Purpose: The purpose of this study was to examine the effect of digital filtering on multifocal electroretinography (mfERG) parameters of patients sent for Plaquenil maculopathy screening.

Methods: This was a retrospective review of patients' records for patients that underwent HCQ maculopathy screening between December 2014 and October 2019 at USF Eye Institute, Tampa, FL. Only patients who underwent multifocal electroretinography (mfERG) were included. Recording of mfERG was performed binocularly on Espion mfERG system (Diagnosys LLC: Lowell, MA) with DTL electrodes using 61 hexagons stimulus, according to ISCEV mfERG standards. Each recording was subjected to four levels of digital bandpass (FFT/Adaptive) filtering: Level 1 (10-100 Hz), Level 2 (10-90 Hz), Level 3 (10-80 Hz) and Level 4 (10-60 Hz); spatial averaging was tuned off. The effect of filtering was evaluated on grouped ring averages (P1 amplitude) and the results were compared between Level 1 and the other levels of filtering by Dunn's multiple comparisons test.

Results: The retrospective review identified the records of 40 patients (4 males, 36 females), aged 54.7 +/- 14.1 years. Level 4 filtering induced significant decrease in P1 amplitudes compared to Level 1 for all rings ($p > 0.001$); Level 2 filtering did not cause a significant decrease ($p > 0.05$), while Level 3 filtering caused a significant decrease in ring #1 and ring #2 for left eyes ($p < 0.05$), but not in the other rings. Amplitude reduction associated with Level 4 filtering was most pronounced in ring #1 (~10%), while it was less pronounced for the rest of the rings (4.9%-5.7%). When percent difference between P1 amplitude decrease was plotted vs. P1 amplitude values, an interesting pattern emerged: there was a clear negative correlation between amplitude reduction and amplitude for rings #1 to #3 (Level 3 and 4), while it was present only for ring #3 at Level 2. No correlation was observed for rings #4 and #5 at any level of filtering. This result could be clinically important as it indicates that digital filtering has the most pronounced effect at lowest level of amplitudes, where it could be most useful.

Conclusions: The results of this study indicate that careful consideration should be given to digital filtering when evaluating the amplitudes of mfERG recordings for Plaquenil maculopathy screening. Future analysis will expand to effects on timing.

TITLE: Looking for Low Vision: Deep Learning and Natural Language Processing to Predict Visual Prognosis

SESSION TITLE: Visual Function, Vision QoL and visual impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.Y. Wang, B. Tseng, Ophthalmology, Stanford University, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sophia Wang: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Tseng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Low vision rehabilitation improves quality-of-life for visually impaired patients, but referral rates fall short of national guidelines. Automatically identifying from electronic health records (EHR) patients with poor visual prognosis could allow targeted referrals to low vision services. Since most clinical information is in free-text progress notes, we hypothesize that using information from notes would improve the ability to predict patients' visual prognosis over using purely structured information such as demographics and billing codes. The purpose of this study was to build deep learning models using natural language processing to integrate EHR data that is both structured and free-text to predict visual prognosis.

Methods: We identified 5612 patients with low vision (best documented visual acuity (VA) <20/40) on ≥ 1 encounter from EHR from 2009-2018, with ≥ 1 year of follow-up from the earliest date of low vision. Patients who did not improve to $> 20/40$ over 1 year were identified. Ophthalmology notes on or prior to the index date were extracted. Structured data available from the EHR included demographics, billing and procedure codes, medications, and exam findings including VA, intraocular pressure, corneal thickness, and refraction. To predict whether low vision patients would still have low vision a year later, we developed and compared deep learning models that used structured inputs to models that used both structured and free-text progress notes, represented by previously developed ophthalmology domain-specific word embeddings. Standard performance metrics including area under the receiver operating curve (AUROC) and F1 score were evaluated on a held-out test set.

Results: Among the 5612 low vision patients in our cohort, 40.5% (N=2278) never improved to better than 20/40 over one year of follow-up. Deep learning models utilizing structured inputs were able to predict low vision prognosis with AUROC of 79.1% and F1 score of 65.7%. Deep learning models further augmented with free-text inputs were able to achieve AUROC of 81.0% and F1 score of 69.0%.

Conclusions: Free text progress notes within the EHR provide valuable information relevant to predicting patients visual prognosis. Deep learning models utilizing data from EHR to predict ophthalmology outcomes should incorporate information from unstructured free-text progress notes where possible.

ABSTRACT BODY:

Purpose: Sodium iodate (NaIO_3) is selectively toxic to retinal pigment epithelium (RPE), inducing RPE cell death and subsequent photoreceptor degeneration. We explored differences in NaIO_3 -elicited responses of RPE and other retinal cells associated with mouse strains and dosing regimens.

Methods: A single dose of NaIO_3 at 15 mg/kg was injected intravenously into adult male C57BL/6J and 129/SV-E mice while control animals were injected with the vehicle (PBS). Morphological and functional changes were characterized by fundus imaging, spectral domain optical coherence tomography (SD-OCT), ERG, histological, and immunofluorescence techniques.

Results: The 15 mg/kg NaIO_3 dose initially induced a transient increase in scotopic ERG a-, b-wave and c-wave amplitudes in 12 hours post-injection, followed by progressive structural and functional degradation at 3 days in C57BL/6J and at 1 week in 129/SV-E mice, including depression of ERG response, loss of RPE cells, retinal structure disruption, and thinning of retinal thickness. Strain-difference existed in these two strains: 129SV-E mice showed slower photoreceptor degeneration (7 days post-injection) compared with C57BL/6J mice (3 days post-injection), which indicated that C57BL/6J mice are more sensitive to toxicity of NaIO_3 . Immunofluorescence imaging revealed Müller cell activation following NaIO_3 administration. RPE cell death occurred in a large posterior-central lesion, with a ring-like transition zone of highly irregular, abnormally shaped cells that appeared as early as 12 hours after NaIO_3 treatment in both strains. RPE cells in the far periphery survived with generally normal morphology.

Conclusions: The morphological and functional effects of NaIO_3 on RPE and retina were dependent on timing, dosage, and strain of mouse. Transient rise and fall of ERG response were thoroughly characterized in both strains. Far peripheral RPE cells were much more resistant to damage than central RPE. It may be that peripheral vs central RPE cells have fundamentally different properties, or location-specific factors mediate these differences in resiliency.

ABSTRACT BODY:

Purpose: Oxygen exposure and extreme prematurity are among two of the strongest risk factors for severe retinopathy of prematurity (ROP), however current screening criteria focuses on birth weight and gestational age (GA) at birth. Improved risk models may reduce the screening burden for low-risk infants and improve disease detection for infants with the most severe ROP, including aggressive posterior ROP (APROP). The purpose of this study was to evaluate the additive predictive value of quantifying oxygen exposure in early life for detection of treatment-requiring (TR-) ROP and APROP.

Methods: Demographics and oxygen exposure parameters were manually extracted from the electronic health record for each week of life (WOL) for 244 infants, 33 of whom eventually developed TR-ROP and 5 of whom developed APROP. Cumulative minimum, maximum, and total fraction of inspired oxygen (FiO₂) were calculated by summing values per WOL. Using 5-fold cross-validation, models using various combinations of birthweight, GA and FiO₂ were trained using random forest tuned with randomized grid search for prediction of future TR-ROP. Performance was evaluated using mean area under the receiver operating curve (AUROC) and precision-recall curve (AUPRC). To test the predictive value of oxygen exposure for APROP, cumulative minimum FiO₂ exposure was also plotted against eventual ROP outcome (no treatment, TR-ROP without APROP, or APROP) and an AUROC score was generated.

Results: On 5-fold cross-validation, the models trained on GA + cumulative minimum FiO₂ exposure had slightly higher performance than the models trained on GA alone (Figure 1, mean AUROC = 0.93±0.06 vs. 0.91±0.06, AUPRC = 0.76±0.08 vs. 0.74±0.13 respectively) for TR-ROP. For APROP, the AUROC of cumulative minimum FiO₂ exposure was 0.92 with clear dose response between oxygen exposure and level of ROP (Figure 2).

Conclusions: Quantitative oxygen exposure variables can be extracted and used to augment the identification of high-risk infants for developing TR-ROP, including APROP. Future work should focus on prospectively evaluating models that account for oxygen exposure.

ABSTRACT BODY:

Purpose: The mitochondrial mt3243A>G mutation is a common cause of retinal degeneration in patients with MIDD and MELAS. The relationship between mutational burden in peripheral tissues and severity of retinal disease is not currently well understood. We developed a digital PCR assay to screen blood and skin samples from 8 patients with clinically diagnosed and molecularly confirmed mt3243A>G disease. Using this platform, we correlated onset of visual symptoms with blood and skin mutational burden and explored the relationship between mitochondrial DNA copy number and mt3243A>G.

Methods: DNA was isolated from cultured dermal fibroblasts and peripheral blood mononuclear cells donated by 8 patients (ages 27-64) known to have retinal disease caused by the mt3243A>G mutation. The proportion of mutant (G) to wildtype (A) alleles was measured using digital PCR or TA-cloning with Sanger sequencing of resulting clones. Additionally, the mitochondrial DNA copy number was assessed by digital PCR. Patients were evaluated clinically by a single ophthalmologist. Molecular testing was performed masked to clinical information.

Results: The proportion of mt3243G allele varied greatly both between individuals and between cell type (blood: range 7%-39%, mean 19.13%; skin: 13%-82%, mean 45.63%). However, there was a strong correlation between blood and skin mt3243G proportion within the same individual ($R^2 = 0.606$, P value = 0.023). Additionally, a correlation between mt3243G proportion and mtDNA copy number was observed in cultured skin fibroblasts ($R^2 = 0.626$, P value = 0.019), but not in blood. Finally, we found that age of onset of visual symptoms correlated with proportion of mt3243G in blood ($R^2 = 0.820$, P value = 0.002) but not in skin (Figure 1).

Conclusions: Our results indicate that precise measurement of mt3243G mutational burden in peripheral tissues may be clinically relevant in retinal disease. Higher mutational burden of mt3243G correlated with an earlier onset of visual symptoms. Digital PCR offers a robust method to measure mutational burden in diseases caused by heteroplasmic mutations such as mt3243A>G. Future studies investigating the mechanisms by which mt3243 mutational burden is maintained in various cell types may shed light on the heterogenous phenotypes present in this family of disease.

ABSTRACT BODY:

Purpose: To evaluate the incidence of acute complications following an intravitreal injection.

Methods: A retrospective cohort study was performed at a private retinal practice in Ohio. Using the practice management software database, patients with intravitreal injections over a recent 2 year period were collected. From this group of patients, the search was further refined to include only those with unscheduled or urgent visits within 7 days of an injection. Data collected included: age, gender, eye involved, medication injected, diagnostic reason for injection, reason for urgent follow-up, length between date of injection and urgent follow-up, visual acuity on injection visit and urgent visit, intraocular pressure on day of injection and on date of urgent follow-up, and type of anesthesia during the injection.

Results: A total of 73,286 injections were performed by 15 retinal specialists during the study period, with 441 injections (n=441) resulting in urgent follow-up visits (0.60%). The mean patient age was (72.1 ± 30.4) years, with 187 patients male (42.4%) and 254 female (57.6%).

Medications injected over the 2 years were: Eylea (60.3%), Lucentis (22.4%), Avastin (13.4%), Ozurdex (2%), Triesence (1.6%) Beovu (1.59%), Iluvien (0.2%), and Yutiq (0.03%).

Medications injected in eyes with urgent visits included: Eylea (42.9%), Avastin (37.4%), Lucentis (7.9%), Ozurdex (6.8%), Beovu (2.7%), and Triesence (2.3%).

The length in days between date of injection and urgent follow-up was a mean of 3.96 ± 2.14 days.

Reason for urgent follow-up included: blurred vision in 164 patients (37.2%), seeing flashes or floaters or having posterior vitreous detachment (PVD) in 55 (12.5%), pain in 42 (9.5%), corneal abrasion in 43 (9.8%), subconjunctival hemorrhage in 33 (7.5%), corneal dryness or foreign body sensation in 30 (6.6%), endophthalmitis in 20 (4.5%), vitreous hemorrhage in 18 (4.1%), iritis or uveitis in 11 (2.5%), miscellaneous complications in 9 (2.0%), elevated intraocular pressure in 7 (1.6%), and choroidal neovascular membrane in 4 (0.9%), retinal detachment or tear in 4 (0.9%), and traumatic cataract in 2 (0.45%).

Conclusions: Intravitreal injections resulted in an incidence of 0.60% urgent unscheduled follow-up visits within 7 days of injection in this large retinal specialty practice. Blurred vision and symptoms of PVD were the most common causes of urgent visits.

TITLE: Progressive shortening of Steady-State Pattern ERG latency with increased LHON severity

SESSION TITLE: Optic Neuropathies - Pathophysiology and Therapies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: V. Porciatti, D. Alba, W.J. Feuer, J.L. Davis, B.L. Lam, Bascom Palmer Eye Institute, University of Miami, Coral Gables, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Vittorio Porciatti: Commercial Relationship: Code N (No Commercial Relationship) | Diego Alba: Commercial Relationship: Code N (No Commercial Relationship) | William Feuer: Commercial Relationship: Code N (No Commercial Relationship) | Janet Davis: Commercial Relationship: Code N (No Commercial Relationship) | Byron Lam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the baseline Pattern ERG (PERG) of Leber hereditary optic neuropathy (LHON) patients with different stages of severe visual loss (≤ 35 ETDRS letters) before gene therapy (GT).

Methods: The study was part of a phase I GT trial investigating the safety of a scAAV2 investigational product (IP) containing a wild-type synthetic nuclear encoded ND4 subunit for G11778A LHON. Patients (n=28) were enrolled into groups I (GT I: chronic bilateral), II (GT II: acute bilateral), and III (GT III: unilateral, better eye acuity ≥ 70 letters) and tested with PERG prior to IP injection and compared to PERG measurements of 210 normal control (NC) subjects. Steady-state PERGs (SS-PERG) were recorded simultaneously from both eyes and analyzed in the frequency-domain to retrieve amplitude (nV) and phase (deg), which was converted in latency (ms). The SS-PERG latency corresponds to the time-to-peak of the P50 wave of the standard transient PERG. The 2 baseline measurements of each eye were averaged. Then measurements from the 2 eyes of groups GT I, GT II, and NC were averaged yielding 1 measurement per patient. For group GT III, measurements from asymptomatic (GT III-A) and symptomatic (GT III-S) eyes were analyzed separately. Mean amplitudes and latencies were compared with GEE methods followed by post-hoc least significant difference (LSD) tests to account for inclusion of two measurements of GT III patients.

Results: Ages were similarly distributed in the different subject groups. PERG amplitudes of LHON patients were lower than those of normal controls ($p < 0.001$), but did not differ among patient groups. SS-PERG latencies differed by disease stage (see table) with G III-A shorter than NC ($p = 0.002$) but longer than G III-S ($p = 0.01$). G II (acute bilateral) latencies were further shortened than G III-S ($p = 0.03$). G I latencies were shorter than NC but did not differ from other GT patient groups (all $p > 0.1$).

Conclusions: While the baseline SS-PERG amplitude was much reduced in all LHON groups and did not distinguish between disease stage, SS-PERG latency progressively shortened with increasing disease severity. Latency shortening is consistent with LHON pathophysiology whereby smaller/slower axons are primarily affected resulting in the residual response being dominated by larger/faster axons. These results may inform timing of GT injections for preservation of small axons.

ABSTRACT BODY:

Purpose: Neonatal hypoxic ischemic encephalopathy (HIE) is one of the most common causes of neonatal death and long-term disability. The effect of HIE on visual outcomes, especially the effect of seizure and the correlation of brain MRI finding with visual function abnormalities is not well studied. We aim to study the visual outcomes in infants with HIE.

Methods: We did a retrospective chart review of neonates admitted to University of Illinois, Chicago, with a diagnosis of HIE. We analyzed the visual outcomes of these neonates in their subsequent follow up visits. Univariate and multivariate analysis were performed to determine the predictors of abnormal visual outcomes with a P value less than 0.05, considered significant.

Results: We had 57 neonates (34 Male/23 Female) with a diagnosis of HIE during the study period 2009-2019, which were divided into mild (27) moderate (23) and severe (7) HIE based on SARNAT scoring. Mean birth weight (BW) was 3265 ± 618 grams. 12% had severe HIE, and 11(13%) required inotropic support. 34(59.6%) underwent therapeutic hypothermia (TH), 13 (22.8%) had seizures. 14 of the 48 (29.2%) neonates who underwent MRI of the brain had abnormal imaging findings. 4/14 had lesions of occipital cortex, 7 had optic radiation abnormalities, 10 had DW restrictions, and 4 had geniculate body lesions. 16 (28%) patients had visual assessment on follow up exam, out of which only 2 had visual abnormalities. One of them had reduced visual acuity, and other one had refractory amblyopia. One patient with visual abnormality had a full-term gestation, with an APGAR of 0,0, 2, 4, 7 and a BW of 3420 g, had severe HIE with seizures, had use of inotropes, TH, and seizure medications. Another patient was also a full-term, with an APGAR of 1, 4, 7, BW of 3040 had mild HIE, with no seizures, and no use of TH or inotropes. We didn't find any significant predictors of abnormal visual outcomes. In our cohort, severe HIE was associated with imaging abnormalities ($p=0.003$), inotrope use ($p=0.01$), seizures ($p<0.001$) and use of TH ($p<0.001$).

Conclusions: Severe HIE was found to be associated with imaging abnormalities of visual pathways on brain MRI. However, the sample size was small and had limited follow up to show any significant association between HIE and abnormal visual outcomes. Future research may focus on obtaining larger sample size and better follow up of neonates with HIE, especially with severe HIE.

ABSTRACT BODY:

Purpose: Significant percentages of emergency room (ER) patients needing an ocular fundus examination do not always receive one by primary providers in the ER. A key reason is the difficulty in using the standard direct ophthalmoscope available in that setting. We have developed and demonstrated the remote application of a robotically aligned OCT (RAOCT) system capable of self-aligning and acquiring high quality volumetric retinal images of subjects from the ER.

Methods: Patients presenting with eye complaints in the ER with ophthalmology referrals were recruited over 7 nonconsecutive days. Hemodynamically unstable patients were excluded.

5 consented subjects under an IRB approved protocol were imaged by the RAOCT system with the operator either 6 feet behind a Plexiglas barrier (2 subj.) or in a separate room remotely connected to the RAOCT system via the local network (3 subj.). Figure 1 shows the layout of the imaging room and the live information transmitted to the operator including 2-way teleconferencing, OCT acquisition, and face/pupil tracking. The RAOCT system used a swept source retinal OCT system ($\lambda_0=1043\text{nm}$; 100 kHz) to capture 32° FOV retinal images including both the fovea and optic nerve head in single acquisitions. Rectangular volumes (700 A-Scans x 250 B-Scans) and full width repeated B-scans (2000 A-scans x 100 B-scans) were taken. The operator confirmed robot-subject alignment and triggered acquisition via a remote terminal session to the RAOCT computer (or directly when non-remote).

Select volumes were semi-automatically segmented and used for thickness maps. Repeatability was described by the standard deviation of repeated retinal thickness measures in the central 1 mm.

Results: Figure 2 shows thickness maps with representative B-scans for non-remotely (2A) and remotely (2B) imaged subjects. The central zone mean range was 294-300 μm with a mean SD of $\pm 1 \mu\text{m}$ and 260-301 μm with a mean SD of $\pm 2 \mu\text{m}$ for non-remotely and remotely imaged subjects respectively.

Conclusions: We have demonstrated remote imaging of ER patients with RAOCT. RAOCT has the potential to help non-specialist personnel evaluate the eye in non-specialty settings with further potential for telemedicine applications.

ABSTRACT BODY:

Purpose: To assess the long-term effects of adding lutein/zeaxanthin and omega-3 fatty acids to the Age-Related Eye Disease Study (AREDS) supplements on age-related macular degeneration (AMD) progression and adverse side-effects.

Methods: The AREDS2 clinical trial randomly assigned participants with bilateral intermediate AMD or late AMD in one eye to lutein/zeaxanthin and/or omega-3 fatty acids or placebo. Secondary randomization also evaluated varying doses of beta-carotene (0 vs. 15 mg) and zinc (25 vs. 80 mg). At the end of the clinical trial, a follow-up study was conducted with 6-monthly telephone calls to the surviving AREDS2 participants from the central coordinating center to collect outcome data and adverse events for safety monitoring for an additional 5 years. Medical records were obtained from treating physicians to validate any self-reported diagnosis or treatment of late AMD and cataract and side-effects. AREDS2 supplements with lutein/zeaxanthin, vitamin C and E, and zinc plus copper were provided to all participants during this additional follow-up. Repeated measures logistic regression was used in the primary analyses.

Results: 6360 study eyes (3887 participants) were analyzed and 3047 (48%) progressed to late AMD. The main effects of lutein/zeaxanthin vs. no lutein-zeaxanthin and of omega-3 fatty acids vs. no omega-3 fatty acids resulted in hazard ratios of 0.91 (95% CI: 0.89-0.99) ($p=0.03$) and 1.00 (0.92-1.09) ($p=0.91$), respectively. When the lutein/zeaxanthin main effect analysis was restricted to those randomized secondarily to beta-carotene, the HR was 0.80 (0.69-0.92) ($p=0.003$). On direct analysis of lutein/zeaxanthin vs. beta-carotene, the HR was 0.85 (0.74-0.98) ($p=0.026$). For the comparisons of low vs. high zinc and no beta-carotene vs. beta-carotene, the HRs were 1.04 ($p=0.48$) and 1.04 ($p=0.50$), respectively. For those randomized to beta-carotene, the odds ratio (OR) of developing lung cancer was 1.92 (1.11-3.31) ($p=0.02$) while the OR for those randomized to lutein/zeaxanthin was 1.19 (0.82-1.73) ($p=0.35$).:

Conclusions: The 10-year Follow-on study replicated the findings of the randomized clinical trial at 5 years.

Lutein/zeaxanthin, when compared with beta-carotene, had an incremental beneficial effect on progression to late AMD. Beta-carotene doubled the risk of lung cancer, providing support for lutein/zeaxanthin as a replacement of beta-carotene in the AREDS2 supplements

ABSTRACT BODY:

Purpose: Dolphin ocular surface (OS) are subjected to continuous adaptation mechanisms between air and aquatic ecosystem. Knowledge on dolphin tears composition may help understanding human OS disorders. We wanted to address tear metabolomic signature in aquarium dolphins

Methods: Tear samples from the external eye canthus were collected from four dolphins (*Tursiops Truncatus*), aged 19-33 years, housed at the Madrid Zoo Aquarium. 40-50 microliters of tears from each dolphin were processed by high-resolution magic angle spinning (HR-MAS) metabolomic platform. HR-MAS spectra were acquired on a Bruker Avance DRX 600 spectrometer, operating at a ¹H of 600.13 MHz frequency. Precise chemical shift region was analysed. Resonances between 0.50-5.26 parts-per-million of spectrometric frequency were considered.

Quantification of signals pertaining to specific regions was done and data analysis routines were performed.

Metabolite assignment was based on academic/proprietary spectral databases and our previous reports. Principal component analysis was applied to the data set to sharpen separation between animals.

Results: Mean age of 1 male and 3 female dolphins was 28 ± 7 years. Dolphins are primarily monocular (with limited capability for binocular vision), similarly in air and water. Neither ocular nor systemic diseases were previously recorded in these cetaceans. Macroscopic appearance of dolphin tears was a greasy gel-like, visco-elastic secretion. 19 metabolites were identified in dolphin tears, being the most abundant: glucose, glycoproteins, fatty acids, and mobile lipids. In the rank of millesimal we found citrulline, lactate, creatine phosphate, carnitine, acetate, and choline. Absence of the lipid/cholesterol fraction was noticed. Study limitations include the small sample size and the necessity of larger metabolomic assays and other indicators, such as tear osmolarity, to complete knowledge on dolphin tear composition

Conclusions: This is the first description of dolphin tear metabolomics. The identified metabolite composition suggests that the circumorbital conjunctival gland may be analogous to the terrestrial lacrimal gland. Dolphin tear metabolites may act by reducing the hydrodynamic resistance on the OS, also protecting the eyes against infectious agents. Our data suggest that dolphin tears is a comprehensive resource to further study OS correlations in humans

ABSTRACT BODY:

Purpose: There are currently no eye-specific molecular biomarkers in clinical practice for retinoblastoma (RB), a rare, pediatric intraocular cancer, because direct tumor biopsy is prohibited. We overcome this problem by using the aqueous humor (AH) as a liquid biopsy source of cell-free tumor DNA (ctDNA). This study aims to detail the first prospective data using the AH liquid biopsy to identify diagnostic and prognostic molecular biomarkers present at diagnosis and discuss the validity and clinical utility of the platform.

Methods: Subjects included 7 eyes of 6 RB patients with at least 12 months of follow-up. The AH liquid biopsy was used at diagnosis and prospectively throughout therapy until the eye was cured or required enucleation due to persistent disease. Cell-free DNA (cfDNA) was isolated and sequenced to assess genome-wide somatic copy number alterations (SCNAs) and mutation in RB1 gene. Results were compared to peripheral blood RB1 testing. Tumor fraction (TFx) was calculated using ichorCNA. Primary clinical endpoint was ocular salvage versus enucleation.

Results: Tumoral genomic information was detected in 100% of diagnostic AH samples. Of the 7 diagnostic AH samples, 5/7 were positive for RB SCNAs. Mutational analysis identified RB1 variants in 5/7 AH samples, including the 2 samples in which no SCNAs were detected. Two eyes failed therapy and required secondary enucleation; both had poor prognostic biomarkers (chromosome 6p gain and MYCN amplification) present in the AH at the time of diagnosis. No patients had any complications from AH sampling or demonstrated extraocular spread of disease.

Conclusions: This initial prognostic study demonstrates feasibility, safety, and utility of an AH liquid biopsy at diagnosis. Molecular profiling of AH provides impactful tumor-derived diagnostic and prognostic information from a single 100 µL AH sample. In the context of previously established pre-analytical, analytical, and clinical validity, this provides evidence for larger, prospective studies to further establish the clinical utility of the AH liquid biopsy and its applications to precision oncology for RB.

ABSTRACT BODY:

Purpose: To evaluate the outcomes of gonioscopy-assisted transluminal trabeculotomy (GATT) for the management of open-angle glaucoma in the setting of uveitis.

Methods: A retrospective chart review was performed of patients diagnosed with uveitis who underwent GATT between January 1st, 2014 and December 31st, 2019 due to medication-refractory open-angle glaucoma in the setting of uveitis. The primary outcomes analyzed included success rate, defined as IOP reduction >20% from baseline or IOP between 5-21mmHg at the 3-month visits; on a stable number or fewer IOP lowering agents, and no need for additional glaucoma surgery. Additional endpoints include IOP, number of glaucoma medications, and steroid regimen.

Results: 16 eyes from 13 patients were included in the study. The average age was 45.3±12.7 years (56% female). Average follow-up period was 29.5±14.7 months (range of 7.2-48.9 months). The predominant cause of glaucoma was inflammatory in 56%, steroid-induced in 19% and a mixture of both in 25%. At 12 months, the cumulative success rate was 81%. The 19% of eyes that failed required reoperation due to IOP spikes >25 mmHg. Mean IOP was 37.8±13.0 mmHg at baseline and 12.2±3.0 mmHg at 12 months (68% reduction; p<0.0001). The average number of glaucoma medications was 4.6±1.3 at baseline and 2.2±0.7 at 12 months (52% reduction; p<0.0001). At the 12-month visit when compared to the baseline, not only were a greater number of patients on both oral and topical steroid regimens, the mean dose was higher. Transient hyphema was the most common post-operative complication seen in 44% of eyes at 1 week, but all cases self-resolved by 1 month.

Conclusions: This small retrospective study shows that GATT is successful, effective and safe for the management of glaucoma in uveitic adult eyes. As a conjunctival-sparing, minimally-invasive procedure, GATT is promising as an initial treatment for refractory glaucoma in uveitis.

ABSTRACT BODY:

Purpose: Based on retrospective studies, metformin has been suggested to have a beneficial role in lowering the risk of AMD. The DPPOS is a follow-up phase of a large multicenter randomized clinical trial to investigate the effects of treatment with metformin or an intensive lifestyle modification (lifestyle), compared to placebo on preventing the onset of type 2 diabetes in a population at high-risk of developing diabetes. The DPPOS provides a unique opportunity to study the effects of metformin and lifestyle changes in preventing or delaying the development of AMD.

Methods: Color fundus photographs (FP) and optical coherences tomograms (OCT) were evaluated by the Wisconsin Reading Center in 1592 participants at year 16 of study follow up for presence and severity of diabetic retinopathy and AMD. AMD was classified as early, intermediate, or advanced (neovascular AMD or geographic atrophy) based on FP and OCT. Drusen size was classified as small, intermediate, or large. Differences in the prevalence and severity of AMD across the randomized groups were evaluated using Pearson's Chi² test.

Results: Participants were randomly distributed between three interventional arms; 514 in the lifestyle arm, 549 in metformin, and 529 in the placebo arm. All 3 arms were balanced for baseline characteristics including age, gender, race, smoking habits, body mass index, and education level. AMD was identified in 479 (30.1%) participants; 229 (14.4%) had early, 218 (13.7%) intermediate and 32 (2.0%) had advanced AMD. There was no significant difference in the presence of AMD between the three groups: 29.6% in lifestyle, 30.2% in metformin, and 30.7% in the placebo (p = 0.93). There was also no difference in the distribution of early, intermediate, and advanced AMD between the intervention groups (p = 0.095, Figure).

Conclusions: There was no statistically significant difference in the prevalence and severity of AMD between the three treatment groups after 16 years of follow-up. These data suggest neither metformin nor lifestyle changes for weight loss have a beneficial effect on lowering the risk of AMD. Additional observational analysis with cumulative years of metformin as main exposure is ongoing and may reveal further information.

ABSTRACT BODY:

Purpose: Previous studies have suggested that cataract surgery may increase the risk of developing late age-related macular degeneration (AMD). The Age-Related Eye Disease Study 2 (AREDS2) and AREDS2 Follow-On (A2FO) studies provided longitudinal information to assess the association between incident cataract surgery (CS) and risk of developing late AMD.

Methods: AREDS2 (2006-2012) was a randomized clinical trial evaluating the potential benefit of a modified nutritional supplement (lutein/zeaxanthin, zinc, and other nutrients) on the development of late AMD; A2FO (2013-2018) provided an additional 5 yrs of follow-up on a subset of AREDS2 participants. AREDS2 assessed CS status and AMD score at annual visits and, every 6-mos between visits, obtained information on CS and late AMD treatment (tx) by telephone. A2FO, initiated after the randomized trial concluded, assessed CS status and information on diagnosis and tx of late AMD at 6-monthly study visits via telephone only. Information regarding CS and tx for late AMD obtained by telephone was confirmed by medical record review. We identified case eyes (incident CS after AREDS2 randomization and no late AMD before or at the time of CS). The study visit when CS was first noted was used as the "baseline" visit for case eyes. We identified potential control eyes (no CS during AREDS2 or A2FO, no late AMD at AREDS2 randomization or before year 1). The year 1 study visit was used as the "baseline" visit for control eyes. We performed 1-1 propensity score matching (SAS 9.4) on age (at "baseline" visit), AMD score at the visit preceding the "baseline" visit, length of follow-up after the "baseline" visit, sex, education level, treatment group, smoking status, diabetes, aspirin use, and statin use. Matched pairs analysis and conditional logistic regression models were used to assess risk of developing late AMD (defined as photographic grading of late AMD or medical record documentation of diagnosis or tx of late AMD).

Results: There were 1201 case eyes and 2645 potential control eyes. Propensity score analysis identified 1081 matched pairs. 412 case eyes (CS) and 433 control eyes (no CS) developed late AMD after the "baseline" visit: matched pairs odds ratio, 0.92, 95% CI, 0.77-1.10, p=0.34.

Conclusions: In the AREDS2 and A2FO studies, cataract surgery did not appear to increase the risk of developing late AMD.

TITLE: Ability of different enface OCT slab methods to detect RNFL reflectance defects in glaucoma

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Cheloni, J. Denniss, School of Optometry & Vision Science, University of Bradford, Bradford, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Riccardo Cheloni: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Denniss: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optimal methods to extract enface OCT slab images to detect retinal nerve fibre bundle (RNFB) defects are undetermined. We explored the ability of several methods for slab extraction to objectively assess glaucomatous RNFB reflectance defects in enface OCT images.

Methods: Dense SD-OCT scans were performed in 16 eyes with glaucoma (median age: 70, range 61-77) and 19 age-similar controls. Enface slab images depth-averaging reflectivity below the inner limiting membrane (ILM) were generated with 6 different methods. Five methods considered single slabs of various thickness and depth (Figure 1). One novel method combined seven 16µm thick slabs from 8 to 116µm below the ILM (Figure 2), seeking to explore all depths with potential RNFB presence. In the combined slabs method, defects were defined when occurring in any slab. All methods adjusted for the individual position of the raphe, fovea and optic disc. Superpixels of glaucoma eyes were considered abnormal if reflectivity fell below the kernel density estimated 1st percentile of control data. Ability to detect glaucoma defects was measured by proportion of abnormal superpixels. Proportion of superpixels below the 1st and 5th percentile in controls was used as a surrogate for false positive rate. Differences in performance between slab methods were tested with linear mixed models.

Results: Ability to detect glaucomatous defects varied significantly among slab methods ($\chi^2_{(5)}=119.9$, $p<0.0001$), with the combined slabs method detecting 5-9% more abnormal superpixels than others (all $p<0.0001$). No method found abnormal superpixels at the 1% level in controls. Proportion of abnormal superpixels in controls at the 5% level varied slightly between approaches ($\chi^2_{(5)}=15.5$, $p=0.009$), being similar or slightly larger (1.8-2.2%) for the combined slabs approach.

Conclusions: Slab extraction method affects ability to detect glaucoma abnormalities in enface OCT images. Our novel method evaluates all depths with potential RNFB presence by combining several thin slabs at each location, resulting in greater detection of glaucomatous reflectance abnormalities.

ABSTRACT BODY:

Purpose: Alkali chemical burns to the cornea can ultimately lead to blindness. Slit lamp exam is traditionally used to assess damage to guide management; however, it is limited by poor depth analysis and obstruction by tissue scarring. Anterior segment optical coherence tomography (AS-OCT) is a non-invasive, high-resolution imaging modality that can potentially be used to overcome these limitations and provide fast, depth-resolved evaluation of corneal wound healing and remodeling.

Methods: Following an IACUC-approved protocol, acute injury model of alkali burn was performed by applying a 2 mm diameter circle of filter paper soaked in 1.0M NaOH to the right eye for 30 seconds, while the left eye was treated with PBS as a control. AS-OCT was performed on the cornea and iris simultaneously, before and after the chemical burn, as well as at 7 and 14 days following the burn. Corneal thickness of each eye was measured at nine points on a central cornea slice in ImageJ and OCT angiography (OCTA) was performed on the images captured by AS-OCT using a custom algorithm.

Results: We determined that alkali burns result in increased corneal thickness immediately post-injury (+70.33%), peaking on day 7 (+105.02%) and regressing slightly on day 14 (+101.95%). AS-OCT observed epithelial bullae and corneal opacity by day 7, and Descemet's membrane detachment by day 14. In addition, beginning on day 7, OCTA showed development of neovascularization from the limbal area towards the center of the cornea. An anterior chamber inflammation was also noted, with hyper- and hypo- reflective stromal cysts, as well as expansive edemas, on day 7.

Conclusions: AS-OCT was able to, with high sensitivity, detect edema/swelling, opacification, and neovascularization resulting from alkali burn. It also provided cross-sectional information for non-invasively exploring angiogenesis and tissue remodeling, as well as 3D visualization of the anterior chamber and corneal layers, regardless of the amount of corneal scarring. AS-OCT can be a valuable adjunct to standard diagnostic tools for the assessment of corneal alkali injury and wound healing.

ABSTRACT BODY:

Purpose: A broad variety of progressive retinal diseases are caused by mutations in PRPH2. This gene encodes peripherin-2/rds (P/rds), an integral membrane protein that shapes rod and cone photoreceptor outer segment (OS) disks. Instances of human pattern dystrophy have been associated with a TYR285stop nonsense mutation predicted to truncate the protein's cytoplasmic C-terminus. To advance understanding of inherited retinal degenerations caused by defects in PRPH2, we have generated and are investigating a TYR285stop gene-edited mouse model.

Methods: TYR285stop mice (Prph2^{Y285x/Y285x} and Prph2^{Y285x/+}) generated via CRISPR/Cas9 gene editing were outcrossed onto the C57BL6/J background until congenic. Prph2^{Y285x/Y285x} and Prph2^{Y285x/+} mutants were compared at postnatal day 21 to WT and to Prph2^{rds/rds} and Prph2^{rds/+} age-matched controls. Phenotyping assays included: western blotting, retinal layer thickness evaluations in paraffin sections, retinal whole mount IHC 3D imaging, full-field electroretinography (ERG), and rod spherule synaptic ribbon counts.

Results: Prph2^{Y285x/Y285x} mice developed significantly reduced (25%) numbers of photoreceptors which were unable to elaborate OSs. In contrast, the Prph2^{Y285x/+} disease model mice developed normal numbers of photoreceptors, which elaborated OSs with abnormal ultrastructure, but a near-normal IS-OS layer thickness. Compared to WT, Prph2^{Y285x/+} retinas expressed less P/rds (49%), rhodopsin (45%), rom1 (49%), and GARPs (66%). Scotopic ERG showed that although rod photoreceptor a-waves were significantly reduced (50%), rod-mediated b-wave amplitudes were maintained at WT levels. Photopic ERG showed that cone-mediated responses (b-wave amplitudes) were also near-normal. No changes were detected in the number of synaptic ribbons present in rod terminals.

Conclusions: The P/rds C-terminus was found to be essential for in vivo protein stability and function for OS morphogenesis and structure. The most striking phenotype observed for the new Prph2^{Y285x/+} disease model was a robust functional compensation, which restored rod-derived signaling, likely lost as a result of OS structural damage. The new findings may reflect an example of homeostatic plasticity at the photoreceptor-bipolar cell synapse, and introduces the possibility this mechanism also applies to instances of human pattern dystrophy associated with the TYR285stop defect.

ABSTRACT BODY:

Purpose: Past studies have shown that social isolation and loneliness are risk factors for increasing mortality among older adults. Adults with vision loss and hearing loss are likely to experience greater social isolation and loneliness compared to healthy controls. During the COVID-19 pandemic, in-person interactions were discouraged due to the risk of infection, public-health messaging and governmental stay-at-home orders. This study was designed to understand the impact of the COVID-19 pandemic on the social interactions and emotional wellbeing in adults with sensory loss.

Methods: Three groups of older adults -- vision loss (N = 13, legally blind), hearing loss (N = 24, hearing-aid or cochlear-implant users), and controls (N = 18) -- were recruited from the Twin Cities Minnesota community (mean age = 68.18, range = 57 to 80). Participants were interviewed every 4 to 6 weeks from the end of April to the end of October using the same set of questions. The initial interview at the end of April included retrospective responses to the questions regarding participants' status at the beginning of March, prior to pandemic restrictions, and the beginning of April, after the onset of pandemic restrictions.

The survey questions addressed (1) demographic and health information, (2) average number of in-person and electronic social interactions per week, (3) sense of loneliness, (4) accessibility of daily services such as grocery shopping, (5) mental health, (6) worry levels about COVID infection, and (7) impact on daily activities.

Results: There was a significant decline of in-person social interactions in all three groups after the pandemic started, accompanied by a significant increase of electronic social interaction.

From late April to October, the number of in-person interactions increased in the control and hearing-loss groups but remained depressed in the vision-loss group. The number of electronic social interactions did not change significantly during this time period.

All three groups had worse scores on the patient health questionnaire (PHQ-9) after the start of the pandemic. Participants with vision loss demonstrated higher worry levels about touching things. Participants with hearing loss worried more about understanding speech from people wearing masks.

Conclusions: Our results have shown the widespread impact of the pandemic on social interactions and emotional wellbeing of older adults with sensory loss.

TITLE: Anterior Segment Ultrasound Biomicroscopy Image Analysis Correlation with Physical Eye Exam Findings

SESSION TITLE: Anterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Saga, M.R. Levin, J.L. Alexander, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|C. Martinez, W. Madigan, Children's National Hospital, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Anusha Saga: Commercial Relationship: Code N (No Commercial Relationship) | Camilo Martinez: Commercial Relationship: Code N (No Commercial Relationship) | Moran Levin: Commercial Relationship: Code N (No Commercial Relationship) | William Madigan: Commercial Relationship: Code N (No Commercial Relationship) | Janet Alexander: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal measurements obtained from the physical exam are the gold standard used to monitor the progression of pathological states (for example keratoconus and congenital glaucoma) despite the availability of newer technologies. We tested the hypothesis that structures measured from ultrasound biomicroscopy (UBM) images correlate with related physical exam findings using a prospective comparative clinical study.

Methods: Ultrasound biomicroscopy (UBM) images were obtained from a total of 181 eyes and 53 patients (mean age 6 years, +/- 12 years, median age to years) who were prospectively enrolled after consent in this study at the University of Maryland, Baltimore, Maryland. Ruler and calipers were used to measure external corneal diameter from color photograph (Figure 1a). ImageJ was used to measure angle to angle width of the anterior chamber (Figure 1b). Correlation coefficient and significance testing for eyes with and without glaucoma were performed.

Results: Preliminary data suggests a statistically significant correlation between angle to angle (AA) distance and corneal diameter in glaucoma patients ($r = 0.6$, $p = 0.007$). Correlation for non glaucoma eyes was weak ($r = -0.189$) and not significant ($p = 0.3$) (Figure 2). The linear relationship does not hold for angle to angle distances less than 10mm. Bland Altman plots were constructed to evaluate the agreement between image-based and ruler measurements.

Conclusions: This is the first study identifying relationships between physical exam findings and quantitative features extracted from UBM images in the anterior segment.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) allows morphological evaluation in the manner of an invivo biopsy, using properties of coherent light through a spectrophotometry technique. The description of abnormal findings requires a normal informational base from which qualitative and quantitative comparisons can be made. Purpose of the study is to describe the morphology of the conjunctiva of ocularly healthy individuals and to compare the thicknesses of the conjunctiva-tennon complex, by age group in a Mexican population. Therefore, establishing a normative database of morphometry of the conjunctiva by age group.

Methods: Cross-sectional study of 112 non-consecutive cases using a Cirrus 4000 OCT device (ZEISS) in the anterior segment modality of each quadrant. Measurements were done at 3 mm from the limbus of thickness of the epithelium, stroma, and the full-thickness conjunctiva, using the cube acquisition format and high resolution 5-line scan in 90 and 180 degree orientation. SPSS 25 statistical software was used for data analysis, considering significant p-value ≤ 0.05 as statistically.

Results: One hundred and twelve participants between 10 and 90 years of age were included; fourteen individuals from each 10-year cohort, of whom half were male and half were female. The mean thickness of the total superior, inferior, temporal and nasal conjunctiva was $245.30 \pm 27.20 \mu\text{m}$, $237.85 \pm 25.36 \mu\text{m}$, $239.65 \pm 27.39 \mu\text{m}$, $241.04 \pm 28.04 \mu\text{m}$, respectively. The mean upper, lower, temporal and nasal epithelial thickness was $45.28 \pm 10.48 \mu\text{m}$, $47.47 \pm 12.01 \mu\text{m}$, $45.25 \pm 11.07 \mu\text{m}$, $44.86 \pm 11.59 \mu\text{m}$, respectively. The mean superior, inferior, temporal and nasal stromal thickness were $199.5 \pm 24.23 \mu\text{m}$, $193.09 \pm 23.81 \mu\text{m}$, $194.25 \pm 26.28 \mu\text{m}$, $194.52 \pm 27.54 \mu\text{m}$, respectively. When comparing the means by cohort, a incremented thickness was evident at a younger age, presenting a significant inverse correlation between thickness and age in all quadrants (upper $r = -0.455$; lower $r = -0.463$; temporal $r = -0.438$; nasal $r = -0.475$). All such correlation were statistically significant ($p < 0.001$).

Conclusions: The conjunctiva is a surgical target and might be affected by many conditions, knowledge of the morphometry of the healthy conjunctiva allows to have a point of comparison in cases where it is modified, either by pathologies or surgical events. This study provides with a normative database in a Mexican population.

ABSTRACT BODY:

Purpose: Previous studies support that exercise could potentially be used as a neuroprotective method in patients with retinitis pigmentosa (RP) as well as in animal models of RP. The underlying molecular mechanisms of exercise-induced neuroprotection are elusive. This study investigates the neuroprotective effects of voluntary exercise on retinal structure, function and inflammatory response in an adult mouse model of autosomal dominant retinitis pigmentosa (adRP).

Methods: Adult I307N rhodopsin mice (n=25) were divided into active or inactive groups and received free-spinning or locked running wheels, respectively. After exercising for two weeks, the mice received either a 5-minute period of bright light ("BL"; 6000 lux) or natural light ("dim"; 50 lux). At one and two weeks post-BL, optomotor response (OMR) and electroretinograms (ERG) were measured. After four weeks of exercise, the mice were euthanized and eyes were enucleated for histological and multiplexed cytokine protein expression analysis.

Results: OMR revealed significantly greater spatial frequency and contrast sensitivity thresholds for the active+BL group compared to inactive+BL ($p<0.001$). Histological analysis showed a preservation of the outer nuclear layer between active+BL and inactive+BL ($p=0.007$). ERG a- and b-wave amplitudes in active+BL trended higher compared to inactive+BL, however they did not reach statistical significance ($p>0.05$). Cytokine expression profiles were different for active+BL and inactive+BL animals with trending reductions in interferon gamma-induced protein 10 (IP-10; $p=0.085$) and keratinocyte-derived chemokine (KC; $p=0.093$) in active+BL animals, which are involved in chemotactic signaling of microglia and leukocytes.

Conclusions: Our results show that voluntary exercise is protective against retinal degeneration in an adult mouse model of adRP. Exercise preserved visual function and prevented increased expression of inflammatory cytokine expression. These results suggest that exercise regimens should be assessed as a therapeutic intervention to delay progression of RP in patients.

TITLE: Naso-temporal asymmetry for global motion perception in children with deprivation amblyopia

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Chakraborty, Chicago College of Optometry, Northwestern University - Downers Grove Campus, Downers Grove, Illinois, UNITED STATES|A. Chakraborty, B. Thompson, School of Optometry and Vision Science, University of Waterloo, Waterloo, Ontario, CANADA|K.R. Kelly, E.E. Birch, Retina Foundation of the Southwest, Dallas, Texas, UNITED STATES|B. Thompson, Centre for Eye and Vision Research Limited, Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): Arijit Chakraborty: Commercial Relationship: Code N (No Commercial Relationship) | Krista Kelly: Commercial Relationship: Code N (No Commercial Relationship) | Eileen Birch: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Thompson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have reported a naso-temporal asymmetry for global motion perception, favoring nasalward motion, is present in children and adults with a history of unilateral enucleation. Deprivation amblyopia from unilateral cataract or other forms of unilateral visual impairment results in a less complete form of monocular deprivation. We investigated whether this directional asymmetry is also present in the fellow eye of children with deprivation amblyopia.

Methods: 25 children (10.33 ± 2.44 years) with deprivation amblyopia (VA: 0.5 to 1.6 logMAR) from a history of monocular visual deprivation and 30 age-matched controls (9.85 ± 3.68 years) participated in this study. Global motion perception for horizontal translation motion was measured for the fellow eye in the deprivation amblyopia group and in a random eye of the control group. Motion coherence thresholds (MCT) for nasalward and temporalward random-dot-kinematograms were measured using interleaved 2-down 1-up staircases. LogMAR visual acuity was measured by age-appropriate clinical tests.

Results: Overall, the deprivation amblyopia group exhibited a robust naso-temporal asymmetry in favor of nasalward motion (mean nasal MCT: $10.5 \pm 6\%$ vs mean temporal MCT: $17 \pm 10.5\%$, $t_{24} = 4.39$, $p < 0.001$). No such asymmetry was observed in the control participants (mean nasal MCT: $13.8 \pm 6.8\%$ vs. mean temporal MCT: $13.6 \pm 6.6\%$, $t_{29} = -0.23$, $p = 0.820$). The ratio of temporalward/nasalward MCT asymmetry was significantly higher ($t_{52} = 4.04$, $p < 0.001$) in the deprivation amblyopia group (ratio: 1.86 ± 1.10) compared with the control group (ratio: 0.99 ± 0.34). Furthermore, a linear regression revealed that intervention age, age at testing, and gender did not significantly predict the extent of motion asymmetry in the deprivation amblyopia group.

Conclusions: Naso-temporal asymmetries for global motion perception are present in the fellow eye of children with monocular deprivation. This asymmetry highlights the importance of binocular visual input for the normal development of extrastriate areas such as V5/MT+ that support motion integration. Our results are consistent with the previous reports of similar directional asymmetry in motion perception in monocular enucleation.

TITLE: Photopic electroretinograms recorded using a portable device at baseline in patients undergoing treatment for diabetic macular edema

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Maguire, O.A. Mahroo, A. Laidlaw, C.J. Hammond, Guy's and St Thomas' NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Matthew Maguire: Commercial Relationship: Code N (No Commercial Relationship) | Omar Mahroo: Commercial Relationship: Code N (No Commercial Relationship) | Alistair Laidlaw: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Hammond: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Around 25% of patients do not respond to anti-VEGF therapy for diabetic macular edema (DME). Poor response can be determined after 3 months of treatment. Early prediction of poor response might allow the timely choice of alternative treatment strategies. We prospectively recorded and analysed baseline electroretinograms (ERGs) in treatment-naïve patients treated with anti-VEGF for DME to examine for baseline predictors of poor response.

Methods: Patients were prospectively reviewed for the VIDEO trial (ISRCTN59902040). ERGs were performed using a handheld ERG device (RETeval, LKC technologies, MD USA) prior to 1st injection (baseline). Light-adapted flash and flicker stimuli were delivered corresponding to international standard. Waveforms were recorded using skin sensor electrodes affixed beneath the lower eyelid. Patients were classified as poor or good responders after 3 months. Poor response was classified on optical coherence tomography as central 1mm macular subfield thickness greater than 350 microns after 3 injections. Baseline demographics were collected and compared between groups. Only the treated eye was included from each patient.

Results: 23 patients were included for analysis. 14 eyes were classified as responders and 9 as non-responders. Baseline demographics were comparable between groups. Peak times were similar between the two groups. Mean flicker ERG amplitudes and flash a-wave and b-wave amplitudes were greater at baseline in responders, although the differences failed to reach statistical significance. For responders and no-responders respectively, mean flicker ERG amplitudes were 16.1 and 22 microvolts respectively ($p=0.13$); mean flash a-wave amplitudes were 4.9 and 6.1 microvolts respectively ($p=0.34$); mean flash b-wave amplitudes were 19.1 and 24.9 microvolts respectively ($p=0.18$).

Conclusions: Portable photopic ERG recording was rapid and well-tolerated. Eyes that went on to display poorer responses to 3 antiVEGF injections had smaller average ERG amplitudes at baseline than those that responded to treatment, but the difference did not reach statistical significance. A limitation was the small sample size, and larger studies will be able to test this with greater power.

TITLE: Assessing Outcomes in Pars Plana Vitrectomy for Epiretinal Membrane using Indocyanine Green versus Brilliant Blue

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.D. Karl, W.R. Bloom, M.P. Ohr, Department of Ophthalmology and Visual Sciences, The Ohio State University Wexner Medical Center, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Matthew Karl: Commercial Relationship: Code N (No Commercial Relationship) | William Bloom: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Ohr: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The objective of this single institution retrospective chart review study is to assess visual outcomes in patients who underwent pars plana vitrectomy with membrane peel for epiretinal membrane using indocyanine green (ICG) versus brilliant blue (BB) dye.

Methods: A retrospective chart review was performed for patients who underwent pars plana vitrectomy for epiretinal membrane between April 1, 2012 and April 1, 2020. Data collected included de-identified demographics, visual acuity (VA), and optical coherence tomography (OCT) central macular thickness (CMT) through post operative month (POM) three.

Results: 60 eyes of 60 patients were included. 23 eyes received intraoperative BB, 37 received intraoperative ICG. There was no significant difference in baseline VA or CMT. No significant difference in VA or CMT was found in patients receiving intraoperative ICG versus BB during pars plana vitrectomy for epiretinal membrane from baseline to POM three (VA: $-0.15 \pm .25$ with ICG and $-0.16 \pm .23$ with BB, $p = 0.90$; -78.8 ± 87.4 with ICG and -98.7 ± 78.4 with BB, $p = 0.36$). Patients receiving ICG had a greater improvement in VA from baseline to POM one than patients receiving BB (-0.17 ± 0.24 with ICG and -0.03 ± 0.26 with BB, $p = 0.04$), however that difference did not persist through the end of the follow up period. Results are summarized in Table 1.

Conclusions: No significant difference was found between VA or CMT in patients receiving intraoperative ICG versus BB, suggesting both of these vital dyes are safe to use during pars plana vitrectomy for epiretinal membrane removal. This study may be limited by sample size and short follow up.

ABSTRACT BODY:

Purpose:

To report the initial results of CyberKnife stereotactic body radiotherapy (SBRT) on patients with ciliochoroidal (CBCh) melanoma in our population.

Methods:

Cyberknife SBRT (Accuray, Sunnyvale, CA, USA) was offered as a therapeutic alternative to enucleation and ruthenium-106 brachytherapy. Inclusion criteria included: treatment naïve ciliochoroidal melanoma ≥ 9 mm in initial height and Stage $\geq T3$. Exclusion criteria included ecographic evidence of extrascleral tumoral extension, neovascular glaucoma and systemic metastasis. Ocular akinesia was achieved with 2.5mL of 0.75% bupivacaine retrobulbar block on two surgical times. CT/MRI fusing was performed and target volumes and structures at risks were delineated. Cyberknife radiosurgery was performed delivering a single fraction with a mean dose of 25 Gy to the 70% isodose line. Local tumor control was defined as either shrinking of the tumor or absent progression.

Results: Five patients with CBCh melanoma were treated under this protocol. Mean age was 51.4 years (range 44 - 60 years), 40% were female. Mean tumor height before treatment was 11.07 ± 1.98 mm. Mean follow-up of patients was <12 months. Three patients had serous retinal detachment associated with the tumor at presentation. All of the patients had local tumor control after a single-session radiosurgery within the follow-up period. No acute toxicity was observed, and none of the patients required enucleation during this short follow-up time.

Conclusions:

A multidisciplinary approach with Cyberknife SBRT is an effective and safe therapy for medium to large-sized CBCh melanoma. Further follow-up periods are needed to confirm these findings and to evaluate long-term ophthalmic events.

TITLE: Incidence, severity and identification of risk factors of retinopathy of prematurity in our setting.

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Duran Carrasco, A. Afonso-Rodríguez, M. Alberto-Pestano, N. Pérez-Llombet-Quintana, M. Gil-Hernández, OPHTHALMOLOGY, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Canarias, SPAIN|

Commercial Relationships Disclosure (Abstract): Oswaldo Esteban Duran Carrasco: Commercial Relationship: Code N (No Commercial Relationship) | Alberto-Manuel Afonso-Rodríguez: Commercial Relationship: Code N (No Commercial Relationship) | María-Magdalena Alberto-Pestano: Commercial Relationship: Code N (No Commercial Relationship) | Nicolás Pérez-Llombet-Quintana: Commercial Relationship: Code N (No Commercial Relationship) | María-Antonia Gil-Hernández: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) can affect the quality of life in children from early age. We determine the incidence and severity of ROP and identify associated risk factors, in 2015 – 2019 period in our area.

Methods: A descriptive and retrospective study of premature infants examined in our service from January 2015 to December 2019 was carried out. All newborns with a gestational age (GA) less than 32 weeks and / or a birth weight (BW) less than 1500 g were included, as well various risk factors (RF) that may influence the development of ROP were evaluated. Subsequently we realized statistical analysis of the data.

Results: 166 patients were evaluated, with a mean GA of 29.63 weeks and a mean BW of 1260.57 ± 322.85 gr. The incidence of ROP was 10.4% (17 patients), presenting 76.5 % of cases severe stage of ROP. we preformed laser therapy in all these cases and intravitreal ranibizumab as adjuvant treatment in 11.8 % of cases, getting complete regression of retinopathy in all patients.

The frequency of the risk factors was: O₂ therapy in 87.9%, with a mean duration time of 24.72 ± 25.34 weeks. Respiratory distress 83.7%, ductus persistence 52.9%, intracranial hemorrhage 58.8%, sepsis 76.5% and transfusion 70.6%.

The ROP group was compared with a similar newborns group, regarding GA and BW as well the use of O₂, that did not develop ROP. We only find statistically significant difference in the development of ROP comparing frequency of sepsis (OR = 4.28 CI = 1.21-15.13) and transfusions (OR = 6.5 95% CI = 1.12-37.4).

Conclusions: In our hospital, 10.4% of premature infants with risk characteristics developed ROP, 76.5% of these kids showed severe retinopathy, so treatment was applied obtaining complete ROP regression in all patients. Use of O₂ and respiratory distress have been associated RF, however only sepsis and transfusions showed significant differences in our research. According with the expectation of growth in the incidence of this pathology due mainly to the advancement of life support maneuvers employed in modern pediatrics, we must continue to apply these screening criteria in our center, because it has allowed the early detection of all cases of severe ROP in our center.

TITLE: R9-SOCS1-KIR Peptide Abrogates Lipopolysaccharide Mediated Inflammation: Implications for the Treatment of Endotoxin Induced Uveitis

SESSION TITLE: Translational Immunology and Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.M. Ahmed, Molecular Genetics and Microbiology, University of Florida, Gainesville, Florida, UNITED STATES|A.P. Patel, Florida State University, Tallahassee, Florida, UNITED STATES|A.S. Lewin, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chulbul Ahmed: Commercial Relationship(s);University of Florida:Code P (Patent) | Anil Patel: Commercial Relationship: Code N (No Commercial Relationship) | Alfred Lewin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Suppressor of Cytokines Signaling 1 (SOCS1) is a cytoplasmic protein that limits the extent and duration of inflammatory response. We have shown that a cell penetrating peptide from the kinase inhibitory region (KIR) from SOCS1 (denoted as R9-SOCS1-KIR) can dampen the signaling emanating from JAK/STAT and TLR2/4 pathways. We have examined the ability of this peptide to counteract the inflammation caused by lipopolysaccharide (LPS), which is released during an infection or from leaching of intestinal microbiota.

Methods: R9-SOCS-KIR or its inactive control peptide were tested for anti-inflammatory properties in a mouse macrophage cell line, J774A.1, used as a surrogate for microglia and treated with LPS. Induction of inflammatory markers was tested by ELISA using the supernatants from treated cells, or Western blot analysis of treated cell extracts. Activation of inflammatory transcription factors was analyzed by following their nuclear translocation. ARPE-19 cells that were differentiated by growing for 4 weeks and treated with LPS with or without R9-SOCS1-KIR were used to evaluate the integrity of tight junction protein by immunostaining and by measurement of transepithelial electrical resistance (TEER).

Results: Treatment of J774A.1 cells with LPS resulted in secretion of NO and IL-1b, which was attenuated by R9-SOCS1-KIR. Induction of inflammatory markers, cyclooxygenase 2 (COX2) and iNOS observed in cells treated with LPS was suppressed when R9-SOCS1-KIR was simultaneously present. Treatment with LPS resulted in nuclear translocation of p65, the active subunit of NF-kB and the MAP kinase p38, both of which were prevented in the presence of R9-SOCS1-KIR. Uniform distribution of Zona occludens 1 (ZO-1) along the cell membrane was disrupted and TEER reduced by treatment with LPS, both of which were prevented by R9-SOCS1-KIR.

Conclusions: Protection against inflammatory insults afforded by R9-SOCS1-KIR in a macrophage cell line and a cell line from retinal pigment epithelium suggests that it has therapeutic potential against inflammatory ocular disorders, including infection induced uveitis.

ABSTRACT BODY:

Purpose: Telehealth has a variety of proposed uses in ophthalmology and has become a valuable asset to health care in the COVID-19 pandemic. This retrospective, observational study characterizes the use of virtual visits and compares the outcomes of these visits to in-person visits during the pandemic period at a large academic institution.

Methods: 2,943 virtual and 56,174 in-person visits occurring at Cole Eye Institute, Cleveland Clinic, were identified. A random sample of 3,000 in-person visits was selected for comparison. Canceled, incomplete and duplicated visits, as well as visits for patients aged less than 18 years old were excluded. Pearson's chi-square test of independence and test of proportions were used to assess relationships between categorical variables.

Results: 2,266 virtual visits and 2,590 in-person visits were included. The visits distribution across ophthalmology specialties is summarized in table 1. 72.3% of the virtual visits resulted in a planned follow-up compared to 70.3% following an in-person visit ($p=0.121$). 15.9% of virtual patients were discharged compared to 10.8% of in-person patients ($p<0.001$). 5.6% of virtual patients were referred to a primary care doctor or different ophthalmology subspecialty compared to 6.9% in-person patients ($p=0.081$). 6.0% of the patients had an outpatient surgery scheduled after a virtual visit compared to 4.8% in-person patients ($p=0.08$). 0.2% of the virtual patients had a clinic procedure scheduled compared to 7.2% in-person patients ($p<0.001$). Loss to follow-up occurred due to cancellations (4.6% and 3.5% in the virtual and in-person visits, respectively, $p=0.11$), no shows (2.8% and 2.1%, $p=0.2$) and no schedule (10.4% and 2.3%, $p<0.001$). 84.6% of the completed follow-up visits after virtual visits were in-person and 15.4% were virtual, in comparison to 97.4% and 2.6% after an in-person encounter ($p<0.001$).

Conclusions: The similar number of follow-up, referral and outpatient surgery outcomes across virtual and in-person visits suggests that teleophthalmology is a viable alternative for patient care. Virtual follow-ups occurred more often after a virtual visit. Discharges and unscheduled follow-up visits were also more prevalent in the virtual setting, implying a higher risk of care discontinuation in this group. Further research into the applications of telehealth for ophthalmology may be beneficial.

ABSTRACT BODY:

Purpose: Neuroinflammation in the retina is a major cause of vision impairment in blinding diseases such as diabetic retinopathy (DR). Previous studies from our laboratory have shown that inhibition of spermine oxidase (SMOX, a member of polyamine oxidase family) using the pharmacological inhibitor MDL 72527 reduced neurodegeneration in models of retinal excitotoxicity and DR. Utilizing the experimental model of retinal excitotoxicity, the present study was undertaken to determine the impact of SMOX blockade in retinal neuroinflammation.

Methods: Adult mice (8-10 weeks old) were given intravitreal injections (20 nmoles) of NMDA (N-Methyl-D-aspartate) or NMLA (N-Methyl-L-aspartate, control). Intraperitoneal injections of MDL 72527 (40 mg/kg body weight/day) or vehicle (normal saline) were given to NMDA and NMLA treatment groups. Retinal flat mounts or cryostat sections were prepared for immunostaining and fresh frozen retinal samples were used for Western blotting studies. NIH Image J was used for quantitation.

Results: Immunofluorescence staining of retinal flat mounts using Iba1 (Ionized calcium-binding adaptor molecule 1) antibody was utilized to study activation of microglia. An increase in retinal microglia presenting activated morphology was observed in NMDA retinas (7 days post injury) compared to their NMLA controls. Treatment with MDL 72527 reduced this effect in the NMDA retinas. Quantification studies demonstrated that excitotoxicity-induced upregulation of Iba1 positive cells with activated morphology was significantly reduced in response to SMOX blockade (N=5, $p<0.01$). The increased protein levels of Iba1 in NMDA retinas were reduced in response to MDL 72527 treatment ($p<0.01$, N=4). Excitotoxicity-induced upregulation in the number of CD 68 (Cluster of Differentiation 68) positive cells was significantly decreased in response to SMOX inhibition (N=4, $p<0.05$, 3 days post injury). Analysis of molecular pathways revealed a significant increase in NRF2 expression in MDL 72527 treated excitotoxic retinas compared to respective vehicle group ($p<0.05$, N=3, 3 days post injury), suggesting the involvement of antioxidant signaling in response to SMOX blockade.

Conclusions: Our study suggests the critical involvement of SMOX signaling in retinal neuroinflammation thus offering a new therapeutic target for vision disorders.

ABSTRACT BODY:

Purpose: Bacterial keratitis (BK) represents a leading cause of corneal blindness worldwide. This study aimed to generate potent hybridized human-derived host defense peptides (HDPs) as novel topical antimicrobial therapy for BK.

Methods: Hybrid peptides were rationally designed through combination of functional amino acids in parent HDPs, including human cathelicidin (LL-37) and human beta-defensin (HBD)-1 to -3. Minimal inhibitory concentrations (MICs) were determined using broth microdilution method, and cytotoxicity was evaluated against human corneal epithelial cells (HCE-2) and human erythrocytes. Time- and concentration-dependent antimicrobial activity was examined using time-kill kinetics assay. In vivo safety and efficacy of the most promising peptide was examined using corneal wound healing and Staphylococcus aureus (ATCC SA29213) keratitis murine models, respectively.

Results: A second-generation hybrid peptide (HDP23) demonstrated good efficacy against methicillin-sensitive and methicillin-resistant *S. aureus* (MIC=12.5-25.0µg/ml or 5.2-10.4µM) and *S. epidermidis* (MIC=3.1-12.5µg/ml or 1.3-5.2µM), and moderate efficacy against *P. aeruginosa* (MIC=50µg/ml or 20.9µM). HDP23 (2x MIC) killed all the bacteria within 30 mins, which was 8 times faster than amikacin (20x MIC). At 200µg/ml (16x MIC), HDP23 was shown to be relatively safe against HCE-2 (<30% toxicity) and erythrocytes (<10% toxicity). Pre-clinical murine studies showed that HDP23 0.05% (500µg/ml) achieved a median reduction of *S. aureus* bacterial viability by 94% (or 1.2 log₁₀ CFU/ml) while not impeding corneal healing.

Conclusions: Rational modification of human-derived HDPs, via hybridization of LL-37 and HBD, has led to the generation of an efficacious and safe topical antimicrobial agent that has potential for treatment of Gram-positive BK in humans.

ABSTRACT BODY:

Purpose: To develop a French version of the V-FUCHS instrument and to validate its use among French-speaking patients with FECD before and after DMEK surgery.

Methods: The original V-FUCHS 15-item instrument was designed to assess visual acuity (VA) and glare in FECD patients (Wacker et al. 2018). It was translated from English to French by a professional translator and back translated to English by a second independent translator, followed by the adjustment of minor semantic dissimilarities by an English-speaking ophthalmologist. The French questionnaire was first administered at the HMR Cornea Clinic and best corrected visual acuity (BCVA), modified Krachmer grade, and straylight (C-Quant, Oculus) were measured. Four weeks later, patients received by mail a second copy of the same questionnaire to be completed at the same time as they did the first time. Construct validity, internal consistency, test-retest reliability, and predictive validity were assessed.

Results: A total of 123 French-speaking patients, aged 41 to 86 years, were recruited from July 2019 to October 2020 and classified into five groups: Mild, Moderate, or Severe FECD; Unilateral or Bilateral DMEK for FECD, and Healthy controls (n = 36). Construct validity was confirmed by infit and outfit statistics (range 0.5-1.5) from an Item-response theory model. Cronbach's alpha demonstrated excellent internal consistency for both VA ($\alpha=0.92$; 95% CI 0.9-0.94) and glare ($\alpha=0.9$; 95% CI 0.87-0.94) factors. ICCs showed good test-retest reliability for both VA (raw score: 0.725 [0.634-0.797]; latent score: 0.705 [0.622-0.772]) and glare (raw: 0.820 [0.764-0.863]; latent: 0.816 [0.759-0.860]) factors. A significant correlation was observed between the modified Krachmer grade and both the VA (raw: $r=0.585$, $p<0.001$; latent: $r=0.6232$, $p<0.001$) and glare ($r=0.609$, $p<0.001$; $r=0.605$, $p<0.001$) factors. BCVA was also correlated with both VA ($r=0.316$, $p<0.001$ and $r=0.310$, $p<0.001$) and glare ($r=0.312$, $p<0.001$ and $r=0.303$, $p<0.001$) factors. A weak but significant correlation was found between the glare factor and C-Quant measurements ($r=0.286$, $p<0.01$ and $r=0.254$, $p<0.01$).

Conclusions: The proposed French version of the V-FUCHS instrument provides a valid and reliable tool for the assessment of visual disability in Francophone patients with FECD.

ABSTRACT BODY:

Purpose: Panretinal photocoagulation (PRP) and laser barricade (LB) are both commonly complicated by epiretinal membrane (ERM) formation but there is little literature on the development of a significant ERM (SERM) that distorts the foveal contour. We performed a retrospective, single-center chart review to better characterize SERM, as seen on macular ocular coherence tomography (OCT).

Methods: Charts of patients with billing codes for retinal laser therapy from 2013 through 2019 at the Gavin Herbert Eye Institute were retrospectively reviewed. Subjects with a history of autoimmune disease, uveitis, immunosuppression during or after treatment, prior laser treatment and pars plana vitrectomy, prior intraocular infection and ocular trauma, existing ERM, and less than 1 year of follow-up and inadequate imaging were excluded. Results between laser treatment groups and by ERM severity were compared using the appropriate statistical tests.

Results: A total of 72 patients and 79 eyes met study criteria with 49 patients (68%; 26 LB and 23 PRP) and 54 eyes (68%; 28 LB and 26 PRP) developing ERM (see Table 1). Median time to ERM formation was 10.5 months overall, including 11.2 months for LB patients and 9.5 months for PRP patients ($p=0.45$). There was a statistically significant difference in median laser energy exposure between the LB and PRP groups (8.3 J to 33.2 J for the PRP group, $p<0.001$). Eleven patients and 12 eyes developed SERM over a median of 30.6 months. A total of 4 eyes with LB compared to 8 eyes with PRP developed SERM ($p=0.029$; see Table 2). Median laser energy was 8.4 J, 19.2 J, and 26.7 J among eyes with no ERM, non-SERM, and SERM, respectively. There was a statistically significant difference in median laser energy between those with no ERM and with non-SERM ($p=0.042$) and between those with no ERM and with SERM ($p=0.03$) but not between those with non-SERM and SERM ($p=0.31$). Median follow-up time was 24.9 months in patients with no ERM and 59.7 months in those with SERM ($p=0.045$).

Conclusions: Compared to eyes treated with LB, eyes with PRP were exposed to statistically significantly more laser energy and a greater proportion of PRP eyes developed SERM. Total laser energy exposure may play a role in the develop of ERM, including membranes that distort the foveal contour. However, the results must be interpreted cautiously given the significantly shorter follow-up time in patients that did not develop ERM.

ABSTRACT BODY:

Purpose: To investigate the feasibility of using anterior segment optical coherence tomography (OCT) angiography to evaluate the conjunctival and scleral vasculature.

Methods: The corneoscleral junction of the eye was imaged with a spectral-domain OCT angiography system (AngioVue, Optovue Inc., Fremont CA) operating at 840 nm wavelength and 70,000 axial-scans per second scan speed. An Angio Cornea scan pattern sized at 6 mm x 6 mm was used to image the temporal and nasal limbus of normal volunteers. The participants were instructed to rotate the eye towards the nasal side while the temporal side of the eye was scanned, and vice versa. The split-spectrum amplitude-decorrelation angiography (SSADA) technique were used to detect the blood flow. The flow projection is a prominent artifact in scleral OCT angiography due to high reflectance of the sclera. Custom software was used to resolve flow projection artifact, identify the posterior conjunctival boundary in structural OCT images, and generate the depth-resolved conjunctival and scleral angiograms.

Results: The nasal and temporal limbus of four normal eyes were imaged. Projection-resolved OCT angiography were calculated. En face OCTA of the conjunctival and scleral vascular networks were generated and delineated distinct patterns. OCT angiography of the bulbar conjunctival showed radial loop of vessels that ended at the limbus. OCT angiography of the sclera showed a dense network of no particular orientation. The OCT angiography detected a much denser vascular network including vessels not visible on the slit-lamp photo.

Conclusions: Projection-resolved OCT angiography can visualize the superficial conjunctiva vessels and the deeper episcleral and scleral vasculature separately.

ABSTRACT BODY:

Purpose: To compare nonmydriatic handheld retinal imaging with ETDRS standard 7-field 30⁰ fundus photographs (ETDRS photos) for assessment of DR and DME severity.

Methods: Following a standard imaging protocol, nonmydriatic retinal images were taken using handheld retinal cameras [Aurora(AU), Smartscope(SS), RV700(RV)] and compared to dilated ETDRS photos. Images were evaluated at a centralized reading center by 4 independent graders (2 certified graders, 1 ophthalmologist, 1 retina specialist) using the International DR/DME classification. A senior retina specialist adjudicated all differences. Kappa statistics [simple (K),weighted (KW)] assessed agreement for DR/DME. Sensitivity and specificity for any DR, referable DR [(refDR) moderate nonproliferative DR (NPDR) or worse, any DME or ungradable images] and vision threatening DR [(vtDR) severe NPDR or worse, clinically significant DME (CSME) or ungradable images] were calculated.

Results: Images from 177 eyes of 92 patients with diabetes were evaluated. Severity by ETDRS photos, DR: no DR 40.1% eyes, mild NPDR 19.2%, moderate 14.7%, severe 10.2%, and proliferative DR 15.8%; DME: No DME 72.9%, DME 6.8%, ciDME 17.0%, 3.4% ungradable. Ungradable rate for DR/DME for AU: 13.0%/15.8%; SS: 15.3%/18.1% and RV: 35.6%/36.7%. Agreement of clinical DR grading between handheld retinal and ETDRS photos are shown in table 1. Among the devices, AU (exact 58.8%; w/in 1-step 83.1%) had the highest agreement with ETDRS photos. These are higher than SS (56.5%; 80.2%) and RV (47.5%; 62.7%). Ungradable images were associated with a higher rate of refDR on corresponding ETDRS photos (AU 4.8x, SS 2.9x, RV 2.1x, p<0.0001). Table 1 shows the sensitivity/specificity for any DR, refDR and vtDR. AU, SS and RV had 71-97% specificity and 82-96% sensitivity for any DR, refDR and vtDR.

Conclusions: Despite a standardized protocol of image capture and evaluation, the ungradable rate of these devices varies from 13%-36%. In this cohort, there was a 2.1 to 4.8-fold increased risk of refDR among ungradable images. Thus, although handheld nonmydriatic retinal devices are able to achieve substantial agreement with DR in some cases, additional methods may be needed to reduce ungradable rates and appropriately triage eyes that require specialized care.

ABSTRACT BODY:

Purpose: The electronic health record (EHR) is a critical part of patient care. EHR data has potential for use in large-scale research. However, the quality of this research is reliant on accuracy of the data in the EHR. Our aim is to assess the accuracy of the EHR in capturing glaucoma patients' current ophthalmologic medication by comparing their documentation in the medication list and in progress notes.

Methods: Progress notes and medication list data from the EHR were extracted by 3 independent reviewers for encounters containing ICD codes with the word "glaucoma" at the Casey Eye Institute from 1/1/2019 to 12/31/2019. All ophthalmologic medications were included and further stratified according to type: prescription eye drops/ointment, over-the-counter (OTC) eye drops/ointment, and oral medications. For each encounter analyzed, the current medication list was manually abstracted from the progress note text and compared to the EHR medication list at the time of the encounter. A subset of 20 encounters were used to generate an analysis protocol and as cross-validation amongst reviewers (96.4% agreement).

Results: Overall, 9066 encounters met the inclusion criteria. 150 encounters were randomly selected for analysis. Prescription medications were most common (93% of encounters), followed by OTC medications (43%), and oral medications (9%). The average number of ophthalmic medications per encounter was 1.97, while the average number of discrepancies per encounter was 0.55. 57% of encounters contained some discrepancy. Prescription medications were more frequently included in the medication list but left out of the progress notes, whereas, OTC medications were more commonly mentioned in the notes, but left out of the medication lists. Overall, a large portion of encounters (26%) had 2 or more medication list discrepancies.

Conclusions: Medication discrepancies were found to be present in a large percentage of encounters. Approximately 1 in 4 medication entries had a discrepancy between the medication list and the note. These findings demonstrate significant inconsistencies in the EHR medication records, which may affect research that uses this data. There is opportunity for improving the accuracy of medication documentation in the EHR which could have benefits for both research as well as clinical care.

TITLE: Real-Time In Vivo Assessment of Retinal Reattachment in Humans using Swept-Source Optical Coherence Tomography

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Bansal, W. Lee, T. Felfeli, R.H. Muni, Ophthalmology, St Michael's Hospital, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Aditya Bansal: Commercial Relationship: Code N (No Commercial Relationship) | Wei Wei Lee: Commercial Relationship: Code N (No Commercial Relationship) | Tina Felfeli: Commercial Relationship: Code N (No Commercial Relationship) | Rajeev Muni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the physiology of retinal reattachment in humans using swept-source optical coherence tomography (SS-OCT) in real-time.

Methods: A prospective cohort study of consecutive patients with fovea-involving rhegmatogenous retinal detachment undergoing pneumatic retinopexy (PnR). SS-OCT was performed at presentation and every 2 hours for the first six hours, at day 1, 2, 5, and at week 1, 2, 4, and 6 after PnR. The outcome was defined as the longitudinal assessment of early post-operative SS-OCT findings to determine the stages of retinal reattachment.

Results: Fifteen eyes of 15 consecutive patients were included. All 15 patients (100%) achieved successful retinal reattachment with PnR. Reattachment occurred in five specific reproducible stages based on SS-OCT findings: Stage 1, defined as a redistribution of fluid and approach of the neurosensory retina towards the retinal pigment epithelium (RPE) occurred in 100% (15/15) of patients (Fig 1B, Fig 2B). Stage 2, characterized by a reduction in cystoid macular edema and improvement of outer retinal corrugations was also achieved in 100% (15/15) of patients (Fig 1C&D, Fig 2C). Stage 3, defined by the initial contact of the neurosensory retina to the RPE occurred completely in 66.7% (10/15) and incompletely in 33.3% (5/15) of patients (Fig 1E, Fig 2D). Stage 4, defined as a deturgescence of the inner and outer segments of the photoreceptors occurred completely in 66.7% (10/15) of patients (Fig 1F, Fig 2E). Stage 5, characterized by recovery of photoreceptor integrity occurred in three specific sub-stages, 5A: external limiting membrane (ELM) recovery (10/15, 66.6%) (Fig 2F), 5B: ellipsoid zone (EZ) recovery (7/15, 46.6%) (Fig 2G), 5C: interdigitation zone (IDZ)/foveal bulge recovery (3/15, 20%) (Fig 1G, Fig 2H). 20% (3/15) of patients had delayed progression through Stage 2 which led to the formation of outer retinal folds (Fig 2I). Similarly, 33.3% (5/15) of patients had delayed progression to Stage 3 and developed residual subfoveal fluid blebs (Fig 2J).

Conclusions: This study characterizes the in vivo physiology of retinal reattachment in humans using high-resolution SS-OCT. The reattachment process occurs in five specific and reproducible stages and delayed progression through certain stages can lead to post-operative anatomic abnormalities such as outer retinal folds and residual subfoveal fluid blebs.

TITLE: Mouse breeding strategies for successful preclinical studies

SESSION TITLE: Gene editing and ocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Mirjalili Mohanna, A.J. Korecki, E.M. Simpson, Centre for Molecular Medicine and Therapeutics at British Columbia Children's Hospital, Vancouver, British Columbia, CANADA|S. Mirjalili Mohanna, E.M. Simpson, Medical Genetics, The University of British Columbia, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure (Abstract): Seyedeh Zeinab Mirjalili Mohanna: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Korecki: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Simpson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Well-designed animal studies are critical for establishing the safety and efficacy of ocular gene therapies or drugs prior to clinical trial. Mice have been widely used as a mammalian model in preclinical studies due to their physiological and genetic similarities to humans, relative ease of breeding, and short generation time. Aniridia is a rare congenital blindness with unmet therapeutic needs, which is caused by mutations in the PAX6 gene. Here we will highlight the importance of breeding strategies for successful preclinical studies using cohorts of Pax6 mutant mice as an example.

Methods: First generation hybrid mice are a good choice for therapy development as they are genetically identical, but carry genomic polymorphisms as does the human population. To generate a cohort of age-matched mice with significant statistical power, 8 129S1/SvImJ Pax6 mutant (MMRRC #050624-MU) male studs were chosen based on age (>6 weeks, <8 months) and experienced (5 days of mating with a surplus female followed by 5 days of rest). 8 C57BL/6J ROSA-stop-tdTomato (JAX #007914) females were crowded (group housed in a single cage for 8-10 days prior to mating to suppress estrus cycle). To increase the rate of pregnancy, mice were mated in pairs. After one week, females were removed and singly housed in a fresh cage. Cages were checked (by looking from outside the cage to minimize stress) for births daily 18-27 days after the mating. This breeding strategy was used monthly to generate cohorts. Investigator blinding was not possible during the breeding and treatment due to the phenotype of the Pax6 mutant mice, but it was practiced during assessment of outcome (histological analysis) to minimize bias and maximize result validity.

Results: We have used this breeding strategy 9 times to successfully generate 52 ± 8 (MEAN \pm SD) age-matched (\pm 3.5 days) mice per cohort. The following breeding colony size will help investigators calculate financial costs for generating a single experimental cohort of mice. 8 singly housed studs, and 8 single breeding cages were required to generate the experimental cohorts. With a maximum of 5 adult mice per single cage, 10-12 cages were allocated to weans from each cohort.

Conclusions: We demonstrated the practicality of the suggested breeding strategy by generating age-matched reporter mice in an efficient and timely manner. We have also offered investigators insight on space requirements to generate these mice.

ABSTRACT BODY:

Purpose: The aim of this study is to assess the impact of varying optical zone diameters of multifocal lenses used for myopia management by measuring their effects on the choroidal volume.

Methods: This is a prospective study made on 18 myopes (14 F; 4 M, -2.18D), randomly fitted with customized bifocal contact lenses with different distance zone diameters (L1: 2.3 mm, L2: 4 mm, L3: 7 mm, same peripheral add power of +10D). Visual demand, activities and food intake were controlled. Choroidal thickness was measured using OCT at baseline (no lens) and after 45 minutes of wear. A 15-min washout was observed between measurements. Choroidal volume variation was estimated through computer analysis. (Matlab).

Results: Choroidal volume changes were noticeable with each lens from baseline (L1: +1.25% \pm 7.04 L2: -2.55% \pm 3.98 L3: -7.74% \pm 7.66), with an increase in the choroidal volume only for the smaller distance zone diameter. Significant difference was found between L1 and L3 ($p=0.003$), and between L2 and L3 ($p=0.045$). The choroidal volume response in the central 1X1 mm zone varied for each lense (L1: max= +12.54 mm³ , min= -17.37 mm³ ; L2: max= +11.62 mm³ , min= -15.83 mm³ ; L3: max= +6.95 mm³ , min=-12.46 mm³).

Conclusions: The results of this study indicate that a reduced optical zone diameter is more effective in increasing the choroidal volume. Future work is needed to determine the impact to rely on smaller diameters for myopia control.

TITLE: Growth characteristics of primary human corneal endothelial cells (HCEnC) at ambient and 2.5% oxygen

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Floss, C.F. Mueller, M. Sousa, S.P. Patel, Ophthalmology, University at Buffalo School of Medicine and Biomedical Sciences, Buffalo, New York, UNITED STATES|M. Sousa, Research Service, VA Western New York Healthcare System Buffalo VA Medical Center, Buffalo, New York, UNITED STATES|S.P. Patel, Ophthalmology and Research Service, VA Western New York Healthcare System Buffalo VA Medical Center, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jamie Floss: Commercial Relationship: Code N (No Commercial Relationship) | Christian Mueller: Commercial Relationship: Code N (No Commercial Relationship) | Maria Sousa: Commercial Relationship: Code N (No Commercial Relationship) | Sangita Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The corneal endothelium in vivo is exposed to approximately 2.5% O₂ ([O₂]_{2.5}) while standard culture conditions with ambient air expose HCEnC to ~18% O₂ ([O₂]_A). Oxidative stress is known to contribute to corneal endothelial disease. The purpose of this study was to evaluate the effects of [O₂]_A and [O₂]_{2.5} on the growth of primary HCEnC cultures. We hypothesized the physiologic condition of [O₂]_{2.5} would be more favorable to growth of HCEnC than [O₂]_A.

Methods: Protocols were approved by the Univ at Buffalo and VA IRBs. Human donor eyes were enucleated within 16 hrs of death and used immediately for cultures. Dissociated HCEncs from each cornea were distributed into 96-well format culture plates; one plate at [O₂]_A and another in an environmental chamber at [O₂]_{2.5} (2.5% O₂, 5% CO₂, balance N₂; Billups-Rothenberg, Inc., Del Mar, CA). Following 10-14 days of growth in complete medium, cells were matured for 10-14 days in basal medium. Nuclei were stained with DAPI and digital fluorescence images acquired for cell count analysis (ImageJ, NIH) with conversion to cells/mm² (endothelial cell density; ECD) based upon growth area. Positive cell growth for each well was considered ECD>50 cells/mm². We compared mean ECD under each condition with two tailed Student's t-tests and compared percentage of wells with growth under each analysis condition with two tailed Fisher exact tests with statistical significance at p<0.05.

Results: We analyzed 34 corneas from 20 donors (mean age 72 yrs; range 36-98 yrs; 16 female corneas; 18 pseudophakic corneas). Percentage of wells with growth were greater at [O₂]_{2.5} vs [O₂]_A overall and notably in corneas from pseudophakic eyes but did not reach statistical significance (Table). Of the wells with growth, there were no significant differences in ECD between [O₂]_A and [O₂]_{2.5} overall or when compared by age or lens status.

Conclusions: Our results suggest that [O₂]_{2.5} is more favorable for initiating HCEnC growth than [O₂]_A but does not result in increased ECD. The favorable effects of [O₂]_{2.5} on growth were most apparent with pseudophakic donors which may reflect increased cell stress in these donor corneas, relieved by culture under physiologic O₂ conditions. These findings contribute to our understanding of culture conditions to optimize HCEnC expansion for in vitro study or transplantation.

TITLE: Can EHR Data Automatically Calculate Ophthalmic Quality Measures?

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Hribar, Medical Informatics & Clinical Epidemiology, Oregon Health & Science University School of Medicine, Portland, Oregon, UNITED STATES|M. Hribar, J.S. Chen, A. Chen, Ophthalmology, Oregon Health & Science University School of Medicine, Portland, Oregon, UNITED STATES|M.F. Chiang, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michelle Hribar: Commercial Relationship: Code N (No Commercial Relationship) | Jimmy Chen: Commercial Relationship: Code N (No Commercial Relationship) | Aiyin Chen: Commercial Relationship: Code N (No Commercial Relationship) | Michael Chiang: Commercial Relationship(s);Genentech:Code F (Financial Support);Novartis:Code C (Consultant);InTeleretina LLC:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: Meeting quality measures (QM) is an important for ophthalmic care and reimbursement. QMs use data recorded in the electronic health record (EHR); ideally they are calculated using automated data queries. The quality of EHR data can limit this automatic calculation and require manual chart review for full measure determination. This study examines the ability of EHRs to adequately capture necessary clinical data to calculate QMs.

Methods: Thirty ophthalmic QMs developed by the American Academy of Ophthalmology were assessed for required data elements by reviewing published specifications. The location of each data element was determined in our institution's EHR (Epic, Verona, WI). Challenges for each of the data elements were noted by manually reviewing samples of each data element.

Results: We found 15 categories of data elements in the ophthalmic exam, imaging, visit/procedure, and patient data. Most/all of the QMs used patient age, and procedure & diagnosis codes that were easily extracted. Nevertheless, lack of specificity in diagnosis code data and incomplete problem lists made patient identification for some QMs difficult. Exam data was frequently used; most were stored in free-text fields and needed text processing (e.g. extracting and converting Snellen visual acuity fields to LogMar scale) but non-standard entries were impossible to automatically process (i.e. text instead of numeric data). Two elements were only in notes and required natural language processing (NLP): lid position and marginal reflex distance. Similarly, data from OCT and visual field imaging were in free-text fields and notes; these, too, required additional processing. Finally, patient medications were easily extracted from lists, which were often not complete and required NLP or manual review of notes. In summary, for the study EHR, most measures required text processing or NLP and over half of the measures would require manual review if medication or problem lists were not complete.

Conclusions: The study EHR was unable to capture and report most data elements important for ophthalmic clinical care, quality measure calculation, and research without customization. Generalizability of these results to other EHRs merits studying. Ultimately, tools for automatically extracting this data, as well as improvements and standardization in EHR design and use are required to address this problem.

TITLE: Intraocular Pressure (IOP) Performance with 27-Gauge Dual-Cutting 20,000cpm Beveled Vitrectomy Probes

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Zhu, Alcon Laboratories Inc, Lake Forest, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ying Zhu: Commercial Relationship(s);Alcon:Code E (Employment)

ABSTRACT BODY:

Purpose: As IOP maintenance during vitrectomy surgery is a critical parameter, this study aims to 1) understand the IOP performance of 27+® Gauge (Ga) dual-cutting, 20K cuts per minute (cpm) beveled vitrectomy probes under different system settings, and 2) help surgeons to optimize their system settings during surgery.

Methods: 27+® HYPERVIT® beveled 20K cpm vitrectomy probes were driven by a CONSTELLATION® Vision System (Alcon Vision, LLC.) to aspirate sterile irrigating solution (BSS®) in a hollow acrylic eye model. A digital transducer (OMEGA, PX409-001GUSBH) was connected to the bottom of eye model to detect IOP change during aspiration. Six samples were tested under core duty cycle and vacuums of 250mmHg, 450mmHg and 650mmHg. Cut rate ranged from 2500cpm to 20,000cpm. Both system IOP compensation enabled and disabled were used. Average IOP during aspiration was calculated for each test setting and statistical analyses were performed using Kruskal-Wallis test with statistical significance level of $p < 0.05$.

Results: At 450mmHg, without IOP compensation, the IOP ranged from 15.46 ± 0.33 to 15.62 ± 0.33 mmHg when the cut rate changed from 2500cpm to maximum cut rate of 20,000cpm. When IOP compensation was enabled, IOP ranged from 28.21 ± 1.74 to 28.43 ± 1.71 mmHg for cut rate from 2500cpm to 20,000cpm. Statistical analysis indicated that there was no significant difference between results using various cut rate for both IOP compensation enabled and disabled ($p > 0.05$). At the maximum cut rate and without IOP compensation, IOP was 22.81 ± 0.37 mmHg under 250mmHg, 15.62 ± 0.33 mmHg under 450mmHg and 8.33 ± 0.32 mmHg under 650mmHg. Corresponding average flow rate was 3.23 ± 0.1 cc/min under 250mmHg, 5.57 ± 0.17 cc/min under 450mmHg and 7.46 ± 0.27 cc/min under 650mmHg. When IOP compensation was enabled, IOP at maximum cut rate significantly increased to 29.24 ± 0.75 mmHg (28% improvement) for 250mmHg, 28.43 ± 1.71 mmHg (82% improvement) for 450mmHg and 27.42 ± 2.64 mmHg (229% improvement) for 650mmHg compared with result without system's intervention ($p < 0.05$).

Conclusions: 27+® Ga Dual-Cutting 20Kcpm vitrectomy probes have constant IOP performance under different cut rates. IOP ranges during aspiration are improved with IOP compensation enabled. Using 27+® Ga 20K cpm vitrectomy probe and IOP compensation can help surgeons use different operation settings to attain a controllable and efficient process.

TITLE: Optimal timing for surgical repair of macula-involving rhegmatogenous retinal detachment

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Xu, Midwestern University Arizona College of Osteopathic Medicine, Glendale, Arizona, UNITED STATES|C. Yee, C.J. Flaxel, Oregon Health & Science University, Portland, Oregon, UNITED STATES|K. Traustason, Orion Eye Institute, Redmond, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): David Xu: Commercial Relationship: Code N (No Commercial Relationship) | Claudine Yee: Commercial Relationship: Code N (No Commercial Relationship) | Kristine Traustason: Commercial Relationship: Code N (No Commercial Relationship) | Christina Flaxel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the effect of time to surgical repair on post-operative visual acuity in order to establish an evidence-based standard of care for the repair of macula-involving rhegmatogenous retinal detachment.

Methods: Retrospective chart review was conducted for patients who underwent surgical repair of a macula-involving rhegmatogenous retinal detachment at two ophthalmology services from 2008 to 2019. Exclusion criteria were post-operative best corrected visual acuity (BCVA) worse than 20/30 before detachment, recurrent detachments, and patients without adequate follow-up. Multivariate linear and logistic regression models were constructed using eyes with a known duration of macular detachment. The primary outcome measure was post-operative BCVA as dependent on duration of macular detachment.

Results:

Three hundred forty eyes from 340 patients met inclusion criteria; 277 eyes had a known duration of macular detachment and were included in linear and logistic regression models. Surgical repair occurred an average of 7.5 ± 8.8 days following macular detachment (range 0 to 76). Mean post-operative BCVA was logMAR 0.15 (95% CI, 0.13 to 0.18) in eyes with 3 or fewer days of macular detachment, and mean post-operative BCVA was logMAR 0.28 in eyes with 4 or more days of macular detachment (95% CI, 0.24 to 0.33; difference, logMAR -0.13 ; $P < 0.001$). Post-operative BCVA increased by 0.007 logMAR units with each additional day of macular detachment ($P < 0.001$). One hundred of 108 eyes (92.6%) that underwent surgical repair within 3 days of macular detachment had post-operative BCVA of logMAR 0.30 or better (Snellen 20/40), compared to 123 of 169 eyes (72.8%) who had surgical repair after 4 or more days of macular detachment (OR 0.21; 95% CI, 0.097 to 0.474; $P < 0.001$). For each additional day of macular detachment, the odds of achieving logMAR 0.30 decreased by a factor of 0.93 (95% CI, 0.89 to 0.96; $P < 0.001$). Pre-operative vision and duration of macular detachment were associated with post-operative BCVA; patient age, surgical eye, and lens status did not significantly affect post-operative BCVA.

Conclusions: Longer duration between macular detachment and repair is associated with a progressive decline of post-operative visual acuity. Surgical repair within 3 days of macular detachment improves visual acuity outcomes and should be the standard of care for macula-involving rhegmatogenous retinal detachments.

TITLE: Interleukin (IL)-27 regulates corneal immunopathology and viral clearance during herpes simplex virus-1 (HSV) infection

SESSION TITLE: Corneal Immunology and T cell Responses

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F. Antony, M. Sandey, A. Mishra, A. Suryawanshi, Pathobiology, Auburn University, Auburn, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ferrin Antony: Commercial Relationship: Code N (No Commercial Relationship) | Maninder Sandey: Commercial Relationship: Code N (No Commercial Relationship) | Amarjit Mishra: Commercial Relationship: Code N (No Commercial Relationship) | Amol Suryawanshi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: HSV induced stromal keratitis (SK) is one of the leading causes of infectious blindness in the world. Although the role of inflammatory cytokines is well defined in SK, the role of a regulatory cytokine IL-27 has not been explored yet. In this study, using murine model of SK, we investigated the role of IL-27 response in cornea after HSV infection. Further, we explored IL-27- mediated regulation of inflammation and antiviral responses during corneal HSV infection.

Methods: IL-27RKO and C57BL/6NJ mice were ocularly infected with HSV. Eye swabs were collected on days 1, 3 and 5 post-infection (pi) for viral titration. The progression of SK lesions were scored on days 8, 11 and 14 pi. Further, the infiltration of neutrophils, macrophages and effector T cells in cornea, lymph node and spleen were analyzed on days 2 and 15 pi. Additionally, bone marrow-derived macrophages from IL-27RKO and C57BL/6NJ mice were cultured ex vivo to investigate IL-27 mediated anti-inflammatory and antiviral responses.

Results: Our data suggested an increased IL-27 production after corneal HSV infection which is mainly produced by dendritic cells and macrophages. In addition, IL-27RKO mice showed significantly increased SK pathology compared to control animals. The increased SK severity in IL-27RKO mice was mainly driven by enhanced migration of neutrophils, macrophages and Th1 cells to cornea. Mechanistically, IL-27 mediated signaling is critical for induction of type-1 interferon (IFN) responses by macrophages after HSV infection. In accordance, we observed significantly higher viral load in the corneas of IL-27RKO mice when compared to the control mice. Further, when stimulated with HSV our data showed reduced IFN- β production and increased viral titers in IL-27RKO macrophages.

Conclusions: Our data indicate that increased IL-27 response is critical for optimum production of IFN- β by macrophages and thus viral clearance. Further IL-27 plays a regulatory role during SK pathology by modulating Th1 cell differentiation and migration. Collectively, our results indicate that modulating IL-27-mediated responses may represent a useful therapeutic approach to control viral replication and inflammation during HSV induced SK pathology.

TITLE: Social Determinants of Health in Diabetic Retinopathy in the US: Evidence from the National Health and Nutrition Examination Survey (2005-2008)

SESSION TITLE: Diabetic Retinopathy Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.H. Nwanyanwu, J. Andoh, E. Chen, Y. Xu, Y. Deng, Yale University, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kristen Nwanyanwu: Commercial Relationship: Code N (No Commercial Relationship) | Joana Andoh: Commercial Relationship: Code N (No Commercial Relationship) | Evan Chen: Commercial Relationship: Code N (No Commercial Relationship) | Yunshan Xu: Commercial Relationship: Code N (No Commercial Relationship) | Yanhong Deng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of preventable blindness. According to Healthy People 2020, five key areas of social determinants of health (SDH) are: social and community context (which includes racial discrimination), education, economic stability, neighborhood and the built environment, and health and healthcare. This study defines a novel set of variables formulated from the National Health and Nutrition Examination Survey (NHANES) and identifies the SDH associated with DR.

Methods: Our NHANES analysis included participants with and without diabetes (HbA1c>6.5% or self-reported), ages 40 years or older with available fundus photography. We compared those with DR to participants with diabetes without DR. We also compared those with DR to the rest of the cohort. Covariates included sociodemographic factors and other SDH variables identified or calculated based on literature review: Depression screening (PHQ-9), Social Support Index, Food Insecurity, and Household crowding. Rao-Scott Chi-Square test was used for categorical variables and t-test was used for continuous variables, with consideration of the survey design.

Results: Among the total 5,399 (weighted 107.6M) participants over age 40 with fundus photography, there were 315 (weighted 4.0M) participants with DR and 692 (weighted 10.3M) participants with diabetes (Table 1). Among those with diabetes, DR was more prevalent in Black, Mexican-American, and Other Hispanic participants ($p=0.0022$). There were no other statistically significant differences in the SDH between those with DR and those with diabetes without DR. When compared to the entire cohort without DR (Table 2), DR was more prevalent in these sociodemographic categories: Black, Mexican-American, and Other Hispanic participants, born in Mexico, less formal education, lower household income (all $p<0.05$). DR was also more prevalent in these other SDH variables: Spanish primary language, food insecurity, no routine place for healthcare, fewer rooms in homes, fewer close friends, and higher depression scores (all $p<0.05$).

Conclusions: Among participants with diabetes, racial discrimination was the only SDH more prevalent DR. SDH variables were more prevalent in participants with DR compared to the overall population. Interventions that include SDH modification may contribute to a decrease in blindness from DR.

Kirby Center for Molecular Ophthalmology, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Shuo Huang: Commercial Relationship: Code N (No Commercial Relationship) | Chi-Hsiu Liu: Commercial Relationship: Code N (No Commercial Relationship) | Zhongxiao Wang: Commercial Relationship: Code N (No Commercial Relationship) | Zhongjie Fu: Commercial Relationship: Code N (No Commercial Relationship) | William Britton: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Blomfield: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Dunaief: Commercial Relationship: Code N (No Commercial Relationship) | Jing Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) dysfunction and atrophy occur in dry age-related macular degeneration (AMD) and are associated with chronic oxidative stress. Previously, we found that systemic deficiency of nuclear receptor REV-ERB α , a redox-sensitive transcription factor, results in RPE dysfunction and degeneration in mice due to dysregulation of the oxidative stress response in RPE. Here we investigated if RPE-specific knockout of REV-ERB α is sufficient to induce RPE degeneration in mice.

Methods: Mice with RPE-specific deletion of REV-ERB α , BEST1-cre:Rev-erba^{fl/fl} (RPE-KO), was generated by breeding Rev-erba^{flox/flox} (fl/fl) mice with BEST1-cre (cre) mice, with both fl/fl and cre mice as controls. Knockout efficiency and specificity of REV-ERB α in RPE were measured by RT-qPCR, Western blot, and immunostaining of RPE/choroid flat mounts and cross-sections. RPE degeneration of fl/fl (n=4), cre (n=5) and RPE-KO (n=7) mice were monitored by fundus imaging at 3, 6 and 9 months old, and sub-retinal lesions were quantified. RPE atrophy was analyzed by immunostaining of RPE/choroid flat-mounts. RNA and protein expression of REV-ERB α target genes including antioxidant regulators and enzymes was examined in fl/fl and RPE-KO RPE. Oxidative DNA damage was evaluated by immunostaining of 8-hydroxy-2'deoxyguanosine (8-OHdG).

Results: REV-ERB α knockout was specific to RPE cells in RPE-KO mice with up to 80% efficiency in cell counting and mRNA and protein levels. Fundus imaging of RPE-KO mice showed significantly greater number of whitish yellow lesions at both 6- and 9-month-old, compared to both fl/fl and cre controls. In addition, RPE-KO mice showed more severely distorted RPE patches in flat-mounts by immunostaining of β -Catenin, compared with cre controls. Significant downregulation of NRF2 and its target genes Sod1, Sod2 and Catalase was found in RPE-KO vs. fl/fl RPE at both mRNA and protein levels. Furthermore, RPE-KO mice exhibit elevated oxidative stress with 8-OHdG staining, compared to cre RPE at 6 months old.

Conclusions: These findings suggest that RPE specific depletion of REV-ERB α leads to fundus lesions and RPE degeneration similar to those in systemic REV-ERB α knockout mice, demonstrating an RPE cell-autonomous role of REV-ERB α in regulating RPE function and health, potentially through modulating NRF2 transcription and antioxidant self-defense.

ABSTRACT BODY:

Purpose: Since the beginning of the COVID-19 pandemic, news related to the pandemic have created a feeling of fear, particularly among high-risk groups including elderly patients. We performed a prospective, cross-sectional study to assess the fear associated with COVID-19 and the fear of vision decrease related to the delay of treatment in neovascular age related macular degeneration patients (nAMD) during the pandemic.

Methods: 160 actively treated nAMD patients were enrolled between September to November 2020 in a tertiary university hospital in Québec, Canada. Exclusion criteria included: patients with memory disorders and patients with incomplete questionnaire. For each participant, demographic and clinical data were collected. The fear was rated in a questionnaire composed of two sections: the Fear of COVID-19 Scale (FCV-19S) and eight additional questions to assess ophthalmology-related COVID-19 statements. A multivariate linear regression model was built for FCV-19S score and a multivariable ordinal regression model for ophthalmology-related statements.

Results: The mean level of FCV-19S was 17.05 ± 4.38 . In the multivariate analysis, it was significantly higher in women ($p < 0.001$) and patients with elementary school level (compared to high school education level) ($p = 0.009$). In the ophthalmology-related statements, 16% of patients feared vision loss because of difficulties in maintaining regular follow-ups during the pandemic. The female gender was significantly associated with a higher tendency to postpone their appointment ($p = 0.03$) and to prefer "sacrificing" their vision to avoid contracting COVID-19 ($p = 0.05$). No association was found between the patients' underlying nAMD characteristics (visual acuity, bilaterality, duration) and higher fear of vision loss.

Conclusions: Despite the massive impact the pandemic has had on our functioning in most aspects of life, the anxiety related to COVID-19 and delaying ophthalmology treatments remained relatively low in nAMD patients. Greater explanations to address this fear may reduce anxiety level, especially among female patients and those with an elementary school education level.

Commercial Relationships Disclosure (Abstract): Alexander Laskaris: Commercial Relationship: Code N (No Commercial Relationship) | Prisca Bustamante: Commercial Relationship: Code N (No Commercial Relationship) | Thupten Tsering: Commercial Relationship: Code N (No Commercial Relationship) | Christina Mastromonaco: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Coblenz: Commercial Relationship: Code N (No Commercial Relationship) | Julia Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is often asymptomatic and well controlled; unfortunately 50% of patients develop metastasis plummeting survival to 15%. There is an urgency to identify mechanisms by which these melanocytic tumors are disseminating. Recent studies have focused on extracellular vesicles (EVs); biomolecule containing nanoparticles with propensity to mediate metastasis. We have previously shown UM cell line-derived EVs can induce oncogenic transformation in fibroblasts, resulting in tumor formation in vivo. Further, our group has characterized proteomic profiles of EVs from UM cell lines. The purpose of this study was to characterize EV proteomic profiles in a rabbit model of human UM. In addition, through species classification of EV protein content, to differentiate tumor originating proteins from homeostatic EV proteins.

Methods: Peripheral blood was obtained from 7 rabbits inoculated intraocularly with human UM cells (line 92.1) in a 20-week animal model. EVs were isolated by differential ultracentrifugation from rabbit plasma at week 0 and week following tumor (weeks 10+). Confirmation of EV yield was demonstrated by nanoparticle tracking analysis (NTA). EV proteins were isolated and subjected to mass spectrometry analysis. Raw proteomics data was matched against rabbit and human databases then loaded into Q+ Scaffold_4.4.8 software for visualization, statistical comparison and quantification.

Results: NTA data confirmed presence of EVs ranging in size of 165-210nm. EV protein concentrations showed an increase in protein content correlating with increased tumor size. Statistical analysis in scaffold highlighted significant differences in human and rabbit protein profiles between week 0 and weeks 10+ in all rabbits. Lists of differentially expressed human and rabbit proteins were compiled separately, referenced against literature and loaded into DAVID Bioinformatics database for functional gene ontology analysis. Interestingly, trends seen in human proteins were mirrored by their rabbit homologs.

Conclusions: Here we provided a unique insight into primary UM derived EVs through a rabbit model. Furthermore, the data suggests rabbit host EV compositions may be influenced and adapting to primary UM. This experimental model proves promising for future assessments of primary UM EV contents with hopes to eventually broaden our understanding of metastasis.

ABSTRACT BODY:

Purpose: LCHADD is an early-onset autosomal recessive fatty acid metabolism disorder due to mutations in HADHA, the LCHAD Trifunctional Multienzyme Complex Alpha Subunit gene, associated with progressive vision loss. Due to high early mortality, previous studies focused mostly on very young patients. Herein, we characterized 4 LCHADD patients in the second to third decade.

Methods: We retrospectively evaluated the records of 4 genetically and biochemically confirmed LCHADD patients (3M/1F; ages 13-21yo) with complete eye exams inclusive of ETDRS acuity, kinetic perimetry, full-field flash (ff)ERGs, multi-focal (mf)ERGs, electrooculograms (EOG), spectral domain (SD)-OCT, wide-field fundus autofluorescence (WF-FAF), fluorescein angiography, and color photography.

Results: According to the classification proposed by Tyni et al. (1998), 1 case was stage 2 OU, 2 cases were stage 3 OU, and 1 case progressed from stage 3 to 4 in OD and stage 2 to 3 in OS over a 7-year period. Mean visual acuity was 20/60 (range 20/20 – 20/400). All cases had central/paracentral scotomas and progressive central choroidal and retinal pigment epithelium (RPE) atrophy. The widespread RPE atrophy presented as nummular, coalescent hypo-autofluorescent patches with peripheral sparing on WF-FAF. SD-OCTs showed ellipsoid zone (EZ) loss with outer retinal tubulations, subretinal hyperreflective material, ectatic lesions, RPE loss with marked hypertransmission defects, and severe choroidal thinning. Consistent with the widespread RPE disease, EOG Arden ratios ranged from borderline low (1.67) with severe light peak delays to markedly reduced (≤ 1.48). ffERGs ranged from normal to moderate reductions and delays in rod and cone responses, with disproportionately reduced a-waves and increased b/a-wave ratios, consistent with prevailing outer retinopathy. mfERGs showed either severe generalized or patchy response density depression, consistent with markedly reduced macular cone function.

Conclusions: LCHADD exhibits choroideremia-like progressive features primarily affecting the RPE, choroid, and photoreceptors, beginning in the posterior pole with eventual foveal and progressive coloboma-like macular lesions and centrifugal involvement. Our report adds new mfERG and EOG data in a series of older patients, improving our understanding of the pathophysiology and characteristics of later-stage LCHADD.

TITLE: Perceptual Learning of Hue Discrimination in Jewelry Appraisers

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Lovell, J.C. Rabin, Rosenberg School of Optometry, University of the Incarnate Word, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Julie Lovell: Commercial Relationship: Code N (No Commercial Relationship) | Jeff Rabin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Perceptual learning can improve visual acuity, contrast sensitivity, vernier acuity and stereo-acuity in adult amblyopes beyond the critical period for visual development. Latent neural connections and/or development of new connections may underlie these improvements, coupled with the relative balance of excitatory and inhibitory neurotransmitters. Recently we reported superior hue discrimination in largely elderly jewelry appraisers who must discriminate subtle changes in hue to ensure optimal gemstone valuation. We report that the basis for this enhancement depends on M and S cones.

Methods: Jewelry appraisers (n=18, mean 57 ± 12 YO) undergoing color vision certification on the FM 100 hue test in accord with the National Association of Jewelry Appraisers (NAJA) were invited to participate in a study to assess performance on the Ishihara (to rule out hereditary color deficiency), FM-100 Hue (currently used by NAJA), desaturated D15 and the cone contrast test (Innova Systems, Inc) which quantifies L, M and S cone contrast sensitivity (CS). Subjects provided written informed consent for our IRB approved protocol.

Results: All subjects passed the Ishihara and desaturated D15 tests confirming normal color vision. Combined M and S cone CCT scores were predictive of FM 100 Hue total error score (TES; $F = 7.76$, $P < .02$, $r^2 = .45$). 17 of 18 subjects had 100 Hue TES scores which were >2SD below age-matched normal means indicating enhanced hue performance. Partial TES analysis revealed error rates were greatest on the blue-yellow (BY) axis.

Conclusions: Elderly jewelry appraisers show enhanced hue discrimination due to a highly practiced, reward-based repetition—tenets of perceptual learning. Correlation between M and S CCT and FM Hue scores suggests greater importance of M and S cone hue discrimination and CS for accurate gemstone discrimination. This is evident in Fig. 1 which shows perception of a highly valued gemstone (<https://www.thepearlsource.com/blog/most-valuable-gemstones/>) in normal, protan, deutan and tritan views (<https://www.color-blindness.com/coblis-color-blindness-simulator/>). The protan (lacks L cones) and normal views essentially match while deutan (lack M cones) and tritan (lack S) views appear different from the normal, highly valued view, exemplifying M and S cone importance in gemstone hue discrimination.

ABSTRACT BODY:

Purpose: The Pediatric Eye Questionnaire (PedEyeQ) assesses eye-related quality of life (ER-QOL) and functional vision in children with any eye condition. Previous studies have compared mean scores in clinical and control populations, but not whether it is meaningful to apply normal thresholds to identify individuals with reduced ER-QOL and functional vision. We evaluated PedEyeQ scores in children with bilateral visual impairment (VI).

Methods: 48 children (22, 0-4 years, 18, 5-11 years and 8, 12-17 years) with bilateral VI (best-eye acuity worse than 20/70) and 310 visually normal controls (104, 0-4 years, 104, 5-11 years and 102, 12-17 years) were prospectively enrolled. Children aged 5-17 years completed the Child PedEyeQ (Functional Vision, Bothered by Eyes/vision, Social, and Frustration/worry domains). Parents completed Proxy PedEyeQ (0-4 years: Functional Vision, Bothered by Eyes/Vision, Social; 5-17 years: same domains plus Frustration/Worry and Eye Care) and Parent PedEyeQ (Impact on Parent and Family, Worry about Child's Eye Condition, Worry about Child's Self-perception/Interactions, Worry about Child's Functional Vision). PedEyeQ domains were Rasch-scored and converted to 0-100. The 5th percentile of scores in the normal cohort defined the "reduced" threshold for each domain in each age group. Proportions with reduced scores were calculated.

Results: Proportions of VI subjects with reduced Child scores ranged from 78% (Functional Vision) to 39% (Frustration/worry) for 5-11 years and from 100% (Functional vision, Frustration/worry) to 88% (Bothered by Eyes/vision, Social) for 12-17 years. Proportions with reduced Proxy scores ranged from 100% (Functional Vision, Bothered by Eyes/Vision) to 55% (Social) for 0-4 years, 94% (Functional Vision) to 61% (Frustration/Worry, Eye Care) for 5-11 years, and 100% (all except Frustration/Worry) to 88% for 12-17 years. Proportions with reduced Parent scores were 95% or 100% for 0-4 years and 83% to 100% for 5-11 years; all domain scores (100%) were reduced for 12-17 years.

Conclusions: A high proportion of visually impaired children and their parents have reduced PedEyeQ domain scores, supporting the application of a normal threshold to identify individuals with reduced ER-QOL and functional vision. Nevertheless, variability of scores by self-report in young children may create challenges for interpreting domain scores in 5- to 11-year-olds.

ABSTRACT BODY:

Purpose: The cadherins junction protein, alpha-catenin (ACat), is primarily located in the cell membrane of healthy retinal pigment epithelium (RPE) cells, but undergoes a redistribution to the cytosol in cells which exhibit damage-induced changes in morphology. Previously, efforts to quantify the correlation between cytosolic ACat levels and individual cell morphological metrics in situ were limited by small sampling areas, access to prohibitive computational power, and sufficient programming expertise. Here, we introduce two separate analysis protocols allowing for unbiased, computationally minimal, and easy-to-use quantification of ACat cellular distribution using the open-source Cell Profiler application and the commercially available IMARIS software suite.

Methods: Damage to mouse RPE was induced by one of three methods (sub-retinal injection, light induced retinal degeneration, or systemic sodium iodate). Image sets of entire RPE sheets were acquired via confocal microscopy of fluorescently labeled ZO-1, ACat and nuclei. Maximum intensity projection images of each RPE sheet were processed using IMARIS 9.6 (Bitplane, Inc.) where individual cells were segmented, identified, and quantified morphologically. Incorrectly segmented cells and artifacts were manually rejected. ACat cytosolic intensities were derived using ZO-1 defined cell identification. For comparison, the same image sets were then processed using Cell Profiler without manual rejection of segmentation errors.

Results: Entire RPE sheets from both control and damage groups were accurately and successfully segmented using both Cell Profiler and IMARIS analysis protocols on a single lab computer. Segmentation morphometrics of abnormal cells following damage matched previously reported (K. Donaldson, ARVO2017) results showing positive correlations between abnormally sized (area, perimeter) cells and increased ACat cytosolic expression. Once optimized, Cell Profiler and IMARIS protocols were able to be applied uniformly across image sets, enabling unbiased and repeatable segmentation and quantification.

Conclusions: We present both open- and closed-source solutions using Cell Profiler or IMARIS for successful and efficient segmentation of RPE flatmounts. Additionally these protocols allow for simultaneous quantification of cytosolic ACat, a marker for abnormal RPE cells in damage models.

ABSTRACT BODY:

Purpose: The high treatment burden of frequent intravitreal (IVT) anti-VEGF injections for treatment of nAMD and DME presents an opportunity for sustained release (SR) technologies to increase the interval between injections. To address this unmet need, duration of effect of a single IVT injection of an SR formulation of bioerodible polymer microsphere particles loaded with the DARPin anti-VEGF abicipar pegol (abicipar SR) compared to a bolus dose of aflibercept was evaluated in a rabbit model of persistent retinal vascular leak (PRVL).

Methods: New Zealand Red rabbits previously injected IVT with DL-2-amino adipic acid (0.8 mg; OD) to induce PRVL were injected IVT with 50 µL of either abicipar SR (500 µg drug load; n=8) or aflibercept (700 µg bolus; n=7). Duration of effect was determined by quantitation of retinal leak area compared to pre-treatment leak area using fluorescein angiography bi-weekly for 32 weeks after injection. Retinas were then collected, fixed, and immunofluorescent co-labeling of retinal vasculature with IB4 and CD31 antibody was performed. Confocal images of retinal whole mounts were acquired and the degree of vascular regression in the area of baseline retinal leak was determined by calculating the ratio of CD31/IB4 signal overlap, which inversely correlates with the extent of vascular regression.

Results: A single IVT injection of abicipar SR completely inhibited retinal leak in all eyes for 22 weeks versus 10 weeks with aflibercept treatment. Complete leak suppression persisted in 71, 43, and 17% of abicipar SR-treated eyes at Weeks 24, 26, and 28, respectively. Robust suppression (>90% reduction of baseline leak area) was shown 26 weeks after abicipar SR treatment, which was significantly longer ($P<0.05$) than 12 weeks with aflibercept treatment. IHC analysis of retinal vasculature revealed that abicipar SR and aflibercept induced regression of neovessels within the baseline leak area to a similar extent. Intra-ocular inflammation was not observed in either treatment group.

Conclusions: These data demonstrate that a single IVT injection of abicipar SR was well tolerated in NZW rabbits and suppressed retinal leak for 6 months. Compared to aflibercept, abicipar SR was at least twice as durable with a minimum of 14 additional weeks of activity.

ABSTRACT BODY:

Purpose: Retinal vein occlusions (RVO) result in the overexpression of a variety of intraocular cytokines that contribute to sequelae, such as macular edema. The ability to link imaging biomarkers with specific underlying pathways could enhance therapeutic decision-making. This study correlated cytokine expression with ultra-widefield fluorescein angiography (UWFA) quantitative imaging biomarkers in RVO.

Methods: The IMAGINE RVO study is a post-hoc assessment of the WAVE clinical trial to determine associations between cytokine expression and quantitative imaging features. The WAVE study was a randomized clinical trial that

evaluated the impact of targeted retinal photocoagulation (TRP) on treatment requirement with intravitreal ranibizumab in 30 eyes with RVO. Eyes had aqueous humor samples collected and UWFA performed at baseline. Fifty-four cytokines associated with inflammation and angiogenesis were evaluated using multiplex arrays. Quantitative assessments of ischemia and leakage on UWFA were determined using an automated feature analysis platform with manual validation. Associations between cytokines and quantitative UWFA features were assessed using Spearman's correlation coefficients.

Results: Twenty-seven of the 30 eyes in the WAVE study had sufficient samples for analysis. Increased macular ischemia was associated with ANGPTL4 ($r=0.66$, $p=0.0002$), VEGF ($r=0.52$, $p=0.007$), and MCP-1 ($r=0.40$, $p=0.04$). Increased peripheral ischemia was associated with ANGPTL4 ($r=0.52$, $p=0.007$) and VEGF ($r=0.60$, $p=0.002$), while decreased peripheral ischemia was associated with IL-12p70 ($r=-0.45$, $p=0.02$) and MCP4 ($r=-0.44$, $p=0.02$). Increased macular leakage was associated with ANGPTL4 ($r=0.42$, $p=0.03$) and VEGF ($r=0.63$, $p=0.0008$). Increased peripheral leakage was associated with ANGPTL4 ($r=0.57$, $p=0.002$), VEGF ($r=0.61$, $p=0.001$), and LIF ($r=0.42$, $p=0.03$), while decreased peripheral leakage was associated with FGF-4 ($r=-0.47$, $p=0.02$).

Conclusions: Multiple quantitative UWFA features were associated with intraocular cytokines in eyes with RVO. VEGF and ANGPTL4 correlated with both increased ischemia and increased leakage on UWFA. Further research is needed to evaluate the possibility of using these imaging biomarkers as surrogates for cytokine expression and correlating these features with treatment response.

ABSTRACT BODY:

Purpose: Dimethyl sulfoxide (DMSO) is an FDA-approved treatment for interstitial cystitis. Research shows that DMSO also acts as a neuroprotectant in models of traumatic brain injury, ischemic stroke, and Alzheimer's Disease. We tested the hypothesis that systemic treatment with DMSO would be protective in the light induced retinal damage (LIRD) and the retinitis pigmentosa Pdeb6^{rd10/rd10} (rd10) mouse models.

Methods: 3.5 ml/kg DMSO or Dulbecco's Phosphate Buffered Saline (PBS) vehicle was used for all experiments. Male Balb/c LIRD mice ages 75 to 120 days were intraperitoneally (IP) injected the afternoon before and morning of bright light exposure (5000 lux x 4h). Male and female rd10 pups were injected 8-11 times with DMSO or PBS. Injections between postnatal day 4 (p4) and p12 were subcutaneous, and IP injections were used between p13-p23. Mice in naïve groups received no injections. Retinal function was assessed by electroretinogram (ERG). Retinal preconditioning was assessed by injecting 5, 3, and 1 day prior to bright light. To determine whether DMSO protection is mediated by processes that require significant time, DMSO was injected immediately following bright light and again the next morning. Finally, the effect of DMSO on retinoid cycling was assessed by measuring ERGs following photobleaching (1000 lux x 30 sec). Statistical analysis was 2way ANOVA with Tukey's multiple comparisons test.

Results: LIRD model: a- and b-wave amplitudes at 24.9 cd s/m² decreased 93% and 92% respectively for the vehicle bright group but only 30% and 33% for the DMSO bright group when compared to vehicle dim. DMSO injected 5, 3, or 1 day prior to bright light was not protective, nor was injecting after bright light. DMSO treatment did not slow functional recovery from photobleaching.

rd10 model at p23: scotopic a-wave amplitudes decreased 42% for the vehicle group but increased 107% for the DMSO group when compared to naïve. Photopic a- and b-wave amplitudes decreased 8% and 20% for the vehicle group but increased 65% and 56% respectively for the DMSO group when compared to naïve.

Conclusions: Systemically-delivered DMSO protected retinal function in the LIRD and rd10 models. DMSO did not provide protection by retinal preconditioning or slowing retinoid cycling, nor did it provide protection when given after bright light. DMSO-induced retinal protection may require more time, suggesting gene/protein expression and/or post-translational modification mechanisms.

ABSTRACT BODY:

Purpose: In DRCR Protocol I Early Analysis, 26% of patients were non-responders to anti-vascular endothelial growth factor monotherapy, but visual gains with steroid switch therapy in Protocol U were limited by duration of diabetic macular edema (DME). Study of an earlier multi-factorial approach is indicated. This study assesses treatment for DME with the dexamethasone 0.7 mg implant (DEX) after limited response to 1-3 monthly anti-vascular endothelial growth factor injections (AVF).

Methods: This multi-center, retrospective series included 58 initially treatment-naïve patients with < 200 µm reduction in central retinal thickness (CRT) and/or < 5 Early Treatment Diabetic Retinopathy Study (ETDRS) letters gained after 1-3 intravitreal bevacizumab or aflibercept AVF, who were then switched to DEX with ≥ 6 weeks subsequent follow-up.

Results: Baseline mean ± standard deviation (SD) best-corrected visual acuity (BCVA) was 55 ± 14 letters. CRT was 453 ± 172 microns. After patients received one (26%), two (6%) or three (68%) monthly AVF, mean BCVA was 57 ± 14 letters (p=0.57) and CRT was 412 ± 134 µm (p=0.16). After subsequent DEX, BCVA was 65 ± 13 letters (p=0.0001 compared to baseline and p=0.003 compared to post-AVF) and CRT was 280 ± 57 µm (p<0.0001 compared to both baseline and post-AVF).

Conclusions: In this cohort, patients with DME who had a limited visual and anatomic response to 1-3 monthly doses of either intravitreal bevacizumab or aflibercept demonstrated significant improvements after subsequent treatment with the dexamethasone 0.7 mg implant. Earlier intervention with DEX for treating DME may result in more rapid visual and anatomic gains compared to AVF monotherapy in certain patients.

ABSTRACT BODY:

Purpose: Studies which examine the degree to which holistic issues related to keratoconus (KC) management are non-existent, but could be an important component to increasing patient satisfaction.

Methods: An internet-based, 22 question, IRB approved RED-Cap survey of providers who managed at least one KC patient per week. Descriptive analyses are presented. Respondents were not required to answer every question, and some questions allowed more than one response.

Results: Of the 296 respondents, 245 providers with an average of 23.1 +12 years in practice met entry criteria. Respondents (n=220) averaged caring for 27.2 +35 KC patients each month. Only 19% of respondents (n=220) administer symptom questionnaires. Of respondents that do (n=42), 28 use them only at the initial visit, 18 use them at every follow up, and 15 do so annually (more than one answer allowed). The majority (98%, n=220) ask about contact lens comfort at every visit. 51% (n=220) of respondents perform dry eye testing as part of follow up examinations. Point of care tests include ((n=299); multiple responses allowed): MMP-9 (n=17), osmolarity (n=23), lipid layer thickness (n= 33), meibography (n=38), KB light test(n=4), break up time (n=108), vital dye staining (n= 78), Schirmer test (n=32), Dry Eye Test 9 (n=19), other (n=19). It is uncommon for patients to be asked about depression related to their condition. Only 4% of providers always ask, 13% most of the time, 45% sometimes, 27% rarely ask and 11% never broach this topic (n=222). Providers rarely refer to support groups or mental health professionals. Only 2% do so all of the time, 6% most of the time, 26% offer sometimes, 43% do so rarely and 23% never refer for such services (n=222). 92.7% of respondents felt that patients were honest about problems related to their disease.

Conclusions: This is the first survey among eye care providers to examine holistic aspects of long-term keratoconus management. Results demonstrate that symptom questionnaires, inquiries about quality-of-life /depression and referrals to mental health professionals are seldom addressed. Dry eye is emerging as a problem for KC patients yet only half of respondents routinely test for this comorbid condition, which can negatively impact contact lens tolerance and overall quality of life. Results of this study identify several high impact, low-cost improvements to current practice patterns.

TITLE: Oral All-trans Retinoic Acid Treatment Induces Myopia and Alters Scleral Biomechanics in Mice

SESSION TITLE: Refractive control: Molecular and Anatomical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Brown, C.R. Ethier, M.T. Pardue, Biomedical Engineering, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|D. Brown, M.T. Pardue, Atlanta VA Center for Visual & Neurocognitive Rehabilitation, Decatur, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Dillon Brown: Commercial Relationship: Code N (No Commercial Relationship) | C Ethier: Commercial Relationship: Code N (No Commercial Relationship) | Machel Pardue: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Both correlational and causal evidence support a connection between increased ocular retinoic acid (RA) concentrations and myopic axial elongation in mammals; however, RA's effects on scleral biomechanics, influential to eye size, are not known. Here, we treated mice with all-trans RA (atRA) to test the hypothesis that exogenous atRA alters scleral biomechanics and causes myopia in mice.

Methods: Male C57BL/6J mice (n=10) were trained to voluntarily ingest sugar pellets and were fed daily (2.5 g pellet/kg) from P29 to P44/45. Pellets dosed with atRA (added at a 1:100 ratio prior to forming pellets) were introduced between P30-31 in a randomly selected subset of animals (n=6 atRA, n=4 control), yielding a daily 25 mg atRA/kg dose. Refractive error (RE) was measured once per week beginning prior to atRA treatment. From a subset of animals (n=8), one eye per animal was randomly selected for biomechanical measurements (n=4 control, n=4 atRA). After sacrifice, sclerae were isolated for biomechanical quantification of tensile stiffness and permeability using unconfined compression and a biphasic material model.

Results: All animals voluntarily ingested the pellets. Oral atRA treatment significantly influenced RE development (interaction: treatment*age, $p < 0.001$), leading to relative myopia at 1 week compared to the control mice (mean \pm STD, 0.3 ± 2.7 vs 4.3 ± 0.4 D, $p = 0.024$), with the difference increasing at 2 weeks (-1.0 ± 2.6 vs 6.3 ± 0.1 D, $p < 0.001$). Changes in RE were accompanied by significantly altered scleral biomechanical properties. Sclerae from atRA fed animals were significantly less stiff compared to control sclerae (95% CI, [83.8, 118] vs [131.6, 186]kPa, $p < 0.001$). Permeability trended towards increasing with atRA treatment but did not reach significance (95% CI, [3.9, 7.4] vs [2.9, 5.5] $\text{m}^2 \cdot 10^{-18}$, $p = 0.18$).

Conclusions: Exogenous atRA is highly myopigenic in mice, a novel result that corroborates previous findings in guinea pigs. Further, we show for the first time that atRA affects scleral biomechanics, indicative of scleral remodeling. The decreased tensile stiffness of the sclera accompanying the atRA-induced myopia is comparable to that measured in mammals experiencing sustained myopigenic visual cues, e.g., form deprivation and lens defocus. This work motivates additional study into the role of RA in the retinoscleral signaling cascade that enables myopigenic visual cues to influence eye size.

ABSTRACT BODY:

Purpose: There is increasing evidence that the diabetic status of tissue donors can adversely impact corneal graft survival. Here, we evaluated the hypothesis that the diabetic state induces an altered corneal microenvironment with increased antigen-presenting cell (APC) maturation that in turn leads to heightened host sensitization and increased graft rejection.

Methods: Type I diabetes mellitus was induced in C57BL/6 mice by injecting 50mg/kg streptozocin (STZ) for 5 days. The altered glycemic state was confirmed by a glucometer. On day 28, mice with blood glucose levels of 300mg/dL were considered diabetic. Corneas were then harvested and either digested for analysis through flow cytometry, or grafted into normal BALB/c recipient mice. Two weeks after transplantation, immune cells from the corneas and draining lymph nodes (DLN) of recipient mice were analyzed by flow cytometry and allospecific cytokine production was evaluated through a mixed lymphocyte reaction.

Results: A significantly higher frequency of CD45⁺ cells (p=0.0009) and higher expression levels of MHC-II by APC (p=0.048) were observed in corneas from diabetic donors compared to normal mice. Allograft survival was decreased in diabetic donors (0%) compared to normal donors (52%, p=0.0002) through eight weeks of follow-up. The frequency of CD45⁺CD11b⁺ APC (p=0.014) as well as their expression of the maturation markers MHC-II (p=0.006), CD80 (p=0.007) and CD86 (p=0.03) was significantly increased in recipients receiving grafts from diabetics as compared to non-diabetic donors.

Conclusions: Our preliminary data suggest that diabetes mellitus leads to increased maturation of resident corneal immune cells and that transplantation of diabetic donor corneas leads to heightened host alloimmunity and increased graft rejection.

ABSTRACT BODY:

Purpose: Diopsys® NOVA fixed-luminance flicker full-field electroretinogram (ffERG) is a potential alternative to classic ffERG testing for measuring the electrical activity of cone cells . Pupil size has been shown to effect electrical response. The index study aims to quantify the relationship between pupil size and ffERG magnitude using this device.

