drug release rates from ~2 to ~17 µg/day and rate of release. During a refill-exchange procedure, ~98% of the previous implant contents get replaced with fresh drug in one 100-µL injection stroke.

Conclusions: The PDS is an intraocular drug delivery system that continuously and reproducibly delivers ranibizumab over a period of months while maintaining potency. Archway phase 3 trial results support the efficacy of the PDS, as PDS 100 mg/mL Q24W had equivalent vision outcomes to ranibizumab Q4W averaged over weeks 36/40.

ABSTRACT BODY:

Purpose: Dual inhibition of angiopoietin-2 and vascular endothelial growth factor-A with faricimab, a bispecific antibody designed for intraocular use, may promote vascular stability with sustained efficacy through extended durability in patients with neovascular age-related macular degeneration (nAMD). Here we report primary 1-year results of the ongoing phase 3 TENAYA and LUCERNE trials, comparing efficacy, safety, and durability of faricimab with aflibercept in patients with nAMD.

Methods: TENAYA (NCT03823287) and LUCERNE (NCT03823300) are identical, phase 3, randomized, double-masked, active comparator-controlled, 112-week studies of faricimab in nAMD. Treatment-naïve patients were randomized 1:1 to receive faricimab 6.0 mg up to every 16 weeks (Q16W) or aflibercept 2.0 mg every 8 weeks (Q8W). Patients in the faricimab arm received 4 initial every-4-week (Q4W) doses and were assessed for protocol-defined disease activity at weeks 20 and 24. Patients with no evidence of active disease at weeks 20 and 24 received Q16W dosing through week 60; those with active disease at week 20 received Q8W dosing; patients with active disease only at week 24 received every-12-week (Q12W) dosing. From week 60, faricimab-treated patients follow a personalized

treatment interval based on a protocol-driven treat-and-extend regimen through week 108. Patients randomized to aflibercept received 3 initial Q4W doses and then Q8W dosing through week 108. Efficacy and safety outcomes were assessed at Q4W study visits. The primary efficacy endpoint is mean change in best-corrected visual acuity from baseline averaged over weeks 40, 44, and 48. Secondary endpoints include the proportion of patients on faricimab Q16W, Q12W, and Q8W regimens; proportion of patients gaining ≥ 15 or ≥ 10 ETDRS letters from baseline; and changes from baseline in anatomic outcomes. Safety outcomes include incidence and severity of ocular and nonocular adverse events.

Results: In phase 2 studies, faricimab at up to Q16W dosing intervals was associated with robust vision and anatomic improvements, comparable with ranibizumab Q4W. TENAYA and LUCERNE are ongoing global phase 3 trials; year 1 study results will be presented at the meeting.

Conclusions: TENAYA and LUCERNE phase 3 trials are evaluating efficacy, safety, and extended durability up to Q16W of intravitreal faricimab in patients with nAMD.

ABSTRACT BODY:

Purpose: Describe the origin and interim results of a phase 1b safety study, APL2-103, supporting two large phase 3 studies of intravitreal pegcetacoplan for geographic atrophy (GA) secondary to age-related macular degeneration (AMD).

Methods: In December 2018, the phase 3 DERBY and OAKS studies of intravitreal pegcetacoplan for GA were voluntarily paused due to transient intraocular inflammation (IOI, n=4) after dosing with a new formulation developed for phase 3 trials. An investigation to determine the exact cause was conducted. Quality review of the manufacturing process revealed an impurity in the active pharmaceutical ingredient introduced during scale up. Additional manufacturing steps to eliminate the impurity were implemented, and the resulting product was tested in several animal studies. APL2-103, a 24-month phase 1b, open-label, single-arm safety study of monthly pegcetacoplan was initiated in GA subjects with low vision (Snellen 20/200 to 20/800) before further dosing in phase 3 trials.

Results: All four patients with IOI in the phase 3 studies recovered fully (mean BCVA before: 47.5 letters [range 38-67] and after: 45.5 letters [29-68]). Phase 3 studies were re-initiated in March 2019 after a drug product lot without the impurity revealed no signs of investigator-assessed IOI in 10 subjects who completed a 7-day follow-up evaluation in APL2-103 across 4 clinical sites. APL2-103 continues supporting drug product lot evaluation before use in DERBY/OAKS. Safety findings in APL2-103 after phase 3 re-initiation were consistent with all previous and ongoing intravitreal pegcetacoplan programs. In APL2-103, one patient developed new-onset exudation, and no cases of IOI were observed with the phase 3 formulation. An exploratory interim efficacy analysis of APL2-103 in bilateral GA patients with 12 (n=9) and 18 (n=7) months of follow up revealed that the GA growth rate in pegcetacoplan-treated eyes was slower than untreated fellow eyes by 31% at month 12 and 52% at month 18.

Conclusions: The likely root cause of intraocular inflammation was identified and eliminated. These findings highlight the value of ensuring safety following manufacturing or formulation changes. APL2-103 continues to support the fully enrolled phase 3 studies, with an acceptable safety profile.

ABSTRACT BODY:

Purpose: The PDS is an investigational drug delivery system that includes a pars plana implant for continuous delivery of ranibizumab into the vitreous. Ranibizumab release from the implant is mediated by passive diffusion. In the ongoing phase 3 Archway trial (NCT03677934) in patients with neovascular age-related macular degeneration (N=415), serum and aqueous humor samples were collected to characterize the PK of ranibizumab administered via the PDS refilled Q24W.

Methods: In the PDS with ranibizumab 100 mg/mL Q24W and monthly intravitreal ranibizumab 0.5 mg injection arms, serum PK samples were scheduled to be collected at randomization and at weeks 4, 24, 36, and 96 from all patients. At selected sites, samples were taken at days 2 and 7 and at weeks 12, 48, and 72 in the PDS arm, and 1–5 days after an injection in the monthly ranibizumab arm. Optional aqueous humor samples were collected from patients in either arm at weeks 24, 28, 48, 52, 72, 76, and 96; serum samples were also collected at this time. The PK-evaluable population consisted of patients who did not receive ranibizumab injections in the study eye or fellow eye after implant insertion or prior intravitreal bevacizumab treatment. Ranibizumab concentrations were measured using a validated enzyme-linked immunosorbent assay with lower limits of quantification of 15 pg/mL for serum and 20,000 pg/mL for aqueous humor.

Results: Based on Archway primary analysis data, in the PDS arm (n=94), geometric mean (coefficient of variation) serum concentrations ranged from 419 (54%) pg/mL at week 4 to 340 (94%) pg/mL at week 24. In the monthly ranibizumab arm (n=79), geometric mean serum ranibizumab concentrations ranged from 1880 (57%) pg/mL near maximum concentration (1-5 days after injection) to 58.1 (171%) pg/mL at Week 4 (C_{trough}). The aqueous humor PK profile reflected the same trends seen in serum, with PDS 100 mg/mL Q24W (n=42) maintaining concentrations above monthly intravitreal ranibizumab C_{trough} (n=46).

Conclusions: The PDS continuously releases ranibizumab over the Q24W refill interval at steady concentrations. Ranibizumab concentrations with PDS 100 mg/mL Q24W are within the range experienced with monthly intravitreal ranibizumab 0.5 mg injections. Aqueous humor PK were consistent with serum PK.

ABSTRACT BODY:

Purpose: MYOC (myocilin) mutations account for 3-5% of primary open angle glaucoma (POAG) and 10-20% of early-onset glaucoma. We aimed to understand the true population-wide penetrance and characteristics of glaucoma among individuals with the most common MYOC variant (p.Gln368Ter) and the impact of a POAG polygenic risk score (PRS) in this population.

Methods: We used phenotype and genotype data from the UK Biobank and identified those with p.Gln368Ter variant. POAG PRS was computed based on a large POAG GWAS meta-analysis. Two masked graders reviewed fundus photographs (FPs) for disc-defined glaucoma (DDG).

Results: 200 of 73,563 participants with complete data carried the p.Gln368Ter heterozygous genotype and 177 had gradable FPs. 132 had no glaucoma, 45 (25.4%) had probable/definite glaucoma in 1+ eye and 19 (10.7%) had bilateral glaucoma. There were no differences in age, ethnicity, or gender among groups ($p > 0.05$ for all). Of those with DDG, 14 (31%) self-reported or had ICD 9/10 code for glaucoma while 31 (69%) were undiagnosed. Subjects with DDG had higher cornea corrected intraocular pressure (IOPcc) after adjustment for IOP lowering medications ($p < 0.001$) vs. those without DDG. This difference in IOPcc was more pronounced in individuals with DDG with prior glaucoma diagnosis vs. those undiagnosed ($p < 0.001$). The majority of participants with p.Gln368Ter mutation had IOP in the normal range (≤ 21 mmHg), though this proportion was lower in those with DDG ($p < 0.02$) and those with prior glaucoma diagnosis ($p < 0.03$) (Tab1). The prevalence of DDG increased with each decile of PRS. Subjects with DDG had significantly higher PRS compared to those without glaucoma (1.05 ± 0.60 vs. 0.83 ± 0.56 , $p = 0.03$). Of those with DDG, individuals with prior diagnosis of glaucoma had higher PRS compared to undiagnosed individuals (1.63 ± 0.40 vs 0.82 ± 0.50 , $p < 0.001$) and had 27.5 (95% CI 2.5-306.6) times adjusted odds of being in the top decile of PRS for POAG (Fig1).

Conclusions: Nearly 1 in 4 individuals with the p.Gln368Ter mutation had evidence of glaucoma, a substantially higher penetrance than previously estimated, with 70% of cases undetected. While IOP plays an important role, a large portion of carriers have IOP in the normal range, despite similar age, including those with DDG. PRS increases disease penetrance and severity of disease, supporting the utility of PRS in optimizing risk stratification among MYOC p.Gln368Ter variant carriers.

TITLE: Metabolism of primary human corneal endothelial cell (HCEnC) cultures grown at ambient and 2.5% oxygen

SESSION TITLE: Corneal endothelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C.F. Mueller, S.P. Patel, Ophthalmology, Jacobs School of Medicine and Biomedical Sciences, Buffalo, New York, UNITED STATES|S.P. Patel, Ophthalmology and Research Service, VA Western New York Healthcare System Buffalo VA Medical Center, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Christian Mueller: Commercial Relationship: Code N (No Commercial Relationship) | Sangita Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress is central to the pathophysiology of Fuchs endothelial corneal dystrophy. Typically, HCEnC cultures are grown in 5% CO₂, room air incubators ([O₂]_A). However, [O₂] in the anterior chamber is approximately 2.5% ([O₂]_{2.5}). The purpose of our study was to investigate in vitro metabolism of HCEnC grown at [O₂]_A and [O₂]_{2.5}. We hypothesized that cells grown at [O₂]_{2.5} would have greater glycolytic activity and decreased oxidative respiration compared to cells grown at [O₂]_A.

Methods: Protocols were approved by the Univ at Buffalo and VA WNY IRBs. Donor eyes (n=5 [O₂]_A and n=6 [O₂]_{2.5}, mean age 74) were obtained within 24 hrs of death for initiating HCEnC cultures. [O₂]_A cells were grown in a humidified, 5% CO₂, 37°C incubator. [O₂]_{2.5} was created in a humidified chamber (Billups-Rothenberg, Inc., Del Mar, CA) with 2.5% O₂, 5% CO₂, balance N₂ at 37°C. Mitochondrial respiration (O₂ consumption rate [OCR]) and glycolysis (extracellular acidification rate [ECAR]) were measured with the Seahorse XFe24 (Agilent Technologies, Inc., Santa Clara, CA). OCR and ECAR measurements were performed at baseline (B) and following additions of oligomycin (O), FCCP, rotenone/antimycin A (RA) and 2DG. We calculated basal respiration (B-RA for OCR and B-2DG for ECAR), ATP-linked respiration (B-O), proton leak (O-RA), max respiration (FCCP-RA), spare capacity (FCCP-B), non-mitochondrial O₂ consumption (RA), and glycolytic reserve capacity (O-B). Mean values were compared between [O₂]_A and [O₂]_{2.5} using unpaired two-tailed t-tests with significance at p<0.05.

Results: OCR analysis showed significant differences between [O₂]_A and [O₂]_{2.5} in proton leak, spare capacity, and non-mitochondrial O₂ consumption (Table). There were no significant differences between groups for basal respiration, ATP linked respiration, and max respiration. ECAR analysis showed significant differences between [O₂]_A and [O₂]_{2.5} in basal glycolysis and glycolytic reserve capacity.