Methods: 12 patients (24 eyes) with no known ocular diseases were enrolled in the study. Retinal activity was examined using Diopsys® ffERG before and after dilation. Eyes were initially anesthetized with proparacaine hydrochloride 0.5 % ophthalmic solution and then dilated with tropicamide 1% and phenylephrine 2.5% ophthalmic solutions. Eyes were dilated to a minimum of 5 mm before Diopsys® measurements were made. Paired t-test and robust linear regression were performed on the data set.

Results: Mean age was 34.9 ± 8.4 years and 25% were female. Mean value of pupil diameter and magnitude before and after the dilation was 2.54 ± 0.38 mm/ 7.01 ± 0.90 mm and 10.45 ± 2.92 μ V / 16.56 ± 4.1 μ V , respectively. There was a statistically significant difference in magnitude of response before and after dilation (p : <0.0001). In dilated eyes, linear regression analysis demonstrated an increase in magnitude with each millimeter increase of pupil size (r^2 : 0.44; Coeff.: 2.99; p : <0.0001) (figure1). It also demonstrated a 12% increase in change of magnitude with each millimeter unit increase in pupil size (r^2 : 0.15; Coeff.: 1.12; p : 0.07) (figure2).

Conclusions: Pupil size affects electrophysiologic response of the retina and should be measured and documented. Physicians should take pupil size into consideration when making clinical judgments based on Diopsys® ffERG. The normative values for ffERG devices should include pupil size variability to ensure better clinical judgments.

TITLE: Sick cell retinopathy: is there a role for follow-up?

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Gallo, F.M. D'Alterio, J.S. Talks, Eye Department, Royal Victoria Infirmary, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM | M. Hall, Hematology Department, Royal Victoria Infirmary, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM |

Commercial Relationships Disclosure (Abstract): Beatrice Gallo: Commercial Relationship: Code N (No Commercial Relationship) | Francesco D'Alterio: Commercial Relationship: Code N (No Commercial Relationship) | Melanie Hall: Commercial Relationship: Code N (No Commercial Relationship) | James Talks: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The role of regular ophthalmic screening in patients with sickle cell retinopathy is controversial and there are no studies guiding the frequency of review, hence the scope of this study.

Methods: Retrospective observational study of 66 eyes of 33 patients (20 females, median age 30 years, age range 17-60 years) with sickle cell disease screened for retinopathy with fundoscopy, ultrawide-field pseudocolour fundus pictures (Optos plc, Dunfermline, UK) and OCT-angiography. Type and progression of retinal findings were recorded at each visit.

Results: 25 patients had SS (sickle cell anemia) and 8 patients had SC (sickle cell/hemoglobin C compound). Ethnicity was African in 21 patients, Caribbean in 8 patients, Asian in 2 patients and Caucasian in 2 patients. 9 patients were on systemic treatment (8 hydroxycarbamide, 1 blood transfusions), 24 were not on treatment (1 received allogeneic transplant), 6 of whom refused treatment. Median follow-up duration was 18 months (range 0-47 months) and median number of visits was 2. Retinopathy was observed in 39 eyes (unilateral in 7 patients and bilateral in 16 patients). Retinal abnormalities included peripheral vascular closure (24 eyes, 15 patients), black sunbursts (17 eyes, 13 patients), sea-fan neovascularization (9 eyes, 5 patients) (Figure 1) and pale retinal patches (5 eyes, 3 patients). At baseline, there was no statistically significant difference in the distribution of the retinal abnormalities according to disease subtype ($p > 0.05$) and according to treatment group. Over the follow-up period, retinopathy progression was observed in 4 eyes from 2 patients (6.3%) affected by SS who refused systemic treatment. Progression consisted in new retinal hemorrhages (1 eye), new sea-fans (1 eye) or fibrosis enlargement (2 eyes), and was not vision threatening. In 4 eyes from 2 SS patients the OCT-A showed foveal avascular zone enlargement and superficial and deep capillary plexus drop-out (Figure 2).

Conclusions: No correlation was found between disease subtype and retinal abnormalities. Progression of retinopathy was detected in a small number of patients refusing systemic treatment that should be considered. Given the low rate of progression, a low frequency in monitoring sickle cell retinopathy would be adequate. Studies on larger cohort of patients are needed to confirm our clinical impression.

ABSTRACT BODY:

Purpose: Deep learning (DL) algorithms have been shown to perform well for classifying plus disease in ROP. However it is common for DL algorithms to have reduced performance on external datasets compared to the datasets that they were trained on. In this study, we demonstrate the efficacy of a DL algorithm, trained on a North American population, on two external multinational datasets.

Methods: Retcam images were obtained from India and Thailand through databases hosted by partner institutions, Aravind Eye Hospital (AEH) & Khon Kaen University (KKU) respectively. After filtering out images with inferior quality, Indian dataset consisted of 8811 images captured from 1275 eye-exams, while the Thai dataset had 1299 images from 385 eye-exams all from at risk infants. Both the Indian and Thai datasets were additionally labelled by 2-3 North American experts and gold standards were obtained through mutual consensus among all raters for each dataset. The performance of the iROP-DL model, trained on Retcam images from American population, was evaluated on both the external Retcam datasets after screening out all the non posterior-pole (PP) images.

Results: The two external datasets included many images which were out of distribution compared to the original training and testing iROP population (multiple views of the retina, anterior segment photos, samples with considerable pigmentation), and thus presented challenges for evaluation of the algorithm. The Table shows low performance before PP-filtering (AUC's 0.88 & 0.78 for India and Thai respectively), which improved considerably after PP-filtering (AUC's 0.89 & 0.84) and later by using consensus labels (AUC's 0.97 & 0.95). As shown via UMAPs in Figure, similar to iROP (yellow), AEH (blue) and KKU (red) also have Normal, pre-plus and plus feature points properly aligned in space (resulting in excellent performance), though they are segregated from iROP owing to demographic differences.

Conclusions: Applying DL algorithms on external datasets is prone to challenges due to demographic or phenotypic differences, or differences in acquisition methodology. After PP-filtering, we demonstrate excellent performance for the i-ROP DL system on the international datasets compared to the original test set. UMAP visualization further substantiates our point and highlights segregation of the external datasets owing to remaining ethnic/phenotypic differences.

ABSTRACT BODY:

Purpose: Human corneal epithelial stem cells or limbal stem cells (LSCs), have been recognized to locate in corneal limbus for three decades. However, the molecular identity and definitive markers of LSCs are still elusive. This study aimed to uncover novel cell types in heterogenous basal limbus of human cornea for identifying LSC population at single cell resolution.

Methods: Single cells of human limbal basal epithelium were isolated from young donor corneas. Single-cell RNA-Sequencing was performed using 10x Genomics platform, followed by clustering cell types through the graph-based visualization method Uniform Manifold Approximation and Projection (UMAP) and unbiased computational informatic analysis. Tissue RNA in situ hybridization with RNAscope, immunofluorescent staining and multiple functional assays were performed using ex vivo donor corneal tissues and in vitro culture models of primary human limbal epithelial cells (HLECs).

Results: Single-cell transcriptomics of 16,360 limbal basal cells revealed 12 cell clusters belonging to three lineages. A smallest cluster (0.4% of total cells) was identified as LSCs based on their quiescent and undifferentiated states with enriched top expressed genes known as markers of putative epithelial stem cells. TSPAN7 and SOX17 are discovered and validated as new LSC markers based on their exclusive expression pattern and spatial localization in limbal basal epithelium by RNAscope and immunofluorescent staining, as well as their functional role in cell growth and tissue regeneration models with RNA interference in cultures. Interestingly, five cell types/states mapping a developmental trajectory of LSC from quiescence to proliferation and differentiation are uncovered by Monocle3 and CytoTRACE pseudotime analysis. The transcription factor networks linking novel signaling pathways are revealed to maintain LSC stemness.

Conclusions: This human corneal single-cell transcriptomics identifies the LSC population and uncovers novel cell types mapping the differentiation trajectory in heterogenous limbal basal epithelium. The findings provide insight into LSC concept and lay the foundation for understanding the corneal homeostasis and diseases.

ABSTRACT BODY:

Purpose: Virtual reality-based oculokinetic perimetry (VR-OKP) is a mobile, short, screening visual field test. The purpose of this study is to examine whether VR-OKP could be implemented in a remote fashion and used to assess the stability of the visual field.

Methods: Glaucoma subjects with known glaucomatous defects who had taken an in-person VR-OKP test in 2019 were re-enrolled and underwent the same test remotely in 2020. An exit survey comparing patients' preferences for visual field testing was also conducted remotely. Subjects underwent Humphrey visual field 24-2 (HVF) testing within 3 months of VR-OKP both in 2019 and 2020. For unadjusted comparisons between HVF and VR-OKP, we compared mean sensitivities and fraction of points. A non-parametric bootstrap analysis that resampled eyes with replacement was done to calculate the 95% confidence interval of the Spearman correlation coefficient between HVF sensitivity versus VR-OKP fraction seen at each point of the 54 test locations.

Results: The cohort consisted of 19 eyes of 11 patients (55% female, 73% Caucasian, 27% Asian, mean age 61.4 ± 12.6 yrs) with moderate to advanced glaucoma (2020 average HVF mean deviation $-4.23 \text{ dB} \pm 5.12$). VR-OKP from 2019 to 2020 had a decreased mean percent change of $-6.31\% \pm 17.22$ ($p=0.13$) compared to HVF testing from 2019 to 2020 which had an increased mean change of mean deviation of $+2.41 \text{ dB} \pm 1.35$ ($p<.00005$). The Pearson's Correlation Coefficient between 2019 VR-OKP fraction seen and 2019 HVF mean sensitivity was 0.74, while it was 0.56 in 2020. Spearman correlation coefficients of HVF sensitivity vs VR-OKP fraction seen at each point ranged from -0.01-0.86 (median = 0.33). Subjects found VR-OKP to be as comfortable as HVF ($p=0.8$) and less fatiguing ($p=0.03$).

Conclusions: This study highlights the feasibility of a remote option for visual field assessment. The correlation between VR-OKP and HVF in 2019 was higher than in 2020. One explanation is that the 2019 test was taken with in-person instruction, whereas the 2020 test was administered remotely. While the mean percentage change in VR-OKP was non-significant, the 2019 to 2020 change in HVF was statistically significant and showed improvement, which may be due to long term fluctuation. This short VR-OKP test is less fatiguing to patients, can detect non-progression even when taken at home, and could potentially be deployed to decrease patients' risk of COVID-19.

ABSTRACT BODY:

Purpose: Although approximately 30-50% of aqueous outflow resistance lies distal to Schlemm's canal (SC), the morphology of the aqueous outflow pathway distal to SC has not been thoroughly examined. This study investigated the morphology of the outflow pathway from SC to the intra-scleral veins (ISVs) in an experimental model of glaucoma in cynomolgus macaques.

Methods: Argon laser photocoagulation was used to create burns to ~270 degrees of the trabecular meshwork (TM) of one eye (n = 6) or both eyes (n = 2) of each monkey until intraocular pressure was consistently elevated. Discrete regions of the TM were left untouched. Contralateral eyes (n = 5) were used as controls. Monkeys were sacrificed at 60 months or more after the last treatment. Eyes were enucleated and perfused at 15 mmHg for 30 min to measure outflow facility, perfusion-fixed with Karnovsky's fixative for 1 hr, and then immersion-fixed overnight. Anterior segments of each eye were cut into 24 to 36 radial wedges and embedded in Epon-Araldite. Semi-thin sections (2 μ m) of select wedges were cut, stained, and imaged. Width, height, and cross-sectional area (CSA) of SC of non-lasered regions of laser-treated eyes and control eyes, as well as number and CSA of ISVs of non-lasered and lasered regions of laser-treated eyes and control eyes were compared. Statistical analyses were conducted using R.

Results: Mean outflow facility was significantly decreased in laser-treated eyes (0.12 μ L/min/mmHg; n = 8) compared to control eyes (0.34 μ L/min/mmHg; n = 5; P = 0.02). Median CSA, width, and height of SC were not different between non-lasered regions of laser-treated eyes and control eyes (P > 0.05). SC was partially or completely obliterated in lasered regions. Median number of ISVs was significantly decreased in lasered regions (1.4 ISVs) compared to non-lasered regions (3.7 ISVs) of laser-treated eyes (P \leq 0.01) and control eyes (6.0 ISVs; P \leq 0.01). Median CSA of ISVs did not differ between groups (P > 0.05). Lasered regions displayed looser, more disorganized scleral stroma in the region surrounding the TM.

Conclusions: Partial or complete obliteration of SC, decreases in ISV number, and changes in scleral composition may account for a portion of the increased outflow resistance in SC and the distal aqueous outflow pathway in monkey eyes with laser-induced OHT.

ABSTRACT BODY:

Purpose: The center region of the human retina undergoes prolonged development to enable foveal formation. Many of these processes, ranging from synaptogenesis to cellular migration, begin at the embryonic stage. This study examines the genetic regulation of cell-type specific processes during embryonic foveal development.

Methods: We combined single-cell RNA-seq and single-cell ATAC-seq to analyze human retinas at fetal weeks (Fwk) 18-19. Foveal center (~1mm in diameter), macula (~2 mm in diameter), and peripheral retina were dissected and dissociated for single-cell transcriptomic and genomic analyses. Single-cell libraries were prepared with 10x Genomics and sequenced with Illumina NovaSeq. Sequencing results were processed using cell ranger and downstream analysis using community single-cell analysis tools and customized scripts.

Results: We obtained ~64,000 cells from scRNAseq and ~24,000 cells from scATACseq. From the scRNAseq dataset, we identified major cell classes of the retina, including progenitor cells, differentiating cells in transition states, photoreceptors (PR), horizontal cells (HC), bipolar cells (BC), amacrine cells (AC), retina ganglion cells (RGC), Müller glia (MG), microglial and others, in all the three regions. Similar to previous studies, we observed asynchronous development between the central and peripheral retinas: Fovea and macula showed earlier differentiation compared to the peripheral retina as determined by percentages of progenitors and transition cells among regions. Interestingly, we found that cones show gradient enrichment along retinal eccentricity as follows: 98.03% of total PRs in the foveal center, 62.28% in the macula, and 13.09% in the peripheral retina. We further identified cell-type- and region-specific gene expression and functional pathways. We integrated the analysis of gene-expression differences with chromatin accessibility results to map genetic regulatory networks of foveal genes.

Conclusions: Our study provides a transcriptomic and genomic landscape of embryonic foveal development.

TITLE: Astrocyte Gap Junction Protein Cx43 Modulates the Light Response of Mouse Retinal Ganglion Cells

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Boal, Medical Scientist Training Program, Vanderbilt University, Nashville, Tennessee, UNITED STATES|N.R. McGrady, M.L. Risner, D.J. Calkins, Department of Ophthalmology and Visual Sciences, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|A. Boal, J.M. Holden, Neuroscience Graduate Program, Vanderbilt University, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrew Boal: Commercial Relationship: Code N (No Commercial Relationship) | Nolan McGrady: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Holden: Commercial Relationship: Code N (No Commercial Relationship) | Michael Risner: Commercial Relationship: Code N (No Commercial Relationship) | David Calkins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Astrocytes play key supportive roles in neuronal signaling, including providing metabolic support and buffering the extracellular environment. They form broad networks via gap junctions, primarily composed of the protein connexin-43 (Cx43). These networks allow the passage of important biomolecules between cells, connecting distant brain areas. This is a key component for the functioning of various neural circuits, such as in the hippocampus. However, it is less known how astrocyte networks affect retinal circuitry. Here, we evaluate the consequences of Cx43 knockout on the response properties of retinal ganglion cells (RGCs).

Methods: Conditional astrocytic Cx43 knockout (Cx43 ^{-/-}) was induced in GFAP-CreERT2/Cx43(fl/fl) mice by oral tamoxifen gavage. 1 week post-induction, mice were sacrificed and retinas were dissected in a dark room under red light. Retinas were constantly perfused with Ames' medium supplemented with 20mM glucose. Whole-cell current clamp signals were amplified and digitized at a sampling rate of 50kHz. RGCs were classified by light response, dendritic stratification, and soma size. Cx43 ^{-/-} was confirmed by PCR. Recordings were analyzed using the pyABF package and custom python code, and statistical tests were done in GraphPad Prism.

Results: α ON-S cells from Cx43 ^{-/-} mice showed an increased light response latency compared to WT controls ($p = 0.002$), though the rest of the light response was largely unaffected. α OFF-S cells, however, showed significant differences in light response between groups. α OFF-S cells from Cx43 ^{-/-} mice had a significantly lower spike rate ($p = 0.02$) and an increased response latency ($p = 0.02$). The hyperpolarizing response to light was also altered. Cells from Cx43 ^{-/-} mice had a lower mean amplitude of hyperpolarization ($p = 0.04$), although the peak amplitude was unchanged ($p = 0.24$). Cx43 ^{-/-} also affected RGC membrane properties. Cx43 ^{-/-} mice α ON-S cells showed a steeper slope in the firing frequency vs. current relationship ($p = 0.01$) and had a higher overall spontaneous membrane potential variability ($p = 0.01$).

Conclusions: These results suggest that Cx43 ^{-/-} differentially alters the light response and membrane properties of RGCs. Thus, the astrocytic networks formed by Cx43 contribute significantly to RGC encoding of light.

ABSTRACT BODY:

Purpose: To determine whether changes to the lens intracellular hydrostatic pressure gradient that drives water efflux from the lens also alters the subcellular location of AQP5 water channels in the rat lens.

Methods: Enucleated rat eyes were dissected to produce four scleral flaps that exposed the lens but left it attached to the ciliary muscle via the lens zonules. The flaps were pinned to the bottom of a recording chamber and the preparation incubated in AAH in either the absence or presence pilocarpine or tropicamide, to decrease and increase zonular tension, respectively, or different combinations of TRPV1/4 activators and/or inhibitors. The effects of perturbations on hydrostatic pressure and AQP5 membrane localization were monitored by a pico-injector-microelectrode system¹ or immunohistochemistry and confocal microscopy², respectively.

1. Chen et al., IOVS 60:4416-4424, 2019.

2. Petrova et al., IOVS 61:36, 2020.

Results: Tropicamide decreased surface hydrostatic pressure but did not alter the predominately membrane localization of AQP5. In contrast, reducing zonular tension by pilocarpine resulted in a change in AQP5 immunolabeling from membranous to cytoplasmic, which was correlated with a significant and sustained increase in surface hydrostatic pressure. The increase in pressure and the removal of AQP5 from the membrane induced by pilocarpine could also be mimicked by first incubating lenses in the TRPV4 inhibitor HC067047, before then applying the TRPV1 activator capsaicin.

Conclusions: Our pressure measurement results showed that the hydrostatic pressure of the rat lens can be manipulated pharmacologically by changing of the zonular tension or by changing the activity of the TRPV4 and TRPV1 mechanosensors. Our immunolocalization results suggest fiber cells can respond to hydrostatic pressure by shuttling AQP5 out from the cell membrane to dynamically regulate the efflux and influx of water in the rat lens.

TITLE: Predictors of vocational rehabilitation success among legally blind individuals in Massachusetts

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Osypiuk, A.G. Malkin, C. Idman-Rait, N. Ross, New England College of Optometry, Boston, Massachusetts, UNITED STATES|T. Arango, Psychology, Northeastern University, Boston, Massachusetts, UNITED STATES|N. Skrocki, Massachusetts Commission for the Blind, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kamila Osypiuk: Commercial Relationship: Code N (No Commercial Relationship) | Tiffany Arango: Commercial Relationship: Code N (No Commercial Relationship) | Alexis Malkin: Commercial Relationship: Code N (No Commercial Relationship) | Cecilia Idman-Rait: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Skrocki: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Ross: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vocational rehabilitation (VR) services aim to help legally blind individuals secure, regain or retain employment following vision loss, as rates of employment among legally blind VR consumers are reportedly low. We evaluated factors contributing to successful VR among individuals receiving services from the Massachusetts Commission for the Blind (MCB) to inform future improvements in services and outreach.

Methods: Using existing data from MCB's central registry of legally blind consumers, logistic regression was used to examine potential predictors of rehabilitation success. Age, gender, race, and diagnosis were explored as possible predictors. Case events between Jan 1, 2018 to Sept 4, 2020 were included in analyses (n=938). Rehabilitation success was a binary outcome defined as maintaining employment for 90 days.

Results: Mean age of consumers was 42 years (SD 17.5); 51% were men, 65% were white. Most common diagnoses included retinal degeneration (13%), glaucoma (8.7%), and diabetic retinopathy (DR) (6.92%). Half of case events had a successful outcome (n=468). Common reasons for unsuccessful outcomes were lack of interest (35%) and being unable to locate the consumer (27%). Those younger than 39 years were 36% less likely to have VR success than those aged 40-44 (OR=0.64; 95% CI= 0.38-1.07; p=0.09). Gender was not a significant predictor of VR success (p=0.30). Those with DR were 45% less likely (OR=0.55; 95% CI= 0.31-0.96; p=0.04) and those with glaucoma were 44% less likely (OR=0.56; 95% CI= 0.33-0.94; p=0.03) to have VR success than those with congenital diagnoses. Asian, black, biracial, and biracial white-latinx consumers were all less likely to be rehabilitated than whites (p's <0.05). There was a significant interaction between race and age among those ≤ 39 years, with those who are biracial being 78% less likely (OR=0.22; 95% CI= 0.06-0.6; p=0.007) and those who are latinx-white being 64% less likely (OR=0.36; 95% CI= 0.18-0.70; p=0.003) to have VR success than whites.

Conclusions: The significant association between age, race, and diagnosis with VR success suggests that these factors should be considered in VR programs. Glaucoma and DR are more prevalent among black and latinx populations, who had lower rates of VR success and are under-represented in VR programs. More targeted outreach and tailored rehabilitation programs may be warranted for these populations.

ABSTRACT BODY:

Purpose: To compare the effect of three commonly used anti-inflammatory eye drops containing cyclosporin (0.05%), lifitegrast (5%), and tacrolimus (0.1%) in cell survival.

Methods: Healthy donor corneal transplant tissues were obtained from San Diego Eye Bank. Corneal epithelial cells were scraped from the surface of the corneal rim after 1 h treatment in dispase II. Cells derived from donor tissue were first plated in a well of 12 well plate, passaged to a well of 6 well plate, and finally passaged to a 96 well plate for drug application. Wells were separated into the following five treatment groups: cyclosporine 0.05%; lifitegrast 5%; tacrolimus 0.1% and two controls, a balanced salt solution (BSS) group and a no treatment group. The cells were exposed to medium containing 10% of eye drops (cyclosporine final 0.005%, lifitegrast final 0.5%, and tacrolimus final 0.01%) and eye drop containing medium were washed out after 2 m, 1 h, 2 h, 4 h, and 24 h (N = 6-10 wells for each condition).

Results: The effect of cyclosporine became statistically significant at 24 h compared to control groups [survival rate: 26 +/- 27% (mean +/- SD, N = 6)]. The effect of lifitegrast became statistically significant at 24 h compared to control groups [survival rate: 14 +/- 14% (mean +/- SD, N = 6)]. The effect of tacrolimus became statistically significant at 1, 2, 4 and 24 h [survival rates: 7 +/- 11% at 1 h, 32 +/- 37% at 2 h, 14 +/- 19% at 4 h, and 0 +/- 0% at 24 h (mean +/- SD, N = 10-14)]. BSS application had no effect on cell survival compared to no treatment group. In other words, application of medium containing cyclosporine and lifitegrast had no significant effects up to 4 h, although tacrolimus affected in 1 h.

Conclusions: Epithelial cell culture cytotoxicity was more moderate in cyclosporin and lifitegrast, and more harsh in tacrolimus containing eye drops. These findings may serve as a useful resource to select anti-inflammatory eyedrops in a clinical setting and provide further insights into the study of inflammatory signaling and cell death pathways.

TITLE: The spectrum of reading difficulties in children with Cerebral Visual Impairment (CVI): a qualitative study

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Ghahghaei, S. Harris, D. Singh, A. Chandna, The Smith-Kettlewell Eye Research Institute, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Saeideh Ghahghaei: Commercial Relationship: Code N (No Commercial Relationship) | Spencer Harris: Commercial Relationship: Code N (No Commercial Relationship) | Devanish Singh: Commercial Relationship: Code N (No Commercial Relationship) | Arvind Chandna: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Reading difficulties are increasingly reported in children with CVI even in the presence of good visual acuity. CVI is now the commonest cause of childhood visual impairment in the western hemisphere and consequent lack of proficiency in reading is likely to have negative consequences for development, academic success and the well-being of the child and society. Oculomotor dysfunction, crowding and delayed comprehension have been suspected but not systematically investigated. We set out to address this gap by documenting the spectrum of reading difficulties.

Methods: We conducted remote, in-depth 40 to 60 minute, semi-structured interviews of parents of children with CVI (and recorded, if permitted). An open statement 'Please tell me about your child's journey in reading' commenced the interview. If needed, interview guides were provided to ensure consistency between participants. Notes were taken, problems were documented Specific questions were reserved for end of interview if not covered by parent's description.

Results: Data from 7 parents (target N = 10) were analyzed by first transcribing then coding interviews . A spectrum of reading difficulties were identified which indicated a range from lower to higher level visual processing. The frequency of reporting each difficulty across participants was calculated. For example, of the 7 parents, 4 reported the need for large fonts (frequently reported in literature) and 2 reported that 'sometimes nothing works' (rarely reported in literature). These documented difficulties indicated the following neurophysiological correlates; in isolation or in combination: (1) acuity and accommodation (2) crowding (3) oculomotor problem (4) restricted visual field (5) spatial attention (6) or central attention.

Conclusions: In-depth interviews with parents reveal multiple reading difficulties in children with CVI presenting in different ways frequently and rarely reported by clinicians. The six areas identified from our study provide a framework for further focused interviews and quantitative research designed specifically to investigate these areas with a potential for targeted (re)habilitation techniques to be assist the child to overcome these difficulties.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor is a major mediator of both diabetic macular edema (DME) and proliferative diabetic retinopathy (PDR). In our clinical practice, we have observed a significant number of patients with PDR without any DME. The purpose of our study was to identify demographic, medical, ophthalmologic and OCT image characteristics that significantly affect development of DME and types of DME in patients with PDR.

Methods: Observational, retrospective case series of PDR patients seen in the retina clinics at a single large acute-care teaching hospital in an urban setting between December 2018 to October 2020. IRB approval was obtained. Vitreomacular interface (VMI) status was classified as: vitreomacular adhesion without traction (VMA), vitreomacular traction (VMT), or macular posterior vitreous detachment (PVD). Eyes were excluded if they had received retinal laser or intravitreal injection of a pharmacotherapeutic agent <1 year from OCT date, had any prior intraocular surgery or comorbid ophthalmic disorders associated with DME.

Results: A total of 293 eyes of 210 screened patients with PDR met our inclusion criteria. Of the eyes, 66.2% had DME and 33.8% had no DME. In PDR patients, when comparing those with DME to those without DME, there were significant differences ($p<0.05$) in average visual acuity, retinal thickness, cube volume and dialysis status. There were no significant differences in ERM ($p=.196$) and VMI status ($p=0.340$). In eyes with center-involving (CI)-DME, VMI status was observed as follows: 44.4% with VMA, 7.8% with VMT, and 47.8% with PVD. In eyes with non-center-involving (NCI)-DME, VMI status was observed as follows: 67.3% with VMA, 1% with VMT, and 31.7% with PVD. CI-DME eyes were significantly more likely to have a PVD than NCI-DME eyes ($p=0.001$). There were 90 CI-DME eyes, 82.2% of which had ERMs, and of those with ERM, 66.2% had CI-ERM. There were 104 NCI-DME eyes, 45.2% of which had ERMs, and of those with ERM 44.9% had CI-ERM. CI-DME eyes were significantly more likely to have an ERM ($p=<0.001$) and CI-ERM ($p=0.019$) than NCI-DME eyes.

Conclusions: In this exploratory study evaluating only patients with PDR, we determined that ERM and VMI status did not have a significant association with DME writ large. However, VMI status and the presence of ERM may influence the development of CI-DME more specifically.

ABSTRACT BODY:

Purpose: Beta glucans are common contaminants in the manufacturing of biopharmaceuticals. The effects of beta glucans on the eye are not well characterized, but the level of beta glucans in intravitreal ophthalmic formulation of biologics are an important consideration in both manufacturing and safety testing. This 8-day study aimed to characterize the in-life and histopathological changes following intravitreal (ITV) administration of beta glucans and determine a no observed effect level in rabbit eyes.

Methods: Female Dutch Belted rabbits were treated with a single ITV beta glucans dose (derived and concentrated from sugars in a vehicle formulation) at nominal concentrations ranging from 10 to 1000 pg/eye. Concentrations of beta glucans dosages were measured pre and post-dosing using a Factor G based assay, and measured actual post dose values were reported as the administered dosage for each portion of the study. A non-terminal, unilateral dose range finding (DRF) portion of this study established 10 to 1000 pg/eye to be well tolerated and provided a range to be confirmed in a larger bilateral definitive study with six treated groups (N=4 animals per group) including a vehicle control. Overall animals were monitored for up to 1-week post-treatment via clinical ophthalmic examination using the modified standardization of uveitis nomenclature (SUN) Working Group Grading Scheme to score aqueous/vitreous cell and flare/haze. At the end of the definitive study animals were necropsied and eyes processed for histopathologic evaluation.

Results: No beta glucan-related findings were identified in treated animals compared to vehicle control. Single dose ITV injection of beta glucan was well tolerated in-life in the DRF portion of the study up to the maximum dose tested of 1,000 pg/eye. Doses up to 800 pg/eye (maximum dose in the definitive part) was well tolerated both in-life and on histopathologic examination. Nominal administered values were up to 1,000 pg/eye for both study portions, however samples used in the definitive study were measured post dose to be 800 pg/eye.

Conclusions: Single dose ITV beta glucans, isolated and concentrated from sugars, in a vehicle formulation did not elicit an inflammatory response or resulted in histopathologic changes. Thus, the no observed effect level (NOEL) over 8-days in rabbits was 800 pg/eye.

ABSTRACT BODY:

Purpose: Genetic defects in MTTP are responsible for abetalipoproteinemia, combining spinocerebellar and retinal degeneration. Retinal findings in abetalipoproteinemia are only infrequently reported. We provide a detailed phenotypic description of the retinal degeneration linked with MTTP variants in a cohort of retinitis pigmentosa (RP) patients.

Methods: Patients previously diagnosed with abetalipoproteinemia and patients with gene defects in MTTP identified through next generation sequencing were investigated at the national reference center for rare ocular diseases of Quinze-Vingts hospital. Best corrected visual acuity (BCVA), slit-lamp examination, Goldman perimetry, full field electroretinography (ffERG) and multimodal imaging including color photos, short (SWAF) and near infrared wavelength autofluorescence, optical coherence tomography (OCT) were done for all patients.

Results: Four female patients from four unrelated families were selected. Median BCVA at baseline was 20/40 (range: 20/25 – 20/250). ffERG showed cone-dominated responses. Isopter V4e of Goldman visual field was constricted in all patients. Three patients had fundus findings typical of RP. Two had atrophic patches at the posterior pole. One had angioid streaks and “peau d'orange” aspect. SWAF showed various features. One patient had a ring of increased autofluorescence; another had a water-shed hyperautofluorescent line beneath the macula. One individual had numerous hyperautofluorescent dots scattered over the posterior pole. One patient had confluent hypoautofluorescent patches with scalloped edges. OCT showed a destruction of outer retinal layers outside the macula in all patients. In one individual OCT discovered a type 2 subretinal neovascularization. Two patients had prominent ataxia and peripheral sensitive-motor neuropathy. One patient developed a parietal hemorrhage related with low vitamin K plasmatic level. One patient developed an acute myeloid leukemia. Two patients are free of neurological symptoms to date. All patients descended from inbreed pedigrees. Three individuals harbored known homozygous variants in MTTP. Genetic data were lacking for one patient.

Conclusions: Abetalipoproteinemia represents 0.2% of our RP cohort. Retinal degeneration in abetalipoproteinemia can take various and atypical aspects. It could be the first clinical sign of the disease. On the basis of these findings, we strongly recommend adding MTTP to inherited retinal degeneration gene panels.

ABSTRACT BODY:

Purpose: In a murine model of diabetic retinopathy (DR), intravitreal injection of human CD34⁺ stem cells from bone marrow(BMSCs) was associated with the preservation of retinal vasculature. Since miRNAs(miRNA) have been implicated to play a role in the pathogenesis of DR, this study tested the hypothesis that intravitreal injection of human CD34⁺ BMSCs alters miRNA expression patterns in the recipient retina in eyes with DR.

Methods: Streptozotocin-induced diabetic mice(C57BL/6J) were used as a model for diabetic retinopathy with chronic systemic immunosuppression using Tacrolimus and Rapamycin to avoid rejection of human cells. Human CD34⁺ BMSCs were harvested from the mononuclear cell fraction of bone marrow from a healthy donor using magnetic beads. The right eye of each mouse received an intravitreal injection of 50,000 healthy CD34⁺ BMSCs or phosphate buffered saline(PBS). After one week time point, the mice were euthanized, and the eyes were removed for microarray analysis of the retina. Ingenuity Pathway Analysis (IPA) was used to identify activated pathways.

Results: Microarray expression analysis showed changes in the expression of 11 miRNAs in the murine retina following CD34⁺ BMSC injection compared to PBS-injected control. Two of these miRNAs are known to be involved in DR pathogenesis: let7c-1 (FC= -1.53, p<0.01) and mir-455 (FC=1.5, p< 0.01). Downregulation of let-7c has been seen in diabetic microvascular complications, while upregulation of miR-455-5p attenuates high glucose-triggered oxidative stress injury. IPA identified that the top canonical activated pathway was "HOTAIR Regulatory Pathways," which can be modulated by let-7c-1. Potential targeting of long non-coding(lnc) RNA HOTAIR by microRNAs is a novel finding for DR – this lncRNA has been implicated in promoting apoptosis, inhibiting cell metastasis, and angiogenesis in cancer, but not yet in diabetic retinopathy.

Conclusions: Gene expression analysis showed that intravitreal injection of CD34⁺ BMSCs harvested from a healthy donor has a robust effect on miRNA expression in the murine retina with DR. Expression of specific miRNAs implicated in the pathogenesis of DR was affected, including let-7 and miR-455. Both miRNAs play important roles in regulating the lncRNA HOTAIR pathway that affects endothelial cell dysfunction and indirectly affects VEGFA transcription.

ABSTRACT BODY:

Purpose: We previously generated a murine Dhdds K42E knockin (KI) mouse model of RP59 that exhibited incipient neuroinflammation and gliosis, but no overt retinal degeneration or cell loss, even by 1 year of age. Here, we further evaluated the phenotype of this animal model.

Methods: K42E homozygous (Dhdds^{K42E/K42E}) KI mice were bred to 4th generation, and compared to age/sex-matched wildtype (WT) mice. Phenotypes were assessed by electroretinography (ERG, n=8-10), whole cell patch-clamp recordings, and fundus imaging (n=3-4) at postnatal 180 days. Immunohistochemistry (IHC) was performed on retinal frozen sections using antibodies to PKC α , synaptotagmin-1, and ribeye.

Results: Scotopic and photopic ERG a-wave responses were comparable in WT and KI mice. These results were confirmed by single cell recordings. By contrast, KI mice exhibited significant reductions in scotopic b-wave (358 ± 34 μ V KI vs. 642 ± 67 μ V WT; p <0.01) and photopic b-wave (178 ± 26 μ V KI vs. 273 ± 32 μ V WT; p <0.05) amplitudes. KI retinas exhibited no overt signs of degeneration or disorganization. IHC did not reveal obvious abnormalities in localization or levels of the markers analyzed, and synaptic ribbons were properly localized and exhibited normal appearance.

Conclusions: This genetic mouse model of RP59 exhibits a negative ERG (reduction in b-wave without a concomitant reduction in a-wave), indicating defective photoreceptor-to-bipolar cell synaptic transmission. The findings suggest that the defect is postsynaptic, involving ON bipolar cells.

ABSTRACT BODY:

Purpose: A retrospective study to investigate our experience with intravitreal injections (IVI) of brolucizumab 6 mg/0.05 ml for the treatment of neovascular age-related macular degeneration (NVAMD) over 1 year.

Methods: A chart review from 11/13/19-11/12/20 was performed on eyes treated with brolucizumab for NVAMD. Our analysis included demographics, ETDRS visual acuity, injection history, adverse events, and medical history. The eyes with intraocular inflammation (IOI) were compared to those without (control). Characteristics of the IOI group were also studied.

Results: Ninety-nine eyes of 88 patients were analyzed. There were 10 treatment-naïve eyes and 89 non-naïve. The average maintenance extension of non-naïve eyes was 3 weeks. However, for eyes with a positive extension on maintenance (58 eyes or 68.2%), the average extension was 9 weeks. Within this group, there were 24 super-responder eyes (defined as injection burden reduction of at least 50%). Of the 99 eyes injected with brolucizumab, 8 eyes experienced IOI. All 8 eyes were diagnosed with vitritis, which persisted for an average of 69 days and was easily managed with topical treatment. Two of the IOI eyes experienced retinal vasculitis: one losing 3 letters and one losing 10 letters of vision. Of the 6 eyes that solely experienced vitritis, the average vision change from IOI to the most recent visit was -2 letters. However, 1 eye lost 10 letters of vision. The average number of days from the first brolucizumab injection to the presentation of IOI was 81 days. Female eyes tended to have a higher incidence of IOI, however, this was not statistically significant. Reactions occurred after 1-2 injections in 7 of the 8 eyes with IOI. Atrial fibrillation (afib) in IOI and control groups was seen respectively: 3 out of 8 (37.5%) and 9 out of 91 (9.9%) eyes ($P<.05$). 30% of naïve eyes had IOI as compared to 5.6% of non-naïve eyes ($P<.01$).

Conclusions: Vitritis was the most common IOI seen with brolucizumab, and had adequate visual recovery with treatment. There was a suggestion that risk factors for IOI include naïve use and afib. Increased maintenance intervals were seen on brolucizumab. There was also a group of super-responders that decreased their injection burden by at least 50%. Our data suggest this drug should not be used as primary treatment but could be considered for patients requiring frequent injections.

ABSTRACT BODY:

Purpose: To determine agreement of 1-field (1F, macula centered) and 2-field (2F, disc/macula) mydriatic handheld retinal imaging with standard ETDRS photography for DR/DME.

Methods: Images from 177 eyes of 92 patients with diabetes were evaluated. By ETDRS photos: no DR 40.1% eyes, mild NPDR 19.2%, moderate 14.7%, severe 10.2%, proliferative DR 15.8%; no DME 72.9%, DME 6.8%, CSME 17.0%, ungradable 3.4%. Ungradable rate for DR and a summary of results are shown in Table 1. DME was ungradable in AU:10.2%, SS:13.0%, RV:5.7%. 2F imaging increased exact agreement of DR grading between handheld retinal imaging and ETDRS photos by 8.3% AU, 15.2% SS, 6.3% RV; agreement within 1-step was increased by 6.1% AU, 10.1% SS, 1.3% RV. 2F imaging with AU/SS increased K and K_w although it remained moderate. 2F imaging did not substantially increase sensitivity for any DR, refDR and vtDR across all devices.

Results: Images from 177 eyes of 92 patients with diabetes were evaluated. By ETDRS photos: no DR 40.1% eyes, mild NPDR 19.2%, moderate 14.7%, severe 10.2%, proliferative DR 15.8%; no DME 72.9%, DME 6.8%, CSME 17.0%, ungradable 3.4%. Ungradable rate for DR and a summary of the results is shown in table 1. DME was ungradable in AU:10.2%, SS:13.0%, RV:5.7%. 2F imaging increased exact agreement of DR grading between handheld retinal imaging and ETDRS photos by 8.3% AU, 15.2% SS, 6.3% RV; agreement within 1-step was increased by 6.1% AU, 10.1% SS, 1.3% RV. 2F imaging increased kappa agreement with ETDRS photos for DR by 11.3% AU and 15.6% SS. 2F imaging did not significantly increase sensitivity for any DR, refDR and vtDR across all devices.

Conclusions: Handheld 1F imaging with a field of view less than 60° do not meet established standards for sensitivity (80%) and specificity (90%) in identifying DR and refDR. Ungradable rate was reduced by 36-50% and agreement with ETDRS was increased (6.3-15.2%) with the acquisition of a second field. The benefit of a second field decreased as the field of view of the device increased. For the tested instruments, a minimum handheld 1F 60° or 2F imaging are needed to adequately determine referable DR in DR screening programs.

ABSTRACT BODY:

Purpose: To assess the efficacy of the 24-2 Guided Progression Analysis (GPA) for detecting progression of glaucoma, GPA performance was compared to progression assessed with a single follow-up optical coherence tomography (OCT) test.

Methods: From a prospective study (MAPS) [PI: CGDM], 99 eyes from 99 individuals, including 69 suspect or glaucomatous eyes and 30 healthy controls (HC) had best-corrected visual acuity better than 20/40; an open angle; and a 24-2 mean deviation (MD) better than -6 dB at baseline. All eyes had a recent test at least 12 months after the first of two baseline tests, which were within an average of 5.6 days. In addition, each eye had at least 4 24-2 VF and OCT tests (mean 9.2 tests), with VF and OCT tests obtained on, or close to, the same date. The OCT test consisted of a circle scan of the disc and a cube scan that included the macula. The commercial 24-2 GPA software characterized eyes as “Likely Progressing” (LP), “Probably Progressing” (PP) or “neither” LP or PP. For a post-hoc analysis (E-OCT method), authors familiar with OCT rated the likelihood of progression on a scale from 0-5% (definitely not progressing, OCT-NP) to 95-100% (definitely progressing), OCT-P based upon circumpapillary b-scans, retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) thickness maps, and change/difference plots (see Fig). **Results:** The 24-2 GPA identified 13 eyes as either LP or PP. The E-OCT also classified 13 eyes as P, but 6 (46%) of these 13 OCT-P eyes were “missed” by the 24-2 GPA (red in Table). All 6 GPA misses showed clear progression of glaucoma as indicated by the plots/maps in Fig. Further, 6 of the eyes identified by the GPA as PP or LP (green in Table) were rated as OCT-NP or OCT-neither. These 6 eyes were likely false positives (FP) as: 2 were HC; the post-hoc analysis could not confirm progression in any of these 6; and reasons for a FP were identified on most (e.g., variable VFs, rim artifacts, and/or high local sensitivity at baseline).

Conclusions: The 24-2 GPA missed almost half of the eyes identified as progressing on a single OCT follow-up scan. In addition, FPs occurred. Given the GPA takes a minimum of 4 tests to identify “possible progression”, the results suggest that the testing burden on patients can be reduced with OCT.¹ 1. ABSTRACT BODY:

Purpose: To assess toxicity and efficacy of subretinal gene replacement in BBS10 mice. Overexpression toxicity in BBS1 mice occurred with gene therapy;BBS1 is part of the BBSome, while BBS10 is part of the BBS/CCT chaperonin complex.

Methods: A knock out mouse model of Bardet Biedl Syndrome type 10 (BBS10) was developed. AAV2/5-Bbs10FLAG and AAV2/Anc80-Bbs10FLAG vectors were created. Subretinal 2 ul injections of 1E12, 2E12 or 4E12VG/ml were performed in 62 Bbs10^{-/-} and 12 WT mice. Immunoblotting and immunohistochemistry were utilized to assess protein production and restoration of Bbs10 gene function. ERG, OCT, and visually guided swim assay (VGSA) were used to assess efficacy. Due to COVID-19, long term data was collected only for 12 mice treated with 2E9 or 4E9 AAV2/Anc80-Bbs10FLAG and 3 controls.

Results: Neither AAV2/5-Bbs10FLAG nor AAV2/Anc80-Bbs10FLAG were toxic in WT or Bbs10^{-/-}. One month after injection, FLAG was detected in treated, but not untreated Bbs10^{-/-} eyes, documenting presence of BBS10 protein. BBS7, undetectable or barely detectable within photoreceptor cilia in untreated Bbs10^{-/-} eyes, was present in photoreceptor cilia in treated Bbs10^{-/-} eyes. VGSA was partially rescued via either AAV2/5 or AAV2/Anc80 treated at P30-P60 when tested in the dark at age 3.5 months (p= 1.36E-005) and in both light and dark at age 7 months (p= <0.0001 light; p= 0.0094 dark). VGSA improvement endured in AAV2/Anc80 treated mice at 9-12 months old (p=0.0113). Treated eyes had higher amplitude ERG than untreated fellow eyes at 10-11.5 months old (highest p=0.0425). OCT at 11-14 months demonstrated presence of outer nuclear layer in 5/11 treated eyes compared to 0/11 untreated fellow eyes and 0/6 untreated control eyes. 5Hz flicker response was not present at any age in untreated Bbs10^{-/-} (n=18 eyes), but developed in 9 of 12 eyes treated before 4 months old. 4 of 12 treated eyes still had recordable 5 Hz at 11-14 mos, all treated with 4E9. Histology at 11 months demonstrated robust ONL, inner and outer segments with numerous cones, and normal localization of STX3 adjacent to the injection site in 2 treated eyes.

Conclusions: In the Bbs10^{-/-} mouse subretinal gene therapy with AAV2/Anc80-Bbs10FLAG rescues retinal phenotype. Lack of 5 Hz flicker ERG response in untreated eyes was rescued with early high titer gene therapy suggesting that

BBS10 plays an early role in cone development and/or function. Human BBS10 clinical trials are needed.

SUBMITTER (NAME ONLY): Anastasiya Vinokurtseva

TITLE: Treatment of ocular inflammation: effects of COX-2 acetylating immuno-resolvents (CAIRs) in THP-1-derived macrophages and a rat model of endotoxin-induced uveitis

SESSION TITLE: Translational Immunology and Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Vinokurtseva, J.J. Armstrong, H. Liu, C.M. Hutnik, Ophthalmology, Western University Schulich School of Medicine & Dentistry, London, Ontario, CANADA|J.J. Armstrong, P. Kiser, C.M. Hutnik, Pathology, Western University Schulich School of Medicine & Dentistry, London, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Anastasiya Vinokurtseva: Commercial Relationship: Code N (No Commercial Relationship) | James Armstrong: Commercial Relationship: Code N (No Commercial Relationship) | Hong Liu: Commercial Relationship: Code N (No Commercial Relationship) | Patti Kiser: Commercial Relationship: Code N (No Commercial Relationship) | Cindy Hutnik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Current treatments for uveitis lack adequate efficacy and impede the body's endogenous inflammation-resolution. Targeted acetylation of cyclooxygenase-2 (COX-2) enzyme redirects its activity from pro-inflammatory to pro-resolving, amplifying resolution of the acute phase of inflammation, and mitigating sequelae of chronic inflammation such as scarring and connective tissue changes. COX-2 acetylating immuno-resolvents (CAIRs) are agents capable of specifically acetylating COX-2 and include locally delivered acetylsalicylic acid (ASA) as well as a more potent derivative compound, o-(acetoxypheyl)hept-2-ynyl sulfide (APHS). We hypothesized that intravitreal injection of CAIRs would reduce histological markers of inflammation in an animal model of uveitis and reduce expression of pro-inflammatory genes in THP-1 macrophages.

Methods: Lipopolysaccharide (LPS) or vehicle was administered subcutaneously to Lewis rats 6 hours prior to intravitreal (IVT) experimental injections. Control animals received vehicle IVT OU while LPS-induced rats received either IVT ASA or APHS OD, with vehicle OS. 25 hours following LPS-induction, both eyes underwent histopathological assessment of the anterior and posterior segments. Effects of experimental treatments on cytokine production were assessed in vitro with phorbol 12-myristate 13-acetate (PMA)-induced THP-1 macrophages. Cells were co-treated for 6 hours with LPS and either ASA or APHS. Total RNA was extracted and expression of pro-inflammatory markers IL-1 β , TNF α and COX-2 was assessed via RT-qPCR.

Results: Eyes of LPS-treated animals, receiving CAIRs IVT showed marked reduction in inflammatory cell infiltration in both anterior and posterior ocular segments, compared to vehicle-treated contralateral eyes of the same animals. In vitro, LPS-treated macrophages demonstrated significant upregulation in inflammatory cytokines IL-1 β , TNF α and COX-2; CAIRs counteracted this effect in a dose-dependent manner.

Conclusions: CAIRs were well-tolerated and efficacious in this rat model of endotoxin-induced uveitis. They also demonstrated significant efficacy in vitro, reducing macrophage pro-inflammatory signaling. These compounds show initial promise as potential novel inflammation-resolving treatments. Next steps are to compare the safety and efficacy of CAIRs to current clinical therapies within this model.

ABSTRACT BODY:

Purpose: Staphylococcus aureus is a frequent cause of eye infections, with isolates exhibiting increased antimicrobial resistance to commonly prescribed antibiotics. This study aimed to determine the antimicrobial susceptibility patterns and virulent determinants of S. aureus strains isolated from infectious and non-infectious adverse events from USA and Australia.

Methods: 51 strains of S. aureus from different ocular conditions (11 microbial keratitis [MK], 26 conjunctivitis and 14 from non-infectious contact lens corneal infiltrative events (niCIEs), were analysed for susceptibility to antibiotics commonly used to treat these conditions, using the broth dilution method. The presence of 13 virulence genes was determined by PCR.

Results: All strains were sensitive to vancomycin (100%) and gentamicin (98%). The susceptibility to other antibiotics decreased in the following order: chloramphenicol (80%), oxacillin (70%), ciprofloxacin (45%), ceftazidime (13%), azithromycin (10%) and polymyxin B (2%). All Australian MK strains but only 11% of USA MK strains were susceptible to ciprofloxacin and oxacillin ($p = 0.107$). 75% of Australian conjunctivitis strains from Australia were susceptible to ciprofloxacin compared to 37% of USA conjunctivitis strains ($p=0.278$). Most (90%) Australian niCIEs and USA conjunctivitis (96%) but only 55% of USA MK strains were susceptible to chloramphenicol ($p = 0.0036$). 84% of all strains were multi-drug resistant. All strains possessed Eap which aids in adhesion. Most strains possessed fnbpA, except 2 strains from niCIEs. No MK possessed clfA whereas all strains from niCIEs and 61% of conjunctivitis strains possessed clfA gene. pvl (Panton-Valentine leukocidin), which is associated with community-acquired MRSA, was present in most Australian MK and conjunctivitis strains but not in non-infectious strains ($p = 0.018$). Australian conjunctivitis strains were more likely to possess pvl than USA conjunctivitis strains ($p = 0.031$).

Conclusions: Knowledge of the rates of resistance to antibiotics may be important in decisions on treating these diseases. The differences in possession of virulence genes may be related to the pathogenesis of these conditions.

ABSTRACT BODY:

Purpose: DR is a common complication of diabetes, and remains a leading cause of vision loss in the US and globally. We aimed to characterize the disease progression and treatment patterns (tx-pats) of DR and DME in children and adults in the US.

Methods: A retrospective cohort study was conducted with the Truven Health Marketscan data from 2011 to 2019. ICD-9 and ICD-10 were used to identify patients (pts) with index diagnoses of diabetes mellitus (DM), DR by severity, and DME. Pts included had ≥ 12 months medical/pharmacy enrollment, DM pts had ≥ 2 diagnoses at least 30 days apart in outpatients or ≥ 1 diagnosis in an inpatient setting. At least one diagnosis was required for DR/DME. For progression and tx-pats analysis, pts were required to have ≥ 180 days of follow-up (F/U) before and after DR/DME index. We excluded pts with prior history of any type of treatments of interest (tx-I; i.e. anti-VEGF, laser, corticosteroid, vitrectomy).

Results:

In total, 253 children and 165,404 adult DR pts were included and examined for progression and tx-pats longitudinally, and 74 children and 63,639 adult DME pts for tx-pats. The prevalence in children with DM is 0.7% and 0.2% for DR and DME, respectively.

The majority (84%) of pediatric DR pts were initially diagnosed with mild Non-Proliferative DR (NPDR), and 2.4% developed DME in a median of 2.1-year F/U. DR progression, and treatments for DR/DME were rarely observed in children.

Among the adult DR pts, 66.9%, 12.3%, 2.2%, and 18.6% had an initial diagnosis of mild, moderate, severe NPDR and Proliferative DR, respectively; 8.5% of them progressed and 15.3% developed DME in a median of 1.9-year F/U. No significant difference was observed between type-1 and type-2 DM pts. In addition, 14.2% of the DR and 52.6% of DME pts received ≥ 1 type of tx-I, the percentage of pts who received treatment increased by DR severity (Table 1). Treatment with Anti-VEGF, laser, and vitrectomy was more frequently observed than corticosteroid.

Conclusions: This work provides a deeper understanding of the DR characteristics in pediatric pts, showing rare DR progression and treatments for DR/DME. The majority of adult DR and half of DME pts did not receive any tx-I. Additional research is warranted to understand the drivers of treatment decisions in pts with DR and DME.

ABSTRACT BODY:

Purpose: State-of-the-art techniques can be used to identify Humanin-G (HNG) fragments and dimers for possible use in future therapeutic investigation in age-related disease such as age-related macular degeneration, Alzheimer's disease and cancer.

Methods: For long-term stability analyses, HNG solutions were stored for 11 months at 4°C. For High-Resolution Mass Spectrometry (HRMS) studies, samples with a concentration of 30 µM HNG in HPLC water were used to analyze 11-month-old HNG products.

Mass spectrometric analysis was performed using Xevo G2-XS Quadrupole Time-of-Flight (HRMS) mass spectrometer coupled to UPLC. The UPLC method was run on a Water BEH C4 column using a 25 minutes linear gradient at 0.3 mL/min from 97% A to 97% B where A is 0.1% Formic Acid in water and B is 100% Acetonitrile. For HRMS analysis, positive electrospray ionization mode was utilized. A capillary transfer temperature of 300°C and a spray voltage of 3.0 kV were used to accomplish ionization. A resolution of 30,000 Full Width at Half Maximum (FWHM) was used for a full scan experiment within a range of m/z 100–2000 in addition to 15,000 FWHM with an isolation window adjusted to m/z 2.0 for. Leucine Enkephalin was used as a lock mass for nominal mass correction, and a CsNaI ladder was used for detector calibration.

Results: The HRMS spectrum of Humanin-G degraded molecules and humanin-G homodimers are presented in Figure 1A and Table Peptide Sequences (PS). In Humanin-G, disulfide dimerization was observed upon incubation of Humanin-G in HPLC water after 11 months at +4°C constant. Humanin-G homodimers (molecular mass 5312), the main ions were +9, +8, +7, +6, +5, charged states at m/z 532.31, 591.23, 665.01, 759.85, 886.34, 1063.40, (Fig. 2, Table PS). Humanin-G homodimers were detected at the highest intensities. HRMS detected other dimerized Humanin-G fragments (Fig. 1, 2 and Table PS). Dimerized Humanin-G fragments are shown in Figure 3 and Table PS.

Conclusions: For the first time, long-term stability properties of HNG peptide and its degradation products have been analyzed in detail using advanced HRMS technologies. Our data suggest that Humanin-G homodimers represent a more stable form than a single Humanin-G peptide. Our results may help researchers design better in vitro and in vivo experimental parameters to further understand the critical role of HNG in physiological conditions and human diseases.

ABSTRACT BODY:

Purpose: To analyze the effect of common and rare genetic risk variants in AMD development in the Epidemiologic Coimbra Eye Study (CES).

Methods: Population-based cohort study. Participants underwent standardized interviews and ophthalmologic examination in the CES for AMD prevalence and incidence in central Portugal(NCT01298674,NCT02748824). Staging at both visits was performed with Rotterdam classification in a centralized reading center. Genomic DNA was isolated from blood samples. The genotyping assay was based on single-molecule molecular inversion probes for target selection and used next-generation sequencing to sequence 87 single nucleotide polymorphisms (SNPs). A total of 792 samples and 69 successfully genotyped SNPs were tested for association under an additive model, using the progression/no progression to AMD as a binary outcome. A logistic regression analysis was performed to assess allelic odds ratio (ORs) at 95% CI for each variant, adjusted for age and sex, significance level was set to 0.05.

Results: We included 142 participants who developed AMD (stages 2,3,4) during the 6.5-year follow-up and 650 controls (no AMD). Both common and rare variants were found to be associated with increased risk of developing AMD: CFH rs35292876 (OR,3.07;95%CI 1.19,7.43;P=0.015); ARMS2 rs10490924 (OR,1.51;95%CI 1.08,2.1;P=0.016); CFHR5 rs10922153 (OR,1.42;95%CI 1.09,1.85;P=0.010); and ARMS2-HTRA1 rs3750846 (OR,1.52;95%CI 1.08,2.12;P=0.015). Protective variants associated to reduced risk of progression to AMD were also identified: CFH rs10922109 (OR,0.68;95%CI 0.51,0.90;P=0.007); CFH rs1410996 (OR,0.66;95%CI 0.49,0.86;P=0.003); CNN2 rs10422209 (OR,0.63;95%CI 0.40,0.95;P=0.035); C2-CFB-SKIV2L rs429608 (OR,0.43;95%CI 0.24,0.71;P=0.002); COL10A1 rs3812111 (OR,0.76;95%CI 0.58,0.99;P=0.045); and SYN3-TIMP3 rs5754227 (OR,0.56;95%CI 0.33,0.91;P=0.026).

Conclusions: Both common and rare variants were found to be associated with the development of AMD in our epidemiological longitudinal study, while others were protective. Genetic characterization is important to pursue in different populations, as the identification of potential genetic therapeutic targets is of major interest. We will also explore the correlation between genetics, clinical and phenotypic features in risk assessment.

TITLE: Spatial averaging effects on multifocal ERG amplitudes

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Yu, G. Kiri, USF Health Morsani College of Medicine, Tampa, Florida, UNITED STATES|S. Bijan, S. Bhaleeya, R.T. Tzekov, Ophthalmology, USF Health Morsani College of Medicine, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Su-Yuan Yu: Commercial Relationship: Code N (No Commercial Relationship) | Sara Bijan: Commercial Relationship: Code N (No Commercial Relationship) | Gaurav Kiri: Commercial Relationship: Code N (No Commercial Relationship) | Swetangi Bhaleeya: Commercial Relationship: Code N (No Commercial Relationship) | Radouil Tzekov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the effect of spatial averaging on the multifocal electroretinography (mfERG) averaged ring amplitudes in patients screened for hydroxychloroquine (HCQ) toxicity.

Methods: This was a retrospective review of the records of patients screened for HCQ retinopathy at the USF Eye Institute (University of South Florida) during the period of 2015-2020. Only the records of patients referred internally were used. Patients were tested binocularly with Diagnosys mfERG system (Diagnosys LLC, Lowell, MA) using 61 hexagons grouped in five rings. The effects of the lowest level (level 1, or 4%) of spatial averaging on the mfERG P1 and N2 amplitude ring averaged values were evaluated.

Results: The records of 40 patients (4 males, 36 females) aged 54.4 ± 14.1 yrs. were selected for analysis. The use of spatial averaging had a differential effect on different rings. The effect was most pronounced on ring #1 (central element) amplitudes: for P1 the median change was (right/left eyes) $-2.3/-1.7$ nV/d² (-13.3%/-12.1%); for N2 the median change was $-2.5/-1.8$ nV/d² (-13.6%/-11.9%) and this decrease was significantly different than 0 for all comparisons ($p < 0.001$, one sample Wilcoxon test). In contrast, the effect on the rest of ring amplitudes was small, the median absolute effect was either 0 or 0.1 nV/d² (median % change was $< 2.5\%$), although for ring #4 values this change was significant ($p < 0.02$, one sample Wilcoxon test), except for N2 amplitude left eyes. The analysis of percent change vs. amplitude demonstrated no linear relationship for P1, while there was a negative relationship for N2 (ring #1, #2 and #3 left eyes and ring #1 left eyes), however, the presence of outliers was noted and once these were removed, the relationship remained significant only for ring #1 left eyes ($R^2 = 0.1347$, $p = 0.0198$).

Conclusions: For both P1 and N2 amplitudes spatial averaging has a substantial effect, especially on the amplitude of the central element (ring #1). As this is an mfERG amplitude is an important parameter, which could affect the interpretation of the results, use of spatial averaging should be avoided when analyzing mfERG results for HCQ screening.

ABSTRACT BODY:

Purpose: The Treat-and Extend (T&E) method is often used by retina specialists in clinical settings in the treatment of neovascular age-related macular degeneration (nAMD). This study evaluated the outcomes of regular intravitreal ranibizumab, aflibercept, bevacizumab, or brolucizumab in patients with nAMD in the United States over the course of seven years.

Methods: This is a retrospective, interventional, consecutive case series. 165 eyes from 137 treatment-naïve patients diagnosed with nAMD after August 2010 were treated at a single site by one physician with ranibizumab, aflibercept, bevacizumab, or brolucizumab for ≥ 1 year using a T&E regimen. Patients needed to receive ≥ 6 injections in the first year and ≥ 3 injections in the following years to be included in this study. Snellen best-corrected visual acuity (BCVA) was converted to ETDRS letters using a standardized formula. The main outcome measures were: BCVA change from baseline to end of patient follow-up, mean number of injections per year, and percentage of eyes losing ≥ 15 letters or gaining ≥ 15 letters.

Results: The average (standard deviation [SD]) baseline patient age was 78 years (8.5); 60% of patients were female. The mean follow-up period was 5 years, with 165, 158, 143, 113, 98, 64 and 32 eyes completing 1, 2, 3, 4, 5, 6, and 7 years of follow up, respectively. The average BCVA at baseline was 53 letters. Mean (SD) changes from baseline in BCVA were 8.2 (21.8) letters, 7.0 (25.0) letters, 4.4 (26.7) letters, 4.2 (27.6) letters, 4.4 (28.7) letters, 4.6 (26.2) letters, and 4.6 (37.0) letters for years 1, 2, 3, 4, 5, 6, and 7 respectively. The mean number of injections received by patients in year 1 was 8. In years 2 through 7, the mean number of injections received by patients was 6. At the final follow-up, 23.4% of male eyes and 25.7% of female eyes had lost ≥ 15 ETDRS letters and 28.1% of male eyes and 27.7% of female eyes had gained ≥ 15 letters.

Conclusions: The Treat-and-Extend regimen was effective in maintaining visual acuity in patients with nAMD treated with ranibizumab, aflibercept, bevacizumab, or brolucizumab for up to 7 years of treatment in patients who received a minimum of 6 injections in the first year and a minimum of 3 injections in follow-up years 2 through 7. To reduce overall treatment burden, the Treat-and-Extend regimen is an effective treatment option for patients.

ABSTRACT BODY:

Purpose: Host factors, including age, are associated with increased severity of toxoplasmic retinochoroiditis and shorter intervals to recurrence. We have previously shown that more severe inflammation of an episode also predicts shorter intervals to the next recurrence. We sought to determine if severity of an episode predicts other characteristics of recurrences as well.

Methods: We used a dataset of 210 patients with ocular toxoplasmosis from 7 international sites (North/South America, Europe). Longitudinal data for each episode were available for 46 patients with multiple documented recurrences. We compared the following factors at first visits of first-observed episodes to the same factors at first visits in all subsequent episodes: anterior chamber (AC) cell; vitreous haze; and intraocular pressure (IOP). We also compared duration of lesion activity between first-observed episodes and all subsequent episodes.

Results: Of 46 patients, there were 129 episodes (range 1-7 episodes/patient) including 558 visits with active disease. At first visits, AC cell was >1+ in 12 (27.3%) patients during first-observed episodes and in 11 (13.8%) episodes for all subsequent episodes. Median duration of lesion activity was 53 days (interquartile range [IQR] 27-91 days) for first-observed episodes and 45 days (IQR 32-68 days) for subsequent episodes. Those with >1+ AC cell at first-observed episodes more likely had >1+ cell at any subsequent episode (odds ratio [OR] 21.4 [95% CI 3.82-119.7], p=0.0002); agreement between episodes for individual patients was moderate (Kappa coefficient 0.478 [CI 95% 0.222-0.733]); however, >1+ AC cell was not related to elevated IOP (>21mmHg) subsequently (p=0.64). There were no relationships between first-observed episodes and all subsequent episodes for vitreous haze (p=0.18), elevated IOP (p=1.0), and duration of lesion activity (p=1.0).

Conclusions: Severe AC reactions during episodes of toxoplasmic retinochoroiditis predict not only shorter intervals to recurrences, but more intense inflammatory reactions in recurrent episodes. Despite a previously reported relationship between AC cell and elevated IOP at presentation, neither factor predicted elevated IOP at recurrences. Risk factors related to the characteristics of recurrent ocular toxoplasmosis have implications for management decisions, including the need for secondary prophylaxis against recurrence.

TITLE: Agreement between trend-based and qualitative analysis of the retinal nerve fiber layer thickness for glaucoma progression on Spectral domain-optical coherence tomography

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.C. Thompson, S. Asrani, Ophthalmology, Duke University, Durham, North Carolina, UNITED STATES|A. Li, Ophthalmology, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Atalie Thompson: Commercial Relationship: Code N (No Commercial Relationship) | Ang Li: Commercial Relationship: Code N (No Commercial Relationship) | Sanjay Asrani: Commercial Relationship(s);Heidelber engineering:Code R (Recipient)

ABSTRACT BODY:

Purpose: To evaluate the agreement between trend-based analysis versus qualitative assessment of the retinal nerve fiber layer (RNFL) thickness for glaucomatous progression on Spectral domain-optical coherence tomography (SDOCT).

Methods: Retrospective cohort of 190 eyes from 103 patients with glaucoma or glaucoma suspect diagnoses who underwent SDOCT imaging during 4 different clinic visits. Trend-based progression was characterized by a significantly negative slope. Progression by qualitative analysis was determined by review of RNFL thickness profiles from automated segmentation and raw B-scan SDOCT images.

Results: The slope was significantly greater in those with progression than without progression for both trend-based and qualitative analysis ($p < 0.001$). However, the qualitative grading classified a significantly greater proportion of eyes as progressing compared to trend-based analysis in both the superotemporal (ST) RNFL (23.2% vs. 10.5%, $p = 0.001$) and inferotemporal (IT) RNFL (27.4% vs 8.4%, $p < 0.001$). The trend-based and qualitative classifications of progression showed poor agreement in both the ST (Kappa 0.0135) and IT RNFL (Kappa 0.1222). The agreement between trend-based and qualitative analysis was lower among eyes with artifacts (ST 58.11%; IT 68.7%) than those without artifacts (ST 80.2%; 74.8% IT). Moreover, among eyes with artifacts, there was no significant difference in slope between those qualitatively categorized as progressing versus not progressing ($p > 0.05$). The figure shows an example of false progression on SDOCT due to vitreomacular traction release.

Conclusions: There is poor agreement between a trend-based definition of glaucoma progression and qualitative analysis of the change in RNFL on SDOCT. Careful qualitative review of SDOCT imaging may identify specific areas of glaucoma progression that are not captured by trend-based methods especially in the presence of artifacts.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a common complication of diabetes that leads to progressive vision loss. Although hyperglycemia (HG) plays an important role in its pathogenesis, a growing body of evidence suggests that pro-inflammatory conditions in the eye enhance DR development and progression. In this study, we investigated the combined effect of HG and inflammation on the early stages of disease by assessing retinal function and metabolic homeostasis.

Methods: HG was induced in C57Bl/6 mice within one week of administering a single intraperitoneal injection of streptozotocin (150 mg/kg), while control mice received a sham injection. After confirming HG, mice received an intravitreal injection (IVT) of 500 ng/ml of each pro-inflammatory cytokine TNF- α and IL-1 β (HG+cytokines group, n=6) or a sham injection (HG-only group, n=6). Control mice received an IVT of pro-inflammatory cytokines (cytokines-only group, n=6) or a sham injection (control group, n=6). The retinal function (focal electroretinogram on the superior retina) was evaluated two days after IVT and the retina was immediately collected for biochemical analysis to determine retinal glucose, lactate, ATP, glutamate and glutamine levels.

Results: A similar significant decrease in the a-wave amplitude was observed in both HG-only and HG+cytokines groups at higher light intensities 2.6 and 3.2 log cd.s/m² (p<0.01) compared with control. A significant decrease in the b-wave amplitude was observed in the HG-only group at 2.6 log cd.s/m² (p<0.05) and it was significantly further decreased in the HG+cytokines group at the higher light intensities 2, 2.6 and 3.2 log cd.s/m² (p<0.05). While the HG-only group showed elevated glucose levels (p<0.01), the HG+cytokines group showed a significantly higher retinal glucose (p<0.001), lactate (p<0.001), ATP (p<0.001), glutamine (p<0.05) levels, and a significant decrease in glutamate (p<0.05) levels compared with control. The cytokines-only group showed no significant changes compared with control.

Conclusions: The presence of pro-inflammatory cytokines in the eyes of HG mice altered the retinal metabolic homeostasis and retinal function in the photopic range. These findings support the idea that combined presence of HG and inflammation may enhance DR development. Hence, early intervention to prevent inflammation-triggered retinal changes in diabetic patients may improve the disease outcome.

TITLE: To Analyze the dead space syringe for intra-vitreous injections

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Teixeira, I. Silva, A. Pereira, Ophthalmology, Universidade Catolica de Brasilia, Taguatinga, DF, BRAZIL|C. Salaroli, Cornea, Clinica de Olhos Teixeira Pinto, BRAZIL|

Commercial Relationships Disclosure (Abstract): Anderson Teixeira: Commercial Relationship: Code N (No Commercial Relationship) | Isadora Silva: Commercial Relationship: Code N (No Commercial Relationship) | Amelia Pereira: Commercial Relationship: Code N (No Commercial Relationship) | Camila Salaroli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We described a novel method to quantify the waste volume left into the plastic syringe after anti-VEGF injection and elected the best plastic syringe to use during intra-vitreous injections.

Methods: We evaluated the amount of fluid retained in eight different types of insulin/tuberculin syringes with permanent needle design and without needle design used to perform intra-vitreous injections commercially available in the Brazilian marketing. Firstly, we divided the syringes types in group of ten samples and they all were weighted using a precise (0.01g) caliper balance.

In a second phase we filled the syringes with water, removed air bubbles and then pushed the syringe piston to the mark of 0,05ml. All the syringes were immediately weighted again. Then, we simulated an intra-vitreous injection pushing the piston to the end (mark 0.00) and we immediately weighted.

Results: All results are described in the table 2 and 3. Mean residual weight into the dead space of syringes with permanent needle design was between 0.002 to 0.006 g and the syringe without needle was 0.032g. No statistic significant was observed in samples of syringe with permanent needle design but comparing all syringes with permanent needle design to the syringe without needle all results were statistically significant ($P < 0.01$). This indicates that a significant amount of volume loss is due to dead space if we use syringe without needle design.

Conclusions: Our study showed if we use a syringe without needle a residual volume of 58 per cent of the total amount injected remains in dead space, which means a despise of one dose treatment (0.05ml) for each two injections . During the years of 2006 to 2015 almost one billion injections were performed in USA. Considering the use of syringe with permanent needle we should save almost half treatment dose per injection and consequently reducing the cost treatment.

In conclusion, we highly incentive physicians to use syringe with permanent needle to perform intra-vitreous injections. New techniques to compounder into multiple doses the anti-VEGF using syringes with permanent needle is necessary to reduce the treatment cost per patient.

ABSTRACT BODY:

Purpose: High-fat diet (HFD) alters the composition of the gut-microbiome-a condition known as gut dysbiosis. Both HFD and gut microbiome are implicated in the pathogenesis of retinal diseases including age-related macular degeneration (AMD) and diabetic retinopathy (DR). However, retinal transcriptome changes secondary to diet-induced gut dysbiosis have not been delineated. Here, we study the effect of HFD-induced gut dysbiosis on retinal gene expression and biologic pathways.

Methods: Fifteen weeks-old male C57BL/6J wild-type mice on normal diet (ND) and 23% HFD for 8 weeks were used (4 mice/group). Bacterial community structure is assessed from fecal DNA using 16S rRNA sequencing done on the Illumina MiSeq DNA platform and analyzed via QIIME software to determine the relative microbiome abundance. Whole retina RNA-sequencing (RNA-seq) was performed on NovaSEQ6000 using the paired-end method. Differentially expressed genes (DEGs) were identified (p-value <0.01); biologic pathways associated with the DEGs were found using the Kyoto Encyclopedia of Genes and Genomes (KEGG). Functional enrichment network and upstream transcription factor analysis were performed using EnrichR.

Results: Mice fed HFD have increased relative abundance of phyla of Firmicutes and Verrucomicrobia and decreased abundance of Bacteroides phylum. RNA seq identified a cohort of 30 DEGs, 14 of which were upregulated, and 16 were downregulated in the HFD group. DEGs included hypermethylated in cancer 1 (HIC1) and heat shock protein family A member 1B (Hspa1b) which are strongly associated with AMD. Pathway analysis revealed that DEGs are involved in purine, pyrimidine, arginine, and glutathione metabolism and mitogen-activated protein kinases (MAPK), cGMP-dependent protein kinase (cGMP-PKG), and phosphatidylinositol 3-kinase (PI3K)/protein kinase B (AKT) signaling pathways. Transcription factor polymerase 1(PARP1) and forkhead fox M1 (FOXO1) involved in retinal degeneration and epithelial-mesenchymal transformation of retinal pigment epithelium cells, respectively were also affected.

Conclusions: To our knowledge, this is the first study demonstrating that HFD-induced gut-dysbiosis regulates the retinal transcriptome, involving genes known to play a key role in AMD. Altering the gut microbiome via diet may have future implications for treating retinal diseases, especially AMD.

TITLE: Myopia-related changes to retinal astrocytes and associated retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) of juvenile marmosets

SESSION TITLE: Molecular and Structural

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Lin, A. Toychiev, A. Nour, R.K. Ablordeppey, M. Srinivas, A. Benavente-Perez, SUNY College of Optometry, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Carol Lin: Commercial Relationship: Code N (No Commercial Relationship) | Abduqodir Toychiev: Commercial Relationship: Code N (No Commercial Relationship) | Ana Nour: Commercial Relationship: Code N (No Commercial Relationship) | Reynolds Ablordeppey: Commercial Relationship: Code N (No Commercial Relationship) | Miduturu Srinivas: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Benavente-Perez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal astrocytes are key elements of neuronal support. We hypothesize that the mechanical elongation of the globe due to myopia progression affects astrocytes and predisposes the myopic eye to ocular complications. In this study, we characterized the effect of lens-induced myopia on retinal astrocyte coverage and distribution in relationship to RNFL and GCL thickness of common marmosets (*Callithrix jacchus*).

Methods: Eight myopic and ten control (myopic average Rx: -5.49 ± 2.48 D, age: 195 ± 16.75 days; controls average Rx: -1.10 ± 0.62 D, age: 293 ± 90.56 days, $p < 0.01$) marmoset retinal whole mounts were labeled with anti-GFAP and anti-Sox9 to visualize astrocytes within the superficial layer. Astrocyte numbers, RNFL and GCL thickness were quantified at the parafoveal, peripapillary, and peripheral retinal regions using confocal microscopy and optical coherence tomography (OCT). Ocular magnification was corrected using Kang's method. Statistical analysis was performed using Mann-Whitney U non-parametric testing at a confidence level of 95%.

Results: Myopes had less astrocytes (controls 248.55 ± 18.55 , myopes 154.96 ± 23.3 , $p < 0.05$), thinner RNFL (controls $33.80 \text{ mm} \pm 12.4$; myopes $24.57 \text{ mm} \pm 3.3$, $p < 0.01$) and thinner GCL (controls $23.38 \text{ mm} \pm 2.9$; myopes 21.52 ± 2.9 , $p = 0.02$) in the parafovea compared to controls. In control eyes, the number of astrocytes increased as the overall GCL ($R^2 = 0.19$, $p < 0.01$) and peripapillary RNFL ($R^2 = 0.81$, $p < 0.04$) thickened; while in myopic eyes, these were not significant. In control eyes, the RNFL thickened as eyes grew normally (superior and nasal peripapillary $R^2 = 0.80$, $p < 0.02$; $R^2 = 0.86$, $p = 0.02$; temporal parafovea $R^2 = 0.79$, $p < 0.05$; temporal periphery $R^2 = 0.97$, $p < 0.02$). In myopic eyes, on the opposite, the GCL thinned as eyes grew larger and developed myopia in the superior periphery ($R^2 = 0.86$, $p < 0.01$).

Conclusions: Untreated marmosets exhibit a thickening of the RNFL as their eyes grew normally and this was accompanied by an increase in the astrocyte bodies observed. Myopic marmosets, however, exhibited lower astrocyte numbers, their RNFL and GCL thinned as eyes grew myopic. These results suggest compromised glial structure and function, leading to inadequate ability to regulate local ions and support neural tissue in eyes with progressing myopia.

ABSTRACT BODY:

Purpose: There is a significant paucity of neuroprotective strategies to reduce the vulnerability to glaucoma-related cellular stressors. Recent work has suggested that patients with glaucoma have reduced plasma levels of nicotinamide adenine dinucleotide (NAD), a precursor for vitamin B3 (niacin). Additionally, mouse models have found a similar age-related decline in NAD with subsequent neuroprotection of retinal ganglion cells with very high-dose oral vitamin B3. We aimed to evaluate whether dietary vitamin B3 and 50 other vitamins, minerals and micronutrients explain variation in glaucoma-related endophenotypes in the general population.

Methods: A population-based cross-sectional study was performed with 1,977 predominantly female participants from the TwinsUK registry. Energy adjusted intakes for 51 nutrients were estimated through a validated food frequency questionnaire. Endophenotypes evaluated included intraocular pressure (IOP), retinal nerve fibre layer (RNFL) thickness and vertical cup to disc ratio (VDCR) adjusted for disc area. Linear mixed models adjusted for age, sex and family structure were used to investigate the associations of individual nutrients and endophenotype. A backwards stepwise regression model was completed for each endophenotype, including all associated nutrients after stratifying intake into quartiles.

Results: Within the study cohort, mean (SD) age was 60.1 (± 14.6) years. Mean endophenotype values measured were IOP: 13.3mmHg (± 2.81), VCDR: 0.4 (± 0.12) and RNFL: 96.1 μ m (± 10.10). Dietary vitamin B3 was not associated with any endophenotypes. Multivariate regression models evaluating lowest versus highest quartiles of dietary intake identified two nutrients associated with RNFL thickness, magnesium ($\beta = -1.83$, $p = 0.04$) and thiamine ($\beta = 2.03$, $p = 0.02$); thiamine intake demonstrated a dose-related association with a thicker RNFL for each quartile. Flavonoids intake was associated with reduced IOP ($\beta = -0.401$, $p = 0.05$), and vitamin E ($\beta = -0.017$, $p = 0.03$) and selenium ($\beta = 0.019$, $p = 0.04$) were associated with VCDR.

Conclusions: Dietary thiamine intake has a dose-response relationship to RNFL thickness, longitudinal studies are required to see if it protects against RNFL loss. In a healthy population dietary vitamin B3 did not appear to be protective for glaucoma-related endophenotypes. Dietary flavonoid intake appears to be associated with lower IOP.

ABSTRACT BODY:

Purpose: Prosthetic visual acuity is limited by the pixel size and by crosstalk from the neighboring electrodes. For acuity better than 20/200, pixels should be under 50 μ m, and local returns are required for the crosstalk suppression. However, small bipolar pixels over-constrain the field penetration and thus limit the efficacy of retinal stimulation. Sequential activation of the photodiode pixels transforms active electrodes into transient returns. We explore this approach for dynamic confinement of electric field in the retina by spatiotemporal control of the images projected onto the photovoltaic array.

Methods: The electric field in the retina generated by a photovoltaic subretinal implant with 425 hexagonal monopolar pixels of 40 μ m in pitch was modeled using the finite element method and linear combination of the elementary electric fields emanating from each electrode individually. We quantified the spatial coupling among the pixels and calculated the dynamics of the photodiode circuit in the multidimensional form. Electric fields predicted by the model were compared to the potential mapped by micropipette ex-vivo, as well as that recorded from corneas in implanted rats.

Results: Spatiotemporal modeling shows that the electric field generated by active electrode elevates the local potential on neighboring dark pixels and thereby transiently increases their discharge current by up to 10 fold, effectively transforming them into return electrodes. The distance between the active electrode and the transient return defines the penetration depth of the electric field into tissue. Ex-vivo measurements of the electric potential match the model predictions. Amplitude of the corneal signal in rats increases with the width of the grating projected onto the implants, from 40 to 180 μ m, confirming the configurability of the stimulation depth in-vivo.

Conclusions: Current conducted by photodiodes in an array is affected by other electrodes due to spatial coupling of the electric potential in electrolyte. Therefore, spatiotemporal modulation of light on the array can transform the active electrodes into transient returns. Such optical approach to current steering enables a flexible control of the lateral and axial confinement of electric field, which allows optimization of the stimulation depth and selectivity in every patient, depending on the retinal thickness and its proximity to the electrodes.

ABSTRACT BODY:

Purpose: The natural history of retinitis pigmentosa (RP) is known to vary across different inheritance patterns and across genetic etiologies. Two large groups of disease include RP caused by mutations in ciliary genes and RP caused by mutations in non-ciliary genes. This study aims to determine differences in disease progression in patients with mutations in ciliary and non-ciliary genes using spectral-domain optical coherence tomography (SD-OCT) and 30Hz flicker response in full-field electroretinograms. Study of the natural history of disease is critical to improve understanding and may guide clinical therapies by demonstrating which will require more aggressive and earlier intervention.

Methods: Retrospective chart review was performed of patients with genetically confirmed diagnoses of RP. SD-OCT images were obtained from 285 patients, 188 of whom were found to have mutations in ciliary genes. 30Hz flicker amplitudes were obtained from 69 patients with mutations in ciliary genes and 33 patients with mutations in non-ciliary genes. SD-OCT images were evaluated through measurements of ellipsoid zone (EZ) length and central foveal thickness (CFT) using the built-in caliper tool on the Spectralis HRA+OCT. The amplitudes of the 30Hz flicker electroretinograms were collected from a Diagnosys Espion Electrophysiology System.

Results: Longitudinal analysis of SD-OCT images revealed that the EZ deteriorated at a mean rate of 26.4µm/year in the ciliary gene cohort as compared to 15.7µm/year in the non-ciliary gene cohort. Measurement of CFT revealed a mean decrease of 0.7µm/year in the ciliary gene cohort as compared to 1.06µm/year in the non-ciliary gene cohort. 30Hz flicker amplitude decreased at a mean rate of 1.4µV/year in the ciliary gene cohort and 0.8µV/year in the non-ciliary gene cohort. The mean follow-up period for SD-OCT images was 4 years, while the mean follow-up period for 30Hz flicker measurements was 2.2 years.

Conclusions: Our study suggests that on average, RP due to mutations in ciliary genes may progress faster than RP due to mutations in non-ciliary genes as seen by EZ measurements and 30Hz flicker amplitudes. Therefore, patients with ciliary gene mutations may require more aggressive and earlier therapeutic intervention, and EZ line measurements and 30Hz flicker amplitudes may serve as viable outcome measurements for future clinical trials.

ABSTRACT BODY:

Purpose: Ex vivo expansion of corneal endothelial cells (CEnC) has the potential to alleviate the global shortage of donor corneal tissue that limits access to corneal transplantation. However, successful expansion of ex vivo corneal endothelial cells (evCEnC) is limited by early cellular senescence and loss of CEnC-like morphology. To determine whether or not oxidative stress plays a role in the expansion capacity of evCEnC, we cultured evCEnC with and without SkQ1, a mitochondria-targeting antioxidant, and measured the level of intracellular free radical (IFR) levels.

Methods: To determine the optimal SkQ1 dose range that will lead to minimal cell toxicity and maximal oxidative stress protection in CEnC, HCEC-21T, a CEnC line, was cultured in media supplemented with 0nM (untreated), 50nM, 250nM, 500nM or 750nM of SkQ1 for 3-5 days. Then the cells were treated with or without tBH, an oxidative stress inducing agent, and cell viability was assessed by MTT assay.

To determine the impact of SkQ1 treatment on IFR levels, evCEnC were isolated from donor corneas and then split into two culture (SKQ1-treated and untreated), which were each grown to confluence. DCFH-DA assay was performed to measure differences in IFR levels.

Results: When compared to untreated cells, HCEC-21T treated with 50nM or 250nM SkQ1 retained 98.8% and 96.9% cell viability, respectively, while HCEC-21T treated with 500nM or 750nM SkQ1 retained 65.8% and 22.7% cell viability, respectively. Under 100 μ M tBH oxidative stress induction, cell viability protection was observed in a SkQ1 dose-dependent manner with 250nM and 50nM SkQ1 treatment leading to 36.3% and 18.2% cell viability, respectively, while 0nM SkQ1 treatment yielded 14.8% viability.

Compared to their tBH-untreated counterparts, evCEnC treated with 50nM and 250nM SkQ1 demonstrated a ~7.5% and ~22.5% decrease, respectively, in IFR concentrations at passage 0. Additional evCEnC isolations are being assessed in order to perform statistical analyses.

Conclusions: Supplementing culture media with SkQ1 provides a CEnC line with tBH-induced oxidative stress protection and decreases IFR concentrations in cultured evCEnC. The preliminary findings of this study suggest antioxidants, such as SkQ1, may increase the expansion potential of ex vivo CEnC by reducing oxidative stress levels.

ABSTRACT BODY:

Purpose: Myopic macular degeneration (MMD) is rapidly increasing in prevalence worldwide, and severe forms can cause irreversible loss of vision. Recent studies have shown an association between decreased choroidal thickness and increased grade of MMD. Our cross-sectional study aimed to further characterize this choroidal thinning by analyzing choriocapillaris alterations in MMD.

Methods: We recruited controls (n=51 eyes) and high myopes (spherical equivalent ≤ -6 diopters; n=16 eyes) from clinic at the University of California San Francisco. Axial length (AL) from A-scan, best corrected visual acuity (BCVA), fundus photos, and swept-source optical coherence tomography angiography (SS-OCTA) were measured. Fundus photos were graded for stage of MMD by 2 independent ophthalmologists. Inclusion criteria for subjects were those with Grade 2 MMD (diffuse chorioretinal atrophy) and high axial myopia (AL ≥ 26.5 millimeters [mm]). Subjects without MMD, with ages from 19-88 years old (mean=56) and AL from 21.65 to 25.84mm (mean=23.87), were used as controls. Exclusion criterion was BCVA worse than 20/40. 3x3mm SS-OCTA scans were acquired and choriocapillaris (CC) mean thickness was measured by identifying CC peaks in OCTA A-scan intensity profiles. CC flow void percent (CC FV%) was quantified using a fuzzy C-mean thresholding method on enface OCT-A images of an 8-um CC slab below Bruch's membrane. Multivariate regression models were analyzed comparing CC thickness and CC FV% between subjects and controls, with a linear correction for age.

Results: Subjects with diffuse chorioretinal atrophy had both a significantly decreased CC thickness and increased CC FV% compared to controls. CC thickness in subjects with diffuse chorioretinal atrophy measured 5.23 ± 0.68 um (mean \pm standard deviation) versus 15.45 ± 1.82 um in controls ($p < 0.001$). CC FV% in subjects with diffuse MMD measured 26.5 ± 0.04 versus 11.6 ± 0.04 in controls ($p < 0.001$).

Conclusions: Patients with diffuse chorioretinal atrophy and good visual acuity had a 66% reduction in CC thickness and a 230% increase in CC FV% compared to controls. Although these patients have essentially normal BCVA and outer retinal landmarks on optical coherence tomography, they demonstrate significant choriocapillaris alterations that are consistent with reduced perfusion to the outer retina. These results point to a potential vascular etiology for MMD.

ABSTRACT BODY:

Purpose: Vision Threatening Diseases (VTD) (age-related macular degeneration [AMD], cataract, diabetic retinopathy [DR], and glaucoma) account for 37% of all blindness. Screening and follow-up are crucial in preserving vision. During COVID-19, clinics reduced access, using telemedicine for diagnosis and follow-ups. The efficacy of remote screening and triage in the management of single or multiple VTDs was evaluated.

Methods: We screened 41 subjects (19-85 years, 37% male, 17% Caucasian) (20 controls, 21 subjects). Demographics, 45-degree retinal photos, ganglion cell complex (GCC), and optic nerve head (ONH) images were collected using a non-contact puff-tonometer, non-mydratic retinal camera, and an OCTA. Demographics and images were transmitted to two readers (onsite telemedicine screener [TS] and remote ophthalmologist [RO]) for triage. Triage was categorized: immediate referral to specialist, follow-up in person via clinic or telemedicine visit, or no follow-up necessary during COVID.

Results: TS made 19 referrals (46%), 6 in person follow-ups (15%), 15 no follow-ups (37%); RO made 17 referrals (41%), 2 in person follow-ups (5%), 22 no follow-ups (54%). TS identified 12 subjects as possible VTD(s) while RO identified 11 subjects. TS and RO agreed on 8 glaucoma, 7 cataract, 3 DR, and 3 and 2 AMD cases, respectively. Glaucoma was identified using IOPs, retinal funduscopy, and OCT imaging. Mean intraocular pressures were 12.9 and 15.7 (OD, OS) in glaucoma and 14.2 and 14.0 in controls. Funduscopy was used for overall retinal health while OCT images were used to analyze GCC, ONH, nerve fiber layer, cup to disc ratio, and anterior chamber angles. AMD and DR were identified by funduscopy and OCT imaging. 11 of the subjects were known clinic patients; both RO and TS referred all 11 to specialty clinics, matching the in-person clinic management.

Conclusions: During the COVID pandemic, triaging patients can minimize person-to-person contact and help control the spread of the virus. Both readers agreed on the management and triage of a variety of patients with TS and RO differing only on 2 referrals and 4 in person follow-ups. Telemedicine is a promising alternative to in-person patient care for management and triage of vision threatening diseases. Further enrollment and follow-up are needed to increase robustness.

AUTHORS/INSTITUTIONS: H. Stubeda, Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, CANADA|L. Shuba, M. Nicolela, B.C. Chauhan, J.R. Vianna, Department of Ophthalmology and Visual Sciences, Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, CANADA|

Commercial Relationships Disclosure (Abstract): Herman Stubeda: Commercial Relationship: Code N (No Commercial Relationship) | Lesya Shuba: Commercial Relationship: Code N (No Commercial Relationship) | Marcelo Nicolela: Commercial Relationship(s);Allergan:Code S (Non-remunerative);Alcon:Code C (Consultant);Alcon:Code S (Non-remunerative) | Balwantray Chauhan: Commercial Relationship(s);Centervue:Code S (Non-remunerative);Heidelberg Engineering:Code C (Consultant);Heidelberg Engineering:Code S (Non-remunerative);Novartis:Code S (Non-remunerative);Santen:Code S (Non-remunerative);Topcon:Code S (Non-remunerative) | Jayme Vianna: Commercial Relationship(s);Eadietech:Code C (Consultant)

ABSTRACT BODY:

Purpose: STATPAC is a widely used statistical package for visual field analysis, however, its normative dataset and methods are proprietary. The visualFields (vF) statistical package is a tool analogous to STATPAC but with opensource normative dataset and methods, which provides an advantage for collaboration. The purpose of this study was to determine whether vF analyses agree with STATPAC.

Methods: We defined 3 separate statistical environments containing unique normative datasets: STATPAC, vF with its native normative dataset (vF-SUNYIU), and vF with a new normative dataset of healthy fields from previous studies at our centre in Halifax (vF-Halifax). We created a glaucoma dataset using fields from patients in our glaucoma clinic. All data from Halifax were 24-2 SITA Standard, using only one field per subject. The glaucoma fields were analysed with the 3 environments generating 3 sets of total deviation (TD), pattern deviation (PD), global mean deviation (MD), and pattern standard deviation (PSD) values, which were compared with Bland-Altman plots. We also applied five criteria for glaucomatous fields, i.e., Glaucoma Hemifield Test, Hoddap-Anderson-Parrish 2, Foster, United Kingdom Glaucoma Treatment Study, and Low-pressure Glaucoma Treatment Study within each environment and determined agreement in the criteria results with Kappa statistics.

Results: The Halifax normative dataset contained 163 subjects. The glaucoma dataset contained 1848 subjects with mean (standard deviation) age of 67.1 (12.1) years, and mean STATPAC MD of -3.36 (5.25) dB. The agreement in TD and PD values between STATPAC and the two vF environments was high in the -26 to +5 dB range, but there was notable disagreement below -26 dB, in which both vF environments underestimated field loss by on average 1dB (Fig.1 A&B). The agreement in MD and PSD values between STATPAC and the two vF environments demonstrated a trend where vF underestimated field loss by up to 1dB as field loss increased (Fig.1 C&D). In contrast, agreement in values between vF-SUNYIU and vF-Halifax was high and uniform (Fig.1 A-D). The inter-environment agreement of glaucoma criteria exceeded kappa 0.725 in all cases (Fig.2).

Conclusions: Although STATPAC and vF may have differences in computation of TD values for severely damaged locations, our results highlight a robust agreement, which suggests vF is a viable alternative to proprietary statistical packages.

TITLE: Inter-tissue antioxidant exchange between the lens and vitreous: A novel mechanism for maintaining high levels of ascorbate in the vitreous

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.M. Martis, B. Li, P.J. Donaldson, J.C. Lim, Physiology, The University of Auckland Faculty of Medical and Health Sciences, Auckland, Auckland, NEW ZEALAND|R.M. Martis, B. Li, P.J. Donaldson, J.C. Lim, The University of Auckland New Zealand National Eye Centre, Auckland, Auckland, NEW ZEALAND|

Commercial Relationships Disclosure (Abstract): Renita Martis: Commercial Relationship: Code N (No Commercial Relationship) | Bo Li: Commercial Relationship: Code N (No Commercial Relationship) | Paul Donaldson: Commercial Relationship: Code N (No Commercial Relationship) | Julie Lim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Based on our observation that the human lens is able to export glutathione to the vitreous, we have proposed the concept of antioxidant exchange between the lens and the vitreous to ensure oxygen levels at the back of the eye are maintained at low levels. Here we investigate whether ascorbate (AsA) and oxidized AsA (DHA) are exchanged between the lens and the vitreous and determined how these levels are altered as a result of removal of the lens.

Methods: Human lenses of varying ages were cultured in artificial aqueous humour under hypoxic conditions for one hour, and lactate dehydrogenase activity (LDH), AsA and DHA levels measured in the media and lens (n=7). Immunohistochemistry was conducted to localize potential AsA efflux transporters. To determine changes in antioxidant levels in the vitreous, samples were collected from patients (60-86yrs) undergoing vitrectomy with an intact lens or IOLs and antioxidant levels quantified using biochemical assays.

Results: After one hour, minimal LDH activity (<0.5%) was detected in the media for all donor lenses suggesting that membrane integrity was preserved. AsA and DHA were both detected in the media with ~6.9% AsA efflux and ~66.34 % DHA efflux. Immunolabelling revealed connexin 46 to be localized to the membranes of the fibers cells in the anterior and posterior surface of the lens, placing it in an ideal position to mediate AsA or DHA efflux into the vitreous. Measurements of glutathione levels in the vitreous of patients with an intact lens versus an intraocular implant demonstrated that total GSH levels were reduced by ~7-fold indicating that loss of the natural lens may contribute to altered antioxidant levels in the vitreous.

Conclusions: The study demonstrates that the lens is able to export AsA and DHA into the vitreous and that connexin 46 may be involved in mediating this process. In addition, preliminary evidence suggests that removal of the lens results in a decrease in GSH levels in the vitreous. Since it is proposed that the lens exports GSH into the vitreous to maintain high AsA levels, removal of the lens would potentially disrupt antioxidant exchange between the lens and vitreous. These findings highlight the inter-dependence of the lens and vitreous for maintaining antioxidant levels and minimizing oxidative stress in the eye.

TITLE: Catching Eyes: An Analysis of Medical Student Publications in the Ophthalmology Match

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Srinivasan, B. Zhou, V. Taruvai, S. Nadkarni, A. Song, A.S. Khouri, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nivetha Srinivasan: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Varun Taruvai: Commercial Relationship: Code N (No Commercial Relationship) | Shree Nadkarni: Commercial Relationship: Code N (No Commercial Relationship) | Amy Song: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ophthalmology is an increasingly competitive specialty with 790 applicants applying to 484 spots in the 2019 Match. Research is an important factor used to evaluate potential applicants. Each year, SF Match releases an ophthalmology match summary report detailing different metrics of applicants. However, this dataset fails to include research output. We aim to analyze the temporal trends in publication volume by medical students who successfully matched into ophthalmology.

Methods: The Doximity Residency Navigator, sorted by reputation, was used to identify the top 30 ophthalmology residency programs in the United States. All residents from the class of 2022 and 2017 were identified from program websites; 158 residents were analyzed from the class of 2022 and 145 residents were analyzed from the class of 2017. Publication volume (first author, second author, ophthalmology journal, and total publications) from before September 15th of the application year for each resident was recorded using PubMed and Google Scholar. Using Welch's t-test, publication volumes were statistically compared against all others.

Results: Total publications (mean \pm SE) for residents were 2.95 \pm 0.33 for the class of 2022 and 1.67 \pm 0.23 for the class of 2017; mean publications in ophthalmology journals were 1.00 \pm 0.18 (2022) and 0.58 \pm 0.13 (2017); mean first author publications were 0.95 \pm 0.12 (2022) and 0.64 \pm 0.11 (2017) and mean second author publications were 0.63 \pm 0.10 (2022) and 0.37 \pm 0.06 (2017) (Table 1). Both total publications and second author publications were significantly higher for the class of 2022 than the class of 2017 ($p<0.01$; $p<0.05$) with observed differences of 55.4% and 52%, respectively. Although there were no significant differences in first author publications ($p=0.069$) or in ophthalmology journals ($p=0.069$), the observed p-values support the trend of increasing research among students.

Conclusions: Overall, the authors found a temporal trend towards increased publications amongst applicants. While this study helps map out a 5-year period, it does not delineate between abstracts, presentations, or publications; further studies are needed to determine the individual value of these subcategories. Nevertheless, this analysis emphasizes both the growing importance of research and can help future applicants navigate the ophthalmology match.

ABSTRACT BODY:

Purpose: The MI-SIGHT program is a telemedicine-based glaucoma and eye health screening program that includes treatment for refractive error, the leading cause of reversible vision loss in the US. Impoverished communities are disproportionately comprised of racial/ethnic minorities who are at higher risk both of glaucoma and visual impairment due to untreated refractive error. We hypothesize that embedding glaucoma screening programs that include treatment for refractive error in trusted community clinics will engage underserved communities in glaucoma screening. We will describe the baseline characteristics and screening outcomes of the initial cohort of participants in the MI-SIGHT Program and how they learned about the program

Methods: Using community-engaged research methods, the MI-SIGHT program was established in a free clinic in Eastern Michigan. Participants completed a baseline survey assessing demographic information and how they learned of the program. Participants underwent refraction, measurement of intraocular pressure and central corneal thickness, external and fundus photos, and retinal nerve fiber layer OCT, which was transmitted to the grading ophthalmologist via the electronic health record. An ophthalmic technician assisted participants in choosing glasses from a low-cost online retailer, and fit the glasses when participants returned to learn about the ophthalmologist's diagnosis and recommendations

Results: Seventy-two participants (65% female; mean \pm SD age 55.2 \pm 16.0 years) were included from 8/1/20-11/20/20. The initial cohort was 43% Black and 15% were of Hispanic ethnicity. 68% of participants did not have insurance and 85% of participants had an annual income < \$30,000. (Table 1) More than half of the participants (58%) learned of the program through the clinic staff and 11% learned of it from flyers in the clinic's dental and food pantry services. Based on the testing, participants presented with: glaucoma or suspected glaucoma (28%), visual impairment (26%), diabetic retinopathy (14%, 45% of those with diabetes), and macular degeneration (6%)

Conclusions: The MI-SIGHT program was set up in a free clinic widely trusted by community members, which enabled engagement of participants from underserved populations who are at high risk of vision impairment and eye disease

ABSTRACT BODY:

Purpose: Stargardt disease (STGD1, OMIM: 248200) is mainly caused by missense, frameshifting or nonsense mutations in the ATP-binding cassette transporter gene, ABCA4. However, sequence variants that alter splicing are also pathogenic. Herein, we describe an in vitro investigation of aberrant splicing in ABCA4 variants detected in a STGD1 cohort using patient-derived fibroblast-based assay. In addition, retinal pigment epithelium (RPE) cells differentiated from patient-derived induced pluripotent stem cells (iPSC) were used to further validate such splicing errors.

Methods: A cohort of 68 patients clinically diagnosed with STGD1 were recruited in this study. Genomic DNA obtained from recruited STGD1 patients was analysed by a commercial Stargardt/Macular dystrophy screening panel, targeting all exons of ABCA4 and flanking intronic regions, as well as already-known deep-intronic variants of ABCA4. Fibroblasts were propagated from 68 patients, total RNA was extracted and ABCA4 transcript structure was analysed by RT-PCR. The iPSCs reprogrammed from 2 patients carrying heterozygous c.[5461-10T>C;5603A>T] alleles were differentiated into RPE cells and the ABCA4 transcripts re-examined by RT-PCR.

Results: A total of 73 unique ABCA4 alleles were identified. Biallelic ABCA4 variants were detected in 66 patients (66/68, 97.06%) and 2 patients (2/68, 2.94%) had a single ABCA4 variant detected. Only exons 13-50 of ABCA4 could be readily amplified from fibroblast RNA. In this region, 9 out of 55 (16.36%) variants, carried by 19 patients (28%), resulted in aberrant splicing. The most prevalent splice variant, c.5461-10T>C, is complexed with c.5603A>T and carried heterozygously by 7 patients (10%). This variant results in mature ABCA4 mRNA transcripts missing exon 39, or exons 39 and 40. The splicing defect was also evident in patient-derived iPSC-RPE cells.

Conclusions: Patient-derived fibroblasts are useful for identifying ABCA4 splicing variants affecting exons 13-50. The iPSC-RPE cells provide a feasible platform for further validating retina-specific splice variants of ABCA4 that may be amendable to splice intervention therapies.

ABSTRACT BODY:

Purpose: This study investigated the changes in short-term axial length (AxL) and vision performance during exposure to simulated optical designs with coaxial and non-coaxial plus power lenslets, induced by adaptive optics (AO).

Methods: An optical design with multiple lenslets of plus power (0.79 mm in diameter at pupil plane) distributed evenly over its optical zone (40% fill factor) was created through a spatial light modulator AO system. Between the plus power lenslets, the remaining optical area (60%) was optimally focussed for distance vision. Two types of plus power zones were tested; (i) coaxial, where lenslets created a single focal point (+10 D) in front of the retina on the optical axis, and (ii) non-coaxial, where lenslets created multiple focal points (+10 D) in front of the retina, with the central ray of each lenslet directed to the fovea. Six healthy young with normal vision subjects participated in the study. Subjects watched a movie through the AO system and AxL was measured with a Lenstar LS-900 biometer before, at 20 mins and after 40 mins exposure to the test designs. VA was tested with high-contrast tumbling E letters displayed on a micro-display in the AO system and contrast sensitivity (CS) was tested with an E letter target (0.5 logMAR) that was controlled by a QUEST algorithm.

Results: At the end of 40 mins, coaxial and non-coaxial designs caused a significant and similar reduction in axial length compared to baseline (-5.7 ± 3.6 vs -8.3 ± 6.2 μm respectively, both $p < 0.05$) (Figure 1). The optical design with coaxial plus power lenslets caused a larger loss of VA of 0.15 ± 0.04 logMAR compared to the design with non-coaxial plus power lenslets with 0.07 ± 0.05 logMAR loss ($t=3.2$, $p < 0.05$) (Figure 2). A greater loss of CS was also found with the coaxial plus power zones causing a loss of 0.08 ± 0.02 of Weber contrast compared to the non-coaxial design, with a CS loss of 0.03 ± 0.02 . ($t=4.8$, $p < 0.005$).

Conclusions: Optical designs utilizing non-coaxial plus power lenslets were found to produce similar shortening effects on short-term axial length, while causing a smaller loss in visual performance than designs using conventional coaxial plus power lenslets.

TITLE: Rapid protocol for induced retinal ganglion cell differentiation from human stem cells

SESSION TITLE: Stem cells/gene therapy/transplantation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. Luo, K. Chang, B. Tanasa, J.L. Goldberg, Ophthalmology, Stanford University, Palo Alto, California, UNITED STATES|M. Wernig, Pathology, Stanford University School of Medicine, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ziming Luo: Commercial Relationship: Code N (No Commercial Relationship) | Kun-Che Chang: Commercial Relationship: Code N (No Commercial Relationship) | Bogdan Tanasa: Commercial Relationship: Code N (No Commercial Relationship) | Marius Wernig: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goldberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) replacement therapy could provide an approach to vision restoration in glaucoma and other optic neuropathies. Here we developed a rapid protocol for directly induced RGC differentiation from human stem cells.

Methods: We directly induced RGC-like cells (iRGCs) from hiPSCs and hESCs by overexpression of NGN2. Cells gained their RGC fate in less than two weeks in the full-Sato medium (RGC culture medium) supplied by Notch inhibitor, DAPT. Immunostaining and qRT-PCR were performed to confirm their RGC characteristics. Calcium imaging stimulated by GABA agonist muscimol was used to evaluate their electrophysiologic maturities. Then, we utilized single-cell RNA sequencing (scRNA-seq) to further delineate the iRGC differentiation and compare their transcriptomic profiles to fetal and organoid RGCs. All experiments were conducted at least three times independently. Data were analyzed by ANOVA and post-hoc t-test with Tukey correction, with a P-value of <0.05 considered statistically significant. All use of animals conformed to the ARVO statement for the Use of Animals in Research, and was approved by the IACUC and the Institutional Biosafety Committee of Stanford University.

Results: Within one week of induction, neuronal morphology including neurite growth was observed. Progeny expressed RGC markers, including BRN3a, ISL1, HuD, and NEFL after 8 days of differentiation. qRT-PCR confirmed the reduction of pluripotent genes (POU5F1 and NANOG) and the upregulation of neuronal genes (PAX6, BRN3a, and ISL1). iRGCs demonstrated muscimol-induced calcium influx similar to immature primary mouse RGCs. Unbiased clustering in scRNA-seq data showed that iRGCs distributed closely but not overlapping with day-59 and day-82 fetal human RGCs, indicating high similarity. Compared with day-45 retinal organoid-derived RGCs, iRGCs largely overlapped in most clusters. However, for some marker genes including BRN3a, Brn3b, and NEFL, iRGCs demonstrated expression patterns more similar to fetal RGCs than to retinal organoid RGCs.

Conclusions: In the present study, we describe a new, effective method that generates a homogeneous population of iRGCs after over-expression of a single transcription factor in human stem cells. These iRGCs are highly similar to two-month-old fetal RGCs, although they develop in less than two weeks. The simplicity of this system may benefit the translational studies on human RGCs.

TITLE: Burden and Predictors of Undetected Eye Disease in Adult African Americans: The African American Eye Disease Study (AFEDS)

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Dhablania, M. Torres, B. Burkemper, R. Varma, Southern California Eye Institute, Los Angeles, California, UNITED STATES|B. Burkemper, R. McKean-Cowdin, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nathan Dhablania: Commercial Relationship: Code N (No Commercial Relationship) | Mina Torres: Commercial Relationship: Code N (No Commercial Relationship) | Bruce Burkemper: Commercial Relationship: Code N (No Commercial Relationship) | Roberta McKean-Cowdin: Commercial Relationship: Code N (No Commercial Relationship) | Rohit Varma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To estimate the burden of and to evaluate the factors associated with undetected eye disease (UED) among a population-based sample of African American adults ≥ 40 years of age.

Methods: Data for these analyses were extracted from the African American Eye Disease Study (AFEDS), a population-based study of adult African Americans, aged 40 years and older, residing in and around the city of Inglewood (Los Angeles County, California). All participants underwent a detailed home interview and a comprehensive eye examination, including an assessment of ocular conditions such as age-related macular degeneration (AMD), glaucoma, ocular hypertension, diabetic retinopathy, cataract, and refractive error. Participants with any eye disease ($N = 3500$) were included in these analyses, and the prevalence of UEDs was calculated. Chi-square test analyses were used to evaluate bivariate associations between risk indicators and any UED. The independent association with UED and the predisposing, enabling, need and health behavior characteristics was explored using multiple logistic regression analysis. Standardized β coefficients were used to determine the relative contributory effect of each independent factor on the presence of UED.

Results: Of the 7957 eligible participants in the AFEDS, 6347 (80%) completed both the in-home interview and the clinical examination. Fifty-five percent (3500 of 6347) of the participants had eye disease. Twenty-six percent (914 of 3500) of them had undetected eye disease. The primary undetected eye diseases included diabetic retinopathy (75.1%), cataracts (60.8%), refractive error (55.0%), ocular hypertension (33.3%), open-angle glaucoma (16.5%), and AMD (7.5%). The major risk factors for UED included having diabetes mellitus odds ratio (OR): 4.1, never having had an eye examination (OR: 2.4), having had an eye examination more than 5 years ago (OR: 2.2), lower educational attainment (OR: 2.0), having poor or very poor general vision (OR: 1.7), and trouble getting glasses (OR: 1.6).

Conclusions: These findings provide evidence of the significant burden of UED among African Americans. Interventions that address the modifiable risk factors (e.g., trouble getting glasses, never having had an eye examination) may improve detection of eye disease and decrease the burden of visual impairment in this high-risk minority population.

ABSTRACT BODY:

Purpose: To evaluate the outcome of pneumatic displacement of submacular hemorrhage with Subretinal Air and without tissue plasminogen activator (TPA) for thick submacular hemorrhages (SMH).

Methods: Retrospective analysis of patients with submacular hemorrhage managed surgically via pneumatic displacement without TPA from 2015 and 2020. Surgical intervention across all doctors included subretinal Balanced Saline Solution (BSS) infusion with subretinal sterile air, and intraocular gas tamponade with and without postsurgical anti-vascular endothelial growth factor (VEGF) injection. 24 patients with SMH and at least 8 months of follow up were identified. All medical records and color fundus photographs were reviewed for data collection. The primary outcome measure was best-corrected visual acuity (BCVA) 12 months after treatment. Secondary outcome measures included central retinal thickness (CRT), recurrence rate, and complications.

Results: Patients had a mean age of 81 ± 8.6 years. Wet age-related macular degeneration was the most common etiology associated with thick SMH (92%). Complete blood displacement was observed by final follow up in 92% of the cases and none in 8.0%. Mean logMAR BCVA improved from 1.2 ± 0.27 (20/320 at baseline) to 0.9 ± 0.42 (Snellen 20/160; $p = 0.001$) at final follow-up. 63% of the patients gained at least 2 lines by the 12 months of follow up. Mean central retinal thickness was also improved from $569\mu \pm 220$ at baseline to $252\mu \pm 63$ by 12 months of follow up ($P < 0.001$). Early postoperative complications included vitreous hemorrhage in two cases and retinal detachment in 2 patients. It was noted that 11 patients (46%) developed subretinal fibrosis at 12 months of follow up.

Conclusions: Vitrectomy with subretinal BSS injection and pneumatic displacement without TPA was found to be effective for displacement of thick submacular hemorrhage with improvement in visual acuity

ABSTRACT BODY:

Purpose: In the human choroid, melanocytes (HCMs) contribute functions including melanin-related light absorption and uptake of free radicals, with a potential for immunoregulation via local secretion of chemokines/cytokines and expression of Toll-like receptors (TLRs). The biological responses of HCMs to a proinflammatory stimulus (lipopolysaccharide (LPS) - a TLR4 ligand), related to possible roles in the choroidal stromal microenvironment were studied using transcriptome and pathway analyses, and protein-based methods.

Methods: Primary HCMs isolated from human donor eyes (n=4; <18 hours post-mortem delay; University of Sydney HREC) were established in melanocyte growth medium. RNA from HCMs (P3 to P5: control and LPS-stimulated (1µg/ml, 18 hours) was used to establish cDNA libraries, that were sequenced (Illumina HiSeq 2500) and analysed using bioinformatics (including gene ontology (GO) and gene set enrichment analysis. We confirmed several novel cell-cell adhesion and cell-extracellular matrix (ECM) genes using immunoblotting and immunohistochemistry.

Results: 100 differentially expressed genes were detected (98 genes upregulated, 2 genes downregulated; fold change $\geq \pm 2$, $p < 0.01$) were found for control versus LPS-stimulated HCMs. As expected, a number of most differentially expressed genes included CCL and CXCL cytokines (for example, CCL20, CCL2 and CXCL5; 43 to 316-fold, $p < 0.01$). Genes that can mediate intercellular adhesion and cell-ECM interactions also were highlighted (for example, ITGA1 and 11, CCN3, MMP14, COL7A1 and FN1; 1.4 to 23-fold; $p < 0.01$). We also verified several LPS-induced genes, finding changes in HCM protein expression for CCN3, MMP14, FN1 and ICAM1. We also confirmed in situ immunolabelling in donor human eye choroid sections with confocal microscopy.

Conclusions: Our study confirms a proinflammatory shift in biological processes and genes for LPS-stimulated HCMs. Furthermore, we observed gene and protein expression patterns not previously highlighted, including significant GO terms related to "cellular adhesion" and "cell-matrix adhesion", "cell adhesion mediated by integrins" and "collagen binding involved in cell matrix adhesion". Taken together, these observations suggest HCMs can contribute more to the complex choroidal biology than light-absorption, with roles in maintaining and regulating the local choroidal microenvironment, normally and during inflammatory conditions.

SUBMITTER (NAME ONLY): Tyler Knight

TITLE: Lensectomy as Treatment for Refractory or Progressive Retinopathy of Prematurity Narrow-Angle Glaucoma

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Knight, D.A. Morrison, K.M. Joos, Ophthalmology, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tyler Knight: Commercial Relationship: Code N (No Commercial Relationship) | David Morrison: Commercial Relationship(s);Regeneron - unrelated ROP project:Code F (Financial Support) | Karen Joos: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Anatomical narrow angle and glaucoma from increased lens thickness, and/or scarring and forward displacement of the lens-iris-diaphragm can result from threshold retinopathy of prematurity (ROP) treated with laser or cryotherapy. This study investigates the efficacy of lensectomy in treatment of anterior chamber angle narrowing in ROP patients.

Methods: This retrospective study was approved by the Vanderbilt University Medical Center (VUMC) Institutional Review Board and Vanderbilt Institute for Clinical and Translational Research (VICTR). The cohort was identified by querying the VICTR Research Derivative database for clinical data (1995-2020) derived from the VUMC's clinical systems and restructured for research. Patients were identified by ICD-9 or ICD-10 codes for 1) ROP and 2) narrow angle or glaucoma. Patient demographics and clinical course as available in the medical records were recorded in a secure format, including: sex, post-conceptual birth age, treatment of ROP, age at diagnosis of anatomical narrow angle or angle-closure glaucoma, glaucoma medication use, iris procedure performed and outcome, age and angle status at lensectomy, and final outcome. Descriptive statistics were performed.

Results: Initial query yielded 70 patients. 42 patients were excluded for 1) no evidence of narrow angles 2) prematurity without ROP, and 3) limited medical record information/follow up. Of the remaining 28 patients, 48 eyes demonstrated narrow angle or glaucoma: 53.6% were female, mean post-conceptual birth age was 25.1 (23-28) weeks, 90.9% of patients required treatment for ROP. Mean and median age at diagnosis of anatomical narrow angle or angle-closure glaucoma were 9.5, 15 (1-37) years. 66.7% of eyes with narrow/closed angles underwent iridotomy/iridectomy +/- iridoplasty shortly after diagnosis. 57.6% of these eyes subsequently required glaucoma medication. Mean and median age at lensectomy for treatment of narrow angle or angle-closure were 20.3, 17 (2-38) years, with 47.8% occurring during teenage years. Deepening of the anterior chamber occurred in 19/23 eyes after lensectomy.

Conclusions: This case series demonstrated: 1) continued monitoring of patients with history of ROP and narrow angles is crucial into adulthood especially during the teenage years and 2) lensectomy in patients with refractory or progressive narrow angles after iridotomy/iridectomy +/- iridoplasty is efficacious.

ABSTRACT BODY:

Purpose: To evaluate treatment outcome of eyes with CSCR based on multimodal imaging based classification over one year of follow up.

Methods: Retrospective data of eyes diagnosed with CSCR and available history, visual acuity (VA) and multimodal imaging at baseline, 3 months, 6 months and 12 months and treatment details were included. Eyes with macular neovascularization, any other disease and inadequate follow up after treatment were excluded. Eyes were classified as per the multimodal imaging based classification of CSCR at baseline and every follow up into i) simple/ complex CSCR ii) primary episode/ recurrence/ resolved CSCR iii) persistent or not iv) outer retinal atrophy (ORA) present or not and v) fovea involved or not.

Results: Ninety-one eyes of 87 patients were classified into 50 eyes with simple CSCR and 41 eyes with complex CSCR. Complex CSCR cases had higher persistence, ORA and recurrent episodes ($p=0.0005, 0.0008, 0.0008$) while simple cases had higher central macular thickness (CMT) ($p=0.02$) at baseline. The most common choice of treatment was observation (58%) in simple CSCR and PDT (36.6%) in complex CSCR ($p=0.02$). In simple CSCR, logarithm of minimum angle of resolution (logMAR) best corrected visual acuity (BCVA), subfoveal choroidal thickness (SCT) and CMT decreased ($p=0.02, 0.02, <0.0001$) while persistence of subretinal fluid (SRF) and ORA increased ($p<0.0001, 0.0002$) over 12 months. In complex CSCR, CMT decreased ($p=0.0009$) and ORA ($p=0.037$) increased over follow up but the decrease in CMT over 12 months was more significant in simple CSCR compared to complex CSCR ($p=0.002$). In multivariate analysis, baseline BCVA ($p<0.0001$) was a significant predictor of final BCVA. Over a mean follow up of 21.7 ± 16.8 months, none of the simple CSCR eyes converted to complex CSCR. Resolution of SRF, occurrence of ORA and recurrence during the follow up period was not significantly different between simple and complex CSCR ($p=0.86, 0.46, 0.73$).

Conclusions: Both visual and anatomical outcomes changed significantly in simplex CSCR group with observation being the most common treatment. PDT in complex CSCR helped to stabilize the vision. Baseline VA was significantly predictive of final visual outcome.

TITLE: Concept mapping to develop timed measures of low luminance vision-related ADLs

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.A. Bentley, A.A. Black, G. Hindmarsh, J.M. Wood, School of Optometry and Vision Science, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|C. Owsley, Department of Ophthalmology and Visual Sciences, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sharon Bentley: Commercial Relationship: Code N (No Commercial Relationship) | Alex Black: Commercial Relationship: Code N (No Commercial Relationship) | Gregory Hindmarsh: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Owsley: Commercial Relationship: Code N (No Commercial Relationship) | Joanne Wood: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Low light levels exacerbate performance deficits and are particularly challenging for adults with vision impairment. This is an important issue in the evaluation and monitoring of changes in performance following novel eye and vision therapies, as existing performance-based measures do not specifically consider low luminance conditions. This study aimed to identify low luminance activities of daily living (ADLs) relevant to adults with vision impairment as the basis for the development of a battery of timed low luminance vision-related performance-based measures.

Methods: 'Group Concept Mapping' (Concept Systems Inc., NY) was used to identify low luminance vision-related ADLs. The process integrates qualitative and quantitative research methods to produce concept maps and data displays, resulting in comprehensive visual representations of key ideas/activities and their interrelationships. In the first 'brainstorming' phase, 24 adults with vision impairment from a range of eye conditions (mean age 73, SD 14 years) and 26 international low vision experts (mean experience 22, SD 11 years) responded to the focus prompt (via mail, phone or a web-based application): "Thinking as broadly as possible, generate a list of statements detailing specific day-to-day activities a person with vision impairment might find challenging under low light conditions, such as in a poorly lit room or outside at dusk." In the second phase, participants rated the importance of each activity generated and sorted activities by their similarity (in a face to face session or a via a web-based application).

Results: 113 potential ideas/activities were generated, rated and sorted. Using multidimensional scaling and hierarchical cluster analysis, concept maps showing clusters of prioritised activities were produced from the data. Eight groups of activities were identified (from highest to lowest importance ratings): mobility hazard detection and safety; navigating outside the house; social communication; selfcare and safety at home; near reading; distance spot reading; home maintenance; and navigating around the house.

Conclusions: The low luminance ADLs identified will be used to develop relevant and sensitive clinical endpoint measures for objectively assessing the efficacy of eye treatments and low vision rehabilitation outcomes in adults with vision impairment.

TITLE: Risk Factors of Ischemic Stroke in Patient Presenting with Amaurosis Fugax

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Chen, A. Uppuluri, M.A. Zarbin, N. Bhagat, Rutgers New Jersey Medical School
Department of Ophthalmology & Visual Science, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tony Chen: Commercial Relationship: Code N (No Commercial Relationship) | Aditya Uppuluri: Commercial Relationship: Code N (No Commercial Relationship) | Marco Zarbin: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Amaurosis fugax (AF) is associated with increased cerebrovascular morbidities and mortalities. Better risk stratification of AF is crucial in recognizing those at highest risk of developing ischemic stroke. We performed a retrospective, cross-sectional study using a national database to evaluate the risk factors for ischemic stroke in patients with acute AF.

Methods: The National Inpatient Sample database from 2002–2014 was used. All patients 21 years old and above with a primary admission diagnosis of AF were identified using ICD-9 codes 362.34. Patients were further stratified into two age cohorts: 21-50 years and over 50 years. The primary outcome was to evaluate comorbidities associated with in-hospital ischemic stroke. Chi-square and Firth logistic regression analyses were performed using IBM SPSS 25 and R package version 3.4.3, respectively. $p < 0.05$ was considered significant for Chi-square and univariate analyses, whereas $p < 0.005$ was considered significant for multivariable analysis.

Results: A weighted total of 12,142 patients were identified. The average age of patients was 66 ± 14 years, where 87% of cases were over 50 years of age. Whites accounted for 62.1% of cases. The most common comorbidities included hypertension (66.1%), dyslipidemia (44.7%), tobacco use (23.6%), coronary artery disease (CAD) (23.0%), and diabetes mellitus (19.6%). Tobacco use, alcohol use, and hypercoagulable state were statistically more prevalent in the younger group ($p < 0.001$). Surprisingly, ischemic stroke ($p = 0.033$) and myocardial infarction ($p = 0.008$) were significantly more prevalent in the younger cohort.

Multivariable logistic regression analysis detected the followings comorbidities to be independent risk factors for ischemic stroke: Hypercoagulable state (OR 8.98, $p < 0.001$), systemic vasculitis (OR 4.16, $p = 0.003$), CAD (OR 4.05, $p < 0.001$), and atherosclerosis (OR 3.60, $p < 0.001$). In contrast, dyslipidemia was associated with a decreased risk (OR 0.54, $p = 0.003$). Asian/Pacific Islander ethnicity conferred a 5-fold increased risk in stroke compared to Whites ($p < 0.001$).

Conclusions: In-hospital systemic thrombotic complications occurred in 0.3%-0.9% of acute AF cases (average length of stay was 2.62 ± 2.17 days). Presence of hypercoagulable state, systemic vasculitis, CAD, and atherosclerosis increased the risk of ischemic stroke by over 3-fold. Thus, patients should be closely monitored for stroke within the first week of AF diagnosis.

TITLE: Why can't I see 20/20? Factors predictive of suboptimal vision after toric lens implantation

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Gauthier, A. Awidi, Y. Daoud, Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|P. Noble, University of Iowa, Iowa, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Angela Gauthier: Commercial Relationship: Code N (No Commercial Relationship) | Abdelhalim Awidi: Commercial Relationship: Code N (No Commercial Relationship) | Paige Noble: Commercial Relationship: Code N (No Commercial Relationship) | Yassine Daoud: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine patient characteristics and biometry data associated with residual refractive error after toric lens implantation for patients with astigmatism.

Methods: A retrospective case-control chart review of eyes with residual refractive error and eyes that met target refraction at one month and beyond after cataract surgery with toric lens implantation by the same surgeon was conducted. Eyes with residual refractive error were defined as achieving UCVA of 20/40 or worse and BCVA better than 20/40 with a difference in logMAR UCVA and BCVA of 0.3 or more, while eyes that met target refraction achieved an UCVA of better than 20/40 after cataract surgery. All patients were aimed for distance. Pre-operative exam findings, ophthalmologic comorbidities, and intraocular lens measurements were collected.

Results: In total, 30 eyes in 29 patients with residual refractive error and 194 eyes in 167 patients who met target refraction were included. The mean age of patients with residual refractive error was 63.1 years (SD 11.3) vs. 69 years (SD 7.9) for patients who met target refraction ($p=0.009$). Compared to eyes at target refraction, a greater percentage of eyes with residual refractive error had undergone previous LASIK surgery (23.3% vs. 5.7%) and carried a keratoconus diagnosis (6.7% vs. 0.5%). Both groups had a similar prevalence of dry eye (30.0% vs. 30.4%) and ABMD (10.0% vs. 9.3%). A smaller percentage of patients with residual refractive error had Fuch's dystrophy (3.3%) compared to those at target refraction (13.9%). There was no significant difference in axial length between eyes with residual refractive error (24.68 mm, SD 1.84 mm) and those at target (24.60 mm, SD 1.60, $p=0.83$) or anterior chamber depth (3.29 mm, SD 0.52 vs. 3.35 mm, SD 0.42, $p=0.54$). There was a trend toward eyes with residual refractive error having a greater average corneal astigmatism (2.03 D, SD 1.49) compared to eyes at target refraction (1.51 D, SD 0.62, $p=0.076$).

Conclusions: Patients who had residual refractive error after cataract extraction with toric lens implantation on average were younger than those who met target refraction. In addition, a greater proportion of patients who had residual refractive error had previous LASIK and keratoconus compared to those at target refraction. Understanding these factors can help manage visual outcome expectations after toric lens implantation in patients with astigmatism.

ABSTRACT BODY:

Purpose: Transplanted healthy RPE cells may benefit AMD patients. We created allogenic RPE cells (OpRegen) using directed differentiation. Safety and tolerability of OpRegen is being evaluated in a Phase I/IIa clinical study in patients with dry AMD and geographic atrophy (GA) (NCT02286089). We report interim safety and imaging data from all patients in the fully enrolled study (N=24).

Methods: Subretinal transplantation of 50-200k OpRegen cells in suspension to the worse vision eye used either pars plana vitrectomy (PPV) and retinotomy or the OrbitTM Subretinal Delivery System (SDS). Short course, perioperative systemic immunosuppression was used. Endpoints include systemic/ocular safety and retinal structure/function.

Results: Patients (VA <20/200) in cohorts 1-3 are in long-term follow-up (10/12; 2-5 years) or withdrawn (2/12). 12 better seeing patients (<20/64) in cohort 4 completed dosing in November 2020 (7 PPV:5 SDS). OpRegen has been well tolerated to date, with no unexpected adverse events (AEs). Using PPV, the most common ocular AEs were epiretinal membranes (ERM), in 15/17 (88%) eyes, mostly mild to moderate; 3 (18%) severe ERM required surgical

peeling. 2 PPV-treated patients (2/17;12%) developed retinal detachments, which were successfully treated. AEs, all mild, in Orbit SDS patients included one asymptomatic extramacular type 2 CNV, successfully treated with a single anti-VEGF injection, and subretinal hemorrhage (3/7;43%), all self-resolved without sequelae. Subretinal delivery of OpRegen was successful in 7/7 patients by 5 different surgeons. Improvement or maintenance of baseline visual acuity has been noted in 11/12 (92%) cohort 4 patients (-9 to +19 letters), which has been maintained from 2 months to >2 years. Treatment effects, including alterations in drusen appearance, subretinal pigmentation and hyper-reflective areas, suggest persistence of transplanted OpRegen. One patient has potential signs of retinal restoration and reduction in GA area based on OCT analyses of the periphery of the GA, which continues to be followed.

Conclusions: Subretinal transplantation of OpRegen cells in patients with dry AMD and GA appears well tolerated. Imaging findings suggest presence of transplanted cells in the subretinal space. Encouraging structural and clinical changes observed in some patients are being followed.

TITLE: Responses of conjunctival goblet cells to microbial products promote activation of local antigen presenting cells

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Logeswaran, L. Contreras-Ruiz, S. Masli, Ophthalmology, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Abiramy Logeswaran: Commercial Relationship: Code N (No Commercial Relationship) | Laura Contreras-Ruiz: Commercial Relationship: Code N (No Commercial Relationship) | Sharmila Masli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Conjunctival goblet cells (GCs) contribute to ocular immune homeostasis via Thrombospondin-1 (TSP-1)-mediated TGF β 2 activation, which in turn modulates dendritic cell (DC) phenotype by decreasing expression of activation markers, including MHC class II. This study determined the location of antigen presenting cells (APCs) in the conjunctiva and tested the hypothesis that microbial product flagellin (FL)-mediated GC responses disrupt homeostasis to promote APC activation that leads to corneal barrier damage.

Methods: Conjunctival explants or frozen sections from WT (C57BL/6) and TSP-1 $-/-$ mice were immunostained for CD11c, MUC5AC, MHC class II or TSP-1 and examined by confocal or fluorescence microscopy. WT mice were treated with FL (10 ng) topically for 7 days. Corneal barrier was monitored for 4 weeks with fluorescein staining. Primary cultured GCs were treated with FL (0-10mg/ml) or heat-killed pathogenic *S. aeruginosa* strain PA14 for 24 hr. Levels of IL-6 and active TGF β were determined in culture supernatants using ELISA and bioassay respectively. Message for TSP-1 was determined by real-time PCR.

Results: In the conjunctiva CD11c $^{+}$ cells were located adjacent to MUC5AC $^{+}$ GCs. Their cell bodies in the stromal layer, immediately below the epithelial layer, extended processes across the epithelium in TSP-1 $-/-$ conjunctiva previously reported to harbor increased microbial frequency. Such processes were not detected in WT tissue. Frequency of CD11c $^{+}$ MHC class II $^{+}$ cells was increased in FL-treated conjunctiva compared to untreated controls. Primary GC cultures responded to PA14 and FL with an increased IL-6 secretion compared to controls (1193 \pm 58.5, 884 \pm 60.6 vs. 5.6 \pm 0.2 respectively, $p < 0.05$). FL-stimulated GCs secreted reduced active TGF β consistent with their reduced expression of TSP-1 message (1715 \pm 40.7 vs. 4459 \pm 75.2, $p < 0.05$) and immunostaining in FL-treated conjunctiva. These changes correlated with an increased fluorescein staining score 4 weeks after FL treatment compared to the baseline (8.3 \pm 0.5 vs. 2.8 \pm 0.6, $p < 0.05$).

Conclusions: Our results demonstrate that DCs in the conjunctiva can extend trans-epithelial processes, presumably to sample microbes at the ocular surface, and support the hypothesis that their activation can be induced by disrupted GC homeostatic responses by microbial stimuli. These findings implicate GC responses in inducing chronic ocular surface damage.

TITLE: Longterm outcomes of Ahmed glaucoma valve (AGV) and Baerveldt glaucoma implant (BGI) in patients with Boston Keratoprosthesis type I (K-Pro)

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Hakim, M. Harissi-Dagher, Ophthalmology, Universite de Montreal, Montreal, Quebec, CANADA|D. Geoffrion, Ophthalmology, McGill University, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Joseph Hakim: Commercial Relationship: Code N (No Commercial Relationship) | Dominique Geoffrion: Commercial Relationship: Code N (No Commercial Relationship) | Mona Harissi-Dagher: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the long-term outcomes of glaucoma drainage devices (GDD) in Boston keratoprosthesis type 1 (KPro) patients, specifically those of the Ahmed glaucoma valve (AGV) versus those of the Baerveldt glaucoma implant (BGI).

Methods: Retrospective cohort study of 44 eyes (44 patients) implanted with a KPro between 2008 and 2017. KPro eyes with AGV (n=35) were compared to those with BGI (n=9) in the main cohort. A sub-cohort comparing KPro eyes with AGV installed pre-KPro (n=9) to those with BGI installed pre-KPro (n=7) was further examined. The primary outcome was GDD failure, defined by uncontrolled intra-ocular pressure, additional glaucoma surgery or tube removal. Secondary outcomes included GDD related complications, change in best-corrected visual acuity (BCVA), intraocular pressure (IOP) and number of glaucoma medications.

Differences in outcomes were compared using parametric and non-parametric tests, as well as log-rank test to compare time-to-outcome events.

Results: Mean age was 60.0 ± 15.4 years at KPro surgery and mean follow-up time was 5.4 ± 2.3 years. In the main cohort, KPro eyes with AGV had a higher cumulative failure probability over time compared to that of eyes with BGI (57.1% versus 11.1%; $P=0.039$). More eyes with AGV required additional glaucoma surgery procedures compared to eyes with BGI (37.1% vs. 11.1%; $P=0.135$). The occurrence of GDD-related complications was similar between AGV and BGI (37.1% vs 33.3%, $P=0.832$). Regarding BCVA, there was an improvement in 55.6% of eyes with BGI compared to 42.9% of AGV eyes ($P=0.71$.) Change in IOP and number of topical glaucoma medications was also comparable in both groups ($P>0.05$) over the follow-up period. In the subcohort, outcomes between GDDs implanted before KPro surgery were concordant with those of the main cohort.

Conclusions: Compared to AGV, BGI implanted in KPro eyes was associated with lower GDD failure rates and slightly higher occurrence of improved BCVA while having a comparable occurrence of long-term postoperative complications.

ABSTRACT BODY:

Purpose: To construct an objective analysis system of corneal nerve tortuosity and detect the changes of corneal subbasal nerve tortuosity in patients with dry eye disease (DED) and diabetes.

Methods: Grade I to IV nerve tortuosity were evaluated and 80 photos of each grade were randomly chosen from the in vivo confocal microscopy library. Nerve fibers were extracted, segmented and then analyzed by 6 tortuosity related parameters including L_C, Seg_L_C_mean, Cur_mean, Specific_p, ICM and SCC_mean. After verifying the validity of parameters above, a cross-sectional study was conducted. Subjects were divided into four groups: control group, DED without diabetes group, diabetes without DED group, diabetes with DED group. 23 to 28 persons in each group. Basic and DED information includes sex, age, OSDI, TBUT, SIt and CFS score. FPG and HbA1c were detected in diabetic patients. C-BE was detected to evaluate corneal sensation and 2 corneal subbasal nerve photos of each eye were selected for effective tortuosity and density related parameters analysis. Data was analyzed by SPSS 20.0. This study followed the Declaration of Helsinki and was approved by Ethic Committee of Peking University Third Hospital. Informed consents were obtained.

Results: L_C, Seg_L_C_mean, Cur_mean, Specific_p, ICM and SCC_mean increased as the nerve tortuosity increased from Grade I to Grade IV (Fig. 1A/1B). Among the above 6 parameters, Cur_mean and L_C of any two groups were of significant difference (all at $P < 0.01$). Sex and age were comparable among 4 groups. Diagnostic criteria were met in dry eye disease (DED) and diabetes (Fig. 1C). Corneal sensation (C-BE) decreased in diabetes without DED group and diabetes with DED group compared with control group (all at $^{Adj}P < 0.05$), other than in DED without diabetes group ($^{Adj}P \geq 0.05$). Nerve density of diabetes without DED group and diabetes with DED group was lower compared with control group (all at $P < 0.001$), while no significant difference between DED without diabetes group and control group ($P \geq 0.05$). Among the effective parameters of tortuosity, L_C, Cur_mean, Seg_L_C_mean and SCC_mean of last 3 groups were higher compared with control group (all at $P < 0.05$) (Fig. 1D).

Conclusions: L_C and Cur_mean are most suitable parameters to analyze corneal nerve tortuosity. Compared with volunteers, patients of DED or diabetes showed higher corneal subbasal nerve tortuosity.

ABSTRACT BODY:

Purpose: SAF312 is a potent inhibitor of the transient receptor potential cation channel subfamily V member 1 (TRPV1). This first-in-human study evaluated the safety, pharmacokinetics (PK), and cornea esthesiometry of topical ocular SAF312 in healthy volunteers.

Methods: This single-center, double-masked, randomized study comprised of three parts: single-ascending dose (SAD), multiple-ascending dose (MAD), and esthesiometry. Each dose cohort (SAF312 0.15%, 1.5%, 2.5%) included 8 healthy volunteers randomized 3:1 to either SAF312 or vehicle, 1 drop once (SAD), or 1 drop 4-times or 8-times (only for 2.5%) daily for 7 days (MAD). Safety and PK were the primary and secondary objectives. Exploratory objectives included tear production (Schirmer test without anesthesia), tear film break-up time (TFBUT), and blink rate in the MAD groups. Esthesiometry included 12 healthy volunteers randomized equally to 4 sequences consisting of a single drop of SAF312 2.5%, tetracaine 0.5% (anesthetic), diclofenac sodium 0.1% (nonsteroidal anti-inflammatory drug), or vehicle, in a Williams square design.

Results: SAF312 was safe and well tolerated at the maximum concentration 2.5%, 1 drop 8-times daily (7.4 mg/day, supratherapeutic dose) in one eye for 7 days. Most of the adverse events (AEs) were mild and similar between SAF312 and vehicle-treated healthy volunteers (54 healthy volunteers exposed to SAF312). No severe AEs, serious AEs, or deaths were reported. SAF312 was rapidly absorbed into systemic circulation with T_{max} ~0.5 h after single or multiple doses. After supratherapeutic dosing for 7 days, mean steady state exposures (C_{max} , 2 ng/mL and AUC_{0-24h} , 45 h*ng/mL) of SAF312 were low and afforded safety margins of >70-fold compared with systemic exposures in preclinical species at no-observed-adverse-event levels following oral dosing. No clinically relevant changes were observed with SAF312 in the blink rate, tear production, and TFBUT. SAF312 showed no anesthetic effect on the cornea, similar to diclofenac and vehicle as opposed to tetracaine (esthesiometry).

Conclusions: Topical ocular SAF312 was well tolerated with no ocular or systemic safety concerns up to a supratherapeutic (8x daily) dose of the maximum concentration (2.5%); it had no anesthetic effect on the cornea and demonstrated a rapid topical absorption with low systemic exposure in healthy volunteers.

TITLE: Plekha7 knock out (KO) rats show an altered ocular barrier function

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.S. Chan, C. Ho, L.M. Naing, V.A. Barathi, E.N. Vithana, T. Aung, Singapore Eye Research Institute, Singapore, SINGAPORE|A.S. Chan, T. Aung, Singapore National Eye Centre, Singapore, Singapore, SINGAPORE|

Commercial Relationships Disclosure (Abstract): Anita Chan: Commercial Relationship: Code N (No Commercial Relationship) | Candice Ho: Commercial Relationship: Code N (No Commercial Relationship) | Lynn Naing: Commercial Relationship: Code N (No Commercial Relationship) | Veluchamy Barathi: Commercial Relationship: Code N (No Commercial Relationship) | Eranga Vithana: Commercial Relationship: Code N (No Commercial Relationship) | Tin Aung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To characterise the ocular phenotype of Plekha7 knock out (KO) rats. PLEKHA7 is a robust primary angle closure glaucoma (PACG) susceptibility gene reproducibly observed across patient collections of distinct ethnicities.

Methods: Homozygous Plekha7 KO rats were gifted from Geurts Lab (Wisconsin, USA). These rats were created with zinc-finger nuclease technology in the Guerts Lab on an albino Dahl salt sensitive (SS) rat background. Eight age matched KO and SS controls were serially assessed every month from 6 weeks to 12 weeks using tonometry, slitlamp examination, axial length (AC master), anterior segment-ocular coherence tomography (AS-OCT, Visante). Fluorophotometry (FluorotronMaster) was performed with intraperitoneal injection of fluorescein (0.1 mL/100 g body weight). Animals were also sacrificed for immunohistochemistry (IHC) analysis of Plekha7 and barrier proteins (ZO-1 and occludin).

Results: There was no significant difference in baseline parameters between SS control and Plekha7 KO rat eyes ($p > 0.05$). Mean IOP at 12 weeks between the control and Plekha7 KO rats were not statistically significant (11.2 ± 0.8 mmHg SS control vs 10.8 ± 1.1 mmHg Plekha7 KO, $p = 0.150$). Significant anatomical differences at 12 weeks between SS controls and Plekha7 KO were also not detected: axial length ($p = 0.107$), anterior chamber depth ($p = 0.058$), angle in all 4 quadrants (nasal, temporal, superior and inferior, $p > 0.05$). Fluorophotometry readings show higher immediate fluorescein concentration in the vitreous and anterior chamber. Plekha7 IHC expression shows Plekha7 localisation is detected along the intercellular contact between the non-pigmented ciliary epithelium (NPCE) and the pigmented ciliary epithelium, as well as the outer limiting membrane (OLM) of the retina in SS control rats but not the Plekha7 KO eyes (Figure 1). ZO-1 expression is seen in close association with Plekha7 expression in the NPCE and OLM in SS controls.

Conclusions: Plekha7 KO rats show loss of Plekha7 expression in ciliary processes and OLM of the retina. Functionally, these Plekha7 KO rats also show increased fluorescein dye leakage in the vitreous and anterior chamber in comparison to control SS rats. The close association of Plekha7 expression with tight junction protein ZO-1 in the ciliary processes suggests it may contribute to an altered barrier function in PACG pathogenesis.

ABSTRACT BODY:

Purpose: Early diagnosis of infectious uveitis may prevent vision loss, but given the small volume, it is notoriously difficult to test ocular fluid for specific viruses in uveitis. Multiplex PCR is an ideal technique to diagnose viral uveitis, however, sensitivity of commercially available kits is an important concern. This study was aimed to optimize primers to increase sensitivity of multiple real time PCR for diagnosis of two viral uveitis causing agents, herpes simplex virus-1 (HSV-1) and human cytomegalovirus (HCMV).

Methods: In the first steps, we performed uniplex PCR to evaluate the sensitivity of at least four different primers designed to detect each HSV-1 (McKrae strain) and HCMV (AD169 strain). During this step, different pathogen loads of virus were used to test the load dependent sensitivity of primers. After optimization of primers with uniplex PCR, the sequences were further validated at least three times each with multiplex PCR. For this purpose, samples containing different concentrations ranging from low (1×10^4) to high (1×10^6) pathogen load mixed in bovine aqueous humor were used. TaqMan probes with intercalated DNA fluorophore (VIC for HSV-1 and FAM for HCMV) primers were used for multiplex PCR validation.

Results: Primer validation resulted in the sequences F: 5'-GCCTTTTGTGTGTGTGTTGG-3', R: 5'-AGGAAAGAGGAAACAGGCCG-3' being sensitive to detect low (1×10^4) and high (1×10^6) pathogen load of HSV-1 glycoprotein B, while F: 5'-CAAGTGACCGAGGATTGCAA-3', R: 5'-CACCATGTCCACTCGAACCTT-3' was sensitive for detecting low (1×10^4) and high (1×10^6) pathogen load of HCMV immediate-early protein 1. The same sequences designed with TaqMan probes with intercalated DNA fluorophore primers showed efficient detection of either HSV-1 or HCMV in standalone or mixture of both viruses at different pathogen loads. The cycle threshold values ranged between 19 to 11 and 22 to 14 for low and high pathogen load of HSV-1 and HCMV respectively.

Conclusions: The primers optimized for multiplex PCR were found to be highly sensitive and specific for HSV-1 and HCMV. The results were reproducible and can be used for simultaneous or independent detection of either of the two viruses with the use of only 5 μ l of aqueous humor. Further studies will be needed to confirm the efficacy of primers in clinical samples.

TITLE: Impact of short-term exposure to short, middle, and long-wavelength of light and optical defocus on axial elongation in humans

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Verkicharla, S.K. Thakur, Myopia Research Lab, Prof. Brien Holden Eye Research Centre, L V Prasad Eye Institute, Hyderabad, Telangana, INDIA|

Commercial Relationships Disclosure (Abstract): Pavan Verkicharla: Commercial Relationship: Code N (No Commercial Relationship) | Swapnil Thakur: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Given the potential role of light and its wavelength on ocular growth, this study aimed to investigate the effect of short-term exposure to short, middle, and long-wavelength on axial elongation in presence of ocular defocus.

Methods: A total of 7 young adults (4 emmetropes, 3 myopes) were exposed to long (red-623nm), middle (green-521 nm), and short-wavelength of light (blue-460 nm) for a period of 60 minutes each on 3 separate days (between 9 to 11 am). During the light exposure, monocular (right eye) hyperopic defocus of 3D was induced to the right eye with the fellow eye experience normal view (no defocus). The mean (\pm SD) age of the participants was 23 ± 3 years and spherical equivalent refractive error ranged from -0.50 to $+2.50$ D). Smart LED Bulb ((Wipro Enterprises Ltd., Shezhen, PRC, China) was used in a 3x3x3 meters closed room while the participants were asked to watch the video placed at 3 meters from the eye for the experiment period of 60 minutes. Axial length was recorded pre and post the defocus (in less than a minute) using Lenstar non-contact biometer. Participants were asked to score asthenopic symptoms (headache, eye strain, eye discomfort, eye fatigue, dizziness) after the experiment as none, slight, moderate, severe, intolerable.

Results: There was a small but significant increase in axial length from baseline in the right eye (with defocus) after 1-hour exposure to longer ($13 \pm 4 \mu$, $p = 0.02$) and middle wavelength of light ($16 \pm 5 \mu$, $p = 0.01$), but not with the shorter wavelength ($0 \pm 4 \mu$, $p = 0.49$). Emmetropes showed greater axial elongation compared to myopes in both red and green light conditions. Exposure to middle wavelength alone lead to significant changes in axial length in the left eye ($9 \pm 2 \mu$, $p = 0.01$). None of the participants experienced/complained of any asthenopic symptoms during or after the experiment.

Conclusions: One hour exposure to the shorter wavelength of light did not lead to axial elongation, while the middle and longer wavelengths induced small but significant changes in presence of the hyperopic defocus indicating the potential role of chromatic cues on ocular growth and myopiogenesis. Given that short-term exposure to different wavelengths of light did not induce any asthenopic symptoms, the impact of such specific wavelength exposure on children and its application in myopia control warrants further investigations.

ABSTRACT BODY:

Purpose: To measure in vivo lamina cribrosa (LC) deformations induced by chronically elevated intraocular pressure (IOP). Specifically, we measure session-to-session (S2S) LC stretch, compression, shear and effective strains.

Methods: The optic nerve heads (ONHs) of both eyes of three monkeys were imaged using optical coherence tomography (OCT, Spectralis) at baseline and longitudinally (S2S interval 7 to 22 days, 7 to 17 sessions) after unilateral laser-induced chronic elevated IOP (experimental glaucoma EG). To remove acute IOP effects and isolate chronic deformations all scans were acquired after IOP was set to 10 mmHg for 30 minutes. Digital volume correlation (DVC) was then employed to determine the local S2S LC deformations. LC deformations were compared longitudinally and between the EG and control eyes of each monkey.

Results: S2S LC changes were much larger in the EG eyes after lasering compared to the baseline sessions and control eyes. As expected, laser-induced IOP increases were highly variable, prompting further treatments. However, the LC changes induced by the transient increases in IOP were not resolved after IOP returned to normal. S2S LC deformations reached low two digits, locally as large as 10% compression and 16% stretch, suggestive of tissue loss. Interestingly, further analysis indicated that in the sessions immediately after lasering, a small anterior-posterior LC stretch was detected, suggesting that the lamina undergoes thickening, not thinning. Later on, the LC exhibited the expected compression consistent with thinning. S2S LC changes were significantly larger in the EG after lasering compared with the baseline sessions and the control eyes ($p < 0.001$).

Conclusions: The monkey LC suffers clearly detectable deformations as a result of chronically elevated IOP. Changes can be detected even after only a few days of elevated IOP, and are not immediately resolved even if IOP comes back to the normal range.

ABSTRACT BODY:

Purpose: Conjunctival melanomas are relatively rare tumors, accounting for a small percentage of ocular melanomas. However, these tumors carry high morbidity and mortality rates, and early diagnosis and treatment are critical. Recent studies have identified 5-hydroxymethylcytosine (5hmC) as a potential diagnostic and prognostic biomarker in cutaneous melanoma. 5hmC is an epigenetic marker, generated from oxidation of 5-methylcytosine (5mC) by TET enzymes. It has been found at high levels in self-renewing and pluripotent stem cells, and has been postulated to regulate gene expression and initiate DNA methylation. We conducted a study to characterize the expression of 5hmC in benign conjunctival nevi, primary acquired melanosis (PAM) with moderate atypia, and conjunctival melanomas to determine whether 5hmC has utility in distinguishing benign from potentially malignant lesions.

Methods: A total of twelve samples were retrieved from archived cases, consisting of histopathologically confirmed benign nevi (n=4), PAM with moderate atypia (n=4), and conjunctival melanoma (n=4). All specimens were fixed in 10% buffered formalin and embedded in paraffin. Sections of 5 µm were cut, stained with hematoxylin and eosin (H&E), and reviewed by light microscopy. Sequential sections were then subjected to immunohistochemical staining with antibody against 5hmC. Negative and positive controls were performed in parallel. Slides were reviewed and graded by an ocular pathologist.

Results: All four nevi samples exhibited positive nuclear staining for 5hmC; in contrast, all four PAM specimens as well as three out of four conjunctival melanomas did not display staining for 5hmC (p=0.03). One melanoma specimen, rated as spindle cell, exhibited rare positive 5hmC staining.

Conclusions: This is the first study to-date which shows that 5hmC expression is significantly decreased in conjunctival melanomas when compared to benign nevi. In addition, specimens confirmed as PAM with moderate atypia exhibited negative staining for 5hmC, which may reflect their potential to progress to malignant melanoma. Future studies are needed to further delineate the level and specificity of 5hmC expression in different conjunctival melanocytic proliferations, as well as its utility as a clinical marker.

TITLE: Developing CRISPR-Based Treatment Strategies for Selective Editing of Mutant Rhodopsin in *Xenopus laevis*

SESSION TITLE: Gene editing and ocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Ghaseminejad, B.M. Tam, O.L. Moritz, Ophthalmology and Visual Sciences, The University of British Columbia Faculty of Medicine, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure (Abstract): Farhad Ghaseminejad: Commercial Relationship: Code N (No Commercial Relationship) | Beatrice Tam: Commercial Relationship: Code N (No Commercial Relationship) | Orson Moritz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Given that mutations in the rhodopsin gene (RHO) are associated with autosomal dominant retinitis pigmentosa (adRP), highly specific gene-editing strategies in RHO may provide effective treatments for this blinding disease. The Moritz lab has previously described CRISPR-based genetically modified *X. laevis* that carry a 12-base pair (bp) deletion in the Rho.L gene, immediately downstream of the start codon. Phenotypically, we observed significantly lower levels of rhodopsin protein as well as substantial retinal degeneration (RD) in these animals. Utilizing this model, we aimed to prevent the detrimental effects of this 12bp deletion by inactivating the dysfunctional gene.

Methods: Methods: Our approaches involved removing the dysfunctional Rho.L start codon by inducing simultaneous double-strand breaks on both sides of the start codon, generating a loss-of-function allele. We designed a single-guide RNA (sgRNA) to target the defective Rho.L gene, but not the other *X. laevis* rhodopsin encoding genes (Rho.2.L and Rho.S) or the wildtype Rho.L allele. A second sgRNA targeted a relatively non-conserved region of the Rho.L promoter which was not specific for the mutant allele. Both sgRNAs were injected alone and in combination into *X. laevis* embryos. Tadpoles from treated and untreated groups were raised to 14 days. One eye from each sacrificed tadpole was solubilized for evaluating rhodopsin levels using a dot-blot assay. The contralateral eye was sectioned, labelled and imaged for assessing histology. Genetic changes were examined by PCR and Sanger sequencing.

Results: Results: Compared to the untreated animals carrying the 12bp deletion, significantly higher levels of rhodopsin were detected in the CRISPR-edited animals. Histologically, considerable RD in the untreated groups was also prevented in animals receiving the sgRNA edit. Treatment with even the single mutation-specific sgRNA dramatically prevented RD, likely due to frameshift mutations similarly causing loss of function. Treatment of wildtype animals with the sgRNAs did not induce any detrimental effects.

Conclusions: Conclusion: We have demonstrated prevention of RD in animals treated with mutation-specific sgRNAs, compared to untreated animals. Both frameshifts and generation of large inactivating deletions dramatically prevented RD, showing that complex approaches may not be necessary for developing effective treatments.

ABSTRACT BODY:

Purpose: SAF312 is a potent inhibitor of the transient receptor potential cation channel subfamily V member 1 (TRPV1). This Phase 2a study (NCT02961062) evaluated the safety and efficacy of topical ocular SAF312 in post-PRK ocular pain.

Methods: Patients (pts) aged 18-75 years and eligible for PRK with myopia ≤ -4.00 D sphere, ≤ -4.50 D spherical equivalent, and astigmatism ≤ 3.00 D were allowed in this double-masked, vehicle-controlled, multicenter study. Pts were randomized (1:1) to 2 treatment sequences in a bilateral PRK crossover design (SAF312 2.5% followed by vehicle [or vice versa], 1 drop, 4× daily for 72 h post-PRK; Fig 1). The primary endpoints were visual analog scale (VAS) pain severity scores at 6 h and average VAS scores over 0-12 h postoperatively (postop). Incidence of oral rescue medication (ORM) use, wound healing rate, conjunctival hyperemia, and safety were assessed. $P \leq 0.10$ was deemed statistically significant (per primary endpoint power calculation).

Results: All 40 pts (mean \pm SD age: 34 \pm 9.8 years) completed the study. Both primary endpoints were met; difference between SAF312-treated (n=30) and vehicle-treated (n=29) eyes in mean VAS pain scores at 6 h postop was -11.1 (-25%) (90% CI: -17.54, -4.71; $P=0.005$), and at 0-12 h postop was -8.56 (-22%) (90% CI: -14.29, -2.83; $P=0.017$). The mean VAS pain scores were lower with SAF312 than with vehicle from 1 h postop (-53%) up to 30 h postop ($P \leq 0.10$ in 8/11 timepoints). Less ORM (number of pills) was taken with SAF312 (n=40) vs vehicle (n=40) at 0-6 h postop (-25%, $P=0.10$), and up to 0-72 h postop (-14%, $P=0.07$), with a trend of fewer pts needing any ORM at 0-24 h postop with SAF312 (40%) vs vehicle (30%). No delay in wound healing was noted in SAF312- vs vehicle-treated

eyes. Grade 4 conjunctival hyperemia 24 h postop was significantly lower in SAF312- vs vehicle-treated eyes, especially in the superior conjunctiva associated with most surgical manipulation ($P=0.04$). No deaths or serious adverse events (AEs) were reported. Of the 40 pts in this study, 8 and 5 had AEs while on SAF312 and vehicle, respectively; and all ocular AEs (3 in each group) were mild and transient. No AE was drug-related.

Conclusions: Topical SAF312 was well tolerated and effective in reducing ocular pain in the immediate post-PRK period. SAF312 is currently under evaluation for postop corneal induced chronic pain (NCT04630158).

ABSTRACT BODY:

Purpose: Currently there are no standardized automated tools to assess oculoplastic metrics despite the importance of periorbital measurements in assessing clinical disease and surgical outcomes. To date, only the margin reflex distances (MRD1/MRD2) have been previously automated. To address this, we used a deep learning semantic segmentation network to fully automate 9 periorbital measurements.

Methods: Periorbital photos were collected from routine oculoplastics clinic. In the retrospective phase, photos from 397 patients were collected. Three areas in each photo (eye aperture, iris, and eyebrow) were segmented bilaterally by 3 graders. The segmentations were used to train a deep learning semantic segmentation model consisting of a vanilla PSPNet with a ResNet50 backbone and a U-Net-style upsampling arm. Then, a post-processing algorithm was developed to measure: MRD1, MRD2, medial canthal height (MCH), lateral canthal height (LCH), medial brow height (MBH), lateral brow height (LBH), medial inter-canthal distance (MID), and lateral inter-canthal distance (LID). In the prospective phase, three human graders used Photoshop version 22.0.1 to segment and measure the 9 metrics in photos from 46 participants. The images and grader-derived segmentations and measurements formed the independent test set. The trained network and the post-processing algorithm were used to obtain periorbital measurements for the test-set images (Fig 1).

Results: The mean absolute difference range for MRD1 was 0.43-0.57mm between AI and human graders and 0.24-0.30mm between the 3 human graders. For MRD2 it was 0.38-0.39mm between AI and humans and 0.28-0.35mm between human graders. On average the periorbital measures deviated less than 4.5mm between every pair of raters across all metrics (Fig 2). The 95% confidence intervals are largely overlapping between all pairs of raters indicating the variations between human graders were similar to those between humans and AI.

Conclusions: We present, to the best of our knowledge, the first machine learning automation of 9 different periorbital measurements. This tool has similar variability to human graders and could be clinically useful to objectively track disease progression and surgical outcomes.

ABSTRACT BODY:

Purpose: Hyperuricemia has been implicated to be a factor of eye diseases. However, no sufficient evidence in single nucleotide polymorphism (SNP) variations is provided to associate its relation with particular ocular abnormalities. In this study, we investigated this potential relevance based on Taiwan Biobank (TWB).

Methods: A total of 65,076 individuals were enrolled in this study using TWB from 2009-2018, with a mean age of 49.96 (SD=10.91). The TWB is a large-scale national biobank that supplies valuable phenotypic and genetic information to biomedical researchers among Taiwanese population. The study was a case-control study in which the case groups were defined as patients with hyperuricemia (defined as 7 mg or more of uric acid per 100 mL of blood in men and 6.5 mg or more in women before menopause) or self-reported gout, and the control group was age- and gender-matched non-hyperuricemic or non-gouty individuals. The study groups were divided into (1) 55,300 cases with no gout and normal uric acid (2) 7,618 cases with hyperuricemia and no gout (3) 790 cases with gout but normal uric acid (4) 1,368 cases with hyperuricemia and gout. The proportion of variation of groups was compared with that in the control group by GWAS to calculate the relative odds ratio and estimate the significance of each eye disease investigated.

Results: Patients with gout but normal uric acid, compared with those with normal uric acid without gout, had a significantly higher prevalence of eye diseases, including cataract (200/1356 (14.75%) vs 1362/16925 (8.05%)), dry eye (147/1356 (10.84%) vs 1262/16925 (7.46%)), and myodesopsia (212/1356 (15.63%) vs 1722/16925 (10.17%)), after been adjusted for age and gender. Among hyperuricemia-related SNP variants analyzed, rs3741414 and rs1178977 were associated in patients with gout but normal uric acid, concomitant with eye diseases.

Conclusions: The results of this study indicated that gout is a more critical factor in ocular diseases than hyperuricemia, suggesting a potential sub-clinical effect exerted by uric acid or its associated activities in the eye. The two identified SNP variants need further investigation for the underlying mechanism.

ABSTRACT BODY:

Purpose: Quality assurance (QA) in neuro-ophthalmology (NOPH) is often lacking. The QA registry, NODE (Neuro-ophthalmology Database), was established and implemented in tertiary NOPH clinics in Australia. We developed a consensus on triage categories according to Australian standardised triage categories; P1 (consult \leq 30 days), P2 (consult \leq 30 to 60 days) and P3 (consult $>$ 60 days). Triage categories and time-to-consult for common NOPH conditions were compared to evaluate quality of referral assessment at a single site.

Methods: We collected data in NODE on 410 patients at Alfred Hospital, Melbourne. We developed a consensus on assignation of NOPH conditions to triage categories using recommendations from a panel of seven experienced neuro-ophthalmologists. Panelists scored conditions and triage categories using a modified Delphi approach (strongly agree, agree, neutral, disagree or strongly disagree). Consensus was considered when $\geq 75\%$ of the panel strongly agreed or agreed. We analysed the mean days from referral to triage, and, from triage to the initial consultation, and compared that to the developed triage category standard.

Results: Most patients presenting to the service were female (n=262, 64%), aged 21 to 30 years. Common diagnoses were Idiopathic Intracranial Hypertension, IIH (24%), Optic Neuropathy, ON (17%), Headaches, (11%) Cranial Nerve Defects, CND (9%) and Eye Movement Disorders, EOMD (9%). Consensus on triage category assignment was reached after 1 round of scoring from expert panel members. The mean time from referral to triage was performed in <2 days for all the common diagnosis at the NOPH clinic. The mean time (days, +-standard deviation (SD)) from P1 category triage to initial consult for IIH was 26 (± 7), ON 27 (± 11), and CND was 17 (± 5). The mean time (days) from P2 triage to initial consultant for Headaches was 27 (± 12), and EOMD was (± 17). The mean time (days) from P3 triage to initial consultant for Myasthenia Gravis was 30 (± 10).

Conclusions: We have established a consensus agreement on triage categories for neuro-ophthalmological conditions. Further validation using a larger panel of experts would be able to refine this further. Data from NODE demonstrated that most conditions are appropriately triaged and seen. We established a QA framework for other NOPH clinics in Australia.

ABSTRACT BODY:

Purpose: The Eye Surface Profilometer (ESP) allows measurements of corneal and scleral topography that have provided information about the characteristics of the in-vivo human anterior eye shape and have been used in contact lens fitting and design. This study aimed to examine the intersession and intrasession repeatability of sagittal height and corneal spherocylinder measurements from the ESP.

Methods: Forty-five young healthy adult subjects (mean age 25 ± 5 years) with a range of refractive errors had two sessions of anterior eye surface shape measurements captured with the ESP, separated by 20 minutes. At each session, three consecutive scans were captured by a single operator. Spherocylinder data (M, J0, and J45) from the central cornea and sagittal height data from the central 8 mm of the cornea and the region from 8 to 14 mm of corneal periphery/anterior sclera on the nasal and temporal anterior eye surface were assessed to calculate the measurements' intersession and intrasession co-efficient of repeatability (CR) using Bland-Altman analyses.

Results: The intersession CRs of sagittal height measurements for the nasal (5 μm) and temporal (7 μm) central corneal regions were better than the peripheral nasal (24 μm) and temporal (21 μm) regions (all $p < 0.001$). The sagittal height within-subject standard deviations of the three repeated scans were 3, 3, 10, and 11 μm for central nasal, central temporal, peripheral nasal, and peripheral temporal region, respectively. Figure 1 shows the sagittal height Bland-Altman analysis of the central and peripheral nasal and temporal regions.

Intersession CRs of 0.67, 0.22, and 0.13 D and within-subject standard deviations of the three repeated scans of 0.46, 0.08, and 0.10 D were achieved for measurements of corneal power vectors M, J0, and J45, respectively.

Conclusions: Central corneal sagittal height and spherocylinder measurements provided by the ESP are highly repeatable and comparable with other anterior eye topographers, however, sagittal height repeatability reduces towards the periphery. These outcomes should be considered in the clinical and research applications of anterior eye surface topography results from the ESP.

TITLE: Visual motion perception predicts postural sway in older adults with and without vision impairment

SESSION TITLE: Visual Impairment - Driving and Mobility

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.M. Wood, C. Killingly, A.A. Black, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|D. Elliott, University of Bradford, Bradford, West Yorkshire, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Joanne Wood: Commercial Relationship: Code N (No Commercial Relationship) | Callula Killingly: Commercial Relationship: Code N (No Commercial Relationship) | David Elliott: Commercial Relationship: Code N (No Commercial Relationship) | Alex Black: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Accurate perception of body position relative to the environment through visual motion cues provides sensory input to control postural sway. Importantly, the role of visual motion information in older adults is not well established. This study evaluated the extent to which visual motion perception affects postural sway in older adults with and without vision impairment and the interaction with physical function.

Methods: Participants included 234 older adults with vision impairment from a range of eye diseases (mean age = 72.6 ± 7.2 years) and 204 with normal vision (71.6 ± 5.7 years). Participants completed a series of vision tests including binocular visual acuity, contrast sensitivity, visual fields and central motion sensitivity, as well as physical function tests to assess aspects of physical frailty and functional mobility, including walking speed, Timed Up and Go Test (TUGT) and grip strength. Postural sway (path length, mm) was measured using an electronic forceplate (HurLabs) on a firm and foam surface with eyes open. Linear regression analysis was used to identify visual predictors of postural sway and moderated linear regression explored whether this relationship was moderated by physical frailty.

Results: Linear regression models indicated that of the vision tests, impairments in motion sensitivity were most strongly associated with increased sway on foam (standardized $\beta = 0.330$; $p < 0.001$), while of the physical function tests, TUGT (standardized $\beta = 0.334$; $p < 0.001$) was most strongly associated with sway on foam, where poorer functional mobility was associated with increased sway. A moderated linear regression demonstrated significant main effects of motion sensitivity and TUGT for sway on foam ($p < 0.001$), as well as a significant interaction effect (standardised $\beta = 0.164$, $p < 0.001$), such that the relationship between motion sensitivity and sway became stronger when TUGT performance was poorer.

Conclusions: A combination of impaired motion perception and reduced physical function negatively impact on postural stability in older adults with and without vision impairment. This finding provides insight into the visual input to postural stability in older adults and its interactions with other sensory and physical impairments and has implications for the assessment of falls risk in older adults.

ABSTRACT BODY:

Purpose: It has recently been reported that amniotic membrane (AM) transplantation is effective for macular hole (MH) closure and improvement of visual function in refractory MH cases. In this study, we investigated the effects of AM on the morphology and migration of cultivated Müller cells (MIO-M1 cells, an immortalized model of Müller glial cells, University College London, London, UK).

Methods: MIO-M1 were cultured using Dulbecco's modified eagle medium with 10% fetal bovine serum in a humidified 5% CO₂ environment at 37°C. AM was then placed in 24-well plates to create an epithelial-side-up group (epithelial group), a chorion-side-up group (chorion group), and a control group on glass slides (n = 10 each). Then, silicon (3mm in diameter) was placed in the center of each. Each group was then seeded with 0.5×10^5 MIO-M1 cells, with the silicon being removed after 24 hours. Next, phase-contrast microscopy images were taken immediately and at 72-hours post removal of the silicon, and actin filaments were visualized with phalloidin staining. Via examination of the obtained images, the cell morphology was analyzed and the migration ability of the cells was evaluated and compared between the three groups by measuring the cell migration area using ImageJ software.

Results: The MIO-M1 cells showed a bipolar morphology with pseudopodia in the epithelial group and control group, and a nearly circular morphology in the chorionic villus group. In the control group, epithelial group, and chorionic group, the cell migration area was $0.34 \pm 0.26 \text{ mm}^2$, $1.14 \pm 0.48 \text{ mm}^2$, and $0.04 \pm 0.03 \text{ mm}^2$ (mean \pm SD), respectively, with the ability of cell migration being significantly higher in the epithelial group ($P < 0.05$).

Conclusions: Human Müller cells on the chorionic side showed a different morphology from the control and epithelial side, and their migration ability was lower than the epithelial-side cells. When performing AM transplantation for the treatment of MH, positioning the epithelial side of the AM toward the vitreous cavity may promote the migration of Müller cells and assist in the closure of the MH.

ABSTRACT BODY:

Purpose: Light affects a variety of non-image forming processes, such as circadian rhythm and the pupillary light reflex, which are mediated by intrinsically photosensitive retinal ganglion cells (ipRGCs). ipRGCs are most sensitive to short wavelength light. Thus, the spectral properties of light critically impact melanopsin-mediated ipRGC activity. The purpose of this study was to compare the effects of long- and short-wavelength ambient lighting on activity patterns and pupil responses in rhesus monkeys.

Methods: Infant rhesus monkeys were reared under short wavelength “blue” light ($n=20$; 465 nm; 183 ± 28 lux) on a 12-hour light/dark cycle starting at 24.7 ± 2.8 days of age. Animals wore a Fitbit activity tracking device from 25.4 ± 2.4 days until 148.5 ± 7.7 days of age. Activity was quantified as mean daily “steps” during the lights-on and lights-off periods. At 333 ± 12 days of age, pupil responses to 1 second (s) red (651 nm) and blue (456 nm) stimuli were measured. Pupil metrics included maximum constriction and the 6s post-illumination pupil response (PIPR). Data were compared to age-matched monkeys reared under either broadband “white” light ($n=18$; 480 lux) or long wavelength “red” light ($n=20$; 630 nm; 274 ± 64 lux).

Results: During the lights-on period, daily activity was not significantly different for monkeys reared in blue light (1215 ± 648 steps), red light (877 ± 574 steps), or white light (942 ± 523 steps; $P=0.07$). During the lights-off period, monkeys reared in blue light exhibited significantly greater activity (91 ± 68 steps) compared to those in white light (49 ± 34 steps; $P=0.02$). There was no significant difference in lights-off activity between blue and red light (67 ± 35 steps) reared monkeys ($P=0.08$) or between red and white light reared monkeys ($P=0.24$). Maximum pupil constriction and the 6s PIPR to 1s red and 1s blue stimuli were not significantly different between groups ($P>0.05$ for all).

Conclusions: Rearing monkeys in narrowband blue light resulted in increased nighttime activity, whereas narrowband red light did not significantly impact daytime or nighttime activity patterns. Therefore, exposure to 12-hour narrowband blue light resulted in greater circadian disruption compared to red light, potentially due to increased melanopsin activation in the evenings. However, normal pupil responses later in the rearing period suggests that ipRGCs adapt after long-term exposure to narrowband lighting.

ABSTRACT BODY:

Purpose: Mitochondrial diseases are a heterogeneous group of disorders that arise as a result of dysfunction of the mitochondrial respiratory chain. The circular 16.5-kb mitochondrial genome (mtDNA) contains 37 genes, which are essential for normal mitochondrial function. Mitochondrial dysfunction caused by pathogenic/likely pathogenic variants in the mtDNA has been associated with retinal disease and vision loss. The goal of the study was to evaluate mtDNA variants in >2500 patients with inherited retinal disease (IRD).

Methods: We developed a highly sensitive and clinically validated mtDNA assay based on hybridization-based capture of mtDNA and next-generation sequencing (NGS) that is able to detect very low heteroplasmy levels of SNVs, INDELs and deletions. The mean read depth for the mtDNA was 18,224x, and 100% of base pairs were covered with a sequencing depth of at least 1000x. Sensitivity to detect SNVs and INDELs with over 10% heteroplasmy was 100%. For SNVs with 5-10% and <5% heteroplasmy levels the sensitivity was 93.3% and 88.9%, respectively. The mtDNA assay was included in diagnostic sequencing of 2597 IRD patients.

Results: A diagnostic (pathogenic/likely pathogenic) mtDNA variant was identified in 22 patients, contributing to a diagnostic yield of 0.85%. The 22 diagnostic variants included one heteroplasmic large deletion (7542bp) and 21 SNVs. Five of the SNVs were homoplasmic and 16 were heteroplasmic (>7%). Homoplasmic variants were associated mainly with Leber hereditary optic neuropathy (LHON). Diagnostic variants were identified in 8 mtDNA genes: MT-ND1, MT-ND4, MT-ND6, MT-ATP6, MT-TN, MT-TH, MT-TL1, and MT-TV. The most common variant was the retinal disease-associated MT-TL1 m.3243A>G, identified in 11 individuals in whom the retinal disease was most often described as macular/ cone dystrophy. Additionally, we reported a mtDNA VUS, likely to contribute to the patient's diagnosis, in 7 cases.

Conclusions: Adding mtDNA analysis to routine genetic diagnostic process of IRD patients can increase the diagnostic yield by >0.85%. Analyzing the full mtDNA is beneficial as several different variants in mtDNA have been associated with both syndromic and non-syndromic IRD.

ABSTRACT BODY:

Purpose: Patients affected by Coronavirus disease 2019 (Covid-19) suffer from a hypercoagulable state that may potentially affect the retinal and choroidal circulation. The aim of this study was to determine whether retinal and choriocapillaris vessel density (VD) as measured by optical coherence tomography angiography (OCTA) resulted abnormal in patients previously affected by Covid-19.

Methods: The right eye of sixty patients who tested positive for Sars-CoV-2 in a reverse transcription PCR assay were examined with structural optical coherence tomography (OCT) and OCTA. A control group of age-matched healthy subjects was selected for statistical comparisons. Raw OCT and OCTA images, acquired with TOPCON DRI OCT Triton, were exported using Topcon IMAGENET 6.0 software. 3D datasets were analysed to determine retinal thickness and VD in the 5 sectors of Early Treatment Diabetic Retinopathy Study (ETDRS).

Results: The images were gradable in 54 eyes (88%) on which the final analysis was conducted. The study and control group did not differ significantly for sex, intraocular pressure (IOP) and refractive error. Vessel density of the superficial capillary plexus did not differ between groups whereas VD of the deep capillary plexus (DCP) and choriocapillaris in the foveal ETDRS sector was significantly lower in the Covid-19 group compared to controls ($P < 0.01$). No significant difference was found in the VD's recorded in any of the other 4 ETDRS sectors between groups. Within the COVID-19 group, subgroups were identified for therapies, underlying diseases and hospitalization. Based on therapies the lowest VD was recorded among patients treated with antiviral therapy compared to antiplatelet therapy ($P < 0.01$). No significant difference was found between patients affected by hypertension, diabetes or thyroid disease. A significantly reduced VD value was registered in patients admitted in ICU compared to asymptomatic ($P < 0.01$).

Conclusions: In patients with previous COVID, the VD of the retinal DCP and choriocapillaris measured with OCTA resulted decreased. The lowest values of VD were recorded in the eyes of patients who had undergone antiviral therapy and ICU-setting. Future studies are needed to further support our preliminary data that individuals with previous COVID might develop abnormalities of the retinal and choriocapillaris vasculature.

TITLE: Separate pathways for processing local and global motion in the primate retina

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Appleby, F. Rieke, M.B. Manookin, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Todd Appleby: Commercial Relationship: Code N (No Commercial Relationship) | Fred Rieke: Commercial Relationship: Code N (No Commercial Relationship) | Michael Manookin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To successfully guide behavior the visual system must quickly and accurately distinguish between object (local) motion and self (global) motion. Selectivity for local motion has been observed in the superior colliculus of macaque monkeys, but it is not known whether this computation arises earlier in the visual pathway. Further, selectivity for global motion has not been observed in the early visual pathways of primates. Here, we studied local versus global motion processing in several ganglion cell types in the primate retina, including some of the lesser studied types.

Methods: Recordings were performed in an intact, in vitro preparation of the macaque monkey retina. Spike responses or whole-cell synaptic currents in ganglion cells were performed using borosilicate glass electrodes. Several different stimulus classes were used to measure local versus global motion selectivity and also the effects of motion in the receptive-field surround on cellular responsiveness.

Results: We observed a gradient of sensitivity to local versus global motion across ganglion cell types. Local motion selectivity was strongest in broad thorny ganglion cells while global motion selectivity was greatest in On-type smooth monostratified ganglion cells. Other cell types such as parasol and Off-type smooth monostratified cells showed motion selectivities between these two extremes. Further, the degree of local versus global motion selectivity correlated with the effects of the receptive-field surrounds on cellular gain, ranging from strongly suppressive surrounds (local motion) to facilitatory surrounds (global motion).

Conclusions: A set of primate retinal ganglion cells show a range of sensitivity to either local or global motion, bookended by broad thorny and On smooth monostratified cells, respectively. Our results indicate that the encoding of local and global motion arises early in the primate visual stream. Further, the receptive-field surround is critical to the observed motion selectivities with local motion and global motion sensitivities originating from strongly suppressive and facilitatory surrounds, respectively

TITLE: A Novel Tie2 activating monoclonal antibody ameliorates the lesion of choroidal neovascularization in monkey and mouse

SESSION TITLE: CNV

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Lee, B. Park, N. Kang, C. Park, W. Lee, R&D center, PharmAbcine, Daejeon, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure (Abstract): Eun-Ah Lee: Commercial Relationship(s);Pharmabcine:Code E (Employment) | Beom Yong Park: Commercial Relationship(s);Pharmabcine:Code E (Employment) | Nuri Kang: Commercial Relationship(s);Pharmabcine:Code E (Employment) | Cheon Ho Park: Commercial Relationship(s);Pharmabcine:Code E (Employment) | Woen Sup Lee: Commercial Relationship(s);Pharmabcine:Code E (Employment)

ABSTRACT BODY:

Purpose: Tie2 receptor is mainly expressed in endothelial cells that modulates angiogenesis with angiopoietins (Ang) binding. VEGF neutralizing molecules were approved to treat neovascular ocular diseases but there still is a great need to develop therapeutic agents to treat the patients who do not respond well to anti-VEGF drugs. We recently isolated a Tie2 activating antibody, PMC-403 and are evaluated its potential therapeutic potential to treat neovascular diseases.

Methods: Experimental CNV was induced by laser photocoagulation in C57BL/6 mice and in rhesus monkeys. The animals received IVT administration of aflibercept or PMC-403 and the dose dependent responses were measured in multiple assays: 1) FFA, OCT and ERG were evaluated. 2) The number of leakage spots, the percent changes of leakage area, and the maximum retinal thickness of laser-burned spots were evaluated. 3) In the monkey CNV model, the level of mRNA expression of 10 genes related to angiogenesis and inflammation was measured.

Results: In similar to Ang1, PMC-403 activated Foxo-1 phosphorylation, inhibited VEGFR-2 phosphorylation, and reduced the Survivin expression in HUVEC cells. In a mouse CNV model, PMC-403 reduced the thickness and the leakage of retinal blood vessels comparable to aflibercept in accompanied with improvement of the sensitivity of optic nerves. In a monkey CNV models, PMC-403 improved retina thickness and vessel leakage but the response rate was slower in comparison to aflibercept. Interestingly, PMC-403 showed better responses in sensitivity of optic nerves than aflibercept with decreased level of pro-angiogenesis genes such as Ang2, VEGF, PlGF, and PDGF. In addition, the level of pericyte in retina was dramatically increased by PMC-403 without inflammation.

Conclusions: PMC-403 improved sensitivity of optic neurons in animal CNV models through a normalization of leaky blood vessels. These data strongly support the notion that PMC-403 stabilizes retinal and choroidal blood vessels and it can be developed as an effective therapeutic agent to treat a wide variety of retinal and choroidal vascular disorders.

ABSTRACT BODY:

Purpose: Recent studies found that caffeine intake increases tear secretion. However, there is little elucidation on the cascading effects among caffeine, P1 and P2 receptors, and tear secretion. This study investigated the dose- and time-dependent effects of caffeine on tear secretion and whether P1 and P2 purinergic receptors activation may induce changes in external lacrimal gland (ELG) status under the influence of caffeine.

Methods: 5-week and 10-week old ICR female mice (n=3) were orally given caffeine at 17.3 mg/kg in 0.2 ml of 0.9 % NaCl, followed by tear volume (TV) assessments every 10 minutes from 0 to 100 minutes to determine the optimal mouse age for further experiments. After that, 10-week old ICR female mice were randomly divided 3 study groups: (1) Blank (n=3): 0.2 ml of 0.9 % NaCl, (2) 20 mg/kg (n=6): 20 mg/kg caffeine in 0.2 ml of 0.9 % NaCl, and (3) 40 mg/kg (n=6): 40 mg/kg caffeine in 0.2 ml of 0.9 % NaCl. All groups were assessed for tear volume (TV) at 0, 45, and 60 minutes after feeding. The mice were sacrificed after assessments for histopathological, immunohistochemical (IHC), and western blot analysis.

Results: 10-week old mice were more responsive to caffeine induction than 5-week mice. Tear secretion was significantly increased in both 20/45(20 mg/kg caffeine/45 mins) group ($p<0.05$) and 40/45(40 mg/kg caffeine/45 mins) group ($p<0.05$) compared to blank group. The results of IHC and western blot analysis showed that both P1 and P2 purinergic receptors were elevated, most evidently in the 40/45 group.

Conclusions: The results provided some insights in caffeine-induced tear secretion enhancement. First, the ICR female mice external lacrimal gland (ELG) reaches sufficient maturity to respond to caffeine induction at 10-week of age. Second, caffeine enhances tear secretion only within a certain period of time. Third, not only P1 purinergic receptors, but also P2 purinergic receptors are altered in ELG under the influence of caffeine. The interaction of P1 and P2 purinergic receptors and the effects of long-term caffeine intake should be further investigated.

ABSTRACT BODY:

Purpose: Activation of the innate immune cGAS-STING signaling has been detected in retinal pigment epithelium (RPE) of Geographic atrophy (GA) patients, but the regulatory basis is largely unexplored. We have recently shown that transcriptional inert heterochromatin is required for RPE survival. Here, we investigate heterochromatin-mediated regulation of cGAS-STING, and determine the therapeutic potential of methotrexate (MTX), a newly identified heterochromatin-promoting drug and also a commonly used anti-inflammatory agent, in an experimental mouse model of GA.

Methods: In silico analysis was performed to determine the expression of cGAS and STING in dry AMD patients. GA mouse model was established by I.P. injection of sodium iodate. Chaetocin (0.25mg/kg), a heterochromatin inhibitor, or MTX (1mg/kg) was I.P. injected daily for 3 days after SI injection. Fundus photography and immunohistofluorescent analysis determined RPE morphology. Protein cytokine array, western blot and qRT-PCR analysis detected the activation of cGAS-STING pathway. ChIP assay determined the occupancy of heterochromatin on cGAS and STING upon MTX treatment.

Results: cGAS and STING are upregulated in RPE of GA patients and an experimental GA-like mouse model. Disruption of heterochromatin induces cGAS, STING and the downstream proinflammatory factors expression. Systemic application of MTX inhibits inflammatory gene expression in both RPE and retina, attenuates RPE degeneration and immune cell accumulation/activation. MTX promotes heterochromatin formation and thus epigenetically silencing of cGAS and STING.

Conclusions: Together, we demonstrated the anti-inflammatory function of MTX in a GA-like mouse model and revealed a novel mechanism that MTX suppresses cGAS and STING expression through promoting heterochromatin-mediated silencing. This study may provide new treatment strategy for GA.

ABSTRACT BODY:

Purpose: Protease-activated receptor-1 (PAR1) is activated by the action of serine protease Thrombin. Thrombin plays a role in neurological dysfunction in diabetes. Recent studies have indicated that PAR1 and its activating protease thrombin are expressed in the ocular microenvironment of patients with diabetic retinopathy (DR). The aim of this study is to characterize the distribution of PAR1 in the neuroretina, under physiological conditions, and in diabetes.

Methods: Diabetes was induced in 8 weeks old C57BL/6J male mice by intraperitoneal injection of Streptozotocin (STZ, 150 mg/kg). Five weeks following diabetes induction eyes were removed from diabetic mice (n=12) and healthy C57BL/6J male mice (n=12) and were processed for indirect immunofluorescence analysis. PAR1-/- mice were used as control (n=3). In addition, western blot analysis was performed on mouse neuroretina, optic nerve, brain, and platelets samples.

Results: Significant PAR1 staining was observed in the nuclei of all neuroretinal cell layers (retinal ganglion cells, inner and outer nuclear layers) in diabetic mice (glucose blood > 200mg/dl). Significantly weaker staining was observed in control non-diabetic mice. No staining was observed in PAR1-/- mice. Co-staining of PAR1 with photoreceptor markers demonstrated co-localization of PAR1 and rhodopsin in rod outer and inner segments. By contrast, no PAR1 staining was observed in cone outer segments. The specificity of immunofluorescence staining was confirmed with Western blot analysis.

Conclusions: To the best of our knowledge, this is the first demonstration of PAR1 expression in rod retinal photoreceptors and inner nuclear layer cells. This study suggests that PAR1/thrombin pathway may play a role in the pathophysiology of rods in diabetic retinopathy.

ABSTRACT BODY:

Purpose: The qCSF method applies Bayesian active learning to provide an accurate, precise and efficient assessment of spatial vision (Lesmes et al. 2010). To date, qCSF testing has not been informed by regularities in CSF shape observed when individuals are tested across low, medium, and high luminance conditions. To improve CSF analysis, and leverage information provided by cross-test regularities, we developed a hierarchical Bayesian model (HBM), which infers joint posterior distributions of CSF parameters and hyperparameters from qCSF data obtained from 112 subjects tested in three luminance conditions (Hou et al. 2016).

Methods: The CSF was modeled with a log-parabola with peak gain (PG), peak spatial frequency (PF), and bandwidth at half height (BH). The two-level HBM consisted of multiple 3-dimensional Gaussian distributions of CSF parameters at the population and individual test levels. The 3×3 covariance distributions at two levels quantified cross- and within-test regularities. The means of the parameter distributions at the individual test level were sampled from the hyperparameter distribution at the population level, while all individual tests shared the same 3×3 within-test covariance. We compared the average half-width of the 68.2% credible intervals (HWCIs) of the CSF parameters and area under log CSF (AULCSF) estimates with the qCSF and HBM.

Results: The HBM recovered significant correlations among CSF parameters at the population (Fig. 1; $r(\text{PG}\&\text{PF})=0.441$, $r(\text{PG}\&\text{BH})=0.580$, $r(\text{PF}\&\text{BH})=-0.109$) and individual ($r(\text{PF}\&\text{BH})=-0.719$) test levels. The average HWCI (in log10 units) of the estimated CSF parameters and AULCSF decreased with the number of trials in both the qCSF and HBM analyses (Table 1). Analysis of AULCSF estimates obtained with 50 trials provided HWCI values of 0.040 for qCSF and 0.035 for HBM. Relative to estimates of CSF parameters and AULCSF obtained with the qCSF, the HBM reduced the HWCI by 60-74% and 32% with 15 trials, and 30-55% and 13% for 50 trials. The average absolute difference between qCSF and HBM estimates was not statistically significant.

Conclusions: Incorporating both cross- and within-test regularities, the HBM can further improve the precision of CSF and AULCSF estimates, especially when the number of tested trials is relatively small.

ABSTRACT BODY:

Purpose: Photoreceptors rely on continuous nutrient delivery from the choriocapillaris via the retinal pigment epithelium (RPE). With advancing age, choriocapillaris atrophy and reduced choroidal blood flow create a hypoxic environment disturbing metabolism in the RPE that ceases metabolic support for the photoreceptors. Chronic ischemia can induce photoreceptor dysfunction and degeneration, hallmark features of age-related retinal diseases. Learning how hypoxia drives the metabolic stress response in RPE could give insights into hypoxia-induced retinal pathologies and identify strategies to prevent RPE, photoreceptor and vision loss. In this study, we perform proteomic, metabolomic and transcriptomic analyses to characterize the metabolic effects of hypoxia in RPE.

Methods: Primary human retinal pigment epithelial cells were cultured in normoxic (21% O₂) or hypoxic (4% O₂) conditions. After 48 hours, intracellular proteomic and metabolomic profiles were determined using quantitative proteomics and metabolomics (CE-TOF-MS and CE-QqQ-MS). RNA-Seq based transcriptomics was conducted after 4, 8, 12, 24, 48 and 72 hours of hypoxia, respectively. Differential expression and pathway analysis of hypoxia vs normoxia was performed per dataset and timepoint. 48 hour results for all experiments were then assessed jointly.

Results: Hypoxia induced a dependency on anaerobic glycolysis, consistent with increased glucose uptake and lactic acid production. TCA cycle metabolite levels indicate that in hypoxic RPE, reductive carboxylation is favored, whereas oxidative phosphorylation is suppressed. Despite a substantial decrease in ATP, hypoxic RPE maintained an energy status comparable to that of normoxic cells, presumably due to downregulation of anabolic pathways. Reduction in total glutathione and a decreased glutathione redox ratio indicate that hypoxia enhances oxidative stress.

Conclusions: Our study provides a comprehensive metabolic profile of hypoxic RPE that adds to the understanding of hypoxia-induced metabolic reprogramming as a driving force of age-related degenerative diseases in the retina. If confirmed by prospective studies, these findings can be used to develop novel strategies for modifying the metabolic stress response in hypoxic RPE and prevent vision loss.

ABSTRACT BODY:

Purpose: Decorin imparts a neuroregenerative effect that is associated with immune cell alterations in injured corneas. This study aims to explore the dynamic changes of corneal immune cell density (dendritic cells, macrophages and neutrophils) after topical application of decorin in a mouse model of sterile epithelial abrasion.

Methods: Bilateral central corneal epithelial abrasions (2-mm, Alger Brush) were performed on young C57BL/6J mice (n = 8). Decorin, or saline, was applied topically on right or left eye respectively, three times per day for one or five days. A control group (n = 8) with application of saline on both eyes was also included. Wholemout immunofluorescence staining and confocal microscopy was used to assess corneal immune cell density (CD45, Iba1, CD11c, NIMP) in the central and peripheral cornea. Cells were counted manually using ImageJ software. Data were analysed by fitting a linear mixed-effects model using restricted maximum likelihood (REML) and Kenward-Roger tests for fixed effects.

Results: At 1 day after injury, compared to the saline-treated control eyes, greater intraepithelial DC recruitment was observed in decorin-treated eyes (central: 13.2 ± 5.7 VS 7.7 ± 4.0 cells/mm², p = 0.010; peripheral: 23.8 ± 6.2 VS 18.2 ± 4.2 cells/mm², p = 0.009) but not contralateral eyes. At 5 days after injury, there was no difference between groups. The density of macrophages was similar in all groups at 1 day, but was significantly lower in the decorin-treated eyes and contralateral eyes at 5 days post-injury (central: 125.1 ± 19.2 [Decorin-treated eyes] and 156.6 ± 25.0 [Contralateral eyes] VS 180.7 ± 28.3 cells/mm² [saline-treated eyes], p < 0.001 and p = 0.041; peripheral: 114.4 ± 16.1 [Decorin-treated eyes] and 133.3 ± 22.9 [Contralateral eyes] VS 159.8 ± 26.8 cells/mm² [saline-treated eyes], p = 0.001 and 0.026). Relative to saline treated eyes, there was a lower density of central corneal neutrophils in decorin-treated eyes at 1 day after injury (155.4 ± 68.2 VS 235.2 ± 82.2 cells/mm², p = 0.041).

Conclusions: Topical decorin treatment was associated with a higher DC density, and less neutrophils during the acute phase after corneal injury, and fewer macrophages after 5 days. The contralateral effect of decorin on macrophage, but not DCs, indicates there may be different mechanisms for decorin-induced immunomodulation during corneal wound healing.

ABSTRACT BODY:

Purpose: This study assesses short-term intraocular pressure (IOP) change in the fellow eye of glaucoma patients after Mitomycin C-augmented trabeculectomy (TE), filtering canaloplasty (FCP) or PreserFloTM microshunt implantation (PMI) in the treated eye.

Methods: Retrospective chart review of 235 patients (235 eyes) with different types of glaucoma was performed. Patients underwent initial TE (187), FCP (25) or PMI (23) in one eye, while the fellow eye was naïve to any previous glaucoma surgery. IOP was evaluated before and on the 1st, 2nd day and at one week after surgery. Study outcomes were IOP change and proportion of clinically significant IOP elevation (postoperative IOP >21 mmHg) in the fellow eye.

Results: The median preoperative and postoperative IOP in the fellow eye on the 1st day and at one week after TE were 17 (14-20) mmHg, 16 (14-21) mmHg and 14 (12-17) mmHg, respectively. The median IOP change in the operated eyes was -12 (-18 to -7) mmHg and in the fellow eyes -3 (-6 to 0) mmHg at one week after TE ($\rho=0.24$, $p=0.001$). The median preoperative and postoperative IOP on the 1st day and at one week after PMI in the fellow eye were 15 (12.5-18) mmHg, 14 (13-16) mmHg and 14 (12-16) mmHg, respectively. The median IOP change in treated eyes at one week after PMI was -9.5 (-14.8 to -6.3) mmHg and -2 (-4 to 1.8) mmHg in fellow eyes ($\rho=0.82$; $p<0.0001$). IOP in the fellow eye at one week after TE was statistically significantly lower than preoperatively ($p<0.0001$), while the IOP did not change significantly in fellow eyes in FCP or PMI groups. The higher the preoperative IOP was in the fellow eye, the larger was the IOP-lowering effect at one week after TE ($\rho=-0.79$, $p<0.0001$) and after PMI ($\rho=-0.6$, $p<0.01$). A clinically significant IOP elevation was noted in 14.2%, 9.5% and 5% of fellow eyes after TE, FCP or PMI, respectively.

Conclusions: This study shows an IOP lowering effect in the fellow eye of glaucoma patients after TE. The higher the preoperative IOP in the fellow eye of TE and PMI patients, the larger the postoperative IOP lowering effect. The one of the possible mechanisms for IOP change could be central nervous system-mediated reflex.

ABSTRACT BODY:

Purpose: Treatment of acute adenoviral conjunctivitis remains an unmet medical need, with no approved therapies available worldwide. OKG-0301 is a topical ophthalmic formulation of ranpirnase, an RNase A family member, with broad-spectrum antiviral properties.

Methods: The RUBY trial is a 219 patient, prospective, multi-center, double-blind, vehicle controlled, Phase 2 trial evaluating the safety, tolerability, and efficacy of OKG-0301 0.03% and OKG-0301 0.012% versus vehicle. Patients within 72 hours of the onset of signs and symptoms of adenoviral conjunctivitis, along with a positive QuickVue (Quidel) adenoviral conjunctivitis test were randomized and dosed in both eyes QID for five days. Four visits at days 1, 4, 7, & 14, each included a clinical assessment and an ocular swab for viral titer determination. The primary outcome was safety and tolerability of OKG-0301 and secondary outcomes included viral titer (Least Square Means [LSMean] comparison) and clinical assessments, including redness and discharge. An interim analysis was performed to evaluate the initial safety and efficacy of OKG-0301.

Results: Fifty-eight subjects were randomized and included in the Intent To Treat (ITT) population. The modified ITT (mITT), defined prospectively as subjects with > 100 viral copies/mL via PCR at visit 1 and who received at least a single dose of investigational product, included 41 patients. In the ITT population, there were no Treatment Emergent Serious Adverse Events and one patient with a Treatment Emergent Adverse Event suspected due to study medication in the vehicle control group. In the mITT evaluation, OKG-0301 had an antiviral effect via reduction of viral titers relative to placebo (day 7 placebo vs OKG-0301 0.012% vs OKG-0301 0.03% (LOG10 transformed, LSEan +/- SE): 1.06 +/- 0.22 vs 0.34 +/- 0.27 vs 0.62 +/-0.27, respectively, p<0.05; Fig 1). There was neither a better nor worse (NS = non-significant) difference in the clinical resolution of redness and discharge in the active vs placebo groups at day 7.

Conclusions: OKG-0301 is a safe and effective antiviral for the treatment of acute adenoviral conjunctivitis. Its main biological activity appears to be limited to acceleration of viral eradication, with no observed effect on redness and discharge. Further formulation and additional clinical evaluation is warranted to develop OKG-0301 as the first approved treatment of acute adenoviral conjunctivitis.

ABSTRACT BODY:

Purpose: To evaluate real-world health care management of intravitreal ranibizumab 0.5 mg in German treatment-naïve patients within 24 months in the indications documented.

Methods: PACIFIC is a 24-months observational, non-interventional study of 5.014 patients at 186 sites, conducted to evaluate ranibizumab treatment patterns in real-life conditions according to local routine clinical practice in Germany, Switzerland and the Netherlands, respectively.

Results: Upon enrolment, 1572 (45.1%) of 3488 documented German patients were treatment naïve with indication split of neovascular AMD (nAMD (60.8%)), diabetic macular edema (DME (18.5%)), branch retinal vein occlusion (BRVO (10.7%)), central retinal vein occlusion (CRVO (7.7%)) and myopic choroidal neovascularization (mCNV (2.0%)). The mean patient age [years (standard deviation)] was 78.2 (8.5) in nAMD, DME 66.5 (11.8), BRVO 69.3 (11.8), CRVO 71.4 (11.8) and mCNV 58.2 (15.6). The gender distribution female 60.4% (nAMD), 43.3% (DME), 48.2% (BRVO), 47.9% (CRVO) and 58.1% (mCNV) . Visual acuity at baseline [letters (SD)] was for nAMD 52.6 (22.3), DME 62.8 (15.8), BRVO 58.2 (19.1), CRVO 46.9 (26.0) and mCNV 52.7 (23.3). A combination of optic coherence tomography (OCT) and fluorescein angiography (FA) assessment at baseline was performed for nAMD in 56.0%, DME 54.5%, BRVO 59.9%, CRVO 56.8% and mCNV 60.0% of the patients, whereas neither OCT nor FA assessment

at BL was performed for nAMD in 5.4%, DME 6.9%, BRVO 0.6%, CRVO 7.6% and mCNV 10.0% of patients. The average time [days (SD)] from baseline visual acuity to the first injection was for nAMD 8.5 (12.7), in DME 9.9 (14.3), with BRVO 6.2 (8.4), CRVO 7.8 (11.9) and mCNV 10.2 (12.8). The number of injections given within 24 months was in nAMD 10.0 (5.2), DME 9.8 (6.4), BRVO 10.3 (4.1), CRVO 9.6 (5.0) and mCNV 3.0 (2.4). The most common treatment regimen reported at 24 months was “monitor and extend” (nAMD 69.1%, DME 72.5%, BRVO 70.2%, CRVO 79.3% and mCNV 71.0%).

Conclusions: The PACIFIC study provides real-life data on therapy with anti-VEGF ranibizumab and on routine health care structural use. The value of observational insights from routine clinical practice may lead to a better understanding of status quo and challenges in patient health care under real life settings.

ABSTRACT BODY:

Purpose: Previous reports have examined the associations between fruit and vegetable intake, dietary fat consumption, and open-angle glaucoma (OAG). Antioxidants were thought to be neuroprotective while a higher ratio of omega-3 to omega-6 fatty acids diet was associated with an increased risk for OAG. We conducted a secondary analysis of a randomized intervention trial to test if dietary modification (DM) altered the risk of OAG.

Methods: Our analyses were based on an intent-to-treat design, with a follow up to the end of continuous coverage in Medicare part B, death, or the last date that Medicare claims data was available (12/31/2018), whichever occurred first. We linked Medicare claims data to 45,203 women in the Women's Health Initiative Dietary Modification Trial, of which 23,776 participants were enrolled in fee-for-service Medicare Part B and had physician claims. Women were randomized to follow either dietary modification (DM) (a diet low in fat, with increased vegetable, fruit, and grain intake) or the usual diet with no modifications. Primary OAG was defined as the first claim with the International Classification of Diseases (ICD)-9 or ICD-10 codes. We used Cox proportional hazards models to calculate hazard ratios (HR) and 95% confidence interval for risk of OAG in intervention and control groups. Subgroup analyses were performed and P-interaction values were evaluated for selected characteristics.

Results: After exclusion of women with Medicare-derived glaucoma prior to randomization, the final analysis included 23,217 women (mean age = 68.5 ± 4.8 years). Baseline characteristics including diabetes, hypertension, BMI ≥ 30 were balanced between the intervention and control groups. The final models were adjusted for age and race/ethnicity. As reported in Table 1, OAG incidence was 12.9% (mean follow-up = 11.6 ± 7.4 years; mean DM duration = 5.2 ± 3.2 years). After adjusting for BMI ≥ 30 , hypertension, diabetes, and statin use, we found no overall benefit of DM in reducing incident OAG (HR = 1.04, 95% CI = 0.96-1.12). Race and participant age did not modify the relation between DM intervention and OAG risk (P interaction 0.25 and 0.44, respectively).

Conclusions: Analysis suggests that DM does not reduce the risk of incident OAG among women regardless of age or race.

ABSTRACT BODY:

Purpose: PERSEUS-IT (NCT02289924) was a prospective, observational, 2-year (Y) study to evaluate the effectiveness and safety of IVT-AFL in patients with nAMD in routine clinical practice in Italy.

Methods: Treatment-naïve patients with nAMD for whom the decision was made to treat with IVT-AFL per routine clinical practice and local prescribing information were enrolled. The primary endpoint was mean change in best-corrected visual acuity (BCVA; decimals) from baseline to Y1 and Y2. Outcomes were evaluated (at baseline, Week 4, and every 2 weeks thereafter) for the whole study population and for 2 treatment cohorts: regular (patients receiving 3 initial monthly doses, and a total of ≥ 7 injections in Y1 and ≥ 4 injections in Y2) and irregular (any other pattern).

Results: Of 813 patients enrolled, 709 were included in the full analysis set (FAS); BCVA data were available for 342 patients at Y1 (FAS Y1, 140 regular and 202 irregular) and 233 patients at Y2 (FAS Y2, 37 regular and 196 irregular). Main results are summarized in Table 1. In the FAS, mean BCVA change from baseline was +0.09 decimals at Y1 and +0.02 at Y2.

The percentage of patients who achieved a BCVA ≥ 0.5 decimals (70 Early Treatment Diabetic Retinopathy Study [ETDRS] letters) at Y1 and Y2 was 50.0% and 44.6%, respectively. A repeated measures model considering cohorts, time points and interaction cohort/time point, showed that the difference in mean estimated BCVA between cohorts was statistically significant both in FAS Y1 and FAS Y2, while the interaction cohort/time point was significant only in FAS Y1. Central retinal thickness (CRT) showed a consistent decrease across all analysis sets. Ocular adverse events were reported in 4.1% (n=33/810 [safety set]) of patients; the most common was cataract (0.6%; n=5).

Conclusions: PERSEUS-IT showed that treatment with IVT-AFL resulted in substantial functional and anatomic improvements in patients with nAMD treated in a routine clinical setting. The repeated measures model found the trend of estimated mean BCVA over time was significantly different in the two cohorts (regular and irregular), with BCVA higher at each time point in the regular cohort. The safety profile of IVT-AFL was consistent with prior studies.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a multifactorial retinal disease. Amyloid- β (A β) deposition has been reported in patients with AMD among the constituents of drusen, which cause inflammation, oxidative stress and retinal pigmented epithelium (RPE) damage. Hereby, we assessed the effect of vitamin D3 and meso-zeaxanthin combination in several in-vitro models of AMD, challenging retinal cells with three different types of damage.

Methods: Human ARPE-19 cells were exposed to three different stimuli (A β , LPS, H₂O₂) in separate set of experiments. For all experiments, the cells were pre-treated for 24 hours with vitamin D3 (50 nM-1 μ M), meso-zeaxanthin (0.1 μ M and 0.5 μ M) or their combination; then, ARPE-19 were exposed to the different insults in separate set of experiments. The damage of A β , LPS, H₂O₂, and the protective effects of molecules were evaluated with MTT, LDH, ROS assay and the modulation of inflammatory mediators (IL-1 β , IL-6, TNF α , MMP-9 and VEGF) was evaluated with RT-PCR.

Results: The combination of vitamin D3 and meso-zeaxanthin significantly protected ARPE-19 against the damage elicited by A β , LPS, and H₂O₂. These three stimuli significantly ($p < 0.05$) reduced cell proliferation, increased LDH and ROS release after different time of treatment. These effects were significantly ($p < 0.05$) counteracted by the combination of vitamin D3 and meso-zeaxanthin treatment. Further, the expression of inflammatory mediators such as IL-1 β , IL-6 and TNF α was significantly ($p < 0.05$) reduced by vitamin D3 and meso-zeaxanthin combination treatment. Finally, a potentiation effect has been demonstrated by vitamin D3/meso-zeaxanthin; the combination was, in fact, able to reduce significantly ($p < 0.05$) the expression of VEGF-A and MMP-9 mRNA, in ARPE-19 challenged with LPS and H₂O₂ in comparison with the single molecules

Conclusions: These findings demonstrated, at least in these in-vitro paradigms, that combination of vitamin D3/meso-zeaxanthin exerts an enhanced protective effect in ARPE-19 cells damaged by amyloid- β , inflammation (LPS) and oxidative stress (H₂O₂) that represent the initiating events leading to AMD.

ABSTRACT BODY:

Purpose: Geographic atrophy (GA) is an untreatable form of age-related macular degeneration (AMD) affecting five million individuals worldwide. Dysfunction of innate immunity plays a pivotal role in AMD pathogenesis. However, the cGAS-STING signaling, a key cytosolic DNA sensor system in innate immunity, has not been explored in the retina. In this study, we aimed to investigate the regulation of cGAS-STING signaling in retina of AMD patients and the GA-like mouse model.

Methods: To induce the GA-like mouse model, C57BL/6J mice (5-6 weeks) were intraperitoneally injected with 35 mg/kg of sodium iodate (n=5). The control mice were injected with PBS (n=5). In silico analysis of RNA-seq and ATAC-seq data were performed to evaluate the cGAS and STING genes expression patterns in the retina of AMD patients. Hematoxylin and eosin staining, immunohistochemistry and immunofluorescence were performed to evaluate the cGAS-STING signaling activation and cytosolic DNA accumulation in the mouse retina. Real-time PCR and Western blot assay were used to analyze the expression of cGAS-STING signaling and proinflammatory cytokine in control and SI-exposed mice.

Results: Our in silico analysis shows specifically upregulated STING mRNA level and increased chromatin accessibility around cGAS and STING promoters in macular retinas from dry AMD patients. Further, we found activation of cGAS-STING signaling in retinas after SI injury, which was caused by the releasing of cytosolic double-stranded DNA (dsDNA) in photoreceptors.

Conclusions:

In summary, our study shows that accumulation of cytosolic dsDNA and activation of cGAS-STING signaling in photoreceptors are pivotal innate immunity response after RPE injury. The results suggest that the cGAS-STING signaling may be a potential therapeutic target for photoreceptor degeneration in GA.

ABSTRACT BODY:

Purpose: Fixation is the state in which the eyes foveate a target. Previous studies on fixation stability were undertaken at distances of 40cm or greater, and thus have not systematically examined the effect of viewing distance (hence vergence). In some cases of visual impairment, evidence suggests that fixation is more stable while viewing at near. However, the effect of vergence on fixation in typical participants is not known. This study, therefore, explores the stability of fixation with viewing distance, in those without visual impairment.

Methods: Eye position was measured at 1000Hz over 15secs for 10 participants (4 females; mean age, 26.9 years; range, 22–37 years), as they binocularly viewed a 0.5° dot, at 300, 100, 50 and 25cm. Using the last 5secs of data, a bivariate probability density function was used to determine the accuracy and precision with which participants fixated. The isocontour surrounding the gaze positions with the highest 68% probability density were selected for further analysis. Accuracy was computed as the vector from the target position to the centroid of the 68% isocontour, while precision was quantified using the isocontour area and shape, as well as the orientation of its major axis. A repeated measures ANOVA was used to compare the effect of distance. Where Mauchly's test indicated assumption of sphericity was violated, the Greenhouse-Geisser correction was used.

Results: There was no significant main effect of viewing distance on mean accuracy ($F_{1.690, 15.208} = 0.935$, $p = 0.399$, $\eta^2 = 0.047$), contour area ($F_{3, 27} = 0.293$, $p = 0.830$, $\eta^2 = 0.022$) or shape ($F_{3, 27} = 0.641$, $p = 0.595$, $\eta^2 = 0.048$). Between participants, the orientation of the isocontour major axis was similar at all viewing distances (Rayleigh test; $p < 0.05$), except for the left eye at 100cm (mean = 34.66°; 95CI ±55.5°; $p = 0.06$) and at 300cm (mean = -41.23°; 95CI ±72.35°; $p = 0.12$), respectively. Within participants, the orientation of the isocontour major axis was similar at all viewing distances in 7 out of the 10 participants (Rayleigh test; $p < 0.05$).

Conclusions: We found no evidence that distance, and therefore convergence, influences the stability of fixation. We conclude that fixation may not have to be more precise for successful near work. The results suggest that, in a typical classroom for example, where viewing distance varies, the ability of typical students to fixate adequately is unaffected.

TITLE: Convolved vs. Optically blurred images-What is the key reason for the observed differences?

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. AISSATI, M. Vinas, C. Benedi-Garcia, S. Marcos, Instituto de Optica Daza de Valdes, Madrid, Comunidad de Madrid, SPAIN|

Commercial Relationships Disclosure (Abstract): SARA AISSATI: Commercial Relationship: Code N (No Commercial Relationship) | Maria Vinas: Commercial Relationship: Code N (No Commercial Relationship) | Clara Benedi-Garcia: Commercial Relationship: Code N (No Commercial Relationship) | Susana Marcos: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Image convolutions are often used to simulate the effects of ocular aberrations on image quality. We studied potential discrepancies in the image degradation/visual performance using convolved images (viewed through corrected optics) or the real aberrations, in both monochromatic & white light (WL)

Methods: On bench & visual acuity measurements in patients were obtained using a custom polychromatic Adaptive Optics (AO). The system allows measurement (Hartman-Shack, HASO) & correction/induction (deformable mirror, DM, MIRA, Imagine Eyes) of high order aberrations (HOAs). Stimuli were displayed in a Digital Micro-Mirror Device (DMD), illuminated with 450, 555, 670 nm, & WL. Image convolutions of a stimulus (20/100 black E-letter, 25 cd/m²) were obtained with standard Fourier Optics (Matlab) using subject's HOAs (diffraction limit (DL) control). An artificial eye was used to image the original stimulus through real HOAs (mapped on DM) or the convolved (conv) stimulus (AO). In subjects (4 young cyclopleged) Visual Acuity (VA, tumbling high contrast E-letter, 8 AFC + QUEST) was measured under natural HOAs & with conv images under AO, for the 3λ & WL (6 mm pupil)

Results: Subject's Visual Strehl ranged from 0.17-0.33. On bench, the stimulus contrast through diffracted/aberrated optics & the conv image with a DL/subject PSF differed on avg by 0.40/0.50 (450), 0.34/0.58 (555), 0.30/0.58 (670) & 0.43/0.53 (WL), with conv images overestimating image degradation. Computer simulations revealed that the second-pass (DL/residual aberration) was only responsible of 11/12% loss in contrast. In subjects, logMAR VA was on avg, 0.10 ± 0.01, -0.08 ± 0.03, 0.03 ± 0.02 & -0.03 ± 0.04 with natural aberrations & 0.27 ± 0.03, 0.10 ± 0.05, 0.18 ± 0.02 & 0.14 ± 0.04 (450, 555, 670 & WL) using conv stimulus. Measured VA is correlated with native optical quality in 555 nm with natural optics ($r^2 = 0.98$, $p = 0.01$) but not in WL ($r^2 = 0.45$, $p = 0.30$). Differences (Natural-Conv) ranged btw -0.07 to -0.29 (avg across λ for each subject). There was not a consistent larger difference in monochromatic vs WL

Conclusions: The use of convolved stimuli underestimates the measured VA (comparison with high contrast stimuli & natural optics). Discrepancies must occur in part from optical grounds, as are also found on bench. Although the magnitude of the native optical aberrations & chromatic effects appear to play some role, they do not fully responsible for the effect, likely associated to approximations in the convolution representation of the images

ABSTRACT BODY:

Purpose: To determine if wall-to-lumen ratio (WLR) is altered in eyes with age-related macular degeneration (AMD) in individuals with and without systematic hypertension.

Methods: OCT 6 x 6 mm en face retinal images centred on fovea (Zeiss HD-OCT 5000 AngioPlex) were examined for a total of 30 eyes with intermediate age-related macular degeneration, 12 eyes with AMD and hypertension and 43 control eyes. All eyes were from participants aged 50 years or over and did not have diabetes mellitus, hypercholesterolemia or any other systemic vascular disease. Three independent graders were randomly allocated one-third of eyes each to identify the largest arteriole and venule closest to the optic nerve head and within 75 pixels of the image border. Graders then measured the inner and outer diameter in duplicate for all identified vessels in all eyes based on a perpendicular line drawn to a tangent of the vessel. WLR was calculated as the difference between outer and inner vessel diameter divided by inner diameter.

Results: An arteriole and venule that fit the above measurement criteria was identified in 85% and 75% of all study eyes respectively. Sub-group analysis indicated this created no significant difference in age (arteriole: $p = 0.15-0.92$; venule: $p = 0.08-0.76$) or signal strength index (arteriole: $p = 0.16-0.62$; venule: $p = 0.06-0.32$) between all study groups. There was no significant difference in arteriole WLR between control and AMD eyes (1.37 ± 0.41 vs 1.28 ± 0.46 , $p = 0.185$) or control and AMD eyes with hypertension (1.47 ± 0.46 vs 1.21 ± 0.51 , $p = 0.103$). For venules, however there was a significant decrease in WLR between control and AMD eyes (1.47 ± 0.46 vs 1.23 ± 0.36 , $p < 0.001$) and control and AMD eyes with hypertension (1.47 ± 0.46 vs 1.21 ± 0.46 , $p < 0.001$). There was no difference in WLR between AMD eyes with or without hypertension for either vessel type ($p = 0.25 - 0.474$). There was strong agreement within and between graders for all arteriole and venule WLR measurements except for graders 1 and 2 in control eyes ($p < 0.05$).

Conclusions: WLR of venules is significantly decreased in venules in eyes with intermediate AMD but is not necessarily exacerbated in conjunction with hypertension. WLR may be a useful measurement in the assessment of retinal vascular health in intermediate AMD.

ABSTRACT BODY:

Purpose: Patients who receive anti-vascular endothelial growth factor (VEGF) treatment for retinal exudative diseases, often experience mental health problems. To support patients in dealing with these problems, a guided Internet-based self-help course, following the principles of cognitive behavioral therapy (called E-PsEYE), was developed. Our aim was to evaluate whether E-PsEYE was cost-effective in comparison with usual care from a societal perspective.

Methods: A single blinded multicenter randomized controlled trial was performed in two parallel groups with a follow-up of 12 months. In total, 174 patients (58% male, mean age 70 year) who experienced mild to moderate symptoms of depression and/or anxiety and received anti-VEGF treatment participated in our study. Main outcome measures were depression (measured with the Patient Health Questionnaire-9), anxiety (measured with the Hospital Anxiety and Depression Scale – Anxiety), and quality-adjusted life years (QALYs, measured with the EuroQoL-5 Dimensions and the Health Utilities Index-3). Costs were based on direct healthcare costs and indirect non-healthcare costs.

Results: Based on intention to treat, significant intervention effects were found on depression (group difference -0.22, 95% confidence interval (CI) -0.43 to -0.01), but not on anxiety (-0.002, 95%CI -0.18 to 0.17). Non-significant societal cost savings were found (mean difference -1130 Euro; 95%CI -5101 to 2841, which is equivalent to -1387 USD; 95%CI -6263 to 3488), mainly due to less productivity losses in the intervention group. Drop-out (20% in total) was significantly higher in the intervention group. The cost-effectiveness acceptability curve showed that the probability of cost-effectiveness was 72% or more at a willingness-to-pay of €0 per QALY and did not increase at a higher ceiling ratio.

Conclusions: Significant intervention effects on depression and small cost-savings were found, however, the difference with usual care was minimal. Therefore, we cannot state that E-PsEYE is dominant to usual care. Future studies should investigate how the cost-effectiveness of E-PsEYE can be improved.

ABSTRACT BODY:

Purpose: Lysophosphatidic acid (LPA) is a bioactive lipid mediator that is essential for a variety of cellular processes including proliferation, differentiation, transcription and survival. LPA signalling is dysregulated in many conditions such as cancer, atherosclerosis, and pulmonary and renal fibrosis. LPA is produced extracellularly by Autotaxin (ATX) and is degraded by three membrane bound lipid phosphate phosphatases (LPP 1-3). It acts via six G-protein coupled receptors on the cell surface (LPA₁₋₆) to activate intracellular pathways. LPA enhances fibroblast proliferation, migration and contraction, and induces expression of pro-fibrotic mediators such as connective tissue growth factor. In glaucoma, there is disturbed extracellular matrix remodelling and fibrosis in the lamina cribrosa of the optic nerve head, and it is within this region that retinal ganglion cell axons degenerate. We wished to assess whether LPA signalling plays a role in mediating fibrosis in the lamina cribrosa in glaucoma.

Methods: We cultured primary human lamina cribrosa cells from age-matched normal and glaucoma patient donors. Quantitative real time PCR was used to assess expression of gene targets within the LPA axis, as well as those involved in fibrosis. These included the LPA₁₋₃ receptors, ATX, the LPPs, Collagen 1a1 (COL1A1), Fibronectin, and Alpha Smooth Muscle Actin (α-SMA).

Results: Genes overexpressed in glaucoma lamina cribrosa cells included ATX, LPP3, LPA₁ and LPA₃ receptors. Expression of the fibrosis genes COL1A1, α-SMA and Fibronectin was also upregulated in glaucoma compared to normal lamina cribrosa cells.

Conclusions: Our results show that the LPA signalling axis is altered in glaucoma. This suggests a role for the LPA axis in the fibrotic changes observed in the lamina cribrosa in glaucoma and may indicate a potential pharmacological target.

ABSTRACT BODY:

Purpose: To contribute to the WHO initiative, VISION 2020: The Right to Sight, an assessment of the causes of global vision impairment in 2020 and temporal change is needed. We aimed to extensively update estimates of global vision loss burden due to age-related macular degeneration (AMD), presenting estimates for 2020, temporal change since this initiative commenced, and distribution by sex and region.

Methods: We did a systematic review and meta-analysis of population-based surveys of eye disease from January 1980 to October 2018. The data from these surveys are collated by the Vision Loss Expert Group in the Global Vision Database. We fitted hierarchical models to estimate prevalence (with 95% uncertainty intervals [UIs]) of moderate and severe vision impairment (MSVI; presenting visual acuity from <6/18 to 3/60) and blindness (<3/60 or less than 10° visual field around central fixation) caused by AMD, stratified by age, region, and year. The analysis focused on adults aged 50 years and older.

Results: In 2020, worldwide, an estimated 1.84 million (1.34 to 2.42) people aged 50+ years were blind due to AMD, and a further 6.22 million (5.03-7.57) moderately or severely vision impaired (MSVI). There had been a 42.1% (39.4-43.3) increase in cases of blindness and a 93.7% (92.4-94.2) increase in cases of MSVI since 2000. Over the same period, the age-standardized prevalence of AMD blindness decreased by 22.6% (21.2 to 24.7), and MSVI increased by 8.6% (7.7-9.4). In terms of the age-standardized prevalence of AMD blindness, the ratio of females to males affected was 1.45:1.00 in 2020 and 1.44:1.00 in 2000. Between 2000 and 2020, the age-standardized prevalence of AMD blindness in males and females decreased to a similar extent (22.2% versus 21.7%). Among GBD super-regions, North Africa and Middle East had the highest crude AMD blindness rates in 2020 in adults aged 50+ (0.18%; 0.13-0.25), followed by the High-Income super-region (0.14%, 0.11-0.18). The most profound reduction (>-30%) in age-standardized AMD blindness rates between 2000 and 2020 was in Southeast Asia, East Asia, and Oceania (-34.1%, -32.8 to -36.1).

Conclusions: Despite a decrease in the age-adjusted prevalence of AMD-related blindness, the increase in the age-adjusted prevalence of AMD-related MSVI and the increase and ageing of the population led to a marked increase in

the number of individuals affected by AMD-related blindness and MSVI.

ABSTRACT BODY:

Purpose: To assess the diagnostic accuracy of fundoscopy and visual evoked potentials (VEPs) in detecting intracranial hypertension (IH) in patients with syndromic and non-syndromic craniosynostosis undergoing spring-assisted posterior vault expansion (sPVE) surgery; to evaluate visual outcomes.

Methods: Children with craniosynostosis undergoing sPVE and 48-hour intracranial pressure (ICP) monitoring at a quaternary centre were included in this retrospective diagnostic accuracy study. Longitudinal data for ICP, fundoscopy, VEP and best-corrected visual acuity (BCVA) were collected between February 2002 and March 2019. Primary outcome measures were papilloedema on fundoscopy, VEP assessments and IH, defined as mean ICP >20 mmHg. Diagnostic indices were calculated for fundoscopy and VEP against ICH. Secondary outcome measures included final visual outcomes.

Results: Fundoscopic examinations within 6 months of ICP assessments were available for 35 children and isolated VEPs for 29 children, of which 22 children had at least three serial VEPs. Specificity for IH was 100% for all measures. Sensitivity was poor for fundoscopy (32.1%; 95% CI: 15.9-52.4), moderate for isolated VEP (65.2%; 95% CI 44.9-81.2) and good for serial VEP stability (82.4%; 95% CI: 56.6-96.2). Median final BCVA was 0.24 logMAR (n=36; IQR: 0.51; range: -0.06 to 2.7). UK driving standard BCVA was achieved by 26 patients (72.2%), defined as >0.30 logMAR in the better eye.

Conclusions: Papilloedema present on fundoscopy reliably indicated IH, but its absence did not exclude IH. VEP monitoring demonstrated higher sensitivity for detecting IH, with serial testing increasing sensitivity even further. To the best of our knowledge, this represents the largest study of its kind.

ABSTRACT BODY:

Purpose: Correcting ocular aberrations of the eye improves certain visual tasks such as visual acuity and familiar face recognition. In addition, the eye appears to be adapted to its native optics. We evaluated how manipulated aberrations influence face gender identification (GI) performance

Methods: We used a custom-built Adaptive Optics (AO) system, with a Hartmann-Shack wavefront sensor (32x32 microlenses; HASO, ImagineEyes, 827mm), an electromagnetic deformable mirror (DM, 52 actuators; MIRA0), a motorized Badal system and a psychophysical channel (CRT monitor). Nine subjects participated in the study (sph=-1.6±2.15D, cyl=-0.6±0.6D, age=30.4±9.6yrs). The subjects' ocular aberrations were measured to estimate their Visual Strehl(VS, max 1). Five conditions were evaluated for GI and Visual Acuity (VA): natural aberrations (Nat), AO-correction (AO), 90deg rotated aberrations (Rot), and 2 external patterns, one better (NatB) and worse (NatW). For the GI experiment, we convolved images for each manipulated aberration condition (set of 200male/200female, randomly presented and alternating conditions in blocks of 100 images). Images were presented through the DM correcting subjects' aberrations. VA was measured with conditions mapped in the DM, using tumbling E letters (8 orientations) and QUEST. Learning effects were analyzed with a logistic regression in a binary model

Results: There was no learning effect through the session. GI performance (%GI) was highly correlated with VS ($r=0.90$; $p<0.005$). %GI for the AO vs Nat conditions were highly correlated ($r=0.68$, $p=0.06$) with higher differences %GI AO-Nat in subjects with poorer optical quality ($\geq 8\%$). %GI was higher for Nat than Rot in the less aberrated subjects with a significant %GINat-Rot vs RMS correlation ($r=0.4$; $p=0.33$). Only 29% of the subjects with poorer optics (avg VS=0.2±0.06) obtained a higher %GI with Nat than with either NatB (0%) or NatW (67%). However, 86% of the subjects with better optics (avg VS=0.4±0.2) performed better with Nat than with either NatB (100%) or NatW (75%). %GI and VA correlated across conditions at subject level ($r=0.42$, $p<0.02$)

Conclusions: Both optical aberrations and neural adaptation to native blur (and its orientation) appear to play a significant role in GI, with a potentially larger role of adaptation to native aberrations in subjects with better optics. VA seems to be a good predictor of GI performance

ABSTRACT BODY:

Purpose: Convergence insufficiency is the most common binocular vision disorder but there is not much data available on its frequency. We performed a prospective cross-sectional study to determine the prevalence of convergence insufficiency at school age.

Methods: Three schools in the Madrid region of Spain participated in the study. We examined a total of 450 children from October 2019 to February 2020: 151 1st grade (mean age 6.45 ± 0.38), 190 6th grade (mean age 11.55 ± 0.44) and 109 8th grade (mean age 13.61 ± 0.48). 79.9% were males and 20.1% females. The inclusion criteria was of children enrolled in 1st, 6th, and 8th school grades, and the exclusion criteria was having any kind of ocular or systemic pathology that could interfere with ocular function, and mentally handicapped children. 3 children in total were excluded. Clinical evaluation: visual acuity, retinoscopy and binocular vision tests were performed, including near and far cover test (CT), near point of convergence (NPC) and Base In (BI) and Base Out (BO) vergences, measured with prism bar. We defined Convergence Insufficiency (CI) as having: BO break or blur point $\leq 15\Delta$ or failing Sheard's criterion; break point of NPC ≥ 6 cm; and difference between near and far foria $\geq 4\Delta$.

Results: 5 children had strabismus (1.12 %). 4 esotropia and 1 exotropia. The prevalence of CI was 2.0% in 1st grade; 4.80% in 6th grade and 4.60% in 8th grade. The difference of frequency between groups was not significant (χ^2 p= 0.37). There was a 23.10% of 1st grade children with a receded NPC; 40.64 % of 6th grade and 34.26 % of 8th grade. BO vergences ≤ 15 DP was found in 17.68% 1st grade children, in 26.7% of 6th grade and in 24.1% of 8th grade. Difference between near and far foria $\geq 4 \Delta$ was found in 11.60% children of 1st grade, 16.6% of 6th grade and 17.6% 8th grade. Only NPC was found to be significantly different between groups (χ^2 p= 0.003). 50.2% of all children didn't have any of the signs. 32.1% had just one sign, 13.8% had two signs and 3.8% had the three signs.

Conclusions: The convergence insufficiency prevalence found in school children in Spain seems to be of similar extent as in other studies, and did not vary between school grades.

ABSTRACT BODY:

Purpose: We have shown previously that administration of low-dose oral dronabinol, a synthetic tetrahydrocannabinol derivate, increases optic nerve head blood flow in healthy subjects. The aim of the present study was to investigate whether dronabinol also has an effect on retinal blood flow and oxygen extraction.

Methods: A randomized, placebo-controlled, double-masked, two-way crossover study was performed in 24 healthy subjects. Two study days were scheduled for each participant, on which they either received capsules containing 5mg dronabinol or placebo capsules. Total retinal blood flow (TRBF) was measured using a custom-built Doppler Optical Coherence Tomography system. Oxygen saturation of major retinal vessels was measured with a commercially available Dynamic Vessel Analyzer. Based on these parameters, retinal oxygen extraction was calculated. Measurements were performed before and after drug administration on both study days.

Results: Placebo did not alter TRBF, retinal arterial or venous oxygen content and retinal oxygen extraction ($p > 0.1$ each). In contrast, dronabinol induced a significant increase in TRBF from 38.9 ± 6.1 to $40.7 \pm 6.7 \mu\text{l}/\text{min}$ ($p < 0.001$), which was accompanied by a significant increase in retinal venous oxygen content (from 0.129 ± 0.008 to $0.132 \pm 0.009 \text{ ml O}_2/\text{ml}$, $p = 0.02$). As no change in retinal arterial oxygen content occurred ($p = 0.12$), retinal oxygen extraction remained stable (2.2 ± 0.4 vs. $2.2 \pm 0.4 \mu\text{l O}_2/\text{min}$, $p = 0.29$).

Conclusions: These results indicate that orally administered dronabinol increases TRBF in healthy subjects without altering retinal oxygen extraction. The drug may therefore be a candidate for improving perfusion in patients with ocular vascular disease. To confirm this hypothesis, further studies in patients are needed.

ABSTRACT BODY:

Purpose: Clinical investigations of intraocular lenses (IOL) are guided by ISO and ANSI standards, which outline parameters for procedures such as contrast sensitivity (CS). The effect of glare on CS is often studied, however, glare strength is not standardized, resulting in varying glare intensities across manufacturers. ISO/ANSI recommend a level of glare that reduces mesopic CS by 0.1 log units at 6 cpd, determined through a pilot study of young, healthy adults, while excluding subjects whose CS increased under glare conditions. Contrary to this, the American Academy of Ophthalmology (AAO) for EDOF IOLs does not specify 6 cpd or the exclusion of subjects. We conducted a pilot study to access how these two criteria might influence the calibration of the glare strength of two commercial systems.

Methods: Adults under 40 years with VA of at least 20/20 and no known ocular abnormalities were enrolled. Mesopic CS at 6 cpd was measured with and without glare in 39 subjects using the Clinical Trial Suite (CTS, M&S Technologies) and in 20 subjects using the CSV-1000 (Vector Vision) at 2.5 meters. Glare strength was set as standard for both devices (150 lux and 12 lux before 1.5 ND filter, for CTS and CSV, resp.). Two attenuated glare levels (69 and 110 lux) were also evaluated with the CTS. Mean delta between CS with and without glare was calculated.

Results: Following ANSI and ISO criteria, mean decrease in CS with glare was 0.16log units for CTS (95% CI 0.05, n=29) and 0.09log units (95% CI 0.08, n=12) for CSV, indicating that standard glare strength was overestimated for the CTS system. Under attenuated glare, decrease in CS on CTS was 0.14 (95% CI 0.06, n=20) and 0.15 (95% CI 0.05, n=24) log units for 69 and 110 lux, respectively, both above 0.1 log unit criteria. Without excluding any subjects (AAO recommendation), mean decrease in CS with standard glare was 0.08 log units (95% CI 0.06) for CTS, while CSV resulted in a mean increase in CS of 0.03 (95% CI 0.09).

Conclusions: Following ANSI and ISO criteria, all glare levels tested on CTS exceeded the requirement of 0.1 log units CS reduction at 6 cpd. Following AAO criteria, the CSV system resulted in a mean increase of CS with the standard settings. These results suggest that different criteria may have been used to calibrate glare strength of both systems, which resulted in ~12 fold difference in strength. Subsequently, clinical data obtained may not be comparable across these systems.

ABSTRACT BODY:

Purpose: Macular atrophy (MA) is found in neovascular AMD, with degeneration of photoreceptors, pigment epithelium and choriocapillaries resulting in significant loss of central vision. The purpose of our study is to evaluate the progression of MA based on optical coherence tomography (OCT) in patients with age-related macular degeneration (AMD) after receiving anti-vascular endothelial growth factor (anti-VEGF) therapy for at least a 6-year period in real life settings.

Methods: This retrospective study included 53 naïve patients (53 eyes) with neovascular AMD from two centers, who were treated with anti-VEGF intravitreal injections and presented without MA at baseline. MA was evaluated in an annual basis using near infrared (IR) and spectral-domain OCT images according to criteria proposed by the Classification of Atrophy Meetings (CAM) group; hyperreflectivity of the choroid, retinal pigment epithelium absence and outer retina atrophy. Incidence and progression of MA were evaluated. Associations with best-corrected visual acuity (BCVA) and total number of injections were also included.

Results: Treatment duration of our patients was 7.34 ± 1.54 years. The mean number of anti-VEGF injections was 24.4 ± 13.6 . BCVA at baseline was 0.38 ± 0.27 logMAR and 0.60 ± 0.35 logMAR at final visit ($p=0.731$). The cumulative incidence of new MA at years 1, 2, 3, 4, 5, and 6 was 2%, 20%, 34%, 42%, 52% and 54% respectively. In patients who developed MA, mean MA area increased from no MA at baseline to $5.66 \pm 67.18 \text{ mm}^2$ at final visit ($p<0.001$). The estimated annual enlargement of MA was 0.86 mm/year based on square root transformation ($1.11 \text{ mm}^2/\text{year}$, untransformed data). Moreover, MA progression doesn't appear to be significantly correlated with age ($R=0.055$, $p=0.784$), gender ($R=0.113$, $p=0.576$), BCVA ($R=0.168$, $p=0.404$) and total number of injections ($R=0.133$, $p=0.255$).

Conclusions: In this real life setting, half of neovascular AMD patients under anti-VEGF treatment without MA at therapy initiation developed MA over a period of at least 6 years. In this study, number of injections did not seem to have a relationship with MA progression.

ABSTRACT BODY:

Purpose: Evidence suggests visual outcomes in exudative age-related macular degeneration (exAMD) are better with treat and extend (TEX) than pro re nata (PRN) protocols. This has not been shown in real-world data and TEX is thought to demand more clinical resources than PRN. This is problematic as the Royal College of Ophthalmologists reports more than 200 vacant UK consultant ophthalmologist posts. We aim to establish if there is value in recommending TEX, to justify stretching resources further.

Methods: Our observational study was performed at a tertiary unit in England. The electronic medical record (EMR) identified patients receiving aflibercept intravitreal injections (IVIs) for exAMD from 2016 with three years of follow up. Visual acuity (VA) was recorded as the best corrected vision in early treatment of diabetic retinopathy (ETDRS) letters. A year of treatment was said to be PRN if 'PRN' was explicitly reported in any visit in that year. Descriptive and comparative statistics were performed with SPSS v.24. Unpaired t-tests were used to compare means between PRN and TEX groups.

Results: 175 eyes (89 left, 87% pseudophakic) from 175 patients (109 female, mean age 79.1 years) were identified with 80 eyes (44.9%) receiving PRN treatment in their second year of treatment and 68 eyes (38.2%) in their third year. PRN eyes had significantly fewer IVIs ($p<0.0001$) than those purely under the TEX regimen in their second (mean IVIs 3.9 (95%CI 3.6,4.2) versus 6.3 (5.9,6.6)) and third years of treatment (mean IVIs 4.5 (4.0,5.0) versus 6.0 (5.7,6.3)). The number of visits to clinic did not differ significantly between the PRN or TEX groups in the second (6.7 (6.3,7.0) and 6.1 (5.6,6.6) mean visits per year respectively ($p=0.077$)) year of treatment, but met an unadjusted threshold for significance in the third year of treatment (7.0 (6.5,7.4) and 6.2 (5.8,6.7) mean visits per year respectively ($p=0.018$)). Change in VA was equivocal between the two treatment groups in the second ($p=0.19$) and third year ($p=0.98$).

Conclusions: These data suggest that a PRN approach offers equivocal visual outcomes to TEX for exAMD patients, whilst imposing significantly fewer IVIs on patients. The burden on clinic appointments between the two regimens is comparable, but PRN's advantages could be realised if disease monitoring was moved to primary care.

ABSTRACT BODY:

Purpose: To evaluate the ocular safety and tolerability of a new formulation based on hypochlorous acid, well-known for its broad antimicrobial spectrum, in rabbit eye in comparison with two commercially available formulations based on sodium hypochlorite and povidone iodine, respectively.

Methods: New Zealand albino rabbits were used, the animals were handled in accordance to the ARVO statement for the use of animals in ophthalmology and vision research. The animals were divided in three groups and received topical instillation (30 µl) of each formulation BID for 7 days. One separate set of animals was used as control (vehicle-treated) group. The safety profile of the new ocular spray based on hypochlorous acid obtained with Microcyn[®] Technology (Ocudox[™] - marketed in Italy by Alfa Intes) was compared with two commercially available ophthalmic formulations based on sodium hypochlorite (ocular spray) and povidone iodine (eye drops), respectively. Clinical score was assessed by slit-lamp and IOP was measured by TonoPen. At the end of the treatment, tear samples were collected, and MMP-9 were measured by ELISA. Then the animals were sacrificed, and cornea and conjunctiva were collected to perform histological examination.

Results: The results showed a good safety profile of the new formulation based on hypochlorous acid. No changes were observed in terms of clinical score, IOP and tear MMP-9 values compared with control group. Further, the histological examination of cornea and conjunctiva was superimposable to the control group. On the contrary, the eyes treated with the formulations based on sodium hypochlorite and povidone iodine showed a significant ($p < 0.05$) increase of MMP-9 levels in the tears (280 ± 10 pg/ml and 105 ± 10 pg/ml, respectively) in comparison with control (40 ± 8 pg/ml). A slight conjunctival hyperemia was only observed in the group treated with povidone iodine formulation. No change in terms of IOP and ocular tissues morphology was observed in all groups.

Conclusions: All together, these findings showed a very good ocular safety profile of the new ophthalmic formulation based on hypochlorous acid. It is worthy of note, that tear levels of MMP-9, a well-known marker of the inflammatory response, did not change in the eyes treated with Ocudox[™] and they were superimposable to the levels of control group.

ABSTRACT BODY:

Purpose: Multiple Sclerosis (MS) causes progressive neurodegeneration that is characterised by demyelination of neurons. MS also affects the visual system, including changes in the retina. For this reason, the Belfast Eye and Multiple Sclerosis (BEAMS) study aimed to comprehensively examine whether the retina could become an imaging and functional surrogate for the development and progression of MS.

Methods: Participants are enrolled and were imaged (17 patients with MS and ten controls). A range of retinal imaging methodologies, optical coherence tomography (OCT; Heidelberg Spectralis) and adaptive optics (AO; Image Eyes RTX1), were reported. OCT images were analysed by on-device segmentation software (Heyex) for peripapillary retinal nerve fibre layer (pRNFL), macular ganglion cell layer-inner plexiform layer (GCL-IPL) and outer nuclear layer (ONL) thicknesses. AO images were analysed by the semi-automated cone density detection algorithm (AODetect) on images captured at 2, 4 and 6° eccentricity. Control (ctrl) participants were compared to patients with (MSON) or without optic neuritis (MSnON), and the data obtained were analysed using SPSS and visualised using GraphPad Prism.

Results: The cohorts were statistically balanced for age and gender. Preliminary results suggest significant thinning ($p < 0.0001$) of the pRNFL and macular GCL-IPL in MSON (pRNFL: $81.23 \pm 3.18 \mu\text{m}$; GCL-IPL: $59.73 \pm 2.47 \mu\text{m}$) but no significant changes ($p > 0.05$) were observed in MSnON (pRNFL: $96.78 \pm 2.18 \mu\text{m}$; GCL-IPL: $10.94 \pm 1.8 \mu\text{m}$) compared to ctrl (pRNFL: $97.16 \pm 2.62 \mu\text{m}$; GCL-IPL: $73.50 \pm 3.18 \mu\text{m}$). No change was detected in the ONL thickness between all groups (ctrl 69.20 ± 3.28 vs MSON 68.02 ± 2.29 vs MSnON 68.81 ± 1.76 $p > 0.05$). There was a significant decrease ($p = 0.002$) of cone densities on AO images in patients with both MSON ($21909 \pm 1166/\text{mm}^2$) and MSnON ($22286 \pm 1005/\text{mm}^2$) compared to ctrl ($24355 \pm 1370/\text{mm}^2$).

Conclusions: The preliminary analysis of the images of the BEAMS study replicates the previously reported thinning of the inner retinal layers. Despite no measurable change in photoreceptor layer thickness on OCT images, here we report, the first time, a significant loss of cone numbers in the macula in MS. Whether the loss in cones leads to functional changes is yet to be determined. Our preliminary results suggest a need for a comprehensive analysis of retinal changes to detect and monitor the progression of MS.

TITLE: Automated Diagnosis of Keratoconus from Corneal Topography

SESSION TITLE: Keratoconus and biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Yildiz Tas, M. Hasanreisoglu, A. Sahin, School of Medicine, Ophthalmology, Koc Universitesi, Istanbul, Istanbul, TURKEY|H. Balim, M. Gönen, Computer Engineering, Koc Universitesi Muhendislik Fakultesi, Istanbul, TURKEY|

Commercial Relationships Disclosure (Abstract): Ayse Yildiz Tas: Commercial Relationship: Code N (No Commercial Relationship) | Murat Hasanreisoglu: Commercial Relationship: Code N (No Commercial Relationship) | Haldun Balim: Commercial Relationship: Code N (No Commercial Relationship) | Mehmet Gönen: Commercial Relationship: Code N (No Commercial Relationship) | Afsun Sahin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To detect the Keratoconus using machine learning and deep learning algorithms.

Methods: The diagnosis of the Keratoconus is done via investigation of corneal topography image of the cornea. Our dataset consists of 1281 topography images labeled by corneal topography imaging device. In each of these images, 7936 points are selected on patient's eye and sagittal slope, tangential slope, and perpendicular distance from eyeball of both front and back of the corneal surface as well as the corneal thickness are measured. Topography images are classified into five groups: Abnormal or Treated, Keratoconus Compatible, Myopic Post-Operation, Keratoconus Suspected and Normal. We split the dataset into train and validation sets with the fraction of 80% to 20%. To benchmark we trained some machine learning algorithms on the train dataset and measured the accuracy of classification in the validation dataset.

Results: We measured the accuracy of classification in the validation dataset.(Table 1) Our current network model can accurately classify myopic post operated, normal and keratoconus compatible patients. However, it still struggles to classify abnormal or treated and keratoconus suspected patients. The development process for neural network is still ongoing. Our current network has 90% accuracy on the validation set and its' confusion matrix on the validation set. (Table 2)

Conclusions: We will try to optimize neural network to achieve better results especially in the subgroup of the keratokonous suspected and treated patients. Furthermore, we aim to develop an attention layer and obtain the location of the key features that plays crucial role on the classification, so that we can generate a decision and support making system for doctors to report easily.

Holmes, Ophthalmology and Vision Science, University of Arizona-Tucson, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sarah Hatt: Commercial Relationship: Code N (No Commercial Relationship) | David Leske: Commercial Relationship: Code N (No Commercial Relationship) | Suzanne Wernimont: Commercial Relationship: Code N (No Commercial Relationship) | Yolanda Castañeda: Commercial Relationship: Code N (No Commercial Relationship) | Christina Cheng-Patel: Commercial Relationship: Code N (No Commercial Relationship) | Erick Bothun: Commercial Relationship: Code N (No Commercial Relationship) | Eileen Birch: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Holmes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have reported reduced eye-related quality of life (ER-QOL) and functional vision in children with strabismus, using the Pediatric Eye Questionnaire (PedEyeQ), but have not evaluated the effect of age when compared with normals.

Methods: 98 children (70 aged 5-11 years and 28 aged 12-17 years) with horizontal strabismus (allowing coexistent amblyopia, refractive error, dissociated vertical deviation) and 206 visually normal controls (104, 5-11 years and 102, 12-17 years) were prospectively enrolled. Children completed the Child 5-11 or 12-17 year PedEyeQ, consisting of Functional Vision, Bothered by Eyes/Vision, Social, and Frustration/Worry domains. Each PedEyeQ domain was Rasch-scored and then converted to a 0-100 scale. The 5th percentile of scores in the 5- to 11- and 12- to 17-year normal cohorts was used to define the threshold for "reduced," for each domain. We compared the proportions of 5- to 11- and 12- to 17-year-olds who had reduced scores in each domain.

Results: A significantly greater proportion of 12- to 17-year-olds vs 5- to 11-year-olds had reduced scores on each of the four Child PedEyeQ domains: Social 89% vs 19%, (mean difference 71%, 95% CI 56% to 85%; P<0.001), Frustration/Worry 75% vs 21% (mean difference 54%, 95% CI 35% to 72%; P<0.001), Functional Vision 57% vs 34% (mean difference 23%, 95% CI 1% to 44%; P=0.044) and Bothered by Eyes/Vision 57% vs 31% (mean difference 26%, 95% CI 4% to 47%; P=0.02).

Conclusions: A greater proportion of adolescents report reduced (below the 5th percentile threshold) functional vision and reduced ER-QOL domain scores compared with 5- to 11-year-olds, especially on the Social and Frustration/Worry domains. This effect of child age likely reflects, at least in part, a more realistic self-concept in adolescents. Interpretation of individual scores in younger clinical populations is also made challenging by the considerable variability in 5- to 11-year-old normal controls, such that thresholds to define reduced scores are relatively low.

ABSTRACT BODY:

Purpose: Pseudophakic donor corneal tissue has been identified as having lower endothelial cell density (ECD) and higher risk of preparation failure compared to donor corneal tissue in eyes without prior cataract surgery. As corneal tissue remains a limited resource, optimal utilisation is essential for all stakeholders. We performed a retrospective, observational audit of donor corneal tissue at a single eye bank to identify the risk factors in pseudophakic eyes that may impact final tissue suitability.

Methods: We reviewed an existing database of donor corneal tissue in NSW Tissue Bank, Australia. Donors who had previously unilateral cataract surgery were identified with the opposite eye serving as an intra-individual control. Demographic data inclusive of age and gender was collated. Corneal assessment data including ECD, biomicroscopy and suitability for both eyes were compared using two sample t-tests.

Results: 191 donors across a 20-year period (1998-2018) were identified as having previously unilateral cataract surgery. The mean age of donors was 73.8 ± 9.2 years with 61.8% donors male. 19.9% of donors had a confirmed history of diabetes. Patient condition at death was rated as good or excellent for 75% of donors. Mean corneal ECD in the pseudophakic eyes was $2798.9 \pm 363.3 \text{ c/mm}^2$ vs. $2952.1 \pm 362.6 \text{ c/mm}^2$ for the phakic counterpart ($p < 0.001$). Biomicroscopy indicated greater incidence of findings in pseudophakic eyes compared to phakic eyes for both suitable and non-suitable eyes (Table 1). Suitability for corneal transplantation was statistically significantly different ($p < 0.001$) with 59% of pseudophakic eyes declared suitable versus 91% of phakic eyes suitable.

Conclusions: Despite mean endothelial cell count in pseudophakic eyes reaching minimum requirements for suitability, the percentage of eyes available for graft surgery was significantly less than the contralateral phakic eye. Increased incidence of corneal endothelial opacities in the pseudophakic eyes was a significant contributing factor in low suitability for eyes with prior cataract surgery.

ABSTRACT BODY:

Purpose: Repetitive transorbital alternating current stimulation (rtACS) is an application of weak electric current near the eyes used in vision rehabilitation of optic neuropathies (ON). Conceptually rtACS entrains neuronal oscillations, augmenting neuronal function. In subjects with ON we evaluated whether rtACS influenced visual structure and function.

Methods: 34 subjects with ON enrolled in a prospective trial underwent comprehensive ophthalmic evaluation, visual field (VF) 24-2 and 10-2 tests (Humphrey Field Analyzer) and OCT (Cirrus HD-OCT) retinal nerve fiber layer (RNFL) and ganglion cell inner plexiform layer (GCIPL) thicknesses at baseline and follow-up (FU) visits. Subjects received rtACS 30- to 45-minutes daily for 10 days. Sham subjects (n=4) underwent the same procedures but received no current. Point-by-point analyses of VF total deviation (TD) values were conducted between rtACS and sham groups. Regression analyses determined rate of change for each TD point per eye (significant points with positive rate of change defined as improved, negative rate of change as progressed; insignificant rate of change as no change) and the association between RNFL and GCIPL between groups.

Results: The number of FU visits with VF tests ranged 2 to 7, with no significant differences detected between rtACS vs sham groups' FU duration. No significant differences were detected between groups' baseline VF 24-2 and 10-2 mean deviation (MD) values (Table 1). The average numbers of improved points (VF 10-2) and progressed points (VF 24-2) were greater for rtACS while the average number of no change points was greater for sham (VF 24-2, $p \leq 0.05$, Table 1). Further analysis of FU duration determined a significant interaction with rtACS; number of improved points (VF 10-2) and progressed points (VF 24-2, $p < 0.02$) were not sustained over time. No significant differences were detected in average RNFL and GCIPL thicknesses between groups.

Conclusions: Preliminary analyses of the effect of rtACS in ON indicate initial improvement but not a clear benefit over time. Detection of differences between rtACS vs sham groups may be biased due to the small sham sample and range of FU duration as VF test-to-test variability is known to increase with worsening VF MD. Future analyses will assess interim effect at early vs late FU time points to evaluate the role of rtACS in vision rehabilitation.

TITLE: Single-cell RNA sequencing reveals early responses to degeneration in rods and cones of the rd10 retina

SESSION TITLE: Applications of single-cell RNA-seq and Transcriptome Studies to Retinal Cell Biology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Karademir, V. Todorova, M. Samardzija, L.J. Ebner, C. Grimm, Lab for Retinal Cell Biology, Universitat Zurich, Schlieren, ZH, SWITZERLAND|

Commercial Relationships Disclosure (Abstract): Duygu Karademir: Commercial Relationship: Code N (No Commercial Relationship) | Vyara Todorova: Commercial Relationship: Code N (No Commercial Relationship) | Marijana Samardzija: Commercial Relationship: Code N (No Commercial Relationship) | Lynn Ebner: Commercial Relationship: Code N (No Commercial Relationship) | Christian Grimm: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In inherited retinal disorders such as retinitis pigmentosa (RP), the initial degeneration of rod photoreceptors is often followed by the secondary death of cones and loss of high-acuity vision. Mechanistic studies of these events are challenging, as cells in different stages of degeneration generally coexist, and the detection of cone responses to rod degeneration is difficult due to the relative paucity of cones in the retina. We utilized droplet-based single-cell RNA sequencing (scRNAseq) to resolve intercellular heterogeneity and elucidate early events in rods and cones during rod photoreceptor degeneration in rd10, an RP mouse model.

Methods: ScRNAseq was performed on rd10 and C57/BL6 wildtype retinas at postnatal day (P) 21 (N=2, 1 male and 1 female per genotype) using the 10X Genomics platform. Data analysis focused on characterizing the transcriptomes of degenerating rods and cones with differential gene expression and trajectory analysis. Transcriptomics data was validated via immunofluorescence in both rd10 retinas and retinas of BALB/c animals damaged by 1 hour of 13'000 lx white light.

Results: Trajectory inference revealed two consecutive phases of rod degeneration at P21. The early phase was distinguished by a marked upregulation of Egr1 (avg. fold change (FC): 4.82 over wildtype rods) and the late phase by Cebpd (FC: 4.55 over Egr1+ rods). Egr1 was also the most highly upregulated transcript in rd10 cones (FC: 5.81 over wildtype cones). Notably, EGR1 was the transcription factor most significantly associated with the promoters of differentially regulated genes in Egr1+ rods in silico. Egr1 upregulation preceded transcriptomic changes related to metabolic dysfunction, synapses, and tubulin remodeling in rods. In cones, it accompanied changes in mitochondrial and signaling pathways, including TNF α and TGF β . Phototransduction genes were downregulated early in both cell types. Immunoreactivity for EGR1 was highly increased in rods and cones of rd10 retinas at P21, with rods losing EGR1 by P28. Cones remained EGR1-positive at least up to P35. EGR1 immunoreactivity also increased 2 hours after light damage, specifically in cones and Müller glia.

Conclusions: Our results identify early cone responses to rod degeneration in the rd10 model and describe various pathways that are initially affected in degenerating rods. Our data suggest EGR1 as a key regulator of these early events.

ABSTRACT BODY:

Purpose: To develop a new pediatric eye treatment questionnaire (PedEyeQ-T), designed to assess the impact of non-surgical eye treatments on function and on eye-related quality of life (ER-QOL) in children under the age of 18 with a variety of eye conditions and eye treatments.

Methods: Child and Proxy master questionnaires were created from specific concerns identified from child and parent interviews. Child master questionnaires (n=34 items), were administered to children (5-17 years old; n=329) currently undergoing any non-surgical eye treatment (glasses, contact lenses, patching, drops, binocular amblyopia treatment, etc.), and Proxy master questionnaires (n= 34 items) were administered to one parent for each child (0-17 years old; n=466). A 3-level frequency rating scale (never, sometimes, always) was used for responses. Exploratory factor analyses were performed to identify domains within function-related items (n=7) and ER-QOL-related items (n=27), labeled based on review of content. Rasch analysis was performed on each domain identified in factor analysis, to reduce items by evaluating differential item functioning (sex, race, age, parent completing), response ordering, local dependence, fit, and targeting.

Results: Factor analysis of Child questionnaires identified 1 domain for function-related items and 2 domains for ER-QOL items. Rasch analysis confirmed unidimensionality of domains and yielded a Child questionnaire with 3 items in a Treatment: Function domain, 10 items in a Treatment: Socioemotional domain, and 6 items in a Treatment: Difficulty domain. For the Proxy questionnaire, Factor analysis identified 1 domain for function-related items and 2 domains for ER-QOL items. Following Rasch analysis the Proxy treatment questionnaire had 3 items in a Treatment: Function domain, 7 items in a Treatment: Socioemotional domain, and 3 items in a Treatment: Difficulty domain.

Conclusions: By following a rigorous process for questionnaire development, we have created the new patient-derived Pediatric Eye Treatment Questionnaire (PedEyeQ-T), for use in children of any age undergoing any non-surgical eye-treatment, with Child and Proxy versions for assessing impact on function and on ER-QOL.

TITLE: Outcomes of cataract surgery in pediatric uveitis patients on systemic immunomodulatory therapy

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Devaro, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|L. Ward, Emory University School of Public Health, Atlanta, Georgia, UNITED STATES|P. Lenhart, J. Shantha, G. O'Keefe, Ophthalmology, Emory University, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sarah Devaro: Commercial Relationship: Code N (No Commercial Relationship) | Laura Ward: Commercial Relationship: Code N (No Commercial Relationship) | Phoebe Lenhart: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Shantha: Commercial Relationship: Code N (No Commercial Relationship) | Ghazala O'Keefe: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Compare outcomes of cataract surgery in pediatric uveitis between 3 treatment groups: no systemic treatment, antimetabolites, and biologic response modifiers (BRM) +/- antimetabolites.

Methods: Retrospective chart review of uveitis patients younger than 18 years who underwent cataract surgery at Emory Eye Center in Atlanta, GA 2008-2020. Data collected included demographics, treatment, visual acuity (VA) and postoperative complications, all summarized as frequencies. SPSS software was used for descriptive and inferential statistical analysis. Univariate analyses were performed to compare treatment groups. VA was tested by time and treatment group adjusting for correlation between covariates and eyes over time.

Results: 51 patients were included; 31 (61%) were female. Mean age at surgery was 10.8 years (range 4-17). Anterior uveitis (62%) was most common anatomic location. Of 65 eyes, 20 (31%) were on antimetabolites, most commonly methotrexate (95%); 19 (29%) were on BRM +/- antimetabolites, most commonly infliximab (68%); and 26 (40%) were on no systemic immunomodulation. Of eyes on no treatment, 54% were on oral corticosteroids perioperatively. 14 (74%) patients on BRM also received antimetabolites (mean duration 19.9 months). Mean age at diagnosis was significantly lower in those on BRM ($p=0.009$). Patients with juvenile idiopathic arthritis (JIA) were more frequently on BRM ($p=0.018$). All groups had similar rates of amblyopia, average length of quiescence and number of flares in year prior to surgery. Postoperative complications (prolonged inflammation or development of cystoid macular edema or posterior capsular opacification) approached significance. Intraocular pressure (IOP) increased in all eyes over time ($p=0.0069$) but was significantly higher in BRM compared with anti-metabolites ($p=0.0002$) or all-comers ($p=0.0128$). VA in all eyes improved after surgery, with significantly better VA in BRM compared to the rest of the cohort ($p = 0.002$).

Conclusions: Cataract surgery improved visual outcomes in pediatric uveitis regardless of treatment. Despite younger age of diagnosis, patients on BRM had significantly better long-term vision but also increased IOP. Postoperative complications were similar across groups. This is the first report of outcomes after cataract surgery in pediatric uveitis comparing available treatments.

ABSTRACT BODY:

Purpose: This work presents the first deep-learning based GA segmentation algorithm for swept-source OCT that provides accurate and reproducible results in GA assessment with high sensitivity to GA changes over time.

Methods: An automated algorithm was trained with 6x6 mm macular SS-OCT scans from 58 GA eyes (38/20 split for training/validation set). It utilizes scan volume data to generate three image inputs characterizing the main OCT features of GA: hyper-illumination in sub RPE slab, regions of RPE loss, and loss of retinal thickness (Figure 1). Advanced data augmentation techniques helped compensate for the small training data size. To evaluate the accuracy of the GA segmentations, 180 SS-OCT macular scans from 30 GA eyes collected from 3 different sites were considered: each eye had 3 repeated scans at baseline and follow-up visits (average of 16.74 months). Area measurements were corrected by their square-root and used to compute enlargement rate per year between the visits. The GA delineations, area measurements and enlargement rates generated by the automated algorithm in addition to algorithm repeatability in repeated scans were compared to the ground-truth manual delineations annotated by two graders.

Results: Figure 2 summarizes the performance of the algorithm. Automated GA delineation accuracy between the algorithm and two graders was measured using the Dice coefficient with average values of 0.88 and 0.87, respectively. GA area measurements produced by the algorithm were comparable and showed no significant difference to those from each grader, with an average absolute difference of 0.19 (p-value 0.73) and 0.19 (p-value 0.77), respectively. GA enlargement rate computed by the algorithm also showed no significant differences to the two graders, with differences of 0.13 (p-value 0.26) and 0.12 (p-value 0.71), respectively. The algorithm also presented a high repeatability for area and enlargement rate measurements, with intra-class repeatability coefficients of 0.997 and 0.947, respectively.

Conclusions: Despite a small training data size, this deep learning based automated GA segmentation algorithm is able to produce accurate and reproducible results in GA assessment with high sensitivity for GA changes over time.

Commercial Relationships Disclosure (Abstract): Kristen Buehne: Commercial Relationship: Code N (No Commercial Relationship) | Kelly Muir: Commercial Relationship: Code N (No Commercial Relationship) | Jullia Rosdahl: Commercial Relationship: Code N (No Commercial Relationship) | Sandra Woolson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Without a cure, glaucoma is managed as a chronic disease, most often with eye drops prescribed to reduce intraocular pressure. This implies that poor medication adherence correlates with disease escalation. With a randomized clinical trial, we tested the hypothesis that patients who receive an adherence intervention are more likely to have a stable glaucoma course and will require less intensive treatment over the following 12 months.

Methods: The study population consists of 200 veterans who report less than 100% adherence to their eye drop regimen. The treatment group received a glaucoma education session with drop administration instruction, and virtual reminders from a “smart bottle” of their eye drops. The control group received a general eye health class, and the smart bottle with the reminder function turned off. The bottle reported the date and time it was opened for both groups, supplying objective data for adherence. We previously reported the primary outcome; that the average glaucoma medication adherence was significantly higher for those in the intervention group compared to those in the control group in the 6 months following randomization (0.85 versus 0.62, $p < 0.0001$). For the secondary outcome described here, masked medical chart extraction determined if participants experienced visual field progression, additional glaucoma medications, or a recommendation for surgery due to inadequate IOP control over the 12 months following randomization.

Results: Of the 34 participants with glaucoma medication added, 16 were in the control group and 18 in the intervention group. Of the 17 participants for whom surgery was recommended, 9 were in the control group and 8 were in the intervention group. Of the 37 participants who experienced visual field progression, 16 were in the control group and 21 were in the intervention group. Overall, 66 participants experienced disease escalation in the 12 months following randomization; 31 were in the control group and 35 were in the intervention group.

Conclusions: An intervention that improved glaucoma medication adherence over 6 months did not reduce escalation of glaucoma therapy or reduce glaucomatous visual field loss in the 12 months following the intervention. Further work is needed to determine risk factors for progression despite improved adherence, likely with longer follow-up to measure potential clinical benefit.

ABSTRACT BODY:

Purpose: To compare the optical and predicted clinical performance of a higher-order aspheric IOL design that provides a continuous change in power from the center to the periphery of the lens with a zonal refractive IOL with a distinct add power of 2D in the central zone using optical bench measurements and simulations.

Methods: Binocular visual acuity (sVA) was simulated using the metrics described in Alarcon et al. BOE 2016, calculated from measurements collected in an average corneal eye (ACE) model, in white light, with 3mm pupil and from -2.5D to 0.5D of defocus. Distance image quality was evaluated by the modulation transfer function (MTF) measured in the ACE model, in white light, for 2, 3 and 5mm pupils. Computer simulations in a physiological eye were performed to determine the halo profile for different pupil sizes for the different IOL designs. Measurements of a standard monofocal and a diffractive multifocal IOL of 2.75D add power were included as references.

Results: The higher-order aspheric IOL provides comparable distance sVA to the monofocal IOL and an extended depth of focus in the intermediate range with a monotonical decrease in through-focus sVA. The zonal refractive design provided a decrease of 1 line of sVA at distance and a bifocal defocus curve with a second peak that corresponds to the add power. The design with the central add power showed a lower contrast for all pupil sizes than the higher order aspheric IOL and at the level of the multifocal IOL for 3 and 5mm. For 2mm, the central add power design provided a reduction in contrast with MTF close to zero. Contrary, the higher order aspheric design resulted in consistent distance image quality through different pupil sizes. The pupil dependency of the zonal refractive design was also visible in the halo pictures simulations, with perception of halos and rings especially for the smaller pupils, which are not visible in the higher-order aspheric IOL for any of the pupil sizes evaluated.

Conclusions: The addition of an add power results in a strong pupil dependence and an optical performance that resembles a standard multifocal IOL, with a bifocal defocus curves, a loss in distance image quality and the perception of halos. The higher-order aspheric IOL, that creates a continuous change in power to extend the depth of focus and improve intermediate vision, provides a pupil independent performance and a consistent dysphotopsia profile.

ABSTRACT BODY:

Purpose: Spectral-domain optical coherence tomography (SD-OCT) has proven useful in defining the retinal layer pathology, most notably ellipsoid zone (EZ) disruption, seen in syphilitic retinitis patients; however, a timeline for EZ recovery after intravenous (IV) penicillin treatment in these patients has yet to be established. Here, we report an SD-OCT image analysis study of syphilitic retinitis patients to quantify EZ recovery in a time-dependent manner to determine successful outcomes in this patient population.

Methods: A retrospective chart review of 8 patients diagnosed with syphilitic retinitis was performed. A positive diagnosis included reactive syphilis IgG (>8.0) and rapid plasma reagin (RPR) serological tests and was confirmed by ocular exam. All patients were treated with at least a 14-day course of IV penicillin. Patients had a baseline SD-OCT scan of the diseased eye(s) within 7 days of treatment initiation and at least one scan during the treatment course. All SD-OCT scans up to 45 days post-baseline were analyzed using software that allowed for total EZ volume quantification following retinal layer segmentation. Clinical information, such as disease laterality, HIV status, and visual acuity, were also collected.