Conclusions: Our results demonstrate that in HCEnC, glycolytic activity is greater but ATP-linked respiration the same at physiologic [O₂]_{2.5} compared to [O₂]_A. Increased proton leak and non-mitochondrial O₂ consumption at [O₂]_{2.5} compared [O₂]_A suggest alternative metabolic pathways are prominent under physiologic conditions. [O₂] is an important consideration in HCEnC metabolism and FECD pathophysiology.

ABSTRACT BODY:

Purpose: Autoimmune Retinopathy (AIR) is a rare disease with progressive retinal degeneration which does not have a gold standard to monitor disease activity. Adaptive optics (AO) technology is recently developed to depict a photoreceptor in retina. Our aim is to evaluate utility of an AO camera in comparison with microperimetry (MP) and spectral-domain optical coherence tomography (SD-OCT) in AIR.

Methods: Three eyes of 3 patients with a confirmed diagnosis of AIR by clinical and serologic findings were assessed. AO images (rtx1, Imagine Eyes, France) of the central 4°x 4°field (not including 0.5°x 0.5° field of fovea) , MP with 4-2 staircase threshold strategy (MAIA Centervue, Italy), and OCT (Spectralis Heidelberg, Germany) were analyzed after merging images using Adobe Photoshop CS6 (Adobe Systems, San Jose, CA). A correlation was investigated among photoreceptor parameters [cone density (CD), regularity, dispersion, and spacing] in AO images, retinal sensitivity (RS) in MP, and outer retinal thickness (ORT) on OCT which were obtained at two separate time-points. AO images from 2 visits were automatically registered and parameters of photoreceptors were calculated with manual method (AO detect 3.0, Imagine Eyes), which had an excellent intraclass correlation coefficient (>0.90) in the prior study.

Results: A total of 22 regions of interest on AO, MP, and OCT images in 1 female (65 yo) and 2 males (14 yo and 56 yo) were assessed. At baseline, mean value of RS and ORT was 18.4±11.4dB and 96.2±49.9µm, respectively. Mean values of AO parameters were 1481±409/deg² (CD), 86.7±5.7% (regularity), 17.6±3.7% (dispersion), and 1.76±0.27 arcminute (spacing). Highest correlation of both RS and ORT were with CD (p=0.78, P<0.0001 and p=0.81, P<0.0001, respectively), followed by spacing (p=-0.75, P=0.0001 and p=-0.79, P<0.0001, respectively). Mean changes of CD, RS, and ORT between two time-points (range of interval: 2-5 months) were -0.9±5.1 dB, -92±157 /deg², and 15.5±26.3 µm, respectively. The correlation of changes in CD with RS, and ORT were 0.40 (P = 0.063) and 0.57 (P = 0.006), respectively.

Conclusions: Cone density appeared to have a significant correlation with retinal sensitivity (as measured by MP) and retinal structure (as measured by OCT). Therefore, measuring the cone density using manual method in AO images may be useful to assess retinal function in AIR patients.

ABSTRACT BODY:

Purpose:

Diabetic Retinopathy (DR) is a leading cause of visual impairment in working age adults. Loss of retinal ganglion cells (RGCs) –the output neurons of the neural retina lining the back of the eye – contributes to visual impairment in this disease. Vascular changes occur with diabetes and these contribute to RGC death (Feit-Leichman et al., IOVS, 2005; Kern and Barber, The Journal of Physiology, 2008). However, little is known about the sequence of morphological and connectivity alterations in RGCs preceding their loss. Knowledge of these alterations would reveal the early impact of diabetes on RGC structure and connectivity. There are four well characterized ‘alpha’ RGC types in the mammalian murine retina with stereotypic lamination and functional profiles: ON-Sustained (ON-SUS), ON-Transient (ON-T), OFF-Transient (OFF-T), and OFF-Sustained (OFF-SUS) RGCs (Krieger et al., PLoS one, 2017). Using a mouse model of diabetes, we aimed to investigate the early effects of diabetes on the morphology and synaptic connectivity of these four RGC types.

Methods:

Male Ins2^{Akita/+} mice (Jackson labs) and littermate controls were collected at a 6-week timepoint: 2 weeks after initiation of hyperglycemia in this strain. Alpha RGCs were biolistically labeled with tdTomato as a cell-fill and fluorescently conjugated PSD-95 as a marker for excitatory synapses (Morgan et al., Neural Development, 2008). RGCs were imaged using a Leica SP8 confocal microscope and image stacks were visualized in Amira (Thermo Fisher Scientific). RGC types were determined by lamination of RGC dendrites in the retinal synaptic layer. Dendritic branching was analyzed by Sholl analyses (Fiji/Image J, NIH). PSD-95 density and asymmetric index were calculated by custom-written Matlab codes. Immunohistochemistry for RGC markers was performed at the 8-week timepoint to determine the density of RGCs across genotypes.

Results:

Average asymmetric index of RGC types was not different between genotypes. At the 8-week timepoint, RGC cell density was not affected across genotypes. RGC branching pattern and synaptic density was selectively altered in retinas from diabetic mice in a subtype-specific manner.

Conclusions:

The morphology and connectivity of RGCs is altered in a subtype-specific manner, within a short duration of diabetes before the onset of RGC loss.

ABSTRACT BODY:

Purpose: Most claims-based studies analyzing factors related to diabetic eye screening adherence have used single-payor databases, such as Medicare or managed care networks, and have focused on patient-level factors. In this study, we used a unique, all-payor database covering over 75% of Wisconsin residents (Wisconsin All-Payer Claims Database) to assess variability in screening rates across health systems and to identify health-system factors associated with screening.

Methods: We included adults with diabetes (18-75 years old) who had claims billed throughout the baseline (10/1/2012 - 9/30/2013) and measurement years (10/1/2013 – 9/30/2014). We excluded patients cared for by a primary care provider with fewer than 20 patients in our dataset. We performed chi-square tests and used multivariate logistic regression models to assess potential predictors of diabetic eye screening based on health system factors, patient demographics, comorbidities, and adherence with hemoglobin A1c and LDL screening guidelines.

Results: A total of 119,347 adults with diabetes from 143 Wisconsin health systems and 2,178 primary care providers met our inclusion criteria. Screening rates varied widely between health systems (31.8%-73.0%), with smaller health systems having lower screening rates. A patient's health system had substantial predictive power regarding whether a patient received diabetic eye screening (chi-square 1840.4, $p < 0.001$). In the multivariate analysis, when we excluded health system to focus on patient-level factors, patients from health systems based in small rural towns were more likely to obtain eye screening compared to patients from urban health systems (OR 1.13, 95% CI 1.08, 1.18, respectively). However, the directionality of the association reversed when health system was included in the model, with patients from health systems based in small rural towns being less likely to obtain eye screening compared to patients from urban health systems (OR 0.90, 95% CI 0.84, 0.95, respectively).

Conclusions: In this state-wide, all-payor claims database, we found significant variability in diabetic eye screening rates across health systems. Health system was a major predictor of screening adherence, with a lower likelihood of screening among patients from smaller and rural health systems. Interventions directed at the health system may be important for increasing diabetic eye screening rates.

ABSTRACT BODY:

Purpose: Single cell (sc) analyses of key embryonic, fetal and adult stages were performed in order to generate the first comprehensive single cell atlas of all the corneal and adjacent conjunctival cell types from development to adulthood.

Methods: Four human adult and seventeen embryonic and fetal corneas from 10-21 post conception week (PCW) specimens were dissociated to single cells and subjected to scRNA- and/or ATAC-Seq using the 10x Genomics platform.

Results: scRNA-Seq analysis of 21,343 cells from four adult human corneas and adjacent conjunctivas revealed the presence of 21 cell clusters, representing the stem, progenitor and differentiated cells in all layers of cornea and conjunctiva as well as immune cells, melanocytes, fibroblasts and blood/lymphatic vessels. A small cell cluster with high expression of limbal stem cells (LSCs) markers was identified and shown via pseudotime analysis to give rise to five other cell types representing the progenitor and differentiated corneal epithelial cells. A novel putative LSCs surface marker, GPHA2, expressed in $0.41\% \pm 0.21$ of the cultured limbal epithelial cells, was identified, based on predominant expression in the limbal crypts of adult and developing cornea and RNAi validation in cultured LECs. Combining scRNA- and ATAC-Seq analyses, we identified multiple upstream regulators for LSCs and transit amplifying (TA) cells and demonstrated a close interaction between the immune cells and corneal epithelial stem and progenitor cells. RNA-Seq analysis indicated the loss of LSCs markers and acquisition of proliferative limbal basal epithelial progenitor markers during ex vivo limbal epithelial cell expansion, independently of the culture method used. Single cell RNA-Seq of 89,897 cells obtained from embryonic and fetal cornea indicated that during development, the conjunctival epithelium is the first to be specified from the ocular surface epithelium, followed by the corneal epithelium and the establishment of LSCs/progenitor cells.

Conclusions: Our scRNA- and ATAC-Seq data of developing and adult cornea in steady state and disease conditions provide a unique resource for defining genes/pathways that can lead to improvement in ex vivo LSCs expansion, stem cell differentiation methods and better understanding and treatment of ocular surface disorders.

TITLE: Assessing Repeatability of Deep-Learning Based Estimation of Visual Function Test Parameters from OCT Volumes

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.J. Antony, R. Garnavi, IBM Research Australia, Southbank, Victoria, AUSTRALIA|H. Ishikawa, G. Wollstein, J.S. Schuman, Department of Ophthalmology, NYU Langone Health, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bhavna Antony: Commercial Relationship(s);IBM Research:Code E (Employment) | Hiroshi Ishikawa: Commercial Relationship: Code N (No Commercial Relationship) | Gadi Wollstein: Commercial Relationship: Code N (No Commercial Relationship) | Joel Schuman: Commercial Relationship(s);Zeiss:Code P (Patent) | Rahil Garnavi: Commercial Relationship(s);IBM Research:Code E (Employment)

ABSTRACT BODY:

Purpose: To assess the repeatability of estimates of mean deviation (MD) and visual field index (VFI) obtained from an automated deep-learning approach that analysed raw OCT volumes.

Methods: OCT scans were acquired from both eyes of 138 healthy, 743 glaucoma suspects and 941 glaucoma patients (Cirrus HD-OCT scanner, 200x200 ONH Cubes, Zeiss, Dublin CA). The scans were acquired at multiple visits, with two or more scans acquired at each visit. Scans with signal strength < 7 were discarded, giving us a total of 19,208 OCT scans. A subset of 5207 eyes (total of 10,414 scans) had repeat scans of that met the inclusion criteria. 24-2 Humphrey visual field (VF) tests were administered at each visit. A single convolutional neural network was trained to estimate the MD and VFI (dual outputs) from downsampled OCT volumes (50x50x128 voxels). The network consisted of 5 convolutional layers, followed by a global average pooling layer and dual outputs to enable the simultaneous estimation of MD and VFI. A mean squared error loss was used to train the network using an Adam optimiser over a total of 200 epochs. A 10-fold cross-validation scheme was used, where the dataset was divided into 10 non-overlapping folds (~182 subjects per fold) – trained on 8-folds, validated on one and tested on one. Each subject was limited to a unique fold. The performance of the method was assessed by computing the median error and interquartile range. The repeatability was assessed using a set of 5207 OCT scans that had repeats available.

Results: The median absolute error (Q1, Q3) for the estimates of MD and VFI were 1.66 (0.79, 2.99) dB and 3.01 (1.48, 6.63) %, respectively. In the reproducibility test, the Pearson's correlation coefficient was 0.91 (CI: [0.91, 0.92]) and 0.91 (CI: [0.90, 0.92]), for MD and VFI, respectively. The median absolute difference between the repeated estimates for MD and VFI were 0.53 (0.21, 0.51) dB and 1.17 (0.45, 1.14)%, respectively.

Conclusions: The deep-learning based approach for estimating visual field test parameters shows repeatability better than expected test-to-test variability.

ABSTRACT BODY:

Purpose: The BLINK Study was a 3-year randomized clinical trial that found +2.50 D add center-distance multifocal soft contact lenses (MFCLs) slowed myopia progression versus +1.50 D add MFCLs and single vision contact lenses (SVCLs). In this analysis, we explore the relationship between peripheral defocus and axial growth.

Methods: 294 myopic children 7-11 years old (60% female) were enrolled (mean \pm SD age = 10.3 \pm 1.2 years). Children had myopia of -0.75 D to -5.00 D (most hyperopic meridian) and <1.00 D astigmatism at enrollment (mean \pm SD spherical equivalent (M) = -2.39 \pm 1.00 D). Children were randomly assigned to one of three lenses: SVCL, +1.50 add MFCL, or +2.50 add MFCL. Autorefraction (horizontal meridian; right eye) was measured while wearing CLs centrally (line of sight) and $\pm 20^\circ$, $\pm 30^\circ$, and $\pm 40^\circ$ from the line of sight while viewing a near target (30cm) and also at distance after cycloplegia. Each child's defocus (M) profile at distance and near were fit using quadratic equations. Models of the first-year change in axial length (measured by optical biometry) were fit including the quadratic coefficient (Qc) for defocus at distance or near, central M, gender, study site, and age.