Results: Of the 8 patients with confirmed syphilitic retinitis, 4 showed bilateral disease. 7/8 patients had macular EZ disruption, while 1 patient showed peripheral retinal changes consistent with syphilis. 5/8 patients (62.5%) were HIV+ at the time of presentation. In patients with macular involvement, 10/13 eyes were analyzed. Throughout IV treatment, the average change from baseline in total EZ volume was +15.6%; however, this change was variable (range, -20.2% - +48.0%). Patients saw a more consistent improvement once treatment was completed. At a mean follow-up time of 15.7 days after treatment, patients showed an average increase of 73.0% (range, 53.6 - 122.8%) in total EZ volume.

Conclusions: With this study, we have shown that the EZ disruption seen on SD-OCT in syphilitic retinitis patients is a temporary pathological finding and can be resolved with IV penicillin. Furthermore, while EZ recovery begins during a patient's treatment course, most of the recovery is observed in the weeks following the conclusion of intravenous therapy.

TITLE: Activity and pharmacokinetics of ICON-4, a New Antibody Targeting Tissue Factor

SESSION TITLE: CNV

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Gaudreault, JJG Pharma Consulting, Basel, BS, SWITZERLAND|G. Burian, GB Biomed Advisors, Oberwil, BL, SWITZERLAND|T. Mlgone, iconic Therapeutics, SSF, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jacques Gaudreault: Commercial Relationship(s);Iconic Therapeutic:Code C (Consultant) | Gabriela Burian: Commercial Relationship(s);Iconic Therapeutic:Code C (Consultant) | Thi-Sau Mlgone: Commercial Relationship(s);Iconic Therapeutics:Code E (Employment)

ABSTRACT BODY:

Purpose: Tissue factor (TF) is a 46 kD transmembrane receptor found on vascular endothelial cells (EC). In addition to its role as initiator of coagulation, TF plays an important role in angiogenesis and inflammation. TF is elevated in the retina of Age-related Macular Degeneration (AMD) patients and in the neovascularization (NV). TF inhibition has the potential to affect these processes and modify disease progression by halting formation and growth of macular NV. A clinical proof of concept for the benefit of TF inhibition was achieved in a Phase 2 trial where ICON-1 (an immunoconjugate targeting TF) was given to patients with neovascular AMD. Intravitreal (IVT) ICON-1 administration at 300 ug/eye every month for 6 months, resulted in a decrease in both retinal thickness and NV lesion growth/activity with subsequent decreased need for anti-VEGF therapy. The objective of these studies is to characterize the pharmacology and pharmacokinetics of a new TF inhibitor, ICON-4, with optimized properties for IVT administration.

Methods: ICON-4, a human IgG1, was characterized with a series of in vitro assays. Characterization included affinity measurements (Biacore), ADCC with either a reporter cell line or PBMCs as effector cells, CDC activity, and ADCP. ICON-4 anti-inflammatory effects were characterized using MDA-231 cells to measure the effect on release of GM-CSF and IL-8. ICON-4 effect on coagulation was assessed using Factor X (FX) conversion assay and thrombin generation assays. ICON-4 pharmacokinetics were characterized in NZW rabbits following single IVT administration of 0.6 and 3.6 mg and ocular concentrations quantified by ELISA.

Results: In all in vitro assays, ICON-4 had better activity compared to ICON-1 with improvement in activity ranging from 3 to 20-fold across the different assays. While ICON-4 was more active in all the assays, it still was inert on coagulation, as it did not impact FXa conversion or thrombin generation. Following IVT administration, ICON-4 had a long vitreous $t_{1/2}$ of 6 days, which was about 2X longer than previously observed for ICON-1.

Conclusions: ICON-4 is a potent TF inhibitor with optimized properties well suited and formulated for IVT administration. ICON-4 high affinity is expected to result in more complete TF inhibition with potential for higher efficacy and/or longer duration of action without enhanced risks of bleeding compared to ICON-1.

TITLE: Antibody-based Nogo-A neutralization reduces neuroinflammation after retinal injury

SESSION TITLE: Retinal Degenerations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Joly, J.B. Mdzomba, L. Rodriguez, A. Dirani, V. Pernet, Centre de recherche du CHUL, Quebec, Quebec, CANADA|P. Lassiaz, F.F. Behar-Cohen, Centre de Recherche des Cordeliers, Paris, Île-de-France, FRANCE|

Commercial Relationships Disclosure (Abstract): Sandrine Joly: Commercial Relationship: Code N (No Commercial Relationship) | Julius Mdzomba: Commercial Relationship: Code N (No Commercial Relationship) | Lea Rodriguez: Commercial Relationship: Code N (No Commercial Relationship) | Ali Dirani: Commercial Relationship: Code N (No Commercial Relationship) | Patricia Lassiaz: Commercial Relationship: Code N (No Commercial Relationship) | Francine Behar-Cohen: Commercial Relationship: Code N (No Commercial Relationship) | Vincent Pernet: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously observed that inactivating Nogo-A, a reticulon protein enriched in Müller glia and in oligodendrocytes, enhanced vascular repair, optic nerve axon regeneration and visual recovery after retinal injury. The mechanisms underlying the effect of Nogo-A in the development of visual defects are not clear. The aim of this study was thus to determine if Nogo-A modulates injury-induced neuroinflammation in the adult mouse retina.

Methods: Excitotoxic injury was induced by intravitreally injecting different concentrations of NMDA (0.5-40 nmol) in adult mouse eyes. Nogo-A level was followed in the vitreous and in the retina of injected animals by Western blotting. Two days after NMDA injection, Nogo-A-blocking antibody (11C7) or a control antibody (IgG) were injected. Quantitative real-time PCR was performed 1 and 7 days after antibody injection to determine gene expression changes for Nogo-A and its receptors, and inflammation and gliosis markers. Microglia was visualized on retinal flatmounts by immunofluorescence. Western blotting and immunofluorescent analyses were also realized on samples from diabetic patients.

Results: Full-length and fragmented Nogo-A proteins were upregulated in the mouse vitreous after NMDA-induced injury. This change was correlated with TNF α trimer release. In injured animals, intravitreal injection of 11C7 significantly improved visual function recovery compared with control IgG delivery. The expression of pro-inflammatory molecules, such as TNF α , was strongly downregulated by 11C7. Immunofluorescent stainings suggested that microglia/macrophages were the main source of TNF α in the damaged retina. TNF α immunofluorescence was markedly reduced in response to 11C7 injection. Further Western blot and histological results suggested that TNF α downregulation may result from cofilin inactivation in microglia/macrophages. In addition, the decrease in Vimentin and Gfap mRNAs in 11C7-treated retinal lysates indicated that 11C7 mitigated gliosis, possibly by downregulating P.Stat3. Increased levels of Nogo-A in the vitreous and in the retina were observed in diabetic donors.

Conclusions: The administration of function-blocking antibody directed against Nogo-A promotes visual recovery after retinal injury. At the same time, the inhibition of neuroinflammation suggests a new function for Nogo-A that could be used to design ophthalmic treatments.

ABSTRACT BODY:

Purpose: Biodegradable, intracameral bimatoprost implant slowly releases bimatoprost to lower intraocular pressure (IOP). In clinical trials, the implant has provided sustained IOP lowering beyond the period of intraocular drug bioavailability. This analysis evaluated the duration of IOP control provided by the implant in a phase 3 clinical trials study extension.

Methods: A 24-month, open-label, multicenter, long-term safety and efficacy extension study (NCT03891446) enrolled patients with open-angle glaucoma or ocular hypertension after their completion of a bimatoprost implant phase 3 clinical trial. Enrollment was optional; not all eligible patients enrolled. This analysis included patients who had received 10- or 15-µg bimatoprost implant in the study eye on Day 1 and Weeks 16 and 32 in a 20-month, randomized, phase 3 ARTEMIS trial (NCT02247804 or NCT02250651); patients were ineligible to receive implants during the study extension. Rescue with topical drops was allowed if the study eye did not meet/maintain IOP expectations (investigator decision). The analysis evaluated IOP and the number of patients who received no additional (rescue) IOP-lowering treatment in the study eye for ≥ 2 years after the last implant administration during the ARTEMIS trial. The study is ongoing; all data available as of 03 Dec 2020 were analyzed.

Results: Among 181 implant-treated patients who completed ARTEMIS and enrolled in the study extension, 48 had not been rescued at the study extension screening, and 32 did not require rescue for ≥ 2 years after their last implant administration. For these 32 patients (16 treated with 10-µg implant, 16 with 15-µg implant), mean (\pm SD) time without rescue after the last implant administration was 2.6 ± 0.5 years (range, 2.0–4.0), and mean (\pm SD) IOP was 23.4 ± 1.9 mmHg at initial (ARTEMIS study) baseline and 18.1 ± 3.1 mmHg at the last recorded visit (still without rescue). Seven patients remained untreated for ≥ 3 years (range, 3.1–4.0); their mean (\pm SD) IOP was 22.8 ± 1.5 mmHg at baseline and 18.0 ± 4.1 mmHg at the last recorded visit (still without rescue).

Conclusions: Patients treated with the bimatoprost implant can have a sustained IOP lowering and require no IOP-lowering treatment for ≥ 2 years after their last administration in a phase 3 trial. The implant releases drug for 3–4 months and the mechanism of action of the long duration of IOP reduction is under investigation.

TITLE: Investigating Sodium Hexametaphosphate as a topical treatment for Band Keratopathy

SESSION TITLE: Cornea, cytokines, anti-inflammatory

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Bennett, L.M. Grover, Healthcare Technologies Institute, School of Chemical Engineering, University of Birmingham, Birmingham, Birmingham, UNITED KINGDOM|L.J. Hill, Institute of Inflammation and Aging, University of Birmingham, Birmingham, Birmingham, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Naomi Bennett: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Hill: Commercial Relationship: Code N (No Commercial Relationship) | Liam Grover: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate Sodium Hexametaphosphate as a potential non-surgical treatment for corneal mineralization in the form of Band Keratopathy, the demineralization capability under varying conditions, the ocular toxicity and the interaction of the polyphosphate with various polymeric hydrogel materials are assessed with the view of creating a long-lasting, topically applied treatment.

Methods: Demineralisation was assessed by measuring the changes in absorbance of aqueous nanocrystalline hydroxyapatite sol treated with concentrations of sodium hexametaphosphate (HMP) ranging from 0.125 - 1M, versus untreated controls.

Ocular toxicity was investigated through in vitro cellular assays of primary corneal cells, including lactate dehydrogenase production assays and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays. The interactions between HMP and chitosan, alginate and gellan hydrogels were investigated using rheometry. Each underwent a series of shear stress ramp assessments from 0-250Pa.

Results: 0.125M, 0.25M, 0.5M and 1M HMP treatments reduced the absorbance of HA sol from 1.000 to a mean (SEM) of 0.419 (0.013), 0.730 (0.028), 0.521 (0.027) and 0.365 (0.017) respectively within 60 minutes. 0.25M, 0.5M and 1M treated samples continue to decrease before stabilising, where as 0.125M treated samples reach a minimum absorbance at 360 mins before then increasing to reach an absorbance of 0.789 (0.034).

The lower concentrations of HMP tested - 0.125M and 0.25M - showed the greatest cytotoxicity at 14.054% and 34.456% after 6 hours of treatment. This corresponds with the lowest formazan production compared to the higher concentration treatment groups, with adjusted absorbance readings of 0.010 and 0.004 respectively.

Chitosan shows increasing viscosity, alginate gradually decreasing viscosity, and gellan an increase followed by a subsequent decrease, with increasing HMP percentage.

Conclusions: The results presented in this study show that Sodium Hexametaphosphate can demineralise hydroxyapatite effectively, can maintain cell viability and can influence the rheological properties of polymeric hydrogels in a concentration dependant manner. A balance should be struck between these behaviours as a topical treatment is developed.

ABSTRACT BODY:

Purpose: Since 2002, cultivated oral mucosal epithelial transplantation (COMET) has been used for ocular surface reconstruction in cases of severe ocular surface disease. The purpose of this prospective, interventional clinical study was to examine the safety and efficacy of COMET for fornix reconstruction in cases of severe ocular surface disease.

Methods: This prospective clinical study involved patients with severe ocular surface disease (i.e., Stevens-Johnson syndrome: n = 5 eyes; ocular cicatricial pemphigoid: n =1 eye) with a 50% or greater adhesion of either the upper or lower conjunctival fornix that underwent COMET for fornix reconstruction at the Department of Ophthalmology, Kyoto Prefectural University of Medicine, Kyoto, Japan between January 2014 and February 2017. Surgical outcomes were defined as changes in each score between at pre surgery (baseline) and at 24-weeks postoperative, with the primary outcome being the fornix shortening score. Secondary outcomes were the Ocular Surface Grading Score (OSGS), the best-corrected visual acuity (BCVA), the results of the 25-item National Eye Institute Visual Function Questionnaire (NEI VFQ-25), and adverse events. The changes in each score from at baseline were analyzed using the one-sample t-test.

Results: From baseline to 24-weeks postoperative, the fornix shortening score significantly improved from 4.7 (median: 4.5; range: 3-6) to 1.2 (median: 0; range: 0-3) ($p=0.001$) and the OSGS significantly improved from 15.2 (median: 14.5; range: 11-20) to 6.2 (median: 5.0; range: 2-14) ($p=0.0052$), yet no significant difference in BCVA was observed. In the NEI VFQ-25 findings, 9 of the 12 subscales improved, with significant differences observed in "General vision" and "Ocular pain" ($p=0.0104$, 0.040 , respectively). No complications associated with COMET were observed post surgery.

Conclusions: Our findings clearly demonstrate the safety and efficacy of COMET for fornix reconstruction in cases of severe ocular surface disease.

TITLE: Utilization of Confocal Microscopy in the Management of Suspected Microbial Keratitis at a Tertiary Eyecare Center

SESSION TITLE: Keratoconus and biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. McLaren, D.S. Jacobs, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts, UNITED STATES|D.S. Jacobs, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Naomi McLaren: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Jacobs: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To better understand the role of confocal microscopy in clinical decision making in the management of suspected microbial keratitis.

Methods: A log of study requisitions was reviewed. The following items were recorded and analyzed: a. Date of confocal imaging, b. Source of request by setting of encounter (Emergency Department [ED], Cornea clinic, community doctor) c. Credential of requesting provider (ED resident, ED attending physician, Cornea Fellow, Cornea attending physician, community doctor), The date of any prior corneal culture(s) was queried from medical record in a pilot study of two seasonal subgroups of consecutive patients (9 winter and 9 summer).

Results: 59 requisitions were logged from Jan 1, 2019 to Nov 30, 2019. 22 (37%) were requested in relation to an Emergency Department encounter (1 by resident, 8 by ED attending, 3 by cornea fellow in conjunction with ED attending, and 10 by cornea fellow), 13 studies (22%) were requested by a cornea fellow in a follow-up clinic, 21 studies (36%) were requested by cornea attending in a scheduled visit, and 3 (5%) studies were requested by a community doctor.

Our pilot sample of winter requisitions showed 3/9 patients were from ED and that 7/9 had culture > 2 days prior, 2/9 had culture 1-2 days prior, and 4/9 had prior confocal imaging or final positive cultures. A sample of summer requisitions found that 5/9 were from the ED and that 1/9 had cultures > 2 days prior, 7/9 had cultures 1-2 days prior, 1/9 was never cultured, and 2/9 had prior confocal imaging or final positive cultures.

Conclusions: Confocal microscopy in the management of suspected microbial keratitis is ordered by a variety of clinicians in a variety of settings at this tertiary care center. Credentials of the requesting physician vary with the season of the initial evaluation, as does the reason for imaging, with surveillance of treated cases being more common in the winter and workup of new infection more common in the summer. The pilot suggests that during summer imaging is requested with no or preliminary culture data. Further review and comparison of confocal and culture results is likely to provide insight into real time utility of this resource in a tertiary care setting.

ABSTRACT BODY:

Purpose: Elm Hill-sourced pigmented guinea pigs (GPs) was previously reported to be resistant to experimentally-induced myopia development, which was presumed to be due to thicker choroidal layer versus other strains. Here we provide further support that choroidal thickness is associated with susceptibility to myopia-inducement.

Methods: Elm Hill-sourced pigmented (n=7 at D13) and albino (n=8 at D7) hyperopic guinea pigs were used to induce unilateral form-deprived myopia (FDM) via facemask. Cycloplegic refraction by retinoscopy and vitreous chamber depth measurement (VCD) via Ascan (Sonomed VuMAX HD Ophthalmic Ultrasound) were obtained in alert animals at baseline (before FDM), and at two weeks FDM and four weeks FDM. At the same time points, fundus and choroidal imaging was obtained by optical coherence tomography (Heidelberg Spectralis OCT) under anaesthesia with ketamine and xylazine (27/0.6 mg/kg body weight).

Results: At baseline, albino GPs had a thinner choroidal layer (mean 49 μ m) with less variation (standard deviation (SD): 9 μ m) than pigmented GPs, which had significantly thicker choroid (mean 119 μ m) but more variation (SD: 42 μ m, p = 0.0009). Thinner choroidal albino GPs developed significant myopia (-4.8 ± 1.7 D after 2 weeks of FD, -5.7 ± 1.5 D after 4 weeks of FD). Among the pigmented GPs, the animal that had a baseline choroid of 56 μ m developed high myopia (-10 D myopia shift with 0.26 mm elongated VCD after 2 weeks of FD and -7 D myopia shift with 0.30 mm elongated VCD after 4 weeks of FD). In contrast, the 6 remaining pigmented GPs with thicker choroidal layers (131 ± 44 μ m) were resistant to FDM.

Conclusions: Our results support the notion that thinner choroidal layers are associated with greater susceptibility to experimental myopia-inducement. This study results also confirms that thicker choroid could protect from, or delay myopia onset, which is a consistent finding in both strains studied.

ABSTRACT BODY:

Purpose: To evaluate the changes in vascular parameters extracted from Ultra-Widefield Fluorescein Angiography (UWFA) of eyes with diabetic retinopathy that received as needed aflibercept injection (IAI) guided by real-time diabetic retinopathy severity scale (DRSS) or panretinal leakage index (PLI) in the PRIME trial.

Methods: The PRIME prospective trial randomized treatment (1:1) to Group 1 (DRSS-guided) and Group 2 (PLI-guided). The centered early-mid phase UWFA frame that captured the maximum vessel area was selected using an automated software for each visit. Selected frames were aligned using Image J and a common region of interest was determined to ensure the same retinal area was analyzed longitudinally. Retinal vasculature was extracted using a machine learning algorithm. Panretinal vessel area and features of panretinal vascular density (mean, median, variance and skewness) were calculated. Longitudinal changes from baseline to week 52 were assessed using paired t-test. Linear regression models adjusting for age, HbA1c and number of IAI were used to identify the factors correlated with the vascular change.

Results: Twenty-six eyes (Group 1 =12, Group 2 = 14) had data available at week 52. Baseline parameters including age (P=0.812), HbA1c (P=0.343) and vascular features (P >0.05) were not significantly different between the two groups except the skewness of vessel density (P=0.032). Group 1 received a mean of 6.7 (range 5-12) IAI and Group 2 received a mean of 7.2 IAI (range 4-9, P=0.591). The mean panretinal vessel area significantly decreased from $79.7 \pm 16.6 \text{ mm}^2$ to $74.62 \pm 14.3 \text{ mm}^2$ (P=0.001). Panretinal mean (P=0.002) and median (P<0.0001) vascular density

significantly decreased, and panretinal skewness of vessel density significantly increased ($P=0.020$). Median vascular density was positively correlated with the change in vessel area ($P=0.024$).

Conclusions: We demonstrated longitudinal progression of panretinal vascular loss in eyes with diabetic retinopathy treated with as needed aflibercept injections. Improved techniques to investigate vascular remodeling and vascular loss independently may provide more insight to ischemia progression in diabetic retinopathy and the impact of anti-VEGF treatment.

ABSTRACT BODY:

Purpose: Due to the Coronavirus Disease 2019 (COVID-19) pandemic, the AAO announced guidelines which recommended the cessation and postponement of all routine and non-urgent clinic visits and elective surgeries. While this decision was important for the public health effort to mitigate the COVID-19 pandemic, the effect this decision had on patients with exudative age-related macular degeneration (AMD) requiring frequent visits for treatment and monitoring is unknown. This retrospective observational study evaluates the effect that the delay in these visits and treatments had on this patient population.

Methods: This study identified patients with exudative AMD undergoing active treatment who had at least one appointment rescheduled due to the COVID-19 pandemic from March to May 2020 at a single institution. Data was collected from the last appointment prior to March 2020, and the first appointment following delay, and compared to age-matched controls from 2019 with the same diagnosis. Average length of time from postponement to follow-up was calculated. Patient demographics, visual acuity (LogMAR), and central macular thickness (CMT) on spectral-domain optical coherence tomography (OCT) were documented. Statistical analysis was conducted using t-tests with a two-tailed hypothesis.

Results: 69 patients (96 eyes) with exudative AMD met inclusion criteria. The mean (SD) age was 83.7 (8.3) years and 74% of patients were female. The mean (SD) number of days of treatment delay was 45.9 (38.6) days. Mean (SD) increase in CMT was 23.84 (82.71) μ m for the eye that had delayed treatment, which was statistically significant ($t=2.49$, $p=0.01$). Mean (SD) change in visual acuity was +0.11 (0.32) LogMAR, which was significantly worse ($t=3.42$, $p=0.001$).

Conclusions: Central macular thickness and visual acuity of treatment eyes were significantly worse as a result of the delay secondary to the COVID-19 pandemic. Further data collection over time is required to determine whether changes in CMT and VA are reversible over time. Further analyses of sequelae of delayed injections may reveal unique insights into subgroups which may be more tolerant of extended injection schedules.

Commercial Relationships Disclosure (Abstract): Felix Yemanyi: Commercial Relationship: Code N (No Commercial Relationship) | Zhongxiao Wang: Commercial Relationship: Code N (No Commercial Relationship) | Shuo Huang: Commercial Relationship: Code N (No Commercial Relationship) | Chi-Hsiu Liu: Commercial Relationship: Code N (No Commercial Relationship) | Yohei Tomita: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Blomfield: Commercial Relationship: Code N (No Commercial Relationship) | Zhongjie Fu: Commercial Relationship: Code N (No Commercial Relationship) | Jing Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pathological ocular neovascularization (NV) frequently results in vision loss and may be influenced by aberrant transport and metabolism of nutrients like amino acids in vascular endothelial cells (EC). Solute carrier (SLC) transporters are responsible for nutrient and metabolic sensing including amino acid transport. Dysregulation of key subfamilies of SLC transporters has been implicated in many metabolic and vascular diseases including neurovascular eye disorders. Here, we determined the specific role of SLC family 38 member 5 (SLC38A5) in pathological retinal NV using a mouse model of oxygen-induced retinopathy (OIR).

Methods: Neonatal C57BL/6J mice were exposed to 75% oxygen from postnatal day (P) 7 to P12 to induce OIR with pathological NV. Slc38a5 mRNA and protein expression levels were determined in OIR or room air control retinas (n=6/group) and laser capture microdissected retinal blood vessels (n=4/group). OIR was induced in Slc38a5 knockout (Slc38a5^{-/-}) and wild type (WT) control mice (n=5/group) and pathological retinal NV and vaso-oblivation (VO) were evaluated at P17. The effect of Slc38a5 deficiency on developmental retinal angiogenesis was analyzed in Slc38a5^{-/-} and WT mice (n=5/group) at P5 and P10. Glutamine uptake and expression of relevant angiogenic regulators were analyzed in human retinal microvascular ECs (HRMECs; n=3) transfected with siRNA targeting SLC38A5 (si-SLC38A5) or control SiRNA (si-Ctrl).

Results: Slc38a5 mRNA or protein levels were substantially upregulated (p<0.01) in P17 OIR whole retinas relative to normoxic control mice, and specifically enriched in pathological NV. Compared with WT controls, genetic deficiency of Slc38a5 significantly attenuated (p<0.01) pathological NV in OIR retinas without markedly affecting VO. Moreover, knockout of Slc38a5 significantly delayed (p<0.01) developmental angiogenesis in P5 and P10 retinas relative to WT. Compared with si-Ctrl, si-SLC38A5 transfected HRMECs exhibited profound decrease in glutamine uptake associated with downregulation of crucial angiogenic factors and their receptors (IGF2, ANG1 and 2, FGF2, VEGFR1 and 2, IGFR, FGFR2 and 3, TIE2).

Conclusions: These data show that SLC38A5 regulates pathological retinal NV potentially via controlling glutamine uptake and angiogenic regulators in vascular ECs. Thus, targeting SLC38A5 may aid the design of novel therapeutics to ameliorate pathological NV in vascular eye diseases.

TITLE: Modeling of intraocular lenses for patients with age-related macular degeneration by ray-tracing

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: U. Oberheide, S. Tölle, Technische Hochschule Köln, Köln, Nordrhein-Westfalen, GERMANY

Commercial Relationships Disclosure (Abstract): Uwe Oberheide: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Tölle: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macula degeneration (AMD) is the most common cause of blindness in people over 65 years in the western world. These people are permanently dependent on special visual aids in order to be able to perform visual tasks with reduced restrictions like magnifying glasses or screen readers. In the case of cataract formation special intraocular lenses dependent on the stage of disease might also help.

Methods: Three different intraocular lenses for patients with AMD were simulated in the Liou-Brennan eye model with a ray-tracing computational software based on literature and patent file data. First, a sulcus based add-on lens with a central add power for magnification in close range. Second, a fresnel prismatic capsular bag intraocular lens, which shifts the central scotoma to peripheral regions and third, a double lens system with a sulcus based lens with high positive dioptric power and a capsular bag lens with high negative dioptric power and slight decentrations to deflect light from the center.

Results: Magnification and beam deflections of the simulated lenses confirm the effect described by the manufacturers. To evaluate the effect for different stages of AMD snellen lines were projected on fictitious retinal defects of different sizes and compared to corresponding visual acuities. The sulcus based add-on lens is suitable for patients with small defects, whereas the two light deflecting lenses can provide a low level of visual acuity even for larger retinal defects. They are mainly limited by maximum angle of deflection and peripheral receptor density.

Conclusions: Dependent on the size of the retinal defect, the simulated lenses offer a possibility to maintain a functional visual acuity in patients with AMD. If the size of retinal disturbance is known the most suitable solution for the patient can be chosen.

TITLE: Correlation between the Standard Patient Evaluation of Eye Dryness (SPEED) and Ocular Pain Assessment Survey (OPAS) in Patients with Dry Eye Disease

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.C. Nau, A. McLeod, Korb and Associates, Boston, Massachusetts, UNITED STATES| M. Alfred, A.C. Nau, A. McLeod, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Meredith Alfred: Commercial Relationship: Code N (No Commercial Relationship) | Amy Nau: Commercial Relationship: Code N (No Commercial Relationship) | Andrew McLeod: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Subjective symptoms of dry eye are best monitored clinically with symptom questionnaires. The SPEED is a validated instrument that has been correlated to the severity of meibomian gland dysfunction (MGD). The OPAS is a validated questionnaire designed to measure ocular pain stemming from any origin. Many patients treated for MGD suffer from persistent symptoms, suggesting peripheral or central neuronal sensitization may be present. This study determined whether responses on the SPEED questionnaire were correlated with OPAS responses in a population diagnosed with evaporative dry eye.

Methods: Ninety-one patients (63 females; 27 males, average age 50.36 ± 16.38 years), diagnosed with MGD using standard structural and functional endpoints were enrolled in this IRB approved study at a private practice in Boston, MA, USA. All participants were given both the SPEED and OPAS questionnaires at a single scheduled dry eye follow up visit. Averages, standard deviations, and correlation coefficients were calculated.

Results: The average SPEED score was 11.45 (SD 5.89) out of a possible high score of 28. The average OPAS score was 46.25 (SD 38.88) out of a possible score of 190. SPEED scores were positively correlated to pain intensity over a period of 24 hours prior to the patient's appointment (correlation coefficient = 0.72) as well as over a period of 2 weeks prior to the appointment (correlation coefficient = 0.71). SPEED scores were positively correlated to the impact on the quality of life (correlation coefficient = 0.64) at 24 hours and 2 weeks prior to the appointment. Patients with a high SPEED score were also likely to have a high overall OPAS score at both timepoints (correlation coefficient = 0.76).

Conclusions: Patients with a high SPEED score were likely to have a high OPAS score, indicating that patients with MGD were experiencing pain that may not be accounted for by the SPEED questionnaire. Use of the OPAS as an adjunctive questionnaire could identify patients with either nociceptive or neuropathic corneal abnormalities who may be recalcitrant to treatment. Insights into the severity of affective disorders and issues related to the quality of life uncovered by the OPAS could lead to more personalized and effective treatment plans for evaporative dry eye.

ABSTRACT BODY:

Purpose: Variants in the PRPH2 gene have been previously linked to a plethora of inherited retinal degenerations (IRDs) including retinitis pigmentosa (RP), macular dystrophy (MD), adult vitelliform macular dystrophy, cone-rod dystrophy and many more. This study aimed to correlate known and novel pathogenic variants in PRPH2 with the resulting patient phenotypes.

Methods: Next-generation sequencing of known IRD-associated genes was performed for over 1000 Irish IRD participants with IRD phenotypes. Detailed clinical examinations of all participants carrying a candidate disease-causing variant in PRPH2 were performed to best determine the specific phenotype. The results of these examinations were then compared for differences and consistencies in disease manifestation.

Results: Potentially pathogenic mutations in the PRPH2 gene were established in 18 participants from 15 different families. This accounts for over 2 percent of all resolved genotypes which is consistent with larger studies of a similar nature. 8 out of 18 (44%) of PRPH2 patients presented with a predominantly macular degeneration, while the remaining 10 (56%) patients presented clinically with a RP phenotype. The most prominent variant in this cohort was c.634A>G, p.Ser212Gly. It was present in 8 patients and associated with an autosomal dominant RP (adRP) phenotype. These cases were additional to the previous study of this mutation by the team in a large Irish adRP pedigree. Nine additional PRPH2 variants were observed in the remaining 10 cases, one of which was a novel variant in exon 1 of the gene, c.440dupA, p.Gly148Trpfs*29. These remaining cases presented with a predominately cone-driven degeneration.

Conclusions: Studies such as this are particularly useful for genes associated with multiple phenotypes. The results may help to inform prognoses when dealing with the mutational spectrum of the PRPH2 gene. Although this study was performed on a relatively small subset of IRD participants, we did not observe significant phenotypic variability between patients with the same PRPH2 mutation. Given we are in the era of gene therapy, accurate genetic diagnoses have never been more important to identify needs and enable access to potential future therapeutics.

TITLE: Cluster-Randomized Controlled Trial of School-Based Visual Screening for Kindergarten Children

SESSION TITLE: Amblyopia: Translational Studies and Trials

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Nishimura, A.M. Wong, Ophthalmology & Vision Sciences, The Hospital for Sick Children, Toronto, Ontario, CANADA|M. Nishimura, D. Maurer, Psychology, Neuroscience & Behaviour, McMaster University, Hamilton, Ontario, CANADA|A.M. Wong, Ophthalmology & Vision Science, University of Toronto, Toronto, Ontario, CANADA|D. Maurer, Dalla Lana School of Public Health, University of Toronto, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Mayu Nishimura: Commercial Relationship: Code N (No Commercial Relationship) | Daphne Maurer: Commercial Relationship: Code N (No Commercial Relationship) | Agnes Wong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Some 10% of kindergarten children have undetected refractive errors and 3-5% need treatment to prevent amblyopia. In many jurisdictions, no universal screening program exists to detect these problems. We hypothesized that offering visual screening to children in senior kindergarten (i.e., age 5) would lower the later prevalence of amblyopia and other visual problems.

Methods: 50 high-needs schools in Toronto, Canada were randomly assigned to screening or no screening (i.e., status quo). Children in senior kindergarten (n = 1468) at 25 schools were screened using 3 tests (visual acuity, stereoacuity, photoscreener). 747 children (50.9%) passed screening, 551 children (37.5%) failed screening, 163 children (11.1%) were absent for screening, and 7 children (0.05%) opted out. Children who failed screening or were absent were offered a comprehensive eye exam (with cycloplegia) at school with an optometrist and it was attended by 408 (74%) and 49 (30%), respectively. If glasses were needed, they were dispensed at no cost (n = 225). When the children were in Grade 2 (~1.5 years after screening), visual acuity, stereoacuity, and uncyclopleged refractive errors (with photoscreener) were assessed in all 50 schools (n = 2715 children).

Results: The prevalence of amblyopia in Grade 2 did not differ between screened schools (8.6%) and non-screened schools (7.5%), $p = .10$. There was also no difference in the prevalence of visual problems other than amblyopia (45.1% versus 47.1%, $p = .51$). However, in screened schools more children were wearing glasses (5.0% versus 3.5%, $p = .05$), and more children reported that they had lost or broken their glasses (8.3% versus 4.7%, $p = .01$).

Conclusions: Visual screening is effective in identifying children with previously undiagnosed visual problems. However, the benefits may not translate to better visual outcomes 1.5 years later because of other factors (e.g., delays in seeing an optometrist, no support for buying or replacing glasses, parents' (and teachers') lack of understanding about the importance of treatment, lack of treatment compliance). In addition to visual screening, strategies to mitigate these factors are necessary to improve children's visual health.

TITLE: The long-term clinical efficacy of recombinant human nerve growth factor in the treatment of neurotrophic keratitis

SESSION TITLE: Cornea, cytokines, anti-inflammatory

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. bruscolini, M. Sacchetti, A. Moramarco, G. Albanese, A. Cerini, A. Iambiase, Sense Organs, Universita degli Studi di Roma La Sapienza Facolta di Medicina e Odontoiatria, Roma, Lazio, ITALY

Commercial Relationships Disclosure (Abstract): alice bruscolini: Commercial Relationship: Code N (No Commercial Relationship) | Marta Sacchetti: Commercial Relationship: Code N (No Commercial Relationship) | Antonietta Moramarco: Commercial Relationship: Code N (No Commercial Relationship) | Giuseppe Maria Albanese: Commercial Relationship: Code N (No Commercial Relationship) | Alberto Cerini: Commercial Relationship: Code N (No Commercial Relationship) | alessandro Iambiase: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Topical recombinant human nerve growth factor (rhNGF) is FDA-approved to treat patients with neurotrophic keratitis (NK), but current clinical trial data only encompasses 1 year of follow up. We hypothesize that a single course of rhNGF can have a long-term, persistent effect on NK healing and related clinical parameters. Therefore, we evaluated the long-term efficacy of rhNGF in a retrospective, consecutive, observational case series from a single-center setting over a 4-year period.

Methods: A total of 18 patients with stage 2 or 3 NK received rhNGF 20 mcg/ml 6 times a day for 8 weeks. Lesion recurrence during follow-up was evaluated at 12, 24, 36, and 48 months. Clinical efficacy was measured by Cochet-Bonnet aesthesiometer (corneal sensitivity), Schirmer's test (tear production), and Snellen chart [visual acuity (VA)] at baseline, end of treatment (8 weeks), and at 12, 24, 36, and 48 months after treatment was completed.

Results: Four patients experience recurrence during the study; 3 within the first 12 months and 1 within 36 months. Corneal sensitivity was significantly improved by the end of treatment (8 weeks) with improvements persisting throughout 48 months of follow-up ($P < 0.05$). Both tear production and VA were also significantly improved by the end of treatment (8 weeks) and these effects persisted at 12, 24, and 36 months ($P < 0.05$). Improvements in tear production and VA were also seen at 48 months; however, they were not statistically significant.

Conclusions: These results are consistent with our hypothesis that a single, 8-week treatment regimen of rhNGF can have long lasting clinical effects. The long-term clinical utility of rhNGF for the treatment of NK was demonstrated though the low rate of lesion recurrence along with improvements in corneal sensitivity, tear production, and VA over the course of 4 years.

TITLE: Demonstrating the intranasal route as a viable alternative to intravitreal administration of DARC

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Hill, V. Luong, L. Guo, M. Cordeiro, Institute of Ophthalmology, University College London, London, London, UNITED KINGDOM|M. Cordeiro, Imperial College Healthcare, Western Eye Hospital, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Daniel Hill: Commercial Relationship(s);UCL:Code F (Financial Support) | Vy Luong: Commercial Relationship: Code N (No Commercial Relationship) | Li Guo: Commercial Relationship: Code N (No Commercial Relationship) | M Francesca Cordeiro: Commercial Relationship(s);Santen:Code F (Financial Support);UCL Technology Fund:Code F (Financial Support)

ABSTRACT BODY:

Purpose: DARC (detection of apoptosing retinal cells) is an annexin-based technology that fluorescently marks stressed and dying cells in the retina, allowing in vivo assessment of retinal pathology using a confocal laser scanning ophthalmoscope. As the retina is an integral part of the central nervous system, imaging intravitreally-injected DARC facilitates a unique in vivo assessment of neuronal health which is applicable to a wide range of neurodegenerative animal models. To reduce discomfort associated with intravitreal administration and potential complications, we investigated whether intranasal delivery of fluorescent annexin can be used as an alternative route in DARC treatment.

Methods: 10 female 3xTg transgenic Alzheimer's disease (3xTg-AD) model mice were used as a model of retinal cell death and 10 C57 mice were used as healthy controls (all animals from The Jackson Laboratory). Intranasal administration of DARC involved restraining the animal and carefully administering 5 µL of aqueous-buffered DARC to each nostril, using a p20 pipette. Retinas were imaged at baseline and 2 hours after intranasally administered DARC, in vivo, at the 488 nm wavelength, using a Multiline Spectralis OCT. After in vivo imaging, animals were sacrificed, and the retinas were extracted, fixed, and imaged with fluorescent microscopy. Automated spot counts were collected for both in vivo and ex vivo images.

Results: Administration of DARC via the intranasal route allowed discrimination between healthy and diseased animals both in vivo and ex vivo (significantly higher spot count in disease; $p < .05$) and produced images of similar quality (fluorescence brightness and definition) to those acquired from intravitreally administered DARC retinas. It was found that a higher intranasal DARC dose was required compared to intravitreal administration (approximately 10-fold increase).

Conclusions: The intranasal route has been demonstrated as a viable alternative to intravitreal administration of DARC, thus helping to refine animal procedures to minimise discomfort. Future work should focus on optimising an intranasal buffer to enhance delivery and reduce necessary DARC dose, followed by expansion to rat models. In the long term, standardisation of administration route to intranasal across animal and human applications may help to improve the applicability of DARC-enabled animal experiments to the clinic.

ABSTRACT BODY:

Purpose: RPE dysfunction and choroidal neovascularization (CNV) are the major hallmarks of neovascular AMD (nAMD). We previously identified PGC-1 β , a master regulator of mitochondrial function, as a novel stress response gene in RPE positively associated with nAMD. However, the unique pathologic functions of PGC-1 β in RPE during nAMD remained unclear. We hypothesize that PGC-1 β promotes CNV and nAMD by driving RPE toward a pro-angiogenic and pro-inflammatory profile.

Methods: Expression of PGC-1 β in human AMD and age-matched control eyes was analyzed by immunohistochemical staining. Time-course expression of PGC-1 β was measured in murine RPE/choroid in the model of laser-induced CNV. PGC-1 β was overexpressed in RPE of adult WT mice using subretinal injection of pLV-PGC1B. Funduscopy, SD-OCT, TEM, F-actin and IB4 staining of whole mount RPE was performed 4 and 8 weeks after injection. PGC-1 β was induced in matured ARPE-19s using a Tet-responsive adenovirus and doxycycline exposure. Conditioned media collected on PGC-1 β expressing RPE was analyzed using protein arrays.

Results: PGC-1 β was strongly induced in RPE surrounding the fibrovascular lesions in nAMD eyes while no expression could be detected in RPE of both control and atrophic AMD samples. Following laser induction of CNV in mice, PGC-1 β was rapidly induced in the RPE/choroid complex at day 3 (n=6, P<0.05), peaking at day 7 (n=6, P<0.001) post-laser. PGC1B overexpression in the RPE of adult mice led to reduction in total retinal thickness (n=5, P<0.05), pigmentary changes and RPE disorganization characterized by pathological morphology (89% VS 8%, n=4) and larger area (n=4, P<0.05) when compared to pLV-GFP controls. Ultrastructural analysis of PGC-1 β induced RPE showed disordered apical microvilli, shorten basal infoldings, reduced melanosomes and accumulation of undigested outer segments. Vascular leakage and spontaneous CNV were observed in 20% of pLV-PGC-1 β injected eyes (n=15). Analysis of secreted proteins from PGC-1 β expressing RPE revealed the induction of the pro-angiogenic and pro-inflammatory factors AREG (P<0.05), HB-EGF (P<0.05), bFGF (P<0.05), IL8 (P<0.0001) and prolactin (P<0.01) (n=4).

Conclusions: We identify PGC-1 β as a novel biomarker of nAMD. Pathological induction of PGC1B promotes RPE dysfunction and secretion of pro-angiogenic factors, leading to nAMD-like retinal degeneration and CNV in mice.

ABSTRACT BODY:

Purpose: Reduction in macular sensitivity (MS) has been demonstrated in highly myopic (HM) eyes with myopic macular degeneration (MMD) but the correlation with retinal structural changes is still unclear. We aim to evaluate the MS in eyes with various severities of MMD and its association with anatomical parameters of the retina on optical coherence tomography (OCT) and OCT-angiography (OCTA).

Methods: This is a prospective, observational study that enrolled 138 HM eyes from 82 adult participants from the Singapore National Eye Centre High and Pathologic Myopia clinic. The MS were evaluated using Microperimeter MP-3 comprised of 33 points covering 12° diameter of the macular area. The retinal perfusion density (PD) and retinal thickness (RT) were measured from the 3×3mm² macular scan obtained by the PLEX Elite 9000 swept source OCTA. Pair-wise differences of MS between varying severities of MMD, and the vasculature-function and structure-function relationship were evaluated by the multivariable linear mixed models, with adjustment of age and axial length (AL).

Results: Out of 138 eyes, 53 eyes (38.4%) had tessellated fundus, 26 eyes (18.8%) had peripapillary diffuse chorioretinal atrophy (PDCA), 37 eyes (26.8%) had macular diffuse chorioretinal atrophy (MDCA), and 22 eyes (15.9%) had patchy or macular atrophy. MS significantly correlated with BCVA ($r=0.32$, $P<0.001$). Reduction in MS occurred in MDCA ($P<0.001$), and declined with increasing severity of MMD ($P<0.001$), while changes in BCVA were not significant ($P>0.04$). Older age ($\beta=-0.08$, $P<0.001$), longer AL ($\beta=-0.32$, $P=0.005$), worse MMD ($\beta\leq-2.16$, $P<0.001$), presence of staphyloma involving the macula ($\beta\leq-2.98$, $P<0.001$) and fuch's spot ($\beta=-1.58$, $P<0.04$) were independently associated with declined MS. Decreased deep retinal PD in MMD ($\beta=0.14$, $P=0.004$), but not superficial retinal PD ($P=0.33$) or RT ($P=0.51$), was significantly associated with reduction in MS.

Conclusions: We found a vasculature-function relationship between visual function and deep retinal perfusion density as measured by microperimetry and OCTA respectively. These parameters may serve as early indicators of structural and functional abnormalities in highly myopic eyes with MMD.

TITLE: The in vitro Effect of Various Selenium Disulfide Concentrations on Demodex Folliculorum

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Heczko, C. Schell, A. Pansick, M. Vincent, N. Radova, R. Stein, J. Quintero, H. Perry, Ophthalmology, Nassau University Medical Center, East Meadow, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joshua Heczko: Commercial Relationship: Code N (No Commercial Relationship) | Carson Schell: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Pansick: Commercial Relationship: Code N (No Commercial Relationship) | Maria Vincent: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Radova: Commercial Relationship: Code N (No Commercial Relationship) | Rebecca Stein: Commercial Relationship: Code N (No Commercial Relationship) | Jose Quintero: Commercial Relationship: Code N (No Commercial Relationship) | Henry Perry: Commercial Relationship(s);Azura:Code C (Consultant)

ABSTRACT BODY:

Purpose: To evaluate the effectiveness of varying concentrations of selenium sulfide in affecting Demodex folliculorum.

Methods: Sixty-five eyelashes with live Demodex from 29 patients seen at the Nassau University Medical Center (17 patients) and Ophthalmic Consultants of Long Island (12 patients) were observed for 90 minutes under 0.1%, 0.5%, 1.0%, and 4.0% selenium sulfide with either carboxymethyl cellulose (CMC) solution or vaseline ointment as excipients. Positive and negative controls were also evaluated as separate solutions of CMC, vaseline, basic saline solution, 50% tea tree oil, and 100% tea tree oil.

Results: Demodex behavior was affected by concentrations as low as 0.1%. Deaths in the selenium sulfide reagents were observed in the the 4.0% selenium sulfide solution with CMC (36.4% kill rate, 4 of 11 Demodex, average time of death 17.5 minutes) and 4.0% selenium sulfide with vaseline ointment (12.5%, 1 of 8 Demodex, time of death 75 min). No Demodex deaths were witnessed in the other treatment groups. However, Demodex mites in concentrations as low as 0.1% were noted to move away from the selenium.

Conclusions: Selenium sulfide has shown efficacy in killing Demodex at a 4% concentration with the CMC solution and mild cidal activity with 4% vaseline. Concentrations as low as 0.1% show avoidance by Demodex folliculorum suggesting that it might function as a natural insect repellent.

ABSTRACT BODY:

Purpose: Blur perception is influenced by the eye's optical quality during emmetropization. We measured sensitivity to different types and levels of simulated optical blur and optical quality across the visual field in young children with normal vision.

Methods: Children ($n=27$, 7.86 ± 0.91 yrs) with functional emmetropia ($SE\ OD +0.94\pm0.55D$) participated in 2 tests. (1) Blur discrimination thresholds were measured with an adaptive 4AFC task previously used in adults. Dead leaves stimuli were blurred with different pedestal levels and increments of Defocus (DEF) or Spherical Aberration (SA) kernels beyond 0° , 6° , or 12° eccentricity at 40cm. Participants chose which quadrant appeared blurriest. Blur discrimination thresholds were fit with a 2-parameter (Intrinsic Blur, Blur Criteria) dipper function. (2) Optical quality across the central horizontal $\pm 30^\circ$ was assessed using a scanning aberrometer at 4m and 40cm viewing distances. Strehl ratios, defocus and primary SA were computed for 4mm pupils. Outcomes were analyzed with One-way ANOVAs and correlations with axial length (AXL, 22.78 ± 0.74 mm).

Results: (1) Intrinsic blur showed an overall effect of eccentricity (DEF & SA, $p<0.001$), significantly decreasing for 12° vs. 6° (DEF $p=0.003$, SA $p=0.001$) and 0° (DEF $p<0.001$, SA $p=0.001$), but no differences between 6° and 0° . Blur Criteria showed no general effect of eccentricity. Longer eyes showed lower Intrinsic Blur (DEF $p=0.040$, SA $p=0.014$) and Blur Criteria (SA $p=0.032$). (2) Strehl ratios also showed eccentricity-dependence ($p=0.006$), with better quality in the central 12° ($p=0.014$) and nasal retina ($p=0.004$) that increased with AXL ($p=0.003$). Defocus was more negative (hyperopic) peripherally ($p<0.001$). Primary SA showed no effect of eccentricity but was smaller in longer eyes ($p<0.001$). (3) For 0° ($p=0.009$) and 6° ($p=0.020$), Blur Criteria for DEF was correlated with the eye's defocus. For 12° , Blur Criteria for SA was correlated with the eye's SA ($p=0.050$).

Conclusions: Elevated Intrinsic Blur at 12° but not between 0° and 6° indicate a critical role of the 6- 12° retinal area in blur decoding. A similar pattern was observed of eccentricity dependence for optical quality. These correlations indicate a possible relationship of defocus within the central 12° and SA beyond 12° . Less positive SA was found in longer eyes with less hyperopia, these eyes (at higher risk of developing myopia later) also show lower sensitivity to blur.

ABSTRACT BODY:

Purpose: High-fat diets (HFD) affect the pathophysiology of retinal diseases including, age-related macular degeneration (AMD), diabetic retinopathy and glaucoma by altering the gut microbiome which can directly affect the retinal transcriptome as already shown by our team. However, the effects of diet independent of gut microbiome on the retinal transcriptome are currently unknown. The purpose of this study is to investigate if HFD can have direct effects on retinal gene expression and pathways independently of the gut-microbiome by comparing the retinal transcriptome of germ-free (GF) mice on a normal diet (ND) to GF mice on HFD.

Methods: RNA was extracted from whole retinas (4 per group) from 15-weeks old GF C57BL/6J male mice fed ND and HFD (23% saturated fat for 8 weeks). RNA-seq was performed on NovaSEQ6000 using the paired-end method. Differentially expressed genes (DEGs) were identified (cutoff p-value <0.01) and functional enrichment network analyses (cutoff FDR B&H <0.05) were created for the DEGs using Toppgene.

Results: After correction of the raw data, 20,287 genes were selected for differential gene analysis. In GF-HFD group, a cohort of 1195 DEGs were identified, 801 were upregulated and 394 were downregulated. Key genes involved in oxidative phosphorylation, the citric acid cycle and electron transport chain were affected. Cellular organelle functions affected by HFD included the spliceosomal complex, mitochondrion, endoplasmic reticulum (ER). Enrichment analysis showed that pathways associated with neurodegenerative disorders including Parkinson's disease, Alzheimer's disease, and Huntington's disease were affected by HFD. Notable DEGs include vascular endothelial growth factor receptor 3 (FLT4) and receptor accessory protein 1 (REEP), which play key roles in AMD and retinal degeneration, respectively.

Conclusions: This study demonstrates novel data that diet can directly modulate the retinal transcriptome independently of the gut microbiome. Unbiased analysis of the retinal transcriptome identified genes and pathways involved in retinal metabolism and retinal degenerative disorders affected by HFD alone. Future studies are needed to elucidate the complex relationship between retinal disease, diet and the gut microbiome.

ABSTRACT BODY:

Purpose: In this study, we investigated to establish RB1-mutant fibroblast cells by cytosine base editing, characterize them, and treat adenine base editors to correct the mutation.

Methods: Fibroblasts were treated plasmids encoding cytosine base editors, and cells with the intended RB1 mutation (p.R552X) were collected. The following experiments characterized wild-type, heterozygous, and homozygous RB1 mutant cells: 1) quantitative real-time polymerase chain reaction of RB1 mRNA, 2) Western blot, 3) flow cytometry for cell cycle analysis, and 4) cell proliferation assay. Then, each cell was treated with plasmids encoding adenine base editors to investigate the potential of base editing in the context of retinoblastoma.

Results: We successfully established fibroblast cells with heterozygous and homozygous RB1 mutation. Wild-type, heterozygous, and homozygous RB1 mutant cells demonstrated differential characteristics of RB1 mRNA expression, RB1 protein expression, cell cycle distribution, and proliferative potential. We found that adenine base editing of RB1 mutant cells induced the read-through of nonsense mutation.

Conclusions: In conclusion, we suggest that CRISPR-associated base editing might be a tool to mimic the variants in patients with retinoblastoma and correct them for the reversal of disease-related phenotypes.

TITLE: An investigation of ocular surface intracellular cytokines in asymptomatic versus symptomatic soft contact lens wearers using a novel mass cytometry method.

SESSION TITLE: Cytokines, growth factors, anti-inflammatory

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R. Cant, Pharmacy and Optometry, The University of Manchester Faculty of Biology Medicine and Health, Manchester, Manchester, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Rachel Cant: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular discomfort is the primary reason for discontinuation from contact lenses. This discomfort may be mediated by ocular surface inflammation, although its precise molecular basis remains unclear. We have developed a novel mass cytometry panel capable of determining surface markers (enabling cell identification) and levels of intracellular cytokines in cells removed from the ocular surface by impression cytology. We sought to identify the biomarkers associated with contact lens discomfort in a group of symptomatic soft contact lens wearers.

Methods: Ten asymptomatic (CLDEQ-8 score ≤ 10) and 10 symptomatic (CLDEQ-8 score ≥ 20) soft contact lens wearers were recruited. Impression cytology samples were taken from the bulbar conjunctiva and central upper eyelid margin using an Eyeprim device (OPIA Technologies, France). Cells were removed from the Eyeprim membrane and stained with a mass cytometry panel targeting 30 cell surface markers or intracellular proteins. This panel allowed the identification of a range of immune cells, epithelial cells, inflammatory proteins and extracellular matrix remodelling proteins. Samples were analysed using mass cytometry and Cytokit was used to assess protein expression levels.

Results: We observed a x2.2 increase in matrix metalloproteinase-9 (MMP-9), x1.1 increase in macrophage- derived chemokine (MDC) and x2.0 increase in interleukin-23 (IL-23) in the eyelid margin epithelial cells of symptomatic compared to asymptomatic lens wearers. A x1.4 increase in MMP-9 was also observed in the conjunctival epithelial cells of symptomatic compared with the asymptomatic wearers. Furthermore, a decrease in the anti-inflammatory cytokine IL-10 was observed in eyelid margin epithelial cells of symptomatic compared with asymptomatic subjects.

Conclusions: Increased levels of MMP-9, MDC, IL-23 and decreased levels of IL-10 were observed in the eyelid margin and conjunctiva of symptomatic compared with lens asymptomatic soft lens wearers. These have potential as biomarkers for contact lens discomfort, and indeed some of these mediators have previously been implicated in the inflammatory events underlying dry eye disease. This methodology enables measurement of precise levels of inflammatory markers inside specific cell types, making it ideal for the investigation of the ocular surface.

ABSTRACT BODY:

Purpose: Various pathways and cytokines are implicated in pathogenesis of diabetic macular edema (DME). Recent work from our group has identified computational imaging biomarkers (CIBs) of vessel tortuosity from quantitative

ultra-widefield angiography (UWFA) and texture patterns from optical coherence tomography (OCT) that are associated with response to anti-VEGF therapy in DME. The goal of this study was to establish the underlying molecular basis of the radiomic features. Hence, we sought to evaluate the association between underlying expression of specific cytokines and CIBs from UWFA and OCT scans.

Methods: The IMAGINE study is post-hoc assessment of aqueous cytokine expression and in-depth assessment of the imaging studies obtained throughout the DAVE DME study. The study included 24 eyes from 20 patients. The concentrations of cytokines including VEGF, ANG2, MCP-1, IL-6, and IL-8 were measured. 598 texture-based radiomic features were extracted from the baseline OCT images for heterogeneity assessment and 156 morphological and vessel tortuosity features were extracted from the baseline UWFA scans. Biclustering allows simultaneous clustering of rows (patients) and columns (features) of a data matrix and was employed on UWFA and OCT features to identify eyes with similar morphological phenotypes. Pearson correlation coefficients (R) assessed the correlation between the OCT and UWFA features that were identified by the most consistent BCs and the cytokines.

Results: Strong correlations were identified between VEGF and 7 morphology-based FA features ($R=0.44-0.51$, $p<0.05$), 1 tortuosity based FA feature ($R=0.45$, $p=0.004$) and 2 OCT-derived intraretinal fluid (IRF) Laws texture features ($R=0.48-0.49$; $p=0.01$). Strong correlation between IRF Laws texture feature and ANGPTL4 ($R=0.52$, $p=0.008$) were identified. Additionally, IRF Laws feature and u-PAR ($R=0.41$, $p=0.04$), HGF ($R=0.47$, $p=0.01$) and TIMP-1 ($R=0.40$, $p=0.004$) were also observed.

Conclusions: This study demonstrates a link between multiple radiomics-based CIBs and pathway-associated cytokine expression in eyes with DME, including a strong link between VEGF levels with retinal leakage morphology and vessel tortuosity.

TITLE: Quantification of near word acuity thresholds with and without flankers for individuals with keratoconus

SESSION TITLE: Aspects of Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Rijal, D.R. Coates, J.D. Marsack, Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sujata Rijal: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Coates: Commercial Relationship: Code N (No Commercial Relationship) | Jason Marsack: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Residual aberrations are present in the eyes of individuals with keratoconus, even when the eyes are “well corrected” by today’s clinical standards. High contrast visual acuity (VA), the most common method to assess visual performance, does not reflect the full spectrum of challenges that accompany real-world visual tasks. This study aims to move beyond VA and quantify threshold word acuity for “well corrected” individuals with keratoconus.

Methods: To date, 2 typically-sighted individuals (28 and 34 years old) and 1 individual with keratoconus (45 years old) have been recruited. VA was measured at distance with logMAR charts. Residual aberrations were quantified at distance with a wavefront sensor. In addition, subjects were asked to monocularly read words (with and without 4 flanking words) aloud at a 40cm test distance. Ten trials of each condition (5 font sizes and 5 durations at 100% contrast) were randomly presented using Arial font, for a total of 500 trials/eye. Psychometric functions were fitted and thresholds were defined as 80% correct for each font size and duration.

Results: Higher-order root mean square (HORMS) for a 3mm pupil was within normal limits (mean \pm SD = $0.04 \pm 0.02 \mu\text{m}$) for both eyes of the typically-sighted individuals, and elevated for the individual with keratoconus (OD: $0.21 \mu\text{m}$ and OS: $0.14 \mu\text{m}$). All individuals were able to achieve the common clinical standard of 0.00 logMAR (20_{20}) in both eyes. As the word presentation duration was increased to a maximum of 1 second, threshold word acuity decreased with an average slope of -0.17 ± 0.05 (logMAR/log(msec)). There was a moderate correlation between threshold word acuity and HORMS ($r^2 = 0.43$). There was no systematic difference between threshold word acuity with and without flankers for typically-sighted individuals. For the one individual with keratoconus, there was a trend of threshold word acuity being worse in the presence of flankers than without flankers, as HORMS increased.

Conclusions: As stimulus duration is increased, threshold word acuity decreases. In the two eyes with elevated HORMS, threshold word acuity was reduced compared to typical. Flankers impacted threshold levels for the 2 eyes with elevated HORMS. The study is ongoing, and will include more highly aberrated eyes, a range of disease severity and low contrast words.

ABSTRACT BODY:

Purpose: Alzheimer's disease is characterized by accumulation of amyloid-beta plaques and neurofibrillary tangles of Tau protein in the brain, associated with neurodegeneration and deficits in memory and cognition. Retinal pathology has been reported with Alzheimer's disease as well. Here, we aimed to determine whether the TgF344-AD transgenic rat model of Alzheimer's disease, which develops progressive brain pathology and cognitive dysfunction similar to patients with Alzheimer's disease, shows retinal changes associated with cognitive deficits.

Methods: Retinal function was assessed in TgF344-AD transgenic rats (n=7) and wild type littermate controls (Fischer 344 background, n=5) using electroretinography (ERG) at 6 and 15 months of age. Spatial cognition (spontaneous alternation) and exploratory behavior (number of entries) were assessed via Y-maze at 6 and 15 months. Spatial memory was assessed via Barnes maze at 15 months. Rats were euthanized at 16 months, and brains, retinas, and serum were analyzed for amyloid precursor protein (APP) as a marker of disease progression.

Results: TgF344-AD rats exhibited significant cognitive deficits at 15 months of age as measured by Barnes maze ($p < 0.01$), but no changes in spontaneous alternation or exploratory behavior in the Y maze. Significant delays in ERG oscillatory potential (OP) implicit times were observed at 6 months with bright flash ($p < 0.001$) and at 15 months with dim and bright flashes ($p < 0.01$ and $p < 0.001$, respectively). A significant delay was also observed for positive scotopic threshold response (STR) at 15 months ($p < 0.01$). Increased levels of APP were observed in both brains and retinas from TgF344-AD rats.

Conclusions: As expected, cognitive decline was observed in the TgF344-AD transgenic rat model of Alzheimer's disease. Notably, retinal function may be useful in predicting and diagnosing changes in the brain with Alzheimer's disease, as we observed deficits in ERG components generated by the inner retina (OPs) and retinal ganglion cells (STR), suggesting these retinal cell types are vulnerable to Alzheimer's pathology. This work provides a basis for pursuing non-invasive retinal analysis, including ERG, as a way to stage Alzheimer's disease.

ABSTRACT BODY:

Purpose: The intraretinal location of hemorrhage in eyes with central retinal vein occlusion (CRVO) may provide important information regarding disease severity and visual acuity outcomes. The purpose of this post-hoc evaluation is to investigate the reproducibility of grading superficial (nerve fiber layer) vs deep retinal hemorrhage on color fundus photographs (CFP) in participants from the Study of COmparative Treatments for REtinal Vein Occlusion 2 (SCORE2).

Methods: Baseline three-field CFP of 54 study eyes in the SCORE2 cohort were evaluated. A grid was developed to differentiate 9 distinct subfields (Figure 1). Expert graders evaluated for percent involvement of superficial hemorrhage in each of the 9 subfields, and evaluated for percent involvement of deep hemorrhage in 8 subfields, excluding the optic disc. Graders also evaluated eyes for optic disc swelling, disc pallor, cotton wool spots, and retinal folds. Reproducibility was measured using predetermined parameters: exact agreement, agreement within 5%, 10% and 20%. Intergrader reproducibility was calculated using kappa statistics.

Results: All 54 study eyes had gradable images. Average intergrader reproducibility among fields with superficial hemorrhage was 36.6% exact agreement, 56.4% within 5%, 67.5% within 10%, and 85% within 20%. Reproducibility among fields with deep hemorrhage was 66.4% exact agreement, 88% within 5%, 93.1% within 10%, and 98.8% within 20%. Across all fields, the weighted kappa score range for grading percent superficial and deep hemorrhage was 0.43 – 0.71 and 0.49 – 0.69, respectively. Kappa scores for the assessments of disc swelling, disc edema, cotton wool spots, and retinal folds were 0.34, 1.0, 0.8, and 0.64, respectively.

Conclusions: In SCORE2, a novel method for grading area of superficial and deep retinal hemorrhage demonstrated agreement within 20% in ≥85% of the eyes. Intergrader reproducibility for both superficial and deep hemorrhage was moderate to substantial, depending on the field graded. Employing this method in a large scale longitudinal analysis will help define the role of retinal hemorrhage location as a predictive biomarker of therapeutic and visual outcome in CRVO.

ABSTRACT BODY:

Purpose: The photopic negative response (PhNR) is a late component of the light-adapted electroretinogram (ERG), and derives from retinal ganglion cells. We recorded PhNRs from idiopathic intracranial hypertension (IIH) patients and explored associations with severity.

Methods: ERGs were recorded, following mydriasis and exposure to room light, using conductive fibre electrodes with a portable device (RETeval, LKC technologies, MD USA). Red flashes (1.0 cd.s/m^2) were delivered, at 3.4 Hz, on a 10 cd.s/m^2 blue background (averages from 400 flash presentations). The device software gave PhNR amplitudes (at 72 ms or as a ratio to b-wave). ERGs were assessed for drift, noise and reproducibility. The eye with a better quality trace was chosen for PhNR analysis; if both were equally good, the eye with poorer visual field function was chosen. IIH severity was determined using optical coherence tomography-derived retinal nerve fibre layer (RNFL) thickness and Modified Frisén scale (MFS): mild (MFS1-2), severe (MFS \geq 3, RNFL thickness $>$ 150, or atrophic) or in remission (resolved with no atrophy). Patients without papilloedema deemed not to have IIH or any other eye conditions act as controls. P_{72} and p-ratio were compared in the four groups (Kruskal-Wallis), with each group also compared to control (Mann-Whitney).

Results: Of 99 patients, 86 (7 control, 79 IIH) were included; 13 were excluded (9 poor quality ERG, 4 alternative diagnosis). 91% of IIH patients were female; median (IQR) age was 33 (27-39), BMI 34.8 (30.4-40.0). 86% of controls were female; median (IQR) age was 52 (31-64), BMI 34.5 (32.3-42.2). P_{72} and p-ratio differed significantly across groups with a trend towards smaller PhNR amplitudes in more severe IIH, $p=0.0417$ and $p=0.0389$ respectively. Largest differences were observed between severe IIH and controls (median P_{72} : -3.4 vs. -7.1, $p=0.0096$, and median p-ratio: 0.12 vs. 0.23, $p=0.0073$). Comparing severe and mild IIH groups, p-ratio differed significantly (0.12 vs. 0.17, $p=0.014$), but not P_{72} (-3.4 vs. -6.0, $p=0.064$). Patients in remission and controls exhibited non-significant differences (median P_{72} : -5.0 vs. -7.1, $p=0.19$, and median p-ratio: 0.18 vs. 0.23, $p=0.48$).

Conclusions: We found associations between PhNR parameters and disease severity in a large IIH cohort. The PhNR could potentially provide additional assessment of disease severity in these patients.

ABSTRACT BODY:

Purpose: To demonstrate non-inferiority of iLux when compared to LipiFlow in change from baseline in the Impact of Dry Eye on Everyday Life (IDEEL) questionnaire Symptom Bother (SB) module score at 12 months post-single treatment in Meibomian gland dysfunction (MGD) subjects with evaporative dry eye (EDE).

Methods: This was a prospective, randomized, assessor-masked, parallel-group study comparing iLux to LipiFlow in subjects with EDE. Subjects with IDEEL-SB module scores of >16, non-invasive tear break-up time scores of <10

seconds, and Meibomian gland score ≤ 12 in lower eyelids were randomized for bilateral treatment in a 1:1 ratio to receive a single treatment with either SYSTANE iLux or LipiFlow. Subjects attended a total of 8 visits: Screening/Baseline, Treatment, 2-Week, 1-Month, 3-Month, 6-Month, 9-Month and 12-Month /Exit. At each time point, a paper copy of the IDEEL-SB module was provided to each patient for completion without assistance. Non-inferiority in IDEEL-SB module scores (change from baseline) between iLux compared to LipiFlow was assessed at all time points.

Results: A total of 227 treated (iLux 114; LipiFlow 113) patients completed the 12-month follow-up. Treatment difference (iLux minus LipiFlow) and the corresponding one-sided 95% upper confidence limit (UCL) were computed. Non-inferiority was declared if the UCL was less than 12. Non-inferiority of iLux compared to LipiFlow in change from baseline in IDEEL-SB scores was achieved at 2 weeks (2.56), 1 month (3.00), 3 months (2.21), 6 months (2.23), 9 months (1.92), and 12 months (2.42).

Conclusions: This study demonstrated that SYSTANE iLux MGD Thermal Pulsation System is non-inferior to LipiFlow Thermal Pulsation System in the change in IDEEL-SB scores up to 12 months following a single treatment.

ABSTRACT BODY:

Purpose: This post-hoc analysis of the HARBOR trial in nAMD was conducted to determine if SRF resolution in eyes treated with ranibizumab had a concomitant deleterious effect on best-corrected visual acuity (BCVA).

Methods: Eyes from the pooled arms of the HARBOR trial (NCT00891735) were included in the analysis if SRF, with or without intraretinal fluid (IRF), was present at baseline and fluid resolved during the course of the study, based on spectral-domain optical coherence tomography. Among those eyes that also had IRF present at baseline, IRF must have resolved at least one month prior to SRF resolution. Change in ETDRS BCVA was determined by comparing the BVCA in the month before SRF resolution with BCVA in the month SRF resolution was first detected. Patients who lost vision with SRF resolution, defined as a loss of ≥ 4 ETDRS letters, were compared with those who gained/maintained vision, defined as a loss of < 4 ETDRS letters. Outcomes at M12 and 24 were analyzed in eyes with no SRF recurrence after going dry.

Results: Three hundred and forty-nine eyes met inclusion criteria. Mean time to first detection of SRF resolution was 2.3 months. Between the month prior to dry and the month of SRF resolution, 11% (38/349) lost ≥ 4 ETDRS letters (mean -9.0 letters [-10.9, -7.1]) and 89% (311/349) of eyes gained/maintained BCVA (mean 6.3 letters [5.5, 7.0]; Table 1). Among eyes that had no SRF recurrence after going dry, those that lost ≥ 4 ETDRS letters, compared to those that maintained/gained, at the time of SRF resolution had reduced visual outcome gains from baseline at M12 (1.8 vs 13.1 letters) and M24 (0.5 vs 12.8 letters; Table 2). Once dry, there was little difference between groups in the BCVA gained from the month first dry to M12 or M24 (7.2 vs 4.2 and 5.8 vs 4.0 letters, respectively).

Conclusions: Eleven percent of eyes lost BCVA at the time of SRF resolution, and these eyes had reduced long-term visual outcomes at M12 and M24. Loss of ≥ 4 ETDRS letters at the time of SRF resolution may portend worse long-term visual outcomes. Treating eyes to SRF resolution may be deleterious in some. Further studies are warranted.

TITLE: MAIA microperimeter for central vision loss: Repeatability of short-duration fixation stability measurements

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Pyatova, S. Markowitz, Ophthalmology and Vision Science, University of Toronto, Toronto, Ontario, CANADA|R. Devenyi, Ophthalmology, Toronto Western Hospital, Toronto, Ontario, CANADA|L. Tarita-Nistor, Krembil Research Institute, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Yulia Pyatova: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Markowitz: Commercial Relationship: Code N (No Commercial Relationship) | Robert Devenyi: Commercial Relationship: Code N (No Commercial Relationship) | Luminita Tarita-Nistor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Fixation stability has become an important outcome measure for evaluating intervention and/or disease progression in patients with central vision loss. The most common instruments to assess fixation stability in these patients are the Nidek MP (1 and 3) and MAIA microperimeters. Repeatability of short-duration fixation stability has been reported for the MP-1, but not for MAIA. The purpose of this cross-sectional study was to examine the repeatability of fixation stability measured with MAIA microperimeter, for a fixed 20s-duration.

Methods: Fixation stability was evaluated in 32 eyes of 20 patients (8F/12M, mean age 76 ± 8 years) with macular diseases using MAIA and the MP-1 microperimeters, in a random order, twice for each eye and with each instrument. Fixation duration was 20s and all tests were performed in the same day. Based on visual acuity, 17 eyes were identified as the better eye (BE) and 15 as the worse eye (WE). Fixation stability was quantified with the 95% bivariate contour ellipse area (BCEA). The BCEA was recorded from the examination output as well as calculated from the raw data. A log transformation was applied to the BCEA values. Bland-Altman plots were used to determine the bias and the 95% limits of agreement.

Results: For MAIA, the bias and the 95% limits of agreement for the BE, the WE, and the overall sample were 0.1 (-0.56 to 0.76) $\log \text{deg}^2$, 0.0 (-0.72 to 0.72) $\log \text{deg}^2$, and 0.05 (-0.64 to 0.74) $\log \text{deg}^2$, respectively. For the MP-1, these values were 0.06 (-0.46 to 0.58) $\log \text{deg}^2$, 0.03 (-0.33 to 0.38) $\log \text{deg}^2$, and 0.04 (-0.41 to 0.49) $\log \text{deg}^2$. The expected number of raw data points recorded over a 20s interval was 500, but the actual numbers ranged from 241 to 496 for MAIA and from 486 to 512 for the MP-1. Far outliers in the raw data were included in the BCEA values reported in the output for MAIA, but not for the MP-1.

Conclusions: The 95% limits of agreement for 20s-fixation stability are larger for MAIA than for the MP-1. Unlike the MP-1, MAIA includes outliers in the BCEA calculation and, in some instances, fails to record all data points. Repeatability of fixation depends on the instrument used and this should be considered when interpreting changes in fixation stability in patients with central vision loss.

ABSTRACT BODY:

Purpose: As myopia progresses, posterior eye elongation is caused by changes in the microstructural properties of the sclera. High-frequency quantitative ultrasound (QUS) allows non-invasive measures of biomechanical parameters associated with changes in tissue microstructure. This study investigated microstructural changes occurring in the posterior sclera (PS) in myopic guinea pig (GP) eyes by means of QUS with a 20- μ m spatial resolution.

Methods: Form-deprivation myopia was induced in young GPs by diffusers worn over the right eye from 6 days of age for 1, 2 or 3 weeks ($n = 5, 9$ and 4 animals respectively). Untreated paired left eyes were used as controls. On the last day of treatment, cycloplegic spherical equivalent refractive error (SERE) and axial length (AxL) were measured. Following euthanasia, both eyes were enucleated and placed in PBS in its natural in vivo anatomical position and raster-scanned using an 80-MHz transducer (i.e., 20- μ m spatial resolution). The acquired 3D data were processed to yield ten QUS parameters. Parameters are reported as the mean from the entire measured PS, and the means for each of the four quadrants (i.e., nasal, temporal, inferior, superior). After computing interocular differences, Pearson correlations between QUS parameters and SERE or AxL were calculated.

Results: SERE was positively correlated with the PS Homodyned-K QUS parameter k ($r = 0.56, p = 0.01$). k quantifies the ratio of the coherent to diffuse scattering and is hypothesized to be sensitive to the orientation of collagen fibrils; k correlations were the largest in the horizontal quadrants (nasal $r = 0.73, p < 0.01$; temporal $r = 0.51, p = 0.03$). SERE was also positively correlated to scatter size ($r = 0.61, p = 0.01$) and acoustic concentration ($r = -0.51, p = 0.03$), which relate to diameter and scattering power of collagen fibrils respectively. Additionally, AxL correlated positively with the nasal quadrant intercept QUS parameter ($r = 0.65, p < 0.01$), which relates to both the diameter and number density of collagen fibrils.

Conclusions: Several QUS parameters were correlated with eye elongation and myopic refractive changes. Since these parameters are related to collagen fiber size, density and microstructure, QUS approaches have the potential to quantitatively and objectively characterize microstructural changes occurring in the sclera during myopia development.

ABSTRACT BODY:

Purpose: To compare the subjective performance of verofilcon A daily disposable silicone hydrogel contact lenses, which have a core with 51% water content and a surface with >80% water content, with those of etafilcon A hydrogel contact lenses, which have a water content of 58%.

Methods: In this prospective, multicenter, clinical study, successful soft contact lens wearers were randomized to wear verofilcon A or etafilcon A lenses for 8 (-1/+2) days (n=92 completed). After a washout period, subjects were dispensed the alternative lenses. Exploratory endpoints included subjective overall lens preference (5-point scale) and subjective ratings (10 point scale) of end-of-day (EOD) vision, overall handling, insertion comfort, EOD comfort, lens handling at insertion, overall comfort, overall quality of vision, vision throughout the day, and lens handling at removal. Furthermore, Likert questionnaires (5-point scale) were completed at end-of-day during the 1-week follow-up visits conducted after the first and second treatment periods.

Results: Of the study subjects, 68 (73.9%) preferred or strongly preferred verofilcon A lenses, whereas 21 (22.9%) preferred or strongly preferred etafilcon A lenses ($p<0.0001$). Mean \pm SD ratings of EOD vision (8.6 ± 1.5 vs 7.7 ± 1.9), overall handling (8.7 ± 1.5 vs 6.9 ± 2.3), insertion comfort (9.2 ± 1.0 vs 7.7 ± 1.9) and EOD comfort (8.0 ± 1.9 vs 7.0 ± 2.2) were all significantly ($p\leq0.0001$ each) higher for verofilcon A than for etafilcon A lenses. Mean \pm SD ratings of lens handling at insertion (9.0 ± 1.4 vs 6.9 ± 2.5), overall comfort (8.6 ± 1.5 vs 7.4 ± 1.8), overall quality of vision (8.9 ± 1.2 vs 8.2 ± 1.8), vision throughout the day (8.9 ± 1.3 vs 8.1 ± 1.8), and lens handling at removal (8.3 ± 2.1 vs 7.7 ± 2.2) were statistically significantly higher for verofilcon A than for etafilcon A lenses. Compared to etafilcon A, the Likert questionnaires revealed higher percentage of subjects wearing verofilcon A who strongly agreed or agreed for questions about lens freshness, comfort, vision and handling.

Conclusions: These results demonstrate that verofilcon A lenses performed better than etafilcon A lenses with respect to overall preference, and other subjective endpoints evaluated in this study.

ABSTRACT BODY:

Purpose: Trabecular bypass stents (TBS) are implanted through the human trabecular meshwork (HTM) to improve physiologic outflow and lower intraocular pressure in open-angle glaucoma. Given the widespread use of TBS, improved understanding of their biocompatibility is imperative. Of the two commercially available TBS, one is comprised of titanium & the other of nickel-titanium (nitinol). This study tested the hypothesis that there would be differences in the viability of primary HTM cells in culture when contacted with one versus the other of these devices.

Methods: HTM cells were grown on glass or gelatin-coated glass substrates & then placed into contact with sterile stents. Cell morphology in the vicinity of the stents was monitored every day for 4 days via optical microscopy, and live-dead fluorescence staining was performed to assess cell viability. The corrected total fluorescence of micrographs imaged under identical conditions ($N \geq 21$ per timepoint) was quantitated w/ ImageJ software. Data were analyzed using two-way ANOVA & compared to stent-free samples w/ Tukey's multiple comparison test.

Results: Cells cultured in contact with nitinol stents for 48, 72 & 96 hours demonstrated progressive cell necrosis, clumping, and in some cases, complete cell layer detachment. However, cells in contact with titanium stents remained attached to the substrate & showed little or no necrosis. Dead-cell staining intensity was greater after nitinol vs. titanium stent contact ($p < 0.0001$, $N = 21/\text{stent}$) across all timepoints examined.

Conclusions: HTM cells remained viable & morphologically intact when in contact with titanium stents, whereas contact with nitinol stents led to necrosis & morphological degradation. These differences were statistically significant & visually apparent.

TITLE: Interaction between CTRP5 & AdipoR1 and its implication to Late-onset retinal degeneration (L-ORD)

SESSION TITLE: Retinal Degenerations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Fausey, C. Zhang, M. Nimmagadda, K.J. Miyagishima, R. Sharma, K. Bharti, National Eye Institute, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrew Fausey: Commercial Relationship: Code N (No Commercial Relationship) | Congxiao Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Malika Nimmagadda: Commercial Relationship: Code N (No Commercial Relationship) | Kiyoharu Miyagishima: Commercial Relationship: Code N (No Commercial Relationship) | Ruchi Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Kapil Bharti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Late-onset retinal degeneration (L-ORD) is an autosomal dominant disorder in which a missense mutation in the CTRP5 gene leads to retinal pigment epithelium (RPE) atrophy and choroidal neovascularization. CTRP5 is a paralogue of Adiponectin family proteins which regulate cell metabolism. We hypothesize that similar to Adiponectin, CTRP5 acts through Adiponectin Receptor 1 (AdipoR1). In L-ORD RPE cells, mutant CTRP5 forms oligomers with its WT counterpart which is believed to interfere with its apical secretion from RPE and reduce binding affinity toward AdipoR1. While in silico ligand/receptor modeling and immunogold labeling suggest an interaction between CTRP5 and AdipoR1, a direct interaction has yet to be confirmed. Here, we aim to biochemically investigate CTRP5-AdipoR1 protein interactions and provide a mechanism of L-ORD disease progression.

Methods: Induced pluripotent stem cells (iPSCs) were generated from fibroblasts of skin biopsies of four siblings, two clinically and genotypically confirmed L-ORD patients with a pathogenic variant in CTRP5 (p.Ser163Arg), and two unaffected siblings that did not carry the pathogenic variant. Cell membrane preparations from iPSC-derived RPE (iRPE) were prepared using a cellular membrane protein extraction kit and, co-immunoprecipitation was conducted via Dynabead technology using AdipoR1 antibodies as the probe. The components of protein complexes were detected via Western blot.

Results: From AdipoR1 probed protein complexes obtained through co-immunoprecipitation, we detected CTRP5 protein in healthy iRPE. However, in L-ORD-iRPE, we detected lower CTRP5, presumably due to the lower expression and lower AdipoR1 binding affinity of mutant CTRP5. This will be further examined by comparing the binding ability of AdipoR1 to tagged p.Ser163Arg CTRP5 and WT CTRP5.

Conclusions: Compromised AdipoR1 and CTRP5 binding in L-ORD iRPE provides a mechanism for disease pathogenesis. Most notably, the presence of mutant CTRP5 could lead to chronically activated AdipoR1 resulting in sustained AMPK activation and RPE metabolic dysfunction. This data allows potential therapeutic opportunities directly through AdipoR1 and AMPK activity modulation thus circumventing the dominant behavior of the CTRP5 mutation in L-ORD patients.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) represents the greatest risk of failure in retinal detachment repair and portends poor visual outcomes. PVR is triggered by fibrovascular proliferation of retinal pigment epithelium (RPE) on the surface of the retina after the RPE undergoes an epithelial-to-mesenchymal transition (EMT). RPE EMT is accompanied by metabolic reprogramming favoring glycolysis. Pyruvate kinase M2 (PKM2) is a key enzyme of glycolysis whose non-enzymatic functions have been implicated in the glycolytic reprogramming and EMT of other cell types. The importance of PKM2 in RPE EMT and PVR is unknown. Here we sought to understand the role of PKM2-driven glycolysis in triggering RPE EMT, and how pharmacologic modulation of PKM2 alters RPE EMT.

Methods: To recapitulate loss of cell contact seen early in the PVR process and induce EMT, primary human fetal RPE (hfRPE) were seeded at 10% density. Immunohistochemistry, western blot, and RT-PCR were utilized to assess the expression of EMT markers and phosphorylation of PKM2 in this in vitro model of PVR. The impact of small molecule (ML-265) pharmacologic modulation of PKM2 on the metabolic profile of hfRPE EMT was evaluated with RT-PCR. The therapeutic potential of ML-265 in attenuating RPE EMT was evaluated in several assays.

Results: HfRPE demonstrated a fibroblastic-like phenotype in this cell culture model of PVR with induction of EMT markers including vimentin, N-cadherin, and TWIST1. PKM2 S37 phosphorylation was increased 7-fold while Y105 phosphorylation was decreased 2.5-fold in the dedifferentiated, fibroblastic-like hfRPE compared to differentiated hfRPE. PKM2 S37 phosphorylation is important for PKM2 dimerization, nuclear translocation, and regulation of glycolytic gene expression via transcriptional co-activation of β -catenin or Hif-1 α . Accordingly, the expression of Hif-1 α , as well as downstream genes of β -catenin and Hif-1 α , such as CCND1, GLUT1, and PDK1, were upregulated in hfRPE EMT. Finally, treatment with ML-265, an allosteric modulator of PKM2 that decreases glycolytic reprogramming, resulted in reduced hfRPE EMT in multiple assays.

Conclusions: This study suggests a critical role of PKM2 in RPE EMT, the triggering event for PVR. Pharmacologic modulation of PKM2 to halt EMT-driven metabolic reprogramming may be an innovative therapeutic strategy in the prevention of PVR.

ABSTRACT BODY:

Purpose: Dysfunction and degeneration of retinal pigment epithelium (RPE) cells leads to detrimental vision diseases such as dry age-related macular degeneration (AMD). One possibility for treating dry AMD is the stimulation of endogenous RPE regeneration, but little is known about the mechanisms that can drive RPE regeneration in vivo. The Hippo signaling pathway regulates cell proliferation and regeneration in many tissues, including during retina regeneration. In the developing RPE, the Hippo pathway is required for proliferation and cell fate decisions. Here, we manipulate the Hippo pathway by inactivating the upstream regulator Neurofibromin 2 (NF2) to investigate whether regeneration in the adult mouse RPE can be achieved after injury.

Methods: We generated Nf2-conditional knockout (CKO) mice using the RPE-specific, doxycycline-inducible tet-on VMD2-Cre. We performed intraperitoneal or retro-orbital injections of sodium iodate (NaIO_3) on 7- to 8-week-old mice to induce oxidative damage mainly to the RPE. Injury and potential regeneration were monitored over the course of 7-11 weeks post injury with electroretinography and optical coherence tomography. Proliferation and extent of regeneration were assessed by EdU incorporation and expression of OTX2 and RPE65 in the presumptive RPE layer 7.5 weeks post injury.

Results: RPE injury reduced ERG A_{max} and B_{max} responses by 80% of baseline at 10 days post-injury. Our preliminary results show that there can be improved tissue integrity and a trend for increased proliferation in adult Nf2-CKOs at 7.5 weeks post-injury. Furthermore, there are more OTX2-positive cells in the presumptive RPE, and several show colocalization with EdU (approx. 4-fold increase compared to damaged controls), suggesting potential de-novo production of RPE cells. We also detect nuclear localization of YAP in Nf2-CKO RPE.

Conclusions: Our results indicate a potential role for Hippo pathway modulation in regenerative proliferation of mature, injured RPE. As mammalian adult RPE cells are post-mitotic, we hypothesize that NF2 normally inhibits regenerative proliferation of mature mammalian RPE through regulation of the Hippo/YAP-TAZ pathway. To investigate a potential mechanism, we are determining whether YAP and the transcription factor TEAD directly regulate RPE-specific gene expression to control RPE specification and maintenance.

TITLE: Thyroid Hormone Regulation of Photoreceptor Viability

SESSION TITLE: Retinal Degenerations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Ma, F. Yang, C.M. Primeaux, X. Ding, Cell Biology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hongwei Ma: Commercial Relationship: Code N (No Commercial Relationship) | Fan Yang: Commercial Relationship: Code N (No Commercial Relationship) | Charles Primeaux: Commercial Relationship: Code N (No Commercial Relationship) | Xi-Qin Ding: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Rod and cone photoreceptors play a central role in visual function. Photoreceptors degenerate in inherited retinal degenerative diseases and age-related macular degeneration. Thyroid hormone (TH) signaling regulates cell proliferation, differentiation, and metabolism. Recent studies have shown a link between elevated TH signaling and photoreceptor degeneration. This work investigates the TH regulation of photoreceptor viability using mouse models.

Methods: Treatment with triiodothyronine (T3) was applied to evaluate the effects of excessive TH signaling. C57BL/6, $Thra1^{-/-}$ (deletion of TH receptor $\alpha1$), and $Thrb2^{-/-}$ (deletion of TH receptor $\beta2$) mice at postnatal day 30 received T3 treatment (20 μ g/ml in drinking water) for 30 days. Serum T3 level was analyzed by ELISA. Retinal function was evaluated by electroretinogram (ERG). Cone density/number was evaluated by immunolabeling of peanut agglutinin (PNA) on retinal flatmounts and rod number was assessed by measuring the thickness of outer nuclear layer (ONL). Photoreceptor death and oxidative damage were analyzed by TUNEL and immunofluorescence staining of oxidative damage markers 8-OHdG and p- γ H2AX. The expression of the cellular stress response genes was evaluated by qRT-PCR.

Results: Treatment with T3 increased serum T3 level by 2-3 folds compared to the control level. Rod and cone ERG responses were reduced by about 60% and 30%, respectively, after T3 treatment. ONL thickness and cone density were reduced by about 18% and 50%, respectively, after T3 treatment. Retinal sections prepared from T3-treated mice showed significantly increased number of TUNEL-, p- γ H2AX-, and 8-OHdG-positive cells. Gene expression analysis showed upregulation of the genes involved in oxidative stress, necroptosis, and inflammatory responses after T3 treatment. Deletion of $Thra1$ prevented T3-induced reduction of ONL thickness whereas deletion of $Thrb2$ prevented T3-induced reduction of cone density.

Conclusions: Excessive TH signaling impairs retinal function, induces oxidative stress/damage and apoptosis, and induces rod and cone degeneration. The effects of TH signaling in rods are primarily mediated by $Thra1$ whereas the effects of TH signaling in cones are primarily mediated by $Thrb2$. This work demonstrates that TH signaling regulates rod and cone photoreceptor viability and TH receptors play differential roles in this regulation.

ABSTRACT BODY:

Purpose: Retinal vessel metrics indicating capillary closure (CC) have shown potential clinical value by identifying eyes at different severity levels and at increased risk for disease progression to more severe stages. We compare the performance of 33 metrics computed based on optical coherence tomography angiography (OCTA) for identification of CC in different ETDRS groups.

Methods: OCTA data from 84 healthy eyes (70 ± 4.8 years) and 78 eyes of diabetic patients (67 ± 7.5 years), ETDRS 10-20 (24 eyes/patients), 35 (31 eyes/patients) and 43-53 (23 eyes/patients), were processed with using different methods: 1) Abnormal intercapillary spaces (AIS) measured using the method proposed by Mendes et al. (2019); 2) Skeletonized vessel density (SVD) and 3) perfusion density (PD), both computed using the Zeiss Meditec Density Exerciser (version 10.0.12787), 4) Entropy, 5) 10 metrics related with the histogram of the slab, 6) Four metrics based on Frangi filter (FF), 7) Coarseness metric of the Tamura filter (CTF) and, 8) 14 features based on Haralick texture features that include the contrast (CT).

The performance of these methods was tested in the superficial capillary plexus (SCP), in the deep capillary plexus (DCP), and in the full retina (FR). Data were acquired using CIRRUS HD-OCT 5000 with AngioPlex® OCTA (ZEISS, Dublin CA) using the acquisition protocol angiography 3x3.

Results: The best separation between the eyes with type 2 diabetics and the control group was obtained in the SCP, with the FR also obtaining a competitive performance. In the SCP the metrics that show better performance were the AIS and the VD (table 1) with a value of AUC equal to 0.89 [CI 95% 0.84-0.94] and 0.85 [CI 95% 0.79-0.91], respectively. The values of these metrics on the ETDRS groups 10-20, 35 and 43-53 show a progressive increase in CC which is correlated with the disease severity (table 2).

Conclusions: On AngioPlex the measurement of CC shows better performance in the SCP using AIS or the SVD. These methods improve the discrimination of eyes with diabetic retinopathy with different degrees of severity (ETDRS groups 10-20, 35 and 43-53).

ABSTRACT BODY:

Purpose: Glaucoma is characterized by progressive dysfunction of the retina; animal models shown that synapses between bipolar and ganglion cells are being dismantled early after intraocular pressure (IOP) elevation. We propose to investigate in detail, and on a large-scale, the relative arrangement of excitatory (E) and inhibitory (I) synapses in the inner retina, as well as in specific bipolar cell populations, to understand whether the degenerative process preferentially impacts specific retinal circuits.

Methods: Transient IOP elevation was induced in albino CD1 mice by photocoagulation of the episcleral and limbal vessels. After 14 days, retinal whole mounts were collected and immunolabeled for the excitatory and inhibitory synaptic proteins PSD95, RibeyeA, Gephyrin, and VGAT. Individual bipolar cell types were immunolabeled using PKC-alpha and Synaptotagmin-2 antibodies. Pairwise statistical comparisons use Wilcoxon-Mann-Whitney test.

Results: The average density of inhibitory (I) and excitatory (E) synapses in the inner plexiform layer (IPL) of lasered eyes was reduced compared to control eyes (E: $P=0.1$, I: $P=0.01$), but their loss is non-uniform across the IPL, with a spatial pattern that is sublamina-specific. Axons of rod bipolar cells significantly lose both ribbon and gephyrin density (E: $P=0.04$, I: $P=0.04$), while Type-6 ON cone bipolar axons preserve both (E: $P=0.6$; I: $P=0.6$). In contrast, Type-2 OFF cone bipolar axons preserve their ribbon density (E: $P=0.4$), while significantly increasing inhibitory inputs (I: $P=0.005$).

Conclusions: Excitatory and inhibitory synapses are unevenly disassembled in the inner retina, with more excitatory synapses lost in the OFF sublamina and more inhibitory synapses lost in the central region of the IPL. Within these distributions, specific bipolar cell types are either unaffected, equally affected, or asymmetrically affected in their E/I balance. These findings will help focus the investigation of specific cell types and microcircuits experiencing high synapse loss and ultimately guide the design of stimuli to probe their function in early glaucoma.

TITLE: TSP1 Deficiency Inhibits Steroid-induced IOP Elevation in Mouse Eyes

SESSION TITLE: Pharmacological intervention or cellular mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R. Ren, H. Gong, Ophthalmology, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ruiyi Ren: Commercial Relationship: Code N (No Commercial Relationship) | Haiyan Gong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Thrombospondin-1 (TSP1) is a matricellular protein that is expressed in the trabecular meshwork, and its expression increases in glaucoma patients. TSP1-deficient mice were found having lower IOP in a previous study. This study aimed to investigate whether IOP elevation can be inhibited in TSP1-deficient mice using a steroid-induced ocular hypertension (SIOH) mouse model.

Methods: TSP1-deficient mice (N=14) and wild type (WT) mice (N=14), both including equal males and females, were randomly divided into saline-treated and dexamethasone (DEX)-treated groups (4 groups in total, n=7/group). Both eyes of each mouse received 10µl of saline or 0.1% DEX eye drops respectively twice a day for 5 weeks. IOP was measured weekly. IOP data were analyzed with both Student's t-test and Three-way ANOVA with repeated measurements.

Results: TSP1-deficient mice showed a ~2mmHg lower IOP at the baseline ($p<0.001$) when compared to WT mice, and this difference remained consistent between two saline-treated groups for 5 weeks. DEX treatment significantly elevated IOP in week1 ($p<0.001$) and peak IOP occurred at week 4 in WT mouse eyes compared to the saline-treated group. However, in TSP1-deficient mice, DEX did not induce a significant increase in IOP until week2 and the peak of IOP was at week2. The mean DEX-induced elevation in IOP was 3.4mmHg at week1, 5.6mmHg at week2, and 5.9mmHg at week5 in WT mice, while 0.2mmHg at week1, 2.2mmHg at week2, and 1.1mmHg at week5 in TSP1-deficient mice. The mean percentage increase in IOP induced by DEX over saline-treated control was 25% at week1, 41% at week2, and 42% at week5 in WT mice, while 3% at week1, 19% at week2, and 9% at week5. Therefore, DEX-induced increase in IOP was a half in TSP1-deficient mice when compared to WT mice at week2, and about 1/4 at week5. Three-way ANOVA also showed a significant main effect of the genotype ($p<0.0001$) and significant interactions of both genotype X treatment ($p<0.0001$) and genotype X time ($p<0.0001$).

Conclusions: TSP1 deficiency showed significant inhibitory effects on DEX-induced IOP elevation in mouse eyes. These effects included the delayed start-point of IOP elevation, lower peak IOP increase, and unsustainable IOP elevation. Our data suggest that TSP1 may play a role in SIOH. The mechanisms of its inhibition effects and morphological association in the outflow pathway need to be elucidated in further studies.

ABSTRACT BODY:

Purpose: Overproduction of reactive oxygen species (ROS) and activation of ROS signalling pathways cause damage to the eyes. We studied the oxidative stress (OS) markers and the effects of a daily, core nutritional supplement regimen containing antioxidants and omega 3 fatty acids (A/ω3), in type 2 diabetic (T2DM) eyes.

Methods: A case-control study was carried out in 480 participants, classified into: 1) T2DM patients (n=287) with (+)/without (-) non proliferative diabetic retinopathy (NPDR) and controls (CG; n=194). Participants were randomly assigned to one A/ω3 daily pill. Evaluation through 38 months permitted to outline patient characteristics, NPDR features, and blood classic and emergent parameters, including OS by products and candidate genes. Statistics were performed by the SPSS 24.0 program.

Results: Significantly higher circulating pro-oxidants (p=0.001) and lower antioxidants (p= 0.0001) were detected in the T2DM patients versus the CG. Significantly higher plasma malondialdehyde/thiobarbituric acid reactive substances (MDA/TBARS; p=0.006) and lower antioxidant load, as from the plasma total antioxidant capacity (TAC; p=0.042) and vitamins B₁₂ (p=0.05) and C (p=0.020) levels, were detected in the T2DM+NPDR versus the T2DM-NPDR. Vitamin C is a cofactor for enzymes involved in collagen synthesis. Overexpression of matrix metalloproteinase-9 (MMP-9) gene (a secreted type IV collagenase involved in extracellular matrix remodelling and cell migration) was found in the T2DM+NPDR versus the T2DM-NPDR groups and the CG (p=0.021). Importantly, the A/ω3 regime significantly reduced the pro-oxidants (p<0.05) and increased the antioxidants (p<0.05) in all groups, with special benefit for the diabetic retina.

Conclusions: This follow-up study reinforces the need for new strategies to increase the antioxidant load, as in the case of A/ω3 supplement regimen, that may serve as dietary prophylaxis and adjunctive intervention for better eye care in patients at risk of diabetic blindness.

ABSTRACT BODY:

Purpose: Evaluate the predictive ability of a deep learning-based, automated, macular fluid segmentation algorithm to determine long-term visual acuity (VA) outcomes in wet age-related macular degeneration (wARMD) patients using baseline swept-source optical coherence tomography (SS-OCT) and OCT-angiography (OCT-A) data.

Methods: Twenty-two SS-OCT volumes of the macula, comprising 5,632 images from 22 wARMD subjects were used to assess retinal layer thicknesses, quantify intraretinal fluid (IRF), subretinal fluid (SRF) and fluid in serous pigment epithelium detachments (PED). Layer thicknesses were manually corrected and fluid segmentation was performed using a novel, deep learning algorithm with results validated relative to two expert graders. OCT-A data was used to manually define the extent of the choroidal neovascularization (CNV) in each scan. Patients received 2 mg of intravitreal aflibercept injections monthly for 3 months, then bimonthly for 12 months. Baseline OCT morphological features and measurements were correlated using the Pearson correlation coefficient (PCC) to changes in VA to determine which features impacted the long-term visual outcomes.

Results: Total fluid volume at baseline and change in LogMar at week 52 relative to baseline had the closest correlation (PCC=0.652, p=0.005). Fluid was subsequently sub-categorized into IRF, SRF and PED, with PED volume having the next highest correlation (PCC=0.648, p=0.005). Average total retinal thickness in isolation gave a lower correlation (PCC=0.334, p=0.189), and mean CNVM size (um²) from 3 mm OCT-A scans was very low (PCC=0.072, p=0.784). When two features were combined and correlated with visual outcomes, the best correlation increased to PCC=0.695 (p=0.002) using mean CNVM size and total fluid volume.

Conclusions: In isolation, total fluid volume best correlates with change in LogMar values between baseline and week 52. In combination with complimentary information from OCT-A, an improvement in the linear correlation score was observed. Average total retinal thickness provided a lower correlation and thus provides a lower predictive outcome than other metrics assessed. Clinically, a machine-learning approach to analyzing fluid metrics combined with lesion size may provide an advantage in personalizing therapy predicting VA outcomes.

TITLE: A Prospective Longitudinal Four-Year Analysis of Ellipsoid Zone Loss in Stargardt Disease

SESSION TITLE: Genetics of Retinal dystrophies and Functional Genomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Chen, W.M. Zein, L. Huryn, R.B. Hufnagel, A. Turriff, C.A. Cukras, B.P. Brooks, B.G. Jeffrey, National Eye Institute, Bethesda, Maryland, UNITED STATES|M.A. Chen, Howard University College of Medicine, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michelle Chen: Commercial Relationship: Code N (No Commercial Relationship) | Wadih Zein: Commercial Relationship: Code N (No Commercial Relationship) | Laryssa Huryn: Commercial Relationship: Code N (No Commercial Relationship) | Robert Hufnagel: Commercial Relationship: Code N (No Commercial Relationship) | Amy Turriff: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cukras: Commercial Relationship: Code N (No Commercial Relationship) | Brian Brooks: Commercial Relationship: Code N (No Commercial Relationship) | Brett Jeffrey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To quantify the rate of ellipsoid zone (EZ) loss over a four-year period in patients with Stargardt disease

Methods: 16 patients with Stargardt disease with two or more variants in ABCA4 were followed prospectively at baseline, 6, 12, 24, 36, and 48 months with Spectral-domain OCT (SD-OCT) volume scans spanning a $30^{\circ} \times 15^{\circ}$ rectangle centered on the fovea (37 B scans). The length of central discontinuity of the inner segment/outer segment band (EZ band) was measured manually on the Heidelberg for each SD-OCT B-scan and area of EZ band loss (mm^2) was calculated using the Riemann sum. Using a radius linear model, the square-root transformed area of EZ band loss (mm) was calculated.

Results: Twenty-five eyes from sixteen patients were included in this 4-year prospective longitudinal study. The median age of patients at the baseline visit was 34 years (range 12-63) with median best-corrected visual acuity of 20/125 (range 20/32-20/200). The mean (\pm SD) EZ band disruption at the baseline visit was 2.33 ± 0.63 mm. The length of EZ disruption was highly correlated between right and left eyes ($P < 0.0001$; $R = 0.97$) and was correlated with age ($P = 0.025$; $R = 0.56$) but not visual acuity. The median rate of growth in EZ band disruption was 0.061 mm and ranged from minimal change (0.019 mm/yr) to high rates of growth (0.267 mm/yr) but was linear for each eye measured. The rate of growth in EZ band loss was also highly correlated between eyes ($P = 0.0004$; $R = 0.85$) but was not correlated with age, visual acuity or size of EZ band disruption at baseline.

Conclusions: Measuring the rate of EZ disruption provides a direct structural measure that is related to loss of photoreceptors. While the rate of EZ loss varied between patients, all patients demonstrated linear growth over a four-year period. This information is highly relevant to clinical trial planning and sample size calculations. The high correlation in rate of loss EZ band loss between the two eyes suggest that one eye could serve as a control in therapeutic trials aimed at treating a single eye.

TITLE: Eph-ephrin signaling plays a role in fiber cell alignment and influences lens shape and resilience

SESSION TITLE: Lens Mechanics, Crystallins and Pathology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Cheng, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Catherine Cheng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Eph-ephrin bidirectional signaling is essential for lens transparency. Our studies in mouse lenses demonstrate that the ephrin-A5 ligand and the EphA2 receptor are needed for normal lens epithelial cells. Loss of EphA2 leads to disorganized lens fiber cells. We determined whether EphA2 and ephrin-A5 are important for lens biomechanical properties and morphometrics.

Methods: We used tissue mechanical testing and confocal microscopy to examine mouse lenses with genetic disruption of EphA2 or ephrin-A5.

Results: Biomechanical testing revealed no change in the stiffness of EphA2(-/-) and ephrin-A5(-/-) lenses compared to littermate controls. However, knockout lenses were more resilient and recovered almost completely after load removal. Morphometric analysis revealed that while there is no change in the overall lens volume, there is a decrease in lens aspect ratio (equatorial/axial diameter) in both knockout lenses. Confocal microscopy and quantitative image analysis from live lenses before, during and after compression revealed that knockout lenses had misaligned Y-sutures leading to a change in force distribution during compression. Knockout lenses displayed decreased separation of fiber cell tips at high loads and had more complete recovery after load removal, which leads to improved whole-lens resiliency. Further analysis revealed misalignment of the fiber cells tips and the lens suture between each shell of newly added fiber cells.

Conclusions: In summary, disruption of Eph-ephrin signaling in the lens leads to changes in resilience and lens shape. Since EphA2(-/-) lenses with disorganized fiber have no obvious change in lens stiffness, the data suggests that hexagonal fiber cell shape and organized packing are not required for normal lens stiffness. Interestingly, EphA2 and ephrin-A5 are needed for normal patterning of lens fiber cells tips and the formation of a well-aligned Y-suture with fiber tips stacked on top of previous generations of fiber cells. The data suggests that alignment of the Y-suture may affect the overall elasticity and resilience of the lens.

ABSTRACT BODY:

Purpose: Choroideremia (CHM) is an X-linked retinal degeneration that leads to progressive damage to the outer retina. Previous studies on histology and adaptive optics (AO) have reported that the photoreceptors are relatively well-preserved in areas where the RPE is intact. In this study, we investigate RPE structure in CHM using adaptive optics enhanced indocyanine green (AO-ICG) imaging to reveal the extent to which RPE is affected.

Methods: Following comprehensive ophthalmic examination, AO-ICG imaging was performed on two female carriers and two affected male patients (n=8 eyes) with molecularly confirmed CHM. Fluorescent AO images of ICG-labeled RPE cells were acquired across a range of retinal locations in which RPE cells were intact, depending on the locations of discrete RPE atrophy. Following manual identification of RPE cells, measurements of RPE spacing and density in CHM were compared to published normative data.

Results: The late phase AO-ICG fluorescence pattern, corresponding to the RPE layer, was markedly different in both carriers and patients with CHM when compared to the expected pattern observed in healthy subjects. In all eyes, areas of dramatically enlarged RPE cells were observed in areas where fundus autofluorescence and optical coherence tomography confirmed the presence of an intact RPE layer. Measurements of RPE cell spacing and density confirmed that there was lower-than-normal RPE density and higher-than-normal RPE spacing for all eyes when compared to normative data (BOE 8(10):4348-4360, 2017). Based on RPE cell spacing measurements, the affected male patients had a greater degree of RPE enlargement (z-scores: 9 to 74; spacing increased by up to 5.2) compared to female carriers (z-scores: 7 to 44; spacing increased by up to 3) across the range of retinal locations measured (0-4.5 mm).

Conclusions: AO-ICG can be used to detect subclinical changes to the RPE structure and may be useful to monitor the efficacy of future therapies in CHM. The observation of interspersed enlarged RPE cells in female carriers and contiguous enlarged RPE cells in affected males, together with previous studies support the notion that the RPE is a primary site of degeneration in CHM.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) dysfunction plays an important role in the progression of age-related macular degeneration (AMD). Our previous studies have showed there is accumulation of damaged nuclear DNA (nDNA) fragments in AMD donor macular RPE cells. This accumulation induced RPE cellular senescence and pro-inflammation via STING pathway. More and more studies found long-term low dose rapamycin treatment, a mTOR inhibitor, reduced inflammation and cellular senescence without side effects. In this study, we explored whether low-dose rapamycin reduces pro-inflammatory factors secretion and cellular senescence induced by accumulation of cytosolic nDNA fragments in RPE cells.

Methods: RPE cell viability was tested by CCK-8 assay. Since lysosomal DNASE2A is essential for damaged nDNA fragments digestion, CRISPR/Cas9 was used to generate DNASE2A^{-/-} RPE cells to produce accumulation of cytosolic nDNA to mimic AMD donor RPE cells. AMD donor RPE cells and DNASE2A^{-/-} RPE cells were treated with 1nM rapamycin for 5 weeks. Cytosolic nDNA, components of mTOR and STING pathway and pro-inflammatory factors were measured by immunostaining, Western blot and ELISA. Cellular senescence was tested by SA-β-galactosidase staining. Autophagy inhibitor was used to explore cytosolic nDNA removal mechanism. nDNA secretion and LC3 conversion was measured.

Results: High-dose rapamycin (≥25μM) significantly decreased ARPE-19 and DNASE2A^{-/-} RPE cell viability while low dosage did not. Long-term low dose rapamycin treatment increased AMD donor macular RPE cells and DNASE2A^{-/-} RPE cells to secrete damaged nDNA fragments via enhancing autophagy. In this way, rapamycin reduced accumulation of cytosolic nDNA fragments in AMD donor macular RPE cells and DNASE2A^{-/-} RPE cells, which led to attenuate mTOR activation and cellular senescence induced by accumulation of cytosolic nDNA fragments in DNASE2A^{-/-} RPE cells. Furthermore, we also found STING and NFκB activation were inhibited by low-dose rapamycin treatment, thereby pro-inflammatory factors secretion (IL-1β, IL-6, IL-8) was reduced in AMD donor macular RPE cells and DNASE2A^{-/-} RPE cells.

Conclusions: Our studies show long-term low dose rapamycin treatment reduces RPE cellular senescence and pro-inflammation induced by accumulation of cytosolic nDNA fragments and has the potential to alleviate progressive RPE dysfunction in AMD.

ABSTRACT BODY:

Purpose: The aim of the study was to assess the safety and repeatability of the measurements taken with a new non-contact esthesiometer -Brill Engines esthesiometer (BEE) and to compare the sensitivity obtained with the Cochet-Bonnet esthesiometer (CBE).

Methods: Young healthy male volunteers were included in the study. Corneal central sensitivity was measured with the new BEE and with the CBE. The procedure was performed three times on the same day and repeated in the same way for 3 days.

Measurement was performed according with the manufacturer instructions. BEE was mounted in the slit lamp and CBE measurement was used manually. A sub-umbral esthesiometry strategy was performed.

To assess whether the data followed a normal distribution, the Shapiro-Wilks test was used. Repeatability was determined by the intraclass correlation coefficient between each day. Likewise, the data obtained with the BEE were compared with those obtained with the CBE. They were also analyzed using the Bland-Altman test. A 95% confidence level was considered statistically significant.

Results: Nineteen consecutive healthy volunteers mean age 23.50 ± 3.62 years underwent and complete the participation in the study. Schirmer test was 7.47 ± 4.12 mm, with a range of 5 to 18 mm and OSDI test was 3.89 ± 3.59 , with a range of 0 to 12.64.

No adverse effected, ocular surface or corneal damage were detected and both test were well tolerated by volunteers. The mean values of corneal sensitivity measured with the BEE was 6.08 ± 0.30 mbar, with a minimum of 5 mbar and for the CBE was 0.61 ± 0.09 g/mm², with a minimum of 0,57 g/mm².

Intraclass correlation coefficient (ICC) of the BEE was 0.764 for a single measurement and 0.907 for the mean of all measurements. Correlation between both esthesiometers ICC was 0.388 and 0.559. Bland Altman plots showed the great majority of data were inside the boundaries (2 SD).

Conclusions: A new non-contact air jet corneal esthesiometer was tested in healthy volunteers with good tolerance, no adverse effects. The BEE showed good repeatability and correlation parameters. Brill Engines esthesiometer could be used as non-invasive alternative of the Cochet Bonnet esthesiometer.

ABSTRACT BODY:

Purpose: Farber disease (FD) is a rare monogenic lysosomal storage disorder caused by mutation of ASAH1, leading to deficiency of acid ceramidase (ACDase) and accumulation of ceramide characterized by retinopathy, macular red spots, corneal opacities, and nystagmus. As gene therapy has been demonstrated to be a promising therapeutic avenue for the treatment of recessive diseases, we evaluated the efficacy of rAAV-mediated hASAH1 over-expression in a mouse model of FD, using in vivo ocular imaging, electroretinography (ERG), post-mortem histology, and mass spectrometry (MS) to assess efficacy.

Methods: Expression and function of ACDase from the rAAV2/2[MAX].hASAH1 vector was assessed by western blot (WB) and activity assay in HEK293T cells. 3-4 week old FD mice (Asah1^{P361R/P361R}) and littermate controls (Asah1^{+/+} and Asah1^{P361R/+}) received a unilateral intravitreal injection of rAAV2/2[MAX].hASAH1 (2×10^{10} vg/eye); the contralateral eye received a sham buffer injection of equal volume (2 μ L). Animals were followed up by confocal scanning laser ophthalmoscopy (cSLO), optical coherence tomography (OCT), and ERG at 5-6 and 8-9 weeks. Eyecups were harvested post-mortem for correlative histology and MS to determine the quantity of each ceramide species.

Results: WB/ceramidase activity assay showed the rAAV2/2[MAX].hASAH1 vector expressed high levels of biologically functional protein. cSLO imaging of untreated Asah1^{P361R/P361R} eyes (N=8) revealed increased hyperreflectivity and autofluorescence surrounding the optic nerve associated with elevated ceramide levels, retinal thickening and decreased ERG amplitudes. rAAV2/2[MAX].hASAH1 treatment (N=8 eyes) significantly reduced central retinal thickening ($P \leq 0.038$), ceramide accumulation ($P = 0.0006$), and limited fundus hyperreflectivity and autofluorescence, but did not lead to functional rescue. Unexpectedly, ACDase over-expression in Asah1^{+/+} and Asah1^{P361R/+} control eyes induced abnormal retinal thickening and ceramide accumulation, similar to FD.

Conclusions: rAAV-mediated over-expression of ACDase effectively prevented the development of anatomical lesions in FD mice, but was not sufficient to rescue function. That over-expression of ACDase in control eyes resulted in increased ceramide accumulation and the development of FD-like lesions indicates that modulating ceramide levels as a therapeutic strategy in diseases other than lysosomal storage disorders may be contraindicated.

TITLE: Serine Phosphorylation of IQGAP1 Regulates Choroidal Endothelial Activation and Neovascularization

SESSION TITLE: CNV

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Wang, E. Kunz, A. Ramshekar, M. Hartnett, John A Moran Eye Center, The University of Utah, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Haibo Wang: Commercial Relationship: Code N (No Commercial Relationship) | Eric Kunz: Commercial Relationship: Code N (No Commercial Relationship) | Aniket Ramshekar: Commercial Relationship: Code N (No Commercial Relationship) | Mary Elizabeth Hartnett: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Serine phosphorylation of IQGAP1 regulates signaling leading to neurite cell growth. We previously found that knockout of IQGAP1 inhibited VEGF-mediated choroidal endothelial cell (CEC) activation and migration, a necessary step in the development of choroidal neovascularization (CNV) in neovascular age-related macular degeneration (AMD). We, therefore, tested the hypothesis that IQGAP1 mediates the development of CNV through IQGAP1 serine phosphorylation.

Methods: Serine phosphorylation of IQGAP1 was measured by Co-immunoprecipitation (Co-IP) with anti-IQGAP1 and western blot with anti-phospho-serine antibodies in 1) primary human CECs transfected with plasmid DNA expressing wild type IQGAP1 (IQ-WT) or IQGAP1 with serine mutation into alanine at sites 1441/1443 (IQ-S/A) and treated with control PBS or VEGF (20 ng/ml) for 15 mins, and in 2) retinal pigment epithelium (RPE)/choroid tissues from wild type mice 7 days after laser treatment. Mice with IQGAP1 mutated at serine 1441 (Crispr/IQ) were created by CRISPR-Cas9 edited gene mutation. Seven days post laser, CNV lesion volume was measured in lectin-stained RPE/choroidal flatmounts of Crispr/IQ and littermate controls. IQGAP1 serine phosphorylation was determined in CECs isolated from three different donors and in RPE/choroid tissues from three lasered mice and three non-lasered controls. The volume of CNV lesions were measured in 7 Crispr-IQ mice and 16 littermate wild type controls.

Results: Compared to PBS, VEGF activated serine phosphorylation of IQGAP1 in IQ-WT transfected CECs. VEGF-induced IQGAP1 serine phosphorylation was abolished in CECs transfected with IQ-S/A. In RPE/choroid tissues and compared to non-lasered controls, laser treatment caused a 3-fold increase in IQGAP1 serine phosphorylation. Crispr-IQ mice had a trend toward reduced CNV lesions ($p=0.07$) compared to littermate wild type mice.

Conclusions: VEGF treatment and laser injury activate IQGAP1 by inducing serine phosphorylation. Serine phosphorylation of IQGAP1 mediates experimental CNV in vivo. These data may provide insight into mechanisms underlying neovascular AMD.

ABSTRACT BODY:

Purpose: Potential spaces in anatomy refer to the area between apposed organs or tissues and can represent “druggable” targets, including the epidural space, used to deliver anesthetics, and the suprachoroidal space (SCS), currently undergoing clinical trial with several therapeutics. In clinical trials, optical coherence tomography (OCT) imaging has demonstrated acute and transient opening of the SCS in preclinical and clinical studies. This imaging study characterized the biomechanical response of injection into the SCS in comparison to intravitreal (IVT) injection.

Methods: Suprachoroidal and IVT injections were performed in ex vivo porcine eyes and the biomechanical response was visualized using the imaging modalities: external photography, spread visualization via ultraviolet (UV) with fluorescence, internal endoscopy, and cryo-freeze sectioning under microscopy. Suprachoroidal injections were performed with the SCS Microinjector®. IVT injections were performed with a 1-mL syringe and standard 30-G needle. Tissues change, injectate spread, and globe behavior were analyzed for both therapeutic delivery methods.

Results: Imaging modalities demonstrated differences between suprachoroidal and IVT injection in distribution of injectate, tissue change, and globe behavior. When evaluated under UV light, suprachoroidal injection of fluorescing particles showed spread circumferentially and posteriorly. No injectate spread was visible with IVT injection, as fluorescence is muted by the pigmented choroid and RPE. Cryofreezing and section showed suprachoroidally injected injectate spread posteriorly toward the macula, between sclera and choroidal tissues. IVT injection showed a bolus of injectate located in the vitreous. Endoscopic footage of an ex vivo porcine suprachoroidal injection show a localized depression of the choroidal tissues when the procedure is begun, followed by SCS expansion as fluid is injected. Corresponding imaging during IVT delivery demonstrated differences in spread of injectate within the globe.

Conclusions: In contrast to intravitreal delivery, suprachoroidal drug delivery results in acute opening of the SCS, supporting the potential to target affected tissue layers in chorioretinal disorders.

ABSTRACT BODY:

Purpose: Inherited retinal degenerations are caused by an unusually large number of genetic mutations. Approaches to delay retinal degeneration in a mutation-independent manner would accelerate the delivery of the treatments to the patients. Previous studies demonstrated that activation of the mTORC1 (mammalian Target of Rapamycin Complex 1) pathway had beneficial effects in a broad range of mouse models of retinal degeneration and attributed these observations to the improved glucose metabolism. mTORC1 activation supported the survival of cones in mouse models of rod degeneration, slowed down the early stages of retinal degeneration in PDE6b mutant mice and increased retinal resistance to the RPE injury. Recent studies performed outside of the vision research field suggest that activation of mTORC1 could increase the total proteasomal pool and activity in cell cultures and mouse brains. Therefore, here we investigated the stimulation of mTORC1 also as an approach to delay vision loss caused specifically by proteostatic stressors.

Methods: mTORC1 was stimulated genetically in rods by knocking out its negative regulator Tsc2 (Tuberous Sclerosis Complex 2) in $Tsc2^{flx/flx}$ mice using rod-specific transgenic CRE mouse line. The heterozygote P23H rhodopsin knock-in mouse ($P23H^{+/-}$) was used as a model of retinal degeneration caused by protein misfolding and mice expressing reporter of proteasomal activity (Ub^{G76V} -GFP) were used as a tool to assess the status of ubiquitin-proteasomal system (UPS) in vivo. Proteasomal activity was measured in retinal lysates with fluorogenic substrates. Protein translation and autophagy were probed with puromycin- and chloroquine-based WB methods. Retinal health and function were evaluated with OCT, funduscopy, morphometric studies and ERG.

Results: Genetic activation of mTORC1 delays the late phase of rod photoreceptor loss in $P23H^{+/-}$ mice by approximately 3 months. This improvement is accompanied by stimulation of proteasomal activity and more efficient protein degradation through the UPS as assessed using the Ub^{G76V} -GFP reporter mice. Stimulation of mTORC1 in $P23H^{+/-}$ rods did not result in measurable changes in autophagy and translation.

Conclusions: These findings focus attention on a previously unappreciated ability of the mTORC1 pathway to modulate UPS in degenerating rods and position it as a promising therapeutic target for treating retinal degenerations associated with protein misfolding.

ABSTRACT BODY:

Purpose: Nonparaneoplastic autoimmune retinopathy (npAIR) is an insidious disease that is difficult to monitor due to often-unremarkable findings in clinical exam; therefore, it might be beneficial to use ancillary imaging/tests to evaluate the disease state. We conducted the index case-series to describe ocular changes in patients with npAIR and to assess the utility of different imaging modalities/tests in monitoring the disease course.

Methods: Eight patients (16 eyes) from a tertiary eye care center, with a verified diagnosis of npAIR using the criteria proposed by Sen (Sen et al., 2014), were recruited. Multimodal testing using functional [Goldmann perimetry (GVF), microperimetry (MP), and electrophysiologic testing (ff-ERG, mf-ERG, VEP)] and structural [wide angle fundus photography (WAFP), wide angle fundus autofluorescence (WFAF), wide angle fluorescein angiography (WFA), spectral domain optical coherence tomography (SD-OCT), and adaptive optics scanning laser ophthalmoscopy (AOSLO)] tests were performed at different time points and results were analyzed.

Results: The median age of patients was 46.0 [15.5-66.7] years and 50% were female. Initial results showed frank abnormalities in both functional (14 of 16 eyes on GVF, 15 of 16 eyes on MP, 11 of 16 eyes on ff-ERG, 12 of 14 eyes on mf-ERG, 14 of 14 eyes on VEP) tests and structural (14 of 16 eyes on WAFP, 14 of 16 eyes on WFAF, 13 of 16 eyes on SD-OCT, 5 of 7 eyes on AOSLO) imaging. WFAF appeared normal except in cases of transient macular edema (3 of 16). Subjects were followed up for the median duration of 11.5 [3.0-18.7] months. Follow up imaging of GVF (8 of 10 eyes), mfERG (4 of 8 eyes), and MP (7 of 16 eyes) demonstrated changes which were not always consistent with each other. Ff ERG (9 of 10 eyes) and VEP (7 of 8 eyes) remained mostly unchanged. No significant changes were noted on WAFP and WFAF. Measurable changes were noted in 4 of 12 eyes on SD-OCT and 6 of 6 eyes on AOSLO. Decrease in retinal sensitivity on MP often preceded subjective symptoms.

Conclusions: Multimodal testing in npAIR patients is crucial to identify and follow changes over time. Deterioration, especially in severe cases, is often subtle, but ongoing as shown by changes in multiple modalities. Most structural modalities might not be able to measure changes once npAIR have become severe. Functional modalities might be able to detect early changes that precede subjective worsening.

ABSTRACT BODY:

Purpose: Uveitis is the fourth leading cause of preventable blindness among adults in the United States. We aim to determine risk factors associated with visual acuity outcomes in uveitic patients.

Methods: A retrospective study of patients with ocular inflammation from 01/2011 to 12/2016 at Robert Cizik Eye Clinic was done. Those with inflammation caused by rebound post-surgical inflammation or less than 24 months of follow up were excluded. If both eyes were eligible, both were included. Eyes were classified into anterior, intermediate, posterior, panuveitis, and scleritis. Demographics and baseline medical and ocular characteristics were recorded. Ocular symptoms, best corrected visual acuity (BCVA) and additional procedures were collected at follow-up. Risk factors, including demographics, ocular history, type of uveitis, flare, and additional ocular procedures were identified and estimated using a mixed effect model with a backward selection procedure.

Results: 224 eyes from 166 patients were included. Mean age was 50.9 years (± 19.6 , 3-86) at initial uveitis diagnosis. 103 (62%) were female. 65 (39%) were Black, 60 (36%) White, 12 (14%) Hispanic, 7 (4%) Asian, and 11 (7%) Other. 144 eyes (64%) had anterior uveitis, 13 (6%) had anterior and intermediate uveitis, 17 (8%) had posterior uveitis, 39 (17%) had panuveitis, and 11 (5%) had scleritis. At baseline, BCVA was 0.64 logMAR (± 0.69), 62 eyes (28%) had glaucoma, 40 (18%) had retinal diseases. 77 of 215 eyes reported flare (36%). Panuveitis had the worst BCVA compared to other uveitis types ($P < 0.001$) at months 6, 12 and 24. At month 6, Asian and Black races had worse BCVA by 0.60 logMAR (± 0.23 , $P = 0.012$) and 0.50 (± 0.11 , $P < 0.001$), respectively, compared to White. BCVA was continuously worse in Black race compared to White by 0.37 logMAR (± 0.11 , $P = 0.001$) and 0.40 logMAR (± 0.12 , $P = 0.001$) for month 12 and month 24, respectively. Eyes without retinal disease had better BCVA at month 6 ($P = 0.025$) and month 24 ($P = 0.009$) by 0.28 logMAR (± 0.12) and 0.36 logMAR (± 0.14), respectively. BCVA at 12 months was affected by number of ocular procedures performed (0.13 logMAR (± 0.05) per procedure ($P = 0.012$)).

Conclusions: Panuveitis and eyes with history of retinal disease had worst visual outcomes. Black race, compared to White, Hispanic, and Other is associated with the worst BCVA in all forms of uveitis in 6, 12, and 24 months follow up visits. Flare did not significantly affect BCVA.

ABSTRACT BODY:

Purpose: To update estimates of the global vision loss burden due to uncorrected refractive error (URE), presenting temporal change since the beginning of Vision 2020 and distribution by sex and region.

Methods: Data gathered from population-based surveys of eye disease from January, 1980, to October, 2018 were collated. We fitted hierarchical models to estimate prevalence (with 95% uncertainty intervals [UIs]) of moderate and severe vision impairment (MSVI; presenting visual acuity from <6/18 to 3/60) and blindness (<3/60) caused by URE, by age, sex, region, and year. Prevalence of near VI from uncorrected presbyopia, defined to avoid double counting individuals with both distance and near VI, was based on 25 studies.

Results: In 2020, 2.29 million (95% UI 1.79 to 2.80) people aged 50+ years were blind due to URE globally, and 86.1 million (74.2-101.0) had MSVI, a 21.8% increase in blindness and 72.0% increase in MSVI since 2000. Age-standardised prevalence of URE blindness and MSVI decreased by 30.5% and 2.4% respectively during this time. The age-standardized ratio of women to men for URE blindness was 1.05:1.00 in 2020 and 1.03:1.00 in 2000. For MSVI, this ratio was 1.08:1.00 in 2020 and 1.06:1.00 in 2000. South Asia had the highest regional 50+ age-standardised URE blindness and MSVI rates in 2020 (blind: 0.33%, 0.26-0.40; MSVI: 10.3%; 8.82-12.1), and also the greatest reductions in age-standardised URE blindness between 2000 and 2020 (46.3%). In 2020, an estimated 419 million (295-562) people 50+ had near VI from uncorrected presbyopia, a 75.3% increase since 2000. Three-quarters of global near VI from presbyopia occurred in Asia (312 million, 217-418).

Conclusions: Raw prevalence of VI from URE grew due to population aging, even as age-standardised prevalence fell since 2000. The striking decline in age-adjusted URE blindness (compared to MSVI) suggests successful targeting of the most severe cases, such as prevention of aphakia with intra-ocular lenses. Further reduction in the burden of VI from URE can be realised by adding refractive services to universal health coverage and otherwise improving access. Focusing on the 50+ population provides an incomplete view of VI due to URE, which frequently affects younger persons. The very large burden of presbyopia and sparsity of available data underscore the need for more research

on this condition.

ABSTRACT BODY:

Purpose: Non-arteritic anterior ischemic optic neuropathy (NAION) is the most common acute optic nerve-related cause of vision loss in people over age 50; however, NAION has no proven treatment. Previously, we demonstrated that interleukin-6 (IL-6) is upregulated in an experimental rodent model of NAION (rNAION), based on deep sequencing data from rat optic nerve and retinal tissue. In this experiment, we tested the hypothesis that IL-6 inhibition would decrease inflammatory response and preserve retinal ganglion cells (RGCs) in the rNAION model.

Methods: rNAION was induced in 4 adult male Sprague-Dawley rats. On post-induction day 1, optic nerve edema was assessed by slit lamp and optical coherence tomography (OCT), and animals were paired in terms of similar amounts of edema. One from each pair was treated with subcutaneous sarilumab (human IL-6 inhibitor), whereas the others received vehicle (saline). At 1 week post-induction, rats were euthanized, and eyes and optic nerves were isolated and post-fixed in 4% paraformaldehyde-PBS. Post-fixed retinas were isolated, and RGCs immunostained with Brn3a antibody. Cryopreserved optic nerve laminar sections were immunostained with Iba1 (for microglia), CD68 (for macrophages), and SMI312 (for neurofilaments).

Results: There was no appreciable reduction in resident microglia or extrinsic macrophage recruitment (Figure 1) and no appreciable RGC preservation (Figure 2) in rNAION animals treated with sarilumab compared with controls.

Conclusions: IL-6 inhibition does not appear to reduce inflammatory cell recruitment or to preserve RGCs in rNAION, when administered 1 day after disease-state induction, despite known IL-6 upregulation in this disease model.

Possible explanations for this finding include (1) a narrow time window for therapeutic anti-inflammatory treatment in rNAION, in which case this treatment avenue is not likely to be clinically relevant; (2) the IL-6 response is a nonspecific inflammatory epiphenomenon and may not specifically modulate damage-inducing inflammation in rNAION; or (3) the fully humanized sarilumab antibody is functionally limited in its effects in rat. Further study with a rodentized IL-6 inhibitor may further elucidate the role of IL-6 inhibition in rNAION.

ABSTRACT BODY:

Purpose: The role of optical coherence tomography angiography (OCT-A) in the follow-up of patients with exudative neovascular age-related macular degeneration (enAMD) has not been clearly clarified. Quantitative OCT-A parameters used to describe macular neovascularization (MNV) may be biomarkers that help predict anti-VEGF treatment burden and functional response. We performed an observational and prospective study to evaluate the association between quantitative OCT-A parameters and clinical outcomes over a 24-month follow-up interval.

Methods: Patients with enAMD were treated using a treat-and extend regimen following a loading dose of three anti-VEGF injections (IVI). Swept-source OCT-A was performed at baseline, after the loading dose and at 12 and 24 months. A quantitative analysis was performed for fractal dimension (FD), lacunarity index (LAC), blood flow surface area (SA), and vessel density (VD). Good functional response was defined as a final BCVA superior to/or within 5 letters of the 12th month visit. High treatment burden was defined as having at least 5 IVI in the second 12 months. Associations between quantitative biomarkers, functional outcomes and treatment burden at 24 months of follow-up were assessed. Statistical significance was defined as p-value < 0.05.

Results: Sixty-two eyes of 62 patients with enAMD were enrolled, 50 of whom (81%) completed the 24-month protocol. The median BCVA was 63 ETDR letters (21) at baseline, 74(25) at 12 months and 72 (28) at 24 months. 15 patients (30%) were classified as good functional responders. The median number of injections in the second year was 6 (2), with 40 patients (82%) classified as "high treatment burden". A lower FD at the 12th month-visit was associated with a good functional response (p=0.008, area under the curve (AUC) = 0.74). Low treatment burden was associated with lower SA at the 12-month visit (p=0.013, AUC = 0.76).

Conclusions: FD and SA were two quantitative parameters of MNV blood flow derived from OCT-A that were associated with clinical outcomes whilst LAC and VD were not. The 12-month visit evaluation may give insights regarding the functional outcome and treatment burden for the following year, corroborating the hypothesis that OCT-A may play a role in a comprehensive enAMD follow-up.

ABSTRACT BODY:

Purpose: The coronavirus pandemic has prompted unprecedented delays to treatment with anti-VEGF intra-vitreous injections due to the need to reduce hospital attendances and prioritize the patients at highest risk of vision loss. This study aims to quantify the effect of these delays on visual acuity (VA) outcomes and optical coherence tomography (OCT) features for patients receiving treatment for neovascular age-related macular degeneration (nAMD).

Methods: A retrospective data analysis of an electronic medical record was performed on a random sample of 681 eyes receiving anti-VEGF injections between 1 January and 23 March 2020 for nAMD. Data collected included whether the review was delayed (defined as delayed by 8 weeks or more from planned) and the VA at baseline and follow up. For those eyes not delayed, a VA at 20 weeks was recorded to provide a control group, as this was the mean number of weeks until the delayed group was seen. For the delayed group, the OCT features at follow up were also noted.

Results: The sample of 681 eyes was analysed, of which 194 (28.5%) had been delayed by 8 weeks or more. The mean number of weeks delay was 12.7. Mean change in VA for eyes in the delayed group was significantly worse compared to those not delayed. VA change in the delayed group was 60.1 to 55.2 (-4.9) letters and VA change in the non-delayed group was 61.4 to 59.9 (-1.5) letters ($p = 0.001$). 161 eyes that were delayed had a repeat OCT at their delayed review; mean CMT (μm) had increased from 311 to 342 and 118 eyes (73.3%) showed evidence of intraretinal and/or subretinal fluid. By November 2020, 25.1% of eyes had not returned to within 5 letters of their baseline vision.

Conclusions: Delayed appointments due to COVID-19 affected a significant proportion of nAMD patients receiving intra-vitreous injections. nAMD eyes which were delayed experienced significant visual loss compared to those who were not delayed. This was associated with worsening of disease activity on OCT.

ABSTRACT BODY:

Purpose: To compare changes in anterior segment optical coherence tomography (AS-OCT) parameters in patients with primary angle closure suspect (PACS) undergoing laser peripheral iridotomy (LPI).

Methods: One-hundred eyes with PACS underwent prophylactic LPI in the temporal iris. Clinical exam including visual acuity, intraocular pressure (IOP) and gonioscopy were assessed. AS-OCT parameters including anterior chamber (AC) depth, lens vault (LV), trabecular iris space area (TISA), angle opening distance (AOD), and nasal and temporal iris thickness were measured at baseline and repeated at 1week, 1 month and 3 months post-laser. Data were analyzed with paired t-test, one-way ANOVA and Wilcoxon test using SPSS V27.

Results: Seventy-six percent of enrolled participants were female (mean age 58.5 ± 11 years). LPI was performed temporally in all eyes at an average 43.4mJ/eye. Clinically on gonioscopy, 82% of angles were deeper at 3-month follow-up ($p=0.000$). The mean visual acuity (logmar 0.12 to logmar 0.08, $p=0.001$) and mean IOP improved from baseline (15.4mmHg) to 3-months (14.9mmHg; $p<0.001$) post-LPI. AOD at 500um and 750um showed significant deepening in the temporal quadrant at 1 week that persisted until 3-months post-LPI ($p=0.001$). Similarly, deepening of the LV, TISA at 500um and 750um from Schwalbe's line and thinning of the temporal iris at 500 um and 750um showed significant improvements at 3-months post-LPI ($p=0.005$, $p=0.001$, $p=0.001$, $p=0.001$, $p=0.001$), respectively. Nasal iris thickness at 500um from the angle was also significantly reduced ($p=0.009$) from baseline, although LPI was performed only in the temporal quadrant. Further, deepening of the ACD ($p=0.001$) was observed at 3-months follow-up.

Conclusions: Deepening of the angle clinically by gonioscopy reflect the long-term changes on AS-OCT parameters demonstrated at 3-months follow-up. AS-OCT showed significant deepening of the angle by reducing lens vault, deepening the TISA, ACD and thinning the temporal and nasal iris. Gonioscopy and AS-OCT are useful tools for screening and assessing patients with PACS. Our results will provide all practicing ophthalmologists with a better understanding of the reliability of AS-OCT in screening and follow-up for patients with PACS to guide further clinical management.

TITLE: Activation of NFkB and NLRP3 Inflammasome in the corneal epithelium following short-term desiccating stress

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Yu, S.C. Pflugfelder, J. Alam, C.S. De Paiva, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zhiyuan Yu: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Pflugfelder: Commercial Relationship: Code N (No Commercial Relationship) | Jehan Alam: Commercial Relationship: Code N (No Commercial Relationship) | Cintia De Paiva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine if 24-hour exposure to desiccating stress activates NFkB and NLRP3 inflammasome pathways in the mouse cornea epithelium.

Methods: 6-to-8-week-old C57BL/6J mice were housed under normal humidity (nonstressed) or subjected to desiccating stress from a drafty, low humidity environment combined with SC scopolamine QID for 1 day to suppress tear production (DS1). Eyes were embedded and sectioned for immunofluorescent staining or the corneal epithelium was scraped for immunoassay, caspase-1 assay, western blot or real time PCR. A TransAM kit was used to detect phospho-NFkB p65 in the nuclear fraction. Western blot and real-time PCR were performed to detect NFkB and NLRP3 pathway proteins and gene transcripts, respectively.

Results: There was significantly increased nuclear p-p-65 protein and gene expression of the NFkB inducible cytokine IL-12 (1.9-fold) and its receptors (IL-12Rb1 and IL-12Rb2, 3 and 1.9-fold, respectively) in DS1 compared to nonstressed control. NLRP3 and Caspase 1 proteins (6.4 and 3.1-fold, respectively), RNA transcripts (1.4 and 1.9 fold, respectively), as well caspase 1 enzyme activity (1.5-fold, P=0.006) increased in DS1. IL-18, the inflammasome inducible cytokine protein increased 3.1-fold, while RNA expression of its receptor IL-18Rap increased 1.5-fold (P=0.001). There was no change in IL-1b expression. Immunostaining for NLRP3, Caspase 1 and IL-18 increased in the cornea epithelium at DS1 compared to nonstressed.

Conclusions: These findings indicate that two key innate inflammatory pathways (NFkB and NLRP3 inflammasome) are activated following short term desiccating stress. Cytokines stimulated by these pathways, IL-12 and IL-18, are required for full expression of the dry eye associated cytokine IFN-γ by T and natural killer cells.

ABSTRACT BODY:

Purpose: Genome-wide association studies have identified genetic variants associated with primary open-angle glaucoma (POAG), including ABCA1 gene rs2472493 and GAS7 gene rs9913911. However, no studies have been performed in heterogeneous populations such as Brazilian. Therefore, the aim of this study was to investigate the association of the ABCA1 rs2472493 and GAS7 rs9913911 with the risk of POAG development in a sample of the Brazilian population.

Methods: This was a cross-sectional, candidate gene association study structured as case control. The study was performed with 1036 subjects, encompassing 520 POAG patients and 516 controls. All participants were over 40 years old and underwent a complete ophthalmic evaluation. The genotyping of the variants was performed through Taqman® assays and the results were confirmed by Sanger sequencing in 10% of the samples from each group. The association of the variants was tested by chi-square test and logistic regression analysis.

Results: We identified the association of rs9913911 variant of the GAS7 gene with POAG development in the presence of the A risk allele ($p = 0.0255$; OR = 1.602; CI95% = 1.060-2.421). In the presence of the AA genotype the risk of developing POAG was even higher ($p = 0.0032$; OR = 1.881; CI95% = 1.222-2.896). No significant association was observed for rs2472493 of the ABCA1 gene for alleles or genotypes. However, in the presence of the A risk allele of GAS7 rs9913911 and the G risk allele of ABCA1 rs2472493, an additive effect was observed ($p = 0.0018$; OR = 2.677; CI95% = 1.557-4.602).

Conclusions: Our study confirms the association of the rs9913911 (GAS7 gene) with POAG risk in a sample of the Brazilian population and an additive effect when rs9913911 (GAS7 gene) and rs2472493 (ABCA1 gene) are analyzed simultaneously. This is an important finding for future diagnosis and treatment strategies for the Brazilian population. Further studies are needed to evaluate the frequency of these alleles based on ancestry analyses.

TITLE: Head-down tilt reverses neuroretinal rim thinning in healthy eyes

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Venkata Srinivasan, L.P. Pardon, H. Cheng, P. Chetty, N.B. Patel, Optometry, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Varsha Venkata Srinivasan: Commercial Relationship: Code N (No Commercial Relationship) | Laura Pardon: Commercial Relationship: Code N (No Commercial Relationship) | Han Cheng: Commercial Relationship: Code N (No Commercial Relationship) | Pratik Chetty: Commercial Relationship: Code N (No Commercial Relationship) | Nimesh Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In healthy eyes, the neuroretinal rim tissue is thickest in the early morning and thins through mid-afternoon. We hypothesize that this change of the neuroretinal rim is a reflection of the translaminal pressure difference as one goes from a supine to sitting or standing position. The purpose of this study was to determine if head-down tilt (HDT) reverses this neuroretinal rim thinning.

Methods: Twenty-six healthy subjects presented to the lab on two separate days at 11 AM. Baseline measures included visual acuity, standard automated perimetry, optic nerve photos, and intraocular pressure (IOP with rebound tonometry), all performed in a seated position. Optic nerve head (ONH) and peripapillary tissue were imaged using radial and circular optical coherence tomography (OCT) scans centered on the ONH, aligned to the fovea-Bruch's membrane opening (BMO) axis. Following 3 hrs in either a seated or 6° HDT, IOP and OCT scans were repeated in that position. OCT data were exported, and programs written in MATLAB were used to quantify global minimum rim width (MRW), peripapillary total retinal thickness (TRT), choroid thickness, retinal nerve fiber layer (RNFL) thickness, BMO area, and BMO position referenced to a 3.5mm plane aligned to the choroid-sclera junction (BMO height). Data are presented as mean ± SEM.

Results: Each of the 26 subjects completed both seated and HDT sessions and one randomized eye from each was used for analysis. Compared to seated baseline measures, IOP decreased by 1.7 ± 0.5 mmHg ($p < 0.01$) in the seated position and increased by 3.1 ± 0.7 mmHg in the HDT position ($p < 0.01$). The average BMO area was 2.1 ± 0.1 mm² and did not change with time or posture ($p > 0.05$). The mean BMO height did not change in the seated condition but was anteriorly displaced in HDT (6.8 ± 3.1 μm, $p = 0.04$). While there was no significant change in MRW in the seated position (0.8 ± 0.8 μm, $p = 0.3$), MRW increased in HDT (4.2 ± 1.7 μm, $p = 0.02$). Similarly, for an annulus of 250 μm from the BMO, TRT in the seated position showed no significant change ($p > 0.05$), but increased in HDT (3.4 ± 1.1 μm, $p < 0.01$).

Conclusions: Thinning of the neuroretinal rim which occurs during waking hours is reversed in HDT. This provides support that changes in the translaminal pressure difference from supine to seated or standing are partly contributory to this diurnal change.

TITLE: TRPV1-dependent NKCC1 activation in mouse lens involves integrin and the tubulin cytoskeleton

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Shahidullah, A. Mandal, N.A. Delamere, Physiology, The University of Arizona, Tucson, Arizona, UNITED STATES|M. Shahidullah, N.A. Delamere, Ophthalmology and Vision Science, The University of Arizona, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mohammad Shahidullah: Commercial Relationship: Code N (No Commercial Relationship) | Amritlal Mandal: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Delamere: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In earlier studies we showed the response of the mouse lens to hyperosmotic solution involves TRPV1-dependent ERK1/2 and NKCC1 activation. In studies on different tissues, other investigators have suggested the cytoskeleton plays an important role in responses to osmotic stress. In the present study, we examine whether integrins and tubulins are involved in the activation of NKCC1 in mouse lens epithelium.

Methods: Lenses were obtained from Wild-type (WT) and TRPV1 knockout (KO) mice. Rubidium (Rb) uptake by the intact lens was quantified by atomic absorption spectrophotometry. Previous studies used bumetanide-sensitivity to validate Rb uptake as a measure of lens NKCC activity. ERK1/2 phosphorylation was detected and quantified by Western blot analysis. Cytoplasmic calcium was measured in cultured lens epithelium loaded with Fura-2 using a ratiometric imaging technique.

Results: In WT mice, an integrin agonist leukadherin 1 (LA-1, 25 μ M) increased Rb uptake by intact lenses from a control value of 3.9 ± 0.4 to 5.2 ± 0.4 ($n=7$, $P<0.05$). LA-1 also increased the cytoplasmic calcium concentration in cultured WT lens epithelium from 197 ± 18 to 341 ± 25 nM in ($n=5$, $P<0.001$). In TRPV1 KO lenses, LA-1 failed to produce a significant change of Rb uptake. Moreover, LA-1 failed to increase cytoplasmic calcium concentration in cultured lens epithelium from TRPV1 KO mice. Importantly, the rise of Rb uptake caused by LA-1 in WT lenses was prevented by the putative tubulin stabilizer, paclitaxel (100 nM). The Rb uptake response to LA-1 was abolished by a TRPV1 antagonist, A889425 (1.0 μ M). LA-1 was observed to cause ERK1/2 activation in WT cultured lens epithelium. The TRPV1 agonist capsaicin and hyperosmotic solution (350 mOsm) were shown to cause a similar pattern of ERK1/2 activation in WT cultured lens epithelium. The ERK1/2 responses were transient and displayed a peak at ~5 min. Paclitaxel as well as A889425 markedly reduced the magnitude of the ERK1/2 activation responses to hyperosmotic stress and LA-1.

Conclusions: The findings suggest a functional link between integrins, the tubulin cytoskeleton, and the TRPV1-dependent increase of NKCC1 that occurs when the lens is subjected to hyperosmotic stress. It is noteworthy that the integrin agonist LA-1 as well as hyperosmotic stress both were found to activate ERK1/2, an important step in the signaling associated with activation of NKCC1 in the lens.

ABSTRACT BODY:

Purpose: Aflibercept (Eylea®) is a VEGF inhibitor indicated for the treatment of patients with Wet AMD, MEfRVO, DME, and DR. Aflibercept is a fusion of the second Ig domain of VEGFR1 with the third Ig domain of VEGFR2 and that fused with to the Fc segment of human IgG, creating a chimeric protein with a very high VEGF binding affinity ($K_D \approx 0.2\text{-}1\text{pM}$). The goal of this study was to characterize a VEGF Mini-Trap generated by removing the Fc portion of the aflibercept, resulting in a smaller protein that could retain the VEGF binding and inhibitory properties of aflibercept and potentially provide higher molar dosing intravitreally. We hypothesize that this higher dosing could result in longer-lived activity.

Methods: We generated REGN7483F (VEGF Mini-Trap) using the IdeS protease derived from *Streptococcus pyogenes*. This enzyme cleaves just below the hinge region of the Fc. Aflibercept was incubated with agarose-immobilized IdeS for 60 mins, then the supernatant was collected and purified by protein A affinity chromatography. REGN7483F and aflibercept were characterized for binding kinetics by BiaCore, potency in a VEGFR1 bioassay, homogeneity by SDS-PAGE, thermal stability, solubility, viscosity, and complex formation with VEGF₁₆₅ by SEC-MALS and negative-stain electron microscopy.

Results: REGN7483F and aflibercept showed similar binding affinity for VEGF₁₆₅ (K_D 1.27 pM and 1.32 pM) and stoichiometric inhibition of VEGF₁₁₀ in the VEGFR1 bioassay. SDS-PAGE showed molecular weights expected for aflibercept (~65 kD) and REGN7483F (~ 32 kD). REGN7483F exhibited a similar degradation pathway as aflibercept under thermal stress analysis. In the base formulation buffer, REGN7483F showed low viscosity (< 14 cP at 120 mg/mL) and high solubility (> 160 mg/mL). SEC-MALS of aflibercept and REGN7483F in complex with VEGF₁₆₅ showed both favored a discrete 1:1 cis-complex containing one VEGF₁₆₅ dimer held between the two arms of REGN7483F or aflibercept.

Conclusions: REGN7483F has comparable binding affinity, bioassay blocking potency, stability and degradation pathway as aflibercept. Each exhibited a discrete 1:1 complex with VEGF₁₆₅. At a concentration of 110 mg/mL (viscosity ~12 centipoise), REGN7483F provides 5.5X molar equivalents of VEGF binding sites as the commercial

aflibercept formulation. Therefore, REGN7483F shows favorable properties as a potential next-generation VEGF inhibitor.

ABSTRACT BODY:

Purpose: Lacrimal gland adenoid cystic carcinoma is a rare but very lethal cancer originating in the cells of secretory glands. With the 10-year survival rate of 20%, the only life extending technique is to remove the eye and surrounding socket contents entirely. ACC is a very slow growing but aggressive cancer, even with radical treatment, most patients will present with metastatic disease to the brain, lung, liver, or bones several years out from initial diagnosis and before symptoms are noticeable. Due to the rarity of LGACC, it is not well understood which leads to diagnosing, treating and monitoring disease progression difficult. Previously, genome analysis of ACC of the head and neck has uncovered a high mutation rate of MYB and NOTCH in patient samples, yet these two genes remain untreatable as there are no successful therapeutics for these targets. We aim to further understand the molecular drivers of LGACC and discover novel targets for specifically treating LGACC.

Methods: We have RNA sequencing data for 7 primary LGACC tumors, mass spectrometry data for 12 primary tumors and RNA sequencing for 15 cell lines derived from tumors to further understand the molecular signatures of LGACC. We used trimalore and star to prepare and align the RNA sequencing data. We completed extensive statistical analysis using edgeR and limma packages in R for RNA and proteomics, respectively.

Results: The RNA sequencing of the tumor samples revealed the most significantly differentially expressed gene ontology group is the extracellular matrix, including HAPLN1, FABP7, and VCAN. The mass spectrometry data also showed the significant role of extracellular matrix proteins and metabolic regulation. We compared the differentially expressed genes in the mass spectrometry and RNA sequencing data and discovered 194 genes that were differentially expressed in both analysis types. The complete analysis revealed that genes and proteins in the extracellular matrix are significantly differentially expressed between cancer and normal tissue.

Conclusions: With this extensive analysis of the molecular signatures, we now have a deeper understanding of the drivers of this slow growing, lethal cancer. This analysis lays the groundwork for the development of reliable molecular diagnostic, prognostic, and surveillance assays as well as therapies specifically targeting differential expression signatures.

ABSTRACT BODY:

Purpose: Endomucin (EMCN) is a type I integral membrane glycoprotein selectively expressed by venous and capillary endothelium. Our previous findings showed that EMCN knockdown significantly inhibits VEGF165-induced VEGFR2 internalization and downstream activities. The goal of this study is to further define the specificity of EMCN for VEGF/VEGFR2 system by determining the role of EMCN in VEGF121-induced VEGFR2 activation. We also examined the potential role of EMCN in fibroblast growth factor (FGF) signaling and angiogenesis-related activities in endothelial cells.

Methods: EMCN was knocked down in human retinal endothelial cells (HRECs) using siEMCN, with non-targeting siRNA as a control. Whole cell lysates of HRECs with or without EMCN knockdown, followed by VEGF165 or VEGF121 stimulation at 5, 10, 30 and 60 min, were harvested. Protein levels of total VEGFR2, phospho-VEGFR2 (Y1175), total Akt, phospho-Akt, total Erk, phospho-Erk, total Src and phospho-Src were examined by western blot. A wound-healing assay was used to examine endothelial cells migration.

Results: VEGF165 and VEGF121 stimulation significantly increased HRECs wound closure compared to control (1 ± 0.02 vs. 1.15 ± 0.02 , $p=0.004$; 1 ± 0.02 vs. 1.18 ± 0.03 , $p=0.0001$. $N=3$ for both). SiEMCN treatment led to a significant suppression of EMCN protein levels compared to non-targeting siRNA group by 95% ($P<0.05$). EMCN knockdown prevented HRECs migration induced by VEGF165 (1 ± 0.03 vs. 1.04 ± 0.03 , $p=0.9$, $n=3$) as well as VEGF121 compared to control (1 ± 0.03 vs. 1.07 ± 0.02 , $p=0.5$, $n=3$). The levels of phospho-Src significantly increased following VEGF121 stimulation for 10 min ($n=3$, $p<0.05$); EMCN knockdown inhibited phospho-Src expression compared control ($n=3$, $p<0.05$). No significant differences were detected between EMCN knockdown and control for the expression of phospho-VEGFR2, phospho-Akt and phospho-Erk. FGF stimulation significantly increased HRECs wound-closure ($n=6$, $p<0.0001$), but EMCN knockdown did not significantly affect FGF-induced HRECs migration compared to control ($n=6$, $p<0.001$).

Conclusions: EMCN is essential for VEGF165- and VEGF121-induced endothelial migration and VEGFR2 internalization. However, EMCN does not play a significant role in FGF-induced endothelial cells migration. Our data indicate a specific role for EMCN in the VEGF/VEGFR2 system.

ABSTRACT BODY:

Purpose: To compare spectral-domain optical coherence tomography (SDOCT) measured circumpapillary retinal nerve fiber layer (cpRNFL) among four glaucomatous optic disc phenotypes in early glaucoma.

Methods: In this longitudinal study, 218 early glaucoma eyes that had at least 3 years of follow-up and a minimum of 4 SDOCT scans were recruited from the Diagnostic Innovations in Glaucoma Study (DIGS) and the African Descent and Glaucoma Evaluation Study (ADAGES). The optic discs were classified into four types based on appearance: generalized cup enlargement (GE), focal ischemic (FI), myopic glaucomatous (MY), and senile sclerotic (SS). A linear mixed-effect model was used to compare the rates of global and regional cpRNFL thinning among optic disc phenotypes.

Results: Of the 218 early glaucoma eyes that were followed for an average of 5.9 years, 76 were classified as generalized cup enlargement (GE), 53 focal ischemic (FI), 22 myopic glaucomatous (MY), and 67 senile sclerotic (SS) discs. After adjusting for confounders, the SS group (mean (95% CI): -1.01 (-1.30, -0.73) $\mu\text{m}/\text{year}$) had the fastest mean rate of global cpRNFL thinning followed by FI (-0.77 (-0.97, -0.57) $\mu\text{m}/\text{year}$), MY (0.59 (-0.81, -0.36) $\mu\text{m}/\text{year}$) and GE (-0.58 (-0.75, -0.40) $\mu\text{m}/\text{year}$) at $p < 0.001$. The inferior temporal sector had the fastest mean rate of cpRNFL thinning among the regional measurements except for the MY group (-0.68 (-1.10, -0.26) $\mu\text{m}/\text{year}$), $p = 0.002$. In the multivariable analysis, higher mean intraocular pressure during follow-up ($p < 0.001$) and optic disc phenotype ($p = 0.014$) were associated with faster cpRNFL thinning. The GE ($p = 0.002$) and MY ($p = 0.010$) phenotypes were associated with significantly slower global rates of cpRNFL thinning when compared to the SS phenotype.

Conclusions: Rates of cpRNFL thinning were different among the four glaucomatous optic disc phenotypes. Those patients with early glaucoma with SS phenotype have the fastest cpRNFL thinning. These patients may benefit from more frequent monitoring and the need to advance therapy if cpRNFL thinning is detected.

ABSTRACT BODY:

Purpose: Toll-like receptors (TLRs) have a key role in triggering the innate immune response. TLR activation causes the production of various pro-inflammatory cytokines, chemokines, and antimicrobial peptides (AMPs) commonly found on the ocular surface. Histatin peptides are potent anti-microbial agents that may have salubrious effects in ocular epithelia. Multiple ocular surface diseases (OSD) including dry eye disease (DED), are driven by inflammation. Here, we investigated how histatin 5 (Hst5) modulates the expression of TLRs in an in vitro experimental model of DED.

Methods: Hyperosmolarity was induced by adding 125 mM NaCl with or without co-treatment with Hst5 in human corneal epithelial (HCE) cells. Cell viability was measured using WST-assay kit following the manufacturer's instruction. The expression of TLRs (TLR2, TLR3, TLR4 and TLR7) and pro-inflammatory cytokines (IL-6, IL-8 and TNF- α) were examined by qPCR. NF- κ B activation was examined by detecting I κ B- α degradation using Western blotting and p65 translocation to nucleus using immunofluorescence staining.

Results: Experimental results showed that Hst5 abrogated cell death induced by hyperosmolar condition in HCE cells. Hyperosmolar conditions significantly induced TLR2 and TLR7 in HCE cells. TLR signaling was inhibited by co-treatment of Hst5. Application of Hst5 reduced the synthesis ocular surface disease relevant pro-inflammatory cytokines significantly. We also found that activation of NF- κ B was reduced in response to Hst5.

Conclusions: Thus, Hst5 application can reduce hyperosmolarity related TLR signaling and innate immune inflammation in the ocular surface.

ABSTRACT BODY:

Purpose: Important information can be gathered from non-saturated system responses, such as those obtained from the retina with very dim flashes (i.e., below the rod Vmax) of the scotopic electroretinogram (ERG). This study focuses specifically on the oscillatory potentials (OPs) of these responses to assess how their synchronicity evolves with flash strength, in rats and mice.

Methods: Scotopic ERGs (Intensity: -6.3 to $0.9 \log \text{cd.s.m}^{-2}$; dark-adaptation: 12 h) were performed on 6-8 adult pigmented (C57BL/6; PM) and albino (Balb/c; AM) mice as well as pigmented (Long-Evans; PR) and albino (Sprague-Dawley; AR) rats. ERGs were band-passed filtered (zero-phase FIR filter; order: 150) in 3 frequency bands (65-90 Hz; 90-115 Hz; 115-140 Hz) and a Hilbert transform was performed on each time series leading to a harmonic signal modulated with a time varying envelop. A threshold on the envelopes was set to delimit OP burst segment. The total OP burst duration and mean peak time difference (PTD) between each frequency band envelope were measured.

Results: The OP bursts duration behaved in opposite ways between pigmented and albino animals. In PM and PR the burst duration peaked between -3.9 and $-2.7 \log \text{cd.s.m}^{-2}$, while it was minimal in AM and AR. This difference between pigmented and albino animals was also seen when considering the synchronicity of the OP burst as measured with the PTD. Indeed, at $-3.9 \log \text{cd.s.m}^{-2}$, PM and PR had a large peak of PTD (38.2 ± 11.7 ms and 27.1 ± 13.4 ms, respectively), while AM and AR had very low PTDs, except for the dimmest flashes (Peak PTDs: AM = 21.4 ± 15.2 ms at $-5.1 \log \text{cd.s.m}^{-2}$; AR = 15.6 ± 0 ms at $-6 \log \text{cd.s.m}^{-2}$). Regardless of animal species and pigmentation, all animals had a minimal PTD at the 4 brightest flash intensities (PTD at $0.9 \log \text{cd.s.m}^{-2}$: AM= 3.4 ± 1.6 ms; PM= 3.5 ± 0.8 ms; AR= 4.7 ± 1.4 ms; PR= 5.9 ± 0.8 ms).

Conclusions: Our results suggest a clear distinction between the scotopic OP bursts of pigmented and albino animals. The synchronicity peak found in pigmented animals matched the peak in burst duration, suggesting that longer OP bursts seen at dimmer flashes are more disorganized in their frequency contributions than the shorter bursts seen in albino animals at the same intensities. The increased synchronization observed at the brightest intensities in all animal tested, could suggest an optimization of the retinal (neuronal) response.

ABSTRACT BODY:

Purpose: To present a series of patients where difluprednate was used as a sole topical agent for scleritis treatment. Discuss its effectiveness and side effect profile.

Methods: An observational retrospective study of all patients with scleritis who used difluprednate as a single treatment agent from 1/1/2018 to 1/1/2020. Data collected at each visit was: age, race, sex, anatomic location of scleritis, presence of nodules or necrotizing sclera, changes in scleritis activity, IOP, number of difluprednate drops used, BCVA, and lens status. Exclusion criteria: use of NSAIDs, corticosteroids, and immunosuppressive drugs. Primary outcome was clinical resolution of scleritis. Resolution was defined as no anterior chamber cell, complete blanching of the ocular surface with 10% phenylephrine: no nodules or necrosis. Secondary outcome measures: change in lens status or cataract surgery; IOP elevation defined as IOP ≥ 24 mm Hg.

Results: Twenty-five patients (35 eyes) were analyzed. Median age was 60 years (range 13-78) and 60% were female. Caucasians were the largest group (16; 64%). Forty percent had bilateral disease; 44% of patients had an underlying systemic disease. The majority (86%) had diffuse anterior disease. Eighty percent (28 eyes) achieved quiescence. Nine eyes had IOP elevation; 4 eyes had a decrease in 2 or more lines of vision, of which one required cataract surgery. Overall, 5 eyes underwent cataract surgery. Causes of decreased vision were, dry eye associated with difluprednate (2 eyes), cataract progression (1 eye), and compressive optic neuropathy unrelated with difluprednate use (1 eye).

Conclusions: Difluprednate use alone achieved disease suppression in most eyes treated for anterior scleritis with few having progression of cataracts or IOP elevation. Further studies are needed to assess the efficacy of adjunct difluprednate use in patients refractory to NSAIDs and non-steroidal immunosuppressant treatment alone.

ABSTRACT BODY:

Purpose: Risuteganib (RSG) is a novel synthetic peptide that regulates integrin functions and has shown promising efficacy in an intermediate dry AMD phase 2 clinical study. We previously reported that RSG protected against retinal pigment epithelial (RPE) cell injury induced by hydroquinone (HQ), a major oxidant in cigarette smoke and atmospheric pollutants, agents implicated in age-related macular degeneration (AMD) pathogenesis. Many transcription factors (TFs) are important regulators of genes that control cellular response to oxidative stress. Herein, we investigate the effect of RSG on expression of several TFs regulated by HQ in human RPE cells.

Methods: Cultured human RPE cells in triplicate wells were treated with HQ at different concentrations in the presence or absence of RSG (400 μ M, Allegro Ophthalmics, LLC) for various treatment times. Expression of TF genes associated with cellular stress response, including activating transcription factor 3 (ATF3), DNA damage-inducible transcript 3 (DDIT3; encodes the multifunctional TF, CHOP), and DNA-binding protein inhibitors (ID-2 and ID-3), were analyzed by qPCR. Expression of ATF3, CHOP, nuclear factor erythroid 2-related factor 2 (NRF2), and X-box binding protein 1s (XBP1) were evaluated by Western blot.

Results: Compared to untreated cells, HQ significantly increased mRNA expression of ATF3, DDIT3, ID2 and ID3 ($P<0.05$). RSG+HQ cotreatment significantly further upregulated HQ-induced ATF3 and DDIT3 ($P<0.05$) and decreased HQ-induced ID2 and ID3 mRNA levels ($P<0.05$). Levels of ATF3, Nrf2, CHOP, XBP1 proteins were significantly upregulated by HQ and further upregulated by RSG+HQ cotreatment ($P<0.05$).

Conclusions: RSG modulated multiple transcription factors involved in oxidant injury pathways, supporting a multifunctional role of RSG on RPE cells against oxidative stress.

ABSTRACT BODY:

Purpose: The Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study is an ongoing prospective cohort study initiated in 2004 to evaluate the influences of socioeconomic status and race on the incidence of age-related diseases in the United States. Participants are urban African American and white adults recruited from 13 neighborhoods in Baltimore City. An ophthalmic component was added in 2017 to evaluate the prevalence and characteristics of eye disease in this population.

Methods: In the HANDLS study, mobile research vehicles are used to evaluate all participants every 4 years. Detailed testing is performed to assess nutrition, cognition, and biologic biomarkers. Participants in wave 5 also underwent color fundus photography (TopCon TRC-NW400 non-mydratic camera) at their study visit. The images were graded by ophthalmologists who were masked to the other clinical data. Presenting visual acuities (VA) were collected beginning in 2019. Data were analyzed using R statistical software.

Results: A total of 965 participants (mean age: 59.3±8.8 years) underwent fundus photography. The participants were 60.8% women (587) and 63.4% African American (612). The image quality was gradable in 1646/1930 (85.3%) of photos.

Roughly half of eyes (1018) were found to have abnormal findings, most commonly glaucoma/glaucoma suspect (295 eyes [15.3%]), hypertensive retinopathy (156 eyes [8.1%]), macular degeneration (100 eyes [5.2%]), and retinal hemorrhage (39 eyes, [2.0%]). Cup-to-disc ratios of the optic nerves were graded as ≥ 0.5 in 434/1761 eyes (24.6%).

Of the 427 participants with VA data, the majority (375; 87.8%) had VA $\geq 20/40$ in at least one eye. Moderate visual impairment was seen in 51 (11.9%) participants who had VA between 20/50 and 20/200 in the better seeing eye.

Conclusions: Fundus photography in this cohort identified potential ocular pathology with recommendation for follow-up with an ophthalmologist in about half of participants. Future work will assess the influences of socioeconomic status and race on eye disease. Analysis of the retinal images will determine their correlations with other medical tests, including cognitive testing, nutrition, and biologic biomarkers.

ABSTRACT BODY:

Purpose: CME is a common occurrence in patients with RP. In this study, we have compared isopter area measured by Octopus perimetry and EZ width measured by Spectral domain Optical Coherence Tomography (SD-OCT) in RP patients with or without CME.

Methods: Retrospective chart review of RP patients with Octopus and SD-OCT done on the same day was performed. Patients with visual acuity ≥ 50 letters, and no ocular co-morbidities such as history of retinal detachment and vitreomacular interface abnormality were included. Ellipsoid zone (EZ) width ($^{\circ}$) and foveal thickness (mm) were measured using Heidelberg HEYEX software. A MATLAB program was written to measure the I4e, III4e, and V4e isopter areas ($^{\circ}^2$) from Octopus maps. Mann-Whitney U and two-proportion Z test were performed to compare the CME with the non-CME group.

Results: Forty eyes of 24 patients (9 males, age 22-63 years) qualified based on criteria listed above. Twelve eyes of 7 patients had CME. Peripheral island of III4e was found in 8 non-CME eyes vs. 2 CME eyes ($p=0.49$), and I4e found in 6 non-CME eyes vs. 1 CME eye ($p=0.32$). Table 1 shows the results.

Conclusions: Patients with CME had a statistically significant reduction in all isopter areas, both central and peripheral, as well as a decline in EZ-width when compared to non-CME eyes. This along with the lack of peripheral islands of vision on Octopus perimetry in CME eyes may suggest that CME is more likely to be present in more advanced disease. Further studies are recommended to study the relationship between presence of CME and stage of RP.

ABSTRACT BODY:

Purpose: Preclinical and clinical studies have shown that human corneal stromal stem cells (CSSC) prevent corneal scarring and regenerate transparent stromal tissue. CSSC treatment blocked neutrophil infiltration into the injured stroma via the paracrine action of extracellular vesicles (EV). This study investigated the mechanisms by which CSSC EV suppress corneal inflammation and fibrosis.

Methods: Conditioned media of primary human CSSC cultures were collected for EV isolation. Total RNA library of EV fractions was analyzed by RNAseq and microRNAs (miRs) specific to CSSC of high regenerative potential were identified. Target gene search and enriched pathway analyses from single or combinations of miR were studied by TargetScan, miRDB, and DAVID bioinformatics. Transfection of miR having statistical significance in association to inflammatory, fibrosis, and immune pathways were examined by (1) mouse macrophage (RAW264.7) for M1/M2 phenotype switch assay; and (2) the fibrosis assay of human corneal stromal fibroblasts after TGFβ1 and ascorbate treatment.

Results: A total of 17 miRs were significantly enriched in EVs of human CSSC having high regenerative potential and scar reduction in mouse corneal wound model. Using target gene search and pathway analyses, 9 miR combinations were predicted to be significantly associated with signaling cascades of tissue inflammatory and fibrosis responses, as well as tissue regeneration ($P < 10^{-6}$). Transfection of miR mimics to RAW cells showed that 4 groups suppressed M1 phenotype (reduced pro-inflammatory iNOS and MCP1 expression) after lipopolysaccharide (50 ng/ml) treatment. Among them, 1 group was shown to revert pre-M1 RAW to M2 phenotype (increased anti-inflammatory Arg1 and Ptgs1 expression), similar to interleukin-4 (20 ng/ml) treatment. These miRs also downregulated the fibrosis gene expression (αSMA and tenascin C) of human CSSC treated by TGFβ1 (10 ng/ml) and ascorbate.

Conclusions: Specific miRs produced by CSSC and delivered via EVs exerted anti-inflammatory and anti-fibrotic activities. Further in vivo study will demonstrate their therapeutic efficiency in preventing corneal scarring and regenerating transparent corneal tissues after injury.

ABSTRACT BODY:

Purpose: Corneal neovascularization (CoNV) can lead to visual impairment, affecting over 1.4 million people in the United States. It is caused by a variety of pathologies associated with angiogenic stimuli. Several medical and surgical management regimens are currently available, but they are only partially effective. Conbercept (KH902), an anti-vascular endothelial growth factor (VEGF) drug, can successfully inhibit ocular neovascularization, but it requires repeated dosing. In this study, we investigated the long-acting anti-angiogenesis and safety of rAAV-delivered KH902 in mouse corneal injury models.

Methods: We employed two rAAV serotypes with different transduction efficiencies to deliver KH902 gene via single intrastromal or subconjunctival administration. rAAV-mediated eGFP expression was used as a guide to determine transduction efficiency and cell tropism in the cornea. The levels of KH902 mRNA expression mediated by each rAAV serotype were analyzed by Droplet Digital PCR. The potential toxicity was determined through analyzing the central corneal thickness at various timepoints and immune response at two weeks after high- and low-dose rAAV gene delivery. We tracked and quantified the CoNV progression for 12 weeks post-injection of rAAV-KH902 in CoNV models in vivo. The levels of DLL4/Notch signaling and ERK activation, markers for VEGF stimulation, were tested by Western blot.

Results: We found that the two different serotypes when administered by intrastromal injection conferred KH902 expression in corneal keratocytes with different efficiencies, while rAAV rarely transduced cornea tissue via subconjunctival injection. After reaching peak expression at 1-2weeks, KH902 mRNA expression in the cornea gradually decreased but was still detectable at three months following a single intrastromal injection. High doses of rAAV-KH902 induced a strong corneal inflammatory response; while at low doses, inflammation was at a minimum. Furthermore, rAAV-KH902 reduced DLL4/Notch signaling and ERK activation in alkali burn-induced CoNV mouse model. Our data suggest that rAAV-mediated KH902 gene therapy can dramatically inhibit CoNV for an extended period of time in both alkali burn- and suture-induced CoNV mouse models without adverse events.

Conclusions: Our study demonstrates the potential and relative safety of rAAV-based anti-angiogenesis therapy in the treatment of corneal neovascularization progression.

ABSTRACT BODY:

Purpose: Machine Learning (ML) models suffer from a lack of interpretability, particularly in healthcare settings. We used Google Brain's What-if Tool (WIT) in a retrospective cohort study to analyse the decision boundaries of a multi-classification model that predicts visual acuity (VA) outcomes for patients with wet age-related macular degeneration (AMD).

Methods: Our AMD dataset consisted of 3961 eyes from patients who had attended Moorfields Eye Hospital in the UK and were undergoing anti-vascular endothelial growth factor treatment. For each patient, VA was measured at the start of treatment and one year later using Early Treatment Diabetic Retinopathy Study charts. VA after one year of treatment was binned to labels of "Good" for scores of 70+, "Neutral" for scores of 36-69, and "Poor" for scores of 35 or below. A Google Cloud AutoML Tables model was then trained on this data to predict these VA outcome labels based on VA at baseline, age, ethnicity and gender.

We report the AUROC, precision and recall performance of the model. To explore decision boundaries, nearest counterfactual analysis using L1 distance was performed using the WIT – a model-agnostic explainable artificial intelligence tool - as a Jupyter notebook extension.

Results: The trained AutoML model performed with an AUROC of 0.892, a precision of 73.1% and a recall of 71.9%. We present a case study of an 84-year-old British male patient with an initial VA of 70, and his nearest counterfactual, an 84-year-old British female patient, also with an initial VA of 70. The ground truth for both patients was "Good"; this was correctly predicted in the male patient, whilst the model predicted a "Neutral" outcome for the female.

Conclusions: We present a novel way in which clinicians can easily view nearest counterfactuals using the WIT, allowing for a greater understanding into how ML models arrive at their decisions at the level of an individual patient. In our example, there is no clinically strong evidence to support the model's prediction of a "Neutral" outcome in the female patient in comparison to the male patient. Importantly, minimal coding experience is required in both the training of the model on AutoML Tables and the analysis using the WIT. This approach could therefore contribute to the democratisation of ML in healthcare.

ABSTRACT BODY:

Purpose: Arrestin and glial fibrillary acidic protein (GFAP) are expressed in photoreceptors and Müller cells, respectively, and play an important role in phototransduction. Harmonin is a scaffolding protein involved in the development and function of ciliated cells including photoreceptors and inner ear hair cells; however, its role in the retina remains unclear. Mutations in harmonin lead to Usher syndrome (Usher), the most common genetic cause of deaf-blindness. Acadian Usher Type 1C is attributed to the USH1C c.216G>A splicing mutation, and knock-in mice display severe hearing impairment, balance disturbances, and visual dysfunction similar to patients. To understand the effects of the 216A mutation on protein expression in the retina, we performed quantitative discovery-based proteomics of retinal extracts from wild type (WT), Usher, and 216A-targeted antisense oligonucleotide (ASO)-treated Usher mice. We hypothesize that Usher retinas have abnormal Arrestin and GFAP protein expression compared with WT controls. Furthermore, we predict that ASO treatment, which improves Ush1c expression and restores visual function in Usher mice, also restores normal Arrestin and GFAP expression in the retina.

Methods: Juvenile Usher mice were treated with 216A-ASOs by intravitreal injection (IVI) and allowed to recover for 2.5 months post-IVI. Visual function was measured in ASO-Usher, Usher, and WT mice at 3 months of age using electroretinogram (ERG) analysis. Retinas were then harvested and processed for proteomic analysis using liquid chromatography and mass spectrometry (LCMS) and confirmed with immunohistochemistry (IHC) and western blot analysis.

Results: ERGs were significantly increased in ASO-Usher mice compared with untreated Usher controls. LCMS identified significantly differentially expressed proteins in WT versus Usher (155/3659) and ASO-Usher versus untreated Usher (124/3663) retinas. Among these, Arrestin levels were significantly decreased and GFAP levels were significantly increased in Usher retinas compared to WT. Expression levels were significantly improved following ASO treatment as measured by LCMS, IHC, and western blot analyses.

Conclusions: These data demonstrate that ASO treatment improves visual function in Usher mice, as well as restores WT Arrestin and GFAP expression levels in the retina, suggesting a new role for harmonin in the healthy retina.

ABSTRACT BODY:

Purpose: To evaluate the predictive power of an artificial intelligence (AI) construct to predict primary open-angle glaucoma (POAG) from single nucleotide polymorphisms (SNPs) and to identify potentially novel genetic factors associated with glaucoma.

Methods: We included 1012 participants of the Ocular Hypertensive Treatment Study (OHTS) from multiple ancestries. A total of 817 participants remained without evidence of POAG (controls) and 195 participants eventually developed POAG (cases) over ~15 years. We developed a case-control genome-wide association study (GWAS) to identify SNPs that were independently associated with glaucoma and selected top scored SNPs (Fig. 1). We then developed a machine learning model composed of feature subset selection and learning to identify the most promising subset of SNPs that were highly predictive of POAG development. We finally developed an independent machine learning classifier to predict glaucoma from the discovered subset of SNPs (Fig. 1). We evaluated the accuracy of the model using cross-validation of the receiver operating characteristics curves.

Results: The top 1000 highly scored SNPs, out of ~1 million, were selected for the downstream analysis. Machine learning discovered 63 SNPs, out of 1000 (Table 1), that were collectively predictive of glaucoma with an AUC of 0.88 (95% CI: 0.86 – 0.90) without using any additional glaucoma endophenotype features. The AUC of the model using 750 subjects from only (self-reported) European race was 0.93 (95% CI: 0.90 – 0.95). The discovered SNPs were mapped to 45 independent genes, of which eight were previously known to be associated with glaucoma traits and 37 genes remain as potential candidates for development of the POAG.

Conclusions: The combined statistical modelling and machine learning frameworks achieved a high accuracy in predicting glaucoma. Successful development of this learning model may assist clinicians in using DNA testing to identify individuals with ocular hypertension who are at-risk of glaucoma development and future vision loss. Independent datasets are desirable to further validate the findings in this study.

ABSTRACT BODY:

Purpose: Emerging evidence indicates that some non-coding RNA molecules may harbor short open reading frames (sORFs) that code for functional micropeptides that may play a major role in regulating many pathophysiological processes. However, the functions of these remain largely unexplored given their small size. sORFs can act independently as ligands or signaling molecules by engaging with and modulating larger regulatory proteins to fine-tune complex biological systems. In this study, we attempt to identify potential protein-coding sORFs from LINC00276, a non-coding RNA identified in differentiated ARPE-19 cells.

Methods: Bioinformatic analyses based on evolutionary conservation were used to identify sORFs with the potential to encode conserved micropeptides. Also, we employed the Coding Potential Calculator version 2 (CPC2) algorithm, a novel discriminative algorithm assessing sequence intrinsic features at the DNA/RNA level, to predict high-quality sORFs. The identified sORFs were then cloned into pEGFP-N1 vector in-frame with C-terminus GFP and 6xHis tag. The expression of these constructs in ARPE-19 cells was analyzed by immunofluorescence and western blotting after transfection.

Results: In a screen of LINC00276 transcripts, we identified an evolutionarily conserved sORF with the potential to encode a highly conserved 19 amino acid (aa) micropeptide located in exon 2, which is common to both LINC00276 transcripts. Using CPC2, we identified another sORF encoding a 74 aa peptide located in exon 4, only present in the second transcript of LINC00276. Expression of these constructs in ARPE-19 cells yielded peptides corresponding to the predicted molecular weight of the fusion peptides, detected by western blot. Both micropeptides, of 19 and 74 aa, showed GFP expression but a distinct GFP expression pattern was observed with the 74 aa micropeptide in ARPE-19 cells.

Conclusions: In this study, we provide evidence for the presence of two putative micropeptides encoded in LINC00276. These may play a role in modulating the expression of genes associated with RPE differentiation. Further studies on the identification and functional characterization of the micropeptides are required to elucidate their biological functions and may provide further insight into the cellular role of LINC00276 in regulating RPE characteristics.

ABSTRACT BODY:

Purpose: Atomic Force Microscopy (AFM) has proven to be a useful method for characterizing corneal mechanical properties ex vivo. However, traditional setups are bulky and cannot be used in vivo. Self-sensing cantilevers (SSCs) are an alternative technology that can be used to replace the traditional AFM cantilever and optical lever system to perform biomechanical measurements. In this study, we compared the performance of a SSC system to a traditional AFM optical lever system in measuring the Young's Modulus of elasticity of the full-thickness cornea.

Methods: To avoid variability associated with cadaver tissue, experiments were conducted on a realistic corneal model designed to practice corneal dissection (Cordelia, Bioniko Models). To restore hydration of the corneal model, it was placed in deionized water at room temperature for 30 minutes. After this, it was adhered to a Petri dish and placed in a custom AFM system that has been optimized for biomechanical studies (Ziebarth et al. Mol Vis 2007 Apr; 13:504-510). Traditional AFM cantilevers (1.75N/m, 50mm diameter, sQUBE) were used to measure Young's modulus of the corneal model in 2 different locations on 3 different days, with at least 10 scans recorded in each location each day. A piezoresistive, self-sensing AFM cantilever (Agar Scientific, Ltd., Essex, UK) was then used to measure the mechanical response of the same sample. A total of 14 measurements were performed at 4 different speeds (7.5mm/s, 10mm/s, 15mm/s, and 30mm/s). All data was analyzed using custom software written in MATLAB.

Results: Using the traditional AFM system, Young's modulus of elasticity of the corneal model was 25.8 ± 4.3 kPa. Using the SSC, we were able to record a consistent linear response during indentation of the corneal model. The slope (voltage/displacement) and change in voltage were consistent, independent of speed of indentation or day of measurement. The slope was 0.50 ± 0.06 N/m, and the change in voltage was 7.85 ± 0.81 mV. These values are directly correlated to the Young's modulus of elasticity of the sample.

Conclusions: SSC technology can be used to measure biomechanical properties of the cornea, similar to traditional AFM systems. However, due to its small form factor, it has the capability of being applied in instances of large and geometrically complex samples.

TITLE: Feasibility of Intravitreal Aqueous Chlorhexidine Gluconate for the Treatment of Bacterial Endophthalmitis

SESSION TITLE: Diabetic retinopathy/retinal pharmacology/physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.R. McKay, B.B. muirhead, F. Lasowski, H. Sheardown, D. Wong, Department of Ophthalmology and Vision Sciences, University of Toronto Temerty Faculty of Medicine, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Bryon McKay: Commercial Relationship: Code N (No Commercial Relationship) | Ben muirhead: Commercial Relationship: Code N (No Commercial Relationship) | Frances Lasowski: Commercial Relationship: Code N (No Commercial Relationship) | Heather Sheardown: Commercial Relationship: Code N (No Commercial Relationship) | David Wong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Endophthalmitis is a rare but significant vision threatening emergency. The time from symptom onset to treatment is a significant factor in final visual outcome. Standard of care is treatment with fortified broad-spectrum antibiotics that require specialist pharmacy preparation creating a delay in care. Aqueous chlorhexidine gluconate is a readily available, stable antiseptic with broad-spectrum antimicrobial, anti-viral, and anti-fungal action. The purpose of this study is to determine the feasibility of intravitreal injection of aqueous chlorhexidine in terms of retinal toxicity and antimicrobial efficacy in an animal endophthalmitis model.

Methods: Intravitreal injections of aqueous chlorhexidine (0.1%, 0.01%, and 0.001%) were administered to 3-month-old brown Norway rats (n=3 per group). Each group received either 2µL of 0.1%, 0.01% or 0.001% chlorhexidine in one eye (n=3 eyes per group) with the contralateral eye receiving a sham injection of 2µL saline to serve as the control (n=3 eyes per group). The animals were assessed using fundus imaging, optical coherence tomography (OCT), and electroretinography (ERG) at 6h, 24h, 72h, and 1-week post injection. Animals were sacrificed at 1 week and eyes were fixed in 4% paraformaldehyde for histochemical analysis.

Results: 0.1% Chlorhexidine vs. sham: All 3 eyes in the treatment group developed visually significant cataracts by one week. ERG analysis demonstrated severely impaired B-wave in the treatment group at 24h. ERG was normal in the sham group. 0.01% Chlorhexidine vs. Sham: 2 of 3 treatment eyes developed mild cataract by 1 week. Fundus imaging revealed normal retinal morphology in both groups. ERG analysis demonstrated a mild reduction in B-wave amplitude in the 3 treatment eyes compared to the sham eyes. 0.001% chlorhexidine vs. Sham: There were no significant lenticular changes in treatment or sham injected eyes. Fundus imaging demonstrated normal retinal morphological in both groups. ERG amplitudes were similar vs sham eyes.

Conclusions: These data demonstrate concentrations of chlorhexidine above 0.01% injected into the vitreous may have toxic effects on the retina and predispose to cataract formation. This suggests concentrations below 0.01% may be the safe upper limit for intravitreal aqueous chlorhexidine. These data support that aqueous chlorhexidine may be safe for intravitreal use.

TITLE: Primary cilia and the reciprocal activation of AKT and SMAD2/3 regulate stretch-induced autophagy in trabecular meshwork cells

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Sim, A. Nettesheim, A. Dixon, P.B. Liton, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Myoungsup Sim: Commercial Relationship: Code N (No Commercial Relationship) | April Nettesheim: Commercial Relationship: Code N (No Commercial Relationship) | Angela Dixon: Commercial Relationship: Code N (No Commercial Relationship) | Paloma Liton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously reported autophagy activation in primary-cultured human trabecular meshwork (TM) cells upon mechanical stress. Here we investigate its mechanosensor and downstream signaling pathway, as well as its role in IOP homeostasis.

Methods: Human TM cells were subjected to cyclic mechanical stretch (CMS, 8% elongation, 1 cycle/sec) for up to 24 h. Autophagy activation was monitored by measuring LC3-II and p62 levels or LC3 puncta formation using western blot or confocal microscopy. Primary cilia (PC) were disrupted by chloral hydrate (CH, 4 mM for 3 day). Ca^{2+} channels were inhibited with 10 μM of amiloride, amlodipine and HC067047. Hedgehog signaling was inhibited by cyclopamine (10 μM). TGF β and AKT signaling were inhibited chemically (10 μM of LY2109761 or SB431542 for TGF β and 4 $\mu\text{g/ml}$ of SC66 for AKT) or genetically (siRNAs targeting SMAD2/3 and AKT1). The effect of deciliation on outflow facility were measured in pig eyes by using iPerfusion system.

Results: Primary cilia disruption with CH abolished autophagy induction, as evaluated by LC3-II and p62 levels (0.23 ± 0.18 and 0.63 ± 0.31 fold, $p < 0.05$, $n = 5$ and 3 , respectively) in CMS cells. Inhibiting Ca^{2+} channels or hedgehog signaling had no effect on it. In contrast, SMAD2/3 knock-down reduced the CMS-induced increase in LC3-II level by approximately 3 folds ($p < 0.01$, $n = 3$). However, similar effect was not observed by the inhibition of TGF β receptors. Intriguingly, AKT inhibition increased LC3-II levels, and the levels were significantly lowered by 1.5~2 folds ($p < 0.01$, $n = 3$) together with SMAD2/3 knock-down in both NS and CMS cells. Furthermore, knock-down of SMAD2/3 or AKT1 reciprocally decreases AKT1 phosphorylation at S473 or SMAD2/3 protein level. In addition, deciliated cells showed higher levels of pAKT1/AKT in both NS (2.36 ± 0.57 folds, $p < 0.01$, $n = 6$) and CMS (3.42 ± 2.14 folds, $p < 0.05$, $n = 6$). Finally, removal of PC disrupted the homeostatic IOP compensatory response and prevented the increase in LC3-II protein levels in response to elevated pressure challenge in pig eye (CNT VS deciliated; 2.55 ± 0.14 VS 1.31 ± 0.44 folds, $p < 0.05$, $n = 3$).

Conclusions: Our results strongly indicate that PC act as a mechanosensor for CMS-induced autophagy, and a novel cross-regulatory talk between AKT1 and SMAD2/3 signaling is critical components for its mechanism of action, which play a role in regulating IOP homeostasis.

ABSTRACT BODY:

Purpose: To determine if the growth of geographic atrophy (GA) is influenced by the presence of adjacent non-exudative type I macular neovascularization (MNV), we investigated local GA growth rates along segments of the GA margin at different distances to the adjacent type I MNV. We quantitatively computed the correlations between the local GA growth rates and their positions relative to the MNV lesions in a cohort of eyes having both type I MNV and GA.

Methods: Patients were enrolled into an ongoing institutional review board-approved prospective swept source OCT (SS-OCT) imaging study. Patients selected for this study were diagnosed with non-exudative type I MNV adjacent to an area of GA. Eyes with GA embedded within an area of type I MNV were excluded. The interval between the baseline and follow-up visits was 1 year. SS-OCT angiography (SS-OCTA) 6×6mm scans (PLEX Elite 9000, Carl Zeiss Meditec, Dublin, CA) were acquired centered on the fovea. GA was outlined using hyper-transmission defects identified on an en face structural slab positioned 64-400 µm beneath Bruch's membrane. MNV was outlined using an en face OCTA image from a slab projected between the RPE and Bruch's membrane. Regions of interest were manually traced and confirmed by two independent retina specialists. Pearson correlations were computed between the distance to the adjacent type I MNV versus local growth rates along segments of the GA margin, which were estimated using a biophysical GA growth model (Figure 1). P-values associated with the null hypothesis of no Pearson correlation were estimated using a Monte Carlo permutation scheme that incorporated the effects of spatial autocorrelation.

Results: To date, 9 eyes have been imaged and analyzed. In 7 of the eyes, global growth rates were lower than the average known growth rates for GA (Table 1). In 8 of the eyes there was a positive correlation between distance-to-MNV lesion and local GA growth rates; however, in all but 1 eye, correlations were weak (Table 1; Figure 1).

Conclusions: SS-OCT imaging combined with local GA growth analysis enabled measurement of quantitative associations between MNV position and GA growth direction. Our results are consistent with the possibility that there may be a very weak inhibitory effect of non-exudative MNV on the local growth of GA.

ABSTRACT BODY:

Purpose: HSV-1 LAT locus contains several miRNA and two sncRNA sequences. Currently, the function of the two sncRNAs in vivo is largely unknown. LAT is known to play a role in efficient establishment of latency and wild type reactivation, which are in part dependent on the antiapoptotic activity of LAT. Recently, the sncRNA sequences of LAT were shown to promote cell survival in vitro. Therefore, we tested what role, if any, one of these two sncRNAs is playing in vitro and in vivo by constructing a mutant virus (Δ sncRNA1), which lacks the sncRNA1 sequence.

Methods: We constructed an HSV-1 recombinant virus lacking sncRNA1 in McKrae background (i.e., Δ sncRNA1). Replication of the Δ sncRNA1 virus, was measured by plaque assay and LAT stability and expression of ICP0, ICP4 and gB transcripts in infected cells were measured by qRT-PCR. Female C57BL/6 mice were infected ocularly with 2×10^5 PFU/eye of wild type (WT) HSV-1 strain McKrae, LAT-deficient HSV-1 (dLAT2903) or Δ sncRNA1 virus. Virus replication in the eye (days 1-7) and eye disease (day 28) were determined. Level of latency, expression of viral and host transcripts and reactivation from latency were measured on day 28 post infection.

Results: Deletion of the 62 bp sncRNA1 sequence was verified by whole genome sequencing of the mutant virus. Δ sncRNA1 replicated slightly less efficiently in vitro, but similar to dLAT2903 and wt McKrae in vivo. There were no differences in eye disease, latency or reactivation between Δ sncRNA1 and wt McKrae. Interestingly, mouse mortality after ocular infection with Δ sncRNA1 was significantly higher when compared to either dLAT2903 or wt McKrae.

Conclusions: Our results suggest that sncRNA1 sequence of LAT may act to dampen the virulence of HSV-1 during an acute infection. The exact mechanism is currently not known, but likely involves regulating the host immune response to the virus. This hypothesis is currently being tested by Nanostring® assays.

TITLE: Serotonin receptor expression and function in mouse retina

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.E. Gibson, B.J. Frankfort, Neuroscience, Baylor College of Medicine, Houston, Texas, UNITED STATES|S.E. Gibson, G. Shen, Y.H. Park, M. Polo-Prieto, B.J. Frankfort, Ophthalmology, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Solomon Gibson: Commercial Relationship: Code N (No Commercial Relationship) | Guofu Shen: Commercial Relationship: Code N (No Commercial Relationship) | Yong Park: Commercial Relationship: Code N (No Commercial Relationship) | Maria Polo-Prieto: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Frankfort: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the retina, serotonin is implicated in neural processing, visual acuity, and neural development. There is some evidence that Selective Serotonin Reuptake Inhibitors (SSRIs), which increase the availability of extracellular serotonin, have a protective association against retinal neurodegenerative diseases such as glaucoma. Despite this potential importance, little is known about the mechanisms by which serotonin functions in the retina. For example, serotonin acts through serotonin receptors (HTRs), but little is known about the cellular distribution of HTRs in the adult retina. As glaucoma is a disease of retinal ganglion cells (RGCs), the purpose of this study is to investigate the expression and function of serotonin receptors in RGCs.

Methods: Adult mouse RGCs were isolated via immunopanning and underwent RNA sequencing as part of a previous study (Park et al., 2019). Sequence data were re-analyzed to determine the relative expression level of all known Htr genes. Immunohistochemistry (IHC) was performed in mouse retinal whole-mounts and 50 µm sections using primary antibodies to HTR1B and HTR1D, and imaged using confocal microscopy. Visual behavior was determined in Htr1b knockout (KO) mice using contrast-dependent optokinetic responses (OKRs) under scotopic and photopic conditions.

Results: Twelve Htr genes were expressed in adult RGCs, with Htr1b and Htr1d at the highest levels. IHC confirmed that HTR1B protein was present diffusely throughout the ganglion cell layer and inner plexiform layer, and that HTR1D protein was present in the ganglion cell layer where it labeled some but not all RGCs. Preliminary OKR analysis of 8-week old Htr1b KO mice (N = 6 eyes) showed reduced scotopic contrast sensitivity compared to heterozygous littermate controls (N = 18 eyes). However, contrast sensitivity did not vary significantly between groups at 20 weeks of age.

Conclusions: HTR1B and HTR1D are both expressed in RGCs, with HTR1B showing a broader pattern. Furthermore, our results suggest that HTR1B may be required for normal scotopic visual function in young adults but not older adults and therefore play a transient role in vision. Further studies will confirm these results and investigate additional roles of key serotonin receptors in RGC biology.

TITLE: Tutorial on Biostatistics: Receiver-Operating Characteristic (ROC) Analysis for Correlated Eye Data

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Rosner, R. Glynn, Harvard Medical School, Boston, Massachusetts, UNITED STATES|G. Ying, M.G. Maguire, Penn Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bernard Rosner: Commercial Relationship: Code N (No Commercial Relationship) | Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship) | Maureen Maguire: Commercial Relationship: Code N (No Commercial Relationship) | Robert Glynn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To demonstrate methods for Receiver-Operating Characteristic (ROC) analysis of correlated eye data.

Methods: Using data from the Telemedicine Approaches to Evaluating Acute-Phase Retinopathy of Prematurity Study we previously developed a model for predicting development of treatment-requiring ROP (TR-ROP). The prediction model was based on data from 771 infants with birth weight <1251 grams who completed 1 retinal imaging session by 34 weeks of postmenstrual age and 1 subsequent retinopathy of prematurity (ROP) examination to determine TR-ROP. The factors in the model were: birth weight (BW), gestational age (GA), and findings from the first image session (IM). We calculated the AUC from a prediction model using BW, GA and IM and compared it to the AUC using BW and GA only. We used three methods to estimate the AUC and difference of AUC's for correlated eye data: the Naïve method (NA) treating eyes as independent, the Obuchowski (OB) and Cluster Bootstrap (CB) methods. The OB method empirically estimates the design effect and effective sample size to derive SE's and CI's for AUC estimates and can be used with covariates that are either continuous or ordinal. The CB method selects bootstrap samples (BOOT) by randomly sampling with replacement the same number of subjects as in a given sample and includes all eligible eyes from those subjects. The AUC is computed using BOOT and the process is repeated B times. The 95% CI for AUC is based on the 2.5th and 97.5th percentiles of the ordered distribution of AUC from the B samples.

Results: A comparison of the AUCs from the models predicting TR-ROP using BW and GA only, and using BW, GA and IM are shown in Figure 1 and Table 1. The point estimates of the AUC from the model with BW and GA were identically 0.802 from the NA and OB approaches, and quite similar to the CB approach, but the 95% CIs differed. The NA approach had a narrower width for the 95% CI (0.066) than the OB (0.093) or CB (0.090) approaches. The inclusion of IM findings significantly improved the AUC by 0.076, with narrower 95% CI of Δ AUC from the naive analysis (0.053) than from the OB (0.070) and CB approaches (0.070).

Conclusions: In ROC analysis of correlated eye data, ignoring inter-eye correlation leads to an inappropriately narrower 95% CI, while the OB or CB approaches can properly account for inter-eye correlation.

TITLE: Rho is involved in regulation of myocardin-related transcription factor and myofibroblast transdifferentiation of RPE cells

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Tamiya, G. Jagatheesan, S. Ueda, Ophthalmology and Visual Sciences, University of Louisville School of Medicine, Louisville, Kentucky, UNITED STATES|S. Ueda, Tokyo Ika Daigaku Byoin, Shinjuku-ku, Tokyo, JAPAN|

Commercial Relationships Disclosure (Abstract): Shigeo Tamiya: Commercial Relationship: Code N (No Commercial Relationship) | Ganapathy Jagatheesan: Commercial Relationship: Code N (No Commercial Relationship) | Shunichiro Ueda: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myocardin-related transcription factor (MRTF) has been implicated as a key signaling molecule involved in transdifferentiation of retinal pigment epithelial (RPE) cells into myofibroblasts, which play a critical role in development of fibrosis. The purpose of this study was to examine the role of Rho signaling in MRTF function and myofibroblast transdifferentiation of RPE cells.

Methods: Transforming growth factor-beta2 (TGF-b2) was used to stimulate primary cultured porcine RPE cells. Confocal microscopy was utilized to examine immunocytochemically stained MRTF-A. Myofibroblast markers, alpha-smooth muscle actin (aSMA) and tropomyosin-1 (TPM1), was examined by western blot analyses. Myofibroblast function was assessed by collagen hydrogel contraction. The following inhibitors were used: CCG-1423, cell permeable C3 transferase, and Y27632 for inhibition of MRTF signaling, Rho and ROCK, respectively.

Results: TGF-b2 stimulation induced MRTF-A nuclear localization and myofibroblast differentiation, characterized by significantly increased myofibroblast marker expression as well as enhanced hydrogel contraction. CCG-1423 prevented induction of these myofibroblastic traits by TGF-b2, confirming the critical role of MRTF in myofibroblast transdifferentiation. Rho inhibitor suppressed MRTF-A nuclear localization, and significantly reduced myofibroblast marker expression as well as hydrogel contraction. In contrast, ROCK inhibition had little effect on TGF-b2 induced MRTF localization or myofibroblast differentiation, and significantly reduced hydrogel contraction only at a higher concentration.

Conclusions: Our data show Rho, but not its downstream effector ROCK, is involved in the regulation of MRTF localization and function. Further understanding of mechanisms involved in Rho activation as well as signaling linking Rho to MRTF nuclear localization may reveal novel targets for therapeutic intervention for fibrotic complications in which RPE cells play a significant role such as proliferative vitreoretinopathy or exudative age-related macular degeneration.

ABSTRACT BODY:

Purpose: Inflammation is a protective host response evoked during injury or microbial Infection. However, persistent inflammation can cause ocular tissue damage, warranting newer non-immunosuppressive anti-inflammatory therapeutic. In this study, we investigated the anti-inflammatory and adjunct therapeutic role of a bioactive lipid mediator, resolvin D1 (RvD1), in combination with antibiotics and steroids.

Methods: Endophthalmitis was induced in wild type C57BL/6 mice via intravitreal injection of *S. aureus*. Six hours post-infection, eyes were treated with RvD1, sub-MIC levels of vancomycin, and dexamethasone either alone or in various combinations. Untreated eyes and eyes with PBS injection were used as controls. The disease progression was monitored via ophthalmoscopic examination, electroretinography (ERG), histopathological exam, and bacterial burden estimation. The level of intraocular inflammatory cytokines and chemokines was assessed by qPCR and ELISA.

Results: Intravitreal injection of RvD1 either alone or in combination with vancomycin significantly improved the disease outcome as revealed by the drastically reduced bacterial burden, intraocular inflammatory cytokines (IL1 β and IL-6), and chemokines (MIP2 and KC), and preserved ERG 'a' and 'b' wave response. Among the combination therapies, RvD1 + vancomycin exhibited better resolution of inflammation in comparison to the dexamethasone + vancomycin combination. Importantly, RvD1 treatment protected mice even with the sub-MIC levels of vancomycin, whereas dexamethasone failed to exert protection under these conditions. The histopathological analysis also revealed that RvD1 can protect retinal tissue architecture either alone or in combination with vancomycin.

Conclusions: Our study demonstrates that RvD1 could be used as an adjunct therapy in combination with antibiotics to treat bacterial endophthalmitis. RvD1 therapy can also reduce the dosage of the overall antibiotics required to control bacterial proliferation in this devastating ocular complication.

ABSTRACT BODY:

Purpose: To investigate the role of infiltrating hematogenous macrophages in optic nerve fibrotic scar formation and explore the potential effect of macrophage depletion in retinal ganglion cell (RGC) protection and optic nerve regeneration after traumatic injury.

Methods: Col1 α 1-GFP mice and C57BL/6 mice received clodronate encapsulated liposome injection to deplete hematogenous macrophage. Phosphate buffered saline (PBS) liposomes were used as injection vehicle control. Intravenous liposome injection was performed via the retro-orbital sinus 3 days prior to optic nerve crush (ONC) and 1, 4, and 7 after ONC. To further dissect the role of hematogenous and resident macrophages in scar formation, we used Dil liposomes to label hematogenous macrophages. Immunofluorescence staining was used to characterize fibrotic scar after macrophage depletion and differentiate the role of hematogenous macrophage and resident microglia.

Results: Hematogenous macrophages accumulated centrally in the fibrotic scar at the optic nerve crush site, while resident microglia were present at the edge of the scar. Hematogenous macrophage depletion reduced fibrotic scar formation in both Col1 α 1-GFP mice and C57BL/6 mice. The spindle-shaped optic nerve fibrotic scar was not present in the macrophage depleted treated group compared to the control-treated group. Macrophage depletion did not protect RGCs in the retina after traumatic optic nerve injury.

Conclusions: We characterized the fibrotic scar which forms after traumatic optic nerve crush and demonstrates that optic nerve scar formation is dependent on the infiltration of hematogenous macrophages. Depletion of hematogenous macrophages may be the first step towards axonal regeneration and functional recovery by reducing optic nerve scar formation.

Commercial Relationships Disclosure (Abstract): Jerome Roger: Commercial Relationship(s);Variant:Code F (Financial Support);PCT/EP2020/056199:Code P (Patent);Variant:Code I (Personal Financial Interest) | Elodie-Kim Grellier: Commercial Relationship(s);PCT/EP2020/056199:Code P (Patent) | Sophie Lourdel: Commercial Relationship: Code N (No Commercial Relationship) | Muriel Perron: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Efficacy and safety of gene therapies for recessive retinal diseases (RDs) have been proven with preclinical success translated into clinical effectiveness. However, this approach is rarely chosen for dominant forms. Based on our published work, we decided to focus on dominant-negative mutations in the transcription factor CRX. We developed a mutation-independent AAV vector that could circumvent the clinical and genetic heterogeneity of CRX mutations.

Methods: To express CRX specifically in photoreceptors, the Rhodopsin Kinase 1 promoter and the AAV vector serotype AAV2/5 were chosen (AAV-CRX). To assess the efficacy of AAV-CRX for different CRX-associated diseases, we used $Crx^{Rip/+}$ mice, a model of Leber Congenital Amaurosis and we established a new model for cone dystrophy, $Tg(CRX^{R41W})$ carrying the human CRX^{R41W} mutation driven by Crx promoter. Subretinal injection was done in PN30 animals. Immunohistochemistry, immunoblot, and electroretinogram (ERG) were used for $Tg(CRX^{R41W})$ characterization and gene therapy efficacy assessment.

Results: $Tg(CRX^{R41W})$ characterization revealed a dose-dependent deleterious effect of CRX^{R41W} . Indeed, heterozygous $Tg(CRX^{R41W})$ carrying a single insertion displayed a functional retina while homozygous $Tg(CRX^{R41W})$ exhibited reduced cone function after 3 months. Presence of multiple copies led to rapid and severe photoreceptor degeneration after 2 months. Our results corroborated the relevance of increasing the amount of CRX^{WT} to counteract the dominant-negative effect of mutant CRX. We first verified that AAV-CRX injection led to specific and high expression of CRX in $Crx^{Rip/+}$ immature photoreceptors with no toxicity. In AAV-GFP $Crx^{Rip/+}$ injected retina, photoreceptors still lacked outer segments and visual transduction protein expression. In contrast, 3 months after injection, AAV-CRX led to i) rod and cone opsin expression, ii) outer segment formation, iii) some degree of ERG response whereas it remained flat in controls iv) fully restore behavior response to light stress using a Dark/Light box test. Homozygous $Tg(CRX^{R41W})$ mutant mice are also currently being tested.

Conclusions: Overall, our gene therapy approach shows promising results for treating CRX-associated RDs. It also highlights the potential interest of gene therapy to treat patients with RD carrying dominant-negative mutations.

ABSTRACT BODY:

Purpose: The subretinal injection used during delivery of gene therapy vectors forces the neural retina to detach from the retinal pigment epithelium posing a risk of photoreceptor damage. Here, we use adaptive optics scanning light ophthalmoscopy (AOSLO) to assess the integrity of the cone mosaic and evaluate cone densities before and one-month after subretinal injections of AAV2-hCHM in subjects with choroideremia (CHM).

Methods: Low dose (up to 5×10^{10} vector genome (vg) per eye, n=5) or high dose (up to 1×10^{11} vg per eye, n=4) AAV2-hCHM was delivered via unocular subfoveal injection in 9 CHM patients, ages 26-57. The macular regions of both eyes were imaged pre- and one-month post-injection using a custom-built, multimodal AOSLO. Images were montaged within each timepoint, then manually aligned across timepoints with cellular accuracy. Cone inner segments were manually identified in pre- and post-injection images at multiple regions of interest (ROIs) in both eyes in all subjects. Bound cone densities were compared between timepoints and between injected and uninjected eyes. AOSLO images were compared with spectral-domain optical coherence tomography (SD-OCT).

Results: AOSLO images showed preservation of the cone inner segment mosaic at one-month post injection in all 9 AAV2-hCHM injected eyes, with the exception of foveal disruption in one patient. Cone-by-cone longitudinal alignment was attained at multiple ROIs in every case. There was no significant difference in cone density across timepoints or between injected and uninjected eyes. Cone densities were the same for injected eyes pre- vs one-month post-injection (mean \pm standard deviation = $22,400 \pm 12,000$ vs $24,000 \pm 11,200$ cones/mm²) and uninjected eyes ($24,500 \pm 11,700$ vs $24,300 \pm 12,100$ cones/mm²). Post-injection SD-OCTs showed retention of the foveal inner segment ellipsoid zone (EZ) in all eyes, but loss of EZ definition and cone outer segment tip signal in the patient with foveal disruption.

Conclusions: Cone mosaic integrity is maintained following subretinal delivery of AAV2-hCHM, providing strong evidence in support of the safety of the surgical injections and short-term exposure to this viral vector. Individual vulnerability to the subfoveal injection may account for the foveal cone loss observed in one patient. Future studies will evaluate the integrity of the cone mosaic following long-term AAV2-hCHM gene augmentation.

ABSTRACT BODY:

Purpose: Diopsys[®] NOVA is a novel full-field electroretinography (ffERG) device with the ability to make rapid measurements of retinal electrophysiologic function. Diagnosys[®] ffERG is a clinical gold-standard ffERG device that can take upwards of four hours to make measurements. The purpose of this study was to investigate whether Diopsys[®] NOVA fixed-luminance flicker ffERG magnitude measurements correlate with amplitude measurements of Diagnosys[®] 30 Hz flicker ffERG.

Methods: Eighteen patients (36 eyes) with a variety of retinal diseases were subjected to conventional 30 Hz flicker ffERG followed by Diopsys[®] NOVA fixed-luminance flicker ffERG. Diopsys[®] magnitude measurements were compared to conventional ffERG amplitude measurements, and a Pearson correlation was used to evaluate any existing correlation. A Bland-Altman plot was also utilized to determine agreement between ffERG modules.

Results: Mean age of patients was 51.3 ± 22.7 years old. 67% of patients were female. The average Diopsys[®] magnitude measurement was 9.79 ± 5.20 μ V while the average Diagnosys[®] amplitude measurement was 56.77 ± 31.85 μ V. A significant, positive correlation ($r=0.936$, $P<0.001$) was observed between magnitude (Diopsys[®]) and amplitude (Diagnosys[®]) measurements. All data points lay within ± 1.96 SD of the mean difference, and a negative bias of -46.98 μ V for the Diopsys[®] NOVA fixed-luminance ffERG flicker measurements. As magnitude and amplitude increased, the difference between these values also increased.

Conclusions: There is a statistically significant positive correlation between values of Diopsys[®] NOVA fixed-luminance flicker ffERG amplitude and Diagnosys[®] 30 Hz flicker ffERG magnitude. Agreement between the two systems of measurement is also demonstrated. Additionally, the Diopsys[®] based measurements have a negative bias compared to those of the conventional, gold-standard ffERG machine. This negative bias can be attributed to the skin electrodes used by the Diopsys[®] NOVA device in lieu of conventional ffERG corneal electrodes. These results suggest that the rapid Diopsys[®] NOVA module can produce accurate information assessing limited retinal function.

TITLE: Assessing the Severity of Fuchs Endothelial Corneal Dystrophy by using Scheimpflug Tomography

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.V. Patel, E.J. Treichel, K.H. Baratz, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sanjay Patel: Commercial Relationship(s);GlaxoSmithKline:Code C (Consultant);Senju Pharmaceuticals:Code C (Consultant);Santen Inc.:Code C (Consultant);Emmecell:Code C (Consultant) | Emily Treichel: Commercial Relationship: Code N (No Commercial Relationship) | Keith Baratz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Scheimpflug imaging can be used to predict the prognosis of Fuchs endothelial corneal dystrophy (FECD) by detecting tomographic patterns consistent with the presence of subclinical corneal edema based on posterior elevation and pachymetry maps. In this study, we developed a severity scale for FECD based on these maps, and evaluated intra- and inter-observer variation for assessing severity.

Methods: In a cross-sectional study, eyes with a range of severity of FECD were examined by two cornea specialists and underwent Scheimpflug imaging (Pentacam, Oculus). An ordinal scale was developed to assess the severity of FECD ranging from normal (grade 1) to severe edema (grade 6), based on loss of parallel isopachs, displacement of the thinnest point of the cornea, and posterior surface depression within the central 4 mm of the cornea. Subtle findings suspicious for early tomographic edema were defined as grade 2. Progressive severity of edema was based on the depth of posterior surface depression (mild, moderate, advanced, and severe were grades 3-6, respectively). Masked and randomized images were presented to both cornea specialists without associated clinical information. Intra-observer (1 observer evaluating the same images on 2 occasions separated by 2 weeks) and inter-observer agreement were assessed by using the kappa statistic (κ) with 95% confidence interval (CI), and McNemar's test for significant differences.

Results: Exact agreement between repeated assessments by one observer occurred for 97% (277/286) of eyes ($\kappa=0.96$, CI 0.93 to 0.99, $p=0.88$). All disagreements were by 1 grade only. Exact agreement between assessments by both observers occurred for 85% (244/286) of eyes ($\kappa=0.81$, CI 0.76 to 0.86, $p=0.12$). Disagreements were by 1 grade for 40 eyes and by 2 grades for 2 eyes, and mainly occurred because one observer assigned increased severity relative to the other when determining normal tomography from those with suspicious findings of early edema.

Conclusions: Assessing the severity of FECD from Scheimpflug tomography has excellent intra- and inter-observer agreement based on the proposed severity scale. The lower inter-observer agreement was a result of lack of sufficient standardization between observers rather than limitations of the imaging technology. Further investigation is needed to determine if this severity assessment can detect tomographic and clinical progression.

ABSTRACT BODY:

Purpose: To investigate the similarities and differences in reflectivity of individual cone photoreceptors as seen by adaptive optics (AO) scanning light ophthalmoscopy (AO-SLO) in comparison to AO-optical coherence tomography (AO-OCT).

Methods: Simultaneous, co-registered AO-SLO and AO-OCT images unaffected by transverse or longitudinal chromatic aberration were acquired from three subjects at eccentricities from 2.5° to 10° temporal. Images were acquired using a custom multimodal AO ophthalmoscope in which 10% of the 1080 nm light returning from the eye was captured for AO-SLO using a custom-developed avalanche photodiode (Boston Micromachines), with the remaining 90% of 1080 nm light used for AO-OCT. Following manual identification of photoreceptors, the following measurements corresponding to single cones were extracted: (1) AO-SLO intensity, (2) AO-OCT inner segment/outer segment (IS/OS) junction intensity, (3) AO-OCT cone outer segment tip (COST) intensity, and (4) AO-OCT outer segment projection intensity. In addition, outer segment length was measured as the intensity peak-to-peak distance between the IS/OS and COST of each cone.

Results: The variable reflectivity observed in the cone photoreceptor mosaic matched well between the AO-SLO and AO-OCT projection images. AO-SLO intensities of 500 cones identified in the images were significantly correlated with outer segment projection intensity in AO-OCT ($p < 0.01$, F-test on linear regression), with stronger correspondence of the AO-SLO intensity to IS/OS intensity compared to COST intensity. Both the IS/OS and COST layers could be observed in 91% of cones. In the remaining 9% of cones, only a single reflection in the IS/OS was observed with no apparent corresponding COST reflection. When both IS/OS and COST reflections were observed, the IS/OS reflection was brighter for 88% of cones. There was no apparent relationship between AO-SLO reflectivity and outer segment length ($p > 0.01$, F-test on linear regression).

Conclusions: The use of a shared 1080 nm light source for simultaneous acquisition of AO-SLO images and AO-OCT volumes enables direct comparison of cone reflectivity across two inherently co-registered modalities. We show that cone reflectance on AO-SLO images arises more strongly from the IS/OS band, which may have implications for our understanding of cone waveguiding properties and their disc shedding processes.

ABSTRACT BODY:

Purpose: Nitric oxide (NO) is a free radical which plays an important role in immune and inflammatory responses as an important intercellular messenger. In addition, NO has an important role in inflammatory responses in the ocular surface. Histatin peptides are well established antimicrobial and wound healing agents. These peptides are important in multiple biological systems, playing roles in responses to the environment and immunomodulation. Given the importance of macrophages in responses to environmental triggers and pathogens, we investigated the effect of histatin-1 (H1) on LPS-induced inflammatory responses and the underlying molecular mechanisms in RAW264.7 macrophages.

Methods: RAW264.7 mouse macrophages were stimulated by adding 10 ng/mL of lipopolysaccharide (LPS) with or without H1, dose-dependently. The production of NO were determined by Griess assay (Sigma, St. Louis, MO) in RAW264.7 seeded in 96-well plates. Expression of inducible nitric oxide synthase (iNOS) was measured by Western blot analysis. Activation of downstream signaling molecules were detected by Western blotting using phosphorylation specific MAPKs antibodies.

Results: Griess assay testing demonstrated that treatment with H1 inhibited significantly the LPS stimulated NO production in RAW264.7 cells, in a dose dependent manner. iNOS expression was detected in LPS treated RAW264.7 cells, and pre-treatment of H1 inhibited activation. Macrophages did not exhibit cytotoxic response to up to 100 μ M of H1 treatment. Phosphorylation of p38 and JNK1/2 MAPKs were inhibited after pre-treatment with H1; however, pro-survival ERK1/2 MAPK protein was not inhibited by H1 in LPS stimulated RAW264.7 cells.

Conclusions: These results demonstrate that H1 can inhibit LPS induced inflammatory mediator production via suppressing activation of MAPK signaling pathways in macrophages.

ABSTRACT BODY:

Purpose: Clinician interpretation of fluorescein angiograms (FA) can be subjective. In a translational study of FA images, we aimed to quantify variability of clinician FA segmentation and hypothesized a deep learning algorithm can segment FAs for vascular leakage and help detect clinically significant change.

Methods: 200 uveitis patient FA images were obtained. As the ground truth, a team of clinicians segmented images for vascular leakage. A deep learning algorithm with a modified U-net architecture was trained to segment leakage. The Dice Similarity Coefficient (DSC) was used to compare the algorithm's segmentation results to the ground truth segmentation (the DSC ranges from 0 to 1, 0 denotes no overlap between 2 segmentations and 1 denotes perfect overlap). For interrater variability, 2 clinicians independently segmented 20 images and the average DSC was calculated. Lastly, 20 pairs of FA images were used to detect clinically significant changes in leakage (the gold standard being an expert clinician's assessment). For each pair, the difference in percentage of the image occupied by the algorithm's leakage segmentation was calculated and used to create a ROC curve and to determine a threshold for clinically significant change.

Results: The 200 images came from 61 uveitis patients (median 2 images/patient, IQR 1-4). Diagnoses by anatomic location included anterior (2), intermediate (24), and posterior/panuveitis (35). The average FA timepoint was 361 seconds (SD 174). The algorithm achieved a best average DSC of 0.572 (Fig 1). Concordance between 2 clinicians was lower, with an average DSC of 0.374 (Fig 2). Lastly, a threshold of >0.8% change in the percent of the retinal area covered by the algorithm's segmentation had a 90% sensitivity and specificity for discerning clinically significant leakage (AUC: 0.95).

Conclusions: A preliminary deep learning algorithm was developed, had initial success in segmenting leakage in uveitis patient FAs, and was used to determine clinically significant change in vascular leakage. Further algorithm development is needed to improve segmentation accuracy. However, this is a first step to more standardized FA interpretation which can be useful as clinical trial outcomes.

ABSTRACT BODY:

Purpose: To develop a machine learning model for detecting glaucoma progression from retinal nerve fiber layer (RNFL) thickness measurements acquired with optical coherence tomography (OCT).

Methods: We developed an unsupervised Gaussian mixture model with an expectation maximization (GEM) framework to identify clusters with similar RNFL thickness patterns in circular OCT scans (768 A-scans) from 691 eyes of 691 patients. We then identified the top prevalent eigenvectors (patterns) of the clusters representing eyes in the mild and advanced stages of glaucoma. We selected the slopes across these eigenvectors such that 95% of 2540 eyes in a separate longitudinal stable dataset (~9 follow-up visits) were not progressing. We used the selected slopes to test the model on a third longitudinal dataset with 254 eyes (~9 visits) and compared the detection rate of the proposed machine learning model with linear regression of RNFL summary parameters.

Results: Machine learning discovered three clusters within 691 RNFL thickness measurements of 691 eyes (Fig. 1). A total of 12 patterns of RNFL loss (eigenvectors) were prevalent and accounted for about 77% of the total variability in the data (Fig. 2). The machine learning model detected glaucoma progression in 38.6% of the eyes tested, while average RNFL in global, superior, and inferior hemifields detected progression in 15.8%, 13.0% and 15.0%, of the eyes, respectively.

Conclusions: The proposed machine learning construct identified a higher proportion of structural progression based on RNFL thickness measurements than linear regression of summary parameters. Additionally, the model identifies the major patterns of RNFL loss, which may aid clinicians in better monitoring of glaucoma subjects.

ABSTRACT BODY:

Purpose: To evaluate the retinal structural and functional rescue of gene supplementation therapy by subretinal delivery of human RS1 (hRS1) gene carried by AAV2 7m8 vector in mouse models of X-linked juvenile retinoschisis (XLRS).

Methods: Male pups from three mouse models, a knockout with inserted lacZ reporter gene, a C59S point mutant substitution, and an R141C point mutant substitution, were used for subretinal injection 1uL of AAV2 7m8-Rho-hRS1 at a titer of 3e13vg/mL on postnatal day 21 in the right eyes, and the left eyes were used as no treatment controls. In vivo retinal structural restoration was evaluated with optical coherence tomography (OCT) and functional rescue with electroretinography (ERG) at 2- and 4-months post injection. Ex vivo retinal tissues harvested at 4 months post injection were flat mounted for immunohistochemistry (IHC) using anti-RS1 and anti-arrestin antibodies to assess hRS1 expression and local retinal photoreceptor protection. A subset of retinal tissues from each group were examined using Western Blot (WB) to confirm hRS1 expression.

Results: Retinal structural rescue was observed 2 months through 4 months post subretinal injection in all three Rs1 mutant mouse models, manifested by disappearance of retinoschisis and well-organized retinal layers on OCT imaging, while controls eyes showed worsening retinal splitting and disorganization over time. Dark adapted ERG b wave at 2 months represented 17.2%, 28.2%, and 23.5% functional restoration, respectively compared to their control eyes, which maintained through 4 months post injection. IHC in retinal flat mounts showed the retinal areas covered by RS1 positive signal were 50-70%. WB under reducing condition showed monomeric hRS1 band from retinal samples of the treated eyes. Cone photoreceptor protection was observed locally where there was, or even no RS1 expression, to varying extent, in the treated eyes evidenced by arrestin immunostaining. The local structural protection and cone cell benefit were also observed in the treated eyes without functional rescue.

Conclusions: Subretinal delivery of AAV RS1 is effective in all three Rs1 mutant mouse models, providing partial retinal structural and functional restoration. Gene supplementation shows promise for XLRS gene therapy. Less invasive delivery method and robust photoreceptor promoters for more efficient treatment are being explored.

ABSTRACT BODY:

Purpose: People with prediabetes are at higher risk of developing diabetes. We investigate the age-controlled relationship between glucose parameters and ten retinal layer thicknesses in optical coherence tomography (OCT) macular volume scans of non-diabetic and prediabetic participants with/without glaucoma in a large study. The fasting, 30-min, and 2-h plasma glucose (FPG, 30-min PG, and 2-h PG) during an oral glucose tolerance test (OGTT) were employed.

Methods: All eyes of non-diabetic and prediabetic participants with available OGTT and OCT scans from the population-based, sex- and age-stratified LIFE-Adult study (age range: 20-80) were included. Macular volume scans (97 horizontal B-scans with 512 A-scans each) from Spectralis OCT were automatically segmented into ten layers (Figure 1) after exclusion of unreliable B-scans (quality < 20 dB). Pointwise partial Pearson correlation during OGTT adjusted for age was calculated. The analysis was repeated excluding participants with self-reported glaucoma diagnosis or medication.

Results: Figure 2 visualizes the age-controlled correlation of glucose level and A-scans in each layer from 5532 eyes of 2787 participants, including 128 participants with glaucoma. For FPG, a predominantly negative correlation (red) with layer thicknesses of RNFL, ONL, and MZ and a positive correlation (blue) with EZ and OS were observed (Figure 2A). Similar correlation patterns were found for 30-min PG with layer thicknesses of RNFL, MZ, and EZ, with a slightly increasing negative correlation with layer thicknesses of GCL and IPL (Figure 2B). For 2-h PG, there is an apparent negative correlation with layer thicknesses of GCL, IPL, and MZ (Figure 2C). The correlation patterns remained unchanged when participants with glaucoma were excluded.

Conclusions: There were specific correlation patterns between retinal layer thicknesses and measures during OGTT. With the prolongation of the time post-glucose intake, higher glucose level was more clearly related to thinner GCL and IPL and firmly associated with thinner MZ, while the correlation with RNFL, ONL, EZ, and OS became less pronounced. Macular layer thicknesses could be an early indication of the retinal structural change prior to diabetes

and in this cohort did not seem to be impacted by comorbidity of glaucoma.

ABSTRACT BODY:

Purpose: In this study we investigated whether quantitative analysis of leakage on ultra-widefield fluorescein angiography (UWFA) correlated with disease activity and severity in uveitis patients treated with adalimumab.

Methods: This is a retrospective case series. Patients were included if they were diagnosed with uveitis, were taking adalimumab during the 12-month follow-up period, had follow-up visits, and had UWFA imaging taken. Patients were classified as responsive to adalimumab if they had improvement or stabilization of disease on exam and/or imaging at 12-month follow-up; patients were categorized as non-responders if they had worsening disease at 12 months, stopped treatment, or switched to a different medication. Automated software (Early and Late phase Selection Application) was used to select the highest quality late-frame UWFA image. Leakage as a percent of retinal area was quantified using an automated algorithm (Image-Pro Analyzer 7.0). Leakage area and percent change in leakage over time were compared to LogMAR visual acuity, clinical disease activity, and treatment success or failure using linear regression analysis and two-tailed Student's t-test.

Results: A total of 20 patients (13 female, 7 male) were included in this study. 13 of 20 patients (65%) demonstrated some response to adalimumab, whereas 7 of 20 patients (35%) had no treatment response. At 12 months, treatment-responsive patients had a 62% decrease in leakage area compared to baseline, whereas treatment-failure patients had a 513% increase in leakage compared to baseline ($p = 0.02$). There was a small albeit significant correlation between leakage area and visual acuity ($r^2 = 0.08$, $p < 0.001$).

Conclusions: In this study, we show that leakage correlates with visual acuity and clinical response to adalimumab. Quantitative analysis of leakage on UWFA may be a useful novel biomarker in the evaluation of non-infectious uveitis in the clinical and research settings.

ABSTRACT BODY:

Purpose: In different retinal diseases, photoreceptors cells at different eccentricities can be selectively damaged or spared. Previous investigations have identified unique foveal features by comparing gene expression between the foveal versus peripheral retina. We refined these preliminary studies by focusing on differences within the macula, comparing the fovea and the directly surrounding perifoveal retina with single-cell RNA sequencing.

Methods: Paired foveal (1 mm) and perifoveal (4 mm) neural retina samples were acquired from four human donor eyes. Retinal tissue was dissociated in papain for one hour and cryopreserved so that cell suspensions could be thawed in parallel for single-cell RNA sequencing. Resulting reads were mapped to the human genome with CellRanger and analyzed with Seurat.

Results: We recovered 5,856 foveal and 28,637 perifoveal cells that corresponded to all major retinal populations (Figure 1A). Next, we compared foveal versus perifoveal gene expression across all retinal populations. Foveal cone photoreceptors demonstrated increased expression of RPGR and RP1L1, which are mutated in cone-rod dystrophy and occult macular dystrophy, respectively. In contrast, perifoveal cone photoreceptors were enriched in COL4A3, a gene with AMD-associated genetic variants. Perifoveal Müller cells showed increased expression of the visual cycle genes RDH10 and RLBP1 as well as the iron-binding protein transferrin (TF). In addition, we compared results from this study to five independent single-cell RNA sequencing investigations comparing central versus peripheral retina (Figure 1B). Foveal enriched genes from our study were increased in the central retina from these datasets. Likewise, perifoveal enriched genes from our study demonstrated increased expression in the peripheral retina of these datasets.

Conclusions: Single-cell RNA sequencing reveals regional patterns of gene expression across many different retinal cell populations. We identified foveal enrichment or depletion of several transcripts involved in inherited retinal disease.

ABSTRACT BODY:

Purpose: LCA10 is a severe, degenerative inherited retinal disease resulting in childhood blindness, which has no treatment. Sepofarsen is an intravitreal RNA antisense oligonucleotide which showed clinically meaningful results following unilateral injection in a Ph1b/2 trial for LCA10 due to the c.2991+1655A>G mutation in the CEP290 gene. Safety and efficacy of sepfarsen dosed in the second eye was evaluated in the extension trial (Insight; NCT03913130).

Methods: Patients who completed the Ph1b/2 trial, multicenter, open-label, multiple-dose escalation sepfarsen trial were given the opportunity to enroll into the extension trial for continued dosing in their first treated eye as well as initiation of treatment in their second eye with the 160/80µg loading/maintenance dose, using a 6-monthly dosing interval. Nine out of 11 patients from the Ph1b/2 trial enrolled in the extension trial. As main efficacy parameters, change in Best-Corrected Visual Acuity (BCVA) and Full-Field Stimulus Test (FST) were assessed.

Results: At data cut-off in July 2020, 4 patients aged 15–45 years had received 1 intravitreal injection of sepfarsen in their second eye and had completed a 3- or 6-month visit. One patient developed cataract at Month 9 in the second treated eye. No other safety findings were reported. Meaningful BCVA improvements (>-0.8 logMAR) were reported in the second treated eye for 2 of the 4 patients, similar to the improvements observed in their first treated eye. All 4 patients showed a FST improvement ranging from -0.74 to -2.35 log cd/m², generally similar to the FST responses observed in their first treated eyes.

Conclusions: This data analysis strongly corroborates the clinically meaningful vision improvements and safety profile observed in the Ph1b/2 trial. Second eye responses to sepfarsen parallel the first eye treated responses both in visual acuity and retinal sensitivity (FST) improvements. Sepofarsen safety profile for the 160/80µg dose group in this extension trial is consistent with that observed in the Ph1b/2 trial. Further analyses on this ongoing extension trial and

the Ph2/3 trial (Illuminate; NCT03913143) are expected.

ABSTRACT BODY:

Purpose: To evaluate early changes in corneal surface after refractive surgery by LASIK, with an ocular surface analyzer.

Methods: Pre- and 1-week post-operative measurements of OSDI score, Non-Invasive Tear Breakup Time (NIBUT), tear meniscus height (mm), and meibomian gland dropout (%) were made with the ocular surface analyzer LacryDiag (Quantel, Cournon d'Auvergne, France).

Results: 28 eyes of 14 patients were included. Pre- and post-op findings were as following: OSDI score from 8 to 18 ($p= 1.25$); NIBUT from 10.7 seconds to 6.2 seconds OD and 10.9 seconds to 6.3 seconds OI ($p= 1.10$); tear meniscus height from 0.5 mm OU to 0.3 mm OD ($p= 1.64$) and 0.2 mm OI (1.64); and meibomian gland dropout from 21.6 % to 21 % OD and 23.6 % to 23 % OI ($p= 1.50$).

Conclusions: Although statistically significant differences were not found between pre- and post-op measurements, there were clinical and symptomatic differences in patients.

ABSTRACT BODY:

Purpose: In this case series, we aim to evaluate the safety of intravenous high dose pulse methylprednisolone succinate (IVHDM) in the management of different types of severe or refractory non-infectious uveitis in a pediatric population.

Methods: We reviewed all uveitis patients who were 16 years of age or younger and who received IVHDM with a dose of ≥ 500 mg per day (1 to 3 days a month) for at least 3 months during their management at a tertiary care eye hospital between June 2018 and October 2020. Adverse events (AEs) were recorded up to 6 months after the last infusion.

Results: 20 pediatric patients who received IVHDM of dose of 500 mg or higher per day were identified. 6 patients received IVHDM only once and were excluded. The remaining 14 patients received IVHDM for at least 4 months, 1 or 3 consecutive days per month. Age was 11.9 ± 2.4 years and 5/14 were male. Duration of treatment was 12.1 ± 6.2 months. 13 patients received IVHDM in combination with other immunomodulatory therapy (IMT). IVHDM was given at a dose of 10-20 mg/kg/infusion. Mean cumulative dose per patient was 17.25 gm (Range: 3.5-50). Concomitant IMT was intravenous infliximab (8/13), tocilizumab (3/13) or immunoglobulins (2/13). Indications for IVHDM were panuveitis with retinal vasculitis (9/14), isolated retinal vasculitis (2/14), autoimmune retinopathy (AIR) (2/14) and juvenile idiopathic arthritis (JIA) associated optic neuritis (1/14).

There were three separate major systemic AEs in three separate patients: asymptomatic sinus bradycardia during infusions, pyogenic arthritis in a patient with a preexisting autoimmune arthritis and a single event of fainting and convulsions. The most common minor systemic AEs were derangements in blood count (10/14), mild increase in random blood glucose (10/14) and transient increase in liver enzymes (8/14). Cataract developed/progressed in 4 patients; 2 of them had been on long-term topical steroids.

Number of AEs was strongly correlated with duration of treatment (coef.:0.799; $p<0.001$) and moderately correlated with the cumulative dose (coef.:0.572; $p=0.033$). No statistically significant correlation was found with age of patients.

Conclusions: IVHDM might be a relatively safe therapeutic option for pediatric population with aggressive/refractory posterior or panuveitis. The reported AEs in this series can also be attributed to the concurrent IMT or the underlying disease itself.

TITLE: Association between the systemic Omega-3 Index and corneal nerve architecture

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Zhang, L.E. Downie, Optometry and Vision Sciences, The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, Victoria, AUSTRALIA | J.P. Craig, Ophthalmology, The University of Auckland Faculty of Medical and Health Sciences, Auckland, Auckland, NEW ZEALAND |

Commercial Relationships Disclosure (Abstract): Alexis Ceecee Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Craig: Commercial Relationship: Code N (No Commercial Relationship) | Laura Downie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Omega-3 Index is a measure of systemic levels of long-chain omega-3 fatty acids (FAs), eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). The aim of this cross-sectional study was to investigate whether an association exists between the Omega-3 Index and corneal nerve structural parameters, in healthy controls and those with diabetes.

Methods: Participants with diabetes and no or mild peripheral neuropathy symptoms (n=26), and age- and sex-matched controls (n=21), underwent systemic FA analysis and comprehensive ocular surface assessments. Corneal sub-basal nerve structure was assessed by in vivo confocal microscopy and quantified with automated software. Corneal sensitivity was measured with non-contact esthesiometry. The relationship between systemic FA levels and corneal nerve parameters was evaluated using multiple linear regression (MLR), adjusted for age, sex, neuropathy symptom score, and the presence of both diabetes and dry eye disease (according to TFOS DEWS II criteria).

Results: The Omega-3 Index was similar in both groups (median [IQR]; control vs diabetes: 5.54% [4.54–6.06] vs 5.00% [4.25–5.68]; p=0.32). Corneal nerve fibre length (CNFL) was higher in the control group than in the diabetes group (mean \pm SD: 14.71 \pm 2.99 mm/mm² vs 12.60 \pm 3.41 mm/mm²; p=0.03). Using MLR modelling, Omega-3 Index (b=0.33; p=0.02), age (b=-0.46; p=0.001) and diabetes (b=-0.30; p=0.03) were significant factors associated with CNFL (R²=0.39, F=4.22; p=0.002). In a separate model, DHA (b=0.32; p=0.027) and age (b=-0.41; p=0.003) were associated with CNFL (R²=0.37, F=3.99; p=0.003). Neither EPA nor omega-6 levels were related to CNFL. There was no association between systemic FA levels and corneal sensitivity in either group.

Conclusions: This study newly describes a relationship between systemic Omega-3 Index and CNFL, the major anatomical feature of the corneal sub-basal nerve plexus.

ABSTRACT BODY:

Purpose: Uveitis is an inflammatory ocular disease and important cause of visual impairment and blindness. The purpose of this study is to delineate the demography and pattern of clinical coding between 2008 and 2018.

Methods: The Stanford Research Repository (STARR) Tools was used to identify 5,441 patients with International Classification of Diseases (Ninth and Tenth Editions) (ICD) codes for infectious and non-infectious uveitis in one academic institution (Table 1) in patients 18 years or older from 2008 to 2018. Patient demography (age, gender, race, ethnicity), pattern of ICD coding, and types of uveitis was analyzed using custom R scripts.

Results: Of 5,441 unique patients with infectious/non-infectious uveitis, analysis of patient demography revealed that age at first visit significantly increased between 2008 to 2018 ($p<0.001$), with no change in gender, race, ethnicity ($p>0.1$) (Table 1). Analysis of uveitis ICD codes revealed gradual increase in the number of infectious/non-infectious uveitis codes used and marked increase in the complexity of coding. In 2008, there were only 3 ICD codes used to designate infectious/non-infectious uveitis, which increased by 2014. By 2018, there were 9 different ICD codes. The most striking changes in ICD coding was in the frequency of ICD codes 135, 362.18, and 115.92. The most common ICD9 code in the data set was 135 (sarcoidosis); the usage of this ICD code significantly increased over the decade ($p<0.01$). In contrast, ICD9 codes 362.18 (retinal vasculitis) and 115.92 (histoplasmosis retinitis) were not commonly used at the beginning of the decade, but later in the decade, their use significantly increased ($p<0.001$). Despite its introduction in 2016, ICD10 codes were not used frequently. There was only one ICD10 code (B39.9) significantly used ($p<0.05$).

Conclusions: Analysis of patient demography and ICD coding of uveitis between 2008-2018 of uveitis in one academic institution revealed significant increase in age at first visit but not gender, race, and ethnicity and a dramatic increase in the usage of uveitis ICD codes and the complexity of uveitis coding. Despite its introduction in 2016, ICD10 codes are still relatively unused. Given the specificity of ICD10 coding to include laterality, etiology, anatomic parts involved, and severity, improved education and utilization of ICD10 coding can help elucidate the pattern and complexity of uveitis.

TITLE: Long-term Stability of Eccentric Fixation Measured by OCT in Children with Unilateral Amblyopia

SESSION TITLE: Amblyopia: Translational Studies and Trials

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Lehman, D. Hendricks, J. Salvin, J. Jin, Nemours/Alfred I. duPont Hospital for Children, Delaware, UNITED STATES|J. Wang, SUNY College of Optometry, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jingyun Wang: Commercial Relationship: Code N (No Commercial Relationship) | Sharon Lehman: Commercial Relationship: Code N (No Commercial Relationship) | Dorothy Hendricks: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Salvin: Commercial Relationship: Code N (No Commercial Relationship) | Jing Jin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Using OCT, we were able to measure eccentric fixation in children with residual amblyopia (Jin et al, 2020). We found that the OCT fixation shift is significantly higher in amblyopic eyes than in fellow eyes, especially in strabismic amblyopia. However, we do not know whether eccentric fixation is stable over time. Here we report long-term follow-up of the OCT fixation shift in children with amblyopia.

Methods: Children with amblyopia (N=24) and normal controls (N=9) were studied. At their first visit (baseline), they ranged from 4 to 16 (8.5 ± 3.1) years old; amblyopia was classified into anisometropic amblyopia subgroup (N=9) and strabismic amblyopia subgroup (N=15). All had baseline and follow-up visits and the follow-up duration from baseline was 2.7 ± 1.8 years (5 months to 6 years). Spectral-domain OCT was used to estimate fixation shift. We asked the participant to focus on the internal dot target of the OCT. OCT fixation shift, i.e. the distance between the fovea and the fixation point, was measured, adjusted for axial length, and converted into visual degrees. Fixation shifts in the amblyopic eye, the fellow eye, and the right eye of the Control Group were compared by ANOVA. Baseline and follow-up results in the strabismic group were compared with the paired t-test. We also compared fixation shift change with visual acuity change between two visits for anisometropic versus strabismic amblyopia.

Results: At the baseline visit, the mean fixation shift was $0.05 \pm 0.10^\circ$ for control eyes, $1.50 \pm 1.87^\circ$ for amblyopic eyes, and $0.28 \pm 0.51^\circ$ for fellow eyes. At the follow-up visit, changes of fixation shift from baseline were $-0.02 \pm 0.06^\circ$ (CI 95%: -0.10, 0) for control eyes, $0.37 \pm 1.48^\circ$ (CI 95%: -0.62, 2.68) for amblyopic eyes, and $0.10 \pm 0.42^\circ$ (CI 95%: -0.25, 0.90) for fellow non-amblyopic eyes. ($F=0.62$, $P=0.54$). Furthermore, in the strabismic subgroup, the difference between baseline and follow-up fixation shift was $0.64 \pm 1.21^\circ$ (CI 95%: -0.62, 3.92), which did not change significantly ($T=1.37$, $P=0.19$). The visual acuity change and the fixation shift change were not significantly correlated ($R=0.24$, $P=0.39$).

Conclusions: Eccentric fixation, assessed by OCT fixation shift, is relatively stable during long-term follow-up of children with unilateral amblyopia.

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) causes retinal blindness due to loss of rods and later of cones. The P23H rhodopsin knock-in (P23H-KI) mouse develops retinal degeneration that closely mimics RP patients carrying the orthologous mutation. Previously, we found that P23H rhodopsin protein was robustly degraded in P23H-KI mouse retinas, and that Unfolded Protein Response (UPR) regulator genes promoted P23H rhodopsin protein degradation in heterologous cells in vitro. Here, we investigated the role of the UPR regulator gene, ATF6, in rhodopsin protein homeostasis in P23H-KI mice.

Methods: We compared retinas of ATF6^{-/-} Rho^{+/-}P23H C57BL/6 background mice with littermate control ATF6^{+/-} Rho^{+/-}P23H mice from postnatal days 12-60. Whole retinas were collected for western blotting and qPCR analyses of Rhodopsin (1D4) and UPR gene/protein quantification. Enucleations were cryo-sectioned, H&E stained, and retinal laminar anatomy examined and quantified. Full-field scotopic and photopic electroretinography (ERG) recordings were measured on dark-adapted mice at p60.

Results: Significantly increased rhodopsin protein levels (1.91x; p=0.0406) were found in ATF6^{-/-} Rho^{+/-}P23H retinas compared to ATF6^{+/-} Rho^{+/-}P23H mice at p12. Interestingly, IRE1a and BiP/Grp78 protein levels; and Xbp1s and Hrd1 mRNA levels were also significantly increased in ATF6^{-/-} Rho^{+/-}P23H retinas at early ages without gross changes in ONL thickness while Chop and Rhodopsin mRNA expression levels were not altered. By p60, ATF6^{-/-} Rho^{+/-}P23H mice showed increased retinal degeneration in comparison to control mice in all retinal layers by histology and reduced rhodopsin protein levels by immunoblotting. However, full-field scotopic and photopic ERGs were within normal limits for both ATF6^{+/-} Rho^{+/-}P23H and ATF6^{-/-} Rho^{+/-}P23H mice at p60.

Conclusions: We conclude that ATF6 is required for efficient clearance of P23H rhodopsin protein in rod photoreceptors, and loss of ATF6 leads to hyperactivation of the IRE1-XBP1s signaling pathway of the UPR. Despite these compensatory changes, ATF6^{-/-} Rho^{+/-}P23H mice develop more retinal degeneration as they age. Our findings show that UPR controls rhodopsin proteostasis in the retina and suggests that UPR activity influences the kinetics of retinal degeneration in RP patients expressing misfolded rhodopsin.

ABSTRACT BODY:

Purpose: A unique form of retinopathy was identified during the management of pediatric patients with retinal vasculitis and described in the index case series.

Methods: Pediatric patients diagnosed with uveitis were evaluated between January 2020 and December 2020 at a tertiary uveitis clinic. Wide angle fundus photo (WAFP), fundus autofluorescence (FAF), and optical coherence tomography (OCT) images were analyzed to identify potential retinopathy. Retinal vasculitis was detected by fluorescein angiography (FA). Images from both initial and follow-up visits were registered using image registration software. Subjects whose image quality was not sufficient for analysis were excluded. Boundaries of the lesions pertaining to the retinopathy were manually identified and annotated on WAFP using imaging tool. A custom MATLAB algorithm was utilized to assess the progression of the lesion.

Results: 54 pediatric uveitis patients were identified; 5 were excluded due to unavailability of WAFP and/or FA. Among the 49 patients, 26 were diagnosed with retinal vasculitis and were treated.

The retinopathy was detected in 20 patients (30 eyes) during the course of treatment. Mean age of the 20 subjects was 12.8 ± 3.36 years; 40% were female. Retinal vasculitis was observed in 8 patients with panuveitis, 8 patients with chronic anterior uveitis, 3 patients with posterior uveitis, and 1 patient with intermediate uveitis.

On WAFP, the lesions appeared as dark areas that were diffuse, mid-peripheral or peripheral (Image 1A). All subjects (30 eyes) showed hypoautofluorescence on FAF at the same locations as the WAFP (Image 1B). 8 patients (14 eyes) who had OCT images of the retinopathy area demonstrated ellipsoid zone (EZ) disruption (Image 1C).

Progression of the retinopathy over time was analyzed in 10 eyes; all eyes showed improvement of vasculitis with therapy. Mean area of retinopathy decreased from 670.82 mm^2 (baseline) to 479.92 mm^2 (last follow-up), which was not statistically significant ($p=0.16$).

Conclusions: Pediatric retinal vasculitis may be associated with a unique retinopathy pattern. Improvement in the retinopathy may not necessarily correlate to disease activity. The retinopathy might serve as a marker of previous/ongoing vasculitic events.

ABSTRACT BODY:

Purpose: To evaluate the potential prognostic role of biomarkers in Optical Coherence Tomography (OCT) in vitrectomized and non-vitrectomized eyes treated with intravitreal ranibizumab injections, in patients with diabetic macular edema.

Methods: The eyes were grouped in vitrectomized (group 1) and non-vitrectomized (group 2). OCT biomarkers were assessed at baseline and at 12 months.

Primary endpoint: OCT biomarkers difference between both groups - presence of subretinal fluid (SRF), number of hyperreflective dots (HRD), disorganization of retinal inner layers (DRIL), disruption of outer plexiform layer (OPLd), external limiting membrane (ELMd), ellipsoid layer discontinuity (ELd) and presence of cysts in outer and inner nuclear layers (ONLc and INLc).

Secondary endpoint: OCT biomarkers difference and type of responder: 1) good-earlier responder: when beyond the 24th week of follow-up, there was a complete anatomical response (central foveal thickness, CFT, $\leq 300 \mu\text{m}$) with an increase in best corrected visual acuity, BCVA, ≥ 5 letters; 2) non-responder: CFT $>400 \mu\text{m}$ or $\leq 10\%$ of CFT reduction and BCVA gain <5 letters; 3) partial responder: between good and non-responder criteria.

Results: A total of 45 eyes (10 vitrectomized and 35 non-vitrectomized) from 38 patients completed the follow-up. Mean age was 66.8 ± 8.1 years. Comparing good-earlier responders vs partial/non-responders: 1) at baseline, the presence of INL cysts was lower in good responders (26.5% vs 73.5%, $p=0.035$); 2) at the end of follow-up, good responders maintained a lower percentage of INLc (26.5% vs 73.5%, $p=0.035$) and had a lower percentage of DRIL, OPLd and ONLc (12.0% vs 88.0%, $p=0.001$; 8.7% vs 91.3%, $p<0.001$; 17.4% vs 82.6%, $p=0.013$, respectively). An association between INLc and a higher glycated hemoglobin ($p=0.028$) was also observed at 12 months of follow-up.

Conclusions: This study highlights the prognostic value of some SD-OCT parameters, such as fewer INLc, which were associated with a better therapeutic response.

According to our results, a normalization of the macular anatomy through the disappearance of DRIL, OPLd and ONLc with ranibizumab is most likely to happen in early complete responders.

The association between INLc and higher glycated hemoglobin levels reinforces the relevance of systemic metabolic control in diabetic microvascular manifestations.

ABSTRACT BODY:

Purpose: To assess retinal morphology differences in Post-9/11 Veterans with and without a history of blast-induced mild TBI (bmTBI) using optical coherence tomography (OCT) retinal segmentation.

Methods: Seventeen participants with a history of bmTBI (33 eyes; bmTBI+ group) and 11 participants without a history of mTBI (22 eyes; bmTBI- group) during military service participated (mean age: 37 ± 9.9 ; 89% male). Participants were recruited from the Translational Research Center for TBI and Stress Disorders (TRACTS) longitudinal cohort study of Post-9/11 Veterans. All TRACTS participants complete the Boston Assessment of Traumatic Brain Injury – Lifetime (BAT-L), a semi-structured interview assessing TBI history prior to, during, and after military service. Military mTBIs are further classified as due to blast or blunt force trauma. An ophthalmic clinical exam was completed in a subset of TRACTS participants returning for a repeat evaluation from 2015 and 2017. This included Heidelberg Spectralis OCT scans of the peripapillary and macular regions. Peripapillary scans were dedicated to the retinal nerve fiber layer (RNFL) thickness. Macular retinal layers were segmented and included RNFL, ganglion cell layer (GCL), inner plexiform layer (IPL), inner nuclear layer (INL), outer plexiform layer (OPL), outer nuclear layer (ONL), and outer retinal layer thickness using an Early Treatment Diabetic Retinopathy Study (ETDRS) grid centered on the fovea (3 concentric rings at 1, 3, 6 mm).

Results: Linear mixed-effects models assessed differences across the bmTBI groups with grid location, eye, and age as fixed factors. The peripapillary RNFL was thinner in the bmTBI+ group ($p = 0.002$), and the difference was greater in the superior/nasal and inferior/nasal segments ($p = 0.007$). In the macular segmentation, the INL showed evidence of thinning in the bmTBI+ group ($p = 0.014$). In contrast, the ONL and outer retinal layer segment containing photoreceptors were found to be thicker in the bmTBI+ group ($p < 0.001$).

Conclusions: Blast mTBI was associated with thinning of inner retinal layers, in particular the peripapillary RNFL and macular INL. In contrast, outer retinal layers were found to be thicker. These results may support the chronic neuroinflammatory sequelae observed in recent animal models of low-level blast exposure on retinal morphology.

ABSTRACT BODY:

Purpose: Transforming growth factor beta (TGFβ) is a profibrotic cytokine that has been implicated in several disease processes such as cellular growth, differentiation, and extracellular matrix (ECM) synthesis. High levels of both latent and active TGFβ1 are prominent in the aqueous humour of patients with pseudo-exfoliation glaucoma (PXFG). The exact relationship between TGFβ1 induced gene regulation and outflow dysfunction in the TM, contributing to glaucoma development, remains unclear. Here we investigated differential changes in gene expression induced by TGFβ1 in a cell-based model of PXFG.

Methods: Primary normal trabecular meshwork cells isolated from donor human corneal rims (n=5) were treated with 5ng/mL TGFβ1 for 24 hours. RNA was extracted using the Qiagen AllPrep kit and RNA-sequencing was performed commercially. Sequencing libraries were generated using NEBNext® Ultra TM RNA Library Prep Kit on the Illumina platform. Bioconductor was used for primary gene mapping and differential expression. Gene pathways and interaction were analysed using DAVID, Reactome and Cytoscape. Genes from enriched pathways that appeared significant in all three databases were explored.

Results: RNA-sequencing analysis identified a total of 532 significantly ($p < 0.05$) upregulated and 480 downregulated genes in primary TM cells in response to TGFβ1. Significantly differentially expressed genes with a fold increase ≥ 1.5 (n=147) were subjected to a GO and KEGG enrichment analysis. High-ranking gene pathway interactions included TGFβ (PAdj 4×10^{-3}) and SMAD transduction (PAdj 4.9×10^{-7}) signalling, ECM organisation (PAdj 6.1×10^{-7}) and cell to cell communication (PAdj 3×10^{-4}) which strongly correlate to glaucoma.

Conclusions: The interaction between the differentially expressed genes and corresponding pathways, in response to TGFβ1, may play a critical role in PXFG development. Further exploration of the role of the TGFβ1 driven gene expression and pathway activation may elucidate the molecular mechanisms involved in PXFG and aid therapeutic development.

ABSTRACT BODY:

Purpose: Pars plana vitrectomy with ILM peel is a technique used to treat macular holes. The currently accepted technique is to use 0.025% Brilliant Blue G (BBG) dye to stain the ILM, but multiple staining attempts are often needed. Concentrations of 0.05% stain the ILM better, reduce the need for multiple staining attempts, and can thus result in shorter surgical times. Visual and anatomical outcomes were evaluated after use of 0.05% BBG in treatment of macular holes.

Methods: This is a retrospective interventional case study. From Sept. 2014 to July 2017 there were 159 patients identified as having undergone pars plana vitrectomy, 82 of whom were excluded for visually significant pathology including age-related macular degeneration, primary open-angle glaucoma, retinal detachment, retinal tear or other confounding pathology. 25 patients qualified the inclusion and exclusion criteria, and 27 eyes underwent surgical repair for macular hole. Clinical data was collected at baseline, 1, 3, and 6 months post operation. To measure ocular function, best-corrected visual acuity (BCVA), intraocular pressure (IOP), and central macular thickness (CMT) using Optical Coherence Tomography (OCT) were assessed.

Results: Baseline measurements of BCVA, IOP, and CMT were compared to the measurements from each follow-up. The average (standard deviation) baseline BCVA was 58(10) letters, IOP was 16(3), and due to presence of a macular hole there was no baseline data for CMT. 1,3, and 6 months after surgery average CMT was 297(65), 298(81), and 289(61) micrometers respectively. The average BCVA at 1,3, and 6 months was 58(19), 66(14), 67(13) letters respectively with an average change of +6.33 letters post operation. Average IOP measurement for 1,3, and 6 months post operation was 16(5),14(3), and 15(5) mmHg respectively with an average change of -1 mmHg.

Conclusions: Use of high concentration 0.05% BBG appeared to be safe for surgical treatment of macular holes with 100% success rate of closure and significant improvement in BCVA.

TITLE: Evaluation of retinal shape and thickness with wide field OCT in young children

SESSION TITLE: Refractive Error, Emmetropization and Ocular Development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Jnawali, F.A. Vera-Diaz, New England College of Optometry, Boston, Massachusetts, UNITED STATES|P. Bex, Northeastern University College of Science, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ashutosh Jnawali: Commercial Relationship: Code N (No Commercial Relationship) | Peter Bex: Commercial Relationship: Code N (No Commercial Relationship) | Fuensanta Vera-Diaz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Growing evidence suggests that retinal shape and retinal periphery are associated with myopia development and progression, and recent studies implicate a significant role of peripheral retina in emmetropization. However, previous studies on optical coherence tomography (OCT) imaging in children are limited to central 30 degrees retinal and choroidal thickness. We evaluated retinal shape and thickness for retina and choroid up to 55 degrees eccentricity in young children.

Methods: Radial scans (55°, 12 line) centered on the fovea in right eyes were collected with wide-field spectral domain OCT (Heidelberg) in healthy emmetropic children (n=37, ages 7.8±0.9 years) following a thorough vision exam. Images were processed in custom Matlab programs, and corrected for lateral magnification using biometric data collected for each eye (Lenstar) and a 4-surface schematic eye modified for children. Retinal and choroidal thickness were compared across eccentricities of 1, 3, 5, 8 and 12 mm, and across 4 retinal zones using one-way ANOVAs. Retinal curvature in the horizontal (RcH) and vertical meridians (RcV) were correlated with axial length (AXL) and mean corneal curvature (mean K).

Results: Retinae were steeper in the horizontal than the vertical meridian (RcH=12.4±1.8 mm, RcV=14.7±3.8 mm, t=5.31, p<0.001). RcH became steeper with increasing AXL (r=0.38, p<0.05) and mean K (r=0.42, p=0.01), while RcV showed no such relations. There was significant effect of retinal eccentricity for both retinal (p<0.001) and choroidal (p<0.001) thickness (retina central 1 mm: 272.3±21.5 µm, choroid central 1 mm: 366.38±75.13 µm), with the choroid becoming significantly thinner in the periphery. There was significant effect of retinal zone for retinal (p<0.001) and choroidal (p<0.001) thickness, with thinnest retinae temporally and thickest nasally, while the choroid was thinnest nasally and thickest superiorly.

Conclusions: We report asymmetries of ocular shape and retinal and choroidal thickness with wide field OCT in young children that confirm earlier studies and extend measurements to 55° eccentricity. Longer eyes, which are at greater risk of developing myopia, show steeper retinae in the horizontal, but not the vertical, meridian. The asymmetries in the horizontal and vertical meridians may have implications in eye growth and refractive development in children that we are investigating in a longitudinal study.

ABSTRACT BODY:

Purpose: Recurrent macular edema is of increasing interest in the management of diabetic macular edema (DME). The risk factors for the development of DME are well studied, but those affecting the time to recurrence of DME after treatment have not been well defined. Our objective is to identify factors affecting the time to recurrence of DME after treatment.

Methods: A retrospective chart review was performed on DME patients between 1/2010 to 6/2017 at Lyndon B. Johnson General Hospital. Patients over 18 years with DME and treated with anti-VEGF injection were included. If both eyes were eligible, the left eye was used for data analysis. Demographics and baseline systemic and ocular characteristics were recorded. Presence or recovery of DME, injections, and the last known HbA1C were recorded at each clinic visit. The time to recovery and recurrence were calculated. The cumulative number of anti-VEGF injections at the time of recovery and the Mixed Effect Cox regression was used to identify risk factors and estimate their effect on time to resolution and recurrence of DME.

Results: 114 patients were included in this study. 75 patients (65.8%) were female and 76 (66.7%) were Hispanics, 24 (21.1%) black, and 12 (10.5%) white, and 2 (1.8%) Asians. Mean age at anti-VEGF treatment for DME was 58.6 years (+8.0,27-75) with mean duration of DM 15.2 years (+6.9,1-36), and mean baseline HbA1c 8.8 (+2.1,5.7-15.1). During a mean follow-up period of 3.1 years (+1.7,0.1-7.8), 77 (67.5%) DME eyes were resolved for the first time at a mean of 1.2 years (+1.1,0.1-5.9) with a mean of 3.7 anti-VEGF injections (+2.1,1-10). After resolution, 46/77 eyes had a recurrence with mean of 2.0 years. No risk factors were associated with time to resolution, while males (Hazard ratio (HR) = 2.56 with 95% confidence interval (CI) = [1.30, 5.08], P=0.007) and longer duration of DM (HR=1.06 per year, 95% CI= [1.01, 1.18], P=0.013) significantly shorten the time to recurrence. HbA1c and number of anti-VEGF injections were not significant risk factors for resolution and recurrence of DME.

Conclusions: In our review, the duration of diabetes and male gender were significant factors associated with decreased time to recurrence of DME after treatment with anti-VEGF. HbA1c was not associated with time to recurrence. If confirmed by prospective clinical trials, this could help guide monitoring and treatment approach of DME in patients with a long history of diabetes.

ABSTRACT BODY:

Purpose: Ocular manifestations have been described in COVID-19 patients, but it is unknown whether SARS-CoV-2 – the causal agent in COVID-19 – can directly infect posterior ocular tissues. Here, we investigate SARS-CoV-2 host factor gene expression levels and their distribution across retinal and choroidal cell types. The overall aim is to identify particularly vulnerable cell-types to elucidate a potential pathomechanism for observed retinal lesions in COVID-19 patients.

Methods: Datasets from human retina and choroid were retrieved from published datasets. We reprocessed the data from raw quantification matrix following standard Seurat (v.3.1) clustering procedure. To take advantage of the improved Seurat pre-processing and normalization workflow, we used the SCTransform function, thereby we “corrected” log-normalized expression values across datasets. To reannotate the cells, multiple clusterings of different resolutions were generated among which the one best matching published clustering was picked and manual annotation was undertaken using marker genes.

Results: Key genes for SARS-CoV-2 host cell entry are significantly lower expressed in human retinal cell-types compared to choroid. In detail, we observe no expression of ACE2 or TMPRSS2 in the retina, but a scarce co-expression in vessel associated cell-types of the choroid. No differences could be detected between fovea and periphery for both tissues.

Conclusions: Key conclusion:

The human retina is not vulnerable for a direct SARS-CoV-2 infection. Thus, retinal lesions as described in a recent Lancet publication by Marinho et al. are most likely due to a secondary damage (Marinho et al., 2020). However, SARS-CoV-2 entry genes are expressed in vessel-associated cell-types of the choroid. Thus, as described in other organs, the virus might infect the vasculature in terms of an infectious endothelitis, and could subsequently lead to vascular occlusions. Further studies are needed to elucidate whether vascular occlusions of the posterior eye segment correlate with life-threatening cardiovascular complications in COVID-19 patients. Thus, the posterior eye segment might qualify as an in vivo biomarker of systemic vascular disease in COVID-19 patients and imaging techniques of the posterior eye segment could be helpful for manage treatment of COVID-19 patients.

ABSTRACT BODY:

Purpose: Glaucoma specialists provide care for many patients who require regular follow-up appointments. As their practices grow, it can become increasingly difficult to see patients at the recommended follow-up intervals. This study aims to find the factors affecting follow-up delays using computer simulations.

Methods: Three glaucoma specialists were surveyed to estimate the number and severity of glaucoma patients seen in a typical week. Patient severity was categorized as suspects, early, or advanced, and assumed to require follow-up appointments at 52, 26, and 13-week intervals, respectively. Multiple simulations were performed, each creating a new practice for one glaucoma specialist starting with no patients. The survey responses were used to simulate a baseline practice. Further simulations varied multiple parameters to explore their effect on follow-up delays. Simulation parameters included: number of new and maximum follow-up patients per week, patient severity distribution, patient chance of progression and loss of follow-up, proportion of patients discharged, appointment interval spacing (increasing the appointment interval if the patient is stable). For each simulation, we computed the week patients began to have delays and the increasing rate in the weekly mean delay (mean of the delay of patients seen in that week).

Results: The baseline practice had 30 new patients and a maximum of 120 follow-up patients per week. This practice started having follow-up delays at week 111, and the weekly mean delay increases at a rate of 7 weeks of delay per week. Most explored factors had a minor impact on practices delays, including appointment spacing or patient discharging (Fig. 1). The factor most strongly associated with practices delays was the ratio of new to follow-up patients per week (Fig. 2).

Conclusions: Most glaucoma practices are not able to follow patients within the required appointment intervals. While discharging and spacing stable patients reduce practices follow-up delays, these methods are insufficient to avoid large delays over the years. Practices need to reduce the number of new patients to avoid large delays in follow-up appointments; however, this could affect the wait times for initial appointments.

ABSTRACT BODY:

Purpose: The cone contrast test (CCT) is a computer-based contrast sensitivity test that quantifies the type and severity of color vision deficiencies by measuring patient response to varied intensities of visual cues stimulating red, green, and blue cones. Evidence has shown that CCT has greater sensitivity in detecting color vision deficits compared to Hardy Rand and Rittler (HRR) and Ishihara pseudoisochromatic plates. It has also demonstrated clinical utility in evaluating acquired color vision deficiency in glaucoma. In this prospective clinical study, our aim is to use CCT to characterize color vision deficiency in patients with compressive optic neuropathies (ON) secondary to neurological malignancies.

Methods: CCT scores of the right eye (10 control, 8 compressive ON) were included for analysis. Patients with malignancies that led to compression and damage of the optic nerve were included. Patients with glaucoma or other causes leading to ON were excluded. Color vision assessment was performed at 20 inches under photopic conditions using the ColorDx CCT (KonanMedical, Irvine, California USA) as part of normal course of care in a neuro-ophthalmology clinic. CCT provides a numeric, whole number score for each cone class, with lower scores indicating greater color vision deficit. Scores for each group were analyzed by independent sample t-test.

Results: Mean CCT scores for red and green cones were significantly lower in the compressive optic neuropathy group than in the control group. The mean CCT scores for blue cones were also lower in the compressive optic neuropathy group, but the difference was not statistically significant.

Conclusions: This data supports that compressive optic neuropathy is associated with decreased color vision. It reinforces a correlation between optic neuropathy and color vision and the utility of quantifying color vision to follow disease onset and progression. It further highlights that blue cone color quantitation may be less reliable than green and red, as shorter wavelengths can be filtered by anterior segment pathology such as cataracts.

TITLE: Attitudes and perceptions toward the use of medical marijuana for glaucoma

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Bergman, O. Idowu, Ophthalmology, University of Maryland Medical Center, Baltimore, Maryland, UNITED STATES|M. Kaleem, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zachary Bergman: Commercial Relationship: Code N (No Commercial Relationship) | Mona Kaleem: Commercial Relationship: Code N (No Commercial Relationship) | Omolola Idowu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous work has demonstrated that inhaled tetrahydrocannabinol (THC) can lower intraocular pressure (IOP). The stance of the American Glaucoma Society (AGS) is that medical marijuana is not an acceptable treatment for glaucoma. However, the expanding legality of marijuana for both medicinal and recreational purposes makes it vital that ophthalmologists understand how marijuana can impact their patients. The purpose of this study is to evaluate ophthalmologists' perceptions and attitudes towards the use of medical marijuana for glaucoma.

Methods: An electronic survey was sent to members of the AGS which addressed attitudes and perceptions on the use of medical marijuana in the management of glaucoma. Study questions included practitioner demographics, previous experiences, prescribing patterns, and knowledge regarding the use of medical marijuana for the treatment of glaucoma.

Results: Thirty-seven percent of respondents reported having patients who cited using medical marijuana for their glaucoma, and 38% of respondents were asked about medical marijuana by their patients at least once per week. Fifty-five percent of respondents had patients who asked them for medical marijuana prescriptions. When asked if they felt if there was a role for marijuana in the management of glaucoma patients, 27% of survey takers responded yes. Twenty-eight percent of respondents from states where marijuana is currently legal medicinally and recreationally similarly thought there was a role for marijuana in glaucoma, compared with 14% of respondents from states where marijuana is currently not legal for medicinal or recreational use. Fourteen percent of survey respondents kept information on medical marijuana in their office. Finally, 76% of participants responded they would be interested in additional education on the topic.

Conclusions: Medical marijuana is not recognized as an acceptable treatment option for glaucoma by our professional societies. However, it is likely that the legalization of marijuana for both medicinal and recreational purposes will continue to become more widespread. Thus, it is vital that modern day ophthalmologists understand how marijuana can impact their patients.

ABSTRACT BODY:

Purpose: Posterior eye imaging with optical coherence tomography (OCT) and OCT angiography (OCTA) suffers from involuntary eye movements. We have developed a motion-free Lissajous scan OCT method, which enabled accurate assessment of morphology and metrics of diseases. In this paper, further accurate motion correction is enabled by simultaneously using en face OCT and OCTA images for motion estimation. The performance is compared to the previous Lissajous method which uses only OCTA for motion estimation.