Results: After 1 year, mean axial growth was on average 0.13mm less in the +2.50 add group ($p < .001$) and 0.03mm less in the +1.50 add group ($p = .11$) versus SVCLs. Compared to SVCLs, peripheral defocus at distance was more myopic (less positive Qc) with MFCLs (Figure 1). At the 1-year visit, the average Qc in the +2.50 versus the SVCL group was .0005 D/degree² less at distance and .0004 D/degree² less at near. More myopic peripheral defocus at distance and at near in the +2.50 group was associated with less axial growth (distance: $\beta = .31$, or .016mm less axial growth, $p = .005$; near: $\beta = .49$, or .020mm less axial growth, $p < .001$).

Conclusions: More myopic peripheral defocus at distance and near in children wearing +2.50 add MFCLs compared to SVCLs was associated with less axial growth in the BLINK Study, but not by a clinically meaningful amount. The small association suggests that a linear dose-response to peripheral defocus may not fully explain the effects of MFCLs on axial growth. Exceeding a threshold amount of peripheral myopic defocus or mechanisms other than peripheral defocus may cause the significant slowing of axial growth seen with MFCLs.

ABSTRACT BODY:

Purpose: Intravitreal (IVT) injection of DL-alpha-aminoadipic acid (DL-AAA) is a new animal model for persistent retinal neovascularization (RNV) reported in rabbits. This study performs longitudinal multimodal imaging for up to 52 weeks to evaluate DL-AAA RNV in both New Zealand white (NZW) rabbits and Dutch-Belted pigmented (DBP) rabbits.

Methods: Detailed characterization and quantification of this model were performed in these two strains in 32 eyes by optical coherence tomography (OCT), fundus photography, and fluorescein angiography (FA) for up to 16 weeks following DL-AAA administration in 32 eyes and up to 52 weeks in 5 eyes. H & E histology was also performed 8 weeks after injection of DL-AAA.

Results: RNV was successfully generated using 50 µL 80mM DL-AAA solution for DBP rabbits and 80 µL 80mM DL-AAA for NZW rabbits. The incidence of persistent vascular leakage is 100% (15/15) for DBP rabbits and 70.6% (12/17) for NZW rabbits at 16 weeks. Complications with NZW rabbits ultimately decreased the efficiency in NZW rabbits to 58.8% (10/17) of NZW rabbits getting persistent (to 16 weeks) vascular leakage without ocular complications as compared with 100% (15/15) in DBP rabbits. Five eyes (2 DBP and 3 NZW) were selected from those demonstrating RNV at 16 weeks and were monitored for up to 52 weeks. All 5 demonstrated persistent RNV to 52 weeks. Quantification of the mean leakage area (MLA) in NZW rabbits is more challenging than in DBP rabbits due to reduced contrast between the leakage and background in NZW rabbits.

Conclusions: DL-AAA can induce persistent and quantifiable RNV in both DBP and NZW rabbits. DBP rabbits have a higher success rate, lower required volume of DL-AAA, and less challenging method for quantification that could be more desirable.

ABSTRACT BODY:

Purpose: Known AMD risks include demographic variables such as age, sex, and race, but the impact of environmental exposures is currently unclear. We investigate associations of environmental exposures with nvAMD development across the US.

Methods: All patients ≥ 55 years in the IRIS Registry during 2016-2018 (period of interest [POI]) were analyzed. Patients undergoing treatment for nvAMD were identified by nvAMD ICD code and CPT code for anti-VEGF intravitreal injections. Patients without provider-level zip codes matching any zip code tabular area were excluded. Environmental data was obtained from public sources including the US Geological Survey, National Renewable Energy Laboratory, and National Oceanic and Atmospheric Administration. Patients were assigned environmental variables from measurements nearest their zip code. Variable selection was done using elastic-net regularization. Multivariable logistic regression quantified the association of each environmental variable with nvAMD while adjusting for age, sex, race, and phakic status.

Results: A total of 18,166,512 patients were included. All demographic variables, phakic status, elevation, latitude, solar irradiance measured in global horizontal irradiance (GHI) and direct normal irradiance (DNI), and temperature and precipitation variables were included in our model after regularization. After adjusting for demographic factors and phakic status, the strongest environmental associations were DNI (OR: 0.550, 95%CI: [0.524, 0.578]), GHI (3.874, [3.452, 4.348]), and latitude (1.099, [1.092, 1.106]), while elevation had minimal association (1.000, [1.000, 1.000]) (Figure 1). The risk of nvAMD for a 75-year-old, pseudophakic, Caucasian female was calculated for the US (Figure 2).

Conclusions: Strongest associations for environmental factors were seen for DNI, GHI, and latitude. Further studies are warranted to investigate the clinical relevance of these associations.

TITLE: Ethnicity/race and end-stage renal disease, but not glycemic control, are significantly associated with proliferative diabetic retinopathy

SESSION TITLE: Diabetic retinopathy - risk factors and outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R.N. Mankad, L.A. Marek, G. Acosta, A. Cabrera, F. Monickaraj, A. Das, Ophthalmology, University of New Mexico School of Medicine, Albuquerque, New Mexico, UNITED STATES|F. Monickaraj, A. Das, Surgery, New Mexico VA Health Care System, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rushi Mankad: Commercial Relationship: Code N (No Commercial Relationship) | Lauren Marek: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Acosta: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Cabrera: Commercial Relationship: Code N (No Commercial Relationship) | Finny Monickaraj: Commercial Relationship: Code N (No Commercial Relationship) | Arup Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The development of sight-threatening complications of diabetes, namely proliferative diabetic retinopathy (PDR), is understood to be a consequence of several modifiable and non-modifiable factors. We performed a cross-sectional, observational study to identify these factors that are significantly associated with the development of PDR.

Methods: Data was collected from two patient cohorts with type 1 or type 2 diabetes seen between February 1, 2018 and February 1, 2020: a group of 293 patients with confirmed PDR and a control group of 69 patients with confirmed mild nonproliferative diabetic retinopathy (NPDR). Patients in the PDR group were identified by ICD-10 codes and confirmed with a history of panretinal photocoagulation and/or pars plana vitrectomy for vitreous hemorrhage. Data was obtained by an extensive chart review of several systemic parameters. Statistical analysis was done via two-sample t-test for continuous variables and Chi-squared test or Fisher exact test for categorical variables.

Results: Our analysis revealed that the development of PDR was significantly associated with exogenous insulin use ($p<0.001$), elevated systolic BP ($p=0.004$), presence of macroalbuminuria ($p<0.001$), history of dialysis ($p=0.002$), and decreased GFR ($p=0.024$). In our cohort, the prevalence of PDR was higher in both Hispanics and American Indians than for Whites/Anglos. There was a lack of association between HbA_{1c} levels and PDR ($p=0.784$). The majority of PDR patients (56.8%) had good glycemic control (HbA_{1c} $<7.5\%$); similarly, the majority of mild NPDR patients (58%) had poor glycemic control (HbA_{1c} $\geq 7.5\%$). No association was found with total cholesterol ($p=0.713$), LDL ($p=0.355$), HDL ($p=0.440$), and triglyceride ($p=0.412$) levels.

Conclusions: The data suggests that glycemic control is unrelated to the development of PDR, as the majority of our PDR cohort had good glycemic control. The highest incidence of PDR was seen among American Indians and Hispanics. There is a strong association between end-stage renal disease (ESRD) and PDR. Our findings indicate that "other factors," such as genomics, may play a stronger role in development of PDR.

Lo, Science, Edith Cowan University, Joondalup, Western Australia, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Rachael Heath Jeffery: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Thompson: Commercial Relationship: Code N (No Commercial Relationship) | Johnny Lo: Commercial Relationship: Code N (No Commercial Relationship) | Tina Lamey: Commercial Relationship: Code N (No Commercial Relationship) | Terri McLaren: Commercial Relationship: Code N (No Commercial Relationship) | Ian McAllister: Commercial Relationship: Code N (No Commercial Relationship) | David Mackey: Commercial Relationship: Code N (No Commercial Relationship) | Ian Constable: Commercial Relationship: Code N (No Commercial Relationship) | John De Roach: Commercial Relationship: Code N (No Commercial Relationship) | Fred Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate atrophy expansion rate (ER) using ultra-widfield fundus autofluorescence (UWF-FAF) in ABCA4 associated retinopathy.

Methods: Patients with biallelic ABCA4 mutations were evaluated with UWF-FAF and Heidelberg 30°×30° and 55°×55° FAF imaging. Those with atrophy secondary to STGD1 were classified into genotype groups: A (biallelic severe or null-like variants with early-onset disease), B (one intermediate variant in trans with severe or null-like variant) or C (one mild variant in trans with severe or null-like variant, or late-onset disease). The boundaries of definitely decreased autofluorescence (DDAF) were outlined manually and areas (mm²) recorded at baseline and follow-up. Bland-Altman analysis was conducted to examine agreement between observers and devices. Linear mixed modelling (LMM) was used to evaluate predictors of ER in DDAF area and square root area (SRA).

Results: Recruitment of 69 patients, 138 eyes (33 male [47%]; mean±SD age 41±20 years; range 10-83) carrying 61 unique ABCA4 variants. UWF-FAF measurements were equivalent to Heidelberg 30°×30° imaging. Baseline DDAF area was the only significant predictor of DDAF area ER (p<0.001). Age at baseline and genotype group were predictors for DDAF SRA ER. Mean DDAF area ERs were 4.65, 2.00 and 0.62mm²/year for Groups A, B and C. Mean DDAF SRA ERs were 0.25, 0.25, 0.18 mm/year.

Conclusions: UWF-FAF is a feasible and reliable modality for assessing atrophy ER in STGD1. A key novel finding in this study is the effect of genotype on DDAF SRA ER whereby the mean ER for genotype C was significantly lower than both genotypes A and B. The value of ABCA4 mutation severity in predicting atrophy ER warrants further investigation.

ABSTRACT BODY:

Purpose: The purpose of this study was to analyze the morphological features of white spots in the peripheral fundus of patients with Sarcoidosis and Vogt-Koyanagi-Harada disease (VKH), which are classified as granulomatous uveitis.

Methods: Sarcoidosis and VKH patients in Kyushu University Hospital, who had white spots in the periphery of the fundus, were enrolled in the study. Images of the white spots were obtained using Optos® Silverstone, ultra-widefield guided swept source optical coherence tomography (OCT).

We compared the morphological characteristics of those white spots between the two diseases.

Results: OCT Images of white spots were obtained from 13 patients with Sarcoidosis and 9 patients with VKH. Atrophic lesions were observed in 10 cases of Sarcoidosis and 9 cases of VKH, all of which had retinal pigment epithelial (RPE) defects with no morphological differences between diseases. In both diseases, subretinal elevated lesions were seen in some cases (Sarcoidosis; 5 cases, VKH; 3 cases). Those lesions were Dalen-Fuchs nodule-like elevated lesions with RPE perforation or Sarcoid nodule-like lesions under the RPE without RPE perforation. In contrast, hyperreflective lesions in the retina were found only in Sarcoidosis (7 cases), but not in VKH.

Conclusions: The site of the white spots in the peripheral fundus varied, suggesting that each disease have a different morphological pattern.

TITLE:

Attitudes toward glaucoma genetic risk assessment among affected individuals

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Hollitt, J.E. Craig, E. Souzeau, O. Siggs, Ophthalmology, Flinders University, Adelaide, South Australia, AUSTRALIA]

Commercial Relationships Disclosure (Abstract): Georgie Hollitt: Commercial Relationship: Code N (No Commercial Relationship) | Jamie Craig: Commercial Relationship: Code N (No Commercial Relationship) | Emmanuelle Souzeau: Commercial Relationship: Code N (No Commercial Relationship) | Owen Siggs: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Despite the significant progress made in genetic risk prediction, critical gaps in knowledge pertinent to understanding barriers to the implementation of polygenic risk scores (PRS) testing persist. We performed a cross-sectional, questionnaire-based study to better understand the attitudes of individuals with glaucoma toward PRS testing for glaucoma. As the leading cause of irreversible vision loss in the world, with recognised complex heritability, few environmental risk factors, and high treatability to prevent blindness, PRS testing has strong clinical utility for glaucoma.