Methods: A custom-made 1.0- μm swept-source OCT device with a scan speed of 100,000 A-line/s is used. The OCT probe beam scans along a modified Lissajous pattern, which is designed for both OCT and OCTA. The eye motion is estimated by co-registering small overlapped portions of an en face Lissajous scan. Motion-free three-dimensional volumes and en face maps of OCT images were created by using the estimated motion amounts. The lateral motion estimation was performed by two means; (1) using only en face OCTA and (2) using en face OCT and OCTA. In order to compare the image qualities obtained by the two means, the motion-corrected superficial retinal OCTA images were manually scored from 0 (low) to 5 (high) by an expert.

For this comparison, 73 eyes of 64 patients with retinal abnormalities were scanned over $3 \times 3 \text{ mm}^2$ area.

Results: Figure 1 shows motion-corrected en face OCT and OCTA images of a representative case. The mean scores of the motion-corrected superficial OCTA images are 2.9 for OCTA-only motion estimation and 3.0 for OCT-and-OCTA correction. The score of OCT-and-OCTA correction is statistically significantly better than the OCTA-only correction ($p\text{-value}=0.02$, Wilcoxon's signed-rank test).

Conclusions: The motion-free Lissajous OCT with a newly developed OCT-and-OCTA based motion estimation gave better image quality than that with OCTA-only motion estimation.

ABSTRACT BODY:

Purpose: To evaluate the preclinical efficacy of subcutaneously administered D-4517 in a mouse model of laser-induced choroidal neovascularization (CNV) and its toxicity in a repeat dose rat study.

Methods: D-4517, a novel analog of sunitinib chemically conjugated to a hydroxyl dendrimer, selectively targets inflammation in CNV lesions. D-4517 is not metabolized and is renally excreted. Laser-induced rupture of Bruch's membrane was performed in both eyes of C57BL/6 mice (n=8/group) 24 hr prior to dose administration. Mice were dosed with a single subcutaneous (SC) administration of D-4517 at a total mass dose of 40, 200 or 1000 µg. As a positive control group, a cohort of mice were administered aflibercept intravitreally (IVT; 1 µL, 40 µg). The CNV area was measured 14 days after laser treatment by both fluorescein angiography and flat-mounts of the sclera-choroid/RPE complexes stained with Isolectin. To assess the toxicity of D-4517, a repeat dose study was conducted in Sprague Dawley rats (10 male/10 female per group). Rats were dosed daily for 14 days with 30 mg/kg sunitinib (PO) or 12 mg/kg D-4517 (IP; matched exposure to sunitinib) or a single dose of 168 mg/kg D-4517 (IP). Toxicokinetics, clinical evaluation, pathology, and histology were performed on all animals.

Results: A single SC dose of D-4517 (40 µg) resulted in comparable inhibition of CNV to a single IVT aflibercept dose (40 µg). All doses of D-4517 resulted in a significant inhibition of CNV formation compared to the vehicle control with all three dose levels resulting in comparable levels of CNV lesion area suggesting further dose reductions may be feasible. In the toxicology study, free sunitinib was associated with various clinical and pathological changes in addition to mortality in female rats. D-4517 was well-tolerated following single or repeated dosing with no clinical or histologic indications of toxicity.

Conclusions: After a single SC dose, D-4517 effectively inhibits CNV formation comparable to the same mass dose of aflibercept IVT. Previous studies demonstrated that HDs persist inside cells in the CNV lesion for at least one month after a systemic injection. Repeat dose toxicology in rats support at least an 80-fold safety factor for the effective dose. Taken together, these studies support the development of D-4517 as a potential once per month less invasive SC treatment for wet AMD.

TITLE: Epidemiological profile of corneal transplant surgeries at Londrina Eye Hospital (HOFTALON), Brazil

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Vale, R.B. Trevisol, I.L. de Oliveira, T. Matsuo, E. Hoyama, Hoftalon Hospital de Olhos, Londrina, Paraná, BRAZIL|

Commercial Relationships Disclosure (Abstract): Isabela Vale: Commercial Relationship: Code N (No Commercial Relationship) | Rafael Trevisol: Commercial Relationship: Code N (No Commercial Relationship) | Ivan de Oliveira: Commercial Relationship: Code N (No Commercial Relationship) | Tiemi Matsuo: Commercial Relationship: Code N (No Commercial Relationship) | Erika Hoyama: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A retrospective observational clinical study was performed to evaluate the characteristics of patients submitted to corneal transplantation surgeries in 2019.

Methods: Medical records of patients submitted to corneal transplantation from January to December 2019 at HOFTALON, Londrina city, Brazil were included. Sociodemographic data, visual acuity, cause of corneal transplant, topographic exam and complications were evaluated and submitted to statistical analysis. Exclusion criteria were incomplete medical records. Visual acuity was separated in categories: legal blindness, subnormal and normal vision.

Results: From 98 medical records evaluated, 91 patients submitted to corneal transplant surgeries were included. The mean age was 49.9 years, 50.5% were male. Glaucoma was the main ocular comorbidity, present in 11 (12.1%) patients.

The causes of corneal transplant were: keratoconus (35/38.5%), post-FACO decompensation (16/17.6%), primary transplant failure (8). The average waiting time from indication to surgery was 125 days. Regarding the surgical technique, 70 patients (76.9%) underwent penetrating keratoplasty (PK), 17 deep anterior lamellar keratoplasty (DALK) and 4 Descemet membrane endothelial keratoplasty (DMEK). 80 patients (87.9%) presented legal blindness (<20/400) before surgery, 6 (6.6%) subnormal vision (20/200-20/60) and 5 (5.5%) normal vision (20/50-20/20). A total of 61 patients (67%) improved vision after transplantation; of these, 11 improved two categories. 50% (35) of patients submitted to PK had improvement and 48.6% (34) maintained the same vision; 58.5% (10) submitted to DALK also showed improvement of vision. 64.8% didn't have complications, 30.8% presented corneal transplant failure and 4.4% developed glaucoma. 11(39.3%) patients had a successful clinical treatment for transplant rejection. The main treatment for rejection was topical corticosteroids, administered to 17 patients (60.7%) and Corneal rejection was proportionally greater in patients who underwent PK, but no statistical significance was observed. Corneal topography was performed in patients after transplantation, with an average K of 42.79.

Conclusions: Penetrating keratoplasty remains the most used technique in our Hospital and Keratoconus was the main cause of indication for surgeries. The most used treatment for corneal rejection was topical corticosteroids with a good response in our patients.

ABSTRACT BODY:

Purpose: To determine the pre-existing ocular findings that predispose to developing oGVHD in patients following allo-HSCT and evaluate the benefits of early treatment intervention. We performed a 2-year longitudinal, observational clinical study in patients undergoing allo-HSCT (n=105).

Methods: Patients received ocular examination and oGVHD grading in study visits. Examinations included slit lamp biomicroscopy, symptom analysis, Schirmer's I test, Corneal and Conjunctival staining, Bulbar redness scoring, Non-invasive Keratograph Tear Film Break-up Time, MMP-9 test, Lipid Layer Thickness, and Meibomian gland imaging. oGVHD grading was determined using the International Consensus Criteria on chronic oGVHD classification systems.

Results: 61 patients had at least one post-HSCT visit. Of these patients, 74% did not progress to oGVHD. 26% of patients progressed to Probable (n=7) or Definite (n=9) oGVHD. As compared to None oGVHD, greater number of Probable/Definite oGVHD patients had Meibomian gland dysfunction (reduced LLT), ocular surface inflammation (MMP-9 positive), and tear fluid deficiency (Schirmer's <10 mm/5min) in their pre-HSCT examination. Signs and symptoms of oGVHD appeared between 6-9 months post-HSCT. Topical steroid treatment was given in patients with None oGVHD (n=4) or Probable oGVHD (n=3), and these patients did not progress to Definite oGVHD. Topical anti-inflammatory treatment was initiated most commonly due to MMP9 becoming positive. Other common reasons were: (i) tear production reduced to <10 mm/5min; and (ii) increase in OSDI symptom analysis score to >13.6.

Conclusions: Patients who have reduced tear production, Meibomian gland dysfunction, or ocular surface inflammation have a higher likelihood of developing oGVHD after HSCT. Starting anti-inflammatory treatment earlier, based on MMP-9 positivity, increased symptoms of ocular discomfort, or reduced tear production, may prevent progression to Definite oGVHD. Ocular examinations pre-HSCT and every three months post-HSCT, may help to reduce the incidence of oGVHD by facilitating early diagnosis and early therapeutic interventions.

ABSTRACT BODY:

Purpose: To compare the visual deficit in NHPs with blue light induced macular injury to a cohort of AMD patients using similar imaging and vision psychophysics testing.

Methods: For the NHP study, 8 cynomolgus monkeys were unilaterally irradiated (study eye, SE) with blue light centered on the macula (8 mm diameter) for 20 to 30 min; contralateral eye (non-study eye, NSE) remained naïve. For the human study, 10 AMD patients with simplified Age-Related Eye Disease Study (AREDS) scores 3 or 4 and 8 age-matched Controls were enrolled. Both, NHP and human subjects were evaluated with fundus autofluorescence (FAF) and optical coherence tomography (OCT) to quantify retinal pigment epithelium (RPE) disruption and outer nuclear layer thickness (ONL). Contrast sensitivity functions (CSF) were used to evaluate visual function using the same custom software suite. NHPs were placed in a primate chair in a custom-made testing chamber. They were trained to hold and then release a lever when a visual stimulus was detected (i.e., “hit”); otherwise non-response was considered a “miss”. Threshold was operationally defined as two successive misses in a descending method of limits (1.5 to 24 cycles per degree (cpd); 5 steps). For the human subjects, a descending method of limits was combined with a 2 Alternate Forced Choice technique (0.75 – 18.50 cpd; 8 steps). The CSF was fit with a double exponential function.

Results: The clinical presentation of the lesions between NHPs and humans was different. In the NHPs, the lesion was diffuse (late stage AMD; GA); in the humans it was multi-focal (early stage AMD). In NHPs, mean log contrast sensitivity (CS) was 1.27 ± 0.06 (NSE) and 0.73 ± 0.08 (SE). Peak reduction was 0.68 log units at 6 cpd. In the human study, mean log CS in the control subjects was 1.34 ± 0.07 while in AMD patients it was 1.28 ± 0.06 . Peak reduction was 0.16 log units at 3 cpd.

Conclusions: Using similar instrumentation, we found a reduction in CS in the NHP model and human AMD patients. The reduction in CS correlated with the severity of the damage. These results demonstrate that vision psychophysics can be used as a valuable tool in evaluating disease models and efficacy prior to clinical study initiation and inform the best selection of sensitive vision endpoints to use with patients.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has caused significant disturbances as stay-at-home restrictions have prevented adequate healthcare delivery. This investigation aimed to assess the pandemic's impact on the incidence of ophthalmic-related procedures compared to the pre-pandemic period.

Methods: TriNetX (Cambridge, MA, USA) is a real-time, federated healthcare database that was used in this retrospective review. At the time of the study, the database included 60 million unique electronic medical records (EMR) of patients from 41 healthcare organizations (HCOs) across the US. The goal of this study was to analyze the incidence of new ophthalmic procedures that were performed during a period of the COVID-19 pandemic from April 1, 2020 - September 30, 2020. April 2020 was used as the start date as this was the first full month when national lockdown measures were implemented in the USA. Similar incidence data was also extracted from the corresponding time frame of April to July in 2018 and 2019. The 2020 data was then compared to a pooled 2018-2019 data of the same time period through descriptive analyses and an independent samples t-test.

Results: The incidence between fourteen types of ophthalmic procedures experienced a statistically significant reduction between April 1 to September 30, 2020 when compared to overlapping months in 2018 and 2019. Thirteen of the fourteen procedures saw at least a 32.0% decrease in incidence. These procedures included: Keratorefractive surgery (-60.3% change, $p < 0.001$), keratoplasty (-58.4% change, $p < 0.001$), cataract surgery (-50.5% change, $p < 0.001$), pterygium (-49.0% change, $p < 0.001$), oculoplastic (-47.7% change, $p < 0.001$), YAG capsulotomy (-44.3% change, $p < 0.001$), strabismus (-43.2% change, $p = 0.004$), laser trabeculoplasty (-40.1% change, $p < 0.001$), retina surgery (-38.5% change, $p < 0.001$), glaucoma (-36.1% change, $p < 0.001$), panretinal laser photocoagulation (-33.9% change, $p < 0.001$), and intravitreal injection (-32.0% change, $p < 0.001$). The incidence of global trauma during the COVID-19 pandemic was similar to identical months in 2018-2019.

Conclusions: The significant reduction in ophthalmic procedures during the COVID-19 pandemic suggests that patients are delaying ophthalmic care in the US. Further research is necessary to determine the future implications of this disruption in the care of ophthalmic patients during the COVID-19 pandemic.

SUBMITTER (NAME ONLY): Logan Vander Woude

TITLE: Novel Positive Predictive Factors in Ocriplasmin Efficacy in Symptomatic Vitreomacular Traction

SESSION TITLE: Stem cells / gene therapy/ transplantation/ laser/ local therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Vander Woude, G.S. Khurshid, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Logan Vander Woude: Commercial Relationship: Code N (No Commercial Relationship) | Gibran Khurshid: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocriplasmin (OCP) is an enzymatic vitreolysis for symptomatic vitreomacular traction (VMT). Initial trials of OCP yielded tepid results; however, post hoc analysis has provided positive predictive factors for successful outcomes, including age <65 years, phakic eyes, adhesion diameter <1500 microns, and absence of epiretinal membrane (ERM). Continued refinement of positive predictive factors helps to identify optimal patients for OCP treatment. This retrospective case series describes novel positive predictive factors in treating symptomatic VMT.

Methods: This retrospective case series included 11 patients diagnosed with symptomatic VMT and treated with OCP at the University of Florida from 1/1/2015 to 7/1/2020 regardless of their phakic status, presence of ERM, age, or initial visual acuity (VA). Patients were excluded from receiving OCP treatment if they were aphakic, had >8 diopters of myopia or an axial length >28mm, vitreous opacity obscuring posterior pole visualization, diffuse VMT (>1500 microns), stage 2 or greater macular hole, or other concurrent retinal diseases. The de-identified data was then collected and analyzed using Z-test statistical analysis. The primary outcome measured was the resolution of VMT as defined by optical coherence tomography (OCT).

Results: Of the 11 patients treated with Ocriplasmin, 63.6% had resolution of their VMT. Subgroup analysis was conducted for initial visual acuity and adhesion diameter, as measured by OCT. Patients whose initial VA was $\leq 20/50$ all had resolution of their VMT and did significantly better compared to initial VA of $\geq 20/60$ among all patients ($p=0.011$) and when controlling for ERM ($p=0.037$). In subgroup analysis of micro (<500 microns) versus focal VMT (500-1500 microns), micro VMT trended towards greater resolution, 85.7% vs 50%, respectively ($p=0.142$) [Figure 1].

Conclusions: The continued refinement of positive predictor factors is paramount to improving the efficacy of OCP and its cost-effectiveness. The greater resolution rate in micro VMT was not statistically significant in this small case series but warrants further investigation. OCP may have greater efficacy in patients with symptomatic VMT with VA $\leq 20/50$, which may impact useful clinical practice with earlier treatments.

ABSTRACT BODY:

Purpose: When measuring macular thickness using optical coherence tomography (OCT), axial length (AL) is known to affect the size of the scanning area due to transverse magnification effects (TME). However, most studies do not adjust for TME when reporting or analysing macular thickness. In this study, we compared macular thickness with and without TME correction in a large cohort of young adults.

Methods: In a sample of 953 healthy adults in a general population (18-22years; 22% myopes, AL range: 20–28mm), the full retinal thickness at the 9 Early Treatment of Diabetic Retinopathy Study (ETDRS) macular regions (central macula, and the superior, inferior, temporal, and nasal quadrants of the inner and outer macular rings) were obtained using spectral domain OCT. Images were exported into a custom MATLAB program that corrected for TME. Paired t-tests were used to compare TME-corrected and uncorrected measurements. Statistical associations between the TME-corrected or uncorrected measurements with AL and other known predictors of macular thickness (sex, ethnicity, choroidal thickness) were explored using generalized estimating equations.

Results: In the full study sample, failure to account for TME resulted in under-estimation of macular thickness at the central 0.5mm and over-estimation at other regions by 0.1–3.4µm (all $p < 0.001$). Conversely in myopes, uncorrected measurements over-estimated thickness at the central macula and under-estimated at other regions (all $p < 0.001$; difference=1.6–5.9µm). At the central macula, AL was not statistically associated with the uncorrected measurements ($p = 0.77$) but had an inverse relationship with the TME-corrected thickness ($p < 0.001$). At all other macular regions, there were significant associations between AL and uncorrected macular thickness, but not TME-corrected thickness. Sex, ethnicity, or choroidal thickness associations with macular thickness did not differ between the corrected and uncorrected measurements.

Conclusions: In a general population where the majority are non-myopes, the macular thickness measurement error produced by TME is small and may not be clinically significant. However, as the global population becomes more myopic, this measurement error will increase. It is thus important to use TME-corrected macular thickness when exploring associations with AL or when study samples have high rates of ametropia.

ABSTRACT BODY:

Purpose: To analyze a large cohort of individuals with primary central nervous system lymphoma (PCNSL) and vitreoretinal lymphoma (VRL) from a tertiary care center.

Methods: A retrospective review of all patients with PCNSL and VRL at Massachusetts Eye and Ear from January 01, 2004 to April 1, 2020 was performed. Demographics, affected site at diagnosis (eye, central nervous system (CNS), or both), lymphoma subtype, MYD88 mutational status, local treatment type (intravitreal chemotherapy vs radiation), local recurrence, and progression from the eye to the CNS or vice versa were analyzed.

Results: 49 patients (46.9% female) with a median age at diagnosis of 64 years (range, 35-91 years) were analyzed. At diagnosis, 30 patients (61.2%) had CNS, 13 (26.5%) had eye, and 6 (12.3%) had eye + CNS involvement. Median time to diagnosis was 2.7 months (eye + CNS), 2.8 months (CNS), and 10.1 months (eye). Eye involvement was bilateral at diagnosis in 78.9%. Common diagnoses prior to confirming VRL were: vitritis (10.2%), uveitis (6.1%), and retinitis (2.0%); 6.1% received prior steroid treatment. Cytopathology confirmed diffuse large B-cell lymphoma in 46 (93.9%), T-cell in 2 (4.1%), and other in 1 (2.0%). MYD88 mutational analysis was performed in 9 out of 19 patients (47.4%) with eye involvement and was positive in 8 out of 9 patients (88.9%). A total of 56 eyes had initial or subsequent VRL, of which 32 eyes (57.1%) received local ocular therapy: 26 eyes (81.3%) with an intravitreal methotrexate-based regimen (MTX, 400 mcg/0.1mL), 2 eyes (6.3%) with radiation (30 Gy), 2 eyes (6.3%) with combination (intravitreal MTX + radiation), and 2 eyes (6.3%) by enucleation. At last follow-up (median 63.1 months), local ocular recurrence occurred in 5 eyes (19.2%) treated with intravitreal therapy and 0 eyes treated with radiation. Nine patients (69.2%) with initial eye only disease progressed to involve the CNS (median time to progression: 28.5 months) and 13 patients (43.3%) with initial CNS disease progressed to involve the eye (median time to progression: 14.1 months). At last follow-up, 33 individuals (67.3%) were alive.

Conclusions: Time to diagnosis was 3.7 times longer for VRL alone, compared to those with CNS involvement. MYD88 testing was helpful for diagnosis (positive in 88.9%). Both intravitreal MTX and radiation achieved excellent ocular control (80.8% and 100.0%, respectively), however 69.2% ultimately progressed to involve the CNS.

TITLE: Application of Electric Cell-Substrate Impedance Sensing (ECIS) to investigate the effect of mitochondrial bioenergetics on retinal pigment epithelial barrier functionality

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.H. GUERRA, T. Yumnamcha, L.P. Singh, A.S. Ibrahim, Department of Ophthalmology, Visual, and Anatomical Sciences, Wayne State University, Detroit, Michigan, UNITED STATES|A.S. Ibrahim, Department of Pharmacology, Wayne State University, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael GUERRA: Commercial Relationship: Code N (No Commercial Relationship) | Thangal Yumnamcha: Commercial Relationship: Code N (No Commercial Relationship) | Lalit Singh: Commercial Relationship: Code N (No Commercial Relationship) | Ahmed Ibrahim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Disruption of retinal pigment epithelial (RPE) barrier integrity is a hallmark feature of age-related macular degeneration (AMD), but the underlying causes and pathophysiology are not completely well-defined. One of the most conserved phenomena in biology is the progressive decline in mitochondrial function with aging. This study aimed to investigate the role of mitochondrial bioenergetics in maintaining RPE barrier functionality RPE.

Methods: We used ECIS system to monitor in real time the barrier integrity of RPE cell line (ARPE-19) after treatment with one of four mitochondrial electron transport chain (ETC) inhibitors (Rotenone for complex 1, Oligomycin for Complex IV, trifluoromethoxy carbonyl cyanide phenylhydrazone FCCP for uncoupling ATP synthesis from ETC, and cobalt chloride (CoCl₂) as hypoxia-mimetic agent). We investigated how the resistance across ARPE-19 cells changes in three separate parameters: Rb (paracellular resistance between cells), α (basolateral resistance between RPE and its substrate), and Cs (cell membrane capacitance). Statistical analysis was performed using ANOVA test followed by Tukey post hoc test with $p < 0.05$ considered significant.

Results: Treatment with CoCl₂ and FCCP induced a significant reduction in the total resistance and thus the barrier function of ARPE-19 in a dose dependent manner. Treatment with rotenone decreased barrier function in a non-dose dependent fashion, whereas only treatment with a high dose oligomycin (10 μ M vs 1 μ M) disrupted barrier function. Specifically, the ECIS program's modelling of paracellular resistance, basolateral resistance, and capacitance showed that both CoCl₂-induced hypoxia and FCCP- induced uncoupling decreased paracellular resistance and basolateral resistance, but they both led to increases in membrane capacitance, suggestive of cellular swelling. Sufficient inhibition of ATP-synthase (high dose oligomycin), disrupted both paracellular and basolateral resistances; and finally, complex 1 inhibition only disrupted the basolateral resistance.

Conclusions: Our findings suggest that the ECIS is a powerful tool for measuring in real time how the barrier function of RPE cells changes following mitochondrial dysfunction, and recommend its further use in investigation of RPE dysfunction as it relates to the multifactorial pathogenesis of dry AMD.

TITLE: Retinoid X receptor alpha (RXRa) mutant Pinkie and vitamin A deficient B6 mice develop similar spectrum of corneal inflammation

SESSION TITLE: Corneal immunology and neovascularization II

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Alam, Z. Yu, R. Ratnapriya, C.S. De Paiva, S.C. Pflugfelder, Ophthalmology, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jehan Alam: Commercial Relationship: Code N (No Commercial Relationship) | Zhiyuan Yu: Commercial Relationship: Code N (No Commercial Relationship) | Rinki Ratnapriya: Commercial Relationship: Code N (No Commercial Relationship) | Cintia De Paiva: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Pflugfelder: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To test the hypothesis that attenuated retinoid X receptor alpha (RXRa) signaling in the gene mutated Pinkie strain and C57/BL6 (B6) mice with systemic vitamin A deficiency (VAD) develop a similar spectrum of corneal inflammation.

Methods: Cornea immune cells were characterized by flow cytometry, gene expression pattern in the cornea was evaluated by Nanostring immunological array, and immunostaining evaluated expression of cornified envelope (SPRR2) and neovascularization (CD31, LYVE-1) markers and metalloproteinases. Effects of 9-Cis retinoic acid (RA) and all-trans RA (ATRA) on suppression of cyto/chemokine production by stimulated purified monocytes was detected by multiplex immunoassay.

Results: Among the resident CD45⁺ cells in the normal B6 cornea, we found lymphoid (CD45⁺CD3⁺; 21.6%), and myeloid (78.2%) cells which include CD45⁺CD11b⁺Ly6G⁺ (16.9%), CD45⁺CD11b⁺Ly6C^{low}CD64^{high} (13.9%, as macrophages) and CD11b⁺Ly6C^{high}CD64^{low} (19.08%, as classical monocytes). Classical monocytes were the predominant cell population increased in the cornea of Pinkie and VAD strains. Tears cytokines G-CSF, IL-1 α , CXCL-1 and VEGF were significantly upregulated in Pinkie and VAD mice. Both 9-Cis and ATRA attenuated LPS stimulated production of G-CSF, IL-1 α / β , IL-12 and CXCL9 by purified CD11b⁺Ly6C^{high} monocytes in a dose dependent manner. VAD mice lost weight and developed mild to moderate corneal opacity around 12-14 weeks of age. Systemic 9-Cis or ATRA prevented the VAD phenotype. Approximately 20% of Pinkie developed corneal opacification, vascularization and ulceration by age 20 weeks. The ulcerated corneas are densely infiltrated with CD11b⁺ immune cells and have greater immunostaining for SPRR2, blood (CD31+) and lymphatic (LYVE-1+) vessels and MMP-9 compared to age-matched normal B6 corneas. Nanostring RNA expression profiling in the ulcerated cornea revealed high expression of S100a8, S100a9, Plau, Plaur, IL1 β , COX2, CCL2, IL6, CCR4, ICAM1, Pro-Platelet basic protein (PPBP), CCL9, VEGFA, FGF7 and MMP-9.

Conclusions: Corneas from Pinkie with attenuated Rxra signaling and VAD B6 are infiltrated with inflammatory monocytes, have increased expression of proinflammatory and proangiogenic mediators and develop corneal neovascularization and opacification. These findings suggest that RXRa signaling modulates corneal inflammation and maintains corneal health and clarity.

ABSTRACT BODY:

Purpose: Diabetic retinopathy is a leading cause of vision impairment globally. Clinical practice guidelines have been developed to assist practitioners in providing evidence-based care to improve vision outcomes. However, the methodological rigor of these guidelines remains largely unknown. This study aimed to systematically review the quality of existing diabetic eye care guidelines.

Methods: A systematic search of guidelines for comprehensive clinical eye care of adult patients with diabetes was conducted on MEDLINE, Scopus PubMed, EMBASE, ProQuest, Web of Science and websites of relevant guideline developers and professional societies. Four reviewers independently rated the quality of the included guidelines using the Appraisal of Guidelines, Research and Evaluation (AGREE II) instrument. Aggregate scores (%) for six domains and overall quality assessment were calculated. A 'good quality' guideline was defined as the one with $\geq 60\%$ score for 'rigour of development' and in at least two other domains.

Results: Eighteen guidelines met inclusion criteria, of which 13 were evidence-based guidelines (involved systematic search and grading of evidence). In general, guidelines scored high in 'clarity of presentation' (Median (interquartile range (IQR)): 86.6% (76.7% to 94.4%)), and 'scope and purpose' (73.6% (54.2% to 80.6%)) and low in 'applicability' (28.6% (18.0% to 37.8%)) and 'stakeholder involvement' (48.6% (29.2% to 71.5%)). The median scores for 'rigour of development' and 'editorial independence' were 60.2% (30.9% to 78.1%) and 67.7% (24.0% to 83.3%), respectively. The median overall score (out of 7) of all guidelines was 5.1 (IQR: 3.7 to 5.8). The evidence-based guidelines scored significantly higher in overall assessment and all domains except for 'clarity of presentation' compared to expert-consensus guidelines. Half (n=9) of the guidelines (all-evidence-based) were of 'good quality'.

Conclusions: A wide variation in methodological quality exists among diabetic eyecare guidelines, with nine guidelines demonstrating 'good quality'. Future iterations of guidelines could improve by appropriately engaging stakeholders, following a rigorous development process, including support for application in clinical practice and ensuring editorial transparency.

ABSTRACT BODY:

Purpose: Coronavirus-19 (COVID-19) has had immense effects on access to medical care. Loss of medical care is alarming for individuals with pre-existing conditions like Type 1 Diabetes Mellitus (T1DM) which require uninterrupted care for best outcomes. Consistent care and medication use can reduce risk of developing diabetic retinopathy (DR) by 76% or progression by 54%. Healthy habits have also been linked to reduced risk of DR. The purpose of this study is to assess the effect of COVID-19 on care access and health habits in individuals with T1DM.

Methods: Surveys were administered from July-November of 2020 to multinational groups including the Children with Diabetes Conference (USA) and online groups, the American Diabetes Association and Connected in Motion Canadian Conference for T1DM. Data was collected from 125 patients from the USA, UK, Canada, and Bolivia. Age range was 5-81, and average years with T1DM was 17.9. The survey was online so responder rate is unclear, though response rates from previous surveys with similar groups averaged less than 10%.

Results: While 73.6% of respondents saw an ophthalmologist within 1 year and 98.4% had medication without rationing, 40% postponed medical visits. Reasons for postponement included lack of appointments or transportation, financial issues and safety concerns. The majority (86.4%) were from the US where private insurance is prevalent, 12% were from Europe and Canada, where socialized medicine is common. Of respondents, 90.4% are willing to use telemedicine as an alternative. For most, diet remained the same (48.8%); 25.6% stated their diet was healthier and 20% stated their diet was less healthy. 16.8% had problems accessing their usual foods due to the pandemic. A majority (55.2%) reported decreased exercise with 18.4% reporting more exercise. These overall trends were consistent across countries, and gender trends remained the same as pre-COVID, with women having better lifestyle and medical care adherence.

Conclusions: Though patients delayed appointments, most were able to see an ophthalmologist and access medication. Physical activity levels decreased, though diets were mostly unchanged. In individuals with T1DM, disruptions in medical care and health habits can have negative long-term outcomes on overall and eye health. Telemedicine offers a promising solution for mitigating this risk.

ABSTRACT BODY:

Purpose: To compare the costs of fluocinolone acetonide (FA) and dexamethasone (DM) intravitreal implants with steroid-sparing systemic therapy in the treatment of non-infectious uveitis (NIU) and to determine the usage patterns and changes in cost over time of FA and DM implants.

Methods: Retrospective claims-based analysis of a study population in IBM MarketScan, a nationally-representative sample of commercial insurance beneficiaries, diagnosed with NIU from 2007-2016 who received intravitreal FA or DM implantation. Cost of procedure, total healthcare costs, follow up to ophthalmology and rheumatology, and number of repeat or crossover procedures (use of the other implant) were analyzed. Costs were also compared to NIU patients receiving steroid-sparing systemic therapy (SSST) with or without intraocular implants.

Results: Over 200,000 patients with NIU were found in the database, and a total of 109 FA patients, 417 DM patients, and 1060 SSST patients were identified. The total cost to the healthcare system of NIU patients who received FA implants was \$57,272, DM implants was \$21,810, and SSST without an implant was \$37,697 at one year ($p < 0.001$). The charged cost of implanting FA decreased from a peak in 2007 at \$40,603 to \$24,292 in 2016. The charged cost of implanting DM in NIU patients was stable over the study period with an average cost of \$2,051. There were no differences in the number of follow up visits to an ophthalmologist or rheumatologist at one, two, or three years between patients with FA and DM. There were more repeat procedures than crossover procedures for both FA (33.0% vs 4.6% at one year, 53.1% vs 14.3% at three years) and DM (60.0% vs 2.9% at one year, 61.6% vs 7.2% at three years).

Conclusions: In NIU patients, total healthcare costs were highest in patients with FA implants, lower with SSST, and lowest with DM implants. FA intravitreal implant use and cost decreased over time, while DM intravitreal implant use increased with stable cost over time. These findings may help clinicians decide which therapies to use in patients with NIU.

ABSTRACT BODY:

Purpose: With an increase in systemic disease leading to ocular manifestations and an expansion of the elderly population, healthcare is experiencing exponential demand and is projected to outgrow the supply of ophthalmologists. We performed a cross-sectional study to determine the prevalence of ophthalmologists and types of ophthalmology subspecialists in the three largest cities of each southwestern (SW) state (Arizona (AZ), New Mexico (NM), Oklahoma (OK) and Texas (TX)) in the United States (US).

Methods: We used the American Academy of Ophthalmology's "Find an Ophthalmologist" online listing, during December 2020, to determine the number and location of ophthalmologists in the SW US. We collected data on each ophthalmologist, including sex, primary subspecialty, practice type, year of board certification, and academic affiliation. We assigned two age groups based on board certification year (Table 1). We compared our data to previous literature demonstrating a mean US national density of 5.68 ophthalmologists per 100,000 persons in 2017. We identified the three largest cities in each state by population.

Results: There were 550 total ophthalmologists in the three largest cities of each SW state. The majority were male (78.5%) and board certified prior to or during 1997 (56.2%). There were 5.48 ophthalmologists per 100,000 persons, i.e., 18,238 persons per one ophthalmologist (P/O), in the SW region. Texas (21,036 P/O) and Oklahoma (13,240 P/O) were the most and least saturated states, respectively (Figure 1). Tucson had the most ophthalmologists per 100,000 persons (10.11); Rio Rancho (0.99) and Houston (3.59) had the least. Retina (N=128) and cornea/external disease (N=45) were the most reported primary subspecialties; oculoplastics (N=33) and neuro-ophthalmology (N=10) were the least reported.

Conclusions: Our results suggest that there are less ophthalmologists per person in the SW region compared to the 2017 mean national density. This data provides important information to younger ophthalmologists seeking job opportunities, the ophthalmic community for resource allocation, and the general public searching for ophthalmologists in the SW US.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is among the most common microvascular complication of diabetes and can lead to sudden loss of vision. Exploration of deep learning for the classification of DR through optical coherence tomography angiography (OCT-A) is limited by the size of the labelled datasets. Data security is fundamental to, yet hinders, collaboration between institutions. We investigate the approach of sharing the deep neural network (DNN) model during training while keeping the images private using a method referred to as federated learning (FL). In this study, we investigate the relative performance of the cross-institution application of FL for the classification of referable DR (RDR) in OCT en face images.

Methods: This IRB approved study consisted of three independent institutions: SFU (n=403 subjects), OHSU (n=323 subjects), and UW (n=54 subjects) using three commercial OCT image acquisition systems. The input for classification consisted of a combination of the en face angiographic and structural images from the deep and superficial vascular complexes. SFU and OHSU allocated 60% for training, 20% for validation, and locked 20% for testing, while the UW data was reserved as an external test set. Transfer learning of a VGG19 architecture initialized with ImageNet weights were used for 4-fold cross-validated classification. Each participating institution trains the DNN model and uploads the weights to a central FL computer. The models are averaged and then redistributed to each of the participants. We compare the FL performance versus each individual institution (internally) trained and tested model, and across institutions (external).

Results: There was no statistically significant ($P < 0.05$) difference in classification observed through two-tailed t-tests between the FL and internal model across every metric for all datasets (representative results shown in Fig. 1). The FL framework achieved an accuracy of 0.762–0.880 with an associated F1 score of 0.677–0.909 and AUC of 0.910–0.979; the internal models attained performances of 0.809–0.908, 0.778–0.921, and 0.884–0.978, respectively.

Conclusions: The FL approach for RDR classification shows comparable performance to internal models. This study demonstrates potential for more generalizable networks through FL that incorporate learning on data from diverse domains.

ABSTRACT BODY:

Purpose: Alterations in retinal oxygen metabolism are implicated in blindness causing diseases, such as diabetic retinopathy and glaucoma. Therefore, a non-invasive clinical tool to assess oxygen saturation (sO_2) in retinal vessels is desirable. Recent development of visible-light optical coherence tomography (vis-OCT) enabled non-invasive sO_2 measurements in retinal blood vessels at micrometer-scale resolution by three-dimensional (3D) spectroscopic analysis. Nevertheless, such measurements are susceptible to spectral contaminants from the complex retina anatomy and vis-OCT signal detection and processing, decreasing measurement reliability. To overcome limitations posed by spectral contaminants, we developed adaptive-spectroscopic OCT (AS-OCT), a processing technique that enables non-invasive, 3D, environment-independent sO_2 measurements in the human retina.

Methods: We used vis-OCT to image the retinas of 18 healthy volunteers. Light exposure in the eye was $< 250 \mu W$ and imaging acquisition time was 5 sec. We used adaptive spectroscopic OCT (AS-OCT) to identify and remove contaminants from retinal tissues, chromatic aberrations, and spectrally-dependent roll-off. Then, we automatically selected the optimal depths in the vessel for sO_2 measurement. Finally, we measured the attenuation spectrum in the blood vessel and used a least-squares regression fit with known spectra to determine the sO_2 value.

Results: We measured sO_2 in 125 unique retinal vessels near the optic disc (vessel diameters ranging from $37 \mu m$ to $176 \mu m$). Major arteries had $sO_2 = 97.9 \pm 2.9 \%$ (mean \pm standard deviation) ($n = 36$), small arteries (diameter $< 100 \mu m$) had $sO_2 = 93.2 \pm 5.0 \%$ ($n = 36$), and veins had $sO_2 = 58.5 \pm 4.3 \%$ ($n = 53$). Repeated measurement standard deviations were 2.21% and 2.32% for all arteries and veins, respectively. Fig. 1 shows an oximetry map of the optic disc in the retina of a healthy 23 year-old volunteer.

Conclusions: AS-OCT enables environment-independent retinal oximetry in the clinical setting. Repeatability in arteries and veins $< 2.5 \%$ indicates robust measurements that are promising for clinical use.

TITLE: Risk factors of Tube exposure in resident performed glaucoma drainage implant surgery

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Huang, A. Djougarian, J. Lee, F. Anwar, A. Djougarian, Northwell Health Eye Institute, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ping Huang: Commercial Relationship: Code N (No Commercial Relationship) | Anna Djougarian: Commercial Relationship: Code N (No Commercial Relationship) | Jung Lee: Commercial Relationship: Code N (No Commercial Relationship) | Farihah Anwar: Commercial Relationship: Code N (No Commercial Relationship) | alina Djougarian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report a series of cases with glaucoma drainage tube exposure and evaluate the possible risk factors for tube exposure in resident performed glaucoma drainage implant surgery.

Methods: The medical records of all patients at the Queens Hospital Center - NYC Health + Hospitals who underwent Ahmed or Baerveldt glaucoma implant surgery by resident physicians from August 1, 2015 to November 1, 2020 were reviewed. Patients who presented with glaucoma drainage tube exposure and required surgical revision of the tube were identified. Demographic factors, past ocular history, past medical history, current treatment, and time to exposure were abstracted from the identified charts and were compared with a similar number of patients without tube exposure identified during the same period.

Results: Five patients (7 eyes) experienced glaucoma drainage tube exposure. The average time to exposure was 46.7 ± 33.6 months. The exposure group had similar mean age of 67.1 ± 11.8 compared to the non-exposure group's mean age of 66.7 ± 15.4 ($P=0.961$). More males 57.1% and fewer African-Americans 42.9% were identified in the exposure group versus 14.3% male and 85.7% African-American in the non-exposure group. All the patients in the exposure group had a diagnosis of primary open angle glaucoma (POAG). In the non-exposure group, four patients had POAG, one had chronic angle closure glaucoma, one had neovascular glaucoma, and one had uveitic glaucoma. In the non-exposure group, all the tubes were located superiorly while in the exposure group 71.4% of the tubes were in the inferior quadrant. The number of previous glaucoma surgeries was significantly higher ($P=0.018$) in the exposure group (2.57 ± 1.51) compared with the non-exposure group (0.57 ± 0.54). The number of intraocular pressure lowering eye drops was higher ($P=0.052$) in the exposure group (3.29 ± 1.11) compared with the non-exposure group (1.71 ± 0.76).

Conclusions: Inferior location of the glaucoma drainage tube, previous glaucoma surgery, and the number of intraocular pressure lowering eye drops are potential risk factors for tube exposure in resident performed glaucoma drainage implant surgery.

Commercial Relationships Disclosure (Abstract): Anna Britton: Commercial Relationship: Code N (No Commercial Relationship) | Angela Schulz: Commercial Relationship: Code N (No Commercial Relationship) | Georgina Luscombe: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Tong: Commercial Relationship: Code N (No Commercial Relationship) | Brendon Wong: Commercial Relationship: Code N (No Commercial Relationship) | Claude Farah: Commercial Relationship: Code N (No Commercial Relationship) | Stuart Graham: Commercial Relationship: Code N (No Commercial Relationship) | Clare Fraser: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Obstructive sleep apnoea (OSA) is a risk factor for vascular disease including stroke. Studies have shown OSA alters the retinal arterioles and veins, however studies on the microvasculature have yielded conflicting results and none have assessed the effect of continuous positive airways pressure (CPAP) on retinal vessel density. This prospective cohort study sought to examine the impact of varying severities of OSA on retinal vessel density using optical coherence tomography angiography (OCT-A) and whether CPAP treatment attenuates this change.

Methods: 67 adult patients underwent diagnostic polysomnography and retinal vessel imaging between April 2015 – December 2016. Patients were stratified into four clinical severity groups based on their apnoea-hypopnoea index (AHI, events/hour): controls (<5), mild (≥ 5 to <15), moderate (≥ 15 to <30), and severe OSA (≥ 30). Following their sleep study a subset of patients were offered CPAP at the discretion of a sleep physician. At a 24-month follow up, patients had OCT-A scans taken on Spectralis OCT-A (Heidelberg Engineering, Germany). Vessel density was analysed on images of the macula and optic nerve head (ONH) using ImageJ software. Exclusion criteria included the presence of glaucoma, prior optic neuropathy or retinopathy and media opacities.

Results: Of the 67 participants (45 males; mean age 62.3), there were 9 controls, 16 mild, 18 moderate and 24 severe OSA participants. Vessel density was negatively correlated with clinical severity by AHI but this did not reach statistical significance at the superficial vascular complex (SVC), deep vascular complex (DVC) or optic nerve head (ONH) ($p = 0.072, 0.206, 0.294$, respectively). However, for those not using CPAP, vessel density was significantly and negatively correlated by AHI at the macula (SVC $p = 0.010$, DVC $p = 0.049$). Compliant CPAP use abolishes this trend. Vessel density was also significantly and negatively correlated by AHI for diabetic patients in the cohort (SVC $p = 0.013$, DVC $p = 0.042$).

Conclusions: Our results show that retinal vessel density is negatively correlated with AHI in untreated individuals and that adequate use of CPAP abolishes this trend. Untreated OSA in combination with diabetes has the propensity to significantly worsen vascular outcomes.

ABSTRACT BODY:

Purpose: Diabetic retinopathy results in the proliferation of endothelial cells and excessive vascularization in the retina, leading to blindness. In diabetic mice, these structural changes succeed changes in oxygen metabolism in the retinal microvasculature. This suggests that changes in mitochondrial function may precede diabetic retinopathy.

Methods: To investigate intracellular mitochondrial changes, we used Stochastic Optical Reconstruction Microscopy (STORM) to visualize mitochondrial morphology variations in primary mouse retinal pericyte (PC) and endothelial cells (EC) with and without five-day incubation in a high-glucose culture medium. This allowed us to visualize mitochondrial morphology down to a ~50nm resolution level. We then segmented and analyzed the images, looking at size, shape, and distributional changes in the mitochondria over different conditions, using an unpaired t-test to compare between groups.

Results: Preliminary results suggest that in primary PC cells treated with glucose, there is a significant level of mitochondrial elongation compared to untreated PC cells. The median length of mitochondria goes increased from 0.41 to 0.90 μm ($p < 0.05$) between the control and glucose treated cells. Furthermore, the median total area of each 2D cell image covered with mitochondria increased from 208 to 298 μm^2 ($p < 0.05$) with no corresponding increase in cytoplasm or nucleus size and with no corresponding increase in the number of mitochondria.

Conclusions: The elongation of mitochondria in the PC suggests an increased metabolic rate in these cells after glucose treatment. Future studies could explore the relationship between PC metabolic rate and the level of vascularization in the retina.

ABSTRACT BODY:

Purpose: To assess demographic qualities, institutional backgrounds, and academic achievements of program directors in Cornea and External Disease, Refractive Surgery, and Anterior Segment fellowships.

Methods: Program directors of Cornea and External Disease, Refractive Surgery, and Anterior Segment fellowships were identified on the San Francisco Match website. Demographic characteristics, educational and training background, and academic productivity were analyzed using the director's institutional profile, PubMed, and Scopus database. Board certification was confirmed using the American Board of Ophthalmology website. Membership in journal editorial board, Cornea Society board, or Heed fellowship was based on the respective websites. Other fellowship qualities reviewed included academic or private practice type, number of cornea faculty, and sex of chairperson.

Results: We reviewed 47 Cornea and External Disease, 29 Refractive Surgery, and 10 Anterior Segment fellowships. Of reviewed programs, 64.0% were considered academic, 34.9% were private practice, and 1.2% were both. Overall, 23.9% of program directors were women and the mean age was 52.6 ± 2.5 years old. More female program directors were in departments with a female chairperson compared to male program directors ($6 \pm 28.6\%$ vs. $4 \pm 6.0\%$, $p=0.011$). Of program directors, 20.5% were Heed Fellows, and the average number of publications was 44.6 ± 11.8 . Mean H-index was 16.5 ± 3.3 and was higher in Cornea, External Disease, and Refractive Surgery than Anterior Segment fellowships (18.2 ± 15.5 vs. 7.1 ± 11.4 , $p=0.008$). Mean H-index was higher in academic than private practice fellowships (19.9 ± 15.1 vs. 11.2 ± 14.7 , $p=0.011$). Of all program directors, 1.1% were Instructors, 14.8% were Assistant Professors, 25.0% were Associate Professors, 34.1% were Full Professors, 18.2% were Endowed Chairs, 12.5% were on the Editorial Boards of the 3 highest impact journals in ophthalmology and cornea, and 6.8% were Cornea Society Board Members.

Conclusions: The majority of fellowships are academic programs led by program directors with a high number of publications, H-index, and level of professorship. Cornea and External Disease and Refractive Surgery fellowship directors had a higher academic productivity than those in Anterior Segment programs. Female program directors remain the minority and are more common in departments with female chairpersons, demonstrating an opportunity for further representation.

ABSTRACT BODY:

Purpose: Simulating glaucoma pathology and medication-induced changes to the anatomy and physiology of the conventional outflow pathway presents a unique challenge. In this study, we utilized our proprietary 3D-bioengineered glaucomatous conventional outflow model to investigate the ability of QLS-100 to modulate outflow in vitro. QLS-100 is the active moiety of QLS-101, a novel K_{ATP} channel opener with the unique ability to enhance outflow in the absence of ocular side effects such as hyperemia. The effects of QLS-100 on fibrotic and endothelial junctional markers in human trabecular meshwork/Schlemm's canal co-cultures are also described.

Methods: Bioengineered 3D conventional outflow tract constructs, using 4 donors (ages 47-91), were treated with TGF β -2 (5 ng/mL) for 6 days. Constructs were then treated with QLS-100 (1, 10 or 100 μ M), or Y-27632 (10 μ M). The effect of QLS-100 (1 μ M) on outflow facility (hydraulic conductivity) was assessed by perfusion studies where pressure was constantly recorded at various perfusion rates. Protein expression of α -smooth muscle actin (α -SMA), CD31, endothelin-I, fibronectin, VE-cadherin, Phospho- and total eNOS was analyzed via western blot. Cellular expression of α -SMA, fibronectin, Phospho- and total eNOS was determined by immunocytochemistry and confocal microscopy. Statistical significance was determined by one-way ANOVA with a Tukey's multiple comparisons test, or by two-way ANOVA.

Results: QLS-100 significantly increased outflow facility across all donors, as compared to TGF- β 2 or Y-27632 treated donors ($P < 0.0001$ and $P < 0.05$, respectively). QLS-100 did not affect expression of the cell adhesion proteins CD31 and VE-Cadherin, while Y-27632 significantly decreased their content ($P < 0.01$). Neither compound altered protein expression or distribution of endothelin, fibronectin, α -SMA, or phospho- or total eNOS.

Conclusions: QLS-100 significantly improved outflow facility in glaucomatous tissue constructs without impacting protein expression of fibrotic or endothelial junctional markers. Y27632 decreased expression of endothelial junctional markers, which may explain the hyperemia observed with clinical ROCK inhibition. These results indicate that the novel prodrug QLS-101 is a promising treatment that may lower elevated IOP without altering vessel integrity.

TITLE: IOP-Induced In Vivo Deformation and Strains in the Human Optic Nerve Head using OCT

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Saheb Kashaf, H.A. Quigley, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|T.D. Nguyen, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Saheb Kashaf: Commercial Relationship: Code N (No Commercial Relationship) | Thao Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Harry Quigley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We measured in vivo deformation and mechanical strain in the optic nerve head (ONH) in glaucoma patients using optic coherence tomography (OCT) scans of the ONH before and after a short-term change in intraocular pressure (IOP).

Methods: Persons treated for open angle glaucoma underwent imaging by radial ONH OCT scans obtained before and 20 minutes after IOP increase produced by tight-fitting swimming goggles or before and after IOP decrease by laser suturelysis. Bruch's membrane opening and the anterior lamina cribrosa (LC) border were manually marked. Digital volume correlation calculated 3D displacements within the LC, defined as tissue up to 250 μ m posterior to anterior LC border. Displacements were used to calculate anterior lamina depth (ALD) change and LC strains. Generalized estimating equation models accounted for inclusion of both eyes in goggles patients.

Results: In 20 eyes (12 persons, mean field MD= -2.6 dB), goggles-wearing increased mean IOP by 6.6 mm Hg (range 1-16) and produced $-0.32 \pm 0.71\%$ mean compressive anterior-posterior LC strain (Ezz) ($p=0.056$). Suture lysis in 14 eyes (14 persons, mean field MD= -9.5 dB) decreased mean IOP by 13 mm Hg (range: 3-45) and produced $+1.04 \pm 1.37\%$ mean tensile Ezz strain ($p=0.010$). Among suturelysis eyes, greater IOP change was associated with both larger Ezz strain ($p=0.0005$) and larger maximum principal strain (Emax; $p=0.005$). In the goggles group, Emax was significantly smaller with thicker peripapillary nerve fiber layer in corresponding inferior ($p=0.05$) and temporal ($p=0.01$) quadrants. In goggles eyes, a more normal visual field index was associated with a smaller maximum principal strain ($p=0.04$). ALD deepened among goggles eyes (mean = $3.8 \pm 5.98 \mu$ m, $p=0.011$) and moved toward the vitreous after suturelysis (mean = $2.5 \pm 5.93 \mu$ m, $p=0.122$). Greater IOP change was associated with greater ALD change in both goggles ($p < 0.0001$) and suturelysis ($p=0.04$) eyes.

Conclusions: Modest short-term IOP alterations led to measurable changes in anterior LC depth and tissue strains. The association between field damage and strain in goggles wearers may indicate that strains are preexisting correlates of glaucoma susceptibility, or, that strain changes result from glaucomatous injury. Longitudinal studies are planned to elucidate these issues.

ABSTRACT BODY:

Purpose: The assessment of functional progression of glaucoma is an important measurement for diagnosing and monitoring the disease. This retrospective study analyzed change from baseline (CFB) in mean deviation (MD) of visual fields (VF) using Humphrey Field Analyzer 24-2 program (HFA 24-2) in glaucomatous eyes from a clinical study evaluating the Brimonidine Drug Delivery System (Brimo DDS).

Methods: A retrospective analysis of CFB in VF MD was performed on a multicenter, randomized, patient-masked, sham-controlled study evaluating the effects on visual function of Brimo DDS in patients with primary open angle glaucoma. Patients that received a single administration (n=70) of Brimo DDS 132 µg, Brimo DDS 264 µg and sham treatment at baseline in the study eye were included in this analysis. VF testing was assessed over 12 months with primary data analysis at 6 months. Subgroup analysis of VF progression and best-corrected visual acuity (BCVA) over time was split by HFA 24-2 baseline median MD (-15.7 dB, above and below). Statistical analysis was conducted using R Software (v3.6.1) under R Studio and verified by an independent group using SAS[®] analytics.

Results: Study eyes administered Brimo DDS 132 µg (n=21), Brimo DDS 264 µg (n=25), and sham (n=24) were analyzed for VF MD and BCVA. At baseline, the VF MD (mean±SEM) were -14.5±0.9, -15.4±1.1, and -18.0±1.0 dB and BCVA (mean±SEM) were 80.6±1.4, 76±1.6, and 77.3±1.6 letters for Brimo DDS 132 µg, Brimo DDS 264 µg, and sham, respectively. At 6 months, the MD CFB in VF (LS means±SE) for patients below median MD were 0.49±1.12, 1.50±0.93, and -1.09±0.73 dB; the CFB in BCVA (LS means±SE) for patients below median MD were 0.27±1.22, 4.06±1.04, and -0.37±1.08 letters for Brimo DDS 132 µg, Brimo DDS 264 µg, and sham, respectively. Brimo DDS 264 µg treated eyes had a significant CFB in VF MD (p<0.05) at 6 months compared to sham treatment indicating a reduction in progressive VF loss. Brimo DDS 264 µg treated eyes had a significant CFB in BCVA at 1 month (p<0.05) and 6 months (p<0.05) compared to sham treatment indicating an improvement in visual acuity. There was no significant difference between treatment groups above the HFA median MD.

Conclusions: In glaucomatous patients with VF MD below the HFA median, Brimo DDS 264 µg significantly reduced VF loss up to 6 months while providing improvement in vision as early as 1 month.

ABSTRACT BODY:

Purpose: Requests for ophthalmic consultations from the Emergency Department (ED) can be due to a wide range of pathology, including urgent ocular diseases. In this study, we characterize ophthalmic consultations from a level-1 trauma ED, representing a high-acuity tertiary care University Hospital setting.

Methods: In this retrospective chart review, 434 consultations to the ophthalmology department over 60 days were identified; 352 (81%) were from ED. Median age was 43 years (interquartile range: 30 to 55 years), and 158 (43%) patients identified as female. Data collected for each subject includes demographic information, reason for consultation, diagnosis, treatment, and follow-up status.

Results: Of the 352 ED consultations identified, 137 (39%) consultations were related to a trauma. Only 102 (29%) of patients were admitted to the hospital. Most common reasons for consultation included: 81 (23%) for eye irritation/pain, 80 (23%) for decreased/blurry vision, 36 (10%) for ocular involvement of trauma, 28 (8%) evaluation of known orbital fracture, 19 (5%) for eyelid/facial laceration, 16 (5%) for red eye, and 15 (4%) for periorbital edema. Most common final ocular diagnoses included: 42 (12%) orbital fracture, 24 (7%) corneal abrasion, 21 (6%) no ocular pathology, 20 (6%) eyelid laceration (including 4 canalicular involving lacerations, and 16 non-canalicular involving laceration), 14 (4%) conjunctivitis, and 13 (4%) uveitis. In total, 69 (20%) received emergent ophthalmic surgery for their presenting condition. Follow up was requested of 334 patients, of which only 165 (49%) returned to clinic.

Conclusions: Ocular involvement of trauma and other acute disease accounted for a significant portion of ophthalmic consultations in this high-acuity care setting. One-fifth of the consultations required emergent ophthalmic surgery.

ABSTRACT BODY:

Purpose: The iris is a highly clinically relevant structure, but most literature on iris pathology is limited to qualitative observations. In this study, we aim to develop novel quantitative assessment tools for evaluation of the iris. We have developed a standardized measurement protocol of iris parameters with reliability analysis using ultrasound biomicroscopy (UBM) and ImageJ software to establish the rigor and reproducibility of these measurements and provide a quantitative description of the human iris in subjects from infancy to young adulthood.

Methods: 14 pediatric control subjects comprising of 25 total eyes (mean age 1.96yrs, standard deviation 1.18yrs, and median age 1.81yrs) were recruited prospectively and underwent UBM imaging. Two observers measured 19 structural iris parameters on four UBM image types per eye using ImageJ. Each image was analyzed by both observers using two methods: Standard and Edge Finder, which uses an edge detector to delineate tissue borders based on changes in intensity. Reliability analysis was comprised of intra-observer repeatability (IOR) and inter-observer agreement (IOA). IOR was determined by calculating the coefficient of variation (CV) and correlation coefficient (r) for each parameter, and IOA was assessed by determining the intra-class correlation coefficient (ICC) for each parameter.

Results: Axial image types resulted in superior ICC, CV and r values for the majority of parameters with the use of an edge finder tool. Longitudinal image types resulted in superior ICC, CV and r values for the majority of parameters using the standard method of image analysis on the raw image.

Conclusions: The use of an edge finder tool increased measurement reliability in axial image types, but it did not increase reliability in longitudinal images.

TITLE: Adjunctive Use of Netarsudil in Refractory Glaucoma: 1 year Retrospective Analysis.

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Bekerman, B. Zhou, C. Ha, R. Vohra, A.S. Khouri, Rutgers New Jersey Medical School Department of Ophthalmology & Visual Science, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Vladislav Bekerman: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Christine Ha: Commercial Relationship: Code N (No Commercial Relationship) | Reshma Vohra: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship(s);Aerie:Code C (Consultant);Bausch and Lomb:Code C (Consultant);Allergan:Code F (Financial Support);Optovue:Code F (Financial Support);NJ Health Foundation:Code F (Financial Support);Glaukos:Code C (Consultant)

ABSTRACT BODY:

Purpose: Netarsudil is a new class medication targeting rho-kinase inhibition and increasing trabecular meshwork outflow. Published studies have proven its efficacy alone and in combination with latanoprost as primary therapy. This study retrospectively investigated the one year efficacy of adjunctive use of netarsudil in refractory cases of glaucoma at a tertiary care glaucoma clinic. Refractory cases were judged as requiring ≥ 3 topical medications for intraocular pressure (IOP) control.

Methods: Retrospective chart review for patients on ≥ 3 topical medications who received add-on netarsudil was conducted from 01/01/2018 to 08/31/2020. Patients' baseline characteristics prior to add-on therapy were recorded and included type of glaucoma, prior topical, laser, and surgical treatments. A baseline IOP was calculated by taking the average of the two most recent IOP measurements prior to netarsudil add-on treatment. IOP was measured at 3-, 6-, and 12-month intervals ± 4 week windows. A Bonferroni corrected student's T-test was used to test differences between groups with statistical significance set at $p = 0.01$

Results: 69 eyes in 47 patients were included in this analysis. Mean age (\pm SD) was 72.0 ± 12.2 . 22 (47%) African American, 15 (32%) patients were Caucasian, and 10 (21%) Hispanic. Glaucoma diagnosis was as follows: 55 (80%) primary open angle, 4 (6%) uveitic, 4(6%) neovascular, 2 (3%) normal tension glaucoma, 2 (3%) exfoliation. Prior surgeries included: 21 (30%) seton, 13 (19%) trabeculoplasty, 4 (6%) trabeculectomy, 4 (6%) iStent, (1%) iridotomy. Mean IOP mmHg (\pm SD) at baseline was 20.7 ± 5.8 . Follow-up mean IOP mmHg (\pm SD) are as follows: 3-month 17.8 ± 6.7 ($p < 0.008$) in 64 eyes, 6-month 17.8 ± 4.6 ($p < 0.008$) in 56 eyes, 12-month 17.4 ± 6.8 ($p < 0.008$) in 44 eyes.

Conclusions: Adjunctive use of netarsudil in refractory glaucoma showed clinically and statistically significant IOP reductions. This study suggests that adding netarsudil to eyes with previous medical or surgical treatment can provide longer term IOP reduction. Further analysis is required to fully understand the effect of netarsudil in refractory glaucoma.

TITLE: Improving Refractive Outcomes in Patients with Keratoconus Treated with Superior-Masked Topography-Guided Photorefractive Keratectomy

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Gill, S. Greenstein, Ophthalmology, Rutgers New Jersey Medical School Department of Ophthalmology & Visual Science, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aditya Gill: Commercial Relationship: Code N (No Commercial Relationship) | Steven Greenstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Topography-Guided photorefractive keratectomy (TG-PRK) is an effective treatment to improve vision, refraction, and corneal contour in patients with keratoconus. Generally, there is a myopic shift after treatment with TG-PRK which may increase manifest refractive spherical equivalent (MRSE) and anisometropia post-operatively. This study aims to evaluate a novel technique, utilizing a superior mask to cover the peripheral ablation profile to reduce a postoperative myopic shift.

Methods: 13 eyes of 13 patients underwent TG-PRK with superior-masking technique. A LASIK eye drain (Wilson Oph Corp, USA) was cut to mask the superior portion of the topography-guided ablation. Topography measurements were obtained on the Pentacam (Oculus, Germany). Preoperative and 12-month post-operative MRSE, uncorrected distance visual acuity (UDVA), corrected distance visual acuity (CDVA), maximum keratometry (K_{max}), thinnest pachymetry (P_{thin}), and average anterior and posterior radii of curvature (ARC and PRC) were recorded and analyzed.

Results: Compared to baseline vision, the mean UDVA improved from 1.00 ± 0.35 (SD) to 0.45 ± 0.14 logMar lines (LL) ($P=0.004$) and the mean CDVA improved from 0.48 ± 0.31 LL to 0.19 ± 0.08 LL ($P=0.04$) at the 12 month visit. MRSE improved from baseline of -5.85 ± 3.66 D to -1.82 ± 3.75 D at the 12 month visit ($p=0.02$). K_{max} decreased from 60.78 ± 8.87 D pre-operatively to 51.77 ± 4.62 D at the 12 month visit ($P=0.04$). Finally, P_{thin} decreased from $429.08 \pm 46.07\mu m$ at baseline to $408 \pm 73.72\mu m$ at the 12 month visit ($P=0.33$); however these values were not statistically significant.

Conclusions: TG-PRK with a superior mask is a novel technique to minimize the post-operative myopic shift in treated patients with keratoconus. In addition, this technique appears to improve UDVA, CDVA, and cornea curvature after treatment. Additional data will be presented at ARVO 2021.

TITLE: Outcomes of Resident-Performed Cataract Surgery in a Diverse Veterans Affairs Hospital System Population

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.E. Gutkind, E. Meer, N. Bhatt, Ophthalmology, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, UNITED STATES|P. Hua, G. Ying, Center for Preventive Ophthalmology and Biostatistics, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Naomi Gutkind: Commercial Relationship: Code N (No Commercial Relationship) | Elana Meer: Commercial Relationship: Code N (No Commercial Relationship) | Peiying Hua: Commercial Relationship: Code N (No Commercial Relationship) | Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship) | Nirali Bhatt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate visual acuity (VA) outcome and complications, and risk factors for VA outcome from the resident-performed cataract surgery at a diverse Veterans Affairs hospital system population.

Methods: A retrospective chart review was conducted for patients who underwent cataract surgery by residents at the Philadelphia Veterans Administration Medical Center from 01/01/2013 – 12/31/2015. Clinical information including preoperative, intraoperative, and postoperative visual acuity (1 day, month 1, 2-3 and 6) and surgery complications was collected. Descriptive analyses were performed for complication rate, and univariable and multivariable linear regression models were performed for risk factors of VA change from baseline at 1 month and VA change from baseline at all post-operative visits combined.

Results: This study included 1183 patients, with mean (SD) age of 70.8 (9.3) years, 41.7% were African American, 57.6% were Caucasian, and 97.5% were male. The mean (SD) VA in logMAR was 0.69 (0.74) at baseline, and improved to 0.19 (0.36) at 1 month, 0.16 (0.34) at 2-3 months and 0.14 (0.36) at 6 months (Table 1), with 91.3% patients having VA improvement from baseline at 1 month, and 86.5% patients achieved 20/40 or better at 1 month. Analysis by baseline visual acuity levels demonstrated that individuals with baseline visual acuity of worse than 20/40 experienced significant improvement from baseline (Table 1). Complications from cataract surgery were minimal, including hyphema (0.3%), dropped nucleus (1.8%), iris prolapse (0.8%), anterior capsular tears (0.6%), posterior capsular tears (4.0%), zonular dehiscence (1.1%), and vitreous loss (5.4%). In multivariate analysis, younger age ($p < .0001$), worse baseline visual acuity ($p < .0001$) and absence of iris prolapse ($p < .001$) were significantly associated with greater improvement in VA at 1 month.(Table 2)

Conclusions: Resident-performed cataract surgeries achieve significant improvement in visual acuity with a complication rate lower than previously reported in residents, and not substantially greater than in the cataract literature. There is a clear benefit from resident-performed surgery as a means of providing surgery with successful outcomes in this specific population of patients.

TITLE: Alternative healthcare practitioner use and its association with medical eye care in chronic ocular disease patients

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Swink, B.C. Stagg, University of Utah Health, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure (Abstract): James Swink: Commercial Relationship: Code N (No Commercial Relationship) | Brian Stagg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patient utilization of alternative healthcare providers is on the rise in the United States and the impact of this on chronic ocular disease patients is unknown. We performed a retrospective cross-sectional study using nationally representative data to analyze how patients with chronic ocular disease utilize alternative healthcare providers and determine if there was any association between alternative healthcare use and decreased adherence to prescription medication adherence.

Methods: We used multivariate logistic regression models to evaluate the association between ocular disease, regular eye doctor visits, alternative healthcare provider visits, and skipping or using alternative medications to save money. Our study size was 5,264 participants with self-reported diagnoses of glaucoma, age-related macular degeneration, or diabetic retinopathy. These models were adjusted for potential confounders (gender, age, race, ethnicity, educational attainment, vision impairment, insurance status, poverty level, and presence of other medical conditions). We defined alternative healthcare providers as practitioners of homeopathy, naturopathy, traditional medicine as well as shamans, curanderos, machis, pacheros, yerberos, hierbistas, sobadors, Native American healers, and medicine men. All data came from the 2017 National Health Interview Survey (NHIS) and was analyzed using Stata version 16 (StataCorp, College Station, TX).

Results: Participants with chronic ocular disease who utilized alternative healthcare providers were more likely to have regular eye care appointments (odds ratio [OR]: 1.76, 95% confidence interval [CI]: 1.14-2.72, $P=0.01$). These participants were also more likely to use alternative medications or skip medication doses to save money (OR: 5.31, 95% CI: 3.09-9.14, $P<0.001$ and OR:3.84, 95% CI: 1.84, 7.95, $P<0.001$, respectively).

Conclusions: Regular eye care for patients with chronic ocular disease is important in preventing vision loss. Patients who utilize alternative care providers may be at higher risk for vision loss because of medication nonadherence. The underlying cause of the association of medication nonadherence and alternative healthcare utilization is still not clearly understood. More research is required to understand why patients are utilizing alternative care providers and why they are be more likely to be less compliant with their medication.

ABSTRACT BODY:

Purpose: It was hypothesized that stress from COVID-19 would have a negative effect on Central Serous Retinopathy (CSR), a stress associated condition. The purpose of this study was to evaluate the effects of stress from COVID-19 on chronic CSR using a retrospective chart review.

Methods: Charts from 45 patients, 67 eyes, with chronic CSR were evaluated. Data were collected pre COVID-19 shutdown (January 1, 2019 to March 15, 2020) and during COVID-19 shutdown (March 15, 2020 to September 1, 2020) for visual acuity, central subfield thickness (CST), pigment epithelial detachment (PED), and subretinal fluid. Clinical change (improved, stable, or worsened) status was determined by the treating retinal specialist. The data were determined to not be normally distributed via the Shapiro-Wilk test. Statistical significance of the CST and vision data was determined by the sign test. The McNemar Exact test was used to determine statistical significance of PED and subretinal fluid.

Results: Differences in data in pre vs post COVID-19 shutdown were not statistically significant. Clinically, 69% of patients were stable, 14% improved, and 17% worsened. Visual acuity pre COVID-19 shutdown averaged 20/37 (SD 20/46) and during the COVID-19 shutdown averaged 20/37 (SD 20/43); these changes were not statistically significant. CST pre COVID-19 shutdown averaged 281 μm (SD 57 μm) and during the COVID-19 shutdown averaged 288 μm (SD 83 μm); these changes were also not statistically significant. The majority of patients did not change in their presence or absence of PED (94%) or subretinal fluid (85%).

Conclusions: Patients with chronic CSR did not see significant changes to their clinical status, vision, CST, subretinal fluid, or PED when assessed during the COVID-19 pandemic. Stress from onset of the COVID-19 did not appear to have a significant effect on patients with chronic CSR.

ABSTRACT BODY:

Purpose: Treating cone disorders by gene therapy via intravitreal injection is challenging because the inner limiting membrane and retinal thickness limit accessibility of photoreceptors to injected agents. Overcoming this requires pre-clinical testing in non-human primates. Blue cone monochromacy is a cone-based disorder with a variety of underlying mutations, a subset of which is likely amenable to gene therapy, however a suitable primate model does not exist. Thus, our goal is to develop a vector optimized for driving robust expression of a photopigment with an absorption spectrum that allows functional detection via ERG and behavioral testing in retinas expressing endogenous primate cone photopigments.

Methods: The vector contains an optimized expression cassette designed to target expression of a passenger opsin gene to primate cones packaged in the AAV-7m8 capsid for an intravitreal route of administration. The opsin gene comprises partial sequence of middle wavelength opsin cDNA of the Mongolian gerbil (*Meriones unguiculatus*) flanked by partial exon 1 and exon 6 sequences of the human OPN1LW gene. The chimeric photopigment is expected to peak ~493 nm, about midway between the absorption maxima of the macaque monkey S and M photopigments (see Figure). Virus was injected into the eyes of mice that had both M and S opsin genes knocked out. Expression of the transgene was evaluated using photopic ERG. Spectral sensitivity was characterized using flicker photometric ERG.

Results: Photopic ERG responses in the cone opsin knockout mice were rescued by gene therapy treatment. Treated mice gave robust photopic ERG responses compared to knockout controls which gave no detectable cone responses. The characteristics of the ERG waveform were comparable to wild-type mice. ERG flicker photometric spectral sensitivity functions were well fit to a single photopigment template with a spectral peak of 493 nm.

Conclusions: We have developed a gene therapy vector designed to be administered intravitreally expressing a photopigment that is well separated in spectral sensitivity from any of the wild-type cone pigments in Old World primates. It should be possible to isolate the responses from this photopigment if it is expressed in macaque cones using silent substitution in ERG and behavioral experiments to evaluate gene therapy success.

ABSTRACT BODY:

Purpose: Adaptive Optics (AO) ophthalmic imaging is a rapidly evolving technique that provides ophthalmologists and vision scientists with the ability to resolve characteristics of the retina at a cellular level in vivo. We assessed cone photoreceptor regularity of the porcine retina under varying degrees of laser-induced retinal pigment epithelium (RPE) damage that mimicked age-related macular degeneration (AMD)-like conditions. This tested our hypothesis that AO is a useful imaging technique to evaluate photoreceptor regularity under disease conditions in preclinical porcine models.

Methods: AO was performed in n=4 eyes. The rtx-1 was used to image eyes at baseline and reexamine them at biweekly timepoints after laser intervention. We tested micro pulse laser duty cycles (DC) of 1%, 1.5%, 2%, and 3% in rectangular distributions within the cone dense visual streak of the porcine retina. For image analysis, 80x80 pixel regions of interest were analyzed. MATLAB, AODetect software, and an optimized low-pass filter were utilized in quantifying cone photoreceptors in a semi-automated manner. A custom algorithm aided in calculation of cell region and circularity factor. Cone density was defined by the density of recognized cone photoreceptors within an analyzed image segment. Cell region was defined by the region including the cell and the space abutting the borders of the cell. Cell circularity was defined as a quantitative measurement of the cell border curve from 0.0-1.0, where 1.0 was a perfect circle under healthy conditions.

Results: Following RPE damage with laser, all DCs resulted in decreased cone photoreceptor density and cell circularity factor while cell region increased over the course of 4 weeks. Together, these results suggested an increase in cell morphology irregularity in porcine laser models over 4 weeks.

Conclusions: Our results show AO performed on porcine models may prove to be a useful tool in evaluating cone photoreceptor regularity under disease conditions. Our utilization of the rtx1, an AO instrument designed for clinical settings, optimizes our technique for translational purposes. These findings suggest that cone photoreceptor regularity suffers significantly under conditions that mimic AMD over a 4 week period, and help validate AO as an imaging modality to evaluate photoreceptor health at a cellular level.

TITLE: Postnatal growth and neurodevelopment of infants treated with bevacizumab for retinopathy of prematurity

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.L. Zhang, S. Rahmani, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): David Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Safa Rahmani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There continues to be uncertainty regarding the systemic effects of anti-vascular endothelial growth factor (anti-VEGF) agents in the treatment of retinopathy of prematurity (ROP). We performed a retrospective clinical study to investigate postnatal systemic outcomes in ROP infants treated with one anti-VEGF agent, intravitreal bevacizumab (IVB).

Methods: All patients who developed ROP at Ann & Robert H. Lurie Children's Hospital of Chicago and Prentice Women's Hospital from 2008-2019 were identified. Three study groups were formed: infants treated with IVB, infants treated with laser photocoagulation, and infants with history of ROP without treatment. Exclusion criteria included infants with nonviable course or hydrocephalus, a source of non-physiologic weight gain. Baseline characteristics, hospital course, and systemic comorbidities were recorded. Neurodevelopment was assessed with Bayley III scores, if available. Weekly weight, length, and head circumference measurements from birth through 50 weeks postmenstrual age (PMA) were compared and plotted on the Fenton preterm growth chart to examine growth trends over time.

Results: 254 infants (139 male, 115 female) were included: 22 treated with IVB, 55 treated with laser, and 177 with ROP that resolved without treatment. Plot of growth measures on the Fenton growth chart showed that the mean weight for both genders started at the 50th percentile but deteriorated to the 14-31st percentile in girls and the 4-12th percentile in boys by 50 weeks PMA in all three groups. Similar trends for length and head circumference were observed in both genders, regardless of treatment status. One-way ANOVA comparing weekly changes in weight, length, and head circumference from birth to 50 weeks PMA showed no significant differences between study groups. Comparison of composite Bayley III scores at 24 months also trended to be not statistically significant.

Conclusions: There were no significant differences in postnatal systemic growth in children treated with IVB compared to those treated with laser and those not requiring treatment in this large retrospective study. These findings further demonstrate safety of bevacizumab treatment for ROP. Our observation that all three groups showed growth percentile deterioration from birth to 50 weeks PMA suggests that ROP development, regardless of treatment status, may be a negative predictor of postnatal growth.

ABSTRACT BODY:

Purpose: To report on the microbial spectrum and clinical features affecting final visual acuity (VA) outcome in cases of culture-positive endophthalmitis after open globe injury.

Methods: A non-comparative, retrospective, consecutive case series. All patients were diagnosed with endophthalmitis between January 2016 and January 2020 at the Bascom Palmer Eye Institute. Culture-positive isolates from patients with history of open globe injury were identified. Variables included demographic information, time to diagnosis, mechanism of injury, causative organism, and VA outcomes.

Results: Eleven cases of culture-positive endophthalmitis after open globe injury were identified. All patients were male and average age at time of injury was 35.65 years. Penetrating trauma was the mechanism of injury in all cases. Treatment selected included intravitreal antimicrobials in 11 cases, initial pars plana vitrectomy in 8 cases, and silicone oil in 4 cases. Primary evisceration or enucleation was not performed in any patient.

Seven cases of endophthalmitis (64%) were clinically diagnosed prior to open globe repair, whereas 4 cases (36%) developed endophthalmitis after open globe repair. The average time from globe injury to presentation was 7.3 days (range 0 to 42 days). Six cases were associated with an intraocular foreign body (IOFB). Of these, 4 were metallic and 2 were composed of vegetable matter.

Coagulase-negative staphylococcus accounted for the majority of cases (55%, 6/11). Isolates included Staphylococcus epidermidis (n=5) and Staphylococcus hominis (n=1). Virulent organisms represented the remainder of cases and isolates included: Streptococcus mitis (n=1), and Bacillus cereus (n=1), Fusarium (n=1), Colletotrichum gloeosporioides (n=1), and Enterobacter cloacae (n=1).

The mean presenting VA was HM (LogMAR 2.25) and the final average VA was similarly HM (LogMar 2.1) and included 3 enucleations. For patients without an IOFB the mean VA was CF (LogMAR 1.88), as compared to HM (LogMar 2.2) in cases of IOFB.

Conclusions: In agreement with prior studies on open globe injuries, we found coagulase-negative staphylococcus to be the most commonly isolated organism in cases of culture-positive endophthalmitis. In the current study, delayed presentation to care was a common factor in the development of endophthalmitis. VA outcomes for these patients with open-globe related endophthalmitis is generally poor.

TITLE: Dark rearing sector RP-associated rhodopsin mutants display variable levels of retinal degeneration in transgenic *Xenopus laevis*

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Loewen, B.M. Tam, R.T. Scharbach, C.N. Chiu, O.L. Moritz, Ophthalmology & Visual Sciences, The University of British Columbia, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure (Abstract): Aaron Loewen: Commercial Relationship: Code N (No Commercial Relationship) | Beatrice Tam: Commercial Relationship: Code N (No Commercial Relationship) | Ross Scharbach: Commercial Relationship: Code N (No Commercial Relationship) | Colette Chiu: Commercial Relationship: Code N (No Commercial Relationship) | Orson Moritz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: 15% of non-syndromic retinitis pigmentosa (RP) cases belong to a subclass called sector RP. Sector RP is defined by the localization of the disease phenotype to certain quadrants of the retina, usually the inferior. Mutations in RHODOPSIN (RHO) are the primary cause of sector RP, with well-characterized mutations residing in the N-terminal domain (T4K, T17M, and P23H). Dark rearing animals expressing RHO containing sector RP-associated mutations (including T4K, T17M, and P23H) changes the protein's stability, mitigating the retinal degeneration (RD) phenotype; however, many other sector RP-associated RHO mutations have not been investigated in this way. We investigated sector RP-associated mutations outside the N-terminus (T58R and D190G) and an N-terminal mutation that does not interfere with a glycosylation site (L31Q).

Methods: We generated transgenic *Xenopus laevis* by injecting wildtype (WT) oocytes with a mixture of WT sperm nuclei and linearized plasmids containing a human RHO transgene (either WT or containing missense mutations) under control of a *X. laevis* rod opsin promoter. Tadpoles were raised in either cyclic light or constant dark for 14 days before euthanization. Tadpole eyes were enucleated and were either cryosectioned and immunolabelled using anti-mammalian rhodopsin antibodies for confocal microscopy or analysed for rhodopsin levels using a dot blot assay.

Results: We observed mitigated RD in the dark rearing condition for animals expressing the L31Q or T58R RHO transgenes. However, D190G RHO-expressing animals failed to display mitigated RD in the dark rearing condition. Localization of the transgenic rhodopsin in the three mutations was primarily to the outer segment; however, D190G RHO animals display more inner segment localization compared to WT, L31Q, or T58R.

Conclusions: We investigated three sector RP-associated RHO mutations that produced rhodopsin which primarily localized to the outer segment. Similar to previously described models of sector RP, two of these mutations result in RD that is reduced when animals are reared in complete darkness. The localization pattern and the RD of L31Q RHO and T58R RHO mimic the patterns previously seen in T4K RHO and T17M RHO *X. laevis*. However, RD caused by D190G RHO was not alleviated by dark rearing, suggesting that the origin of the sector RP phenotype in D190G RHO patients may be novel.

ABSTRACT BODY:

Purpose: To compare race-related differences in outcomes following pars plana vitrectomy (PPV) for retinal detachment (RD) in the postoperative period between individuals of black and white descent.

Methods: A retrospective cohort study was conducted using TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising multiple large health organizations in the United States. Patients who underwent PPV for RD were identified by CPT code and stratified into black and white cohorts. Cohorts were matched for age, gender, and medical comorbidities (hypertension, diabetes mellitus, cerebrovascular disease, heart failure, nicotine dependence, alcohol related disorders, and body mass index). The primary outcomes were: retinal tear (RT), RD with retinal break, serous RD, epiretinal membrane (ERM), macular edema (ME), cataract, macular hole (MH), macular degeneration, papilledema, retinal vein occlusion (RVO), retinal artery occlusion (RAO), conjunctivitis, dry eye, optic neuritis, other disorders of optic nerve, decompression of the orbit, and endophthalmitis. Outcomes were compared between the cohorts after propensity score matching using logistic regression and greedy nearest-neighbor matching algorithm.

Results: A total of 3,516 patients were included in analysis with 1,758 in each of the black and white cohorts after propensity matching. The white cohort had a significant greater risk of developing RT (RR, 0.47; 95% CI, 0.26-0.85), RD with retinal break (RR, 0.76; 95% CI, 0.7-0.82), serous RD (RR, 0.65; 95% CI, 0.58-0.73), ERM (RR, 0.52; 95% CI, 0.34-0.79), ME (RR, 0.47; 95% CI, 0.28-0.77), and cataract (RR, 0.56; 95% CI, 0.39-0.8) whereas the black cohort had a significant greater risk of developing a MH (RR, 1.74; 95% CI, 1.2-2.53). No significant difference was seen in rate of development of macular degeneration, papilledema, RVO, RAO, conjunctivitis, dry eye, optic neuritis, other disorders of optic nerve, decompression of the orbit, or endophthalmitis between the black and white cohorts.

Conclusions: Race is an important consideration when evaluating for complications following PPV for RD. Whites were more likely to develop RD, ERM, ME, and cataracts whereas blacks were more likely to develop MH. These differences should be considered when evaluating and discussing outcomes with patients both pre and post-operatively.

TITLE: Vitreous hemorrhage and hypotony with dexamethasone intravitreal implant and new injection technique described

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Yu, W K Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|S. Adrean, Retina Consultants of Orange County, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jeffrey Yu: Commercial Relationship: Code N (No Commercial Relationship) | Sean Adrean: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe cases of visually significant vitreous hemorrhage (VH) following dexamethasone (DEX) intravitreal implant in our practice and present two cases which did not clear spontaneously and eventually required surgical intervention, as well as a case of VH and hypotony following DEX implant. We also describe and illustrate a new injection technique in order to minimize incidence of these complications in the future.

Methods: Restrospective case series. In addition, new injection technique is described.

Results: In our practice, the overall incidence of VH was 1.7% (8/467 injections) and those that required surgical intervention was 0.4% (2/467) over a 10 year period, from June 2010 to June 2020. 75% (6/8) VH resolved spontaneously over time, without surgical intervention.

Conclusions: We propose that after the DEX applicator is in the eye, the needle should be pointed up until it is parallel to the IOL. Usually at this point, it can be directly visualized, when standing at the patient's head. The depressor is then slowly depressed and then the DEX implant can be directly visualized slowly entering the eye.

TITLE: Patient profile and outcomes regarding intraocular lens type selection in presbyopic hispanic population

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Hernandez-Delgado, M. Salan-Gomez, S. Garza-Gonzalez, M. Herrera-Rodriguez, S. Guevara-Quintanilla, J. Valdez-Garcia, Instituto Tecnologico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, MEXICO]

Commercial Relationships Disclosure (Abstract): Miguel Hernandez-Delgado: Commercial Relationship: Code N (No Commercial Relationship) | Marcelo Salan-Gomez: Commercial Relationship: Code N (No Commercial Relationship) | Salvador Garza-Gonzalez: Commercial Relationship: Code N (No Commercial Relationship) | Monica Ivonne Herrera-Rodriguez: Commercial Relationship: Code N (No Commercial Relationship) | Sergio Eduardo Guevara-Quintanilla: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Eugenio Valdez-Garcia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the patient's profile regarding intraocular lens (IOL) selection, either multifocal or monofocal. And their differences in age, sex, ocular surgery, IOL power and visual acuities.

Methods: Evaluation of 34 randomly selected presbyopic patients that underwent phaco with intraocular lens (IOL) implantation, 17 with multifocal lens (group 1; G1) and the rest with monofocal lens (group 2; G2) in 2020 at Zambrano Hellion Medical Center, Tecnologico de Monterrey. Patients were evaluated for age, sex, previous ocular or refractive surgery, time from surgery proposal to IOL implantation (TSPTI), time to fellow eye surgery, LogMAR preoperative best uncorrected visual acuity (BUVA) and best corrected visual acuity (BCVA), IOL power, tenth day postoperative visual acuity (VA10), and whether residual ametropia was present.

Results: From the total 34 patients, 52.9% (n= 18) were female and 47.06% (n= 16) male. Mean age at surgery was 62.55 ± 11.04 years, 59.35 ± 8.06 for G1 and 65.76 ± 12.83 for G2 ($p= 0.09$). Of all records, 26.4% (n= 9) had previous ocular surgery, 23.5% in G1 and 29.4% of G2 ($p= 0.70$), but six had previous refractive surgery, 17.6% in G1 and 17.6% in G2 ($p= 1.0$).

TSPTI was 46 median IQR days, 51 days in G1 and 35 days in G2 ($p= 0.18$). Half (n= 17, 64.7% of G1 and 35.29% of G2) of patients had fellow eye surgery in 35 MdnIQR days, 35 days for G1 and 40 days for G2 ($p= 0.51$).

BUVA before surgery was 0.5 MdnIQR with a preoperative BCVA of 0.1 MdnIQR. G1 had better BUVA (0.4, $p= 0.015$) and BCVA (0, $p= 0.0007$) in comparison to G2 BUVA (0.9) and BCVA (0.3).

Mean IOL power was 21.50 ± 4.3 D. IOL power was greater ($p= 0.017$) in G1 (mean SD 22.75 ± 3.6 D) than in G2 (mean SD 19.93 ± 4.6 D).

The sample VA10 was 0 MdnIQR. G1 had better ($p= 0.036$) VA10 (0) compared to G2 (0.2).

Residual ametropia was found in 9 patients, 10.7% in G1 and 26.1% in G2 ($p= 0.15$).

Conclusions: Age, sex and previous surgeries were not significant between groups. G2 had a tendency to have a faster TSPTI, but a slower time to fellow eye surgery. G1 had significantly better BUVA and BCVA preoperatively, as well as better VA10 than G2 with less incidence of residual ametropia, at the expense of greater IOL power requirement. IOL type selection is due to the patients perspective and desire to achieve the best possible visual acuity.

ABSTRACT BODY:

Purpose: The Pentose Phosphate Pathway (PPP), a metabolic offshoot of the glycolytic pathway, is essential for cell survival by providing protective metabolites and molecules. Transketolase (TKT) is the critical enzyme that controls the extent of PPP “traffic flow”. Here, we explored the role of PPP in maintaining the health of human Müller cells.

Methods: Immunofluorescence staining (IF) established that TKT was predominantly expressed by Müller cells in the human retina. We validated TKT expression further in human primary Müller cells (huPMCs) by Western Blot (WB). We inhibited the expression of TKT in huPMCs by small interfering RNA (siRNA) to disrupt PPP. The knockdown efficiency was verified by WB, IF and a TKT activity assay. We then explored the metabolic changes after PPP disruption using 1,2-C¹³ glucose as a tracer. We stressed the huPMCs, with or without TKT knockdown, by exposing the cells to 32k lux white light for 4 hours with 5 lux dim light as control. We evaluated the cell viability by AlamarBlue assay, cell death by LDH assay and metabolic states by ATP, NADPH assays. Finally, we performed a transcriptomic analysis of huPMCs after treatments, followed by protein level validation by WB. We used bioinformatic analysis to reveal the molecular pathways with prominent changes in knockdown and control groups.

Results: The Müller cell was the primary cell type expressing TKT in the retina. huPMCs also expressed TKT. siRNA treatment reduced both protein expression and enzyme activity of TKT. TKT knockdown inhibited de novo synthesis of pyruvate from glucose, while the proportion of consumed glucose that went into TCA cycle increased. The cell viability of huPMC was significantly reduced after TKT knockdown by light stress with no detectable cell death. Likewise, ATP levels and the NADPH/NADP⁺ ratio dropped after photic stress, exacerbated by TKT knockdown. According to Ingenuity Pathway Analysis, the NRF2 pathway was activated after photic stress, while one of the downstream targets, NAD(P)H Quinone Dehydrogenase 1, was reduced by TKT knockdown.

Conclusions: Müller cells express TKT abundantly. Knockdown of TKT not only disrupted the PPP but also impaired overall glucose utilization by Müller cells. Knockdown of TKT made the cells more vulnerable to light stress, possibly by impairing NRF2 anti-oxidative responses.

TITLE: Therapeutic effects of recombinant heparin-binding domain protein in a mouse model of diabetic retinopathy

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. Ji, Y. Su, A. Mackey, Y. Ng, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|Z. Ji, Y. Su, Wuhan University Renmin Hospital, Wuhan, Hubei, CHINA|

Commercial Relationships Disclosure (Abstract): Zhenyu Ji: Commercial Relationship: Code N (No Commercial Relationship) | Yu Su: Commercial Relationship: Code N (No Commercial Relationship) | Ashley Mackey: Commercial Relationship: Code N (No Commercial Relationship) | Yin Shan Eric Ng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is characterized by increased numbers of leukocytes attachment (leukostasis) and vascular hyperpermeability (VP) of the retinal vessels. Previous experimental evidence supports that the heparin-binding VEGF165 isoform, but not the VEGF121 isoform that lacks the heparin-binding domain (HBD), is responsible for inducing retinal leukostasis. Preliminary data showed that the recombinant HBD (rHBD), which likely function as a competitive VEGF165-specific inhibitor for heparan sulfate proteoglycans binding, inhibited VEGF165-induced leukostasis and pathological angiogenesis in an oxygen-induced retinopathy model. Thus, we hypothesize that rHBD also has potential therapeutic effects in a mouse model of DR.

Methods: Streptozotocin (STZ) injection of 6-8 weeks old C57BL/6 male mice were used to induce diabetes (blood sugar levels of at least 250 mg/dL). Retinal VP was measured with the Fluorotron Master Ocular Fluorophotometer (Laboratory Mouse Edition) and retinal leukostasis was quantified by FITC-concanavalin A perfusion assay with retinal flat-mount and fluorescence microscopy. The mice were injected with rHBD (50 pmol) or vehicle control intravitreally 6 months after induction of diabetes. Statistical analysis of data (mean \pm SEM) was performed using t-test and one-way ANOVA.

Results: Retinal VP was significantly increased in diabetic mice compared to non-diabetic mice (29.23 ± 0.90 vs. 17.17 ± 1.06 , $P < 0.0001$). A single intravitreal injection of rHBD significantly reduced retinal VP by about 20% in diabetic mice compared to vehicle injected control (23.78 ± 0.96 vs. 29.41 ± 1.13 , $P < 0.001$). Diabetic mice received vehicle treatment had increased leukostasis compared to non-diabetic mice (9.85 ± 0.74 vs. 3.50 ± 0.31 , $P < 0.0001$), while rHBD injection significantly reduced leukostasis compared to vehicle injected control (3.13 ± 0.38 vs. 9.85 ± 0.74 , $P < 0.0001$), and to the levels comparable to that of the non-diabetic mice.

Conclusions: These data demonstrated that intraocular injection of rHBD significantly suppress retinal vascular hyperpermeability and leukostasis in a mouse model of DR, therefore rHBD could be an efficacious therapeutic for DR.

ABSTRACT BODY:

Purpose: To determine benefit of 5-field (5F) vs 2-field (2F) mydriatic handheld retinal imaging for assessment of diabetic retinopathy (DR) as compared with standard ETDRS 7-field 30⁰ fundus photographs (ETDRS photos).

Methods: Following standard imaging protocol, 5 fields (macula, disc, superior, inferior and nasal) were acquired using 2 handheld retinal cameras [Aurora (AU), Smartscope (SS)] and ETDRS photos following pupil dilation (Figure 1). Images were evaluated at a centralized reading center independently by masked graders (International DR Classification). Simple (K) and weighted (K_w) kappa statistics assessed agreement for DR. Sensitivity and specificity for any DR, referable DR [(refDR) moderate nonproliferative DR (NPDR) or worse, any DME or ungradable images] and vision threatening DR [(vtDR) severe NPDR or worse, clinically significant DME (CSME) or ungradable images] were calculated.

Results: Images from 177 eyes of 92 patients with diabetes were evaluated. By ETDRS photos: No DR 40.1% eyes, mild NPDR 19.2%, moderate 14.7%, severe 10.2%, proliferative DR 15.8%; No DME 72.9% eyes, DME 6.8%, CSME 17.0%; ungradable 3.4%. Ungradable rate for DR: AU, 2F:1.1%, 5F:0%; SS, 2F:5.0%, 5F: 4.5%; and DME: AU:10.2%, SS:13.0%. DR agreement with ETDRS photos are shown in table 1. 5F imaging increased exact agreement w/ ETDRS photos by 32.5% AU and 19.8% SS and w/in 1-step by 8.9% AU, 6.6% SS. 5F imaging increased k agreement w/ ETDRS photos for DR from moderate to substantial for both AU and SS. Reliability indices are shown in table 1. 5F imaging increased sensitivity for any DR, refDR and vtDR on both AU (0.76 to 0.97, 0.78 to 0.88, 0.83 to 0.86) and SS (0.79 to 0.82, 0.79 to 0.87, 0.83 to 0.89).

Conclusions: The peripheral fields obtained using a 5F protocol with 2 handheld retinal cameras substantially increased agreement with ETDRS-determined DR as compared with only posterior 2F imaging. Sensitivity increased while maintaining specificity for identifying refDR and vtDR. The observed DR grading agreement between 5F handheld imaging and ETDRS photos suggests that handheld retinal imaging performed in this manner may be accurate enough for DR screening programs, where their size, cost and ease of use attributes would allow them to be widely deployed in community-based DR screening programs.

Commercial Relationships Disclosure (Abstract): Fei Shang: Commercial Relationship: Code N (No Commercial Relationship) | Jesse Schallek: Commercial Relationship(s);University of Rochester:Code P (Patent);Hoffman-LaRoche:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Alpha smooth muscle actin (α -SMA), a contractile protein, mediates retinal vascular tone and neurovascular coupling. Studies report dense α -SMA surrounding retinal arterioles, but microvessel α -SMA is controversial due to complications of immunohistochemistry (IHC) including antibody penetration and rapid histological degradation. Here we characterize the extent of α -SMA expression in the retinal vasculature using ex vivo and in vivo imaging of transgenic mice.

Methods: We used two transgenic mouse strains (FVB JAX #025406; C57BL/6J #032887) to study the structure of α -SMA fluorescence expression in vessels (mCherry or mVermilion, and GCaMP). Ex vivo, we performed epifluorescence microscopy of flat-mount retinas from mice >10 weeks old (n=7 FVB, n=5 C57). In vivo, we used a custom-build adaptive optics scanning light ophthalmoscope (AOSLO) to capture phase-contrast (796/17 nm) and fluorescence images with safe light levels (GCaMP: Ex 488 nm Em 520/35 nm; mVermilion: Ex 561 nm Em 630/92 nm) (n=3 FVB). We quantified the diameter and branch order of all vessels that could be traced to the optic disc.

Results: Arterioles had strong α -SMA expression that diminished at progressive branch orders. Yet ex vivo retinas showed fluorescence in some of the smallest vessels (3 μ m), suggesting heterogeneous organization. 41% of α -SMA+ vessels were <7 μ m. Both strains had similar expression patterns and we detected α -SMA up to 7th order (5.13 \pm 0.83 μ m; mean \pm SD) (Fig1). Similarly, in vivo imaging showed bright α -SMA in arterioles (visible at 5 μ W) while microvessels required more power (134 μ W). This was likely due to lower volumetric α -SMA. We observed fluorescence up to 5th order (10.54 \pm 2.86 μ m). Simultaneous phase-contrast imaging of the same vessels showed luminal diameter of 3.89 \pm 1.19 μ m necessitating single-file blood flow (Fig2).

Conclusions: Many microvessels that accommodate single-file blood flow were α -SMA+. AOSLO imaging corroborates ex vivo findings and further overcomes histological confounds. This finding suggests microvessels have the potential to regulate hemodynamics at the scale of tens of micrometers. This is noteworthy given the retina's high metabolic demand that may be differential in lateral and laminar organization of neural populations. Ongoing work is examining the contractile calcium response (GCaMP) to determine whether differential control exists at this vascular level.

ABSTRACT BODY:

Purpose: There is little epidemiologic data on exfoliation syndrome (XFS) or exfoliation glaucoma (XFG) in Guatemala, especially in the Baja Verapaz region. XFS is an ocular and systemic proteinaceous disorder that causes abnormal fibrillar extracellular material deposition in the eye, heart, brain, lungs and skin (1,2,3). Solar exposure and outdoor occupation have been linked to XFS development (4). This observational study assessing XFS and demographic factors of this region aims to better understand unique exogenous and endogenous risk factors associated with XFS in Guatemala.

Methods: During Moran Eye Center's global outreach cataract trips in 2016 and 2017, 171 patients were evaluated; 46 XFS and 9 XFG patients over age 49 were identified on site and by chart review (Dr. Orlando Gonzalez, Lions Health Club in Salamá). Age, gender, hometown, ancestry (languages spoken by parents and grandparents), past medical history, family medical history and occupational data were obtained for each patient. Under translated informed consent, blood samples from XFS patients and their family members were collected. This research was conducted under Utah IRB (00081512).

Results: Out of 171 total cataract patients and their cataract-free family relatives, 18 lacked a clear diagnosis of either XFS/XFG or control resulting in 153 viable patients. Of these, 66 were male (43%) and 81 were female (53%) and 6 did not indicate gender. The average age of all patients was 64yrs. Those 55 having XFS and XFG were on average 72yrs. The most common occupations were farming and housekeeping. Higher rates of XFS/XFG were noted in individuals of rural (41%) compared to urban settings (24%). Rates of XFS/XFG in Mayan speaking people were 39% compared with 35% in Spanish speakers. Based on this subset of patients, the prevalence of XFS/XFG appeared to be roughly 35%. Blood analysis is underway.

Conclusions: Although study limitations exist (i.e. small sample size and cataract selection bias), this specific population appears to have a high prevalence of XFS compared with other world populations. Further studies are warranted to better understand possible environmental stressors contributing to XFS. Location, higher altitude, along with a farming occupation may contribute to XFS development and subsequent progression to XFG. To our knowledge, this is the first study looking at the epidemiology of XFS/XFG in Guatemalans.

TITLE: EFFECTS OF DHT AND ESTRADIOL ON ROSIGLITAZONE-INDUCED LIPID PRODUCTION IN IMMORTALISED HUMAN MEIBOMIAN GLAND EPITHELIAL CELLS

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Phan, M.C. Madigan, F. Stapleton, M. Willcox, B. Golebiowski, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Minh Anh Thu Phan: Commercial Relationship: Code N (No Commercial Relationship) | Michele Madigan: Commercial Relationship: Code N (No Commercial Relationship) | Fiona Stapleton: Commercial Relationship: Code N (No Commercial Relationship) | Mark Willcox: Commercial Relationship: Code N (No Commercial Relationship) | Blanka Golebiowski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human meibomian glands and immortalised human meibomian gland epithelial cells (iHMGEc) contain sex hormone receptors and the molecular machinery required for their biosynthesis, suggesting a role of sex hormones in MG biological function. This study aimed to determine the effects of dihydrotestosterone (DHT) and estradiol (E2) on lipid production in iHMGEc cultured in serum-free medium with rosiglitazone (Rosi, a PPAR γ -agonist), a known inducer of iHMGEc differentiation. We also examined the effect of Rosi on iHMGEc viability.

Methods: iHMGEc were cultured to 80% confluence in keratinocyte serum-free medium, then switched for 2-4 days to serum-free media containing various concentrations of DHT, E2, and Rosi, alone and in combination (n=4 wells/each treatment, n=3 experiments/treatment). Cell viability was assessed using the MTT assay. Accumulation of intracellular lipid droplets was quantified using a Nile Red-cell nucleus (DAPI) spectroscopic assay. Differences between treatments were compared using one-way ANOVA with post-hoc comparisons using Tukey's test ($\alpha=0.05$).

Results: DHT (1-100 nM) or E2 (0.1-10 nM) alone did not significantly affect cell viability. However, treatment with Rosi (alone and in combination with DHT and/or E2) significantly decreased iHMGEc viability by up to 50% when used at 50 μ M ($p<0.001$). Lipid accumulation in iHMGEc treated with Rosi (30 μ M) was significantly higher relative to the medium-only control ($p<0.001$), but the addition of DHT (10 nM) and/or E2 (1 nM) had no further significant effect. DHT (10 nM), E2 (1 nM) and DHT+E2 without Rosi did not affect lipid accumulation in iHMGEc cultured in serum-free medium.

Conclusions: The sex hormones DHT and E2 did not induce lipid accumulation in iHMGEc cultured in serum-free medium, nor affect cell viability. In contrast, treatment with Rosi significantly increased lipid accumulation but adversely affected iHMGEc viability when used at the higher concentration (50 μ M). Further investigations are required to better understand the mechanisms of iHMGEc differentiation, cell survival and lipid secretion.

TITLE: Peptide Inhibitors of MARCKS Reverse Endotoxin Induced Uveitis in Rats

SESSION TITLE: Cytokines, growth factors, anti-inflammatory

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T.M. Stonex, B. Salmon, B.C. Gilger, Clinical Sciences, North Carolina State University, Raleigh, North Carolina, UNITED STATES|K. Adler, Molecular Biomedical Sciences, North Carolina State University, Raleigh, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tara Stonex: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Adler: Commercial Relationship(s);Biomarcks, Inc:Code I (Personal Financial Interest) | Beth Salmon: Commercial Relationship: Code N (No Commercial Relationship) | Brian Gilger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Uveitis, the most common form of intraocular inflammation, accounts for 10-15% of preventable blindness in the United States. A potential pathogenic driver (and thus therapeutic target) for uveitis is MARCKS (Myristoylated Alanine Rich C Kinase Substrate) protein. We tested the hypothesis that inhibition of MARCKS, using novel MARCKS inhibitor peptides, would reduce the severity of endotoxin-induced uveitis (EIU) in a rat model.

Methods: EIU was induced in 28 female Lewis rats via subcutaneous administration of 300 µg of lipopolysaccharide (LPS). Three different novel MARCKS inhibitor peptides that mimic the N-terminal region of MARCKS (BIO-11006, or lower molecular weight analogs BIO-91201 or BIO- 91202; Biomarck, Inc., Durham, NC), were administered intravitreally in both eyes at two different concentrations (50µM and 100µM; n=4 rats/treatment group) 4 hours after LPS administration. Phosphate buffered saline (PBS) was injected intravitreally to serve as control (LPS/PBS control group). Ocular inflammation was scored in a blinded manner using slit lamp examinations prior to and following dilation with tropicamide prior to LPS administration, and again at 8, 12, and 24 hours following LPS administration. Optical coherence tomography (OCT) anterior chamber cell counts were done 24 hours after LPS administration. Rats were euthanized 24 hours following EIU induction, aqueous humor collected, and eyes processed for histology.

Results: LPS elicited a significant increase ($p<0.001$) in clinical scores of inflammation at all time points following EIU induction compared to PBS controls. At 12 hours post LPS, the following treatment groups showed significant decreases in clinical scores: BIO-11006 100µM; BIO-91201 50 & 100µM; and BIO-91202 50µM ($p<0.02$). Clinical scores were also significantly decreased at 24 hours post LPS in the following treatment groups: BIO-11006 50 & 100µM; BIO-91201 50 &100µM; and BIO-91202 100µM ($p<0.05$). OCT aqueous humor cell counts were significantly higher ($p<0.001$) in response to LPS at 24 hrs. Each of the peptide treatment groups showed a significant ($p<0.001$) decrease in cell counts at this time point.

Conclusions: MARCKS inhibitor peptides were effective in reducing the clinical severity of ocular inflammation and cellular influx in the EIU rat model of acute uveitis. These results indicate that MARCKS could be an effective therapeutic target to treat uveitis.

TITLE: Corneal nerve-derived calcitonin gene-related peptide (CGRP) attenuates inflammation in chronic dry eye disease

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. zhu, T. Blanco, K. Pang, R. Dana, J. Yin, Department of Ophthalmology, Harvard Medical School, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): shuyan zhu: Commercial Relationship: Code N (No Commercial Relationship) | Tomas Blanco: Commercial Relationship: Code N (No Commercial Relationship) | Kunpeng Pang: Commercial Relationship: Code N (No Commercial Relationship) | Reza Dana: Commercial Relationship: Code N (No Commercial Relationship) | Jia Yin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously demonstrated that chronic dry eye disease (DED) leads to decrease in corneal innervation. Calcitonin gene-related peptide (CGRP) is expressed in trigeminal ganglion (TG) neurons, from which corneal nerves originate, and has anti-inflammatory function. In this study, we aim to investigate the role of TG- and corneal nerve-derived CGRP in chronic DED.

Methods: Chronic DED was induced by placing C57BL/6 mice in a controlled environment chamber for 2 weeks, followed non-desiccating standard vivarium for 4 weeks. Corneal nerve density and CGRP expression in the cornea were determined with immunofluorescence of β -tubulin III and CGRP, respectively. Protein levels of CGRP in the TG and corneas were detected with Western blotting. Topical CGRP was given three times daily 1 week after DED induction and corneal fluorescein staining (CFS) was recorded. Expression of inflammatory cytokines in the TG and frequencies of CD45⁺ leucocytes in the cornea were determined with real-time PCR and flow cytometry, respectively.

Results: In chronic, but not acute, DED, central corneal subbasal nerve density was decreased by 20% (P=0.005) and CGRP expression in the cornea (64% decrease, P=0.002) and TG (50% decrease, P=0.026) were significantly reduced, compared to age-matched control mice. Topical application of CGRP led to a decrease in CFS, compared to albumin-treated control mice (11.4 vs 8.7, P=0.04). CGRP treatment led to lower expression of TNF- α (P= 0.031), IL-1 β (P= 0.017) and IL-6 (P= 0.011) in TG. Frequencies of CD45⁺ cells decreased by 23.7% in CGRP-treated corneas

Conclusions: CGRP expression in the cornea and TG is decreased in chronic, but not acute, DED. Topical application of CGRP alleviates clinical signs of DED and inflammation in the cornea and TG, suggesting a critical role of nerved-derived CGRP in DED and its therapeutic potential

ABSTRACT BODY:

Purpose: The effect of immunosuppression on the development of human embryonic stem cell (hESC) derived retina organoids (ROs) produced by a scalable cGMP compatible process was studied in vitro and after transplantation to the subretinal space of immunocompetent retinal degeneration (RD) rats.

Methods: A Working Cell Bank (WCB) of CSC-14 hESCs (NIH 0284) was established using a scalable cGMP compatible process. ROs differentiated from hESCs were characterized by immunohistochemistry (IHC), flow cytometry, qPCR and a two-way mixed lymphocyte reaction (MLR). Functional and structural imaging of organoids was obtained using fluorescence lifetime imaging microscopy (FLIM) and hyperspectral imaging (HSPEC). Retina organoid sheets were transplanted to the RD hosts and monitored by Optical Coherence Tomography (OCT). Immunosuppressants (20-30mg Tacrolimus [TAC] pellet implant in combination with oral mycophenolate mofetil [MMF]) were applied to the rats. TAC levels in blood were determined by LC-MS. Cytostatic effects on target lymphocyte populations were evaluated by flow cytometry. Visual function was accessed by optokinetic tests and superior colliculus electrophysiology. Sections through transplants were stained with hematoxylin & eosin (H&E) and IHC. The effect of TAC (3 ng/ml) and MPA (0.5 µg/ml) on retinal organoids was tested by FLIM after 1 and 4 weeks exposure.

Results: The WCB of hESCs meets the FDA requirements. In vitro immunogenicity tests showed that ROs are not likely to induce an immune response. IHC of ROs shows early lamination and development of retinal cell progenitors. At 2-3 mo. of differentiation, organoids switched their metabolic status from more glycolytic to more oxidative which remained stable at 4 months. Immunosuppressants TAC and MPA showed no influence on the metabolic activity of retinal organoids after 1 and 4 weeks of exposure. OCT revealed transplant development and photoreceptor rosettes. The transplants developed different retinal cells including photoreceptors; and integrated with the host retina. Therapeutic levels of immunosuppressant remained in the blood and helped transplants survive in the host.

Conclusions: Retina organoids matured and developed photoreceptors in long-term culture and after transplantation. Immunosuppressants did not measurably alter the metabolic status of organoids, and prevented rejection of retinal organoid transplants.

TITLE: The Decline of Ophthalmology in General Medical Education and Strategies to Overcome Barriers to Learning

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Liao, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jennifer Liao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As the U.S. population ages, it is expected that demand for visual care will significantly rise in the next few decades. However, there has been a continuous decline of ophthalmology education in medical school curriculum. This literature review aims to explore research and conceptual pieces on the state of ophthalmology education and investigate potential ways to address current challenges and better prioritize ophthalmology curriculum time in undergraduate and graduate medical education.

Methods: A search was conducted in PubMed and ERIC with the search terms: ((Ophthalmology[Title]) AND (Education[Title])) AND ((Medical student) OR (Resident)). Irrelevant articles and articles published before 2000 were eliminated, yielding 30 final articles.

Results: Five primary themes were identified: challenges to ophthalmological education around the world, potential remedies for optimizing ophthalmology curriculum, competency-based ophthalmology education, utilization of technology in ophthalmology education, and ophthalmology service, ethics, and empathy. Major challenges included the lack of a standardized curriculum and inadequate clinical exposure. A number of remedies were proposed, such as increasing adherence to curriculum guidelines, encouraging relationships between ophthalmology faculty and medical school administration committees, and extending utilization of extracurricular activities. Other recommendations included the incorporation of competency-based education, technology-based curriculum, and self-regulated learning. Programs also explored humanistic aspects of ophthalmology education and its role in expanding underserved care.

Conclusions: In light of challenges in ophthalmology education, ophthalmology programs have increasingly proposed solutions to optimize limited curriculum time. In order to ensure all core competencies are met, there are three major areas to tackle, including: 1) adjusting current curriculum to address learner needs, 2) maximizing learning opportunities by promoting crossover between ophthalmology and other disciplines, and 3) cultivating empathy and service motivation to improve care and increase underserved outreach. Valuable addition to ophthalmology education research would be more qualitative studies engaging the students' and educators' perspectives of ophthalmology curriculum, in order to provide a more holistic view of ophthalmology education.

ABSTRACT BODY:

Purpose: The aim of this study was to determine the willingness of patients to undergo point-of-care diabetic eye screening with primary care providers (PCPs) by means of non-mydriatic fundus photography (nFP).

Methods: An anonymous ten-question survey was mailed out to a random sample of patients overdue for diabetic retinopathy screening examinations. The survey was designed to measure self-reported health status, diabetic and eye-health literacy, perceived barriers to in-person eye examinations, and willingness to undergo nFP. Demographic data was limited to age and gender. Chi-Square Test-Cramer's V, Pearson's correlation coefficients, and linear regression were used in the statistical analyses.

Results: Out of 390 patients surveyed, 62 participants (16%) returned a completed questionnaire by mail. Roughly half of participants were over the age of 65 (56%). Participants generally rated themselves in above-average health (7.0 ± 1.8). The participants' overall rating of health was inversely correlated with concern about losing vision because of diabetes ($F_{4,55} = 2.931$, $p = 0.029$). Ability to drive (79%) was positively associated with the frequency of eye examinations ($F_{3,58} = 6.61$, $p < 0.001$). In contrast, driving had no impact on frequency of seeing PCPs ($p=0.446$ [KMR1]). Despite the survey being sent to patients identified as being overdue for screening examinations for diabetic retinopathy (an average of 731 ± 413 days), more than 90% of participants reported that they obtained eye checkups at least annually despite evidence to the contrary. The most common disincentives reported for obtaining in-person eye examinations were: difficulty in scheduling or inconvenient location (27%); reluctance to have eyes dilated or finding eye examinations uncomfortable (11%); and high out-of-pocket costs (11%). Respondents who cited barriers to obtaining eye examinations were more likely to be interested in nFP compared to those who cited none ($V = 0.360$, $p=0.023$). Patients who stated that they saw their eye doctor frequently were more likely to continue to do so after nFP screening ($V = 0.335$, $p=0.015$).

Conclusions: Diabetic eye screening by means of nFP is likely to be accepted by a majority of patients as a point-of-care test, if offered by PCPs. Patients who experience barriers in accessing traditional in-person eye care services are more likely to favor diabetic eye screening by nFP.

SUBMITTER (NAME ONLY): Sophie Kim

TITLE: Bactericidal effect of povidone-iodine solution and swabs through lidocaine gel

SESSION TITLE: Stem cells / gene therapy/ transplantation/ laser/ local therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Kim, H. Chiang, J. Sohn, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sophie Kim: Commercial Relationship: Code N (No Commercial Relationship) | Homer Chiang: Commercial Relationship: Code N (No Commercial Relationship) | Jeong-Hyeon Sohn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The use of lidocaine gel was reported as a potential independent risk factor in the development of post-intravitreal injection endophthalmitis. Previously, we reported that 10% povidone-iodine (PVI) swabs were able to penetrate lidocaine gel to yield comparable PVI concentration to 5% PVI solution without gel. This follow up study aimed to directly determine the bactericidal effectiveness of various PVI applications by demonstrating growth inhibition of *Staphylococcus epidermidis*.

Methods: Mueller Hinton agar plates were inoculated with *S. epidermidis* (ATCC 12228) from a tryptic soy agar slant. 6mm diameter discs were punched from cellulose filter paper. In the control group, 50 µL of 5% PVI was applied to the discs. 5 variable groups were treated with (1) 3.5% lidocaine gel plus 50 µL 5% PVI, (2) gel with 10% McKesson PVI swab, (3) gel with 10% PDI PVI swab, (4) gel with 5% PVI soaked cotton-tip applicator (CTA), and (5) gel with 10% soaked CTA. An additional plate with a plain disc, disc with lidocaine gel, and PDI PVI 10% swab directly applied served as controls. The discs were placed on the inoculated plates and incubated for 24 hours. Zones of inhibition (ZOI) were measured for each plate.

Results: 10 discs were plated for each group. The gel + 5%, gel + McKesson swab, gel + 5% CTA, and gel + 10% CTA groups yielded smaller ZOIs compared to the control, no gel + 5% (all $p < 0.001$), and to gel + 10% PDI swab (all $p < 0.001$). There was no significant difference between the ZOI of the control versus gel + 10% PDI swab. Both McKesson and PDI swabs yielded a greater ZOI than gel + 5% ($p < 0.001$), however PDI swabs produced a greater ZOI than McKesson swabs ($p = 0.0004$).

Conclusions: The results redemonstrated that the gel barrier significantly decreases the amount of 5% PVI solution in contact with the treated surface. The data suggests that the mechanical force of application with 10% PVI swabs can penetrate the gel barrier with enough PVI to produce a bactericidal effect similar to the control. However, the amount of PVI is dependent on the manufacturer and amount of PVI loaded into the swab.

The main limitation of this study lies in its in vitro nature. Major differences between our model and the human eye may affect interaction with topical PVI. Further investigation with randomized controlled trials are needed to elucidate the relationship between post-injection endophthalmitis and prep method.

ABSTRACT BODY:

Purpose: This study investigates hemiretinal asymmetry in radial peripapillary capillary vessel area density (VAD) of healthy, glaucoma suspect, and primary open angle glaucoma (POAG) eyes of varying severity, and its diagnostic utility, alone and in combination with other ocular parameters, for POAG.

Methods: 6x6-mm optic disc scans were collected on optical coherence tomography angiography to obtain VAD and on OCT to measure circumpapillary retinal nerve fiber layer (RNFL) thickness. Hemiretinal difference in VAD (hdVAD) was defined as the absolute difference between superior and inferior hemiretinal VAD. Age-adjusted multivariable linear regression of hdVAD on POAG severity was performed. Area under curves (AUCs) were calculated from predicted probabilities generated by multiple logistic regression of POAG severity on age-adjusted values of either a single parameter or a combination of parameters. DeLong's test was used to determine the statistical significance of differences in AUCs from various models, thus identifying parameters with the greatest diagnostic accuracy.

Results: 1069 eyes of 1069 participants (602 healthy, 275 glaucoma suspect, and 192 POAG classified into 70 mild, 56 moderate, and 66 severe POAG) were included. After adjusting for age, mean hdVAD was similar between healthy and suspect ($\beta = 0.002$, $P = 0.253$), higher in mild versus suspect ($\beta = 0.013$, $P < 0.001$), higher in moderate versus mild ($\beta = 0.010$, $P = 0.009$), but lower in severe versus moderate ($\beta = -0.012$, $P = 0.001$). AUCs of hdVAD were qualitatively highest for mild (0.674) and moderate (0.685) POAG (versus 0.515 for suspect, 0.602 for severe POAG, 0.655 for any POAG). A combination of hdVAD and global RNFL (gRNFL) had the highest AUC of all parameters for mild (0.809) and any POAG (0.851), which were greater than AUCs of either hdVAD ($P < 0.001$ for both comparisons) or gRNFL ($P = 0.041$ for mild, $P = 0.048$ for any POAG) alone.

Conclusions: hdVAD is higher in early POAG and may help with early detection when damage is focal, but its diagnostic ability appears to be less robust in advanced POAG when damage is diffuse. Combination of hdVAD and gRNFL yielded the best diagnostic accuracy of all parameter permutations for mild and any POAG, suggesting the potential of hdVAD to supplement gRNFL and other ocular parameters in the diagnosis of early POAG.

SUBMITTER (NAME ONLY): Soraiya Thura

TITLE: Risk of posterior subcapsular cataract development among uveitis patients treated with topical difluprednate

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Thura, P. Janardhana, Ophthalmology, University of Massachusetts Medical School, Worcester, Massachusetts, UNITED STATES|S. Thura, P. Janardhana, Ophthalmology, UMass Memorial Medical Center, Worcester, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Soraiya Thura: Commercial Relationship: Code N (No Commercial Relationship) | Priya Janardhana: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We sought to investigate the risk of posterior subcapsular cataract development amongst patients treated for uveitis with 0.05% topical difluprednate.

Methods: This is a retrospective cohort study assessing patients with uveitis who were treated with topical difluprednate from January 1st, 2016 through October 30th, 2020 at an academic medical center. Thirty patients (forty eyes) were evaluated through a chart review to collect clinical data which was then analyzed. Patients that received cataract surgery before being treated with difluprednate for uveitis were excluded.

Results: Twelve eyes (30%) were observed to have had development or progression of PSC. For the eyes that developed a PSC, both the duration (mean of 17.3 weeks versus 13.7 weeks) and total cumulative dose (mean of 334 drops versus 271.6 drops) of topical difluprednate were higher compared to patients who did not develop a PSC. The average time to development of a PSC noted on eye exam after the initiation of difluprednate was 12.9 months. Nine eyes (30%) were noted to have ocular hypertension at some point during the follow-up period, and all of these eyes were controlled with pressure-lowering drops. The current data collection and analysis will continue to include information on confounding variables such as additional topical and oral steroid use, posterior sub-tenon kenalog injections, presence of active uveitis, as well as a stratification of daily drop use and duration of treatment.

Conclusions: In our cohort of uveitis patients, we have found that an increased duration and cumulative dosing of difluprednate treatment is associated with an increased risk of posterior subcapsular cataract formation. Based on our current collected data, we predict that this finding will be significant when controlling for other variables associated with formation of PSC. This is one of only a few studies that have assessed the impact of topical difluprednate on cataract formation in an adult uveitic population. We believe this study will provide further clinical insight into the safety profile and dosing of difluprednate, as well as contribute to our knowledge of topical steroid treatment regimens for patients with uveitis.

TITLE: Influence of anesthesia and electrode type on dual-eye mouse electroretinogram

SESSION TITLE: Electrophysiology: Advances, disease and injury

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. RAJA, W. Jiang, M. Cameron, School of Medicine, Western Sydney University, Penrith South, New South Wales, AUSTRALIA]

Commercial Relationships Disclosure (Abstract): Sushmitha RAJA: Commercial Relationship: Code N (No Commercial Relationship) | Wilson Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Morven Cameron: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A combination of ketamine and xylazine has been used as the choice of anesthetic to record electroretinogram (ERG) in rodents, however, an increase in the sudden death of animals has been reported in recent years. Replacing xylazine with medetomidine, an $\alpha 2$ agonist reports higher survival rates and isoflurane has also been shown to be a suitable alternative, with a much lower mortality rate. In this study, we aimed to assess the suitability of ketamine/medetomidine and isoflurane on mouse ERG. Furthermore, we aimed to determine the best electrode type to minimize crosstalk while recording from both eyes simultaneously. A new conductive material "StaticotTM" (polyester/cotton blended with 8 μ m stainless steel fibers) was trialed as an ERG electrode and compared to highly conductive platinum electrodes.

Methods: ERGs were recorded from mice anaesthetised with either ketamine (72 mg/kg)/ medetomidine (0.5 mg/kg) or 1.75% isoflurane. Both males and females were used with ages ranging between 12-18 weeks. Electrodes (platinum, staticotTM) were embedded in contact lenses and placed on both eyes simultaneously. Dark- and light-adapted ERG responses to a range of light stimuli were recorded.

Results: No differences were observed in either a-wave amplitude or implicit time but ketamine/medetomidine injected animals displayed a reduction in b-wave amplitude and a large increase in b-wave implicit time in comparison with the isoflurane cohort in dark and light-adapted ERGs. Overall, isoflurane ERG parameters were more similar to published values for the ketamine/xylazine than ketamine/medetomidine suggesting that medetomidine significantly suppresses second/third order processing. Recovery from ketamine/medetomidine was longer, even following $\alpha 2$ antagonist reversal (atipamezole 1 mg/kg), and the mortality rate was 37.5% (n=8). The isoflurane cohort showed rapid recovery and no mortality (n=9). Recordings conducted using platinum electrodes showed some cross-communication between the electrodes in the dual-eye ERG, while no such crosstalk was observed with staticot electrodes.

Conclusions: Isoflurane is a viable alternative to the traditional ketamine/xylazine combination and displays rapid recovery and enhanced survival of animals. Staticot conductive fiber is a suitable and cost-effective replacement of traditional electrodes for dual-eye ERG recordings.

TITLE: Clinical validation of Age-Related Macular Degeneration remote monitoring device

SESSION TITLE: AMD: Clinical and translational research I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Yim, L. Azzouz, A. Yu, University of Michigan Medical School, Ann Arbor, Michigan, UNITED STATES|Y.M. Paulus, Ophthalmology, W K Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Angela Yim: Commercial Relationship: Code N (No Commercial Relationship) | Lina Azzouz: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Yu: Commercial Relationship: Code N (No Commercial Relationship) | Yannis Paulus: Commercial Relationship(s);University of Michigan:Code P (Patent)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of irreversible blindness in industrialized countries. While treatments are available, prompt identification of conversion to wet AMD is necessary for optimal patient outcomes. A digital, handheld standalone device using shape discrimination hyperacuity to identify a patient's minimum distortion-detection threshold has been described. This study performs a clinical validation of that device.

Methods: Using a prototype device (KaIEYEdoscope) with an injection-molded 3D printed shell, two tactile buttons, a battery, a processing unit (Raspberry Pi 3), and a 1.5 inch RGB OLED screen, a clinical validation was conducted on 15 patients after approval of the University of Michigan IRB. Patients were presented with a series of circle-like images and, after each image, asked whether the image previously displayed was a perfect circle. The duration of the test and responses to a post-test questionnaire were recorded.

Results: All patients were able to complete the test (n=15, 100%). The total duration of the test took a mean of 70 seconds (standard deviation 9.1 seconds), with a range from 32 seconds to 2 minutes and 23 seconds. Compared to other home monitoring products, ForeseeHome and myVisionTrack (mVT), this device reduced test time by 67% on average. On a Likert scale from 1 to 5 with 1 being the easiest and 5 the hardest, patients rated the test as a mean of 1.545 in difficulty. All 15 patients found the device comfortable to hold for the duration of the test (100%). The device was devised to accommodate refractive errors from +5 D to -10 D and accommodated 100% of the evaluated patients, whom had refractive errors ranging from +1.25 D to -7.0 D.

Conclusions: This clinical validation demonstrates that a digital, handheld standalone device using shape discrimination hyperacuity to identify a patient's minimum distortion-detection threshold can provide a rapid, easy, comfortable testing solution for a range of patients. Further validation and trials are necessary to demonstrate that this device results in improved outcomes of patients with AMD.

TITLE: Changes in Refractive Components After a Short Exposure to Astigmatic Blurs in Young Adults

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Chan, J. Leung, H. Shik, W. Kwok, C. Kee, School of Optometry, The Hong Kong Polytechnic University, Kowloon, HONG KONG

Commercial Relationships Disclosure (Abstract): Kin Ho Chan: Commercial Relationship: Code N (No Commercial Relationship) | Jeffery Tsz-wing Leung: Commercial Relationship: Code N (No Commercial Relationship) | Ho Tin Shik: Commercial Relationship: Code N (No Commercial Relationship) | William Kwan Kwok: Commercial Relationship: Code N (No Commercial Relationship) | Chea-Su Kee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Astigmatism is a very common refractive error in Native American and Asian Chinese. Recent studies have reported the effects of optically imposed astigmatism on ocular parameters in humans and chickens. This study investigated the effect of astigmatism on refractive changes in young Chinese adults.

Methods: Nineteen non-/ low-myopic young adults (age: 18-24 years; spherical-equivalent error: 0DS to -5.00DS, cylindrical error ≤ 0.75 DC) with unremarkable ocular health were recruited. Participants wore a trial frame to watch a movie for 60 minutes, with one eye chosen randomly as the treated eye and the fellow eye served as control. In three separate visits, while the control eye was fully corrected optically, the treated eye was exposed to one of three defocused conditions in random sequence :

1. Myopic defocus (SPH): +3.00 DS
2. With-The-Rule (WTR) astigmatism: +3.00 DC x 180°
3. Against-The-Rule (ATR) astigmatism: +3.00 DC x 90°

Before and after watching the movie, spectacle over-refractions were measured by a Shin Nippon open-field autorefractor.

Results: A significant interaction effect (treatment*time) was found for the interocular difference in J0 astigmatic component ($p < 0.001$): the interocular difference significantly reduced in magnitude for both the WTR condition (Change: -0.25 ± 0.10 D, $p = 0.022$) and the ATR condition (Change: $+0.39 \pm 0.15$ D, $p = 0.017$), suggesting an active refractive compensation to reduce the difference in the perceived astigmatic blur between fellow eyes. However, the change was not significant in the SPH condition ($p = 0.129$). There was also no such effect in the J45 astigmatic component, spherical-equivalent error, and other biometric parameters (all $p > 0.372$).

Conclusions: Optically imposed astigmatic blur for an hour led to bi-directional changes in the astigmatic component, suggesting that young adults are susceptible to refractive changes in response to orientation-dependent astigmatic blur.

ABSTRACT BODY:

Purpose: Use of optical coherence tomography (OCT) in optometry and ophthalmology clinics has improved screening for potential retinal diseases and leads to increased retina clinic referrals and patient travel burden. We evaluated the impact of a pilot tele-OCT program offering remote, asynchronous retina specialist consultation on reducing in-person retina clinic visits and on patient adherence to the recommended follow-up plan.

Methods: We performed a retrospective cohort study of all tele-OCT consults originating from optometry and non-retinal ophthalmology clinics in the Greater Los Angeles Veterans Health Administration from January to December 2019. A retina specialist evaluated tele-OCT consults within three days of each consult and recommended patient-specific follow-up plans, including necessity of in-person retina specialist evaluation. Data on patient demographics, consult notes, and eye care visits were collected from electronic medical records. Patient adherence to the follow-up plan, defined as following up at the recommended clinic within twice the recommended time interval, was calculated. Logistic regression analyses were performed to identify factors associated with patient adherence to the follow-up plan.

Results: In 2019, 158 tele-OCT consults were conducted, of which 44.3% of patients were white, 34.8% were Black, and 10.1% were Hispanic/Latino; 97.5% were male; and mean (SD) age was 70.6 (11.3) years. The most common retinal diagnoses were age-related macular degeneration (n=43, 27.2%) and diabetic retinopathy (n=30, 19.0%). After tele-OCT consultation, 113 (71.5%) patients were recommended continued monitoring in their originating eye clinic, 27 (17.1%) were referred to intravitreal injection clinic, 12 (7.6%) to in-person retina clinic, and 6 (3.8%) to another location. Patient adherence to tele-OCT follow-up plans was 76.4%. Compared to non-adherent patients, patients adherent to follow-up plans were more likely to have ocular symptoms (e.g. decreased central vision, metamorphopsia, or scotoma) (OR 3.53, 95% CI 1.57-7.94, p=0.002) or an intravitreal injection clinic referral (OR 4.61, 95% CI 1.04-20.46, p=0.043).

Conclusions: A tele-OCT program improved clinic efficiency when implemented in a large multidisciplinary eye care practice. Having ocular symptoms or requiring treatment led to patient adherence to tele-OCT follow-up plans.

ABSTRACT BODY:

Purpose: The use of deep learning in surgical training is promising but applications in ophthalmology are scant. The purpose of this study was to train a deep neural network to recognize cataract surgical steps, including routine and complex steps such as use of trypan blue or iris expansion devices.

Methods: We collected 268 resident cataract surgical videos routinely recorded during the residency training of 12 surgeons across 6 sites. Videos were downsampled and cropped to 256x256 at 1 frame/second. Trained annotators labeled 13 steps of surgery: create wound, injection into the eye, capsulorrhexis, hydrodissection, phacoemulsification, irrigation/aspiration, place lens, remove viscoelastic, close wound, stain with trypan blue, manipulating iris (e.g. malyugin ring/iris hooks), subconjunctival/SubTenon's injections, and other (e.g. anterior vitrectomy, placement of capsular support devices). A deep learning model based on the VGG16 architecture was customized and trained to predict the class probabilities that each frame depicted. The model was evaluated on a held-out test set using frame-by-frame top-N accuracy, defined as the proportion of frames where the true class was among the highest N predicted class probabilities. Per-class and micro-averaged area under receiver-operating and precision-recall curves (AUROC, AUPRC) were determined. To evaluate which frame areas were most important for model predictions, class activation maps were visualized using gradient-weighted class activation mapping.

Results: Overall top-1 prediction accuracy was 77.4% (93.2% for top-3 accuracy). The overall AUROC was 0.97 and the AUPRC was 0.85. Evaluation of class activation maps revealed the model was appropriately focused on the instrumentation used in each step to predict. Challenges remain in prediction of rare steps or steps with diverse appearances, including subconjunctival/subTenon's injections, iris manipulation, anterior vitrectomy, for which prediction had poor recall.

Conclusions: Deep learning models can classify cataract surgical activities on a frame-by-frame basis with remarkably high accuracy, especially routine surgical steps. An automated system for recognition of cataract surgical steps could have broad applications, including providing automated feedback metrics to residents on their surgical videos.

ABSTRACT BODY:

Purpose: To contribute to the WHO initiative, VISION 2020: The Right to Sight, we report extensively updated estimates of global vision loss burden due to cataract presenting estimates for 2020, including changes over time.

Methods: Population-based surveys of eye disease from January, 1980, to October, 2018 were collated by the Vision Loss Expert Group of the Global Burden of Disease Study in the Global Vision Database. We fitted hierarchical models to estimate age-standardised prevalence (with 95% uncertainty intervals [UIs]) of moderate and severe vision impairment (MSVI; presenting visual acuity from <6/18 (20/60) to 3/60 (10/200)) and blindness (<3/60 (10/200) and/or less than 10° visual field around central fixation) caused by cataract by age, global region, and year. Data sparsity at younger ages required the analysis focused on adults aged ≥50 years.

Results: In 2020, worldwide an estimated 15.2 million (12.7-17.9) people aged 50+ years were blind, and a further 78.8 million (67.2-91.4) had MSVI, due to cataract. There had been an increase of 29.7% in cases of cataract blindness and 93.1% in cases of MSVI since 2000. Over the same period, age-standardised prevalence of cataract blindness decreased by 27.5% and MSVI increased by 7.2%. Between 2000 and 2020, the age-standardised prevalence of cataract blindness in males decreased to a greater extent than in females (-31.8% vs -24.8%); similarly the increase in cataract MSVI was less for males (+4.7%) than females (+8.9%). Among GBD super-regions, South Asia had the highest cataract blindness and MSVI burden in 2020 (blind: 2.23%; 1.89-2.61, MSVI: 9.46%; 8.11-10.93). The most profound reductions in cataract blindness rates between 2000 and 2020 occurred in Southeast Asia, East Asia and Oceania (-43.0%), North Africa and Middle East (-40.0%), and South Asia (-36.5%).

Conclusions: The World Health Assembly Global Action Plan target of a 25% reduction from 2010 to 2019 in avoidable vision impairment (WHA 66.3 24/5/2013) was met for cataract blindness but not for MSVI. However,

decreases in prevalence were more than offset by global population growth and aging, leaving more people cataract blind and visually impaired than ever before. Globally, immense increases in resource mobilization for treating cataract are required.

TITLE: Using directional OCT to analyze photoreceptor visibility over AMD-related drusen

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Murrell, B. Marsh-Armstrong, D. Valente, R.S. Jonnal, Ophthalmology, University of California Davis, Sacramento, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kelly Murrell: Commercial Relationship: Code N (No Commercial Relationship) | Brennan Marsh-Armstrong: Commercial Relationship: Code N (No Commercial Relationship) | Denise Valente: Commercial Relationship: Code N (No Commercial Relationship) | Ravi Jonnal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dysfunction in AMD is mostly a result of photoreceptor loss. Many clinical and adaptive optics optical coherence tomography (AO-OCT) investigators report reduced cone photoreceptors visibility over associated drusen. Two possibilities explanations are angular disorientation and cell structure disorganization. Our study uses directional OCT to measure contribution of these two factors, potentially guiding future research into early AMD.

Methods:

Three AMD subjects were recruited and dilated. Large drusen were identified using OCT images. The imaging beam was positioned at a series of horizontally displaced locations in the pupil, all imaging the same retinal location. 1200 B-scans of drusen and healthy adjacent retina were acquired at each pupil location. The apparent tissue slope indicates illumination angle. Between 20-50 cross-correlated B-scans were registered and averaged, producing one composite B-scan per subject, per retinal position. In each B-scan, abnormal and apparently-healthy tissues were delineated. Next, the inner-segment-outer-segment junction (ISOS) bands were segmented using a semi-automated procedure, resulting in a trace through both tissue types. Their reflectance and slope were computed at each A-scan in each B-scan. Separately for data from healthy and drusen-affected parts of ISOS segmentation, the relationship between slope and intensity was fit with a three-parameter (directionality, non-directional component B, directional component A) Gaussian equation to quantify angle-dependent and independent components of ISOS reflectance. Healthy and drusen-affected retina were compared for each.

Results: Between healthy and drusen-affected retina, large differences were found in parameters ($p=0.011$) and B ($p=0.004$), and small differences found in A ($p=0.130$). Values were lower in drusen-affected areas of retina than healthy for each.

Conclusions: Reduction in fitted values of A and B values in drusen-affected tissue indicates gross attenuation of ISOS backscattered light. Reduction in indicates a widening of the acceptance angle of drusen-affected cones, suggesting changes in diameter and/or refractive indices of inner segment. Reduced reflectance and directionality of the inner-segment may underlie the low visibility of cones in adaptive optics imaging.

ABSTRACT BODY:

Purpose: Labelling cells with magnetic nanoparticles (MNPs) has gained increasing interest due to their wide biological and medical applications. Magnetic forces used to control MNPs can thereby target or even manipulate specific cell types or organelles during drug delivery, cell imaging and cell tracking. The primary uptake pathway of MNPs is endocytosis, which leads to extracellular excretion or lysosomal degradation, preventing the targeted localization to cytosol and other organelles. Here we explore methods to bypass endocytosis and thereby enhance organelle targeting.

Methods: We generated MNPs conjugated with Alexa Fluor 647 enclosed in cell-membrane-fusogenic liposomes was labeled with lipophilic dye 1,1'-dioctadecyl-3,3,3',3'-tetramethylindocarbocyanine perchlorate (DiI) in the lipid leaflets. Lipid-to-MNP ratio was varied to generate optimal liposome-MNPs based on transmission electron microscope (TEM), dynamic light scattering and zeta potential analysis. The delivery efficiency of liposome-MNPs into the cells was confirmed by Prussian blue staining. The fraction of free MNPs was identified at different time points after delivery of liposome-MNPs to the retinal pigment epithelial ARPE-19. Targeting to endosomes and lysosomes was assessed using CellLight reagents targeting Rab5a and Lamp1, respectively, as well as TEM imaging. A focal magnetic field was applied to assess the movement of intracellular MNPs.

Results: TEM showed liposome coating core-shell structure compared to bare MNPs when the initial lipid-to-MNP ratio increased. Highest MNP delivery efficiency into ARPE-19 cells was observed when the initial ratio of lipid:MNP (w/w) was 1:1. The amount of free MNPs peaked at 70% 24 hours after application of liposome-coated MNPs, indicating separation of MNPs from liposomal coatings. Whereas MNP uptake resulted in endocytosis, confocal microscopy revealed early endosome-localized MNPs from liposome-coated MNPs decreased from 14.4% right after administration to 6.9% after 4 hours, and 6.2% after 24 hours, demonstrating escape from endocytosis. TEM results verified cytosolic and lysosomal location of liposome-coated MNPs. Local magnetic force generated from an electromagnetic probe demonstrated corresponding movement of intracellular MNPs.

Conclusions: This novel fusogenic liposome-MNP delivery can bypass endocytosis to achieve efficient delivery of MNPs to the cytosol, allowing for external control by focal magnetic fields.

ABSTRACT BODY:

Purpose: The transient or persistent disturbance of blood flow is one of several clinical findings of vascular lesions and exacerbate neuronal impairment in diabetic retinopathy (DR). Optical coherence tomography angiography (OCTA) allows us to quantify vascular density or vascular density length, which are modestly associated with DR severity. In this study, we characterized the intercapillary spaces on OCTA images and investigated their clinical significance in DR.

Methods: In this retrospective study, we reviewed 88 eyes of 76 patients with treatment-naïve DR, for whom 3x3 mm OCTA images centered on the macula were acquired using PLEX Elite 9000 (Carl Zeiss Meditec). The superficial slab images with a 2-mm diameter were prepared and processed by binarization. The intercapillary spaces were automatically detected and quantified using 'Analyze Particles' function in ImageJ (NIH, Bethesda, MD). The number of intercapillary spaces was applied to receiver operating characteristics (ROC) curve analyses to discriminate DR from nondiabetic subjects.

Results: The intercapillary spaces were detected in the superficial capillary layer, although they were rarely found in the deep layer. The numbers of intercapillary spaces were 540 ± 117 , 421 ± 162 , 365 ± 145 , 256 ± 162 , 283 ± 109 , and 236 ± 154 in nondiabetic subjects, no apparent retinopathy (of diabetic patients), mild nonproliferative diabetic retinopathy (NPDR), moderate NPDR, severe NPDR, and proliferative diabetic retinopathy (PDR). The numbers of intercapillary spaces were greater in nondiabetic subjects than those in diabetic eyes ($P < 0.001$). Eyes with DR had more spaces than those with no apparent retinopathy ($P = 0.001$). The area under ROC curve (AROC) was better for discriminating diabetic eyes from nondiabetic subjects (AROC = 0.895) than that for discriminating no apparent retinopathy from DR (AROC = 0.771).

Conclusions: The numbers of intercapillary spaces decreased according to the DR severity. The ROC analyses suggested that the number of intercapillary spaces in the macula has a diagnostic significance in diabetic eyes.

ABSTRACT BODY:

Purpose: The Utah Project on Exfoliation Syndrome (UPXFS) was created to investigate the association between systemic disorders and exfoliation syndrome (XFS). Given the data suggesting an association between non-melanoma skin cancer (NMSC), i.e. basal and squamous cell cancer (cancers most often located in areas of sun exposure) and XFS based on the ocular UV exposure hypothesis, a retrospective cohort study was conducted to evaluate the relationship between NMSC and XFS.

Methods: NMSC and malignant melanoma diagnoses (based on ICD-O-3 and ICD-9/10 codes) were obtained from the Utah Cancer Registry (UCR) and University of Utah Healthcare (UUHC) patient records from 1966-2016 and linked to individuals in the Utah Population Database (UPDB) with XFS and without XFS. The occurrence of a melanoma or basal/squamous cell skin cancer diagnosis was estimated in 2,659 XFS patients compared with randomly selected 13,294 participants without XFS in the population matched 1:5 on sex and birth year using a logistic regression model accounting for sex and age from individual matching and adjusting for race and ethnicity.

Results: Among the 2,659 XFS cases, the mean age of XFS diagnosis was 74 years, and 67% were women. Of the 2,659 XFS patients and the 13,294 individuals without XFS, 227 patients (8.5%) and 829 (6.2%) without XFS were diagnosed with basal or squamous cell skin cancer respectively. Compared with those without XFS, in those with XFS, there was an approximate 1.5-fold increased risk of basal or squamous cell skin cancers (odds ratio of 1.46, 95% confidence interval: 1.25-1.71; $p < 0.0001$). We observed no association between XFS and malignant melanoma.

Conclusions: XFS is a systemic disorder related to elastosis, and this data suggests that individuals with XFS may have an increased risk of a NMSC history. These data are consistent with the findings from another study that reported an association between those with NMSC and incident XFS⁷. We hypothesize based on these findings that an underlying pathogenesis of NMSC and XFS may stem from a common triggering event – ultraviolet exposure.

ABSTRACT BODY:

Purpose: Management of neovascular age-related macular degeneration (nAMD) has evolved over the last decade with several treatment regimens and different medications. This study describes the treatment patterns and visual outcomes over ten years in a large cohort of patients.

Methods: This was a retrospective analysis of electronic health records from 27 National Health Service (NHS) secondary care healthcare providers in the UK. Treatment-naïve patients receiving at least three intravitreal anti-vascular endothelial growth factor (VEGF) injections for nAMD in their first six months of follow-up were included in the study. Patients with missing data for age or gender and those aged less than 55 were excluded. Eyes with at least three years of follow-up were grouped by years of treatment initiation, and three-year outcomes were compared between the groups. Data were generated during routine clinical care between 09/2008 and 12/2018. Main outcome measures included visual acuity (VA), number of injections, and number of visits.

Results: A total of 15,843 eyes of 13,734 patients receiving 195,238 injections were included. VA improved from baseline during the first year, but dropped thereafter, resulting in loss of visual gains. This trend remained consistent throughout the past decade. Although an increasing proportion of eyes remained in the driving standard, this was driven by better presenting visual acuities over the decade. The number of injections dropped substantially between the first and subsequent years, from a mean of 6.25 in year 1 to 3 in year 2 and 2.5 in year 3, without improvement over the decade. In a multivariable regression analysis, final VA improved by 0.24 letters for each year since 2008, and younger age and baseline VA were significantly associated with VA at three years.

Conclusions: Our findings show that despite improvement in functional VA over the years, primarily driven by improving baseline VA, patients continue to lose vision after the first year of treatment, with only marginal change over the past decade. The data suggest that these results may be related to suboptimal treatment patterns, which have not improved over the years. Rethinking treatment strategies may be warranted, possibly on a national level or through the introduction of longer-acting therapies.

ABSTRACT BODY:

Purpose: One of the most important clinical data points in evaluating ophthalmology patients is visual acuity (VA). During the COVID-19 pandemic, eye health providers are utilizing telehealth to decrease patient and provider risk related to in-person clinic visits, while still providing high-quality care. This study sought to compare at-home VA tests with in-office clinical VA measurements to determine the validity of at-home VA testing for telehealth visits.

Methods: Patients from 1 comprehensive and 3 subspecialty ophthalmology clinics had VA greater than or equal to 20/200 in the study eye. The patients were prospectively randomized to perform 2 of 3 at-home VA tests (printed chart – University of Arizona/Banner Eye Care Letter Distance Chart; mobile phone app – VeranaTM Vision Test; website test – Farsight.care) within 3 days of their standard of care clinic visit. Patients also completed a survey to assess usability of home tests. At the clinic visit, best corrected Snellen distance acuity was measured to serve as the reference standard.

Results: Of the 44 patients (84 eyes) enrolled, 60% were female and the mean age was 66 years (range 22 to 80). The mean difference between printed chart and Snellen, website test and Snellen, and mobile app and Snellen acuity data was 0.10 (95% CI: 0.09-0.11), 0.13 (95% CI: 0.12-0.14), and 0.12 (95% CI: 0.11-0.13) LogMAR, respectively. The highest degree of correlation was between the website and Snellen tests (0.74, 95% CI: 0.59-0.84) (Table 1).

Patients found the tests easy to perform at home and were neutral regarding confidence in their results and desire to continue with home testing. In the survey, there was no significant difference for between the 3 tests regarding any of the 4 questions ($P = 0.32-0.62$), although there was a trend toward a more positive response with the printed chart (Table 2).

Conclusions: These data suggest that some at-home visual acuity tests are comparable in accuracy to in-clinic Snellen visual acuity tests (within 1 line of difference). Patient surveys indicated the tests were easy to understand and complete at home. Further development and validation of at-home vision testing modalities are needed to provide accurate and accessible tele-ophthalmology care.

ABSTRACT BODY:

Purpose: Inherited retinal disorders (IRDs) are rare intractable diseases, and the access to specialists is difficult world widely. The purpose of this study is to investigate the utility of a data-driven deep learning approach in patients with IRDs, to predict the causative genes based on fundus photography and fundus autofluorescence (FAF) imaging.

Methods: Clinical and genetic data from 156 Japanese subjects with IRDs or no ocular diseases registered to the database of the Japan Eye Genetics Consortium were reviewed. Three categories of genetic diagnosis were selected, based on the highest prevalence of their causative genes: Stargardt disease (ABCA4), retinitis pigmentosa (EYS), and occult macular dystrophy (RP1L1). Fundus photographs and FAF images were cropped in a standardised manner with a macro algorithm. Algorithms for pipeline analyses, based on TensorFlow Inception V-3 were determined with learning parameters (provided by Medic Mind). Images for learning/testing were selected with a randomised 4-fold cross-validation method. The application program interface was established to reach the learning accuracy of concordance (aimed >80%) between the genetic diagnosis and the machine diagnosis (ABCA4, EYS, RP1L1, and normal).

Results: A total of 417 images were examined. The mean overall test accuracy for fundus photographs and FAF images was 88.2% (range, 81.5%-94.4%) and 81.3% (range, 73.5%-87.8%), respectively. The mean overall sensitivity/specificity for fundus photographs and FAF images were 88.3%/97.4% and 81.8%/95.5%, respectively. The mean test sensitivity/specificity per gene category for fundus photographs and FAF images was 88.2%/100% and 97.5%/94.8% for ABCA4-retinopathy, 88.4%/98.1% and 70.7%/99.2% for EYS-retinopathy, 94.4%/92.9% and 64.9%/96.3% for RP1L1-retinopathy, and 82.9%/96.7% and 92.9%/96.3% for normal.

Conclusions: A novel application of deep neural networks in the prediction of the causative gene in IRD from fundus photographs and FAF was highlighted, with a high prediction accuracy of over 80%. These achievements will extensively promote the quality of medical care by facilitating early diagnosis, reducing the cost for referrals, and

allowing unnecessary clinical and genetic testing to be avoided.

ABSTRACT BODY:

Purpose: Colloidal inorganic nanocrystals have great potential as photosensitive biointerfaces that might be used as retinal stimulation devices. We introduced the aluminum antimonide nanocrystals (AISb NCs) as a cell interfacing layer for light-induced capacitive neural stimulation in the blue spectrum.

Methods: A four-layer photovoltaic biointerface was fabricated by sequential planar deposition of indium tin oxide (ITO), zinc oxide (ZnO), organic poly(3-hexylthiophene) (P3HT) and AISb NCs that is excitable under 445 nm blue LED illumination. Biocompatibility tests were performed in vitro on rat primary hippocampal neurons (PHN) and in vivo by subretinal implantation of the biointerface into adult rat eyes. In vitro electrophysiology for AISb NCs based photostimulation of PHN were measured by whole cell patch clamp method.

Results: The AISb NCs based biointerface generated a photovoltage increase from 52 to 98 mV.cm⁻² with a rise time of ~55 µs upon stimulation. MTT viability assay showed no significant decrease in PHN metabolic activity (P>.05). No increase of TUNEL-positive cells was observed in biointerface implanted retinas when compared with sham group (P>.05). The biointerface effectively induced action potential in PHN with >90% success rate when stimulated by LED illumination frequencies up to 10 Hz under ocular safety limits.

Conclusions: The AISb NCs based biointerfaces hold high promise for future bioelectronics. With their high performance and biocompatibility, AISb nanocrystals prove to be applicable candidates for nanoengineered prostheses to rescue vision.

ABSTRACT BODY:

Purpose: Accurately predicting a patient's risk of progressing to late age-related macular degeneration (AMD) is crucial for personalized medicine. We conduct deep learning survival analyses to predict AMD progression and to identify which sets of features, derived from Age-Related Eye Disease Study (AREDS) fundus photographs, are key predictors. While existing algorithms consider data from the present visit only, we evaluate how adding data from prior visits improves predictive performance.

Methods: The dataset comprised 3,768 AREDS participants without late AMD in either eye by year 3. Four survival models were trained and evaluated (Figure 1) to predict progression to late AMD at year 5 (2-year risk) and year 8 (5-year risk), based on data from year 3 only (Model 1) or years 0, 2, and 3 (Models 2-4). Models 1 and 2 were Cox proportional-hazard models (CoxPH). Models 3 used a deep neural network by concatenating visit information using a multilayer perceptron (MLP). Model 4 used a deep neural network to model the time-dependencies of visits using Long-Short-Term Memory (LSTM). Models were trained and evaluated using (a) drusen size and pigmentary abnormalities (i.e., akin to the 5-step AREDS Simplified Severity Scale, the clinical standard), or (b) drusen size, RPE depigmentation, retinal detachments, hemorrhages, and fibrosis, and geographic atrophy (Figure 2).

Results: Figure 2 conveys the results using the two sets of risk factors. We observe that: 1) using deep learning to model the time-dependencies (LSTM) of feature set b outperformed all other models (AUC@2year: 0.918, AUC@5year: 0.930, c-index: 0.902) (Figure 2b); 2) incorporating data from prior visits improved predictive performance (up to 2% in AUC@2year, 1% in AUC@5year, 1% in c-index); 3) using feature set b improved performance over using drusen/pigment only (up to 6% in AUC@2year, 4% in AUC@5year, 3% in c-index), suggesting that the 5-step AREDS Simplified Severity Scale overlooks useful risk factors.

Conclusions: Existing algorithms for predicting progression to late AMD consider data from one time-point only. We demonstrate that incorporating AREDS grading features from previous years in a deep learning framework provides more accurate predictions than the existing clinical standards and basic survival models.

ABSTRACT BODY:

Purpose: There are several cone-dominated dystrophies (CDD) that show normal funduscopy appearance; however, the prevalence of each causative gene and the phenotypic overlap caused by each gene within the CDD are still uncertain. We illustrate the clinical/genetic spectrum of CDD with normal funduscopy appearance (CDD-NF) in a nationwide cohort.

Methods: 1302 patients with available genotype-phenotype correlation analysis results registered to the Japan Eye Genetic Consortium database were surveyed. Patients were classified into one of the three disease categories based on the electrophysiological findings: occult macular dysfunction syndrome (OMDS: confined macular dysfunction, including hereditary occult macular dystrophy (OMD) and occult maculopathy), cone (-rod) dystrophy with normal funduscopy appearance (CORD-NF: progressive generalized cone (-rod) dysfunction), and cone dysfunction syndrome (CDS: non-progressive generalized cone dysfunction). The clinical parameters were compared among the three disease categories, and the overlap of causative genes was investigated in genes identified in multiple families.

Results: 192 patients from 150 families with CDD-NF were recruited, including 76 families with OMDS, 43 families with CORD-NF, and 31 families with CDS. The median age of onset was 30.0 years for OMD, 30.0 years for CORD-NF, and 0.0 years for CDS, respectively. The median LogMAR visual acuity (VA) was 0.52 for OMD, 0.70 for CORD-NF, and 0.80 for CDS, respectively. The causative genes were RP1L1, GUCY2D, and CRX for OMD, POC1B,

GUCY2D, CRX, PDE6C, and CRB1 for CORD-NF, and CNGA3, PDE6C, GNAT2, KCNV2, and RGS9BP for CDS. Out of eight genes identified in multiple families, four genes were found only in a single disease category: RP1L1 (OMD; Miyake disease), CNGA3 (CDS), GNAT2 (CDS), and KCNV2 (CDS); while four genes overlapped the disease categories; POC1B, PDE6C, GUCY2D, and CRX.

Conclusions: The clinical spectrum of CDD-NF was first identified in a large well-characterized cohort: OMD with later-onset and moderate VA decrease, CORD-NF with later-onset and severe VA impairment, and CDS with early-onset and more severe VA decline. The heterogeneous genetic background of CDD-NF was revealed; meanwhile distinct genotype-phenotype relations such as RP1L1-OMD, CNGA3-CDS, and GNAT2-CDS were confirmed.

ABSTRACT BODY:

Purpose: To evaluate the prospective association of circulating metabolites with incidence of diabetic retinopathy (DR) in two Asian cohorts who are at high-risk for diabetes.

Methods: We included 424 Malay and 515 Indian adults with diabetes but were free of DR at baseline who participated in the baseline (2004-2009, aged 40-80 years) and the 6-year follow-up visits (2011-2017) of two population-based cohort studies: the Singapore Malay Eye Study and the Singapore Indian Eye Study. Serum metabolites at baseline (n=225) were quantified using high-throughput nuclear magnetic resonance profiling. DR was assessed from retinal photographs and graded using the Early Treatment Diabetic Retinopathy Study (ETDRS) severity scale. Based on the worse eye score, we defined incident any-DR as ETDRS ≥ 20 , moderate/above DR as ETDRS > 43 and vision-threatening DR (VTDR) as the presence of severe nonproliferative or proliferative DR, or clinically significant macular edema (CSME). Associations between each metabolite (per SD increase) and outcomes were evaluated using logistic regression models adjusting for age, systolic blood pressure, duration of diabetes, HbA1c and follow-up period in each cohort followed by random-effects meta-analysis corrected for multiple testing.

Results: Incidence of any-DR, moderate/above DR and VTDR in Malays were: 13.7%, 6.2% and 3.7%. Corresponding estimates in Indians were 18.3%, 7.7% and 4.2%. After Bonferroni correction, higher levels of four high-density lipoprotein (HDL) metabolites (free cholesterol and total cholesterol in large HDL, phospholipids in very large HDL and concentration of very large HDL particles) were protectively associated with any DR ($p \leq 0.0042$); tyrosine, an aromatic aminoacid showed an inverse association while 3-hydroxy butyrate (ketone body) showed a positive association with moderate/above DR ($p \leq 0.0125$); aminoacid, histidine showed an inverse association with VTDR in the meta-analysis.

Conclusions: We found higher levels of HDL-related metabolites, tyrosine and histidine to be associated with reduced risk of DR while 3-hydroxy butyrate to be associated with increased risk of DR implying the involvement of HDL, aminoacid and ketone metabolism in the pathogenesis of DR.

ABSTRACT BODY:

Purpose: To assess the safety and efficacy of a novel flavonoid (TTF)- based eye drops formulation for retinal degeneration treatment.

Methods: Eye cups of 21 day-old RPE65/rd12 mice were incubated in media supplemented with 8nM TTF or the same volume of vehicle solution for 18 hours. Sections were stained with antibodies directed against cone opsins and counter-stained with DAPI. The number of positively stained cells/mm retina was recorded. Rabbits were treated with TTF eye drops and TTF concentration in anterior chamber tap removed at 5, 45, and 180 minutes was determined by HPLC to determine corneal permeability. RPE65/rd12 mice were treated twice daily, 6 days/week, for 12 weeks with eye drops containing either TTF (12.5mg/ml, n=16) or vehicle (n=16). RPE /retina flat mounts were stained with Iba-I to assess microglial activation and retinal sections were stained with TUNEL to assess treatment effect on photoreceptor apoptosis. Retinal function was determined by electroretinogram (ERG).

Results: Supplementation of 8nM TTF rescued cones photoreceptors from degeneration in the eye cups cultures in vitro. TTF penetrated the corneal barrier in rabbit eyes. The maximal concentration of TTF in anterior chamber taps was 1.7 μ M, 45 minutes following eye drops instillation. Three-week treatment with TTF eye drops significantly reduced microglial activation and migration into the sub retina compared to vehicle (mean \pm SD: 42 \pm 14 microglia cells/retina vs. 143 \pm 28 microglia cells/retina, p=0.0063). The number of TUNEL positive cells in the photoreceptor layer was significantly lower in treated mice compared with control (mean \pm SE: 2 \pm 0.4 apoptotic cells/mm retina vs. 6 \pm 0.8 apoptotic cells/mm, p=0.0013). A significantly higher scotopic ERG a-wave was recorded in treated mice 3 weeks following treatment initiation (p=0.005).

Conclusions: TTF eye drops may present a novel simple treatment for retinal degeneration, reducing microglial activation and inflammation, preventing photoreceptor cell death, and preserving retinal function in a mouse model of RP. No side effects were observed following 12 weeks of daily treatment with the TTF eye drops, supporting the potential feasibility for clinical application as a treatment for incurable blinding diseases.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa 11 (RP11) is an inherited degenerative retinal disease caused by heterozygous mutations in pre-mRNA processing factor 31 (PRPF31) for which there is currently no effective treatment available. RP11 features incomplete penetrance within affected families; the level of PRPF31 expression from the healthy allele determines whether mutation carriers develop symptoms. The CCR4-NOT transcription complex subunit 3 (CNOT3) is a major disease modifier that regulates PRPF31 levels via transcription inhibition. Higher CNOT3 levels are observed in RP11 cases. In this study, we aim to lower CNOT3 expression and function to indirectly upregulate functional PRPF31 from the healthy allele and rescue RP11 disease phenotypes.

Methods: Seventy-four antisense oligomers (ASO) were designed to target exonic splice enhancers to mediate exclusion of selected CNOT3 exons to (i) induce translational frameshift and mRNA decay or (ii) produce truncated low/non-functional CNOT3 isoform(s). PRPF31 expression and function were assessed in RP11 iPSC-derived retinal pigment epithelial (RPE) cells.

Results: We observed an inverse correlation between CNOT3 and PRPF31 mRNA levels in healthy fibroblasts (n=20). In iPSC-RPE cells, we found 10% higher expression of CNOT3 with 17% lower PRPF31 expression in a patient compared to an asymptomatic relative, both carrying a PRPF31 c.1205 C>A nonsense mutation. Fewer and shorter primary cilia were observed in the symptomatic patient RPE compared to asymptomatic, healthy RPE. Lowering CNOT3 levels and function with ASOs demonstrated a 1.7-fold increase in PRPF31 expression in patient RPE and significantly improved cilia number and length. Healthy cilia play an integral role in phagocytosis and are crucial for normal retinal function.

Conclusions: Subtle changes in CNOT3 and PRPF31 levels in retinal cells determine disease penetrance in PRPF31 mutation carriers within an affected family. Modulating expression levels of these proteins can reverse the cellular disease phenotype in RP11. ASOs are effective modulators of CNOT3 expression and function with the ability to increase PRPF31 transcription from the unaffected allele to an expected therapeutic level. Future studies will assess the restoration of transcriptional profiles linked to improved PRPF31 levels in patient derived iPSC-retinal organoids and RPE compared to healthy controls.

ABSTRACT BODY:

Purpose: Antimicrobial resistance (AMR) globally threatens the treatment outcomes of patients with any medical condition. AMR surveillance programs have been recommended by the World Health Organisation (WHO) to support disease prevention and control strategies. A bacterial ocular surveillance program (BOSS) was initiated in Sydney, Australia in 2016. We aimed to report the spectrum and AMR of bacteria isolated from corneal scrapings in bacterial keratitis in 2017 from different areas of the Sydney metropolitan area.

Methods: A retrospective analysis of bacteria isolated from corneal scrapings from patients with bacterial keratitis from four centers across Sydney, New South Wales, Australia, from January 1 to December 31, 2017 was conducted. Sydney Eye and Prince of Wales Hospitals are in the east side of the city, and Westmead and Liverpool Hospitals in the west side. All specimens were processed at NSW Health Pathology. Antimicrobial resistance data were available for specimens from the eastern hospitals.

Results: There were 288 episodes of clinical bacterial keratitis. Of these, 161 inoculated plates isolated 189 organisms (positive culture rate of 56%). There were 127 (67%) Gram-positive organisms and 62 (33%) Gram-negative organisms. Most of the episodes (n = 155, 82%) presented to the eastern hospitals.

Coagulase-negative staphylococci (CoNS) 37% (70/189), *Staphylococcus aureus* 12% (23/189), including four methicillin-resistant (MRSA), and *Pseudomonas aeruginosa* 18% (34/189) were the most common organisms. AMR was found for: CoNS to cefalotin 18%, chloramphenicol 15%, gentamicin 9%, and ciprofloxacin 3%; methicillin-sensitive *Staphylococcus aureus* (MSSA) to chloramphenicol 8%; MRSA to ciprofloxacin 75% and gentamicin 25%; and *Corynebacterium* spp. to chloramphenicol 40%, and ciprofloxacin 40%. All Gram-positive organisms were susceptible to vancomycin. *Pseudomonas aeruginosa* isolates were susceptible to ciprofloxacin, gentamicin, and tobramycin

Conclusions: CoNS were the most commonly culprit of bacterial keratitis and of these, about one-fifth were resistant to cefalotin, a common antibiotic used to initially treat bacterial keratitis. Most MRSA were resistant to ciprofloxacin. Although the BOSS was established in Sydney, a wider system should be implemented across Australia for providing more comprehensive data from different geographic areas to inform both clinical decision-making and empiric treatment strategies

ABSTRACT BODY:

Purpose: Plus disease denotes a severe vascular abnormality in cases of ROP, which may portend to requiring treatment to prevent blindness but its assessment is subjective. Bringing in Artificial Intelligence (AI) automation can not only improve diagnostic consistencies but can also help scale up ROP screening services to remote and underserved regions of the world. We developed and assessed the performance of an AI algorithm to automatically detect the presence of Plus disease in retinal images of premature babies.

Methods: We trained a deep learning (DL) algorithm with 42,641 disc and macula centered images from a tele-ROP screening program in India. The model was trained to indicate the presence of Plus in the images. Since the dataset contained 0.5% of Plus images, it was trained using metric learning, a technique improving DL performance under datasets with strong class imbalance. Pre-Plus images were not presented to the AI during training. The algorithm was tested on two distinct datasets. Test set A consists of 10,976 images, with 169 pre-plus, 70 plus images and rest no plus images. Test set B consists of 108 images, with 39 pre-Plus, 45 Plus images and rest no plus images. The reference standard for training and test sets was the interpretation of ROP specialists.

Results: The sensitivity on test set A was 95.7% (95% CI: 88.0% to 99.1%), with 3 Plus images being misclassified. Specificity with pre-plus as non-referable was 99.6% (95% CI: 99.4% to 99.7%), and 99.9% (95% CI: 99.8% to 100%) if pre-plus images were excluded. The sensitivity on test set B was 97.8% (95% CI: 88.2% to 99.9%) with one Plus image being misclassified. The specificity was 68.3% (95% CI: 55.3% to 79.4%) with pre-plus, and 100% (95% CI: 85.8% to 100%) without.

Conclusions: The DL tool for ROP Plus detection has excellent sensitivity in picking up Plus disease and thus can potentially be used as a triaging tool for infants with ROP requiring immediate treatment. A prospective clinical validation in a real-world setting is under consideration.

ABSTRACT BODY:

Purpose: Decorin (Dcn) is a dermatan sulfate proteoglycan which belongs to the small leucine-rich proteoglycan family and plays critical roles in controlling extracellular matrix assembly homeostasis. This is highly upregulated in mouse and rat posterior capsular opacification (PCO) tissues after extracapsular lens extraction surgery. Herein, we aim to explore the biological role of decorin in the development or prevention of PCO in mice lenses overexpressing human DCN (hDCN).

Methods: All animal and recombinant DNA experiments were approved by the Kanazawa Medical University Ethics Committee. We generated lens-specific hDCN-transgenic mice (hDCN-Tg) using a plasmid in which Pax6-human alpha crystallin (P6a) composite promoter drives hDCN cDNA. Histological analysis of postnatal day (PD) 2, 8 and 48 weeks-old hDCN-Tg and wild type (WT) mice were performed by using Hematoxylin & Eosin (H&E) staining. Expression of DCN in hDCN-Tg on PD2 was confirmed by histochemical staining for lacZ with 5-Bromo-4-chloro-3-indolyl- β -D-galactoside (X-gal) and immunostaining using anti-Dcn Ab. The lens injury model as mouse PCO model was generated in 14 weeks-old hDCN-Tg and WT mice. The histological patterns were evaluated by H&E staining and immunohistochemical analysis using anti- α smooth muscle actin (α SMA) antibody.

Results: X-gal was stained in cytoplasm of lens epithelial cells (LECs) at equatorial to bow region and primary lens fiber from PD2 hDCN-Tg mice. hDCN protein was expressed in LECs and surface fibers in lens sections from PD2-hDCN-Tg. However, X-gal staining and DCN expression was not observed in lens from PD2-WT mice. In histological observation of eye lens in PD2, adult 8 and 48 weeks-old hDCN-Tg, morphological changes were not observed compared to wild type as control. Importantly, overexpression of DCN inhibited fibroblastic EMT changes and α SMA expression observed in mouse wound healing of lens surface in hDCN-Tg.

Conclusions: Our findings reveal that enhanced expression of DCN play a role in preventing EMT of LECs and has potential beneficial effect in the intervention of PCO progression.

ABSTRACT BODY:

Purpose: RPGRIP1 encodes a ciliary protein expressed in photoreceptor cilia. It contains a C-terminal RPGR interacting domain and two C2 domains, which are known to be involved in signal transduction or membrane trafficking. Mutations in this gene are known to cause ~5% of Leber congenital amaurosis (LCA) worldwide, but are also associated with cone-rod dystrophy (CRD) and retinitis pigmentosa (RP) phenotypes. Our purpose was to clinically characterize RPGRIP1 patients in the Israeli and Palestinian populations, perform an extensive literature search to collect clinical data of additional RPGRIP1 patients. From this combined data set we attempted to identify common clinical features and sought genotype-phenotype correlations.

Methods: Clinical data from 16 patients from our cohort and 175 RPGRIP1 patients previously reported by other groups was collected including (when available) family history, best corrected visual acuity (BCVA), refraction, full ocular examination, ocular coherence tomography (OCT) imaging, visual fields (VF) and full-field electroretinography (ffERG).

Results: Out of 191 patients, the majority (158, 83%) were diagnosed with LCA, 9% with CRD, and 8% with RP. Age of onset in all patients for whom this data was reported was during childhood (n=121), all had moderate myopia (n=49, Mean of -4.8D), and average BCVA was 0.06 Snellen (n=116; only 10 patients had VA>0.1). On funduscopy, narrowing of blood vessels was noted early in life. Most patients had mild bone spicule-like pigmentation starting in the midperiphery and later encroaching upon the posterior pole. OCT shows thinning of the ONL, while cystoid changes and edema are relatively rare. VF are usually very constricted from early-on. FFERG responses were non-detectable in the vast majority of cases. Most of the mutations are predicted to be null (297 alleles) and 85 alleles harbored missense mutations. Missense mutations were identified only in two regions: the RPGR interacting domain and the C2 domains. Patients with 2 missense mutations tended to show a milder course of disease (CRD/RP and not LCA).

Conclusions: RPGRIP1 usually causes severe retinal degeneration at an early age, with rapid disease progression. Most patients manifest a LCA phenotype. Missense changes in the conserved domains are usually associated with a less severe disease phenotype (CRD/RP) than null-predicted mutations.

ABSTRACT BODY:

Purpose: The aim of the study was to evaluate the endogenous antioxidant defense system in human induced pluripotent stem cell (hiPSC)-derived retinal pigment epithelium (RPE) cells.

Methods: hiPSC-RPE cells were differentiated according to the manufacturer's instructions for different times in vitro (days in vitro, DIV) on Matrigel[®]-coated 96-well cell culture plates. Oxidative stress was applied using different concentrations of tert-butyl hydroperoxide (tBHP) for 22 h. Resistance of hiPSC-RPE cells to oxidative stress was measured using the general cell viability assays, resazurin assay and lactate dehydrogenase (LDH) release assay. In addition, production of reactive oxygen species (ROS) in cells was quantified using the ROS indicator, chloromethyl 2',7'-dichlorodihydrofluorescein diacetate (CM-H₂DCFDA).

Results: Cell viability as assessed by resazurin assay was similar from DIV13 to DIV19 with IC₅₀ values for tBHP of approx. 0.4 mM. IC₅₀ values started to shift significantly on DIV26 and DIV28, increasing to 0.7 - 0.9 mM. LDH release and CM-H₂DCFDA assays confirmed the shift of IC₅₀ value with concomitantly increased levels of LDH release and ROS generation.

Conclusions: hiPSC-RPE cells have a strong endogenous antioxidant defense system, as evident by strong cellular resistance to exogenous oxidative stress insult. Maturation periods longer than 26 days induce sudden, increased resistance against exogenous oxidative stress in hiPSC-RPE cells. Our results necessitate careful and precise characterization of individual hiPSC-RPE cell pools, as rapid changes in the endogenous antioxidant defense pose a significant confounding factor in experimental designs that utilize hiPSC-RPE cells for drug discovery.

Commercial Relationships Disclosure (Abstract): Jos Rozema: Commercial Relationship: Code N (No Commercial Relationship) | Gareth Hastings: Commercial Relationship: Code N (No Commercial Relationship) | Jason Marsack: Commercial Relationship: Code N (No Commercial Relationship) | Raymond Applegate: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is notoriously difficult to determine optimal refractive corrections for keratoconus patients. To investigate the underlying reasons, we compared how visual image quality, in the form of Visual Strehl (VSX), changes over a range of spherocylindrical spectacle and scleral lens corrections in eye models with and without keratoconus.

Methods: Starting from the previously published SyntEyes models, the ocular biometry sets of 20 healthy and 20 keratoconic eyes were generated, including corneal tomography and all intraocular structures. Using Matlab, these eyes underwent simulated spherocylindrical spectacle or scleral lens correction, followed by ray tracing to determine the residual wavefront aberrations, which were used to calculate VSX to assess resulting visual image quality. For each eye, refractive corrections were applied over the entire range of the phoropter, referred to as 'correction space'; an area of 'optimal correction' (i.e. maximized VSX) is called a 'focus'. To speed up calculations, a smart scanning algorithm was used, consisting of three consecutive scans over increasingly finer grids, considering only those points neighboring a previously calculated point with a VSX above 0.01.

Results: In all 20 healthy eyes the VSX pattern in correction space resembled an hourglass for both the spectacle and scleral lens corrections, with a distinct focus at the narrowest point and a quick drop in VSX away from the focus (Figure). For 18/20 keratoconic eyes the VSX pattern of spectacle corrections resembled a shell. In 9/20 of these cases two foci could be distinguished, separated by a large mean dioptric distance ($13.3 \pm 4.9D$) and a mean orientation difference of $96.4 \pm 32.1^\circ$. In keratoconic eyes scleral lenses always produced an hourglass pattern with a single focus with a VSX lower than in healthy eyes.

Conclusions: Based on the hourglass pattern found in healthy eyes, it is easily understood how the refracting process automatically funnels practitioners towards the optimal correction. The shell pattern of the spectacle correction in keratoconus, on the other hand, presents a far more complex shape with multiple foci. Hence, depending on the starting point, refracting procedures can often lead away from the optimal correction.

ABSTRACT BODY:

Purpose: In vivo confocal microscopy (IVCM) is non-invasive, reproducible, and inexpensive diagnostic tool for corneal diseases, which also helps to detect neurological and metabolic diseases. However widespread and effortless image acquisition with IVCM creates also a serious workload of image processing and analysis for clinicians. Deep learning algorithms are possible solutions for this heavy workload. In our study, we have produced a novel deep learning algorithm based on generative adversarial network (GAN) and we compare its accuracy for automatically segmentation of subbasal nerve plexus in IVCM images with ophthalmology experts and a convolutional neural network(U-Net) based method.

Methods: We have collected IVCM images from various patient groups and anonymized patient information for segmentation procedures. Three graders, U-Net based conventional algorithm and our GAN-based nerve segmentation system traced nerve plexus for each IVCM images. Results for GAN and U-Net based nerve segmentation methods in IVCM images compared with the graders and analyzed with Pearson's r correlation, Bland-Altman analysis, and receiver operating characteristics (ROC) curves. Lastly, different types of noises applied on IVCM images and segmentation performance of GAN-based and U-Net based methods observed under these different noise types.

Results: The GAN-based algorithm demonstrated similar correlation and Bland-Altman analysis results compared to U-Net-based algorithm. When ROC curves applied to both methods, the GAN-based segmentation method showed significantly higher sensitivity and higher specificity compared to U-Net based algorithm for corneal nerve segmentation in IVCM images ($p<.001$). Lastly, the performance of the U-Net-based algorithm deteriorates significantly with real world noise simulation, especially in speckle type noise, compared to GAN-based algorithm ($p<.001$).

Conclusions: This study is the first study for application of GAN-based algorithms on IVCM images. The GAN-based algorithm demonstrated higher accuracy compared to the experts and the U-Net based algorithm for corneal nerve segmentation in IVCM images. The GAN-based algorithm is more reliable than the U-Net based method in IVCM images with different types of noise. In the near future, the GAN-based segmentation method could be used as a facilitative diagnostic tool in ophthalmology clinics.

ABSTRACT BODY:

Purpose: To investigate the effect of blue light (BL) exposure on nucleotide-binding oligomerization domain 2 (NOD2) expression on the mouse ocular surface and to evaluate the role of NOD2 signaling in BL-induced cell death.

Methods: Wild or NOD2 knock-out (KO) C57BL/6 mice were exposed to BL (410nm) twice a day for 10 days at an energy capacity of 100 J/cm² and divided into the WT+BL and NOD2-KO+BL groups. Mice in the WT and NOD2-KO groups were not exposed to BL and served as control. Corneal fluorescein staining scores were measured after 10 days of BL stimulation. 2'7'-dichlorofluorescein diacetate for reactive oxygen species (ROS), enzyme-linked immunosorbent assay for malondialdehyde (MDA), and terminal deoxynucleotidyl transferase-mediated dUTP-nick end labeling for apoptosis were performed 10 days after exposure to BL. In addition, expression of NOD2, ATG16L1, LC3-||, and p62 were evaluated using Western blot.

Results: After exposure to BL, increased ROS and MDA were observed in the WT+BL and NOD2-KO+BL groups, and the WT+BL group showed a higher expression of NOD2 and ATG16L. Mice in the WT+BL and NOD2-KO+BL groups showed a significant increase in the expression of LC3-|| and p62, whereas the NOD2-KO+BL mice had lower LC3-|| expression and higher p62 expression compared to WT+BL mice. In addition, NOD2-KO+BL mice had significantly lower corneal epithelial damage and apoptosis than WT+BL mice.

Conclusions: BL exposure can induce impaired autophagy by activation of NOD2 on the ocular surface. In addition, the ROS-NOD2-ATG16L signaling pathway may be involved in the BL-induced autophagy responses, resulting in corneal epithelial apoptosis.

ABSTRACT BODY:

Purpose: Detecting and grading abnormal retinal development has important diagnostic and prognostic implications in children. The foveal hypoplasia (FH) grading system is based on the stage at which retinal development ceases, and can be described as grade 1 to 4 FH and atypical FH. Correctly identifying the degree of arrested retinal development requires an understanding of the retinal developmental sequence and thus can be challenging for the non-expert. We therefore proposed the development of the first artificial intelligence (AI) based system to accurately identify and grade FH using optical coherence tomography (OCT).

Methods: A representative sample (n=5078) of paediatric OCT scans demonstrating varying degrees of arrested retinal development (normal, grade 1-4 FH and atypical FH) were obtained from the Leicester paediatric OCT database. Foveal scans were acquired from table mounted OCT (n=3037) (Copernicus, Optopol Technology S.A., Poland) and handheld OCT (n=2041) (Envisu 2300; Leica Microsystems, Germany) devices to ensure a high-performing, device agnostic system. The foveal B-scans were extracted, annotated, and segmented. A high-yield training dataset (n=3555) was inputted through a customised convolutional neural network (CNN) (Resnet50) for the training stage. Following the training and fine-tuning of the customised Resnet50, a validation stage to test the accuracy of the model was implemented. The foveal scans in this stage were new and unseen scans to the CNN.

Results: Our binary classification (normal and abnormal foveal morphology) and six-point classification (normal, grade 1-4 FH and atypical FH) achieved 98.1% and 95.0% validation accuracy, respectively.

Conclusions: We have demonstrated, for the first time, the proof-of-concept for the use of a device agnostic, automated AI system in paediatric OCT interpretation. Our system can help to eliminate inter-examiner variability and augment the clinical pathway by increasing time efficiency during busy clinics. The introduction of OCT to routine clinical assessment is imminent. Therefore, our AI system provides a strong foundation for the development of a real-time, frontline diagnostic tool for retinal developmental disorders.

ABSTRACT BODY:

Purpose: To compare the therapeutic effects of 0.1% cyclosporin A cationic emulsion (CsA CE) with that of 0.05% CsA emulsion for ocular surface damage and inflammation in murine dry eye (DE) with different severity.

Methods: After exposure to desiccating stress and subcutaneous injection of scopolamine for 5 days, C57BL/6 female mice were divided into the severe dry eye (SDE) and non-severe dry eye (NSDE) groups based on corneal fluorescein staining scores (CFS). Mice from both groups were topically treated with 0.05% CsA emulsion or 0.1% CsA CE for 10 days. Tear volume, tear film break-up time, and CFS were measured at 5 and 10 days. Western blot for NF- κ B, multiplex immunobead assay for inflammatory cytokines, flow cytometry for CD4+ T cells, histology for goblet cell density, and TUNEL staining for apoptosis were performed at 10 days.

Results: 0.1% CsA CE-treated mice in the SDE and NSDE groups showed a significant improvement in all clinical parameters. Furthermore, in the SDE group, CFS in 0.1% CsA CE-treated mice was lower than that in 0.05% CsA-treated mice at 10 days. In the SDE and NSDE groups, remarkably improved expression of NF- κ B, levels of TNF- α , IL-6, and IL-17, percentage of CD4+ IFN- γ + and CD4+ IL-17+ T cells, density of goblet cells, and number of apoptotic cells on the ocular surface were observed. Specifically, in the SDE group, 0.1% CsA CE-treated mice had significantly decreased NF- κ B activation, inflammatory infiltrations, and apoptosis on the ocular surface and increased conjunctival goblet cell density compared to 0.05% CsA-treated mice.

Conclusions: 0.1% CsA CE was more effective than topical 0.05% CsA emulsion in improving corneal epithelial injury and decreasing inflammatory cytokines and T cells in SDE.

ABSTRACT BODY:

Purpose: Mucous membrane pemphigoid (OcMMP) is an immunobullous disease characterised by a progressive conjunctival fibrosis driven by inflammation. In over 50% of cases, disease progresses in the absence of clinically visible inflammation. The purpose of this study was to analyse tear washings to identify components of inflammation and fibrosis that could be used as putative biomarkers of disease activity and response to therapy.

Methods: Tear washings were obtained by applying 100µL 0.9% NaCl onto the ocular surface and aspirating with a lacrimal canula from 21 OcMMP patients (42 eyes; mean age 74.6(±8.9 SD) years, 14(66%) female, 17(81%) biopsy-positive) and 15 age-matched cataract patient controls(30 eyes; age 72.3(±10.9) years, 8(53%) female). Total protein content (DC Protein Assay (BioRad, USA)) was used to correct for the variation in sample volume. Matrix metalloproteinases (MMP) 8 and 9, myeloperoxidase (MPO), epithelial growth factor (EGF), interleukin (IL)-1β, 6, 8, 10, 13 and TNF-α were quantified with a Luminex Assay (Thermo Fisher Scientific, USA). Total aldehyde dehydrogenase (ALDH) activity was measured using BioVision PicoProbe™ ALDH assay. Statistical analyses were performed using GraphPad Prism 8 (Mann Whitney U non-parametric test).

Results: Based upon the cicatrising conjunctivitis assessment tool (CCAT[®] Score) the majority of OcMMP eyes had none/minimal inflammation (mean score 0.79±1.58SD) at the time of sampling and 29(69.0%) had >50% symblepharon. MMP8, MPO and IL-6 were significantly elevated whereas EGF was significantly lower in OcMMP versus controls (p=0.025, p=0.010, p=<0.001 and p=0.001 respectively, Figure 1). There was no significant difference in the other measured cytokines. Mean ALDH activity was higher in OcMMP eyes (0.4 vs 0.05 mAU/mg, p=0.025, Figure 2).

Conclusions: Despite the absence of clinically visible conjunctival inflammation significant differences in tear film MMP8, MPO, IL-6, EGF and ALDH expression were observed in OcMMP eyes compared to controls. MMP8 and MPO are primarily produced by neutrophils and macrophages. IL-6 is a pro-inflammatory cytokine playing a role in chronic inflammation. ALDH has been linked to progressive conjunctival fibrosis in OcMMP. Taken together, these data could represent a pharmacodynamic biomarker panel for OcMMP to enable measurement of treatment response to novel therapies, and as predictors of disease progression in quiescent eyes.

ABSTRACT BODY:

Purpose: Prominin 1 is a transmembrane domain glycoprotein, ubiquitously expressed in plasma membranes, namely at the protrusion of rod and cone outer segments of the retina. While dominant variants usually take a milder, slowly progressive course, recessive variants are associated with early-onset and progressive retinal degeneration. We performed a retrospective chart review of patients with pathogenic PROM1-variants to improve our understanding of this rare disease and to report two novel mutations.

Methods: Records of 208 patients with inherited retinal disease (IRD) seen at the West Virginia University Eye Institute who had genetic testing between March 2015 and December 2020 were reviewed. We retrieved 6 patients with pathogenic PROM1 variants. Their clinical findings, retinal images, and electrodiagnostic tests were reviewed.

Results: Pathogenic PROM1 variants were found in 6 patients (2.9%) of the genotyped IRD patients.

1. A father and 2 sons were identified with AD variant c.1117C>T. The Ganzfeld ERG was decreased in the father.
2. Two affected siblings diagnosed with cone rod dystrophy harbored two new novel PROM1 heterozygous variants: 1) c.1909C>T (p.Gln637*) and 2) c.2050C>T (p.Arg684*) and a previously reported mutation of ABCA4 c.4793 C>A (p.Ala1598Asp). Parental testing confirmed recessive inheritance. Visual acuity, visual field and ERG significantly deteriorated over 23 years.
3. The sixth patient had PROM1 variant c.642T>A(p.Tyr214*) . He displayed a Best phenotype with normal EOG and visual acuity and imaging remained stable over 4 years of follow up.

Conclusions: We report six patients with pathogenic PROM1 mutations, characterized via genotyping, electrodiagnostic testing as well as imaging studies, corroborating reports on the general trend of AR variant taking a more severe and progressive phenotype. We also report novel AR variants of PROM1 mutation: c.1909C>T and c.2050C>T. These mutations produce premature stop codons in an extracellular domain of prominin 1, resulting in a truncated protein and loss of prominin activity. PROM1 is a key regulator of ABCA4 expression. In that regard, the presence of mutations in PROM1 and ABCA4 in our AR variants is important. Further studies are needed to elucidate the need for PROM1 in ABCA4 expression.

ABSTRACT BODY:

Purpose: The coronavirus pandemic has prompted unprecedented delays to treatment with anti-VEGF intra-vitreous injections due to the need to reduce hospital attendances and prioritize the patients at highest risk of vision loss. This study aims to quantify the effect of these delays on visual acuity (VA) outcomes and optical coherence tomography (OCT) features for retinal vein occlusion (RVO) and diabetic macular oedema (DMO) patients.

Methods: A retrospective data analysis of an electronic medical record was performed on a random sample of eyes receiving anti-VEGF injections for RVO and DMO between 1 January and 23 March 2020. Patients with RVO and DMO were identified and data collected included whether the review was delayed (defined as delayed by 8 weeks or more from planned) and VA at baseline and follow up. For those patients not delayed, a VA at 20 weeks was recorded to provide a control group as this was the mean number of weeks until the delayed group were seen. For the delayed group, the OCT features at follow up were also noted.

Results: 300 eyes were analysed, of which 176 had RVO and 124 had DMO. 65 out of 176 eyes (36.9%) with RVO and 39 out of 124 eyes (31.5%) with DMO had their review delayed by 8 weeks or more. The mean number of weeks delay was 13.3 and 13.7 weeks for RVO and DMO respectively. Mean change in VA for eyes with RVO where their appointment was delayed was worse compared to those not delayed. For delayed RVO eyes, VA changed from 59.7 to 54.5 (-5.2) letters and for non-delayed RVO eyes VA changed from 63.5 to 61.6 (-1.9) letters ($P=0.363$). Mean change in VA for eyes with DMO was comparable between delayed (63.0 to 61.1 letters, -1.9) and non-delayed groups (63.7 to 61.0 letters, -2.7). For the delayed group, mean CMT (μm) changed from 374 to 451 (+77) in RVO eyes and 395 to 387 (-8) in DMO eyes. By November 2020, 23.1% of eyes with RVO and 8.6% of eyes with DMO had not returned to within 5 letters of their baseline vision.

Conclusions: Delayed appointments due to COVID-19 affected a significant proportion of RVO and DMO patients receiving intra-vitreous injections. Delayed reviews in RVO eyes had a greater impact than for DMO eyes, with a higher proportion losing vision both in the short and long term. VA loss was associated with worsening of OCT features in RVO patients.

ABSTRACT BODY:

Purpose: There is an unmet need for new drugs in glaucoma that can effectively prevent glaucoma progression. We assessed the effects of VSN16S and AG-020, the agonists of the cannabinoid receptor, on intraocular pressure (IOP) and neuroprotection using a rat model of ocular hypertension (OHT).

Methods: 20 male Dark Agouti (DA) rats aged 8-10 weeks were randomly located into four groups (n=5): OHT-only, OHT+vehicle, OHT+VSN16S, and OHT+AG-020. All animals had IOP surgically elevated in the left eye (OS) by injection of hypertonic saline into the episcleral veins. Except for OHT-only, animals in the other three groups have received eye drops in OS either vehicle or VSN16S or AG-020 at 10mg/ml, twice daily for 3 weeks following OHT-induction. IOPs were recorded in both eyes at baseline (BL), day1, week1, 2, and 3 using a Tonopen. Animals were in vivo imaged for retinal ganglion cell (RGC) apoptosis in both eyes using DARC (Detection of Apoptotic Retinal Cells) at BL and week3 before culled. Retinal whole-mounts were immunostained with a Brn-3a antibody to assess RGC survival. DARC spots and RGC counts were assessed by blinded algorithm analysis.

Results: Surgical procedure induced a significant increase in IOP profiles in all animal groups compared to the contralateral eye (OD), and peak levels occurred at day1 ($p<0.001$). In the OHT eyes treated with VSN16S, IOPs at week1 exhibited a sharp reduction ($p<0.05$), and integrate IOP at week3 was significantly lower than vehicle controls ($p<0.01$). However, AG020 showed no effect on IOP. Surgically induced IOP elevation resulted in a significant increase in DARC counts (RGC apoptosis) in all groups, compared to the baseline. DARC counts revealed a significant reduction in the OHT eyes treated by VSN16S, compared to the OHT-only and vehicle groups ($p<0.01$), but less of a reduction of DARC counts was observed with AG-020 treatment ($p<0.05$). A significant reduction of Brn-3a⁺ RGC density was seen in the OHT-only group compared to naïve controls ($p<0.05$), and VSN16S treatment demolished the difference although no significance was found on Brn-3a⁺ RGC density between VSN16S and controls.

Conclusions: VSN16S exerted neuroprotective properties in OHT-induced RGC loss, which may be associated with lowering IOP profiles. DARC is a useful tool in the assessment of drug efficacy in retinal neurodegenerative diseases.

ABSTRACT BODY:

Purpose: Adeno-associated virus serotype 2 (AAV2) is a viral vector that can be used to deliver therapeutic genes to the retina. AAV2 capsids can be altered in order to improve the efficiency of gene transfer, for instance, by mutating surface-exposed residues that mediate intracellular phosphorylation and degradation of viral particles. Whilst this strategy has demonstrated promise in terms of improving retinal transduction, the possibility of immune activation following the incorporation of phosphodegrogen mutations into AAV2 has not been explored.

Methods: Adult male C57BL/6J mice were injected intravitreally with either 2E8 viral particles (VP)/eye AAV2, AAV2 (Y444F), AAV2 (Y444F, K556E, S662V), 2E10 VP/eye AAV2 or PBS vehicle. After three weeks, mice were sacrificed, serum samples were extracted and eyes were enucleated for analysis. Serum neutralising antibody (NAb) titres were calculated using an in vitro neutralisation assay. Transduction efficiency was assessed via analysis of reporter expression (GFP), and immunohistochemical analysis was used to identify activation of adaptive and innate immune systems. An in vitro heparan binding assay was used to assess whether phosphodegrogen mutant AAV2 may bind to heparan sulphate proteoglycan (HSPG) with lower affinity than prototypical AAV2.

Results: AAV2 (Y444F) and AAV2 (Y444F, K556E, S662V) exhibited higher transduction efficiency in the retina than wild type capsids. Both mutant capsids induced higher serum NAb titres and levels of CD4+ and CD8+ T-cell infiltration into the retina than wild type AAV2. We also observed elevated immunoreactivity of CD68 and Iba1, suggesting that microglia activation was induced by the mutant capsids. Similarly, we saw morphological changes and increased immunoreactivity in GFAP+ fibrils, suggesting that Muller glia were involved in the immune response to the mutant capsids. Finally, we showed that AAV2 (Y444F) and AAV2 (Y444F, K556E, S662V) exhibit slightly reduced binding affinity to heparan sulphate.

Conclusions: Our results suggest that incorporation of phosphodegrogen mutations in AAV2 results in elevated immune activation vs. wild-type capsids. The underlying molecular basis of this requires further investigation, however, increased permeation of virions into the neural retina due to attenuated heparan binding in the inner limiting membrane may be involved.

ABSTRACT BODY:

Purpose: To identify one-year progression of two nonproliferative diabetic retinopathy phenotypes B and C associated with risk of developing sight-threatening complications in type 2 diabetes (T2D).

Methods: Patients with type 2 diabetes were followed in a one-year longitudinal study. The following systemic factors were evaluated: age, sex, diabetes duration, lipidic profile, inflammatory cytokines and hemoglobin A1c (HbA1c). Ophthalmological examinations were performed at baseline, 6 months and at one-year, and included visual acuity (BCVA), color fundus photography (CFP) and optical coherence tomography (OCT and OCTA). Phenotype classification was performed based on microaneurysm turnover (MAT, on CFP) and central retinal thickness (CRT, on OCT). Only risk phenotypes were included; Phenotype B identified by low MAT (< 6) and increased CRT; and Phenotype C identified by higher MAT (≥ 6) with or without increased CRT. ETDRS grading of seven fields CFP was performed at the initial visit.

Results: To evaluate the relative risks associated with the two phenotypes, B and C, associated with increased risk of developing sight threatening complications, 1421 individuals with T2D and NPDR were recruited (81 eyes classified as phenotype B and 60 eyes classified as phenotype C), and followed for one year. Of these, 136 completed the one-year follow-up or developed DME (considering both clinically significant macular edema (CSME) and center-involved macula edema (CIME). Nineteen eyes (14%) developed either CSME (1) or CIME (18). Eleven eyes with phenotype B (14%) and 7 eyes with phenotype C (12%) developed CIME. One eye with phenotype C developed CSME. During the period of one-year, phenotype C showed a decrease in BCVA ($p=0.008$), in ganglion cell layer (GCL) thinning ($p=0.022$) and in macular vessel density in the inner ring ($p=0.004$), particularly in the deep retinal capillary plexus. No significant changes were detected in CRT in both phenotypes during one-year period of follow-up.

Conclusions: In one-year period of follow-up, phenotype C is the only risk phenotype that is associated with vision loss and shows disease progression at both microvascular level, represented by capillary closure, and neurodegeneration, represented by GCL thinning.

SUBMITTER (NAME ONLY): Katja Hatz

TITLE: Efficacy and outcome predictors of long-term intravitreal anti-VEGF therapy in neovascular age-related macular degeneration following a strict treat-and-extend regimen.

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.B. Hatz, Vista Klinik AG, Binningen, SWITZERLAND|K.B. Hatz, Universitat Basel Medizinische Fakultat, Basel, BS, SWITZERLAND|

Commercial Relationships Disclosure (Abstract): Katja Hatz: Commercial Relationship(s);Novartis Switzerland:Code F (Financial Support);Bayer Switzerland:Code F (Financial Support);Roche:Code F (Financial Support);Allergan:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To determine functional and morphological long-term outcomes and outcome predicting factors in patients with neovascular age-related macular degeneration (nAMD) applying a treat-and-extend regimen (TER).

Methods: Consecutive retrospective case series of treatment-naïve subjects with nAMD starting treatment with either ranibizumab or aflibercept in a strict TER without loading dose and exit strategy.

Results: Two hundred-eleven (211) eyes of 187 patients with a mean follow-up of 60.3 ± 20.9 months were included. Mean BCVA increased from initially 63.9 ± 15.5 ETDRS letters (20/55) to 70.0 ± 14.7 (20/40) after one year (+6.1 letters, $p < 0.001$) and to 68.5 ± 18.1 (20/43) (+4.6 letters, $p = 0.028$) at 5 years. Mean number of injections decreased from 9.9 ± 2.1 during the first year to 7.54 ± 3.6 ($p < 0.001$) at year 5. During follow-up 30.3% of eyes reached exit criteria. Significant predictors of BCVA gain at 5 years were a worse baseline BCVA ($p = 0.001$), a better external limiting membrane (ELM) disruption score ($p = 0.019$) and the absence of central geographic atrophy at diagnosis ($p = 0.006$). The probability of reaching the exit criteria was significantly predicted by a low central retinal thickness (CRT) ($p = 0.025$), a better ELM disruption score at baseline ($p = 0.044$) and the absence of a central pigment epithelial detachment (PED) ($p = 0.05$).

Conclusions: Significant visual gains were sustained after 5 years of follow-up in a TER in a real-world setting. Integrity of ELM at baseline was associated with BCVA gain and anatomic disease stability at 5 years of treatment.

TITLE: The role of placental growth factor (PlGF) in retinal pigment epithelial (RPE) barrier integrity and outer retinal integrity in geographic atrophy

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Cunningham, I. Lengyel, A. Stitt, Wellcome-Wolfson Institute for Experimental Medicine, Queen's University Belfast, Belfast, Belfast, UNITED KINGDOM|T. van Bergen, J. Feyen, Oxurion, BELGIUM|

Commercial Relationships Disclosure (Abstract): Fiona Cunningham: Commercial Relationship(s);Oxurion NV:Code F (Financial Support) | Tine van Bergen: Commercial Relationship(s);Oxurion NV:Code E (Employment) | Jean Feyen: Commercial Relationship(s);Oxurion NV:Code E (Employment) | Imre Lengyel: Commercial Relationship: Code N (No Commercial Relationship) | Alan Stitt: Commercial Relationship(s);Oxurion NV:Code F (Financial Support)

ABSTRACT BODY:

Purpose: PlGF has been widely investigated as a target for the mitigation of neovascular age-related macular degeneration (AMD). Previous investigations suggest PlGF inhibition may also be an effective target for the treatment of outer retinal degeneration seen in geographic atrophy (GA). However, this has only been reported in the light-induced retinal atrophy mouse model. This study tested the hypothesis that PlGF inhibition might protect RPE and the outer retina in the sodium iodate (NaIO_3) mouse model.

Methods: PlGF-2 (50ng/mL) was applied to human foetal RPE (hfRPE) for 24 hours in culture. Barrier integrity was assessed by transepithelial electrical resistance (TEER) and staining for ZO-1 and f-actin. Retinal degeneration was induced in mice by intraperitoneal delivery of 50mg/kg NaIO_3 . PlGF and VEGFR1 expression were assessed by in situ hybridisation (ISH) and immunohistochemistry (IHC). Anti-PlGF antibody (5D11D4) was delivered via intravitreal injection. Control conditions were untreated; PBS vehicle control; and IgG antibody control. Retinal degeneration was assessed by optical coherence tomography and post-mortem analyses of retinal sections and RPE/ choroid flatmounts.

Results: PlGF reduced hfRPE barrier resistance by 66.96% \pm 7.78% compared to untreated RPE (mean \pm SD, p-value \leq 0.0005). There was fragmentation of the ZO-1 network and increased cells with stress fibres. In vivo, 50mg/kg NaIO_3 induced outer retina thinning and RPE and choroidal atrophy. Increased VEGFR1 mRNA was detected in the inner retina of NaIO_3 -treated mice by ISH and in the RPE and choroid by IHC. PlGF was detected in the NaIO_3 -treated choroid by IHC. 5D11D4 treatment significantly preserved portions of intact RPE after 24 hours NaIO_3 exposure compared to vehicle and IgG control groups (p-value \leq 0.005 and \leq 0.05 respectively). At the same time, 5D11D4 treatment improved choroidal vascular area after 72 hours NaIO_3 treatment compared to a vehicle control group, although this was not significant. However, 5D11D4 did not prevent RPE atrophy seen at 72 hours, nor retinal thinning.

Conclusions: These results suggest that while PlGF signalling suppresses RPE barrier activity in vitro, this growth factor does not play a significant role in RPE dysfunction observed during oxidative stress induced-retinal degeneration in vivo, in contrast to previous studies.

ABSTRACT BODY:

Purpose: Dry Eye Disease (DED) in diabetes mellitus (DM) is common. Although, there have been no studies published that evaluate the awareness of DED in DM in the practices of eye care professionals in different regions. In this study, the clinical practice behaviours of eye care professionals based in the UK and Mongolia were compared, with respect to the diagnosis and management of DED in DM.

Methods: An online survey was sent to eye care professionals in the 2 countries (UK and Mongolia). Respondents provided information about practice modality, preferred diagnosis and management of DED in DM.

Results: Only the completed responses (128 from the UK and 68 from Mongolia) were analysed. In the clinical experience of respondents, the mean prevalence of DED in patients with DM was reported as 61.6% (± 21.1) and 57.2% (± 21.7) in the UK and Mongolia, respectively. In addition, the mean prevalence of asymptomatic DED in DM was reported as 50.5% (± 19) and 48.6% (± 18) in the UK and Mongolia, respectively. When comparing the reported prevalence, there were no statistical significant differences detected between the countries ($p > 0.05$). A significant higher proportion ($p < 0.001$) of UK respondents (57.8%; $n = 74$) than Mongolia-based respondents (35.3%; $n = 24$) agreed that the prevalence of DED in DM was higher than those without DM. The majority of UK (71.9%) and Mongolian respondents (61.8%) saw between 1-5 DM patients with DED per week. Both countries reported that DED in DM was diagnosed with the same clinical tests as DED without DM. For DED treatment, respondents mainly prescribed artificial tear supplements (69.4% in the UK; 90% in Mongolia), followed by warm compress and lid scrubs (19.4% in the UK and 6.7% in Mongolia). Half of respondents from both countries agreed that DED in DM receives less attention than diabetic retinal complications during ophthalmic examinations. In addition, they agreed that there needs to be increase in practitioners' awareness of DED in DM. Undergraduate and postgraduate studies were acknowledged as the main source of information for DED in DM among UK and Mongolian respondents, respectively (see Figure 1).

Conclusions: Eye care professionals in both regions had similar practice behaviours for diagnosing and treating DED in DM. According to the responses from the UK and Mongolia, DED was considered as being prevalent in DM.

ABSTRACT BODY:

Purpose: To investigate the association between CLDEQ-8 classes, blink frequency during digital device use, tear film metrics, and a metric that emphasizes blinks that occur after the tear film has destabilized.

Methods: A bilateral, dispensing, randomized, double-masked 2x2 cross over study with a 2-week washout was executed. Two silicone hydrogel investigational soft contact lenses were employed, differing only by hydration method. The study included 6 visits: a baseline evaluation and lens fitting, a 1-week follow-up (FU) after 8 hours of lens wear, and a 2-week FU after 8 hours of lens wear. After a 2-week washout with habitual contact lens wear, this was repeated using the second investigational lens. A total of 37 subjects completed the study. At both 1-week FUs, 2 measures of tear stability were evaluated using the Oculus Keratograph 5M and a customized dynamic iDesign wavefront system, and the interblink interval (IBI) was measured while the subject watched a 5-minute video on a tablet. During this measurement, a video of each subject was recorded and analyzed using custom software to yield the IBIs. Contact Lens Dry Eye Questionnaire-8 (CLDEQ-8) was also administered at these 1-week FUs, however this questionnaire is not validated at the 1-week wear timepoint. Classes were defined using CLDEQ-8 scores, as follows. Poor and fair ≥ 15 ; 7 < good and very good < 15; excellent subjects ≤ 7 .

Descriptive statistics, by class, were calculated for the IBI, NIKBUT, wavefront RMS, and ocular protection index (OPI) calculated using the NIKBUT and IBI.

Results: Mean or median IBI and mean NIKBUT, plotted by class, did not point to a relationship between the metrics and classes. Plots of the wavefront RMS suggested an increase of RMS and plots of the OPI suggested a decrease in OPI with increasing symptom class.

Conclusions: Combining the NIKBUT tear stability and IBI (OPI metric) appeared to provide better agreement with symptom classes defined by CLDEQ-8 as compared to using IBI or NIKBUT alone. Further investigation of dryness symptoms and discomfort during digital device use, and the interaction between the blink frequency and tear film metrics are warranted.

ABSTRACT BODY:

Purpose: The CIRCLE study was conducted to assess the efficacy and the safety of up to 3 intravitreal (IVT) injections of ocriplasmin to induce total posterior vitreous detachment (PVD), in order to reduce the risk of disease progression to proliferative diabetic retinopathy (PDR). A single intravitreal injection of ocriplasmin 0.125mg is approved for the treatment of symptomatic vitreomacular adhesion (VMA)/vitreomacular traction (VMT).

Methods: The CIRCLE study was a multicenter, sham-controlled, double-masked study. Subjects were randomized 2:2:1 to receive up to 3 IVT injections of ocriplasmin 0.0625mg, ocriplasmin 0.125mg, or a sham procedure, 1 month apart. They were followed for 24 months.

Results: Recruitment in the study was stopped early due to a slow recruitment rate. As a result, the study was not powered for its primary endpoint (total PVD by Month 3) and the main goal became the assessment of the safety of up to 3 IVT injections of ocriplasmin. Forty-eight (48) subjects were randomized: 20 to ocriplasmin 0.0625mg, 19 to ocriplasmin 0.125mg and 9 to sham. The subjects were mostly white and male. The mean age at Baseline was 56.2 years. The mean time since the diagnosis of diabetes was 16.9 years. There were no relevant imbalances between treatment arms. The most frequently reported treatment-related adverse events (AEs) in the study eye were Conjunctival Haemorrhage in the ocriplasmin 0.0625mg arm (3 events in 3/20 [15.0%] subjects) and Vitreous Floaters in the ocriplasmin 0.125mg arm (5 events in 3/19 [15.8%] subjects). This is similar to the most frequently observed treatment-related AEs following a single injection of ocriplasmin 0.125mg in patients with symptomatic VMA/VMT. No new type of AE was identified. The majority of AEs were mild or moderate in intensity, started within the first week after injection and resolved within a few days. The frequency or intensity of AEs did not increase following the second or third injection with ocriplasmin.

Conclusions: Up to three (3) IVT injections with ocriplasmin were considered safe, given that no new type of AE unknown to ocriplasmin was identified, as compared to a single injection of ocriplasmin 0.125mg in patients with symptomatic VMA/VMT. Neither the frequency nor the intensity of the AEs increased following the second or third injection with ocriplasmin.

ABSTRACT BODY:

Purpose: Neurodegeneration in Alzheimer Disease (AD) is caused by aggregation of amyloid- β plaques and formation of tau neurofibrillary tangles (NFT). While NFTs are a hallmark of AD, the misfolding and oligomerization of tau protein can start up to 15 years before the first symptoms of dementia. Detecting the disease at an early stage can be complicated and costly. Evidence shows that the visual system follows the pathology in the brain. Indeed, studies have shown significant changes in the visual evoked potentials (VEPs) in patients with mild cognitive impairment as well as AD. The aim of our study was to evaluate whether changes in visual processing may represent an early biomarker of pathological Tau accumulation.

Methods: An animal model of tauopathy, Tg4510, exhibits progressive accumulation of pathological Tau species and neurodegeneration. Transgenic mice at ages of 6, 9 and 16 months were studied against their age matched controls. Retinal response to a white light stimulus was recorded using electroretinography (ERG). Electroencephalography was simultaneously performed to record VEPs. The stimulus was applied at eight different intensities with an appropriate interval in between flashes.

Results: While ERG responses at 6, 9 and 16 months did not differ between transgenic (tg) and control animals, an age-dependent decline in retinal response was observed regardless of genotype. On the other hand, VEP responses to a light stimulus were significantly more pronounced in 6 month tg animals compared to age matched control mice. At 9 months, the difference between tg and control animals was slightly diminished. By 16 months of age, the VEPs in tg mice were weaker compared to their age matched controls, possibly reflecting extensive neuronal loss.

Conclusions: Our findings in younger animals (6 months) may indicate that compensatory mechanisms precede extensive neuronal loss and Tau accumulation. Further histological analysis will help establish the level of correlation between tauopathy and visual processing, which would further strengthen its value as a biomarker

ABSTRACT BODY:

Purpose: To evaluate the functional and morphological long-term outcome of ICGA-guided laser therapy of teleangiectatic capillaries (TC) and to assess their immediate as well as their subsequent morphological response to laser treatment.

Methods: In this retrospective study, the presence of TCs was evaluated in patients with treatment naive or pretreated diabetic macular edema (DME). TCs, presenting as hyperfluorescent spots in late-phase ICGA (>10minutes), were targeted with laser. Customized OCT scans were used to monitor changes in the reflectivity of the TCs lumina during and immediately after laser therapy as well as during follow-up. Additionally, patients were treated with intravitreal anti-vascular endothelial growth factor (anti-VEGF) as needed.

Results: 13 eyes of 10 patients with DME were followed-up for a mean of 24 months (± 8). After targeted laser therapy of only 2 TCs per eye on average mean best-corrected visual acuity (BCVA) improved from 0.25 logMar (± 0.19) at baseline to 0.13 (± 0.10 ; $p=0.035$) at months 12-15 and remained stable at 0.14 (± 0.12 ; $p=0.042$) at each patient's last visit. Mean central subfield thickness (CST) decreased from 406 μ m (± 82) at baseline to 295 μ m (± 39) at months 12-15 ($p<0.001$) and remained stable at 291 μ m (± 50) at the last visit ($p<0.001$). The immediate darkening of the TCs lumina, observed in 11 out of 13 eyes at the first laser session was followed by shrinking of the TCs after a mean of 1.3 months, followed by their full resolution after a mean of 4 months in all of these cases. In the two eyes where no darkening of the TCs lumina was observed, re-treatment was necessary after 6 months due to persistence of the TCs and an increase of the edema. Within a mean follow-up of 2 years additional treatment with anti-VEGF was indicated in only 2 of 13 eyes (1 eye 1 injection, the other 4 injections).

Conclusions: The darkening of the TCs lumina visible in OCT as immediate reaction to focal laser therapy resulted in successful closure of these lesions in all cases. Consequently, a statistically significant improvement in BCVA and reduction in CST could be achieved with targeted laser therapy of only two lesions per eye on average. No anti-VEGF injections were needed in the vast majority of eyes during a mean follow-up of 2 years.

Campbell, Smurfit Institute of Genetics, The University of Dublin Trinity College, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Deirdre Harford: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Aisling Naylor: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey O'Callaghan: Commercial Relationship: Code N (No Commercial Relationship) | Alan Hopkins: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Doyle: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Campbell: Commercial Relationship: Code N (No Commercial Relationship) | Mark Cahill: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The initiating pathophysiological events in the development of early AMD still remain unclear. Inner blood retina barrier integrity in young, healthy adult humans has been shown to cycle in a circadian manner, mirroring tight junction protein claudin-5 cycling. As circadian rhythm disturbance has previously been associated with other neurodegenerative disorders, we conducted a case controlled observational study to test the hypothesis that inner blood retina barrier circadian kinesis is arrested in AMD patients.

Methods: Patients with AMD over the age of 65 (n=16) and age matched controls (n=11) were recruited and informed consent obtained. Participant's chronotype was established by way of the Munich Chronotype Questionnaire (MCTQ). Time points in the morning and evening were defined and OCT, FFA and fundal photos were performed. Quantification of FFA images was performed by a bespoke MatLab based software platform. These findings are part of a longitudinal study named the "Irish Circadian Retina Project" which is still recruiting participants with AMD and age matched controls.

Results: In young healthy subjects, fluorescein signal was evident and more prolonged in the evening compared to the morning and this was significantly increased in the inner macula^{***}, outer macula ^{***} and total area^{**}(n=33 subjects, ^{***}p<0.0005, ^{**}p <0.0026). Analysis of melatonin and cortisol revealed variations as expected, with cortisol elevated in the morning and melatonin increased in the evening. Upon OCT volume analysis of the macula, no significant differences between AM and PM were observed. Similarly, preliminary data from AMD patients compared to age matched controls suggests a region-dependent fluorescein signal differential, with a more prolonged signal in AMD patients.

Conclusions: The preliminary findings of this study suggest that the iBRB is highly dynamic. We have previously demonstrated the potential size-selective passive diffusion from the inner retinal vasculature to the retinal parenchyma with diffusion towards the outer retina and RPE in young, healthy controls. Now, we have demonstrated that this phenomenon appears to be attenuated with age and absent in AMD patients. We suggest that disruption in the circadian mediated integrity of the iBRB may be an early initiating event in AMD development and progression. To our knowledge, this is the first time the iBRB has been implicated in AMD pathogenesis.

TITLE: Association between peripheral refractive error and 12-month changes in central refraction and axial length in Caucasian children

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.E. Leighton, K. Breslin, S.J. McCullough, P. Richardson, K.J. Saunders, Ulster University, Coleraine, Londonderry, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Rebecca Leighton: Commercial Relationship: Code N (No Commercial Relationship) | Karen Breslin: Commercial Relationship: Code N (No Commercial Relationship) | Sara McCullough: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Richardson: Commercial Relationship: Code N (No Commercial Relationship) | Kathryn Saunders: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Controversy exists regarding the influence of peripheral visual experience on axial ocular growth in humans. This longitudinal, observational study evaluates the relations between baseline relative peripheral refraction (RPR), change in central refraction and ocular biometry in children aged 6-7 and 12-13 years.

Methods: Cycloplegic autorefraction at horizontal retinal eccentricities of 0° and ±30° were recorded from right eyes (Shin Nippon SRW-5000). The Zeiss IOLMaster 700 measured central axial length (AL) and lens thickness (LT). Measurements were repeated after 12-months. Refractive data were transposed into spherical equivalent refraction (SER). RPR was calculated by subtracting central from peripheral SER. Correlations between baseline RPR and 12-month change in central SER and AL were explored. Multiple regression analyses evaluated the hypothesis that baseline RPR predicts central SER change.

Results: Baseline myopia was associated with more hyperopic RPR and baseline hyperopia and emmetropia with more myopic RPR (all negative correlation $r/\rho > 0.325$, $p < 0.074$). More hyperopic temporal RPR at 12-13 years was significantly correlated with greater myopic shift in central SER ($r = -0.388$, $p = 0.0008$) and greater axial elongation ($r = 0.376$, $p = 0.011$) over 12-months. More hyperopic nasal RPR at 12-13 years was significantly correlated with greater axial elongation ($\rho = 0.333$, $p = 0.025$) but not with central SER change ($r = -0.158$, $p = 0.301$). Neither nasal nor temporal RPR at 6-7 years were correlated with 12-month change in central SER or AL ($p > 0.675$). Multiple regression analyses indicated that baseline central SER, nasal and temporal RPR and AL at 12-13 years explained 21.8% of the variance in 12-month change in central SER ($r^2 = 0.218$, $p = 0.04$) with temporal RPR the strongest predictor of myopic shift ($\beta = -0.449$, $p = 0.029$). Multiple regression analyses suggest neither RPR, AL or LT at 6-7 years are helpful in predicting subsequent 12-month central SER change.

Conclusions: More hyperopic temporal RPR at 12-13 years is associated with greater short-term myopic progression. This relationship is not seen in younger children. These data suggest that temporal RPR may be a useful metric for eyecare clinicians to consider when developing intervention and review plans for teenage children but are less informative when examining younger children.

Commercial Relationships Disclosure (Abstract): Karen Peynshaert: Commercial Relationship: Code N (No Commercial Relationship) | Kaat De Clerck: Commercial Relationship: Code N (No Commercial Relationship) | Félix Sauvage: Commercial Relationship: Code N (No Commercial Relationship) | An-Katrien Minnaert: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Braeckmans: Commercial Relationship: Code N (No Commercial Relationship) | Stefaan De Smedt: Commercial Relationship: Code N (No Commercial Relationship) | Katrien Remaut: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The inner limiting membrane (ILM) is the primary barrier hindering effective drug delivery to the retina after intravitreal injection. Therefore, we aim to create therapeutic entryways into the retina by puncturing the ILM using photoporation. To explore our concept, we applied indocyanine green (ICG) at the ILM surface of bovine and human retinal explants followed by laser scanning of the retina with 800 nm laser light (Figure).

Methods: To perforate the ILM, we applied varying concentrations of ICG (0,1 mg – 1mg/ml) on top of bovine and human retinal explants followed by scanning of the laser beam at lower and higher laser energies (0,24 and 0,4 J/cm²). For the latter, an Nd:YLF laser was applied to generate 800 nm single laser pulses of a 2 picosecond pulse width and frequency of 1 kHz. Following laser treatment, 100 nm sized PEGylated nanoparticles (NPs) were applied on top of the explants prior to their culture for 24 hours. Finally, retinal cryosections were prepared and immunostained for Collagen IV to check for ILM integrity as well as NP entry into the retina with confocal microscopy.

Results: Bovine retinal explants treated with laser only (0,4 J/cm²) showed an intact ILM. In explants treated with both ICG and laser light, however, the ILM was clearly affected: high ICG concentration and laser energy led to full ILM ablation, while lower conditions led to partial ILM destruction. As anticipated, 100 nm sized NPs were largely unable of crossing the intact ILM of untreated and laser-treated explants. By contrast, complete treatment (ICG and laser) resulted in a massive entry of NPs into the retina for all conditions. Additionally, we effectively ablated the ILM of human explants of patients with varying age (27 – 70 years) which indicates that our approach is also effective for treating the thicker and more complex human ILM.

Conclusions: We have successfully ablated the ILM of bovine and human explants by means of ICG-mediated photoporation. In addition, this ILM damage resulted in extensive entry of NPs into the retina. Future plans include fine-tuning of our approach in accordance with the limitations set by toxicity evaluations ex vivo and in vivo.

ABSTRACT BODY:

Purpose: To assess the degree of agreement in morphological parameters of the human optic nerve head (ONH) measured with in vivo OCT with ex vivo three-dimensional (3D) histology

Methods: The ONH of 6 eyes from 3 brain-dead organ donors (4 healthy and 2 with glaucomatous eyes) were imaged by OCT with IOP set to 10 mmHg by anterior chamber cannulation. After organ recovery, the eyes were enucleated and fixed at 10mmHg, then high-resolution episcopic 3D histomorphometric reconstructions were created. The surfaces of: Bruch's membrane (BM) and opening (BMO), anterior sclera (AS) and scleral canal opening (ASCO), and anterior lamina cribrosa surface (ALCS), were delineated and then interpolated by analytical 3D fitting models in both the OCT and histology volumetric reconstructions. ALCS visibility area was quantified as the sum of the areas of the Delaunay mesh elements connecting the delineation points. Spearman correlations tested the agreement between in vivo vs. ex vivo measures. Limits of agreement (LOA) were calculated for the relative difference between the two measures, and expressed as % of the mean.

Results: Bland-Altman plots of the relative difference between in- and ex-vivo 3D measurements are shown in the Figure. Spearman correlations are shown in the Table. Good correlation and agreement was seen with parameters defining the canal size ($R \sim 1$, Table), with very narrow LOA ($<10\%$ in band width). ALCS depth ($R \sim 0.8$) and choroidal thickness ($R \sim 0.9$) had good correlation between ex- and in-vivo measurements. However, the ALCS was 20-50% deeper and the Choroid was 50-100% thicker when measured in vivo. ALCS global shape index metrics showed moderate correlation (R of 0.6 and LOA of $\sim 30\%$ in width). On average, 31% of the ALCS defined histologically was visible using in-vivo OCT.

Conclusions: While there is a good agreement between in vivo and ex vivo measurements of the anterior ONH canal morphology and moderate agreement in ALCS shape, in vivo imaging provides limited visualization of the entire ALCS.

ABSTRACT BODY:

Purpose: This study compared the therapeutic potential for retinal regeneration of human mesenchymal stem cells derived from abdominal subcutaneous fat (ABSCs) or from orbital fat (OASCs) due to their accessibility and mutual embryonic origin with retinal tissue, respectively.

Methods: Human ABASCs and OASCs were harvested from sub cutaneous and orbital fat by collagenase digestion. Conditioned medium was collected to treat RPE cells under oxidative stress, and was studied for content by cytokine array. Differentiation towards RPE was assessed by qRT-PCR and immunostainig after a co culture system. OASCs, ABASCs, or PBS were transplanted in the sub retinal space of sodium iodate mice, retinas were analyzed By Immunohistochemistry after 3 weeks.

Results: OASCs conditioned medium prevented RPE cell death compared to cells treated with standard medium ($40\% \pm 3.85$ decrease, $p < 0.01$). OASCs and ABASCs showed secretion of anti-apoptotic and neuroprotective cytokines, however, ABASCs showed stronger secretion of immunomodulatory chemokines (threshold > 1.4 folds). OASCs exhibited a potential to differentiate towards RPE lineage evident by upregulation of nuclear OTX2 and PAX6 (929.7 ± 76.2 , 57.6 ± 5.6 folds respectively). ABASCs exhibited a broader differentiation potential into retinal precursors with cytoplasmic localization of OTX2. ABASCs have specifically restored photoreceptor of sodium iodate (SI) mice, exhibited by higher ONL thickness and rhodopsin intensity when compared to PBS (ONL: ABASCs- 51.8 ± 11.7 , PBS- 31.1 ± 5.76 μm . rhodopsin: ABASCs- 27.4 ± 4.09 , PBS- 21.5 ± 2.57 , $p < 0.05$). This effect was correlated with higher retinal infiltration of Iba1+ cells compared to PBS (ABASCs 50.9 ± 14.5 , PBS 28.2 ± 8.17 cells/area, $p < 0.05$). SI induced RPE injury was salvaged by OASCs demonstrated by higher RPE65 intensity (OASCs- 50.2 ± 20.5 , PBS- 23.4 ± 5.51 , $p < 0.05$).

Conclusions: In summary, OASCs exhibited in vitro protective effect on RPE cell death, and differentiation potential to RPE, which translated to salvage of RPE layer in vivo. ABASCs showed immunomodulatory chemotactic secretion in vitro, as well as differentiation ability to retinal precursors, translated to restoration of photoreceptors in vivo. These data suggest a lineage specific therapeutic potential of OASCs and ABASCs in the treatment of retinal degeneration and distinguishes the potential of using each population for future cell therapy application.

TITLE: Differential involvement of adenosine triphosphate (ATP) in hypoxia-induced dilatation of larger and smaller porcine retinal vessels ex vivo

SESSION TITLE: Diabetic retinopathy/retinal pharmacology/physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Ernst, T. Bek, Department of Ophthalmology, Aarhus Universitetshospital, Aarhus N, Central Jutland region, DENMARK|C. Aalkjaer, Institute of Biomedicine (physiology), Aarhus Universitet, Aarhus, Mid Jutland Region, DENMARK|

Commercial Relationships Disclosure (Abstract): Charlotte Ernst: Commercial Relationship: Code N (No Commercial Relationship) | Christian Aalkjaer: Commercial Relationship: Code N (No Commercial Relationship) | Toke Bek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Adenosine triphosphate (ATP) is involved in hypoxia-induced vasodilatation of larger retinal vessels, but the effect on smaller retinal vessels has not been studied in detail. Therefore, the purpose of the present study was to investigate the effect of purinergic antagonists on hypoxia-induced dilatation of porcine retinal arterioles, pre-capillary arterioles and capillaries.

Methods: Porcine superior hemiretinas (n=30) were mounted in a specially designed perfusion chamber, and the diameter of retinal arterioles, pre-capillary arterioles and capillaries were studied during hypoxia with and without the presence of antagonists to ATP-degradation (AOPCP), P2-purinergic receptors (PPADS) and the A2B-adenosine receptor (MRS1754).

Results: Hypoxia induced dilatation of both arterioles, pre-capillary arterioles and capillaries ($p < 0.01$ for all comparisons). The dilatation of arterioles was antagonized by both AOPCP, PPADS and MRS1754 ($p < 0.03$ for all comparisons), whereas dilatation of pre-capillary arterioles and capillaries were antagonized by PPADS ($p < 0.03$) but not by AOPCP or MRS1754 ($p > 0.50$ for both comparisons).

Conclusions: Hypoxia-induced dilatation of retinal vessels is regulated differentially in larger arterioles, pre-capillary arterioles and capillaries. This may form the basis for selective interventions on the diameter of retinal vessels at different branching level.

ABSTRACT BODY:

Purpose: To compare mydriatic handheld retinal imaging with standard ETDRS 7-field color 30-degree fundus photography (ETDRS photos) for assessment of DR/DME

Methods: Following standard imaging protocol, mydriatic retinal images were acquired using handheld retinal cameras [Aurora (AU), Smartscope (SS), RV700 (RV) and InView (NV)] and dilated ETDRS photos (Figure 1). All images were evaluated at a centralized reading center independently by 4 graders (2 certified retinal image/graders, 1 ophthalmologist, 1 retina specialist). All differences were adjudicated by a senior retina specialist. Kappa statistics [simple (K), weighted (K_w)] assessed agreement for DR/ DME. Sensitivity/specificity for any DR, referable DR [(refDR) moderate nonproliferative DR (NPDR) or worse, any DME or ungradable images] and vision threatening DR [(vtDR) severe NPDR or worse, clinically significant DME (CSME) or ungradable images] were calculated.

Results: Images from 177 eyes of 92 patients with diabetes were evaluated. Severity by ETDRS photos: no DR 40.1%, mild NPDR 19.2%, moderate 14.7%, severe in 10.2%, proliferative DR 15.8%; no DME 72.9%, DME 6.8%, ciDME 17.0%; ungradable 3.4%. Ungradable rate for DR/DME for AU: 0%/0.56%; SS: 4.5%/5.7%; RV:4.0%/5.7%; and NV:7.3%/35.6%. Kappa statistics and agreement rates with ETDRS photos for DR/DME are shown in Table 1. Agreement with DR was highest with the AU (K_w =0.79) and lowest with NV (K_w =0.53). DME agreement was similar across all devices (K_w = 0.79-0.83). Agreement for DR severity with ETDRS photos was highest with AU (68.9% exact, 96.6% 1-step). Sensitivity/Specificity for any DR, refDR and vtDR are shown in Table 1. The established standards (0.80 sensitivity,0.95 specificity) were met by AU, SS and RV for any DR and refDR.

Conclusions: Following a standardized protocol, handheld retinal imaging devices have substantial levels of agreement for DR/DME and meet accepted standards for sensitivity and specificity in identifying any DR and refDR. However, the ungradable rate varies greatly, exceeding 35% even with pupil dilation in some devices. None of the handheld devices met the established 95% specificity for vtDR.

ABSTRACT BODY:

Purpose: To identify in vivo confocal microscopy (IVCM) cellular features in Acanthamoeba keratitis (AK) at diagnosis.

Methods: Retrospective observational study of patients aged ≥ 16 years diagnosed with AK at Manchester Royal Eye Hospital from 2012 to 2018. AK diagnosis made by microbiology, IVCM-positive for double-walled cysts/bright spot sign/trophozoite or signet ring sign by experienced grader, or clinical suspicion of Acanthamoeba with improvement after anti-amoebal treatment. IVCM images were graded for morphological features by 2 ophthalmologists masked to clinical features and microbiological diagnosis. Statistical analysis performed in Stata 13.1, with Fisher's exact test for group comparisons.

Results: Of the 27 patients included: 41% were male ($n=11/27$) with median age 29 years (range 16-71 years); 74% were Acanthamoeba culture-positive ($n=20/27$), 81% were IVCM positive for Acanthamoeba ($n=22/27$), 16 were both IVCM and culture-positive, 6 were culture-negative but IVCM-positive, and 1 was clinically diagnosed as AK (culture and IVCM negative). The main risk factor was contact lens wear ($n=21/21$). Median symptom duration at first presentation was 9 days (range 2-42 days), with average BCVA at presentation of logMAR 0.25 (range 0.0-Hand movements). Acanthamoeba appeared in IVCM as bright-spots (86%; 19/22: see image), double-walled cysts (59%; 13/22), signet-ring (23%; 5/22), trophozoites (18%; 4/22) and as lines/clusters in 1 patient. The main epithelial changes detected were: koilocyte appearance with perinuclear halo (64%; 14/22; see image) and hyper-reflective cell borders (59%, 13/22). Nerve beading in basal nerve plexus was observed in 27% (6/22), seen mainly with A. polyphaga ($n=5/6$, $p=0.054$). For both, anterior and posterior stroma, activated keratocytes (65%, $n=15/23$, and 72%, $n=8/11$, respectively) were the most prominent feature. Microtubules connecting adjacent keratocytes were visible in 52% ($n=12/23$), and mostly in A. polyphaga ($n=8/12$, $p=0.036$).

Conclusions: Here we report novel IVCM features in AK of koilocyte appearance of epithelial, and microtubules between keratocytes. These may be initial morphological features of AK infection and could be used as an aid for earlier diagnosis. Larger studies are required to evaluate whether these features are specific to AK, and may therefore be clinically useful as diagnostic or prognostic biomarkers.

TITLE: Human Leukocyte Antigen mapping of paediatric uveitis

SESSION TITLE: Uveitis: Clinical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R. Wennink, S. Hiddingh, A. Haasnoot, V. Kalinina Ayuso, T. de Hoop, E. Spierings, J. van Setten, J. Kuiper, J. de Boer, Universitair Medisch Centrum Utrecht, Utrecht, Utrecht, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Roos Wennink: Commercial Relationship: Code N (No Commercial Relationship) | Sanne Hiddingh: Commercial Relationship: Code N (No Commercial Relationship) | Anne-Mieke Haasnoot: Commercial Relationship: Code N (No Commercial Relationship) | Viera Kalinina Ayuso: Commercial Relationship: Code N (No Commercial Relationship) | Talitha de Hoop: Commercial Relationship: Code N (No Commercial Relationship) | Eric Spierings: Commercial Relationship: Code N (No Commercial Relationship) | Jessica van Setten: Commercial Relationship: Code N (No Commercial Relationship) | Jonas Kuiper: Commercial Relationship: Code N (No Commercial Relationship) | Joke de Boer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Paediatric uveitis is a potentially blinding disease. To date, the aetiology of childhood uveitis is poorly understood. Genome-wide association studies have linked peptide motifs in HLA molecules to susceptibility of paediatric uveitis. Our aim was to comprehensively map the association of HLA alleles with childhood uveitis.

Methods: Whole gene next generation sequencing of all classical HLA-A, -B, -C, -DRB1, -DQB1, and -DPB1 loci was performed in 280 children with different forms of uveitis. Dense genotype data from 499 Dutch controls from Genome of The Netherlands were imputed using the SNP2HLA pipeline, using 5,225 samples from European-ancestry from the Type 1 Diabetes Genetics Consortium as reference panel. Cases and controls were compared using logistic regression models adjusting for sex.

Results: In total, 179 unique classical alleles were determined at second field resolution or higher. For cases with juvenile idiopathic arthritis associated uveitis, we ascertained the strong association to HLA-DRB1*08:01 (OR = 11.12, 95% CI 5.76-21.43; $P = 6.51 \times 10^{-13}$) and HLA-DQB1*04:02 (OR = 10.11, 95% CI 5.32-19.22; $P = 1.69 \times 10^{-12}$). There was no HLA-wide significant association signal for intermediate uveitis (lead allele, HLA-DRB1*15:01; OR = 2.18, 95% CI 1.26-3.77; $P = 0.005$). In contrast, we detected HLA-DRB1*01:02 (OR = 9.98, 95% CI 4.47-22.28; $P = 1.9 \times 10^{-8}$) as the primary association in patients with panuveitis. No unique HLA amino acid polymorphisms were associated with the different forms of uveitis.

Conclusions: These findings suggest distinct genetic susceptibility in paediatric uveitis and might help classifying different forms of uveitis in the future.

TITLE: Global Preferred Practice Patterns for the Management of Central Retinal Artery Occlusion

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.J. Fliotsos, S. Miller, A. Chen, L. Thangamathesvaran, S. Zafar, F. Woreta, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Fliotsos: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Miller: Commercial Relationship: Code N (No Commercial Relationship) | Ariel Chen: Commercial Relationship: Code N (No Commercial Relationship) | Loka Thangamathesvaran: Commercial Relationship: Code N (No Commercial Relationship) | Sidra Zafar: Commercial Relationship: Code N (No Commercial Relationship) | Fasika Woreta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While central retinal artery occlusion (CRAO) is relatively rare, it is associated with vision loss in over 75% of cases. Despite these severe outcomes, there continues to be significant controversy over best treatment practices. Our objective is to summarize global preferred practice patterns for the management of central retinal artery occlusions.

Methods: An online survey was distributed to trauma centers throughout the world to assess institutional management practice patterns for central artery occlusions.

Results: Responses were collected from 33 institutions (response rate 33/42, 78.6%) distributed across Asia (39.4%), North America (33.3%), South America (12.1%), Africa (9.1%), and Europe (6.1%). Approaches to manage CRAO diverged amongst respondents. The majority of respondents performed an anterior chamber (AC) paracentesis (n=31, 93.9%) after the diagnosis was made. The reported permissible time range from onset of CRAO to performing AC paracentesis varied, with 11 centers (33.3%) performing the procedure within 6 hours of onset, 2 centers (6.1%) within 12 hours, and 2 centers (6.1%) within 24 hours. Hyperventilation and/or an ocular massage were each performed at 57.6% of centers (n=19). 39.4% of respondents administered a beta blocker (timolol, n=13). Two centers reported administering tissue plasminogen activator (tPA, n=2, 6.1%); one through an intra-arterial approach and the other through an intravenous route. Only one center (3.0%) routinely uses non-invasive oxygenation for CRAO patients.

Conclusions: Conventional treatment paradigms for central retinal artery occlusions differ considerably. Evidence-based guidelines for the management of CRAO are needed to resolve controversies in care.

TITLE: Visual attention deficits after traumatic brain injury: A systemic review and meta-analysis

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Alnawmasi, S. Khuu, Optometry and Vision Science, University of New South Wales Faculty of Medicine, Sydney, New South Wales, AUSTRALIA|M. Alnawmasi, Optometry and Vision Science, Qassim University College of Science, Buraidah, Qassim, SAUDI ARABIA|

Commercial Relationships Disclosure (Abstract): Mohammed Alnawmasi: Commercial Relationship: Code N (No Commercial Relationship) | Sieu Khuu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Traumatic brain injury (TBI) is frequently associated with a variety of cognitive deficits, primarily attention and memory deficits. Typically, vision is used as an index of attention deficits following TBI and this study focussed on understanding the impact of TBI on visual attention and the degree to which the different attentional components and processes visual attention (such as selective, sustained, divided, and covert orientation of visual attention) are affected differently following TBI.

Methods: A systematic and meta-analytic review was conducted from research examining visual attention following TBI. A literature search before May 2020 was undertaken on different databases for studies that assessed visual attention using different tasks that target specific or multiple aspect or component of visual attention. Two hundred eighty-seven potentially relevant articles were identified through the literature search and the application of the inclusion and exclusion criteria yielded a total of 16 studies.

Results: A total of 103 effect sizes were estimated from 16 studies using the random effect model from 424 cases and 437 controls. The overall combined effect size suggests considerable impact of TBI on visual attention as it was statistically significant and large TBI, but with high heterogeneity (Effect size=0.92, $Q = 563.84$, $p < 0.0001$, $I^2 = 81.91\%$). Sources of heterogeneity may be due to TBI severity, the aspect of visual attention under investigation, and the use of different tasks and paradigms used to investigate them. Combined effect sizes for severe TBI was significantly higher than mild TBI ($t(92) = 2.63$, $p = 0.009$), indicating greater deficits in visual attention with more injury severity. The combined effect sizes for different aspects of visual attention were significantly different ($F(2, 100) = 9.682$, $p = 0.0001$). A subgroup analysis comparing outcome measures (for different aspects of attention) showed that reaction time was significantly more affected compared to performance accuracy ($F(1, 96) = 25.98$, $P < 0.0001$).

Conclusions: Large and significant deficit in visual attention was found following TBI which can last for years after the initial injury. However, different aspects of visual attention were not affected to the same extent. Future TBI studies and clinical approaches should consider this when investigating potential attentional deficits following TBI.

ABSTRACT BODY:

Purpose: To gain insight into the genomic organization and transcript composition of ABCA4, the gene responsible for Stargardt disease type 1, using publicly available human retina RNA-Seq datasets.

Methods: A total of 177 bulk RNA-Seq human retina data from non-visually impaired post-mortem donors were retrieved from publicly available expression databases (Pinelli et al., PMID:27235414 and Ratnapriya et al., PMID:30742112). We re-analysed the whole dataset using an ad-hoc designed pipeline. We removed samples with reported RNA integrity number (RIN) values lower than 5.0. Reads were then aligned and mapped to the GRCh38 release of the human genome. Samples with less than 10 million reads mapped and/or less than 70% of reads aligned to the reference genome were discarded. RNA-Seq alignments were assembled to generate an Observed Transcriptome allowing us to create a single set of assembled transcripts and to identify putative novel transcripts. To identify more abundant transcripts, we quantified transcript expression levels by scaling TPM abundance estimates per sample (scaled TPM). We selected ABCA4 transcripts with a median value higher than 50 scaled TPM counts.

Results: After quality control evaluation, we analysed a total of 161 bulk RNA-Seq samples. We focused our analysis of the ABCA4 genomic region, and identified 26 different ABCA4 transcripts, 14 of which are novel. The latter ones are the result of several partial intron retentions, exon skipping and extension along with a few putative novel exon additions.

Conclusions: This is, to the best of our knowledge, the most comprehensive and extended meta-analysis of the ABCA4 locus carried out relying on RNA-Seq data. Our work yielded a reliable expression quantification of the ABCA4 transcripts in the human mature retina, including 16 putatively novel ones, and paves the way towards a better understanding on the organization of this transcriptional unit and on the molecular mechanisms underlying ABCA4-related diseases.

ABSTRACT BODY:

Purpose: Retinal vein occlusions (RVOs) are known to be associated with several cardiovascular risk factors, but social determinants have been studied less frequently. Additionally, most studies have been conducted on predominantly white, Asian or local populations. Here, we assessed medical and socioeconomic risk factors for developing retinal vein occlusions (RVO) in a diverse nationwide population.

Methods: We performed a case-control study with data in All of Us, comparing 301 adults diagnosed with RVO to controls sampled from >250,000 participants matched by age, gender, and race/ethnicity. Data were extracted regarding demographics, co-morbidities, income, housing, insurance, and substance use. Multivariable logistic regression with bi-directional stepwise variable selection was performed to assess risk factors for RVO. Statistical significance was defined as $p < 0.05$.

Results: The mean (standard deviation) age of 301 adults with RVO in All of Us was 68.1 (12.2) years. The majority (58.7%) were female. Cases were diverse: 24.2% Hispanic or Latino, 25.5% Black or African American, 3.55% Asian and 46.1% white. Most (69.9%) were not currently employed, 38.5% had an annual income of \$25,000 or less, and 22.3% had Medicaid insurance. Traditional risk factors such as hypertension, glaucoma and diabetes mellitus were significantly associated with increased risk of RVO diagnosis (Table 1). Increasing annual income, increasing education level, and all forms of health insurance were associated with decreased risk of RVO, whereas current employment and past street opioid use were associated with increased risk of RVO (Table 1).

Conclusions: In addition to previously associated medical risk factors, multiple social determinants were found to be significant for RVO risk stratification. Past street opioid use was also a novel risk factor that merits further investigation. As a diverse national-level dataset, All of Us offers opportunities for a better understanding of social determinants of eye health, which can inform patient outreach and prevention efforts.

ABSTRACT BODY:

Purpose: Contact lens wear (CLW) can change the balance of the ocular surface environment by increasing evaporation and tear osmolarity. Maintaining ocular surface homeostasis during CLW is an important consideration for clinicians. A novel silicone hydrogel daily disposable (SiHy DD) lens has been developed to help reinforce the balance through integration of osmoprotective erythritol and glycerin polyols into the material and packaging solution. The purpose of this study was to use a transformed human corneal epithelial cell (THCEpiC) model to compare metabolic activity and inflammatory responses of the kalifilcon A(KA) packaging solution and 6 other SiHy DD packaging solutions subjected to hyperosmotic conditions.

Methods: THCEpiC were seeded in a 96 well plate, incubated for 72 hours, media was replaced with fresh basal medium, and the cells were incubated for 24 hours. The packaging solutions of kalifilcon A(KA), delefilcon A(DE), narafilcon A(NA), senofilcon A(SE), somofilcon A(SO), stenofilcon A(ST), verofilcon A(VE) were prepared at 25% and adjusted to a hyperosmolar condition (400 mOsm) with NaCl. 25% HBSS was used as the control. The THCEpiC were exposed to each packaging solution for 24 hours and the cell culture supernatant collected. An alamarBlue assay was performed to evaluate THCEpiC metabolic activity after exposure to the solutions. The cell culture supernatants were quantitated with ELISA specific immunoassays for the detection of inflammatory cytokine (IL-6) and chemokines (IL-8 and MCP-1).

Results: There was a reduction in THCEpiC metabolic activity with SE and SO solutions adjusted to 400 mOsm ($p<0.05$). For THCEpiC cells exposed to 400 mOsm adjusted solutions, there were significantly elevated levels of IL-6 with DE, NA, SE, and SO solutions, significantly elevated IL-8 with DE, NA, SE, SO, ST, and VE solutions and significantly elevated levels of MCP-1 with DE, SO, ST, and VE ($p<0.05$). Cytokine levels of THCEpiC cells exposed to KA 400 mOsm adjusted solution were not significantly elevated.

Conclusions: The novel KA solution exhibited better overall osmoprotective properties as compared to the six other SiHy DD solutions under hyperosmotic conditions. These results suggest that erythritol and glycerin polyols may have utility in reducing corneal epithelial cell response to hyperosmotic conditions associated with CLW.

ABSTRACT BODY:

Purpose: RhoA and its downstream effector ROCK play an important role in proangiogenic endothelial cell polarity, motility, and apoptosis, which are all processes involved in the development of neovascularization. Previous research has shown the use of inhibitors for both rhoA and ROCK to reduce corneal neovascularization (CNV) in alkali-burn induced mouse models. These studies demonstrate the use of these agents in corneal wound healing. Our study is designed to evaluate the effect of a commercially available rho-kinase inhibitor (Netarsudil) on established CNV in a PAX-6 knockout mouse model as regression of established CNV has the potential for visual improvement.

Methods: PAX-6 knockout mice are characterized by congenital iris hypoplasia, foveal hypoplasia and the development of CNV secondary to limbal stem cell deficiency, similar to PAX-6 aniridia in ophthalmic patients. 8 mice (16 eyes) will be divided into two treatment (8 eyes) and a placebo group (8 eyes). The study group is treated with Netarsudil ophthalmic solution (0.02 mg/mL). The placebo group is treated with balanced saline solution. Mice are randomized to be treated once daily or twice daily in one eye, with the opposite eye serving as the placebo. At the start of treatment, anterior segment photography is taken to document baseline CNV. Treatment lasts four weeks. At the end of treatment, mice will be euthanized for corneal immunostaining to quantify CNV.

Results: Two PAX-6 knockout mice are currently undergoing treatment. Two-week treatment results with slit lamp photography show significant CNV and opacification in both the treatment and control eyes (Figure 1). Ongoing treatment with additional mice as the colony grows will continue for 8 mice, based on a power analysis of a 20% expected decrease. The final outcome is percent area of CNV on corneal immunostaining.

Conclusions: This pilot study is designed to evaluate whether inhibition of rho-kinase using a topical, commercially available treatment can regress established CNV in an in vivo mouse model. Final results have the potential to impact future research directions for treatment of CNV.

Heussen, Werner H Spross-Stiftung, Zurich, SWITZERLAND|M.D. Becker, Eye Clinic, Ruprecht Karls Universität Heidelberg, Heidelberg, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure (Abstract): Vita Dingerkus: Commercial Relationship: Code N (No Commercial Relationship) | Gabor Somfai: Commercial Relationship(s);Novartis:Code C (Consultant);Bayer:Code C (Consultant);Allergan:Code C (Consultant) | Florian Heussen: Commercial Relationship: Code N (No Commercial Relationship) | Stephan Kinzl: Commercial Relationship: Code N (No Commercial Relationship) | Matthias Becker: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intravitreal injections (IVI) with prefilled syringes (PFS) are supposed to reduce procedure time and the risk of endophthalmitis. Postoperative rise in intraocular pressure (IOP) is suspected to lead to glaucomatous changes and there are informal reports that IOP can increase greatly following injections by the aflibercept PFS. Therefore, our aim was to analyze the emptying volumes (EV) of the aflibercept PFS depending on the injection technique.

Methods: The amount of the EV was assessed using 40 aflibercept PFS. We measured the EV in four different groups with 10 injections in each group: In the first two groups, the cone was set precisely at the indication line (Normal Volume, NV) and the fluid was ejected without (nP) or with forced pressure (wP) at the end of emptying the syringe (NVnP and NVwP groups). In two further groups, the plunger was set right below the line (High Volume, HV) and was ejected without or with forced pressure (HVnP and HVwP groups). A laboratory weighing scale (AX105 DeltaRange®, Mettler Toledo, Ohio) was used for the measurements of EV calculated with a density of 1.034 mg/ml. The EV data of the four groups were compared by one-way ANOVA test followed by post hoc Tukey HSD test.

Results: The EV values in the NVnP, NVwP, HVnP and HVwP groups were 56.06 ± 10.32 , 70.69 ± 4.56 , 74.22 ± 7.41 and 81.63 ± 3.67 µl, respectively. The EV was significantly different in the four groups (ANOVA $p < 0.001$, $F = 23.56$), the NVnP group was statistically significantly lower compared to all other groups ($p < 0.001$ in all comparisons). The EV in three cases (30%) was below 50 µl in the NVnP group (40.62, 42.35 and 45.64 µl) while in the NVwP group all values were above 64 µl, with 7 values (70%) exceeding 70 µl. In the HVwP group 8 measurements (80%) exceeded an EV of 80 µl.

Conclusions: Our results point toward the importance of the right injection technique with the aflibercept PFS to ensure the correct amount of drug intravitreally. With the right injection technique the drug can be underdosed in one third of the cases. 60% (30 µl) excess volume can be achieved by using suboptimal settings and injection technique. One explanation could be the design including the relatively high syringe diameter of the aflibercept PFS. This should be taken into consideration when applying them in the daily routine and might be addressed in future development of further PFS.

ABSTRACT BODY:

Purpose: Major vascular defects are observed in glaucoma patients, but the mechanisms underlying these alterations are poorly understood. Pericytes, the contractile cells that wrap along capillaries, regulate blood flow in response to metabolic demand. We recently identified inter-pericyte tunneling nanotubes (IP-TNTs), fine tubular processes that connect two distally-located pericytes and are essential for neurovascular coupling. Here, we asked whether pericytes/IP-TNTs contribute to neurovascular dysfunction in glaucoma.

Methods: Ocular hypertension (OHT) was induced by injecting magnetic microbeads into the anterior chamber of mice. Two-photon laser scanning microscopy was used for live imaging of retinal pericytes, IP-TNTs, calcium (Ca^{2+}) signals, light-evoked capillary dynamics and blood flow changes. Ca^{2+} influx induces pericyte contraction, thus we generated mice carrying a pericyte-specific Ca^{2+} indicator (NG2-GCaMP6), and mice with a pericyte-specific conditional deletion of the voltage-dependent Ca^{2+} channel alpha 1C subunit (Cav1.2) (CACNA1Cnull) for analysis of microvascular responses.

Results: Our data show early and sustained reduction of capillary diameter and blood flow at pericyte locations in eyes subjected to OHT relative to sham-operated controls (blood flow - sham: 15 ± 0.6 red blood cell (RBC)/s, OHT-2 weeks: 11.6 ± 0.8 RBC/s, $n=58-86$ capillaries, $N=5-6$ mice/group, Student's t-test $p<0.01$). Vascular deficits correlated with a substantial increase in the number of pericytes with elevated Ca^{2+} , visualized in NG2-GCaMP6 mice (sham: 11.9 ± 2.1 pericytes, OHT-2 weeks: 41.6 ± 2.4 pericytes, $n=167-235$ pericytes, $N=5-13$ mice/group, Student's t-test $p<0.001$). OHT led to IP-TNT rupture with consequent deficits in light-evoked neurovascular coupling (blood flow change - sham: 16.2 ± 3.6 %, OHT-2 weeks: 4.7 ± 1.0 %, $n=29-32$ capillaries, $N=5-6$ mice/group, Student's t-test $p<0.01$). Remarkably, selective blockage of Ca^{2+} influx to pericytes (CACNA1Cnull mice) restored capillary dynamics, blood flow, and light-evoked neurovascular coupling in glaucomatous retinas.

Conclusions: Early calcium-induced pericyte contraction in glaucoma leads to reduced capillary diameter/blood flow and IP-TNT rupture leading to neurovascular impairment. Our data reveal a critical role for pericytes in OHT-related vascular deficits, and suggest that restoration of Ca^{2+} homeostasis in pericytes is effective to rescue neurovascular function in glaucoma.

ABSTRACT BODY:

Purpose: Claudin-5, a tight junction protein enriched in retinal capillary endothelial cells, is a key modulator of inner blood-retina barrier (iBRB) integrity and paracellular permeability. Persistent suppression of claudin-5 in mice fed a high cholesterol diet (HCD) for several weeks has been shown to induce a geographic atrophy (GA) like phenotype. Here, we aim to characterise a potential new model of GA and further investigate the role of claudin-5 cycling at the iBRB. Claudin-5 expression levels were disrupted by inducing heterozygosity at the *Cldn5* locus in endothelial cells using the Cre-loxP system.

Methods: *Cldn5*^{Flx/wt}; Tie2-cre⁺ mice were generated using the Cre-loxP system. Specific expression of Cre recombinase, driven by the endothelial cell promoter, Tie2, allows *Cldn5* heterozygosity to be induced at the iBRB. Heterozygous mice were fed a normal or HCD, and after 6-10 weeks retinal cryosections were imaged and compared to wild-type littermate controls. Additionally, retinal macrophages and microglia were examined using immunohistochemistry and detected using F4/80, Cd68, and Iba1 staining. ImageJ software was used to quantify the relative level of staining in wild-type and heterozygous animals.

Results: Retinal claudin-5 was found to be decreased and an accompanying increase in macrophage markers were detected in the heterozygous mice. Histological analysis showed an accumulation of subretinal cells in heterozygous animals fed a HCD for 10 weeks. Additionally, some of these subretinal cells were CD68⁺, potentially indicating the presence of subretinal immune cells in these mice. A notable disruption of the RPE was evident.

Conclusions: Our results show that the integrity of the iBRB may influence macrophage recruitment to the retina. Claudin-5 has been shown to cycle under the control of the circadian clock transcription factor, BMAL1. It is hypothesised that disruption of this cycling pattern, a process that may occur with age or due to genetic risk factors, could perturb iBRB function, eventually leading to GA. Subretinal immune cell accumulation is another known hallmark of AMD. Therefore, this study further illustrates the important role of claudin-5 cycling and how a disruption in this process may be a key initiating factor in the development of AMD.

ABSTRACT BODY:

Purpose: Blindness is a crippling disability, resulting in higher risks of chronic health conditions. To better understand disparities in blindness risk, we identify risk factors upon first presentation using a large clinical database.

Methods: We performed a retrospective cross-sectional study using the Duke Glaucoma Registry (DGR). The DGR consists of electronic health records (EHR) of over 100,000 patients seen at the Duke Eye Center from 2009 to 2018. Our cohort included patients with glaucoma and a minimum of one good quality visual field and visual acuity measure recorded within 90 days of a first glaucoma encounter (defined as baseline). International Classification of Diseases codes were used to identify glaucoma and exclude concurrent diseases. Patients were classified as being blind by the definition of legal blindness (i.e., central visual acuity less than or equal to 20/200 with correction or a visual field less than or equal to 20 degrees in the better eye). Baseline risk factors included gender, race (Caucasian vs. African American/Black), marital status (married vs. single), intraocular pressure (IOP; measured by Goldmann applanation tonometry), and a history of diabetes. Odds ratios (OR) and 95% confidence intervals (CI) were calculated for risk factors using both univariable and multivariable logistic regression.

Results: Our cohort consisted of 8,694 glaucoma patients with a complete set of covariates, with 324 (4%) blind upon first presentation. In univariable models, African American/black race (OR: 2.16; 95%CI 1.71, 2.74), single marital status (1.68; 1.32, 2.13), a 10-year increase in age (1.20; 1.10, 1.32), and a standard deviation increase in IOP (1.23; 1.11, 1.35), were all associated with an increased risk of presenting with legal blindness. These associations remained significant in a multivariable regression, with male gender becoming significant (1.42; 1.12, 1.79).

Conclusions: Using a large real-world clinical database, we identified risk factors associated with presentation to blindness among glaucoma patients. Our results highlight disparities in healthcare outcomes and indicate public health outreach for vulnerable communities can reduce differential outcomes in blindness.

TITLE: The diagnostic accuracy of Optic Coherent Tomography Angiography (OCTA) in Central Asians with primary open angle glaucoma (POAG) suspects, POAG and normal subjects.

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Khujatova, Corporate fund University medical center, Nazarbayev University School of Medicine, Nur-Sultan, KAZAKHSTAN|A. Talaspayeva, M. Khujatova, Department of Ophthalmology, Republican Diagnostic Center, Nur-Sultan, KAZAKHSTAN|A.S. Khouri, Rutgers New Jersey Medical School Department of Ophthalmology & Visual Science, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Assel Talaspayeva: Commercial Relationship: Code N (No Commercial Relationship) | Madina Khujatova: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To test and identify diagnostic accuracy of a single OCTA in Central Asians for differentiating among normal subjects, POAG suspects and POAG compared to clinical examination.

Methods: Data from Central Asians (Kazakh, Korean, N=59) with confirmed POAG, POAG suspects and healthy subjects age 27 -76 yr were collected. Patients with different stages of glaucoma were included. Visual acuity, refraction, IOP (non contact tonometer, Shin-Nippon NCT -200), slit lamp and fundus examination, ultrasound biometry of lens and vitreous (Alcon Ultrascan B-Scan + A-scan), visual field (HFI 750i, Carl Zeiss), anterior segment (AngioVue OCTA ,Optovue Inc.) were obtained. Anterior chamber parameters were measured. The optic nerve was measured and analyzed in all patients with OCTA (AngioVue, Optovue Inc.). Parameters included RNFL analysis, ONH analysis, GCC analysis, TSNIT NDB Reference.

OCTA images interpretation with a single-page report were exported and analyzed by independent, experienced glaucoma imaging expert, according to a specified grading protocol. The OCTA reader was blinded to any clinical patient information, such as the patient's medical history, visual acuity, IOP, fundus examination, etc.. The OCTA reader assessment was compared to the standard of care clinical examination which had access to exam and all ancillary testing.

Results: An OCTA analysis gave an overall classification rate of 85%.

With two outputs (normal subject, POAG suspect) of OCTA analysis the specificity was 87% and sensitivity 91.4%. The specificity of OCTA for the detection of POAG was 86.6% with sensitivity of 92.5%

Conclusions: A single OCTA assessment demonstrated good diagnostic accuracy when compared to comprehensive exam in its ability to differentiate glaucoma patients from glaucoma suspect and normal subjects in Central Asians. This findings demonstrates that OCTA is a valuable adjunctive tool to assist in glaucoma diagnosis and may provide a method for diagnosis remotely which has value during the COVID pandemic.

TITLE: Oxidative stress in Anterior Segment of Acute Primary Angle-Closure Eyes and Its Correlation with Senescence-Associated Secretory Phenotype

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Huang, D. Ye, Y. Xu, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA]

Commercial Relationships Disclosure (Abstract): Jingjing Huang: Commercial Relationship: Code N (No Commercial Relationship) | Dan Ye: Commercial Relationship: Code N (No Commercial Relationship) | Yue Xu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sudden and dramatic elevation of intraocular pressure (IOP) in acute primary angle closure (APAC) can lead to pathological changes of anterior segment. So far, the mechanisms that connect the two processes are still unknown. We performed a cross-sectional study to evaluate the levels of oxidative stress in anterior segment of APAC eyes and its correlation with senescence-associated secretory phenotype (SASP).

Methods: This study includes 21 patients with APAC, 22 age-matched control patients with age-related cataract (ARC) patients and 5 healthy age-matched donors. Aqueous humor (AqH) samples and iris tissues were collected. Oxidative stress markers in AqH were estimated by relevant reagent kits. The levels of SASP-related cytokines were measured by the multiplex bead immunoassay technique. Immunofluorescence staining was performed to examine the intensity of oxidative stress markers and senescence-associated markers in the iris.

Results: The levels of ROS, MDA, 8-OHdG, SOD and GSH/GSSH ratio were significantly elevated in APAC eyes ($p < 0.001$). ROS levels were increased in older and higher preoperative IOP eyes ($p < 0.01$). Besides, several SASP-related cytokines (GRO α , VEGF- α , TNF- α , IL-1 α , IL-6, IL-8, MMP-10, MMP-10, IGFBP5, IGFBP7, MCP-1, MIP-1 α , TGF- β 1, CCL-2; $p < 0.5$) significantly elevated in the AqH of APAC eyes. Among those cytokines, ROS and MDA were positively correlated with some SASP-related cytokines ($p < 0.01$), while SOD and GSH/GSSH ratio did the opposite. Increased positive cells of oxidative mtDNA damage marker 8-OHdG, apoptosis related marker (Bcl-2, Bax, Bcl-xl, CREB, cleaved caspase-3), and senescence-associated marker (p16, p21 and p53) were detected in the iris tissues of APAC group ($p < 0.001$).

Conclusions: Collectively, we first found that the increase of oxidative stress and premature senescence in the anterior segment of APAC patients. Additionally, the levels of oxidative stress were positively correlated with age, highest preoperative IOP and levels of SASP-related cytokines. These results suggested that there is an important relationship between oxidative stress and premature senescence, and the two factors may be involved in the development of anterior segment pathological changes in APAC eyes.

TITLE: Hyperosmolar eye drops for diurnal corneal edema in Fuchs endothelial dystrophy: a double-blind randomized-controlled trial

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Wacker, D. Zander, D. Böhringer, M. Fritz, V. Grewing, T. Lapp, P. Maier, T. Reinhard, Eye Center, Faculty of Medicine, Albert-Ludwigs-Universität Freiburg, Freiburg im Breisgau, GERMANY|

Commercial Relationships Disclosure (Abstract): Katrin Wacker: Commercial Relationship(s);ProQR Therapeutics:Code C (Consultant) | Daniel Zander: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Böhringer: Commercial Relationship: Code N (No Commercial Relationship) | Marianne Fritz: Commercial Relationship: Code N (No Commercial Relationship) | Viviane Grewing: Commercial Relationship: Code N (No Commercial Relationship) | Thabo Lapp: Commercial Relationship: Code N (No Commercial Relationship) | Philip Maier: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Reinhard: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the efficacy of hyperosmolar eye drops on corneal edema resolution.

Methods: The double-blind randomized-controlled Eye Drops for Early Morning-Associated Swelling (EDEMAS) trial included participants without ocular comorbidities other than Fuchs' dystrophy scheduled for Descemet membrane endothelial keratoplasty (DMEK). One eye was randomized to hyperosmolar eye drops (treatment), while the fellow eye was randomized to artificial tears (placebo). After a baseline exam in the afternoon, participants' corneas were examined using Scheimpflug tomography after eye opening in the hospital in the morning. Imaging was repeated every 30 minutes up to four hours. Participants received eye drops twice. Primary endpoint was decrease in central corneal thickness one hour after eye opening. Secondary endpoints were corneal thickness, subjective visual function, glare, visual acuity, and adverse events over the duration of the study.

Results: 68 participants received the allocated intervention (59 eyes treatment, 55 eyes placebo). Corneal thickness was 626 μm in the treatment arm and 622 μm in the placebo arm after eye opening, indicating an early-morning edema compared to baseline of +21 μm and +24 μm , respectively. Decrease in corneal thickness after one hour was -10.5 μm in the treatment arm (95% CI, -12.8 to -8.2) and -11.2 μm (95% CI, -13.6 to -8.9) in the placebo arm (between-arm difference, 0.7 μm , 95% CI, -2.0 to 3.5; $p = 0.59$), indicating no effect of hyperosmolar eye drops on early-morning associated corneal edema. Corneal thickness decrease, and improvement of visual acuity and glare over the entire course of the study duration were not different between treatment and placebo. Subjective visual function tended to be worse in the treatment arm. Adverse events, most commonly burning after eye drop application, were more common with treatment (30 eyes) than placebo (1 eye; risk difference, 49 percentage points; 95% CI, 36 to 62).

Conclusions: In the double-blind randomized-controlled EDEMAS trial, resolution of early-morning associated edema was not accelerated by hyperosmolar eye drops, which frequently caused adverse events. These results are not compatible with a clinically meaningful effect of hyperosmolar eye drops in Fuchs' dystrophy and do not support their routine use.

ABSTRACT BODY:

Purpose: Aging is the major risk factor for age-related macular degeneration (AMD) but how 'normal' aging contributes to AMD pathogenesis is unclear. Epigenetic mechanisms, mainly methylcytosine (mC) and hydroxymethylcytosine (hmC), affect DNA accessibility, regulate genomic organization and gene expression, and are altered with aging. DNA methylation analyses of AMD patient blood and retinas suggest differential methylation resulting in gene expression changes during development/progression of AMD. In addition, Müller glia are activated in AMD patient retinas. The aim of this study is the validation of a cre/ERT2-NuTRAP mouse model to allow the parallel interrogation of differential mC/hmC genome-wide and the transcriptome specifically in Müller glia with retinal aging.

Methods: Female NuTRAP^{flox/flox} and male Aldh111-cre/ERT2^{+/-wt} mice were bred to generate Aldh111-cre/ERT2^{+/-wt}; NuTRAP^{flox/wt} (Aldh111-cre/ERT2⁺; NuTRAP⁺) mice. At 5 months old, mice received single intraperitoneal injections of tamoxifen (Tam) for 5 consecutive days (100 mg/kg) or were left untreated as controls. After Tam induction mice were euthanized and their retinas harvested and processed for: immunohistochemistry of mCherry, EGFP, GS, and GFAP expressions on retina sagittal sections via confocal microscopy; ribosome bound RNA isolation via TRAP protocol, qPCR validation and stranded RNA-Seq profile; and nuclei suspension preparation and DNA isolation via INTACT method for bisulfite amplicon sequencing (BSAS).

Results: Specific co-localization of EGFP, mCherry, and the Müller glia marker GS was observed in the Aldh111-cre/ERT2⁺; NuTRAP⁺ retinas. RNA-seq bioinformatic analysis revealed enrichment of Müller marker genes and pathways and depletion of other cell type markers in the positive TRAP fraction of Aldh111-cre/ERT2⁺; NuTRAP⁺ retinas, compared to input profiles. qPCR validated enrichment and depletion of selected transcript expressions. BSAS showed site-specific decrease of mC in the promoter region of selected Müller glia-specific genes in INTACT-DNA positive fraction relative to input.

Conclusions: The selective recombination in Müller glia, cell-specific transcriptome enrichments found via TRAP-RNAseq and qPCR, and BSAS findings, suggest the Aldh111-cre/ERT2; NUTRAP model is suitable for the study of Müller glia and its contributions to the transcriptome/epigenome of the aging retina.

TITLE: Impact of visual changes on falls and postural control in patients diagnosed with senil cataract in Anápolis, Goiás, Brazil

SESSION TITLE: Visual Function, Vision QoL and visual impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.A. Nassaralla, D.A. Oliveira, Medical, UniEVANGELICA Centro Universitario de Anapolis, Anapolis, GO, BRAZIL|

Commercial Relationships Disclosure (Abstract): Anna Paula Nassaralla: Commercial Relationship: Code N (No Commercial Relationship) | Deise Oliveira: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this study is to compare the risk of falls, depression symptoms and postural balance in the elderly before and after facectomy.

Methods: This is a cross-sectional study consisting of 17 individuals of both sexes aged ≥ 40 years, diagnosed with cataracts. Data collection was carried out in two phases (the first phase before and the second after facectomy) using the same questionnaires and tests in both of them. They were performed from January 2020 to March 2020. In each phase, all patients responded to two tests of balance and locomotion, identification, quality of life related to visual function and analysis of questionnaires of depressive symptoms. In all analyzes, the same level of significance was used ($p < 0.05$).