Methods: We surveyed 1169 individuals with glaucoma to evaluate their attitude toward polygenic risk testing for glaucoma, drawn from the Australian and New Zealand Registry of Advanced Glaucoma (ANZRAG); one of the largest databases of clinical and genetic data for primary glaucoma in the world. We assessed several factors affecting interest in testing using multivariate regression analysis.

Results: Our results show strong interest towards testing with 68.3% of individuals being likely or highly likely to have taken the test. In particular, those from an urban area (OR 1.526, CI 1.118 – 2.084, p 0.008) or with non-advanced disease (OR 1.383, CI 1.043 – 1.833, p 0.024) showed increased interest. Increased pre-diagnosis perception of risk (OR 2.007 CI 1.245 – 3.234, p 0.004) and worry of developing glaucoma (OR 2.109, CI 1.296 – 3.432, p 0.003) were associated with increased interest in testing. Those who were interested in testing indicated being more likely to change their eye health behaviour (OR 1.532, CI 1.112 – 2.110, p 0.009), recommend testing to family (OR 12.831, CI 6.334 – 25.993, p <0.001) and non-family members (OR 3.670, CI 2.660 – 5.064, p <0.001), as well as undergo testing for prognostication (OR 4.967, CI 2.467 – 10.001, p <0.001).

Conclusions:

In summary, individuals with glaucoma showed a positive attitude toward polygenic risk testing for glaucoma. These findings support the clinical implementation of polygenic risk scores for glaucoma to reduce irreversible vision loss. Further research should be performed to better understand attitudes of those who do not have glaucoma, and the attitudes and knowledge of clinicians toward PRS testing.

TITLE: Evaluation of the effect of preloaded injector tip shapes on insertion resistance of the cornea and postoperative incision sizes in cataract surgery.

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Sobajima, T. Hishida, S. Nagasaka, Y. Soda, Kabushiki Kaisha Nidek, Gamagori, Aichi, JAPAN|

Commercial Relationships Disclosure (Abstract): Tatsuya Sobajima: Commercial Relationship: Code N (No Commercial Relationship) | Takahiro Hishida: Commercial Relationship: Code N (No Commercial Relationship) | Shinji Nagasaka: Commercial Relationship: Code N (No Commercial Relationship) | Yasushi Soda: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Preloaded IOL injectors are commonplace in cataract surgery. A variety of preloaded IOL injectors have been developed with differing designs and varying clinical outcomes. Additionally, there are subtle differences in the recommended incision and the actual clinical reports. Hence, to clarify the effect of different injector tip shapes on the incision, a laboratory set up was used to determine the relationship between the insertion resistance and tip shape, and an ex-vivo study of porcine eyes was performed to determine the postoperative incision width.

Methods: The following injectors were investigated: XY-1 (HOYA), AU00T0 (Alcon), YP2.2R (KOWA), SZ-1 (NIDEK), and NSP-1 (NIDEK).

Bevel angle, slit length, tip angle, and outer circumference length of the injector tips were measured with a shape measuring device. A slit knife was used to create a 2.0 ± 0.08 mm incision in a 0.4 mm silicone rubber sheet that mimicked corneal properties. Subsequently, the tip was inserted at 2 mm/sec with a testing machine to measure the maximum insertion resistance values for each injector. Preloaded IOLs with the same power were inserted from each of the injectors into a 2.0 mm corneal incision in porcine eyes. The post-insertion incision widths were measured with intraocular calipers.

Results: The range of values for tip shapes were:

Bevel angle: 27° (SZ-1) to 48.7° (YP2.2R)

Slit length: 3.3 mm (XY-1 and YP2.2R) to 4.3 mm (NSP-1)

Tip angle: 64.1° (NSP-1) to 96.6° (AU00T0)

Outer circumference length: 5.21 mm (XY-1) to 6.09 mm (SZ-1)

The range for maximum insertion resistance was 0.155 ± 0.018 N (SZ-1) to 0.248 ± 0.022 N (YP2.2R)

Incision width on porcine eyes ranged from 2.30 ± 0.10 mm (XY-1) to 2.50 ± 0.00 mm (SZ-1).

There was no correlation between the postoperative incision width and the maximum resistance to insertion ($r=0.030$).

The circumference length had the highest correlation coefficient with respect to the postoperative incision width and tip shape ($r=0.962$).

Conclusions: The outcomes of this study indicate that shorter outer circumference can mitigate enlargement of incision width. A “sharp bevel angle” and “long slit length” of the injector tip are the main determinants for preventing enlargement. A “sharp bevel angle” is more conducive to overcoming insertion resistance of the cornea.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is one of the major causes of blindness in the developed world. Early detection is crucial to reduce the risk of blindness in DR. Considering this, we have developed an artificial intelligence-based method to reliably detect DR using retinal imaging and traditional risk factors.

Methods: A deep convolutional neural network (CNN) was explicitly trained on the EyePACS dataset [<https://www.kaggle.com/c/diabetic-retinopathy-detection/data>] to perform 'disease', 'no-disease' grading of DR using color fundus photographs. A second, longitudinal dataset of retinal images and clinical data of 2~6 visits of 326 LANDMark study participants was utilised to identify the traditional risk factors most strongly associated with DR development and progression - age, HbA1c, systolic blood pressure, weight, body mass index, and waist circumference.

A support vector machine (SVM) classifier was independently trained to classify 'disease' versus 'no-disease' relying upon these traditional risk factors. In different to native SVMs that do not output probabilities, Platt scaling, a probability calibration method, was used in this work to obtain a "probability" out of an SVM.

The probabilities returned by the CNN and SVM were finally combined to detect DR.

We randomly divided the LANDMark dataset into a training set (90%) and testing set (10%). Since the dataset contained longitudinal data of multiple visits, in order to avoid reverse pair-wise bias or type-I error, we made sure same participant data were not split into training and test set.

Results: The SVM achieved an accuracy of 94% in detecting DR relying upon traditional risk factors. The CNN achieved an accuracy of 92% in detecting DR using color fundus photographs. When combined, an achieved an accuracy of 96%, with sensitivity, specificity and AUC respectively of 96%, 95% and 96% was observed.

Conclusions: A novel approach for the automated grading of DR is proposed. In comparison to state-of-the-art AI-based methods that solely use images to perform DR grading, the proposed method combines the risk factors-based assessment with the image-based assessment, providing an overall improved accuracy, sensitivity and AUC. The proposed method is found to be 4% more accurate and 2% more sensitive (without compromising specificity) than the solely image-based approach.

ABSTRACT BODY:

Purpose: Ocular and periocular traumatism may result in loss of vision. Our previous work showed that hypothermia prevents retinal damage caused by traumatic neuropathy. We generated and characterized small molecules that elicit the beneficial effects of hypothermia at normal body temperature. Here we investigate whether one of these mimetic molecules, zr17-2, is able to preserve the function of retinas exposed to trauma.

Methods: Intraorbital optic nerve crush (IONC) or sham manipulation was applied to Sprague-Dawley rats. One hour after surgery, 5 μ l of 330 nmols/L zr17-2 or PBS, as vehicle, were injected in the vitreum of treated animals. Electroretinograms were performed 30 days after surgery and a-, b-wave amplitude and oscillatory potentials (OP), were calculated. Animals for TUNEL analysis were sacrificed 6 days after surgery. Western blotting was performed for cold inducible RNA-binding protein (CIRP), the target of zr17-2.

Results: Previous studies showed that zr17-2 does not cross the blood-ocular barrier, thus preventing systemic treatment. Here we show that intravitreal injection of zr17-2 results in a very significant increase in CIRP protein expression in the eye, providing mechanistic support for its pharmacological use in ocular conditions. The amplitude of a- and b-waves, as well as the OP, was significantly reduced in IONC-affected retinas ($p < 0.05$). These parameters were significantly corrected by injection of zr17-2 ($p < 0.05$) (Fig. 1). IONC resulted in a very significant increase of TUNEL-positive cells in the ganglion cell layer ($p < 0.001$) whereas injection of zr17-2 significantly reduced the number of apoptotic cells ($p < 0.001$) (Fig. 2).

Conclusions: We have shown that intravitreal injection of the hypothermia mimetic, zr17-2, increases CIRP protein expression and, as a result, significantly reduces the morphological and electrophysiological consequences of ocular traumatism and may represent a new treatment for this cause of visual loss.

Cushley, K. Curran, T. Peto, Centre for Public Health, Queen's University Belfast, Belfast, Belfast, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Laura Cushley: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Bell: Commercial Relationship: Code N (No Commercial Relationship) | Katie Curran: Commercial Relationship: Code N (No Commercial Relationship) | Giuliana Silvestri: Commercial Relationship: Code N (No Commercial Relationship) | Una Graham: Commercial Relationship: Code N (No Commercial Relationship) | David McCance: Commercial Relationship: Code N (No Commercial Relationship) | Tunde Peto: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the barriers and enablers of attendance at the Northern Ireland Diabetic Eye Screening Programme (NIDESP) in young people aged 12-26 years using qualitative questionnaires.

Methods: A qualitative questionnaire was distributed to young people with diabetes mellitus (YPwDM) through Diabetes clinics in the Belfast Health and Social Care Trust (BHSCT) enquiring about barriers and enablers faced for NIDESP attendance. Additionally, YPwDM were asked about their level of knowledge as to how Diabetes Mellitus (DM) might affect their eyes.

Results: The survey was completed by 25 YPwDM; 52% were male and 44% were female, one individual did not state their gender. Respondents were aged between 12 and 26 years of age, 56% were between 16-20 years. Age at diagnosis was most commonly between the ages of 8-11 years old (40%) followed by 12-15 years of age (28%). Those diagnosed between the ages of 1-3, 4-7 and 16-20 were 8%, 4% and 16% respectively, 4% did not respond. Saturation of themes was achieved by this number of responses.

Nearly all (92%) YPwDM were aware that diabetes can affect the eyes, despite this, 84% asked to receive more education on this subject. The main source of information on diabetic eye disease at present is the endocrinologist in charge of the diabetes clinic (in 72% of cases). NIDESP was known to nearly all YPwDM (88%), however 20% were unaware that attendance both at NIDESP and their high street opticians was advisable. The identified main barriers were the timing of the appointments, clash of multiple appointments and missing out on school/work being the main problems. In fact, 76% stated that they would be more likely to attend if diabetic eye screening was completed during their normal diabetes clinic appointment. One respondent strongly suggested that more encouragement from the diabetes team would be required to increase their want to attend NIDESP.

Conclusions: The study concluded that it is not necessarily the lack of knowledge that stops YPwDM attending NIDESP. Relatively modest changes in how information on diabetic eye disease is provided, and by whom; rearranging time of the eye-screening clinics and providing more detailed information could potentially have a major impact on attendance.

ABSTRACT BODY:

Purpose: Dual inhibition of angiopoietin-2 (Ang-2) and vascular endothelial growth factor (VEGF)-A with faricimab, the first bispecific antibody designed for intraocular use, may synergistically promote vascular stability and reduce treatment burden through extended durability in patients with neovascular age-related macular degeneration (nAMD). The phase 3 TENAYA and LUCERNE trials are designed to assess the efficacy, safety, and durability of faricimab compared with aflibercept in patients with nAMD. Here, we present the rationale for the clinical trial design.

Methods: TENAYA (NCT03823287) and LUCERNE (NCT03823300) are identical, phase 3, randomized, double-masked, active comparator-controlled, 112-week studies of faricimab in nAMD. Treatment-naïve patients are randomized 1:1 to faricimab 6.0 mg up to every 16 weeks (Q16W) after 4 initial every-4-week (Q4W) doses or aflibercept 2.0 mg every 8 weeks (Q8W) after 3 initial Q4W doses. Based on disease activity assessments (prespecified anatomical and functional criteria, and investigator discretion) at weeks 20 and 24, patients in the faricimab arm are allocated to receive Q8W, every-12-week (Q12W), or Q16W dosing until week 60. Faricimab-treated patients then follow a personalized treatment interval (PTI), a protocol-driven treat-and-extend regimen with interval adjustment based on individualized treatment response as assessed by prespecified anatomical and functional criteria at study drug dosing visits, up to week 108.

Results: The TENAYA and LUCERNE trials will evaluate the efficacy, safety, and durability of faricimab in patients with nAMD. The primary efficacy endpoint is change in best-corrected visual acuity from baseline averaged over weeks 40, 44, and 48. Secondary endpoints include the proportion of patients receiving faricimab Q16W, Q12W, and Q8W, and changes in anatomic outcomes; safety outcomes include the incidence and severity of adverse events. The PTI phase is designed to tailor treatment intervals according to patients' needs, with individualized dosing up to Q16W, to reduce treatment burden while optimizing outcomes.

Conclusions: The TENAYA and LUCERNE trials are ongoing global trials designed to evaluate the potential for dual Ang-2 and VEGF-A inhibition with faricimab to improve outcomes for patients with nAMD.

ABSTRACT BODY:

Purpose: To assess impact of delayed treatment in diabetic macular edema (DME) in the VISTA/VIVID trials and initiating treatment in moderately severe to severe non-proliferative diabetic retinopathy (NPDR) in the PANORAMA trial.

Methods: In this post hoc analysis in VIVID/VISTA, efficacy outcomes were compared between eyes that received intravitreal aflibercept injection (IAI) 2 mg every 4 weeks (2q4; n=290) or every 8 weeks (2q8 after 5 initial monthly doses; n=286) through 100 weeks, or laser with rescue (with 2q8 regimen) due to vision loss (from week 24 for up to ~76 weeks; n=109). Rescue initiation (RI) in VISTA/VIVID was synchronized to the baseline for initially treated patients, with outcomes assessed at week 100 from baseline. In PANORAMA, eyes with moderately severe to severe NPDR without DME received IAI every 16 weeks (2q16 after loading phase; n=135) or every 8 weeks (2q8/PRN after loading phase; n=134) or sham (n=133). All patients could receive rescue at investigator's discretion for events of PDR/anterior segment neovascularization (ASNV; 1 IAI injection and/or panretinal photocoagulation) or center-involved DME (CI-DME; IAI PRN).

Results: In VISTA/VIVID, mean best-corrected visual acuity (letters) with 2q4 and 2q8, respectively, was 59.8 and 59.1 (baseline) and 71.5 and 70.2 (week 100), and was 59.5 (baseline), 49.0 (RI), and 57.9 (week 100) for laser/rescue. Mean central subfield thickness (CST) (μm) with 2q4 and 2q8, respectively, was 493.1 and 497.6 (baseline) and 289.4 and 290.1 (week 100), and 537.5 (baseline), 538.5 (RI), and 272.9 (week 100) for laser/rescue. In PANORAMA, in the 2q16, 2q8, and sham groups, respectively, 3.0%, 3.7%, and 14.3% of patients were rescued for PDR/ASNV, and 7.4%, 8.2%, and 29.3% were rescued for CI-DME, through 100 weeks. Benefit was seen in the patients treated with IAI versus sham/rescue with respect to progression of diabetic retinal disease.

Conclusions: Patients with DME in VIVID/VISTA who received delayed IAI treatment did not achieve similar final visual acuity as those who initiated IAI at study start, despite achieving similar CST. These analyses from VIVID/VISTA and PANORAMA suggest earlier treatment could be clinically beneficial in both DME and NPDR patients.

TITLE: Sterculic acid treatment promotes cell survival of retinal pigment epithelium cells in a multi-pathway dependent manner.

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Peláez, A. Pariente, Á. Pérez-Sala, R. Ochoa, I.M. Larrayoz, Biomarkers and Molecular Signaling, Fundación Rioja Salud, Logroño, La Rioja, SPAIN|

Commercial Relationships Disclosure (Abstract): Rafael Peláez: Commercial Relationship: Code N (No Commercial Relationship) | Ana Pariente: Commercial Relationship: Code N (No Commercial Relationship) | Álvaro Pérez-Sala: Commercial Relationship: Code N (No Commercial Relationship) | Rodrigo Ochoa: Commercial Relationship: Code N (No Commercial Relationship) | Ignacio Larrayoz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sterculic acid (SA) is a cyclopropene fatty acid presents in Sterculia foetida seeds, although it is also present in many other seeds. Different studies have demonstrated that this lipid has many effects over cells biological activities, generally attributed to its Stearoyl-CoA desaturase (SCD) inhibitory properties. Scd1 has demonstrated to be a new potential target for many diseases as result of the central role this gene in lipid metabolism and body weight control. Lipid accumulation in drusen deposits of retina has been also associated to age-related macular degeneration (AMD) patients. Here we pretend to evaluate the molecular pathways altered by SA treatment to prevent retinal pigment epithelium (RPE) induced cell death.

Methods: Genome-wide transcriptomic analysis were carried out in mRPE cells, exposed to SA for 24 h, and an integrative functional enrichment analysis of genome-wide expression data were made to provide insights into the cellular protective mechanisms induced by SA

Results: The expression of pivotal genes related to lipid metabolism was altered as result of the SA biological activity. Furthermore, steroid biosynthesis, cell death, actin-cytoskeleton reorganization or extracellular matrix-receptor genes were significantly modified by exposition to SA, while the specific SCD1 inhibitor did not alter the expression of these genes.

Conclusions: SA administration to RPE cells regulates crucial pathways in a SCD1 independent way that may be of interest for the treatment of ocular diseases.

TITLE: Effect of short-wavelength light emitting screen technologies on human contrast sensitivity

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Neumann, K. Breher, S. Wahl, Institute for ophthalmic research, University of Tuebingen, Tuebingen, GERMANY|S. Wahl, Carl Zeiss Vision International GmbH, Aalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Antonia Neumann: Commercial Relationship: Code N (No Commercial Relationship) | Katharina Breher: Commercial Relationship: Code N (No Commercial Relationship) | Siegfried Wahl: Commercial Relationship(s); Carl Zeiss Vision International GmbH: Code F (Financial Support); Carl Zeiss Vision International GmbH: Code E (Employment)

ABSTRACT BODY:

Purpose: Blue light (short-wavelength light) is a part of the visible electromagnetic light spectrum for the human eye. Short wavelengths have a higher energetic radiation compared to middle and long wavelengths, which might have multiple effects on retinal processes. This study was conducted to investigate whether commonly available screen technologies are able to elicit changes in contrast sensitivity (CS) and therefore may be used to control myopia eventually.

Methods: In total, 30 right eyes were randomly stimulated with light of different wavelengths: ~480 nm, ~530 nm, ~630 nm and polychromatic light ~380-780 nm, for 3 min each presented on a liquid crystal display, the ViewPixx/3D (VPixx Technologies, Saint-Bruno, Canada). Light stimulation was performed full field (FF) and only on the optic nerve head (ONH). CS was measured before any stimulation as reference and after each stimulation condition using a new and time-efficient CS test with Gabor patches and the method of adjustment for 3, 6, 12, 18 and 24 cycles per degree (cpd). Changes in CS after stimulation conditions were analyzed by three-way repeated measures analysis of variance. In a priorly conducted complementary study on a subset of five participants, the new CS test was verified to a validated CS test regarding agreement, repeatability (COR) and time.

Results: The new CS test was used with 3 trials per spatial frequency (interclass correlation coefficient = 0.94, COR = 0.1310 logCS, duration = 92 ± 17 sec). No critical change in CS after stimulation of the eye (FF or ONH) with short-wavelength light was detected (all $p > 0.05$), see Figure 1. CS measurements regarding spatial frequency differed significantly as expected from the CS function. The results showed, however, that CS differed significantly at 18 cpd after stimulation with polychromatic light from short-wavelength light ($p < 0.0001$). All other influencing factors and their interactions did not show significant effects.

Conclusions: The results of using short-wavelength light stimulation via LED screens to increase CS are inconclusive. Based on the results, melanopsin activation and thus increased levels of retinal dopamine are not easy to detect via indirect psychophysical testing. Direct and indirect links of these basic psychophysical findings to retinal signaling and eventually myopia control using short-wavelength light still require further research.

ABSTRACT BODY:

Purpose: Currently, visual acuity (VA) assessment is performed with maximum optotype contrast at moderately low luminance ($80\text{--}320\text{ cd/m}^2$), barely reflecting visual environments in daily life. Specifically, VA may not adequately assess vision in inherited retinal disorders with increased glare-sensitivity like achromatopsia (ACHM). For a more realistic assessment of patients' visual performance at different contrasts (C) and ambient luminance (AL), approximating daily life conditions, we developed a novel VA test, VA-CAL. Here we present preliminary results in ACHM patients and healthy controls.

Methods: ACHM patients (N=8; age: 16-37, mean 24.9 y) and eye-healthy controls (N=10; age: 22-29, mean 25.5 y) underwent VA-CAL. Landolt C-rings (LCR) were presented at 1m distance on a $10\times 10\text{ cm}$ field in the center of a frosted glass screen ($130\times 130\text{ cm}$), back-lit by 3,060 computer-controlled LEDs ($0\text{--}10,000\text{ cd/m}^2$, 7 steps). LCR contrast was programmable between 10-90 %. VA threshold for each condition was determined by adjusting LCR sizes using the QUEST adaptive staircase method. Participants received auditory feedback after reporting the gap position of LCR (8AFC), presented max. 10 s (ISI 1 s).

Results: As expected, VA of ACHM was well below to controls. In both, VA decreased with lower C. While VA of controls increased with AL up to a maximum between $3,000\text{--}5,000\text{ cd/m}^2$ (max. VA mean \pm SEM: $-0.5 \pm 0.03\text{ logMAR}$ @ C=90 %, AL=3,000 cd/m^2), ACHM reached their max. VA at 30 cd/m^2 (max. VA mean \pm SEM: $0.76 \pm 0.046\text{ logMAR}$ @ C=80 %). With increasing AL, VA in ACHM decreased by about 0.08 logMAR per $1,000\text{ cd/m}^2$ up to AL $3,000\text{ cd/m}^2$, followed by quite steady low VA up to AL $8,000\text{ cd/m}^2$ and a subsequent drop of VA to a minimum at AL $10,000\text{ cd/m}^2$ (min. VA mean \pm SEM: $1.41 \pm 0.08\text{ logMAR}$ @ C=10 %) (Fig. 1).

Conclusions: In this study, a novel computer-controlled method for testing of VA under different conditions of contrast and ambient luminance was developed for a more realistic visual performance assessment of visually impaired patients. Whereas in healthy subjects VA improves initially with increasing levels of AL, in patients with achromatopsia, VA decreases with increasing C and AL. Our results indicate that VA has to be measured within a broader range of C and AL to adequately assess everyday visual performance, especially in patients reporting glare sensitivity.

ABSTRACT BODY:

Purpose: To report the incidence of post-operative retinal displacement detected on fundus autofluorescence (FAF) imaging following rhegmatogenous retinal detachment (RRD) repair with pars plana vitrectomy (PPV), scleral buckle (SB), or PPV/SB.

Methods: Single-center, prospective consecutive series conducted at Wills Eye Hospital (Philadelphia, PA, USA). Optos (Dunfermline, UK), FAF images were performed in eyes post RRD repair between April and December 2020. Images were assessed by two independent graders, masked to surgical technique. Retinal displacement was identified by imprinted retinal vessels on FAF images.

Results: Ninety-four eyes of 88 patients (73% male, mean age 62(±13) years) were included. Nineteen eyes (21%) had a macula-on RRD, 75 (79%) had a macula off RRD. Thirty-two eyes (34%) had proliferative vitreoretinopathy (PVR). Forty-four (46.8%) eyes underwent PPV alone, 9 (9.6%) underwent SB alone, and 41 (43.6%) underwent combined PPV/SB. The mean time from surgical procedure to FAF imaging was 112 days. A total of 9 eyes (9.6%) had retinal vessel imprinting on FAF consistent with retinal displacement. The mean (±SD) displacement was 0.18 mm (± 0.11; range 0.09-0.4 mm). 5 of 44 (11.3%) PPV patients and 4 of 41 (9.8%) of PPV/SB patients had displacement. No displacement was found in the SB only patients. There was no statistically significant difference in the proportion of eyes with displacement between the three surgical groups (p=0.88). All observed displacement involved the inferior vasculature. Two cases of displacement were found in patients with PVR (n=32, 9.1%), and 7 were found in patients without PVR (n=62, 11.3%; p=0.71). Mean (±SD) preoperative logMAR visual acuity was 1.46 (±0.96; Snellen equivalent 20/570) and mean (±SD) postoperative logMAR visual acuity was 0.55 (±0.37; Snellen equivalent 20/70, p<0.001). Among patients with macula-off RRD, the mean (±SD) postoperative logMAR visual acuity in the group without displacement (0.51 ± 0.34, Snellen equivalent 20/64) was significantly better than those with displacement (0.8 ± 0.37; Snellen equivalent 20/126, p= 0.035).

Conclusions: Retinal displacement after incisional retinal detachment repair occurs in approximately 10% of cases. PPV and PPV/SB showed a similar percentage of displacement. In eyes with macula-off detachments, those with displacement had worse postoperative visual outcomes compared to those without detectable displacement.

ABSTRACT BODY:

Purpose: Retinal vascular degeneration can be a cause of vision loss in ischemic retinopathies including diabetic retinopathy. Targeting early microangiopathic damage might be a more effective treatment approach. sGC plays an important homeostatic role in blood vessels maintenance. However, sGC can be rendered nonfunctional by oxidative stress. The presence of sGC in retinal blood vessels, and the effect of sGC activation in retinal vascular disease has not been reported. The purpose of the study was to evaluate the effect of a novel sGC activator (runcaciguat) in the treatment of retinal vasodegeneration.

Methods: Expression of sGC α and β subunits was evaluated in post-mortem human retina specimens by immunohistochemistry. Runcaciguat was evaluated in the mouse oxygen induced retinopathy (OIR) model. Mice were treated daily with runcaciguat via oral gavage from P8 to P12. Retinal wholemounts from P12 or P18 mice were evaluated for vaso-obliteration and/or neovascularization. In STZ model and healthy rats, changes in the circumpapillary RNFL (cpRNFL) and retinal microcirculation following runcaciguat bolus intravenous therapy was evaluated with optical coherence tomography and angiography (OCT/OCTA).

Results: Immunohistochemistry demonstrated that both sGC α and β subunits were expressed in human retinal blood vessels. In OIR mice, runcaciguat treatment reduced both retinal vaso-obliteration and neovascularization in relation to the total retina compared to hyperoxic P12 retinas ($17.65\% \pm 5.35$ vs $30.65\% \pm 13.06$, $p = 0.04$ & $3.05\% \pm 1.3$ vs $8.17\% \pm 4.1$, $p < 0.0001$) and hyperoxic P18 retinas ($0.8\% \pm 0.8$ vs $3.7\% \pm 3.4$, $p = 0.002$, and $7.5\% \pm 2.9$ vs $12.12\% \pm 7.4$ vs, $p = 0.008$, mean \pm SD, one way ANOVA). 2ry to retinal vasodilation, a trend of increased cpRNFL thickness was detected in rat STZ model. The deep retinal vascular plexus diameter was increased in OCTA en Face image analysis and correlated to the runcaciguat plasma concentration (Pearson $r = 0.996$, p value: 0.004, CI. 0.82 to 0.99). The peak increase in the retinal perfusion measured by OCTA was 30 minutes following runcaciguat therapy.

Conclusions: These findings showed sGC was expressed in retinal blood vessels in humans. Together with runcaciguat's effect on retinal vascular perfusion, its protective effects on retinal vaso-obliteration in OIR suggest that runcaciguat could represent a potential novel treatment for ischemic retinopathies including diabetic retinopathy.

ABSTRACT BODY:

Purpose: The highest three-dimensional (3D) resolution possible in in-vivo retinal imaging is achieved by combining optical coherence tomography (OCT) and adaptive optics. However, this combination brings important limitations, such as small field-of-view and complex, cumbersome systems, preventing so far clinical deployment. Here, we introduce Adaptive-Glasses Full-Field OCT (FFOCT), a retinal imaging system allying high-resolution, high frame rate (300Hz), 5° FOV in a compact system (footprint: 30cm by 50cm).

Methods: We used our retinal imager combining a time-domain FFOCT and an SDOCT, enabling correction of axial eye motion in real-time. We previously demonstrated the capacity of this system to achieve foveal cone mosaic imaging without the use of AO, owing to the low sensitivity to ocular aberrations of the FFOCT when using spatially incoherent light, mostly affecting the signal to noise ratio (SNR). To increase the SNR, we implemented a lens-based sensorless AO approach using a multi-actuator adaptive lens (MAL) positioned in front of the eye, like prescribed eyeglasses, in a technique we call the adaptive-glasses approach. The SDOCT signal was used as a merit function for the wavefront optimization.

Results: The FFOCT SNR was enhanced up to a factor of 10 by using the MAL for a dilated pupil. The MAL can adjust the focus axial position within the retina, to image structures in the inner retina as the nerve fiber layer with an 8 µm axial resolution. Moreover, owing to the combination of FFOCT with the adaptive-glasses approach, we can acquire high-resolution FFOCT images over a 5° FOV, without apparent anisoplanatism. This unprecedented combination of wide FOV and high-resolution facilitated important clinical tasks to diagnose retinal disorders, such as image montaging and the computation of photoreceptor-based biomarkers.

Conclusions: We showed that the combination of FFOCT, which presents a weaker sensitivity to symmetric aberrations in terms of lateral resolution [5], and the adaptive-glasses approach, to increase the SNR of FF-OCT image and to favor anisoplanatic correction, opens a new avenue to wide FOV high-resolution retinal imaging in a compact imaging system configuration, taking up essential challenges to facilitate clinical deployment of AO-OCT. The proposed system is moving to the Quinze Vingts National Ophthalmology Hospital to start clinical trials in the beginning of January 2021.

ABSTRACT BODY:

Purpose: To assess the performance of DL employing 7F-CFP in automated identification of eyes with moderately severe and severe NPDR among patients with diabetes in a US primary care setting.

Methods: Eyes of 37,358 patients with diabetes were analyzed using data, including images, collected between 1999 and 2016 (Source: Inoveon Corporation, Oklahoma City, OK). DR severity and the presence of clinically significant macular edema were assessed from 7F-CFP by professional graders at a centralized reading center, and graded using the Early Treatment Diabetic Retinopathy Study Diabetic Retinopathy Severity Scale (DRSS). Prevalence of moderately severe or severe NPDR (DRSS 47–53), considering the worst DRSS score at the patient level, was 2.2% in this cohort. This set was split into 80% for model training, 10% for tuning, and 10% for testing, for a total of 29,890, 3732, and 3736 patients with 1,430,046, 180,534, and 180,135 images, respectively. A DL Inception-v3 model with transfer learning was trained at the image level on all 7 fields of view (including stereoscopy) for being either DRSS 47–53 or not. Predictions were averaged over all fields of view to provide a prediction at the eye level. We report model performance metrics in terms of area under the receiver operating characteristic (AUROC) curve, specificity, sensitivity, and positive predictive value.

Results: The best model was selected based on performance on the tuning set, as well as the optimal cutoff for specificity and sensitivity maximizing the Youden index. The model performed well on the testing set with an AUROC of 0.962 (95% CI, 0.956, 0.967), sensitivity of 0.942 (95% CI, 0.934, 0.950), specificity of 0.946 (95% CI, 0.945, 0.948), and positive predictive value of 0.281 (95% CI, 0.272, 0.290).

Conclusions: DL can support automated identification of eyes with DRSS 47–53. The model presented here can optimize screening of patients at risk of disease progression for participation in preventive clinical trials as well in clinical practice. Future research will further refine this proof-of-concept algorithm, including validation on other independent diverse datasets and in a real-world setting.

ABSTRACT BODY:

Purpose: We developed DL models to predict visual acuity response (VAR) to ranibizumab (RBZ) by using baseline (BL) characteristics and color fundus images (CFIs) of patients with neovascular age-related macular degeneration.

Methods: VAR was formulated as a classification problem with 4 classes (<5, 5–9, 10–14, and ≥15 letters); each class was assigned based on best-corrected visual acuity (BCVA) change from BL to month 12. To solve the classification problem, we designed 3 DL models that processed data from different modalities. Single models were trained to process BL characteristics, including BCVA, age, and optical coherence tomography (OCT) imaging biomarkers (Fig 1A), or CFI (Fig 1B); the third model (multimodal model; Fig 1C) fused the 2 subnetworks to produce the final classification.

This is a retrospective analysis of BL data from 284 patients receiving RBZ monthly treatment in the CATT study (NCT00593450). The distribution across the 4 classes was imbalanced, with 64, 43, 52, and 125 patients in classes 1, 2, 3, and 4, respectively. Performance was assessed based on validation (N=56) and test (N=57) data subsets using accuracy and area under the receiver operating characteristic (AUROC) curve. As accuracy and AUROC can be misleading in an imbalanced dataset, we reported F1 score (macro [m] and per-class) and area under the precision-recall (AUCPR) curve to provide a more informative assessment of model performance.

Results: Evaluation of model performance is shown in Table 1. Performance measures varied considerably among the 3 models (eg, mF1 scores of the test dataset were 0.332, 0.236, and 0.354 for BL characteristic, CFI, and multimodal models, respectively). Additionally, individual per-class results showed large variation, reflecting the presence of a strong class imbalance in the data.

Conclusions: The 3 models showed limited ability to predict VAR to RBZ, but the BL characteristics and multimodal models outperformed the CFI model. Compared with the BL characteristics model, the multimodal model showed slightly better performance. More research is required to explore whether the predictive ability of the multimodal model can be further improved.

TITLE: Full Field Tissue Ablation Profilometer with Submicron Precision

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Vankov, R&D, J&J Vision, Milpitas, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alexander Vankov: Commercial Relationship(s);J&J Vision:Code E (Employment)

ABSTRACT BODY:

Purpose: Accuracy of optical change induced by laser can be achieved with OCT only in average, assuming cornea receives smooth change. Evaporation, liquid on the surface, gravity, translation to measurement bench adds tens of micrometers to measurement errors, resulting in inconsistent measurements. To evaluate laser treatment and visualize local surgical problems, profilometer should provide direct consistent measurement in each point of ablation with at least 10 micrometers of lateral resolution and submicron resolution for thickness.

Methods: Flap of porcine cornea 100 micrometers in thickness made on IFS device, J&J Vision, was placed on mirror, submerged in oil-based fluid with known refractive index 1.4700, and covered with glass cover slip. White light interferometer measures Optical Path Difference (OPD) in this cuvette with 30nm precision. We used Contour GT white light interferometer, Bruker Corp, with 2x objective. Small change in corneal refractive index allows for precise measurement of corneal thickness by OPD measurement. Thickness can be calculated as OPD divided on difference of refractive indexes between oil and tissue, 1.4700 and 1.376, respectively. After ablation with Star S4 IR, J&J Vision, flap with ablated crater was measured again. Subtraction shows laser induced difference.

Results: 8mm corneal flap, ablated with stationary top hat excimer laser beam 4mm in aperture and 19mJ in energy forms crater with central island, well known in refractive surgery. Results for ablation rate in the center was 0.36micrometers/pulse, which is in remarkable agreement with published value 0.37micrometers/pulse, measured with shadow photography. Settings for IFS flap was 100 micrometers and measured on profilometer as 106 micrometers in thickness, 10micrometers peak to valley. Lenticular extracted during SMILE procedure also can be evaluated on profilometer with same precision about 300nm. As far as tissue is embed into oil, no evaporation or hydration can occur. Specimen remain stable for at least 5 days and is not sensitive to transportation.

Conclusions: Full field tissue profilometry with at least 300nm precision is demonstrated on porcine cornea. Profilometer can be used for characterization of LASIK and SMILE laser systems on tissue and have good agreement to independent measurements.

ABSTRACT BODY:

Purpose: Alzheimer's disease (AD) is a neurodegenerative disorder that lacks biomarkers for early diagnosis. The retina displays many characteristics of the AD brain, such as accumulation of amyloid beta (A β) oligomers and loss of function. In AD patients, changes in retinal venous velocity (V) and vascular oxygen saturation have been reported. These parameters as well as retinal oxygen metabolism (MO₂) and delivery (DO₂) have not been investigated in animal models of AD. The purpose of the study was to test the hypothesis that alterations in retinal arterial and venous diameter (D_A, D_V), V, and total retinal blood flow (TRBF), coupled with MO₂ and DO₂ are present in the five-familial AD (5xFAD) mice.

Methods: A total of 16 5xFAD and 16 wildtype (WT) mice were evaluated (age: 3 months). D_A and D_V were measured from retinal images, and V was determined by fluorescence microsphere imaging to calculate TRBF. Phosphorescence lifetime images were analyzed to derive arterial and venous oxygen contents (O_{2A}, O_{2V}) and arteriovenous oxygen content difference (O_{2AV}). MO₂ and DO₂ were calculated from TRBF, O_{2A} and O_{2AV}. Data were available in 13 of 16 mice in each group. Retina and brain tissues were evaluated by ELISA assays to determine A β 42 levels in WT (N=4) and 5xFAD mice (N=6).

Results: In the WT group, D_A, D_V, V, and TRBF were 27 \pm 2 μ m, 30 \pm 3 μ m, 11.1 \pm 3.2 mm/s, and 1.73 \pm 0.52 μ l/min, respectively. In the 5xFAD group, D_V (33 \pm 3 μ m) was increased, while V (7.1 \pm 1.4 mm/s) was reduced (P \leq 0.04). No significant differences were detected in D_A and TRBF (P \geq 0.3). O_{2A}, O_{2V}, and O_{2AV} were 6.5 \pm 1.4 mL O₂/dL, 2.8 \pm 1.9 mL O₂/dL, and 3.7 \pm 1.3 mL O₂/dL in the WT group, respectively. In the 5xFAD group, O_{2A} (7.8 \pm 1.2 mL O₂/dL) and O_{2V} (4.3 \pm 1.6 mL O₂/dL) were increased (P \leq 0.04), while no significant differences were detected in O_{2AV} (P=0.8). In the WT group, MO₂ and DO₂ were 57 \pm 16 nLO₂/min and 107 \pm 39 nLO₂/min, respectively. No differences were detected in MO₂ and DO₂ in the 5xFAD group (P \geq 0.1). Retinal A β 42 was 2.4 \pm 0.8 pg/mg in the WT group and was increased in the 5xFAD group (5.9 \pm 2.9 pg/mg; P=0.04). In the WT group, brain A β 42 was 1.5 \pm 0.5 pg/mg and was increased in the 5xFAD group (5.4 \pm 1.3 pg/mg; P=0.0005).

Conclusions: Taken together, retinal D_V, O_{2A}, and O_{2V} were increased, while V was decreased, whereas MO₂ and DO₂ were not altered in 5xFAD mice with elevated levels of A β 42 protein in the retina and brain.

ABSTRACT BODY:

Purpose: The Port Delivery System with ranibizumab (PDS) is an innovative, investigational drug delivery system designed for the continuous delivery of ranibizumab into the vitreous via diffusion-mediated release kinetics. Target ranibizumab release rates were selected by leveraging clinical and pharmacokinetic (PK) data from trials with intravitreal ranibizumab injections. In vitro testing was used to verify release rates with different ranibizumab concentrations before the phase 2 Ladder trial (NCT02510794) of the PDS in patients with neovascular age-related macular degeneration.

Methods: To mimic the clinical setting in vitro, implants were filled per the clinical "Instructions for Use." Implants with ranibizumab were regularly transferred to new buffer-containing vials to mimic ocular ranibizumab clearance and to sustain similar release kinetics.

A Bradford assay was used to measure released ranibizumab concentrations in each buffer-containing vial. Concentration data were used to calculate an average daily ranibizumab release rate. The activity of ranibizumab released from implants was determined by a Biacore assay. Results from this assay were used to determine a percentage of active ranibizumab, as well as an active ranibizumab release rate. Release rate data were fit using an exponential model to mimic the expected release kinetics of diffusion and compared to predicted release rate kinetics.

Results: Release profiles of the PDS with 3 ranibizumab concentrations (10, 40, and 100 mg/mL) were determined. At day 3.5, mean (SD) ranibizumab release rates were 1.75 (0.07), 6.42 (0.35), and 16.69 (0.67) µg/day for PDS 10, 40, and 100 mg/mL, respectively. At month 6, respective mean (SD) release rates were 1.68 (0.05) and 4.16 (0.05) µg/day for PDS 40 and 100 mg/mL. PDS 100 mg/mL released 73% (SD, 1.92) of drug by month 6. Active drug release from PDS 100 mg/mL was 98%, 88%, and 75% at day 3.5, month 6, and month 12, respectively. Consistent with these data, Ladder serum PK data showed that PDS 100 mg/mL released ranibizumab through at least month 16.

Conclusions: The PDS was designed to release ranibizumab over an extended period of time. Ranibizumab release from the PDS implant was demonstrated to be highly predictable and tunable based on a simple diffusion model. These findings support the median time to first refill of 15.8 months in Ladder PDS 100 mg/mL patients.

ABSTRACT BODY:

Purpose: Low vision and vision impairment present national health concerns due to their association with increased systemic morbidity. Risk factors for low vision including age, gender, and education level have previously been explored, but the potential association between eye care provider availability and low vision has not been thoroughly studied. To address this gap in knowledge, we examined the prevalence and geographic distribution of eye care providers in relation to low vision prevalence in California.

Methods: Data regarding the number of eye care providers in California were obtained from the 2018 American Academy of Ophthalmology records and the 2020 Blue Book of Optometrists. The prevalence of low vision was determined from data reported in the 2014-2018 American Community Survey (ACS). For the purposes of this study, participants who were 18 years or older and reported blindness or difficulty seeing even when wearing glasses were considered to have low vision. The prevalence of eye care providers for each county and Medical Service Study Area (MSSA) in California was calculated as the number of eye care providers, including both ophthalmologists and optometrists, per 100,000 people. The prevalence of low vision at the same geographic areas was calculated as the number of subjects with low vision per 100,000 people. At the MSSA level, linear regression models were performed to determine the association between prevalence of eye care providers and low vision.

Results: Based on ACS data, the population of California who were 18 years and older was 29,594,578. There were 58 counties and 542 MSSAs in California. The prevalence of eye care providers was 22.18 per 100,000 California residents. The prevalence of low vision was 2,411 per 100,000 residents. For the increase of every one eye care provider per 100,000 residents, there was a decrease of 3.32 ± 1.71 per 100,000 in the prevalence of low vision in an unadjusted model. When adjusting for ethnicity, gender, age, income, urbanity of residence location, and access to health insurance, there was a decrease of 6.39 ± 1.35 per 100,000 in the prevalence of low vision for the increase of every one eye care provider per 100,000 residents.

Conclusions: The geographic distribution of eye care providers was widely variable in California. Higher prevalence of eye care providers is potentially associated with decreased prevalence of low vision.

ABSTRACT BODY:

Purpose: OCTA data is able to differentiate vasculature from different retinal plexuses. However, the divisions between superficial, deep, and avascular regions are typically based on segmentation of structural layers which may not perfectly correspond to the vascular plexus divisions. In this work we introduce an automated method to divide the vasculature observed in OCTA volumes according to their plexus using only the angiographic (not structural) data.

Methods: Image slabs from 235 OCTA cubes (33 patients) were handcrafted to contain only vascular data belonging to the superficial, deep, or avascular plexus. In addition to this labeled data, thin slabs from the volume were generated as unlabeled data for qualitative model evaluation. Patient-level partitioning was used to separate images into training, validation, and test sets. Two UNet models were trained and validated (Fig 1). Model 1 used single-class images with image augmentation (flip, rotate, contrast). Model 2 added single-patient synthetic images created by blending a randomly placed and sized region from an adjacent class into each image. Models were evaluated on the reserved test set: quantitatively on both single-class slab and 2-class synthetic images and qualitatively on the unlabeled images.

Results: Both models performed well on labeling single-class images ($DICE \geq 0.90$) but less well on 2-class images, particularly when distinguishing deep and avascular regions (Fig 2A). Model 2 performed only marginally better than Model 1, indicating that deep learning algorithms are robust enough to segment multi-class images even when trained only on single class images (Model 1). Predictions on unlabeled slabs were qualitatively evaluated (Fig 2B).

Conclusions: We present a deep learning model that can learn from single-class images and synthetic combinations of those images to annotate the pixels of unlabelled OCTA slabs according to their location within the superficial, deep or avascular plexus. The method looks promising for differentiating the location of different vascular plexuses within an OCTA volume independently from retinal layer structural information.

ABSTRACT BODY:

Purpose: Glaucoma is one of the most heritable human diseases and hence mapping the specific genes is expected to both provide insights into disease biology as well as enhance our ability to detect who will be at highest risk. While genome-wide association studies (GWAS) have identified 127 open angle glaucoma risk loci to date, these only account for a small fraction of disease heritability. Traditionally glaucoma genes were mapped using a case-control design but we recently showed (Craig et al, Nature Genetics, 2020) that power to identify genes can be dramatically increased (effective sample size increased 2.5 fold) by augmenting cases and controls with glaucoma risk factor data. Our aim here is to leverage the correlation between glaucoma, intraocular pressure (IOP) and vertical cup to disc ratio (VCDR) to identify novel glaucoma risk loci.

Methods: We conducted a multi-trait analysis of glaucoma and its risk factors, using new and existing GWASs we have collected from around the world (34,179 glaucoma cases, 349,321 controls, supplemented by 111,724 individuals with VCDR and 153,604 individuals with IOP measures, drawn from studies in the International Glaucoma Genetics Consortium, UK Biobank and the Canadian Longitudinal Study of Aging). A key novelty over previous work is that VCDR measures were derived using a machine learning approach instead of using human graders, dramatically improving accuracy and power. The input traits were combined in a multi-trait GWAS framework using the software MTAG; an important feature of the approach is that it generates results which are specific to glaucoma risk.

Results: Our analysis of European ancestry samples identified 263 genome-wide significant loci, with most showing very good concordance in other ancestries. Combining across ancestries further improved power and identified 312 independent loci associated with glaucoma. Novel loci implicated by our analysis include associations at the genes TCF7 (implicating overlapping pathways with cataract) and SYN3 (implicating overlapping pathways with macular degeneration). We are currently working on replicating the novel loci in a large case-control cohort.

Conclusions: This work dramatically expands our knowledge of glaucoma genetics by identifying a large number of new risk loci, providing new insights into glaucoma aetiology and helping enable improved prediction of who is at highest disease risk.

ABSTRACT BODY:

Purpose: Uveitis is an uncommon but significantly blinding disease. This retrospective database analysis assessed the baseline clinical characteristics of patients in the IRIS Registry presenting with uveitis.

Methods: The first uveitic eye (random eye chosen if bilateral) of each IRIS Registry patient with a new uveitis diagnosis in 2017 was included. Uveitis diagnoses and associated ocular comorbidities were determined by ICD-10 codes. Uveitis cases were anatomically subdivided into: anterior uveitis (AU), intermediate uveitis (IU), posterior uveitis (PU), panuveitis (PanU), scleritis, retinal vasculitis (RV), and “mixed” (scleritis & any intraocular inflammation). Baseline logMAR best corrected visual acuity (BCVA) was measured on the initial date of uveitis diagnosis. Baseline intraocular pressure (IOP) was defined as the maximum IOP on the earliest date within 30 days prior to diagnosis. New patients were defined as those not previously registered in IRIS prior to 2017. Established patients were those seen prior to 2017 who received a new uveitis diagnosis during 2017. Presenting BCVA and IOP were compared against IRIS Registry patients seen in 2017 without uveitis.

Results: PanU had the worst and scleritis had the best mean BCVA at presentation (20/96 and 20/28 Snellen equivalent, respectively) (Figure 1). Presenting IOP was similar among all uveitis subcategories (mean=15.97 mmHg, range=14.66-16.17 mmHg) and controls (mean=15.55 mmHg). However, there was higher variation in the distribution of baseline IOP in uveitis patients compared to controls (Figure 2). AU had the highest rates of glaucoma and cataract at baseline.

Conclusions: Baseline BCVA was worst in PanU and best in scleritis. IOP varied more among patients with uveitis than those without. Glaucoma and cataract were common baseline ocular comorbidities in patients with uveitis.

ABSTRACT BODY:

Purpose: Macular Thickness Analysis (MTA) is a widely used tool for diagnosing and monitoring patients with ocular pathologies. The robustness of MTA is directly connected to the quality of the optical coherence tomography (OCT) system used to image the eye, which can be limited in low-cost devices. In this study we statistically compare the performance of MTA between a commercial OCT device and a low-cost OCT prototype.

Methods: A low-cost OCT prototype system (ZEISS, Dublin, CA) and a CIRRUSTM HD-OCT 5000 (ZEISS, Dublin, CA) were used to image 70 eyes with a range of ocular pathologies, including age-related macular degeneration (AMD). On each case the resulting OCT volumes were segmented to delineate the inner limiting membrane (ILM) and the retinal pigment epithelium (RPE). The prototype segmentation was used to generate macular thickness maps with 512x512 pixels over an area of 5.78mmx5.78mm. The two maps were registered to each other and the ETDRS grid was centered using the foveal location, manually selected on the CIRRUS scan (Figure 1). The ETDRS grid consists of three concentric circles with radii of 0.5, 1.5 and 2.89mm. A linear regression and Bland-Altman analysis were used to compare the two groups. The coefficient of determination (R^2), slope and intercept of the regression analysis, mean difference and 95% limits are reported for each of the 9 sectors of the ETDRS grid.

Results: A total of 70 eyes from 43 patients were imaged during this study. Table 1 shows the statistical comparison between OCT systems for each sector of the ETDRS grid. The low-cost OCT prototype measured macular thickness slightly higher than the CIRRUS, with mean differences ranging between 4 and 7 microns depending on the retinal sector. R^2 values varied between 0.90 and 0.98.

Conclusions: This study demonstrates the ability of our low-cost OCT prototype to accurately measure macular thickness with similar performance to that of a commercial OCT system. The small differences in thickness measurements are likely not clinically significant and could be compensated. This technology could be useful for monitoring patients with chronic diseases in a cost-efficient way.

ABSTRACT BODY:

Purpose: To study patients with geographic atrophy (GA) across clinical practices in the United States and evaluate clinical characteristics and disease progression in patients with GA.

Methods: Retrospective analysis was conducted of patients with ICD-10 codes for GA (extrafoveal or foveal) in ≥ 1 eye from 2016 to 2017 with ≥ 2 years follow-up. Neovascular AMD in the study eye before GA diagnosis was exclusionary. Presenting clinical characteristics, visual acuity (VA) change, and disease progression through 24 months were analyzed.

Results: A total of 256,635 patients were identified, of which 69,441 were eligible for inclusion. Of these, 44,120 (64%) had bilateral GA (GA:GA) and 25,321 (36%) had CNV in the fellow eye (GA:nAMD). Cohorts were balanced for age, gender, and race. In the GA:GA cohort, study eyes with extrafoveal GA had better VA at index (mean 67 letters) compared to those with foveal GA (mean 59 letters). However, over 2 years, changes in VA were similar for both the extrafoveal and foveal lesion groups with a difference of -6.8 and -6.6 mean letters, respectively. Also in this cohort, 16.7% of study eyes progressed from extrafoveal to foveal GA over a median time of 66 weeks; 11.4% of the extrafoveal study eyes and 10.2% of foveal study eyes progressed to nAMD over a median time of 74 and 66 weeks, respectively. In the GA:nAMD cohort, changes in VA values at index and after 2 years were similar to those seen in the GA:GA group. However, patients with fellow-eye nAMD progressed more often to study eye nAMD in both the extrafoveal (29.3%) and foveal (26.0%) lesion categories, over a median time of 63 and 60 weeks, respectively.

Additionally, 12.5% of study eyes in the GA:nAMD cohort progressed from extrafoveal to foveal GA over a median of 61 weeks.

Conclusions: This analysis confirms that GA is a prevalent and progressive disease with deteriorating impact on vision.

ABSTRACT BODY:

Purpose: Apoptosis signal-regulating kinase 1 (ASK1) is a mitogen-activated protein kinase kinase kinase that has been implicated in various neurodegenerative diseases. However, cell type-specific roles of ASK1 during neuroinflammation remain unknown. In the present study, we investigated the roles of ASK1 in different cell types during neuroinflammation by using an animal model of multiple sclerosis, experimental autoimmune encephalomyelitis (EAE).

Methods: ASK1^{flox/flox} mice were crossed with Lck-Cre+, Cd11c-Cre+, LysM-Cre+, GFAP-Cre+ or CX3CR1-CreER mice to generate five lines of double-transgenic mice, namely T cell-, dendritic cell-, microglia/macrophage-, astrocyte- or microglia-specific conditional knockout (CKO) lines. The resulting CKO mice were named as ASK1^{Lck} KO, ASK1^{Cd11c} KO, ASK1^{LysM} KO, ASK1^{GFAP} KO, or ASK1^{CX3CR1} KO mice for simplicity. EAE was induced in female CKO and wild-type (WT) mice at 6-8 week old by immunization with a myelin oligodendrocyte glycoprotein (MOG)₃₅₋₅₅ peptide, and clinical scores were evaluated daily. Histopathological analysis of the optic nerve and spinal cord was performed. Microglia and astrocytes were cultured and used for molecular mechanism analysis. Microarray and qPCR analysis were used to examine gene expression levels.

Results: The severity of paralytic symptoms in ASK1^{Lck} KO EAE and ASK1^{Cd11c} KO EAE mice were comparable to WT EAE mice, and the clinical symptoms observed in ASK1^{LysM} KO EAE and ASK1^{GFAP} KO EAE mice were ameliorated compared with WT EAE mice. Moreover, the ASK1^{LysM} KO EAE mice showed a reduction in clinical scores from the early stage of the disease, while ASK1^{GFAP} KO EAE mice only showed a reduction during the later stage of the disease. The levels of demyelination observed in the optic nerves of ASK1^{LysM} KO EAE and ASK1^{GFAP} KO EAE mice were milder than the level of demyelination found in WT EAE mice. We found that ASK1 signaling in microglia promoted its polarization towards pro-inflammatory microglia, macrophage infiltration into the central nervous system, and stimulated the induction of an A1 phenotype in astrocytes. Furthermore, ASK1 signaling in astrocytes recruits and activates microglia/macrophages in the later stage of EAE, which contributes, at least partly, to maintaining disease.

Conclusions: Glial ASK1 might be a promising therapeutic target for reducing neuroinflammation.

ABSTRACT BODY:

Purpose: Voretigene neparvovec (VN) is the first ocular gene therapy approved in multiple countries including the USA and Europe for treating patients (pts) with visual impairment due to confirmed biallelic RPE65 mutation-associated inherited retinal dystrophy having sufficient viable retinal cells. PERCEIVE, a registry-based post-authorization safety study, is designed to assess long-term safety of VN in a real-world (RW) setting. Here, baseline characteristics of participating pts treated with VN up to August 2020 are reported.

Methods: PERCEIVE is an ongoing, prospective, longitudinal, multicenter (ex-US), observational, safety study, which commenced December 2019 with the aim to enroll a minimum of 40 pts. All VN-treated pts are encouraged to participate in the study to maximize data collection, including those treated prior to study inception. After receiving VN as per local prescribing information, pts are followed-up as per the routine medical care for 5 years. The objectives are to characterize the long-term safety profile of VN via systematic collection of adverse event data, to follow pregnancy outcomes and assess visual function over time.

Results: Until data cut-off (Aug 2020), of the 15 pts enrolled, 10 pts (16 eyes) have received VN (6 bilateral; 4 unilateral). All treated pts are from Europe (Germany: 6; France: 3; Austria: 1). At the time of enrollment, the mean (standard deviation [SD]) age was 27.6 (9.81) years with a range of 15–51 years (1 adolescent; 9 adults). The majority of treated pts are female (n=7; 70%). For the treated eyes (n=16), baseline mean (SD) visual acuity was 0.96 (0.37) logMAR (n=14; range: 0.5–1.6 logMAR) and full-field stimulus threshold (white light) was –4.32 (9.40) dB (n=15; range: –34.9 to 3.2 dB). Optical coherence tomography (OCT) revealed a mean foveal thickness of 150.5 (41.07) µm (n=15; range: 76–216 µm). Central OCT showed that 11 eyes had an outer nuclear layer with a thickness range of 36–74 µm (n=9), while it was absent in 4 eyes. The ellipsoid zone line was disrupted in 9 eyes and was undetected in 6.

Conclusions: While enrollment and in person follow-up of VN-treated pts has been impacted due to COVID-19, PERCEIVE has started to provide valuable information on baseline characteristics of this vision-impaired population, and effect of VN therapy in a RW setting.

TITLE: Effect of retinoschisin on compartmentalization on novel interaction partners of the retinal Na/K-ATPase-retinoschisin complex

SESSION TITLE: Retinal Degenerations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Schmid, B.H. Weber, U. Friedrich, Institute of Human Genetics, University of Regensburg, Regensburg, GERMANY|A. Bruckmann, Regensburg Center for Biochemistry (RCB), Laboratory for RNA Biology, University of Regensburg,, Regensburg, GERMANY|

ABSTRACT BODY:

Purpose: Mutations in the RS1 gene cause X-linked juvenile retinoschisis (XLRS), a hereditary retinal dystrophy in juvenile or adolescent males. Recently, we and others showed that the retinoschisin protein encoded by RS1 binds to the retinal Na/K-ATPase and modulates its localization in the plasma membrane of photoreceptors. In this study, we aimed to identify interaction partners of the Na/K-ATPase-retinoschisin complex. Specifically, we were interested to examine an influence of retinoschisin on the localization of selected interaction partners, namely the voltage-gated potassium ion channels (Kv). This should provide new insights into the role of retinoschisin as a putative regulator of photoreceptor membrane compartmentalization.

Methods:

Porcine retinal lysates were subjected to co-immunoprecipitation targeting the $\alpha 3$ -subunit of the Na/K-ATPase (ATP1A3). Bound proteins were eluted and separated by SDS-PAGE for mass spectrometric analysis. Recognized proteins were verified in co-immunoprecipitation experiments with murine retinal lysates. Localization of Kv was investigated via immunohistochemistry in eyes from wildtype (wt) and retinoschisin-deficient (Rs1h knockout, Rs1^{tm1Web}) mice. Effect of retinoschisin on thermal stability and total protein level was investigated in Y79 cells or retinoschisin-deficient murine retinal lysates, respectively.

Results: Mass spectrometry from co-immunoprecipitates of porcine retinal lysates targeting ATP1A3 identified the Kv subunits Kv2.1 and Kv8.2. Binding to the retinal Na/K-ATPase was verified in further co-immunoprecipitations with murine retinal lysates. Immunohistochemical analyses in murine retinal cryosections revealed Kv localization to the inner segments and plexiform layers, like observed for the Na/K-ATPase. In retinae from retinoschisin-deficient mice, Kv2.1 and Kv8.2 distribution and total protein amount was altered compared to wt retinae. In contrast, no effect of retinoschisin was noted on thermal stability for Kv2.1 and Kv8.2.

Conclusions: Our data suggest that Kv subunits Kv2.1. and Kv8.2 are part of a macromolecular complex together with the Na/K-ATPase and retinoschisin. Defective compartmentalization of the retinal Na/K-ATPase and its complexing partners may be an initial step in XLRS pathogenesis.

TITLE: Extended measured area tear film stability assessment method by corneal reflex image degradation.

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Aldaba, F. Diaz Douton, J. Pujol, Centre for Sensors, Instruments and Systems Development, Universitat Politècnica de Catalunya, Barcelona, Catalunya, SPAIN|

Commercial Relationships Disclosure (Abstract): Mikel Aldaba: Commercial Relationship(s);Universitat Politècnica de Catalunya:Code P (Patent) | Fernando Diaz Douton: Commercial Relationship: Code N (No Commercial Relationship) | Jaume Pujol: Commercial Relationship(s);Universitat Politècnica de Catalunya:Code P (Patent)

ABSTRACT BODY:

Purpose: Recently a new method for the tear film stability measurement based on the corneal reflex image degradation has been proposed (Aldaba et al. "Tear film stability assessment by corneal reflex image degradation". JOSA A, 36(4), B110-B115). The method on its original version is simple, objective, and non-invasive, but has a main limitation: the reduced measured area. We present a modified version of the method that extends the measured area.

Methods: A new optical design of the original setup for tear film stability measurement based on corneal degradation has been proposed. The new design is based on having normal light incidence on the corneal plane, to do so, the focus of the incident light falls on the center of curvature of the cornea. Four different lenses that theoretically provided a large measured area have been tested: 1) glass spheric lens, 50.00mm focal length, 50.00mm diameter, 2) glass aspheric lens, 50.00mm focal length, 50.00mm diameter, 3) plastic aspheric lens, 35.74mm focal length, 35.00mm diameter, 4) plastic aspheric lens, 49.80mm focal length, 51.00mm diameter. The incidence beam area at corneal plane was measured recording an image at this plane and counting the number of pixels that form the beam. The optical quality of the system was evaluated for each lens by means of the full width at half maximum of the recorded image when using an ophthalmic lens as artificial cornea (PMMA material and radius of curvature 8mm).

Results: The measured incidence beam area for the four tested lenses was: 1.79mm for lens #1, 7.72mm for lens #2, 3.36mm for lens #3 and 7.04mm for lens #4. The full width at half maximum (the lower the value the better the image quality) of the recorded image with the artificial cornea was of 8 pixels for lens #1, 4 pixels for lens #2, 5 pixels for lens #3 and 20 pixels for lens #4.

Conclusions: A new optical design for increasing the measured area of the tear film stability method based on corneal reflex image has been proposed. The new design is based on the normal incidence of the incident beam on the cornea. Four lenses were tested in the setup; two were discarded due to small beam diameter and one due to poor optical quality. One of the lenses provided the desired beam diameter and optical quality, permitting the improvement of the method.

ABSTRACT BODY:

Purpose:

The determination of subjective far and near refractions is a central part of an optometric examination and its determination is yet to be challenged. Still, more and more digital and algorithm-based methods are available. This study investigated whether the algorithm-guided subjective far refraction (QuickPro) of the EyeRefract VX160 and its near refraction determination is comparable with a conventional, subjective refraction determination.

Methods: 96 persons took part in this study (spherical equivalent M = - 11.39 D to + 6.26 D, age: 39 ± 15 years). Two types of measurements were compared: QuickPro (algorithm-guided subjective far refraction) vs. conventional procedure (DNEye® Scanner 2 and subjective refraction). The near refraction (addition) was carried out both using the EyeRefract (Jackson-Cross method) and using a trial frame and Duane's figure.