Results: Regarding the general characteristics of the sample, 17 patients were analyzed, with a mean age of 65 years, 70.6% of whom were female. Of the total number of patients, 11 of them were afraid of falling and, after the procedure, this number decreased by 8. When analyzing the depressive symptoms, which can induce falls, 82.3% of the patients showed improvement, punctuating before the facectomy an average of 32.06 (SD ± 6.67) and after the facectomy an average of 30.53 (SD ± 8.22), being statistically significant ($p < 0.05$). As for the quality of life related to routine activities, such as climbing stairs and identifying environmental obstacles, all patients reported levels of difficulty in the preoperative period, but in the post-facectomy, 64.7% and 58.8% of the patients had no difficulty to climb stairs and identify environmental obstacles, respectively, with an average score of 92.88 (SD ± 15.61) in the first application of the questionnaire and resulting in an average score of 98.18 (SD ± 12.71), being statistically significant ($p < 0.05$).

Conclusions: It is primordial to analyse a multicausal risk factors for falls , however, it was found with the data raised that cataracts is an independent factor for falls. The surgical procedure increased patients' dexterity and confidence when referring to walking.

TITLE: PEDF protects photoreceptors via a CRX-dependent mechanism

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Rebutini, S. Becerra, Section on Protein Structure and Function, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ivan Rebutini: Commercial Relationship: Code N (No Commercial Relationship) | S Patricia Becerra: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pigmented Epithelium-Derived Factor (PEDF) is a neuroprotective peptide expressed and secreted by the Retinal Pigmented Epithelium (RPE) and protects photoreceptors from apoptosis during genetic- related retinal degeneration such as Retinitis Pigmentosa (RP). PEDF-derived peptides protect photoreceptors from apoptosis in rd10 mice, a RP model with mutated Phosphodiesterase 6b (PDE6b). Many forms of RP are also associated with dysregulation of Cone and Rod Homeobox (CRX), which is a transcription factor necessary for photoreceptors differentiation and regulates the transcription of more than 700 genes associated with photoreceptors function, among them the Phosphodiesterase 6a (PDE6a), which is involved in the visual phototransduction system in the photoreceptors. Although rod photoreceptors express both PDE6a and PDE6b phosphodiesterase subunits, it is unclear whether there is a compensatory mechanism involving PEDF signaling and CRX expression in mouse models of RP. The purpose of this study is to address whether the mechanisms of PEDF-induced photoreceptor protection involves CRX expression and its regulatory gene network.

Methods: We employed a wild-type mouse retinal explant model and Zaprinstat, a broad-range phosphodiesterase inhibitor to establish a model of general induction of photoreceptor cell death and define the molecular mechanisms of PEDF as neuroprotective to photoreceptors. We used whole mount immunofluorescence after treating the mouse retinal explants with combinations of PEDF and Zaprinstat, to characterize cellular processes such as apoptosis via TUNEL and the expression of CRX and various photoreceptor markers by confocal microscopy super resolution imaging.

Results: We established a quantitative imaging methodology to assess photoreceptors maintenance and survival in mouse retinal explants by using super resolution confocal microscopy, and found that PEDF treatment increased CRX expression in surviving photoreceptors in Zaprinstat-treated retinal explants and decreased apoptosis, suggesting that PEDF signaling regulates photoreceptors survival via a CRX-dependent mechanism.

Conclusions: We postulate that CRX expression is downstream to PEDF signaling and is a regulatory key component for photoreceptor survival upon retinal degeneration disease induction.

TITLE: Compensatory phagocytic function and effects on Müller glia in the absence of microglia

SESSION TITLE: Glial Cells

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D.M. Mitchell, Z. Blume, R. Dimico, Biological Sciences, University of Idaho College of Science, Moscow, Idaho, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Diana Mitchell: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Blume: Commercial Relationship: Code N (No Commercial Relationship) | Ren Dimico: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Both microglia and Müller glia have been shown to phagocytose dying cells in the vertebrate retina, but the phagocytic activities and respective loads of these two cell types appear to differ depending on context. In the zebrafish retina, microglia appear to act as the primary phagocytes during development (Blume et al., 2020, Dev Dyn) while both cell types may phagocytose dying cells in contexts of disease or injury. Müller glia (MG) act as the source of regenerated retinal neurons in zebrafish, and there is a possible link between MG phagocytic activity and the regenerative response. In addition, microglia appear to influence the outcome of retinal regeneration though their functions in this regard are not well understood. We hypothesized that in the absence of microglia, Müller glia take on the primary phagocytic role to clear apoptotic cells during retinal development and that increased phagocytic load may result in changes in MG-expressed genes known to be associated with damage and regenerative responses.

Methods: Developing retinas from microglia deficient mutant zebrafish and wildtype (wt) siblings were stained and imaged by confocal microscopy to visualize apoptotic cells (TUNEL) and MG (GS). Total numbers of TUNEL+ cells and those phagocytosed by MG were quantified in whole retinas (n=11-13). To analyze MG entry into the cell cycle, retinal cryosections were stained for PCNA and GS and the total number of PCNA+MG were quantified in images from microglia-deficient and wt siblings (n=4-6). Expression of gfap and ascl1a were determined by qPCR (1 pooled sample from 5-10 embryos per genotype).

Results: We found increased accumulation of TUNEL+ cells in microglia deficient retinas compared to wt ($p<0.0001$), and increased numbers but not proportions of TUNEL+ cells engulfed by MG ($p<0.0001$). There was a modest increase in numbers of PCNA+MG in microglia deficient retinas (n=4-6, $p=0.008$). Preliminary data indicated a modest increase in gfap (~1.8 fold), but not ascl1a in microglia deficient retinas compared to wt.

Conclusions: In the absence of microglia, Müller glia increase phagocytic load to clear dying cells from the developing retina. However, it appears they are less efficient than microglia at clearance of engulfed cells. Increased phagocytic activity may induce Müller glia proliferation and increase expression of gfap, however phagocytosis alone does not induce a robust regenerative response.

ABSTRACT BODY:

Purpose: To characterize the pupil light responses (PLR) for small focal chromatic light stimuli presented in peripheral and central retinal locations in patients with a mass effect due to brain tumors with no apparent contact with the visual or PLR systems.

Methods: The PLR for small (0.43°) blue and red-light stimuli presented at peripheral (21°) and central (4.2°) visual field (VF) locations were measured using chromatic pupilloperimetry in 6 patients with brain tumors with no apparent contact with the visual or PLR systems and 32 age-similar controls. All subjects underwent a complete ophthalmic exam, standard Humphrey automated perimetry (24-2), color vision test, best-corrected visual acuity, refraction and Spectral-Domain Optical Coherence Tomography (SD-OCT) imaging. All patients underwent brain MRI before and following tumor removal surgery.

Results: The SD-OCT thicknesses of macular ganglion cell and inner plexiform layers, as well as peripapillary retinal nerve fiber layer, were within normal limits in all patients. Differences in cone-mediated PLR were statistically insignificant between patients and controls. By contrast, rod-mediated percentage of maximal pupil contraction was significantly lower in patients compared to controls in the center of the VF (mean \pm SD: 11% \pm 4 % vs. 16 % \pm 5 %, $p=0.028$, ROC AUC=86.6%, $p=0.005$). Melanopsin-mediated PLR was attenuated in the peripheral VF ($p=0.005$, ROC AUC=95.3% $p=0.001$). The rod- but not the melanopsin-mediated PLR recovered by 4 weeks post-OP.

Conclusions: Chromatic pupilloperimetry may present a fast, objective non-invasive test for diagnosis and monitoring of patients with brain tumors with no apparent contact with the visual or PLR systems. Short and long term mass effects on PLR pathways can be identified by multiparametric analysis of the PLR for focal chromatic stimuli at central and peripheral VF. Localized melanopsin-mediated sustained PLR may provide a novel surrogate biomarker for mass effects.

ABSTRACT BODY:

Purpose: To characterize baseline, follow-up, and testing attributes of a real-world population with non-proliferative diabetic retinopathy (NPDR) and to report progression to proliferative diabetic retinopathy (PDR).

Methods: Retrospective study of patients with diagnosis of diabetes and NPDR based on clinical exam performed at Cleveland Clinic Cole Eye Institute from January 2012 to February 2020. Patients must have had at least 365 days of follow-up after the NPDR index date, and at least two ophthalmic visits during follow-up. Basic descriptive stats were used for a survival analysis with time to PDR. Diagnosis of PDR was determined by initiation of treatment with anti-VEGF or panretinal photocoagulation (PRP) and an ICD-9 or 10 PDR diagnosis.

Results: The cohort consisted of 4555 patients; 10% (435/4474) developed PDR (23.6 cases per 1000 person-years) during follow-up [median, interquartile range (IQR) = 2.9 years (1.8, 4.1)]. The median age of patients was 66 years at baseline; half were female; 25% were Black, and 4053 (89%) had a diagnosis of type 2 diabetes. 1595 patients (35%) had concurrent eye diseases. On average, each patient had approximately 8 retinal images collected (optical coherence tomography, color fundus photographs and/or fluorescein angiography). Of the patients who received anti-VEGF treatment in the first year after NPDR index date (n=572), the median (IQR) real-world frequency of anti-VEGF injections was 5 (2, 9) in the first year. Of the patients who received PRP in the first year after NPDR index date (n=134), the median (IQR) real-world frequency of PRP was 2 (1, 3) in the first year. Over 80% of patients had 20/40 or better visual acuity (VA) in the right (83%) or left eye (82%) at index date.

Conclusions: Real-world data may provide meaningful insights to the characterization of patients and eyes with NPDR and higher risk of progression to PDR. Further data analysis in this cohort as well as future studies to elucidate how retinal imaging and VA correlate in diabetic retinopathy (DR) may lead to better characterization of DR disease phenotypes and aide in further development of algorithms or therapeutics for DR management at all stages.

TITLE: Assessing different combinations of B-scan repetitions to improve detection of flow in optical coherence tomography angiography

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Lewis, S. Kubach, L. De Sisternes, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|T. Bacci, Vitreous Retina Macula Consultants of New York, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Warren Lewis: Commercial Relationship(s);Carl Zeiss Meditec, Inc:Code C (Consultant) | Sophie Kubach: Commercial Relationship(s);Carl Zeiss Meditec, Inc:Code E (Employment) | Luis De Sisternes: Commercial Relationship(s);Carl Zeiss Meditec, Inc:Code E (Employment) | Tommaso Bacci: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal optical coherence tomography angiography (OCTA) is based on the comparison between successive B-scans taken in the same location. Differences between these repetitions are usually due to moving blood. This study examines the effect of using longer time intervals on the detection of flow.

Methods: High resolution retinal OCTA scans usually comprise sets of 4 repeated B-scans, which may be arranged in 3 pairs and processed and averaged to make flow B-scans. In this study, the B-scans in each of these pairs were separated by a time interval ($\Delta t_0 \approx 3.2$ msec) equal to the time between successive B-scans. In addition to this approach, we also used different pair definitions to achieve longer time intervals.

3x3mm OCTA scans were acquired with a PLEX® Elite 9000 (ZEISS, Dublin, CA) and exported as raw amplitude and phase data. 17 eyes from 14 patients were included in the analysis. These scans were processed using a custom angiography algorithm that allowed selection of the repetitions combined to produce the flow signal.

In addition to using sequential scans to calculate flow, new flow B-scans were created by averaging results from comparing repetitions 1- 3, 2- 4, and 1- 4, with time intervals $2\Delta t_0$, $2\Delta t_0$ and $3\Delta t_0$ respectively. The resulting images were compared, and vessel density was calculated in the 4 zones of the inner ETDRS ring.

Results: Figure 1 shows vasculature visualized from combining pairs of temporally adjacent B-scans and the results of redefining these pairs. There is better detection of flow in small vessels, along with some increase in noise, when using pairs having larger values of Δt . Figure 2 shows increased vessel density in the latter method for this test set.

Conclusions: Using B-scan pairs with longer time intervals results in increased sensitivity to flow and better visualization of vascular structure.

TITLE: OCU200 (transferrin-tumstatin fusion protein): A potential therapeutic for DME, DR, and wet-AMD

SESSION TITLE: Cytokines, growth factors, anti-inflammatory

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A.K. Upadhyay, R. Arumugham, P. Naha, D. Singh, R&D, Ocugen, Inc., Malvern, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Arun Upadhyay: Commercial Relationship(s);Ocugen, Inc.:Code E (Employment) | Rasappa Arumugham: Commercial Relationship(s);Ocugen, Inc.:Code C (Consultant) | Pratap Naha: Commercial Relationship(s);Ocugen, Inc.:Code E (Employment) | Dinesh Singh: Commercial Relationship(s);Ocugen, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Purpose of this study was to evaluate efficacy of OCU200 in in-vitro and in-vivo models for ocular neovascular diseases. Angiogenesis and neovascularization are hallmarks for diabetic macular edema (DME), diabetic retinopathy (DR), and wet age-related macular degeneration (wet-AMD). Most approved therapeutics target vascular endothelial growth factor (VEGF), a pro-angiogenic factor with neurotrophic and neuroprotective effects. However, these therapies are effective only in about 50% of patients. OCU200 is a fusion protein designed to have improved efficacy in DME, DR, and wet-AMD patients.

Methods: Effect of OCU200 on in-vitro cell proliferation, invasion and tube formation were assessed by MTT assay, scratch assay and endothelial cell culture on basement membrane matrix, respectively. In -vivo efficacy was evaluated in an oxygen-induced retinopathy (OIR) mouse model (age-P12), dosed intravitreally with various doses of OCU200 (2.5, 5.0, and 10 µg/eye) and compared to an approved anti-VEGF positive control (aflibercept, 20 µg/eye). Retinal tissues were collected at P18 age to assess avascular areas (AVAs) and neovascular tufts (NVs) areas of Isolectin GS IB4 immunostained retinal flat mounts. AVA and NVs regression in retina indicate therapeutic benefit of test compound. Quantitative data was analyzed by paired Student's t test or One-Way ANOVA followed by Dunnett's or Tukey's multiple comparisons test.

Results: OCU200 inhibited cell proliferation, cell invasion and tube formation by endothelial cells. In OIR mice, OCU200 significantly reduced avascular areas at low dose (68% reduction, $P < 0.05$) and high dose (68% reduction, $P < 0.05$), and significantly reduced neovascular tufts (NVs) at low dose (59% reduction, $P < 0.05$) and high dose (58% reduction, $P < 0.05$) compared to vehicle-treated eyes. Aflibercept reduced NVs by 77% ($P < 0.01$). OCU200 showed comparable activity to aflibercept at 2 to 8-fold lower doses.

Conclusions: OCU200 acts on endothelial cells specifically to decrease cell proliferation, cell invasion, and tube formation. In addition, the in vivo results suggest that OCU200 is efficient in reducing neovascularization and damage to retina in mouse OIR model and has comparable/slightly improved activity to aflibercept. These findings demonstrate OCU200 as a potential therapeutic for the treatment of DME, DR, and wet-AMD.

TITLE: Identification of Barriers to Timely Diagnosis of Central Retinal Artery Occlusion and Treatment with Tissue Plasminogen Activator

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Buchowicz, L. Vander Woude, S.S. Iyer, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|J. Wiese, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bryce Buchowicz: Commercial Relationship: Code N (No Commercial Relationship) | Logan Vander Woude: Commercial Relationship: Code N (No Commercial Relationship) | Siva Iyer: Commercial Relationship: Code N (No Commercial Relationship) | Jon Wiese: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Central retinal artery occlusions (CRAOs) are newly characterized as stroke equivalents and may benefit from tissue plasminogen activator (tPA); however, barriers to presentation and evaluation in the timeframe for tPA administration limit our ability to study potential treatments. We performed an observational study to identify and quantify barriers to timely diagnosis of CRAOs.

Methods: This study included 41 newly diagnosed CRAO patients who presented to the University of Florida Emergency Department (ED) or Ophthalmology Clinic between 1/1/2012 and 3/23/2020 as identified using the ICD-9 and ICD-10 codes for "CRAO". Patients were excluded if they presented with concurrent stroke symptoms, had a clearly identified surgical or traumatic etiology, or had decreased mental capacity affecting the accuracy of reported symptoms. Primary outcomes measured were time to presentation after symptom onset, and times from arrival to exam by ED physician, ophthalmology consult, and ophthalmology exam. Statistical analysis included the mean and standard deviation of these outcomes, including further stratification at the 4-hour mark (the requirement for possible tPA administration).

Results: The average time to presentation after onset of vision loss was 38.16 ± 54.43 hours. 11 of 41 of patients presented within 4 hours with an average presentation time of 148 ± 47.82 minutes; however, only 4 of those patients were diagnosed by an ophthalmologist within the window for tPA administration. Of those presenting within 4 hours, the average time from arrival to exam by ED physician, ophthalmology consult, and ophthalmology exam were 28 ± 20.85 , 65 ± 26.2 , and 108 ± 28.79 minutes, respectively. Among all patients, these times were 35 ± 45.69 , 101 ± 26.0 , and 127 ± 61.46 minutes, respectively.

Conclusions: The barriers to timely diagnosis of CRAO include early identification of symptoms and realization of systemic severity by patients and emergency medical services. In addition, there are delays in triage and evaluation by ED and ophthalmology teams, for which we propose a novel protocol to hasten diagnosis (Figure 1). This protocol has been adapted at the University of Florida Shands Emergency Department; further studies will be conducted using this protocol to examine its utility.

ABSTRACT BODY:

Purpose: Pathogenic variants in the PNPLA6 gene cause a broad spectrum of neurological disorders such as spastic paraplegia type 39 (SPG39), Gordon-Holmes syndrome (GHS), Boucher-Neuhauser syndrome (BNHS), Laurence-Moon syndrome (LMS), and Oliver-McFarlane syndrome (OMS). PNPLA6 encodes Neuropathy Target Esterase (NTE), yet it's unclear why NTE enzymatic dysfunction causes early childhood onset retinopathy in a subset of patients. Here, we investigate the relationship between PNPLA6 genotype-associated enzymatic activity and risk of retinal degeneration.

Methods: PNPLA6 variants were detected by NGS, sanger sequencing, and digital droplet PCR. Clinical meta-analysis was performed on 133 previously reported patients by literature search (PubMed, 2008-2020). Statistical analysis was performed in Prism. DNA constructs containing full length NTE underwent site directed mutagenesis to produce the patient specific proteins. NTE activity was determined as previously published (PMID:12791540). Intronic variants were assessed for splice alterations by minigene assay.

Results: Biallelic pathogenic PNPLA6 variants were detected in ten patients with clinical diagnosis of SPG39, BNHS or OMS, including 7 novel variants. Clinical meta-analysis of these and 75 previously reported genotyped patients indicated significant differences in ophthalmic and endocrinologic symptom onset between clinical diagnosis categories. Intriguingly, patients with early onset retinopathy were not more likely to harbor truncating variants, and no differences in disease onset or tissues affected were found between those with and without truncating variants. To examine effects of missense alleles on phenotype, we measured activity in 17 variants observed in two or more patients with the same clinical diagnosis. Residual esterase activity of recurrent missense variants observed in patients with retinopathy was significantly lower compared to those without reported visual symptoms.

Conclusions: Molecular determinants of retinal disease onset is different among clinical diagnoses of PNPLA6-opathies. Enzyme activity of recurrent disease-associate missense variants indicates a relationship between enzymatic activity and likelihood of retinopathy, implicating missense variants as drivers of tissue-specific disease onset. This supports a genotype:activity:phenotype relationship among PNPLA6-opathies that may be valuable for both diagnosis and prognosis.

ABSTRACT BODY:

Purpose: Conjunctiva of the eye is a mucosal immune tissue and harbors a variety of immune cells. It is exposed to diverse microorganisms that come in contact with the ocular surface. Previously, we demonstrated that colonization of the ocular mucosa with the commensal bacterium, *Corynebacterium mastitidis* (C. mast), results in increased resistance of the ocular surface to infectious fungal and bacterial pathogens, and that this effect is mediated by IL-17A produced by $\gamma\delta$ T cells that respond to C. mast. In this study, we investigate the role of TLRs in this process.

Methods: TLR on immune cells at the ocular surface before and after C. mast inoculation in WT, TLR2^{-/-} and TLR4^{-/-} mice. After 28 days, immune cells and their IL-17A production were quantitated in the conjunctiva and eye-draining lymph nodes (DLN) by flow cytometry. To investigate the function of TLRs on $\gamma\delta$ T cells, we co-cultured TLR^{-/-} $\gamma\delta$ T cells with WT CD11c⁺ APC and heat killed C. mast. IL-17A production was quantitated by ELISA and by intracellular cytokine staining. Transcriptomic analysis by RNA-Seq and cellular metabolism by Seahorse assay were performed to confirm pathway analysis results.

Results: Significant increase of TLR2 expression was observed on $\gamma\delta$ T cells in WT mice after C. mast inoculation. TLR2^{-/-} mice failed to recruit $\gamma\delta$ T cells and neutrophils to the conjunctiva upon C. mast inoculation, and IL-17A-producing $\gamma\delta$ T cells were reduced in DLN. In vitro, IL-17A production in response to C. mast by $\gamma\delta$ T cells was dependent on TLR2 expression in both $\gamma\delta$ T cells and APCs. Exogenous IL-1 β or WT APC only partly restored IL-17A production by TLR2^{-/-} $\gamma\delta$ T cells, indicating a need for another TLR2-dependent signal. Kinetic experiments and RNA-Seq analyses demonstrated the dependence of IL-17A production and IL-17A-related gene expression on $\gamma\delta$ -expressed TLR2, which was higher in the V γ 6 than in the V γ 4 subset. Notably, transcriptomic analysis implicated dysregulation of mitochondrial pathways as a result of TLR2^{-/-} deficiency in $\gamma\delta$ T cells, which was functionally confirmed by the Seahorse assay.

Conclusions: Sensing of the commensal C. mast by $\gamma\delta$ T cells requires cell-intrinsic TLR2 expression to maintain their metabolism and function, in order to drive local IL17 response and maintain immune homeostasis at the ocular surface.

ABSTRACT BODY:

Purpose: A reduction of choroidal thickness is generally thought to be associated with the outcomes of photodynamic therapy (PDT) for pachychoroid spectrum diseases (PSD). We performed a retrospective chart review to investigate whether the reduction of choroidal thickness after PDT may influence the visual and anatomical outcomes in PSD.

Methods: Fifty-three eyes of 53 patients (male 40, female 13) who underwent initial PDT were included in this study. Patients were diagnosed with pachychoroid neovascularopathy (PNV) (n= 20), polypoidal choroidal vasculopathy (PCV) (n=24) and central serous chorioretinopathy (CSC) (n=9). The subjects were divided into two groups according to the reduction ratio of central choroidal thickness (CCT) more than 15% (group A) or not (group B) at 3 months post-PDT. The best corrected visual acuity (BCVA), central retina thickness (CRT), and CCT were compared between the groups. For statistical analysis, each clinical factor was evaluated by paired or unpaired t-test where applicable between any two groups.

Results: The group A and group B contained 24 eyes and 29 eyes, respectively. The mean age, the baseline BCVA, CRT, CCT in the group A and group B were 68.0±13.2 vs 71.4±13.6 years, 0.25±0.29vs0.26±0.40(logMAR),301.0±117.0vs319.1±111.8µm and 310.0±111.9 vs 292.5±111.8µm, which showed no significant difference between the groups (P=0.39, 0.85, 0.57 and 0.57, respectively). No significant differences were observed in the post-PDT BCVA 0.18±0.32 vs 0.26±0.42(logMAR) (P=0.46) and post-PDT CRT 207.2±81.8 vs 237.8±102.9µm (P=0.24) between the group A and group B. A multiple regression analysis showed no significant variables associated with the reduction of CCT after PDT.

Conclusions: None of the pre-treatment BCVA, CCT, and CRT was associated with a reduction of CCT after PDT. The reduction of CCT was not associated with an improvement in visual acuity or CRT after the treatment. Decreased CCT might be a result, not a therapeutic role of PDT over the management of PSD.

ABSTRACT BODY:

Purpose: Risks associated with topical corticosteroid (CS) treatment limit their long-term use for controlling inflammatory conditions of the ocular surface and anterior segment. One of their most common side effects is steroid-induced elevated intraocular pressure (IOP). It is believed that CS cause this by promoting fibrosis and collagen deposition in the trabecular meshwork (TM). Rho kinase inhibitors (ROCKi) have been shown to reduce deposition of collagen and fibronectin in TM cell cultures and reverse fibrotic changes in the TM of mice with steroid-induced elevated IOP. We set out to design a new class of CS with ROCKi activity with the hypothesis that such compounds could protect the TM while maintaining anti-inflammatory efficacy. A CS with fewer ocular side effects would be an invaluable tool for the treatment of patients with a variety of ocular inflammatory conditions.

Methods: CS covalently linked to AR-13503, the active metabolite of netarsudil, were designed to deliver physiologically relevant levels of each drug to tissues of the ocular surface. The anti-inflammatory activity of one of these compounds was assessed following topical treatment in a mouse allergic eye disease (AED) model. The AED model has robust ocular surface inflammation and meibomian gland (MG) plugging, two common features of dry eye. Anti-inflammatory activity was further tested in a mouse cornea wound healing (CWH) model that also served to understand the compound's effect on the recovery rate of the corneal epithelium following injury. Lastly, we treated rabbits topically with this compound to assess tolerability and to determine if its ROCKi activity could lower IOP, thereby reflecting a potential to protect the TM from CS activity.

Results: Our novel CS with ROCKi-activity controlled inflammation on the ocular surface in mice with AED and reduced the formation of MG plugs. This activity was comparable to treatment with standard CS used in the clinic. Treatment also reduced inflammation in the CWH model and did not significantly impair corneal re-epithelialization. Importantly, treatment resulted in a moderate IOP reduction and no tolerability issues in rabbits.

Conclusions: CS are invaluable tools in ophthalmology but carry significant risks with long-term use. Our new class of CS with ROCKi activity demonstrated a reduced risk of inducing elevated IOP while retaining anti-inflammatory efficacy comparable to CS used in the clinic.

ABSTRACT BODY:

Purpose: Inherited Retinal Disease (IRD) data are, by definition, rare and research in this area has historically been constrained by the lack of such data. To date, the challenge has been to identify these data and make them available to researchers in the most productive way. MyEyeSite is an early stage research collaboration in the United Kingdom (UK), aiming to design and develop a digital platform for people with rare IRDs that enables patients, doctors and researchers to aggregate and share specialist eye health data. The proposed infrastructure is designed to accelerate research into IRD by curating and making available highly specific data from consenting patients. The ability for this data to be accessed by appropriate researchers will facilitate the planning of disease-specific trials and the development of cost-effective treatments, such as gene therapies.

Methods: A pilot feasibility study was carried out, informed by qualitative data (generated through focus groups and workshops) and quantitative data obtained by survey from patients with IRD. Participants were recruited through ophthalmology clinics at Moorfields Eye Hospital National Health Service (NHS) Trust, UK, and databases managed by the Moorfields Biomedical Research Centre.

Results: 87% of surveyed participants (n=82) were motivated to have a more active role in their eyecare, and to share their data for research purposes using a secure application technology. 94% of our IRD focus group sample (n=50) highlighted themes of: 'frustration with the current system' regarding data sharing within the UK's NHS; positive 'expectations' of the potential benefits of the MyEyeSite app for this patient community with increased access to these specialised data; and concerns about data security and potentially unethical use of data by those outside the NHS. Detailed patient input was also given into the functionality and accessibility of the application prototype.

Conclusions: This pilot study demonstrates that IRD patients wish to be actively involved in managing their own data for both research use and their own eyecare. It reveals their willingness to engage with the detailed design of a technological solution to the issue of the paucity of these datasets and the potential benefits to research and care, not only for the IRD patient community, but for others with rare diseases.

TITLE: New in vitro model of photoreceptor degeneration based on the 661W cell line

SESSION TITLE: Retinal Degenerations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Marigo, L. Huang, M. Kutluer, E. Adani, Life Sciences, Università degli Studi di Modena e Reggio Emilia, Modena, Emilia-Romagna, ITALY]

Commercial Relationships Disclosure (Abstract): Valeria Marigo: Commercial Relationship: Code N (No Commercial Relationship) | Li Huang: Commercial Relationship: Code N (No Commercial Relationship) | Meltem Kutluer: Commercial Relationship: Code N (No Commercial Relationship) | Elisa Adani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) is an inherited degenerative disease characterized by photoreceptor cell death. Several studies, mostly in Pde6b mutant retinas, identified the mechanisms of rod photoreceptor cell death involving excess of intracellular calcium and cGMP, activation of calpain and PKG and nuclear translocation of AIF. One of the limits that hamper the development of novel therapeutic strategies resides on the lack of a reliable in vitro system for high-throughput drug screenings. The purpose of this study was to generate a genetically modified cell line, derived from 661W photoreceptor progenitor cells, able to model the disease in vitro.

Methods: 661W cells were genetically modified to stably express the neural retina leucine zipper (NRL) rod specific transcription factor. qPCR and immunofluorescence were used to select a clone, highly expressing rod specific genes. Cell differentiation was achieved with a culture medium containing retinoic acid (RA), basic fibroblast growth factor (bFGF), taurine and sodium butyrate. A stress protocol for mimicking photoreceptor degeneration was based on the PDE6 inhibitor zaprinast.

Results: 661W cells were infected with a retrovirus expressing the NRL transcription factor. Out of 14 cell clones, one was selected based on expression of Nrl and Cnga1 genes. qPCR analyzed rod-specific gene expression, such as Rho, Pde6b, Cngb1, Gnat, Guca, Crx, and showed significant higher levels in this clone compared to the 661W cell line. Cone-specific genes, otherwise, did not change level of expression. We developed a differentiation protocol based on FBS withdrawal and exposure to bFGF, RA, Taurine and sodium butyrate. After differentiation, based on qPCR and immunofluorescence, cells showed an elongated shape and augmented expression of rod specific genes, when compared to not differentiated cells. To mimic the degeneration process caused by increased cGMP, we exposed the cells to zaprinast, an inhibitor of PDE6, and found an increased cell death accompanied by increased intracellular calcium and calpain activation. The effects of known, previously published, neuroprotective agents were tested in the new in vitro model.

Conclusions: The new in vitro model for rod photoreceptor degeneration will be instrumental for high-throughput screenings and testing of new compounds that can act as novel therapeutic approaches for this blinding disease.

ABSTRACT BODY:

Purpose: No-show appointments may be associated with significant detriments to patient outcome, practice efficiency, and practice financial status. The purpose of this study is to investigate reasons patients failed to attend scheduled appointments at an outpatient ophthalmology clinic at an academic medical center.

Methods: The study protocol was reviewed and deemed exempt from further review by the Penn State College of Medicine Institutional Review Board. A scheduling software was used to identify all adult patients who did not attend their scheduled ophthalmology clinic appointments at Penn State Eye Center from 11/9/20 to 12/16/20. Potential subjects were contacted by phone to conduct a brief phone interview. Subjects willing to participate were asked to specify the reason(s) they did not attend their appointment, and to suggest interventions that would help them attend. Descriptive statistical methods were used to describe the reasons for missed appointments and suggested interventions.

Results: Of the 325 patients identified, 160 (49.2%) were reached by telephone and participated in the phone survey. The most common reason for non-attendance reported was forgetting the appointment (35.6%), followed by being unaware of appointment (20.6%), scheduling conflict (13.1%), and illness (11.9%). Eighteen patients (11.3%) reported transportation difficulty and two patients (1.3%) reported financial burden. Six patients (3.8%) reported concern for the COVID-19 pandemic as the reason for non-attendance. Fifty-seven patients suggested potential interventions that would help them attend their visits, with the most common being the provision of a reminder (49.1%), followed by providing aid with transportation (15.8%) and sending multiple modalities of reminders (14.0%).

Conclusions: In this study conducted at an outpatient ophthalmology clinic at an academic center, the most common reasons for non-attendance were patients forgetting about the appointment and being unaware of the appointment. This finding is supported by the interventions suggested by the patients, which consisted primarily of providing appointment reminders. Patients also noted difficulty with transportation and suggested assistance with transportation to the clinic. These findings may facilitate the development and implementation of specific interventions to decrease the patient no-show rate.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a leading cause of preventable childhood blindness in high- and middle-income countries. Appropriate screening and timely treatment are critical and can reduce the risk of blindness due to ROP. Plus disease is a certain degree of vascular dilation and tortuosity that is usually present in treatment indicated (type 1) ROP. This study uses the semiautomated software ROPttool to quantitatively compare posterior pole vascular changes after bevacizumab versus laser treatment.

Methods: This retrospective study used prospectively-collected narrow-field retinal images from preterm infants screened and treated for ROP. We included retinal images acquired in the session just prior to and in all sessions post-treatment. Using quadrant-level methodology where ≤ 3 images/session were included, we used ROPttool to trace and analyze ≤ 2 vessels/quadrant, following the same vessels over time (Figure 1). For each imaging session, these ROPttool indices were calculated: tortuosity index (TI), dilation index (DI), and combination dilation/tortuosity indices: sum of adjusted indices (SAI) and tortuosity-weighted plus (TWP). We used Wilcoxon signed-rank test to compare each average ROPttool index before and after treatment, and Wilcoxon rank sum test to compare the rates of percent change of each index between bevacizumab versus laser.

Results: Of 15 eyes with type 1 ROP, 6 were treated with bevacizumab and 9 with laser. We included a median of 5 imaging sessions/eye. Compared to pre-treatment values, all ROPttool indices significantly decreased 1 week after bevacizumab ($p=0.03$) and 1 month after laser ($p=0.05$). Those treated with bevacizumab versus laser had higher rates of percent change in TI ($p=0.01$), SAI ($p=0.02$), and TWP ($p=0.01$) 1 week after and in SAI ($p=0.03$) and TWP($p=0.01$) 1 month after treatment (Figure 2).

Conclusions: Regression of vessel dilation and tortuosity in type 1 ROP occurs earlier after bevacizumab versus laser. The quantification of retinal vascular characteristics post-treatment helps guide clinical expectations after bevacizumab versus laser.

TITLE: Antimicrobial Efficacy of Hydrogen Peroxide Contact Lens Care Products in the Presence of Contact Lenses

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Walters, E. Miller, C. McAnally, M.M. Gabriel, P. Shannon, M. Crary, Alcon Laboratories Inc, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rhonda Walters: Commercial Relationship(s);Alcon Research LLC:Code E (Employment) | Elise Miller: Commercial Relationship(s);Alcon Research LLC:Code E (Employment) | Cindy McAnally: Commercial Relationship(s);Alcon Research LLC:Code E (Employment) | Manal Gabriel: Commercial Relationship(s);Alcon Research LLC:Code E (Employment) | Paul Shannon: Commercial Relationship(s);Alcon Research LLC:Code E (Employment) | Monica Crary: Commercial Relationship(s);Alcon Research LLC:Code E (Employment)

ABSTRACT BODY:

Purpose: Hydrogen peroxide (HP) based contact lens care products (CLC) offer outstanding antimicrobial efficacy against a range of pathogenic microorganisms. HP CLCs function using a strong disinfectant that is neutralized over time. HP CLCs are recognized in the market for their enhanced efficacy to preserved multipurpose solutions. In this study, HP CLCs were evaluated for antimicrobial efficacy against strains of Staphylococcus, Pseudomonas, Serratia, Fusarium, Candida, as well as Acanthamoeba trophozoites and cysts in the presence of silicone hydrogel (SH) contact lenses (CL).

Methods: Two CLCs (3% hydrogen peroxide) were tested against ISO strains as well as clinically relevant strains including Fusarium, and Acanthamoeba trophozoites and cysts using a modified version of ISO 18259. Testing was conducted using SH lenses in the manufacturer's contact lens case so that neutralizing discs could be utilized per the instructions for use. Aliquots of 10^4 - 10^6 CFU/mL of each organism were inoculated onto two SH lenses. Organisms were allowed to adhere for three minutes then CLs were submerged in the lens case containing 10mL of hydrogen peroxide product until disinfection time (DT). After DT (6 hours), contents of the lens case as well as both lenses were placed in a glass tube and vortexed vigorously. CLC/CL combinations were sampled and organisms recovered depending on their individual growth requirements. Log reductions were calculated based on inoculum controls generated at time 0 and test samples recovered at disinfection time.

Results: CLCs (3% hydrogen peroxide) showed a high level of efficacy in the presence of SH lenses against all organisms tested. For bacteria, and yeast, both products had >5.0 log kill while for Fusarium, the CLCs had >4.0 log kill with SH lenses. The log reduction for Acanthamoeba trophozoites was >4.5 and for Acanthamoeba cysts, log kill ranged from 2.5-3.7 for both products and all CLs tested. The presence of CL did not negatively affect the antimicrobial efficacy of HP products. HP products can effectively clean CL lenses of a wide range of microorganisms.

Conclusions: Hydrogen peroxide CLCs demonstrated a high level of antimicrobial efficacy against all microorganisms including Acanthamoeba in the presence of SH lenses. Hydrogen peroxide products maintain their antimicrobial efficacy in the presence of contact lenses.

ABSTRACT BODY:

Purpose: Inactivating sequence variants as well as a unique missense variant in the centrosomal CEP78 gene have been identified in autosomal recessive Cone-Rod Dystrophy with Hearing Loss (CRDHL), a rare syndromic inherited retinal disease (IRD) clearly distinct from Usher syndrome. Apart from this, a complex structural variant (SV) implicating CEP78 has been reported in CRDHL. Here we aimed to expand the genetic architecture of typical CRDHL by the identification of complex SVs and characterization of their underlying mechanisms.

Methods: Approaches used, for SVs identification, are shallow whole genome sequencing (sWGS) combined with quantitative PCR (qPCR) and long-range PCR, or ExomeDepth analysis on whole exome sequencing data. Targeted or whole genome Nanopore long-read sequencing (LRS) was used to delineate breakpoint junctions at the nucleotide level. For all SV cases, the effect of the SVs on CEP78 expression was assessed using qPCR on patient-derived RNA. Data mining of human single cell (sc), bulk retinal and cochlear transcriptional datasets was used to further characterize the CEP78 expression profile.

Results: Apart from two novel canonical CEP78 splice variants and a frameshifting variant, three SVs affecting CEP78 were identified in three unrelated individuals with CRDHL: a heterozygous total gene deletion of 235kb and a partial gene deletion of 12kb in heterozygous and homozygous state respectively. Assessment of the molecular consequences of the SVs on patient's materials displayed a loss-of-function effect. Delineation and characterization of the 12kb deletion using targeted LRS revealed the previously described complex CEP78 SV, suggestive for a recurrent genomic rearrangement. A founder haplotype was demonstrated for the latter SV in three cases of Belgian and British origin respectively. The novel 235kb deletion was delineated using whole genome LRS. Breakpoint

analysis showed microhomology and pointed to a replication-based mechanism behind CEP78 SV formation.

Moreover, we correlated CEP78 sc expression with the phenotypic presentation of CRDHL.

Conclusions: Overall, this study supports that the CEP78 locus is prone to distinct SVs and that SV analysis should be considered in a genetic work-up of CRDHL. Finally, it demonstrated the power of sWGS and both targeted and whole genome LRS in identifying and characterizing suspected complex SVs in patients with IRD.

ABSTRACT BODY:

Purpose: The identification of lesions in color fundus photography (CFP) to detect and characterize ocular pathologies requires specialized professionals to manually perform this task. In this study, we explore two different CNN architectures, Inceptionv3 (Iv3) and MobileNetv2 (MbNv2), and test their performance on identifying pathologies in CFPs.

Methods: We gathered 29,329 fovea-centered CPFs from the Epidemiologic (NCT01298674) and Incidence (NCT02748824) studies, previously classified regarding three targets: age-related macular degeneration (AMD), Diabetic Retinopathy (DR) and both AMD and DR. Given the unbalanced nature of data, we split the dataset into 5 balanced sets and tested a majority voting ensemble approach. For each architecture, three experiments (E1, E2, E3) were conducted. In E1, training was performed with non-augmented data, in E2, images were treated with a color correction software developed by Harvard Medical School that standardizes brightness, contrast, and color balance, and in E3 we studied the impact of horizontal flips, brightness changes, and small rotations and translations on the model performance.

Results: Iv3 achieved the best performance in E3 for all the targets with an AUC above 85%, and high sensitivity (>0.67) and specificity (>0.82) for the targeted class. As for MbNv2, each experiment presents different results depending on the target. When targeting AMD, E1 and E2 show similar performance with AUC reaching 0.78, but a slightly smaller sensitivity in E2. As for DR, E2 shows a high value for AUC but a low value for sensitivity (0.41). Finally, targeting AMD+DR, the AUC is equal in all experiments, however, sensitivity is higher (0.64) in E1 and specificity is higher in E2.

Conclusions: MbNv2 is a highly efficient basic architecture that ensures good accuracy in low computational budget and energetically economic devices. The use of the MbNv2 architecture opens the possibility of processing data in mobile devices and may come as an advantage on the screening of blinding age-related diseases in remote and rural areas with weak healthcare infrastructure and systems.

TITLE: Automatic image stitching of video frames captured during indirect retinopathy of prematurity examinations using a condensing lens and camera phone

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Wigdahl, E. Barriga, VisionQuest Biomedical, Albuquerque, New Mexico, UNITED STATES|S. Wilson, M. Barley, Keeler, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Jeffrey Wigdahl: Commercial Relationship(s);Keeler:Code F (Financial Support);VisionQuest Biomedical:Code E (Employment) | Sam Wilson: Commercial Relationship(s);Keeler:Code E (Employment) | Maya Barley: Commercial Relationship(s);Keeler:Code E (Employment) | E Simon Barriga: Commercial Relationship(s);VisionQuest Biomedical:Code E (Employment)

ABSTRACT BODY:

Purpose: To demonstrate software that automatically generates wide-field images of neonates' retinas using videos captured with a low-cost, narrow field smartphone fitted to a headset and an indirect ophthalmoscopy lens. Accurate determination of plus disease is critical for achieving favorable outcomes in infants with ROP. However, given the narrow field of a smartphone-based imager, it can be difficult to judge vascular changes present in an infant's posterior pole. To meet the needs of the developing world, low-cost tools and software need to provide equally actionable information as more expensive counterparts that capture larger field of view images.

Methods: To generate a mosaic, videos must be stripped of extraneous information:

Lens Detection: Circle Hough transform is used to detect the most likely lens candidate in each frame.

Image Quality: A deep neural network was trained with over 100,000 images from three classes (outlier, low, high).

The model is used to determine which frames will be used to create the mosaic.

Grouping: During the ROP exam, the lens is out of frame when the doctor moves to a different area of the retina. The initial grouping of usable frames exploits this so that each group represents a contiguous view of the retina.

Image Stitching: Each group is stitched together, then an attempt is made to stitch the group outputs into a final mosaic. Stitching is performed using FAST key point detection and Rotated BRIEF descriptors to find correspondence between images.

Results: 20 videos were used to test the algorithms with success criteria being the retinal field of view present in the output mosaics. The full field of view, as determined by an independent grader, was manually extracted from the videos and visually compared against the automatic output. The full field of view was found to be present in 18 videos, with only a single view underrepresented in each. An example output and processing pipeline is provided in Fig.1.

Conclusions: We demonstrated an automatic approach that can extract the usable retinal information from a video and create one or more widefield images that can be used for documentation, education, or making an accurate ROP diagnosis.

TITLE: Impaired cone function in drusen regions revealed by phase-sensitive adaptive optics OCT

SESSION TITLE: Adaptive optics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Liu, F. Zhang, D. Hammer, CDRH/OSEL, US Food and Drug Administration, Silver Spring, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zhuolin Liu: Commercial Relationship(s);Indiana University:Code P (Patent) | Furu Zhang: Commercial Relationship(s);Indiana University:Code P (Patent) | Daniel Hammer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study how cone photoreceptor function is affected by drusen.

Methods: Three subjects with no diagnosed ocular disease were imaged with the FDA adaptive optics (AO) imager [1]. Two subjects were found to have drusen in the macula from previous AO imaging. Brief synchronous flashes of visible stimulus were delivered to the retina with a Maxwellian view illumination channel co-aligned to the AO-OCT beam. Two stimulus sources (centered at 530 nm and 625 nm) were selected to change the relative response of the cones. Seven 1° field of view AO-OCT videos were acquired with each stimulus. The phase difference between cone IS/OS and COST signals was calculated and converted to optical path length change (Δ OPL). We then analyzed cone response using principal component analysis and classified cone types (L-, M-, and S-) following the methods described by Zhang et al. [2]. To avoid inter subject variability, cone responsivity and outer segment (OS) length were compared between non-drusen and drusen regions.

Results: Despite the presence of drusen, both IS/OS and COST reflections were present above regions of small drusen (Fig.1 A). The responses of the three cone types were distinctly separated in this study (Fig.1 B-C). In S1, the cones above a ~150- μ m diameter drusen (drusen 1) have significant weaker response compared to the non-drusen region for both L- (drusen: 639.4; non-drusen: 680.7; $p=0.04$) and M- (drusen: 309.6; non-drusen: 402.5; $p<0.01$) cones (Fig.1 C-D). The weaker cell response also prevented separation of the third (S-) cluster from the other two in the drusen region. Intriguingly, the L-cones above drusen 1 had a weaker response to green stimulus compared to the cones in the non-drusen region, suggesting the L- cones spectral sensitivity is affected by drusen. Weaker cone response was also found in the drusen 2 region, with no change in cone spectral sensitivity. Cones in the drusen area also tended to have shorter OS length, suggesting a structure-function correspondence. Similar results were found in S2, but no regional difference in cone functionality was evident in S3, who had no observable drusen.

Conclusions: The presence of drusen results in a weaker cone response to visible stimulation. The ability to measure individual cone function in drusen regions may lead to new functional biomarkers for detection of early age-related macular degeneration.

ABSTRACT BODY:

Purpose: To determine whether three-dimensional (3D) spectral-domain optical coherence tomography (SD-OCT) neuroretinal rim measurements detect glaucoma progression earlier than current standard of care clinical testing i.e., disc photography (DP), visual field (VF) testing, and two-dimensional (2D) retinal nerve fiber layer (RNFL) thickness measurements.

Methods: In this 5-year prospective longitudinal cohort study, 124 eyes of 124 open angle glaucoma patients had yearly DP, VFs, SD-OCT RNFL thickness scans, and optic nerve volume scans (Spectralis, Heidelberg Engineering, Heidelberg, Germany) which were performed on the same day. From high-density optic nerve volume scans, custom-built software calculated the minimum distance band (MDB) thickness, a 3D neuroretinal rim parameter, which quantifies the amount of tissue in the neuroretinal rim. Patients were classified as glaucoma progressors or non-glaucoma progressors using event-based analysis. Progression by DP and VF were determined when 3 masked glaucoma specialists unanimously concurred. Progression by RNFL and MDB thickness were determined if there was change greater than test-retest variability. Kaplan-Meier curves were constructed to analyze time-to-progression data.

Results: Global MDB neuroretinal rim thickness detected glaucoma progression earlier either DP (23 versus 44 months; $P < 0.001$) or global RNFL thickness (23 versus 33 months; $P < 0.001$). Global MDB thickness also detected progression slightly earlier than visual fields (23 versus 32 months), but the difference was not statistically significant ($P = 0.15$).

Conclusions: High-density 3D SD-OCT neuroretinal rim measurements detected glaucoma progression approximately 1-2 years earlier compared to current clinically available structural tests (i.e., DP and 2D RNFL thickness measurements).

ABSTRACT BODY:

Purpose: To use a 3D corneal organotypic model to study which cell types, either alone or in combination, contribute to the assembly of the epithelial basement membrane (EBM).

Methods: A 3D corneal organotypic model was established by culturing the rabbit corneal epithelial cells with either corneal fibroblasts or myofibroblasts embedded in collagen type I for 18 or 30 days. The myofibroblasts were derived either from bone marrow or differentiated from corneal fibroblasts. Fresh rabbit corneas had overnight enzymatic digestion to collect the keratocytes/corneal fibroblasts. The fibroblast were differentiated into myofibroblasts by incubating in TGFb1 (20 ng/ml) and mature myofibroblasts were confirmed with ICC for markers alpha-SMA, vimentin, desmin and vinculin. Immunohistochemistry for laminin alpha-5, laminin beta-3, perlecan, nidogen-1 and collagen IV was performed on cryofixed sections to detect EBM generation and IHC staining for vimentin and alpha-SMA was used to differentiate the fibroblasts and myofibroblasts. Each experiment was repeated at least 3 times.

Results: Expression and localization of EBM components laminin alpha 5, laminin beta 3, perlecan, nidogen 1 and collagen IV at the interface of the epithelial cells and corneal fibroblasts confirmed generation of a normally-assembled EBM in 3D organotypic cultures of epithelial cells and corneal fibroblasts. The presence of vimentin+, SMA– cells in the organotypic culture of corneal fibroblasts with epithelial cells revealed that corneal fibroblasts retained their phenotype after 18 days of culture. Epithelial cells or corneal fibroblasts alone in culture did not produce EBM. EBM was not observed in 3D organotypic cultures of myofibroblasts (either cornea- or bone marrow-derived) with epithelial cells, even with a long term (30 days) organotypic culture. However, a thickened EBM was observed in epithelial cell-corneal fibroblast organotypic cultures when incubation was continued for 30 days.

Conclusions: Corneal EBM assembly is mediated by the coordinated action of epithelial cells and corneal fibroblasts—with both cell types producing EBM component proteins. This in vitro organotypic model can be used to further elucidate EBM assembly in the cornea and to study other functions such as regeneration of epithelial barrier function after injury.

Commercial Relationships Disclosure (Abstract): Yihe Chen: Commercial Relationship: Code N (No Commercial Relationship) | Nai-Wen Fan: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Huckfeldt: Commercial Relationship: Code N (No Commercial Relationship) | Shudan Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Chronic autoimmune uveitis (CAU) is often a treatment-resistant disease, and the underlying pathogenesis remains poorly understood. Our previous work demonstrates the presence of CD44^{hi}IL-7R⁺IL-15R⁺IL-17A⁺CD4⁺ memory Th17 cells in the retina, draining lymph nodes, and spleen in a mouse model of CAU. In the present study, we further determined the pathogenicity of these memory T cells in CAU.

Methods: CAU was induced in wild-type C57BL/6 mice by immunization with 150 µg interphotoreceptor retinoid-binding protein (IRBP) peptide 161–180 plus 300 µg IRBP 1–20 emulsified in 0.2ml Complete Freund's Adjuvant (CFA). Mice also received 0.2µg Bordetella pertussis toxin. Establishment of CAU was confirmed by digital fundus imaging at week 12. CAU mice were sacrificed, draining lymph nodes and spleen were collected, and CD44^{hi}CD4⁺ (memory T cells) and CD44^{-/low}CD4⁺ (control T cells) were isolated using CD4⁺ negative MACS sorting combined with FITC-CD44 FACS sorting. The sorted cells were stimulated with 20 µg/mL IRBP in the presence of 1 µg/ml anti-CD28 antibody in vitro. Next, the cultured cells were evaluated for (i) proliferation profile using fluorescence-based dilution assay (Violet CellTrace™ Cell Proliferation Kit), (ii) activation profile using flow cytometry-based PE-CD154 antigen-specific activation assay, and (iii) cytokine profile using ELISA kit for IL-17A detection in cell culture supernatant. Finally, the sorted cells were also adoptively transferred to normal Rag1^{-/-} mice, and clinical disease in recipients was followed up for 2 weeks using fundoscopy.

Results: The CAU-derived CD44^{hi}CD4⁺ memory T cells showed 2-fold higher proliferation and 20-fold higher CD154 expression upon IRBP re-stimulation compared to control CD44^{-/low}CD4⁺ T cells. The IL-17A expression levels in CD44^{hi}CD4⁺ memory T cell cultures (15.5 ± 0.6 pg/mL) were significantly higher than that in CD44^{-/low}CD4⁺ T cell cultures (8.8 ± 0.4 pg/mL). In addition, Rag1^{-/-} mice receiving CD44^{hi}CD4⁺ memory T cells developed multiple retinal lesions by 2 weeks post-transfer; in contrast, those receiving control T cells showed normally appearing retina.

Conclusions: Our data demonstrate that memory CD4⁺ T cells in CAU are antigen-specific pathogenic effector memory T cells.

TITLE: The roles of SOCS3 in myeloid cell-derived neovascular endothelium formation in a laser-induced choroidal neovascularization mouse model

SESSION TITLE: CNV

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. WANG, D. Tsiрукis, S. Cho, Y. Sun, ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): TIANXI WANG: Commercial Relationship: Code N (No Commercial Relationship) | Demetrios Tsiрукis: Commercial Relationship: Code N (No Commercial Relationship) | Steve Cho: Commercial Relationship: Code N (No Commercial Relationship) | Ye Sun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pathological choroidal neovascularization (CNV) is a common cause of blindness in age-related macular degeneration (AMD). We aim to investigate the underlying molecular mechanism by identifying a novel immunoregulator suppressor of cytokine signaling 3 (SOCS3) which controls the development of myeloid lineage cells into endothelial cells to form the pathological vascular endothelium using a laser-induced CNV mouse model.

Methods: We generated SOCS3 gain-of-function and loss-of-function mice using the Cre/loxP system to modulate endogenous Socs3 levels. Myeloid and endothelial-specific Cre mice and ROSA^{mT/mG} reporter mice were used to trace the origin of neovascularization in the AMD mouse model. Bone marrow from GFP transgenic mice was injected into irradiated mice. Mature endothelial cell markers CD31 and VWF were used for immunostaining. CNV was quantified using image J. Results are presented as mean \pm SEM and were compared using the 2-tailed unpaired t-test. Statistical analyses were performed with GraphPad Prism (v6.0).

Results: Our data showed that bone marrow-derived GFP-positive cells gathered at the neovascularization site, and most of them were Iba-1 positive, which means myeloid cells were involved in CNV. We also found in the endothelial-specific promoter-driven GFP mice with CNV, only partial pathological CNV is GFP positive, indicating that endothelial lineage is not the only origin of pathological CNV. In addition, myeloid specific promoter-driven GFP mice, some of the pathological CNV is GFP positive, indicating that myeloid lineage may contribute to pathological CNV. In laser-induced CNV, myeloid specific deletion of SOCS3 increased CNV by 30-40% ($p < 0.001$, $n = 40-46$ lesions from 10 mice/group), and myeloid specific overexpression of SOCS3 reduced CNV by ~25% ($p < 0.001$, $n = 30$ lesions from 8 mice/group). This data suggests that SOCS3 in myeloid lineage controls pathological CNV formation in the laser-induced CNV.

Conclusions: Our data suggests that the myeloid lineage may contribute to pathological neovascularization and the process was modulated by SOCS3 in neovascular AMD mouse model. This finding provides a novel understanding of pathological neovascularization.

ABSTRACT BODY:

Purpose: Retinal light injury models can be useful in understanding aspects of retinal degeneration and retinal oxidative stress. We recently developed the FCD-LIRD model of light-induced retinal degeneration and demonstrated some retinal recovery from the original damage. In the current study, our aim was to perform cell-type specific analyses using single cell RNA sequencing of the acute and subacute retinal responses to light injury using this FCD-LIRD model.

Methods: C57BL/6J mice (4m old) were exposed to FCD-LIRD. Eyes were collected from control mice and from mice that had been exposed to light injury 4 h, 48h and 5d prior. Retinas were peeled off from the posterior eyecups and 2 mm posterior retina, centered on the optic disc spot, was cut out using a trephine. These retinal samples were then prepared for retinal single-cell suspensions using a Papain Dissociation System. Droplet-based single cell RNA-seq of dissociated retinal cells was performed with the GemCode Single Cell Platform (10X Genomics, Pleasanton). Libraries were sequenced on an Illumina NextSeq 500. Cell Ranger 3.0.0 (10X Genomics) was used to process and analyze the raw sequencing data. Seurat R package (v3.0.0) was used for downstream gene expression analysis. Cell clusters were then identified and named on the basis of known gene markers specific to various cell types found in the retina. Differential gene expression, pathway analyses and trajectory analyses of each cluster were performed, using Seurat and Ingenuity Pathway Analysis software.

Results: Our analysis generated 23 clusters with a resolution of 0.5. In addition to confirming previously published gene markers for retinal cell types, we were able to identify new ones. Using both unbiased and marker-based methods for data processing we identified genes that were significantly altered in each cell type after light injury. Using trajectory analysis we were able to identify several differentiation fates, including some suggestive of activation of pathways for cellular recovery.

Conclusions: Photo-oxidative/photo-inflammatory retinal injury leads to acute and subacute cell type-specific responses. A better understanding of these responses may be helpful in identifying therapeutic approaches to minimize retinal damage and maximize recovery after exposure to injury.

ABSTRACT BODY:

Purpose: This report presents results of a de novo, validated patient-reported outcomes instrument, the Presbyopia Impact and Coping Questionnaire (PICQ), in assessing effects of an optimized formulation of pilocarpine (1.25%; AGN-190584) on daily life, emotional impact and compensatory coping mechanisms in individuals with presbyopia.

Methods: In this multicenter, double-masked, 30-day study (NCT03804268; n=323), individuals with presbyopia were randomized to bilateral treatment with AGN-190584 or vehicle (placebo) once daily. Secondary efficacy endpoints included mean change from baseline in PICQ Coping (8 item) and Impact (6 item) domain scores evaluating use of presbyopia coping behaviors or impacts on daily life during the past 7 days. In prespecified analyses of PICQ domain scores (Day 30 Hour 3 [3 hours after dosing]), the cumulative distribution of change scores from baseline was depicted and the proportion of responders to AGN-190584 (those achieving meaningful change threshold of ≥ 1 point reduction from baseline in PICQ domain scores) assessed.

Results: Baseline PICQ Coping and Impact scores were generally comparable between treatment groups. At Day 30 Hour 3, the mean score differences (95% confidence interval [CI]) between groups for the Coping and Impact domain scores were -0.5 points (-0.6, -0.3) and -0.3 points (-0.4, -0.1), respectively ($P=.011$ for both vs vehicle). The cumulative proportion of participants reporting change in use of coping behaviors showed consistent separation between the two groups, favoring the AGN-190584 arm. Of the AGN-190584 group, 20.2% (95% CI: 10.5, 29.9; $P<.001$) more participants reported a ≥ 1 point reduction in PICQ Coping score vs vehicle. The difference in impact response rates was not significant.

Conclusions: Analyses of PRO efficacy endpoints demonstrated significant improvement in participants' subjective experiences with presbyopia. Participants who received AGN-190584 reported a clinically meaningful reduction in use of presbyopia coping mechanisms, versus participants receiving vehicle, supporting the value of this pharmacologic treatment option.

TITLE: Expression pattern of Chd7 suggests a role in retinal and photoreceptor development

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.A. Krueger, A.C. Morris, Biology, University of Kentucky, Lexington, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Laura Krueger: Commercial Relationship: Code N (No Commercial Relationship) | Ann Morris: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mutations in the chromatin remodeling factor CHD7 are the predominant cause of CHARGE syndrome, a congenital disorder that frequently includes ocular coloboma. Although CHD7 is known to be required for proper ocular morphogenesis, its role in retinal development has not been thoroughly investigated. In this study, we characterize the expression pattern of chd7 in the developing zebrafish retina and begin to study its function using two chd7 mutant lines.

Methods: All animal procedures were performed in accordance with IACUC and guidelines established by the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research. Wild-type and transgenic zebrafish embryos or larvae were collected at 24, 48, 72 hours post fertilization (hpf) and 4, 5 days post fertilization (dpf). Retinas were sectioned, followed by immunohistochemistry with a Chd7 antibody or RNAscope with a chd7 mRNA probe, and imaged with fluorescent and confocal microscopy. A CRISPR chd7 mutant line was obtained and genotyped by Sanger sequencing to identify a 2 base pair deletion. A second mutant line generated by ENU mutagenesis was outcrossed four times, and genotyped by Sanger sequencing to identify a single point mutation.

Results: Chd7 was expressed throughout the developing zebrafish retina at 24 and 48 hpf, when retinal progenitors are actively proliferating and early cells of the retina are beginning to differentiate. At 72 hpf, when most retinal cell types have terminally differentiated, Chd7 expression remained strong in the ganglion cell layer and in some cells in the inner nuclear layer. Strong expression of Chd7 was also observed in the photoreceptor cells of the outer nuclear layer (ONL). By 4 and 5 dpf, when the zebrafish larvae display active swimming and visual behaviors, Chd7 expression remained strong in the ONL, where it co-localized with markers of cone and rod photoreceptors. Incrosses of chd7 heterozygous adults yielded homozygous mutant progeny suggesting that the mutations are not early embryonic lethal in zebrafish.

Conclusions: Our results demonstrate that Chd7 is expressed throughout development of the zebrafish retina and remains expressed in some newly differentiated retinal cell types, including the photoreceptors. Further work is ongoing to investigate this specific patterning of Chd7 and chd7 mutant fish will be used to understand the function that this factor plays in retinal development.

ABSTRACT BODY:

Purpose: To compare corneal nerve alterations in patients with neuropathic corneal pain (NCP) and positive serology for autoimmune antibodies (Ab) with and without IgM against neuronal trisulfated heparin disaccharide (TS-HDS) and IgG against fibroblast growth factor receptor 3 (FGFR3).

Methods: Retrospective chart review of NCP patients (n=35) with autoimmune Ab (those having a positive result for ANA, SS-A, SS-B, c-ANCA, p-ANCA, anti-gliadin IgA, anti-TS-HDS IgM and/or anti-FGFR3 IgG were included in the study). Laser in vivo confocal microscopy (HRT3/RCM) images were analyzed using corneal nerve alterations using Neuron J in a masked fashion, comparing patients with or without anti-neuronal TS-HDS IgM/FGFR-3 IgG. The control group consisted of age- and sex-matched subjects (n=35) from a reference normative database.

Results: The mean age was 50.3 ± 19.0 (20-88) years for patients without anti-neuronal Abs (n=19, 4 males, 15 females) and 48.1 ± 18.7 (27-74) years for patients with anti-neuronal Abs (n=16, 1 male, 15 females), and 47.5 ± 13.5 (27-74) years (n=35, 5 males, 30 female) for controls. The overall pain intensity in the anti-TS-HDS IgM/FGFR-3 IgG (+) group was 5.67 ± 2.99 (1.0-10.0) and similar to 5.20 ± 2.26 (1.0-10.0) in the anti-TS-HDS IgM /FGFR-3 IgG (-) group (p=0.66). The mean total, main and branch subbasal corneal nerve densities in patients with anti-TS-HDS IgM/FGFR-3 IgG were $9,944.7 \pm 1,085.0$ mm/mm², $6,542.7 \pm 563.2$, and $3,402.0 \pm 579.2$, and were significantly lower (p=0.01, p=0.01, p=0.03 respectively) compared to patients without anti-neuronal Abs with $14,406.7 \pm 1,192.1$, $9,046.2 \pm 684.8$, and $5,360.6 \pm 592.9$, and controls ($20,896.0 \pm 697.4$, $9,097.4 \pm 460.6$, and $11,778.6 \pm 564.4$, p=0.001, p=0.005, p<0.001 respectively). The number of mean total and branch subbasal corneal nerves in patients with or without anti-TS-HDS IgM/FGFR-3 IgG were significantly lower compared to healthy controls (p<0.001). The number of mean main subbasal corneal nerves was lower in patients with anti-neuronal Abs compared to anti-TS-HDS IgM/FGFR-3 IgG (-), (p=0.07).

Conclusions: NCP patients with autoimmune conditions demonstrate reduced nerve density compared to controls. NCP patients with anti-neuronal TS-HDS IgM and/or FGFR-3 IgG demonstrate significant corneal nerve fiber loss compared to other autoimmune-mediated NCP patients.

Crabb: Commercial Relationship: Code N (No Commercial Relationship) | Hari Jayaram: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Clarke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To quantify the effect of trabeculectomy on the rate of progression (RoP) of visual field (VF) damage.

Methods: Clinical and VF data from 199 patients that were randomly selected from the cohort of patients that underwent trabeculectomy between 2015 and 2016 were extracted from clinical charts and digital archives at the network of sites of Moorfields Eye Hospital NHS Foundation Trust. Of these, we selected 80 patients who met our criteria of at least three reliable VFs before and after surgery. Reliability was defined by a false positive rate < 15%. The change in RoP was tested using total deviation (TD) values through a mixed effect model with random effects on both intercepts and slopes. The fixed effects modelled a broken-stick regression of TD over time, with a breakpoint at the day of surgery. We used two nested levels of random effects (patient and location within the VF, example in Figure 1). The fixed effect component of the model provided an estimate of the average change in slope between the pre and post-operative period.

Results: We analysed 10 [9, 12] VFs per subject (Median [Interquartile Range]). At surgery, the age was 67 [57, 72] years, the mean deviation was -10.84 [-14.68, -5.56] dB and the intraocular pressure (IOP) was 18 [15, 20] mmHg. One year after surgery, the IOP was 10 [8, 13] mmHg ($p = 0.002$). The mean RoP before surgery was -0.82 [-0.58, -1.07] dB/year (Mean [95% Confidence Intervals]) and it was slowed down by 0.56 [0.23, 0.89] dB/year ($p = 0.001$, Figure 2) after surgery.

Conclusions: Glaucoma patients who underwent trabeculectomy in 2015/16 showed a significant reduction in the rate of progression of the visual fields postoperatively throughout their follow-up.

TITLE: Choroidal Vascularity in Chronic Central Serous Chorioretinopathy

SESSION TITLE: Imaging of posterior segment II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Kaye, A.J. Lotery, Ophthalmology, University Hospital Southampton NHS Foundation Trust, Southampton, Southampton, UNITED KINGDOM|R. Kaye, A.J. Lotery, University of Southampton, Southampton, Hampshire, UNITED KINGDOM|T. Peto, Queens University Belfast, Belfast City Hospital, Belfast, Belfast, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Rebecca Kaye: Commercial Relationship: Code N (No Commercial Relationship) | Tunde Peto: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Lotery: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patients with central serous chorioretinopathy (CSC) are reported to have dilated, hyper-permeable choroidal vessels with leakage into the interstitial space. The vascular component of choroidal tissue can be assessed using the choroidal vascularity index (CVI), a ratio of the luminal component of the choroid to the cross-sectional choroidal area.

The aim of this study was to test for differences in the CVI in patients with chronic (cCSC), fellow eyes and healthy controls. Patients were genotyped for single-nucleotide polymorphisms (SNPs) associated with CSC and their relationship with a patient's CVI analysed.

Methods: Patients were included with cCSC, treatment naive, with a visual acuity of ≤ 79 EDTRS letters, OCT evidence of sub-foveal sub-retinal fluid, and fluorescein/ICG angiography evidence of active CSC. Age-matched controls were included. The central, foveal, EDI-OCT image was agreed upon by 2 ophthalmologists. Images were analysed in ImageJ and binarised. The central sub-foveal choroidal area was selected with a width of 1,500 μ m, the upper border at the retinal pigment epithelium and lower border at the choroid scleral interface. The total selected sub-foveal choroidal area, luminal area (dark pixels), stromal area (light pixels) and CVI were calculated (Fig1). cCSC patients were genotyped for risk SNPs associated with CSC. ANOVA used for statistical analysis.

Results: 106 patients with cCSC and 106 control eyes were included. There was a significant increase in the sub-foveal choroidal area in cCSC patients $2.35 \pm 0.56 \text{ mm}^2$ vs controls $1.82 \pm 0.54 \text{ mm}^2$ ($p < 0.0001$), and in fellow eyes $2.23 \pm 0.58 \text{ mm}^2$ vs controls ($p < 0.0001$). The CVI was reduced in cCSC patients $63.45 \pm 3.10\%$ vs controls $65.43 \pm 2.61\%$ ($p < 0.0001$) and in their affected vs fellow eyes $64.55 \pm 2.90\%$ ($p < 0.01$). There was a significant association between CVI and the presence of the risk SNP rs2379120 at GATA5 ($p < 0.01$) in cCSC patients after Bonferroni correction.

Conclusions: These results suggest the sub-foveal choroidal area is increased in both eyes of patients with cCSC. The relative reduction in CVI in cCSC may suggest a persistence of vessel hyper-permeability over dilation; resulting in an increase in stromal area. Tracking a patient's CVI and relative stromal area could be used to monitor disease. GATA5 may play a role in choroidal vascularity in cCSC.

ABSTRACT BODY:

Purpose: Microbial keratitis is a risk for all users of topical ophthalmic solutions due to microbial proliferation within the formulation upon accidental contamination of the product. Historically, preservatives added to the formulation are included to inhibit the growth of microbes introduced from repeated use. Preservative-free products are viable alternatives for individuals who are sensitive, or have reservations about using traditional preservatives. To mitigate microbial growth without the use of preservatives, a multi-dose packaging system must present a physical barrier to contamination throughout the use period. This study evaluates the potential of microbial ingress into Systane Ultra presented in the NOVELIA® Multi-Dose Preservative Free package over a 30-day use period.

Methods: Two challenge methods were evaluated for 30 days per Note for Guidance on In-Use Stability Testing of Human Medicinal Products (CPMP/QWP/2934/99) to simulate consumer use. First, the tip was challenged daily with low levels (10^2 CFU) of *Brevundimonas diminuta* (ATCC 19146) after actuation to simulate the tip routinely contacting a contaminated surface. Second, after four days of dispensing, the tip was submerged in a high level (10^6 CFU/mL) susp. of *B. diminuta* and actuated to simulate routine use of the product followed by a gross contamination event similar to falling into a heavily contaminated liquid.

Following each 30-day simulation, the internal contents of replicate samples were evaluated for sterility per USP<71>. A passing result indicates the packaging system was able to prevent microbial ingress into the bottle, while a failing result indicates ingress into the packaging system.

Results: For all simulations, a passing USP<71> sterility result was obtained following the 30-day use simulations and microbial challenges of the NOVELIA package.

Conclusions: Systane Ultra Preservative Free when presented in the NOVELIA package with the PureFlow™ 200 nozzle remains contaminate-free over a 30-day use period, even when subjected to extreme cases of accidental contamination. Users who suffer from dry eye disease now have the option of Systane Ultra Preservative Free in a unique multi-dose package.

ABSTRACT BODY:

Purpose: The head-to-foot hydrostatic pressure gradient causes intracranial pressure (ICP) to be ~0 cmH₂O during upright posture on Earth, but the gradient is absent during spaceflight, resulting in a cephalad shift of blood and cerebrospinal fluid. It has been hypothesized that ICP is elevated during spaceflight and may contribute to development of optic disc edema which occurs in some astronauts; invasive ICP measures have not been obtained during spaceflight. On Earth, use of lower body negative pressure (LBNP) redistributes fluid caudally and lowers ICP, so may be capable of lowering ICP during spaceflight. The purpose of this study was to assess ICP during spaceflight using 3 noninvasive techniques (nICP) and to determine if LBNP can lower ICP during spaceflight to levels similar to upright posture on Earth.

Methods: Twelve astronauts were tested three months before spaceflight (preflight) in the seated and supine posture, and ~150 days (FD150) into spaceflight with and without 25 mmHg LBNP. Optic disc edema was determined using fundoscopy and optical coherence tomography (OCT) images. We assessed ICP using 3 noninvasive techniques: ultrasound measures of optic nerve sheath diameter (ONSD), cerebral and cochlear fluid pressure (CCFP) tympanic membrane displacement, and otoacoustic emission (OAE) phase shift. Mixed effects models were used to detect differences between conditions.

Results: One astronaut developed Frisen grade 1 optic disc edema, while OCT imaging showed subclinical retinal thickening in 8 of 12 astronauts. Measures of nICP after 150 days of spaceflight were not greater than nICP measured in either the seated or supine postures preflight. During spaceflight, the use of LBNP resulted in a reduction in nICP assessed by CCFP (94.7 -nL, $p < 0.02$), compared to -39.1 and 66.4 -nL changes in the seated and supine postures related to FD150, respectively. No changes were detected by the other nICP measures.

Conclusions: Despite development of subclinical and Frisen grade optic disc edema in some astronauts, our data suggest spaceflight results in a mild, chronic elevation of ICP similar to the supine position on Earth, and that LBNP did not result in changes indicative of ICP values similar to those of upright posture on Earth. Invasive measures of ICP may clarify these findings. Research is needed to determine if small reductions in ICP induced by LBNP would be sufficient to prevent optic disc edema.

ABSTRACT BODY:

Purpose: Recent studies suggest that the antidiabetic drug metformin has a significant protective effect on age-related macular degeneration (AMD). These studies were based on large registries, were retrospective, mostly case-control designed, and not specific to AMD stage. Here, we evaluated the association between diabetes, metformin, other antidiabetic medications and incident any or late AMD in a large prospective, population-based study.

Methods: In total, 12,939 individuals aged 45+ years from the population-based Rotterdam Study were available for analyses. Diabetes diagnosis was based on general practitioners' records, hospital discharge letters and serum glucose measurements. Diabetic medication data were obtained through linkage with the computer network of pharmacies in the study district and were categorized as monotherapy of metformin, monotherapy of insulin, monotherapy of sulfonylurea, any monotherapy and any combination therapy. AMD features and diagnosis of late AMD were assessed by the EyeNED Reading Center on multimodal imaging. Associations between diabetes, the treatment groups, and incident AMD were determined by Cox regression adjusted for age, sex, BMI, use of statins, antihypertensives and fasting serum glucose.

Results: A total of 1,723 participants were diagnosed with diabetes, of them 688 (40%) used metformin as monotherapy. 1,091 participants were diagnosed with incident any AMD, and 172 with late AMD during a mean follow up time of 6.6 (SD 5.5) years. Diabetes was associated with a lower risk of any AMD (HR 0.74, 95%CI 0.63-0.85), but not significantly associated with late AMD (HR 0.99, 95%CI 0.67 - 1.46). Monotherapy of metformin was borderline associated with any AMD (HR 0.57, 95%CI 0.29 – 1.04), not significant for late AMD (HR 0.51, 95%CI 0.12– 2.27). None of the other medications were significantly associated with any or late AMD, but also had risk estimates which seemed slightly protective (HRs 0.7-0.9).

Conclusions: Our study shows that it is challenging to dissect the effect of treatment from that of the indication in the study of antidiabetic drugs and AMD. If any, metformin has a greater protective effect on AMD than other medications in diabetic patients, but the clinical significance remains to be elucidated in large prospective studies.

Commercial Relationships Disclosure (Abstract): Ashkan Eliasy: Commercial Relationship: Code N (No Commercial Relationship) | Bernardo Lopes: Commercial Relationship: Code N (No Commercial Relationship) | Ahmed Abass: Commercial Relationship: Code N (No Commercial Relationship) | Riccardo Vinciguerra: Commercial Relationship(s);Oculus:Code C (Consultant) | Susana Marcos: Commercial Relationship: Code N (No Commercial Relationship) | Ahmed Elsheikh: Commercial Relationship(s);Oculus:Code C (Consultant)

ABSTRACT BODY:

Purpose: To evaluate the performance of a new Corvis ST parameter denoted the Stress-Strain Index (SSI2) as an in-vivo measure of material stiffness of healthy and keratoconic corneas.

Methods: A large parametric study was conducted on realistic ocular finite element models. The input and output parameters were recorded in a database and used to develop an algorithm for SSI2, which involved the central corneal thickness (CCT), the intraocular pressure (IOP) along with a number of the dynamic corneal response parameters provided by the Corvis ST including the integrated inverse radius (IIR) and the Stiffness Parameter (SP). The algorithm was validated using data obtained by Vincieye Clinic (Milan, Italy) for 414 healthy participants, 79 forme-fruste keratoconus (FFKC) subjects and 222 patients with confirmed keratoconus. IOP was measured with the Corvis ST (OCULUS Optikgeräte GmbH; Wetzlar, Germany), whose measurements also allowed calculation of the SSI2 values using a custom Matlab code. The results were statistically analysed and correlations were evaluated for SSI2 with CCT and age. Topography data obtained using a Pentacam (OCULUS) were also acquired for the same participants, and analysed using Topographic Keratoconus Classification (TKC) (Chen, JCRS, 2019) to categorise the eyes into healthy, FFKC, mild, moderate and advanced keratoconus. IRB approval in the form of written and informed consent was obtained to use the data in scientific research. The study followed the tenets of the Helsinki Declaration revised in 2013.

Results: The mean SSI2 was 1.08 ± 0.21 , 1.02 ± 0.18 , 0.79 ± 0.17 , 0.70 ± 0.21 and 0.63 ± 0.15 in healthy participants and patients with FFKC, mild KC, moderate KC and advanced KC, respectively, showing gradual, consistent and significant decreases with keratoconus progression ($p < 0.05$). As expected, the correlation between SSI2 and CCT was not significant in both the healthy population ($p = 0.552$) and the KC population ($p = 0.205$), while the correlation with age was significant in healthy eyes ($p < 0.05$). The correlation with age in KC eyes was not significant ($p = 0.141$) possibly due to the biomechanical changes in the tissue caused by the disease.

Conclusions: The results revealed consistent reductions in SSI2 with keratoconus progression and independence of corneal thickness. This parameter may be used for personalised medicine to optimise procedures such as corneal cross-linking.

TITLE: Single cell transcriptome analysis of periocular mesenchyme during anterior segment development

SESSION TITLE: Ocular transcriptomics, epigenomics, computational biology and beyond

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: O. Voecking, J.J. Smith, J. Famulski, Biology, University of Kentucky, Lexington, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Oliver Voecking: Commercial Relationship: Code N (No Commercial Relationship) | Jeremiah Smith: Commercial Relationship: Code N (No Commercial Relationship) | Jakub Famulski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Periocular mesenchyme (POM) is a subgroup of neural crest cells, responsible for forming anterior structures, including the anterior segment of the eye. Despite the importance for the development of a healthy eye, knowledge about this cell group is limited. Particularly, only very few genetic markers and their respective roles are known. The purpose of this study is to identify formerly unknown markers of POM cells, to further understand their role in eye development and the genetic interactions required for AS formation. To do so, we employed newly available scRNA analysis over the course of AS development.

Methods: Larval eyes of transgenic zebrafish Tg(Foxc1b:GFP) and Tg(Lmx1b:GFP) were collected every 24 hours between 48hpf and 144hpf. GFP+ cells were isolated via FACS cell sorting and processed with the 10x genomics chromium single cell transcriptome kit. The resulting Illumina sequencing single cell transcriptomes were processed with the Cell Ranger pipeline. Analysis was done with the Cell Loupe Browser 5.0 and Monocle3. Gene expression was studied via in situ hybridization and gene function via Morpholino and Alt R CRISPR induced knockouts.

Results: We collected a total of more than 40,000 Foxc1b+ and Lmx1b+ cells from eyes only, including one biological replicate for each individual time point. Transcriptome analyses showed that these cells were organized in re-occurring clusters during zebrafish anterior segment development. These clusters are partly localized to different structures within the eye, including the cornea, iridocorneal angle, retina and retinal pigment epithelium. Additionally, we found several new markers with specific expression within these spatially limited areas with apparent importance for general eye development, as proven by genetic knockout. These genes include hgd, si:ch211-251b21.1, slc22a7a, ppil1, stmn1a, seta, hmgb2a and b.

Conclusions: Our results provide a base for a single cell transcriptome atlas for anterior segment development in zebrafish. Not only do they reveal previously unknown and uncharacterized genetic markers, but they also give a first insight into potential genetic interactions necessary anterior segment development. This new knowledge might further enable clinicians to increase their genetic screening for anterior segment related diseases and treatment of ocular diseases such as glaucoma.

TITLE: Ethnic differences in the prevalence of myopia in Israeli college students

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Gordon-Shaag, R. Doron, E. Shneor, Dept. of Optometry, Hadassah Academic College, Jerusalem, Jerusalem, ISRAEL|L.A. Ostrin, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ariela Gordon-Shaag: Commercial Relationship: Code N (No Commercial Relationship) | Ravid Doron: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Ostrin: Commercial Relationship: Code N (No Commercial Relationship) | Einat Shneor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Genetics, as well as behavioral factors, such as near work and light exposure, are known to play a role in the etiology of myopia. Education is often used as a proxy for near work, with more educated populations showing a higher prevalence of myopia. Two distinct ethnic populations, Jews and Arabs, study at Israeli colleges. Given that all students are admitted on similar criteria, educational background of these populations is believed to be comparable. This study aimed to assess the prevalence of myopia in college students in Jerusalem and to determine its association with gender and ethnicity (Jew or Arab).

Methods: First year college students (from 2011-2019) underwent a vision screening that included non-cycloplegic auto-refraction (Luneau L80 or VX130) and a questionnaire to assess age, gender, and ethnicity. Students who had undergone refractive surgery were excluded. Myopia was defined as spherical equivalent ≤ -0.50 D and high myopia as ≤ -6.00 D. Prevalence and 95% confidence interval (CI) were calculated, and groups were compared using Chi-square or Fisher test. Odds ratio to evaluate risk factors were calculated.

Results: The study included 807 students (652 women, 377 Jews) with a mean age of 22.1 ± 2.6 (range: 17-30) and mean spherical equivalent of -1.7 ± 2.2 (range: -13.3-+5.7). The prevalence of myopia and high myopia were 66.3% (95% CI: 63.0-69.6%) and 4.6% (95% CI: 4.4-4.8%), respectively. Women had significantly higher prevalence of myopia than men (68.1% vs. 58.7%, $p < 0.03$), but not of high myopia (5.1% vs. 2.6%, $p = 0.28$). Jewish students had significantly higher prevalence of myopia (69.2% vs. 60.3%, $p < 0.02$) and high myopia (5.9% vs. 1.9%, $p < 0.02$) than Arab students. Female gender emerged as a risk factor for myopia (OR=1.54, 95% CI 1.07-2.21, $p < 0.02$), but not for high myopia. Jewish ethnicity emerged as a risk factor for both myopia and high myopia (OR=1.51, 95% CI 1.11-2.05, $p < 0.01$ and OR=3.52, 95% CI 1.35-9.19, $p < 0.01$, respectively).

Conclusions: The prevalence of myopia, approximately 66%, in college students in Israel is higher than the global average. Jewish ethnicity, compared to Arab ethnicity, was a risk factor for myopia and high myopia in this population. As all students had a similar academic background, findings suggest that genetic factors play a role in the refractive differences between Arabs and Jews.

Commercial Relationships Disclosure (Abstract): Bernardo Lopes: Commercial Relationship: Code N (No Commercial Relationship) | Ahmed Abass: Commercial Relationship: Code N (No Commercial Relationship) | Ashkan Eliasy: Commercial Relationship: Code N (No Commercial Relationship) | Haixia Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Ahmed Elsheikh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To introduce and validate a novel method to describe the cone features in keratoconic corneas.

Methods: Corneal anterior and posterior surfaces were described using a spherical coordinate system to generate a new spherical height map to allow the detection of the cone apex. Cone boundaries were objectively estimated using second derivatives of spherical height in an iterative process. Corneal topography exams of 309 keratoconic patients with different disease severities were evaluated with the new automated method as its first validation. In addition, 12 cornea specialists blindly evaluated the tangential and elevation maps relative to the best-fit sphere of 6 patients. Their estimations were cross-checked and compared with the results of the new automated method in order to evaluate the subjective variability and provide a second validation of the method.

Results:

The main cone features in the anterior and posterior surfaces were evaluated in the large clinical dataset. There was strong correlation between the cone height and the disease severity in both surfaces ($R=0.71$, $p<0.01$), while the disease stage did not show significant correlation with cone area in any of the surfaces ($R=0.01$, $p=0.77$). The height of the posterior cone was, on average, larger than the corresponding anterior cone height by $37 \pm 24 \mu\text{m}$ (0–158). In relation to the experts' assessment, there was high inter-subject variability, up to 55%, among experts' estimations of the cone area and low intra-subject agreement in cone apex location using different maps ($p<0.05$). However, there was no statistically significant difference between the automated estimation and the specialists' estimations in both maps ($p>0.05$). The cone boundaries estimated by the automated method were within the range of the specialists' estimations in all cases.

Conclusions:

An objective automated method able to determine the cone's 3D features was developed and validated in a large clinical dataset and against worldwide corneal specialists' estimations. The method's results were in agreement with disease severity and independent of the subject variability observed among different experts. The objective method provided a reliable and unique evaluation of keratoconus features that is independent of maps' type or color-scale.

TITLE: Regulatory role of GRP78 in oxidative stress of Trabecular meshwork cells induced by tunicamycin

SESSION TITLE: Blood flow/ Ischemia/reperfusion/Aqueous humor dynamics/IOP

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Chai, XIAN FOUTH HOSPITAL, XIAN, CHINA|

Commercial Relationships Disclosure (Abstract): Fang Chai: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To clarify the regulatory effect of tunicamycin on endoplasmic reticulum stress by affecting GRP-78

Methods: In this study, the endoplasmic reticulum stress model of trabecular reticulum cells (HTMC and GTM3) was established by tunicamycin, and the cells were treated with GRP78. The morphological changes of cells were observed by electron microscope, apoptosis and ROS content were detected by flow cytometry, and the expression of GRP78, PERK-eIF2a-ATF4/CHOP signal pathway and apoptosis-related proteins were detected.

Results: Tunicamycin could significantly increase the content of ROS in HTMC and GTM3 and increase the rate of apoptosis. The determination of calcium concentration in cells showed that tunicamycin could increase the flow of calcium ions in cells. Tunicamycin can increase the expression of GRP78,IP3R,ATF4,PERK,sXBP1,eIF2a,CHOP,PDI-1. Overexpression of GRP78 can protect cells during stress and reduce the rate of apoptosis. And Co-IP test shows that there is a direct binding effect between GRP78 and eIF2. It is suggested that GRP78 may play a regulatory role by regulating eIF2.

Conclusions: This study proves that tunicamycin can induce oxidative stress in trabecular meshwork cells, and the increase of GRP78 expression can protect cells during stress, and GRP78 may play a protective role by regulating eIF2.

ABSTRACT BODY:

Purpose: Diet has an important role in risk for age-related eye diseases, including AMD and diabetic retinopathy. Humans that adhere to Western and high glycemic index dietary patterns have increased risk for AMD. We have previously shown that aged mice that consumed high glycemic (HG) diets developed AMD-like retinopathy that could be prevented by a low glycemic (LG) diet. We also showed a role for gut microbiota in mediating protection by a LG diet, which we coined the gut-retina axis. Altered gut microbiota have also been associated with human AMD, but experimental evidence and mechanisms for this association are lacking.

Methods: 12-month male C57BL/6J mice were fed HG and LG diets for 12-months. Gut microbiota were manipulated either by continuous oral antibiotic ablation of commensal bacteria (Ampicillin + Neomycin) or via weekly fecal microbiota transplants from mice consuming opposite diets. Eye health was evaluated using fundus imaging and angiography, immunohistochemical detection of retinal microglial/macrophages, histology, and electron microscopy of the RPE. Bacterial 16S rRNA sequencing was used to determine the fecal microbiome composition.

Results: Mice that consumed HG diets developed multiple retinal lesions, consistent with greater retinal damage scores. There were fewer lesions in mice consuming LG diet, or in HG-fed mice receiving fecal transplants from LG mice. Lesions were associated with infiltration of retinal microglia/macrophages in the choroid and outer retina. Ablation of commensal microbiota was associated with retinal and RPE degeneration in some mice. Microbiome analysis revealed that retinal neuroprotection was associated with increased levels of Akkermansia, a commensal bacteria with known beneficial metabolic functions. HG-fed mice receiving LG fecal microbiota transplants also had improved glycemic control relative to HG-fed mice.

Conclusions: Our studies confirm previously observed roles for commensal gut microbiota in mediating protection against diet-induced AMD. Importantly, these protective effects could be transferred via fecal microbiota transplantation, indicating that microbiome-based therapies have therapeutic potential for AMD. Neuroprotection was associated with improved glycemic control, suggesting that metabolic reprogramming may be a critical component of the gut-retina axis, possibly via modulation of innate immune system function.

TITLE: Hypothermia breaks down the barrier function of the corneal endothelium

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.H. Ranganath, M. Thanuja, M. T D, Chemical Engineering, Siddaganga Institute of Technology, Tumkur, Karnataka, INDIA|S.P. Srinivas, Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sudhir Ranganath: Commercial Relationship: Code N (No Commercial Relationship) | M. Y. Thanuja: Commercial Relationship: Code N (No Commercial Relationship) | Manjunatha T D: Commercial Relationship: Code N (No Commercial Relationship) | Sangly Srinivas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The donor corneal endothelium (CE) is exposed to hypothermia during cold storage, which is inevitable before transplantation. Here, we have examined the impact of hypothermia on the barrier function of CE with a goal to enhance the success of corneal transplantation.

Methods: Primary cultures of porcine CE or freshly isolated porcine corneas were employed for the experiments. Since hypothermia is known to cause microtubule (MT) disassembly, which causes a breakdown of barrier integrity in CE (Srinivas, EER, 2012), we immunostained and imaged MT and ZO-1 with and without prior exposure to epothilone B (a microtubule-stabilizing agent; EpoB). To ensure sustained intracellular levels of the agent, we also formulated EpoB-loaded PLGA nanoparticles (ENPs; coated with poly-L-lysine; zeta potential 25 mV). ENPs were spherical ($\sim 95 \pm 10$ nm) with a drug entrapment efficiency of 91% and drug loading of 5% (w/w). The ENPs showed a burst release of EpoB, but the subsequent slow release phase sustained for up to 4 weeks.

Results: An exposure to hypothermia (15 h; 4 °C) led to MT disassembly in cultured CE. The effect was also evident in CE cells associated with ex vivo corneas. Moreover, the impact was similar to that observed in response to TNF- α (20 ng/mL; 24 hrs). Exposure to EpoB (100 nM) or ENPs (0.25 mg/mL) for > 24 h induced MT stabilization with minimal toxicity and importantly opposed the hypothermia-induced MT disassembly. Prior exposure to SB-203580 (a p38 MAPK inhibitor; 20 μ M; 1 hr) reduced the hypothermia-induced MT disassembly. The effect of SB-203580 was similar to the inhibition of the response to TNF- α , which activates p38 MAPK (Srinivas, EER, 2012). Concomitant with the impact on MT, hypothermia led to a disruption of the contiguous ZO-1 at the cellular periphery (Fig. 1B; Fig. 1D shows response to TNF- α), indicating a loss of barrier integrity. However, pre-treatment with EpoB (Fig. 1C), ENPs, or SB-203580 opposed the ZO-1 disruption, indicating that MT disassembly underlies the hypothermia-induced breakdown of tight junctions.

Conclusions: Hypothermia induces MT disassembly via activation of p38 MAPK and subsequently breaks down the barrier function of CE. Sustained exposure to MT stabilizers overcomes the hypothermia-induced barrier failure. The ENPs could serve as a modality to obtain sustained protection of CE against hypothermia-induced stress and TNF- α -induced damage to MT in case of allograft rejection.

ABSTRACT BODY:

Purpose: We report a multi-pronged strategy for ascertaining AMD status in the CAREDS cohort and the prevalence of AMD in CAREDS2 (2016-2019).

Methods: AMD was assessed in CAREDS1 (2001-2004), primarily, from stereoscopic fundus photographs, among 2,005 women aged 53 to 86 years, who attended three study centers in the U.S. (Iowa, Oregon, and Wisconsin). Fifteen years later, in CAREDS2 639 women had died, and surviving women resided in 21 states, requiring updated protocols to assess AMD presence and severity. In CAREDS2 we ascertained AMD in 697 women who either participated in person (487), or by mail (198), or whose AMD status could be additionally assessed from Medicare billing records accessed via the WHI Virtual Data Enclave (12). A multipronged approach was used to reconcile AMD status for each woman, integrating AMD features from: 1) graded stereoscopic fundus photos taken in study visits, or by providers according to study specification, 2) spectral domain-optical coherence tomography (SD-OCT), 3) AMD features abstracted from medical records or questionnaires completed by providers, and from 4) International Classification of Diagnoses-10 codes for AMD in Medicare billing records.

Results: In CAREDS2, participants aged 69 to 101 years, intermediate AMD (n=135) or late AMD (n=38) were identified from fundus photographs. SD-OCT captured an additional 55 women with intermediate AMD (large or reticular pseudodrusen or nascent geographic atrophy). Further capture of AMD outcomes from participants' eyecare providers, either directly or via ICD-10 AMD diagnoses, increased the prevalence of documented clinically significant AMD by an additional 27 cases, for a total of 255 cases. Overall, 37% of women had either intermediate (n=202) or late AMD (n=53). The prevalence of clinically significant AMD (intermediate or late), by age tertile, was 30%, 44%, and 61%, in women <78, 73-83, and >83 years old, respectively.

Conclusions: The multi-pronged approach to ascertaining AMD prevalence, maximizes capture of clinically significant AMD outcomes, which steeply increased in prevalence with age in older women.

ABSTRACT BODY:

Purpose: To examine the associations of capillary density and flow with hematocrit, blood pressure and medical comorbidities using OCTA.

Methods: A cross-sectional study using 3 x 3 mm SS-OCTA images to measure vessel skeleton density (VSD) and flow (flux) in the superficial retinal layer (SRL). Flux is a relatively new measure that approximates the number of red blood cells moving through a vessel segment per unit time. Complete blood count, blood pressure, self-reported/medical-record based history including diabetes status, hypertension status, hypertensive medication use, cigarette smoking and retinopathy status (including edema) were obtained. A generalized linear mixed-effects model was used to evaluate the relationship with OCTA parameters after considering the correlation between eyes. Least-square means were estimated.

Results: A total of 154 eyes from 83 participants [56 women and 27 men, mean [SD] age, 66.2 (8.9) years, 22 with diabetes, 63 with hypertension] were included. Mean VSD was 0.147 ± 0.009 and mean flux was 0.156 ± 0.016 . VSD showed a negative correlation with age ($p=.001$) and retinopathy ($p=.016$), but no significant correlation with hematocrit ($p=.86$) or signal strength ($p=.51$). Flux showed a positive correlation with hematocrit ($p = .006$) and signal strength ($p<.001$), as well as a negative correlation with age ($p=.005$) and diabetes status ($p=.050$). These associations remained even after accounting for hypertensive status, and smoking status. Mean flux was 0.010 lower in OCTA scans with a signal strength of 9 compared with those with a strength of 10, and 0.006 lower for the following comparisons: participants age 65 and above with younger participants, participants having hematocrit of less than 40% with those having higher hematocrit, and diabetics with non-diabetics. A one percent decrease in hematocrit was approximately equivalent to 1.8 years of aging in its effect on the calculated flux.

Conclusions: Retinal blood flow is independently affected by hematocrit and diabetes status even when accounting for known determinants of capillary density such as age and retinopathy status. This effect by hematocrit is not found in OCTA measurements of vessel skeletal density.

ABSTRACT BODY:

Purpose: Chediak-Higashi Syndrome (CHS) is a rare inherited disorder with ophthalmological manifestations that include reduced pigmentation and foveal hypoplasia. We characterized the status of cone photoreceptor and retinal pigment epithelial (RPE) cells in CHS in comparison with foveal hypoplasia arising from oculocutaneous albinism type 1 (OCA1) and Waardenburg syndrome type 2A (WS2A).

Methods: Patients were recruited for high resolution retinal imaging (CHS, 2 eyes from 2 patients; OCA1, 3 eyes from 3 patients; WS2A, 6 eyes from 3 patients). Adaptive optics (AO) imaging was performed from which measurements of cone density (all eyes) and RPE cell-to-cell spacing (CHS and OCA1, 5 eyes from 5 patients) were obtained over a range of retinal eccentricities from the fovea out to ~5 mm. Foveal hypoplasia grades were assigned according to optical coherence tomography (Ophthalmology 118:1653–1660, 2011) and compared to peak cone density wherever possible.

Results: There was considerable variation in the number of cones and RPE cells near the fovea as observed using AO. Cone density near the fovea (eccentricity < 1 mm) was reduced inversely with the foveal hypoplasia grade (IOVS 55:4186-4198, 2014) which ranged from 1 to 3 (lower peak cone densities seen in higher foveal hypoplasia grades). At larger eccentricities, cone densities were mostly normal, with no apparent differences observed between CHS, OCA1, WS2A, or published normative data. RPE cells in CHS imaged using AO-ICG (IOVS 57:4376-4384, 2016) exhibited the characteristic heterogeneous fluorescence signal, similar to OCA1 and healthy controls. RPE cell spacing near the fovea was variable (either within normal ranges or slightly enlarged), with no apparent differences between CHS and OCA1. At larger eccentricities, RPE cell spacing appeared to be normal.

Conclusions: Our preliminary data shows the in vivo status of cone photoreceptors and RPE cells suggesting that foveal hypoplasia associated with CHS, OCA1, and WS2A result in anatomically consistent reductions in peak cone density pursuant to the degree of hypoplasia. Although impacted to a lesser degree, the RPE cells may also play a role in foveal specialization. Additional patients are needed to further explore these findings.

TITLE: The effect of visual feedback on perceptual and oculomotor performance in a gaze-contingent simulated scotoma paradigm

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Skerswetat, A. Sharma, H. Jefferis, K. Costa, T. Arango, P. Bex, Psychology, Northeastern University, Boston, Massachusetts, UNITED STATES|N.C. Ross, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jan Skerswetat: Commercial Relationship: Code N (No Commercial Relationship) | Anubhav Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Hanley Jefferis: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Costa: Commercial Relationship: Code N (No Commercial Relationship) | Tiffany Arango: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Ross: Commercial Relationship: Code N (No Commercial Relationship) | Peter Bex: Commercial Relationship(s); Adaptive Sensory Technology LLC,: Code I (Personal Financial Interest); Massachusetts Eye and Ear Infirmary, P: Code P (Patent); Northeastern University: Code P (Patent)

ABSTRACT BODY:

Purpose: Gaze-contingent simulated scotomas have been used in normally-sighted individuals to mimic central vision loss (CVL) and to study perceptual and ocular-motoric processes. We investigated the effect of visual feedback on eccentric viewing training assessed with fixation stability (Bivariate Contour Ellipse Areas, BCEAs), contrast sensitivity (CS) Area-Under-the-Curve (AUC) and acuity (highest visible spatial-frequency).

Methods:

Performance was measured in phases of 25-50 CS trials/session (≥ 25 correct) in which participants used their peripheral vision to identify 26AFC band-pass-filtered letters. An adaptive algorithm controlled spatial frequency and contrast of the letters. A gaze-contingent binocular scotoma simulated 6° or 9° CVL. Baseline learning (n=8) was measured in six free-viewing trials. Two separate four-phase-protocols investigated two types of visual feedback (target cue, n=10; and scotoma boundary, n=8) across fixation eccentricity and orientation. One freeview session at the start (Phase1) and end (Phase4), and four counterbalanced orientation (eight 45° steps) and eccentricity (6° or 9°) cued sessions with (Phase3) and without (Phase2) visual feedback were performed. Feedback employed letter-surrounding dots (Target-cue) or a scotoma-surrounding ring (scotoma boundary).

Results: Linear regression models identified a significant increase in Acuity ($p < 0.01$) and AUC ($p < 0.01$) and a non-significant trend of BCEAs reduction during baseline. Pre-trial cueing and both feedback types significantly reduced BCEAs ($p < 0.05$) and improved eccentricity-dependent acuity ($p < 0.05$), while AUC results were mixed. Eccentricity-dependent learning was retained in Phase 4 ($p < 0.05$).

Conclusions: Eccentric fixation training delivers sustained functional benefits through both oculomotoric and perceptual learning. The current findings may be transferable into rehabilitation of CVL patients.

ABSTRACT BODY:

Purpose: We previously showed that microglia are key regulators of retinal regeneration in zebrafish. Microglia reactivity to induced rod photoreceptor death stimulates Müller glia to mount a regenerative response. Ablating microglia or suppressing microglia reactivity with dexamethasone (Dex) prior to induction of cell death inhibited regeneration. However, suppressing microglia reactivity after induction of rod death enhanced regeneration kinetics. These data support the concept that microglia play stage-dependent roles during retinal regeneration and that immunosuppression could be a viable therapeutic approach for promoting repair in retinal degenerative disease. Here, we used intravital time-lapse imaging to investigate how post-injury Dex treatment altered microglia reactivity. We also tested what effect targeted delivery of Dex to reactive immune cells following induction of rod cell death had on regeneration kinetics.

Methods: Metronidazole (Mtz) induced rod cell death was enabled by a transgenic line expressing bacterial nitroreductase (NTR) and a fluorescent reporter in rod photoreceptors. A novel intravital imaging technique, Adaptive Optics-Lattice Light Sheet Microscopy (AO-LLSM), was used to capture fast subcellular dynamics of microglia. Imaris was used to quantify aspects of microglia behavior during regeneration \pm Dex. Dendrimer conjugated Dex (Dendrimer-Dex) was evaluated for effects on rod cell regeneration kinetics using an established plate reader assay.

Results: AO-LLSM time-lapse imaging showed that post-injury Dex represses reactivity to rod cell death by reducing the speed of microglia migration rather than altering morphology (sphericity). Compared to free Dex controls, Dendrimer-Dex formulations led to: 1) reduced toxicity, 2) targeted delivery of Dex to reactive microglia, and 3) a further enhancement of regeneration kinetics, from +33% (free Dex controls) to +67% (Dendrimer-Dex treated fish).

Conclusions: These results increase our understanding of the roles microglia play during retinal regeneration and advance the therapeutic potential of immune suppressing drugs and dendrimer-based immune cell targeting in retinal disease settings.

TITLE: Sterol O-acyltransferase 1 (Soat1) is critical for cholesteryl ester production in mouse Meibomian glands

SESSION TITLE: Lacrimal gland and Meibomian gland

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Wilkerson, S. Yuksel, I.A. Butovich, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|I.A. Butovich, The Graduate School of Biomedical Sciences, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amber Wilkerson: Commercial Relationship: Code N (No Commercial Relationship) | Seher Yuksel: Commercial Relationship: Code N (No Commercial Relationship) | Igor Butovich: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cholesteryl esters (CE) are the second most abundant class of lipids produced by the Meibomian glands (MG). The Soat1 gene is encoding a SOAT1 enzyme that is responsible for the formation of cholesteryl esters (CE) from cholesterol (Chl) and fatty acids, and is highly expressed in MG of humans and mice. The purpose of this study was to determine the impact of Soat1 ablation on meibum composition and the homeostasis of the ocular surface and adnexa in mice.

Methods: The ocular surface of 2- to 4-month old male and female knockout (Soat1^{-/-}) and wild-type (WT) mice was assessed via a slit lamp. Their eye geometry was evaluated. Phenol red thread test was used to assess tear production. Tarsal plate (TP) anatomy was evaluated by hematoxylin and eosin staining. Lipid profiling was conducted by liquid chromatography and mass spectrometry (LC/MS). Melting temperature of meibum (T_m) was measured by hot stage cross-polarized light microscopy (HSPLM).

Results: Soat1^{-/-} had noticeably smaller, slit-eye openings (p= <0.001) when compared with WT mice. Slit lamp examination of Soat1^{-/-} mice revealed thick meibum accumulations and meibum protrusions from the MG orifices. Tear production was increased in Soat1^{-/-} mice (p=0.002). Excised TP of Soat1^{-/-} mice had visible MG, central ducts and connecting ductules, but lacked discernible acini. The histology displayed abnormal acini and dilated central ducts. Lipid profiling of Soat1^{-/-} meibum revealed an upsurge of free Chl (reaching 30% of all MG lipids) and an almost complete loss of CE. HSPLM experiments revealed that Soat1^{-/-} meibum had highly elevated T_m: only half of lipids melted at 50°C, requiring temperatures in excess of 100°C to be completely melted. WT meibum melts 50% at 34°C and 100% at 50°C.

Conclusions: Soat1 is essential for the conversion of free Chl into CE in the MG. The increased Chl and lack of CE had detrimental effects on the physical and biochemical properties of meibum leading to an abnormal ocular phenotype. The changes in meibum and the ocular phenotype resemble characteristic signs of MG dysfunction in humans and demonstrate the importance of Soat1 in MG lipid homeostasis.

TITLE: Galectin-3 Inhibition by a Small-Molecule Inhibitor Downregulates Fibrosis-Related Genes and Signaling Pathways in a Mouse Model of Corneal Fibrosis

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Cao, A. Ramadan, N.A. Panjwani, Ophthalmology, Tufts University School of Medicine, Boston, Massachusetts, UNITED STATES|F. Zetterberg, Galecto Biotech AB, Gothenberg, SWEDEN|

Commercial Relationships Disclosure (Abstract): Zhiyi Cao: Commercial Relationship: Code N (No Commercial Relationship) | Abdulraouf Ramadan: Commercial Relationship: Code N (No Commercial Relationship) | Fredrik Zetterberg: Commercial Relationship(s);Galecto Biotech AB:Code E (Employment) | Noorjahan Panjwani: Commercial Relationship(s);Tufts University School of Medicine:Code P (Patent)

ABSTRACT BODY:

Purpose: Previously, studies in our Lab have shown that the treatment with a galectin-3 inhibitor, GB1265, reduces corneal fibrosis. To detect the impact of GB1265 treatment specifically on fibrosis-related genes, we analyzed differentially expressed genes by Nanostring technology using the fibrosis panel.

Methods: Corneal fibrosis was induced by alkali-burn injury in C57B/6 mice. Vehicle alone or GB1265 (10µl of 10mg/ml in vehicle) were topically applied to the eye twice per day from day 1 until day 14. Corneal opacity was scored by slit lamp examination at day 7 and 14 post-injury. On day 14, corneas were harvested, isolated RNA was processed for Nanostring analysis using a mouse fibrosis panel that profiles 770 genes across 51 annotated pathways. Differentially expressed genes were analyzed using nCounter gene expression platform analysis. Subset of genes involved in fibrosis pathway were confirmed by Q-PCR and immunohistochemical staining.

Results: Of the 770 genes in the panel, 230 genes were not expressed above background, 9 genes were not expressed in all replicates (n = 3), 128 genes were not affected by GB1265 treatment. Of the remaining 540 genes, 11.5% were differentially expressed in GB1265-treated corneas compared to vehicle-treated corneas (fold change >2.0; false discovery rate q <0.05). Of the 55 differentially expressed genes in the inhibitor treated group, 52 were downregulated, and 3 were upregulated. MMP-9 and -12, Collagen I and V, LOXL-1 and -2 and Itgb3 were among the significantly downregulated genes. Pathway analysis of differentially expressed genes revealed that three fibrosis-related pathways i.e. TGFβ pathway, Th17 differentiation, and collagen biosynthesis were downregulated whereas none of the pathways were upregulated in the GB1265-treated corneas.

Conclusions: Our data indicated that galectin-3 inhibitor plays an important role in reducing corneal fibrosis by downregulating fibrosis-related genes in the corneas treated with GB1265. This leads us to conclude that GB1265 is an effective galectin-3 inhibitor and could be a potential candidate for developing a new drug to halt the progression of fibrosis after injury.

TITLE: Complementary and Alternative Medicine for Glaucoma in Social Media

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. Bhatti, R. Swamy, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|M. Kaleem, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Junaid Bhatti: Commercial Relationship: Code N (No Commercial Relationship) | Mona Kaleem: Commercial Relationship: Code N (No Commercial Relationship) | Ramya Swamy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Social media has been increasingly utilized by both patients and providers to receive and deliver medical information. The lack of regulation of posts pose a threat of misinformation, making monitoring social media platforms a necessity. In this project we performed a cross-sectional study surveying social media content regarding Complementary and Alternative Medicine (CAM) and its usage for glaucoma.

Methods: Social media posts from Twitter and Facebook were analyzed using a systematic approach. Specific search queries with multiple hashtags were used to identify top posts over the past 10 years for popular CAM types. Descriptive and quantitative information were collected for each post, including account type, credibility, tone, among others. Data was collected using a standardized online form and was organized into spreadsheets which were used for further analysis.

Results: Overall, the data showed most posts to be general discussion (42.9%), article presentation (21.2%), and promotional (14.7%). The majority of posts were by companies (40.4%), medical professionals (32.0%), and unaffiliated individuals (17.9%), with variation between CAM types.

Most posts had no article references (61.5%), while fewer had non peer-reviewed (24.4%) and peer-reviewed (14.1%) articles cited. Posts with peer-reviewed articles were mainly by medical professionals (59.1%). Posts without citations were mainly by companies (42.7%).

Ophthalmologists mostly had article presentation posts (50.0%). Companies mostly had either general discussion posts (46.0%) or promotional material (20.6%), with the majority not referencing articles (65.1%).

Facebook had a higher proportion of medical professionals compared to Twitter (49.2% vs 19.8%). More articles were referenced in Twitter (46.2% vs 27.7%); however, Facebook had the higher portion of peer-reviewed articles (18.5% vs 11.0%).

Conclusions: Patients should be cautious about information they gain on social media as a lack of credibility and financial intentions make many posts, specifically promotional material from companies, potential sources of misinformation. Medical professionals have reliable posts with article citations, however, also tend to have a smaller social media engagement. The results of this study can help educate ophthalmologists and other eye care providers about the source and type of information being presented to their patients on CAM and can counsel their patients accordingly.

TITLE: QUANTITATIVE ANALYSIS OF THE THREE MACULAR CAPILLARY PLEXUSES IN OPEN ANGLE GLAUCOMA AND OCULAR HYPERTENSION USING OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY (OCTA)

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Schilt-Catafal, V. Pérez-Torregrosa, A. Duch-Samper, Ophthalmology Department, Hospital Clínic Universitari de València, València, València, SPAIN|A. Duch-Samper, Associated Professor, Universitat de Valencia, València, València, SPAIN|

Commercial Relationships Disclosure (Abstract): Maria del Mar Schilt-Catafal: Commercial Relationship: Code N (No Commercial Relationship) | Vicente T. Pérez-Torregrosa: Commercial Relationship: Code N (No Commercial Relationship) | Antonio M. Duch-Samper: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A decrease in macular vessel density (VD) has been described in glaucoma eyes (GE). This study aims to investigate whether VD changes occur in all three macular capillary plexuses in GE and in ocular hypertension eyes (OHE).

Methods: A prospective observational study was performed with 111 open-angle GE, 107 OHE and 106 gender-age matched control eyes (CE). Macula was imaged with a 6x6mm scan using DRI-OCT Triton (Topcon), and VD was automatically defined by OCTARA algorithm. Statistical analysis was performed using Kruskal-Wallis Test, Bonferroni Post Hoc analysis and Spearman rank correlation.

Results: Superficial capillary plexus (SCP) VD in GE was lower than OHE and CE (-4,93% and -10,20%), being the temporal sector the most affected. Deep capillary plexus (DCP) VD in GE was lower than OHE and CE (-4,05% and -10,21%), being the nasal sector the most affected. In OHE, SCP and DCP VD was also lower than CE (-5,54% and -6,41%). Choriocapillaris plexus (CCP) VD in GE was lower than OHE and CE (-1,7% and -1,1%), being the nasal sector the most affected ($p<0.01$ for all pairwise comparisons). However, CCP VD in OHE was not significantly different than CE ($p=0,119$).

Correlation analysis showed that SCP VD was low positive correlated with ganglion cell layer thickness (GCL) ($r=+0,366$) and moderate positive correlated with visual field mean deviation (VFMD) ($r=+0,597$), being the superior and the inferior sectors the most correlated ones. DCP VD was negligible correlated with GCL ($r=+0,149$) and low positive correlated with VFMD ($r=+0,303$). The correlation between CCP VD and VFMD was low positive ($r=+0,287$) ($p<0,01$ for all), however the correlation with GCL was not statistically significant ($p=0,59$).

Conclusions: In GE and OHE, the decrease of macular VD can be visualized in both SCP and DCP. However, decreased VD in CCP can only be objectivized in GE. This finding suggests that the vascular damage may occur concurrently among the three plexuses; but at initial phases of the disease, vascular abnormalities may occur specially at the SCP and DCP. Eventually, the SCP VD resulted to be correlated with GCL and VFMD. Therefore, quantitative OCTA may have value in the future to evaluate or follow up GE and OHE. Nevertheless, further research is needed to obtain stronger results.

ABSTRACT BODY:

Purpose: Pediatric rhegmatogenous retinal detachments (RRD) make up a small percentage of all retinal detachments and typically present late with poor visual outcomes. We performed a retrospective clinical study to better characterize the predisposing factors, clinical course, surgical methods, and outcomes of pediatric RRD at a major children's hospital in Dallas.

Methods: We performed an IRB-approved, retrospective review of data for patients under 18 years old who underwent surgical repair for RRD from January 1, 2004 to December 31, 2019. Exclusion criteria included a history of retinoblastoma, the presence of persistent fetal vasculature or active retinopathy of prematurity, and those who had follow-up of less than 6 months. Patient's age, race, gender, laterality, etiology, risk factors, presenting symptoms, fellow eye findings, exam findings at diagnosis, type and location of break, presence or absence of proliferative vitreoretinopathy (PVR), surgical procedures, post-op complications, initial and final best corrected visual acuities, and anatomic success were recorded.

Results: A total of 93 eyes of 87 patients were included. The majority of the patients were male (n = 65; 74.7%) and the median age was 11 (+/- 4.25) years. 90.3% of eyes had at least one predisposing factor of pediatric RRD, including prior ocular surgery (n = 49, 52.7%), trauma (n= 44, 47.3%), myopia (n=35, 37.6%), and congenital anomaly (n=19, 20.4%). 58% of eyes had greater than one predisposing factor. 78.4% (n=73) had macula-off detachments and 36.6% (n=34) had PVR grade C or worse at the time of presentation. 52.7% (n=49) achieved anatomic success after the first operation. Overall, 71.0% (n=66) achieved anatomic success after their final surgery.

Conclusions: The majority of the cases of pediatric RRD in this study are associated with the risk factors of congenital/developmental anomalies, myopia, trauma, or previous ocular surgery. Pediatric patients with RRD often present late as shown by the high incidence of macula-off detachments, as well as the presence PVR Grade C or worse. The majority of patients were able to achieve anatomic success after surgical repair using scleral buckle and/or vitrectomy.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) occurs in 10% of retinal detachments and is the most common cause of failure of retinal detachment surgery. There are currently no approved treatments for inhibiting PVR. We studied the ability of intravitreal HC-HA/PTX3, a soluble matrix component of amniotic membrane, to inhibit PVR in a mouse model. Additionally, we assessed the safety of intravitreal HC-HA/PTX3 on the mouse retina.

Methods: PVR was induced in 38 control and 43 treatment eyes of 6-8 week old female C57BL/6J mice. A posterior vitreous detachment was induced by intravitreal injection of 0.5µL SF₆ gas. One week later, immediately prior to injection, freshly harvested ARPE-19 cells (immortalized retinal pigment epithelial cells [RPE]) were mixed with PBS alone (control) or PBS with HC-HA/PTX3 to yield solutions containing 2×10^4 RPE cells and 0.15 (n=15), 0.30 (n=15), or 0.6 (n=13) µg/ml HC-HA/PTX3 per microliter. 1µL of the solution was injected intravitreally and weekly fundus photos were used to grade PVR development for 4 weeks. Additionally, mice received intravitreal injection of PBS (n=2) or 0.6 µg/ml HC-HA/PTX3 (n=5) and ERG a- and b-wave amplitudes compared after 4 weeks to assess safety. Mann-Whitney U test was used to compare PVR grades.

Results: After 4 weeks, eyes injected with RPE/PBS (control mice) developed a mean PVR grade of 2.75 out of 6 (SD: 1.35), which was significantly higher than mice treated with intravitreal 0.6 µg/ml HC-HA/PTX3 (1.77, SD: 0.73, p = 0.018). The difference in PVR grade compared to control mice approached statistical significance in mice treated with intravitreal 0.3 µg/ml HC-HA/PTX3 (1.93, SD: 1.16, p = 0.062) and was not significantly different compared to mice treated with intravitreal 0.15 µg/ml HC-HA/PTX3 (2.93, SD: 1.44, p = 0.803). There was no difference in a or b wave ERG amplitudes after 4 weeks in mice treated with intravitreal PBS or 0.6 µg/ml HC-HA/PTX3.

Conclusions: Intravitreal HC-HA/PTX3 (0.6 µg/ml) inhibits PVR in a pre-clinical mouse model without any deleterious effects on ERG amplitude measurement.

TITLE: Quantitative and Qualitative Analysis of Retinal Hypoxia in a Mouse Model of Retinal Artery Occlusion (RAO)

SESSION TITLE: Animal imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Uddin, S. Jamal, G.W. McCollum, J.S. Penn, Ophthalmology, Vanderbilt University School of Medicine, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): MD Imam Uddin: Commercial Relationship: Code N (No Commercial Relationship) | Sara Jamal: Commercial Relationship: Code N (No Commercial Relationship) | Gary McCollum: Commercial Relationship: Code N (No Commercial Relationship) | John Penn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To demonstrate the quantitative and qualitative analysis of tissue hypoxia from a single retinal artery occlusion (RAO). Also, to demonstrate the utility of HYPOX-4 for early detection of retinal hypoxia in RAO in real time.

Methods: A major retinal artery was occluded in mice using laser-induced retinal artery occlusion using Rose Bengal. Real time imaging of the retinal hypoxia was achieved using HYPOX-4, a molecular imaging probe developed in our laboratory. Pimonidazole-adduct immunostaining was used as an ex vivo method to characterize retinal hypoxia in RAO. Retinal vasculature was imaged using fluorescein angiography (FA) and IB4 staining. Retinal tissue morphology was evaluated using spectral domain OCT (SD-OCT).

Results: Retinal hypoxia was observed in a mouse model of RAO within few hours of laser-induced retinal artery occlusion in mice. We also observed that occlusion of an artery near the optic disk caused a 'pie-shaped' tissue hypoxia covering about $1/8^{\text{th}}$ of the entire retina. We also observed that occlusion of a vein in the same eye at about same distance from optic disk caused a 'cascade-shaped' tissue hypoxia covering about half of the entire retina (hemi-retinal ischemia). Retinal hypoxia was confirmed ex vivo using standard pimonidazole-adduct immunostaining method. Interestingly, we observed that the total hypoxic retina is about the same (~12% of the entire retina) from a single retinal artery occlusion compared to single retinal vein occlusion (RVO). This study provides the first quantitative and qualitative evidence of retinal hypoxia from single RAO and compared with single RVO in mice at early stage.

Conclusions: This study demonstrated the utility of a new hypoxia sensitive molecular imaging probe, HYPOX-4, to detect retinal hypoxia in RAO in real time at an early stage. This study also demonstrated that the pattern of tissue hypoxia is very different in RAO compared to RVO. Also, HYPOX-4 could be a powerful method to detect retinal hypoxia at an early stage that occurs in RAO and other vascular diseases.

ABSTRACT BODY:

Purpose: To characterize and classify the morphological, clinical, and tomographic characteristics of focal choroidal excavation (FCE) lesions to determine their longitudinal prognostic implications.

Methods: Retrospective, consecutive case series of all patients with FCE who underwent ophthalmologic assessment with multimodal imaging including spectral domain optical coherence tomography (OCT) and fundus autofluorescence, with additional fluorescein, indocyanine, and OCT angiography as indicated. FCE was classified into three subtypes: Type 1 - myopic eyes with small FCE; Type 2 - FCE with larger "U" shape, presumed congenital lesions with no signs of other adjacent ocular pathology; and Type 3 - "V" shaped FCE associated with other chorioretinal pathology. Imaging characteristics, tomographic measurements, and clinical course (development of choroidal neovascular membrane (CNVM) and vision loss) were compared between types.

Results: The study included 36 eyes from 32 patients. 80.6% of eyes were followed longitudinally (26.8 ± 18.8 months). There were 9 Type 1 (myopic) FCE, 10 Type 2 (U-shaped, congenital) FCE, and 17 Type 3 (V-shaped, secondary) FCE. The mean FCE distance to the fovea was greatest in Type 1s ($1791.2 \pm 655.8 \mu\text{m}$) and shortest in Type 3s ($921.2 \pm 718.1 \mu\text{m}$), which was significantly different from each other ($p < 0.006$). The mean choroid thickness both under and adjacent to the FCE was greatest in Type 3s, whereas Type 2 lesions were found to be wider compared to other types. Type 3s were most commonly associated with central serous chorioretinopathy or pachyvessels (52.9%), but also were seen in pattern dystrophy, geographic atrophy, inactive choroiditis, torpedo maculopathy, and adult-onset vitelliform dystrophy. CNVM and breaks in Bruch's membrane was more prevalent in type 3 (41.2% compared with 11.1% for Type 1 and 0% for Type 2, which was significant).

Conclusions: FCE lesions from all three types demonstrated distinct morphological characteristics from one another. Morphological distinction held prognostic implications as type 3 lesions with V-shapes were all associated with other chorioretinal conditions and were more likely to also contain breaks in Bruch's membrane and develop CNVM during longitudinal follow-up. Further long-term analysis of each FCE type is warranted.

TITLE: PEGylated TRAIL alleviates alkali burn induced rat corneal fibrosis by targeting DR5

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Chen, H. Lin, S. Seo, S. Lee, S.C. Yiu, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|Y. Oh, S. Lee, D&D Pharmatech, Gaithersburg, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Minjie Chen: Commercial Relationship: Code N (No Commercial Relationship) | Hui Lin: Commercial Relationship: Code N (No Commercial Relationship) | Stefanie Seo: Commercial Relationship: Code N (No Commercial Relationship) | Yumin Oh: Commercial Relationship(s);D&D Pharmatech:Code E (Employment) | Seulki Lee: Commercial Relationship(s);D&D Pharmatech:Code E (Employment) | Samuel Yiu: Commercial Relationship(s);D&D Pharmatech:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Corneal fibrosis and neovascularization are inevitable outcome of corneal alkali burn injury. Here we determine whether TLY012, a PEGylated TNF-related apoptosis-inducing ligand (TRAILpeg) could provide preventive effects against corneal fibrosis through death receptor 5 (DR5) dependent pathway in a murine alkali burn model.

Methods: To induced corneal fibrosis, ten (10) Sprague-Dawley rats (age 6-8 weeks, male) were treated by applying 0.5N NaOH to the cornea for 90 seconds. After 7 days, rats were randomly assigned into treatment (TLY012, 10 mg/mL, 50uL subconj) or control (PBS 50ul subconj) groups and treated twice a week for the following 14 days. Corneal opacity, neovascularization, edema, and flare were recorded. Analysis of DR5 and α -smooth muscle actin (α -SMA) immunofluorescent staining of rat cornea were performed after rat euthanizing at 21 days.

Results: TLY012 significantly decreased corneal opacity score (0.9 ± 0.19 vs 1.9 ± 0.33 , $*p \leq 0.05$) and neovascularization score (1.0 ± 0.22 vs 2.4 ± 0.33 , $**p \leq 0.01$) compared to PBS group in alkali burn injured rat cornea at D21. TLY012 facilitated corneal flare clearness and transiently slowed corneal edema recovery, but there was no detectable difference between two groups at D21. DR5 were present in corneal epithelium and stroma in PBS treatment group at D21, and its expression was attenuated with TLY012 treatment. Correspondingly, α -SMA staining were noticeably reduced in epithelium and stroma layer with TLY012 treatment. Additionally, TLY012 decreased blood vessel density in corneal stroma induced by alkali injury.

Conclusions: Our experiment showed that TLY012 prevents corneal neovascularization and fibrosis induced by ocular alkali burn injury. These results demonstrated that TLY012 could be a novel candidate for treating corneal fibrotic disease.

TITLE: CRISPR/Cas9-mediated gene-editing of TAPBP to alleviate antigenicity of human corneal-limbal epithelial cells

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Scapin, S. Chauhan, Harvard Medical School, Boston, Massachusetts, UNITED STATES|G. Scapin, S. Chauhan, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Giorgia Scapin: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human Corneal-Limbal Epithelial (HCLE) cells express high levels of Human Leukocyte Antigens Class I (HLA-I), which make them a target for alloimmune rejection. The chaperon Tapasin (coded from the TAPBP gene) is not only important for the proper folding of the HLA-I molecules, but it also plays a vital role in loading the HLA-I with the antigenic peptides before its exposure on the cell surface. The goal of the project is to analyze how the deletion of the TAPBP gene in HCLE cells affects their expression of HLA-I.

Methods: We used the CRISPR/Cas9 gene-editing method to generate the TAPBP gene knockout (KO) in HCLE cells. Specifically, we electroporated the HCLE cells with the Cas9 enzyme and 2 guide RNAs targeting the TAPBP gene. After the recovery of the cells, we performed limiting dilution to generate monoclonal cell lines. We screened such lines by PCR-based genotyping and Sanger-sequencing to uncover the TAPBP-KO clones. We next performed qRT-PCR to verify the abolished expression of TAPBP. To test the ability of the TAPBP-KO cells to express the HLA-I molecules, we performed FACS analysis and compared the HLA-I expression levels with the HCLE wild type (WT) cells.

Results: The comparison of the HLA-I expression in HCLE and in human immune cells (monocytes) demonstrated that both cell types express comparable levels of HLA-I even after the IFN- γ stimulation. Next, we embarked upon the CRISPR/Cas9-mediated KO of the TAPBP gene in the HCLE and tested how TAPBP KO affects the HLA-I expression. We found that 2 electroporation pulses at 1400V gave us 55.7% efficiency and 89% of cell viability. After limiting dilution, we selected 3 monoclonal lines for further analysis. FACS analysis showed a substantial decrease in the HLA-I ABC expression in TAPBP-KO cells (66% vs 99% of WT cells), suggesting that TAPBP-KO cells might escape CD8⁺ T cell-mediated cell death. In contrast, the levels of universally expressed HLA-I E in TAPBP-KO and WT cells remained comparable (93% vs 99%), suggesting TAPBP-KO cells retained their ability to escape from NK cell cytotoxicity.

Conclusions: The deletion of chaperon Tapasin selectively downregulates HLA-I expression in the corneal-limbal epithelial cells, which could prevent their rejection by the immune system.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of vision loss in working age populations worldwide. Patients may not notice any symptoms during the early non-proliferative stage (NPDR) while microaneurysms (MA) can still be detected using fluorescein angiography or optical coherence tomography angiography (OCTA). The purpose of this contribution is to automatically detect MA from OCTA en face images to aid in the early detection and diagnosis of NPDR.

Methods: Patients were enrolled at the New England Eye Center at Tufts Medical Center in Boston. We collected data from 90 eyes (70 patients) with NPDR who were imaged using the OptoVue Avanti system using a field size of 3x3 mm. The system software automatically performs a segmentation of the retinal layers. The OCTA en face images of the superficial capillary layer were used. Two expert graders at the Boston Imaging Reading Center manually labeled MA in these images using custom software. The labeled data were divided into 73 training and 16 testing images. We then trained a 2D nnU-Net to segment the MA. nnU-Net is a self-configuring deep learning tool that can automatically generate 2D and 3D U-nets and uses heuristic and data-based rules to choose suitable hyper-parameters. nnU-Net runs a five-fold cross-validation on the training data, which allows to use the resulting five trained nets as an ensemble.

Results: 12 of the 16 test images contained MA. The number of expert-labeled MA was 21. 11 of those MA were correctly found by nnU-Net. There were 4 false positives, but no false MA were detected on the 4 test images without labeled MA.

Figure 1 shows four of the test images. The top row shows the images without, the bottom row with marked aneurysms. The images show undetected MA (false negatives) marked in red, correctly detected areas in green and false positives in pink. Sub-figure A shows one detected aneurysm and one false negative. B shows two correctly detected MA. C shows a false positive in the center and a not correctly detected aneurysm in the upper image. Both are located directly near a saccade. D shows a correctly identified MA.

Conclusions: nnU-Net detected 11 out of 21 labeled MA. Future work will focus on improving these results by optimizing loss, data augmentation and training of the generated U-Net.

ABSTRACT BODY:

Purpose: Choroidal neovascularization (CNV) is a key feature in the wet form of age related macular degeneration (AMD). Current treatments are inefficient, therefore a better understanding of the pathophysiology of AMD is necessary to develop novel therapeutic approaches. The p75 neurotrophin receptor (p75^{NTR}) is recognized as one of the main surface proteins involved in the transduction of death signals and recently also vascular changes. Here, we aim to determine if p75^{NTR} participates in the development of neuronal and vascular alterations in a mouse model of laser-induced CNV.

Methods: Briefly, mice were anesthetized and their pupils were dilated, then 4 injuries were performed in the retina using a photocoagulation laser with a 532nm wavelength slit lamp. 7 days after laser mice were subjected to electrorretinography (ERG) studies, and posterior sacrifice. Retinas and RPE-Choroid were processed separately for Western blot and immunofluorescence assays in whole mounts and cryosections. Colocalization was analysed in tissues double labeled with p75^{NTR} and one of the following cell markers: F4/80 (macrophages), NG-2 (pericytes), Isolectin IB-4 (blood vessels), glial fibrillary acid protein (glial cells) or β -actin (neurons). WT (N=17) and p75^{NTR} KO (N=12) mice were included in the experimental design and animals without CNV were used as control. GraphPad Prism program was employed for statistical analysis and one way ANOVA or t-test analysis was performed accordingly.

Results: In WT rodents, Western blot of neural retinas of CNV mice exhibited an increased expression of p75^{NTR} protein levels respect to control ($p < 0.05$). Confocal images showed overexpression of p75^{NTR} in macrophages in the RPE-Choroid, and in Muller glial cells around the injured area in the retina. These alterations in the CNV model were accompanied with neuronal dysfunction observed as a reduction in the amplitude of the a-wave by ERG, which was preserved in p75^{NTR} KO mice. In accordance, p75^{NTR} KO mice showed a reduction in the area and perimeter of choroidal neovessels ($p < 0.05$) as well as a decreased macrophage infiltrate by immunostaining.

Conclusions: Altogether these preliminary findings suggest that p75^{NTR} would participate in the development of CNV.

ABSTRACT BODY:

Purpose: Previous studies have shown structural remodeling of rod photoreceptor synaptic terminals (rod spherules, RS) in response to experimental retinal detachment (RD, Erickson, et al., 1983, IOVS, 24: 927). However, these studies relied on conventional electron microscopy, which is limited for 3-D analyses. Here we used the advanced imaging capabilities of electron microscope tomography (EMT) to study the 3-D complexities of the RS in feline retina during remodeling after experimental RD. Our aim was to generate a high-resolution 3-D analysis of the time-course of RS remodeling, and thus enhance our understanding of this process and its potential for reversibility.

Methods: All tissue used in this study was generated in previous studies of experimental RD (Erickson et al., 1983). Here we generated tomograms from RDs of 30min, 1hr, 24hr, 48hr, 72hr, 7d duration and from a control eye without RD. Tomograms were generated from imaging of either single 400nm sections, at 400KeV, or serial 200nm-thick sections, at 120KeV. 3D models were constructed using the software IMOD3D.

Results: At 7d, the RS no longer form a solid layer of terminals across the outer plexiform layer (OPL). Those that remain show several signs of severe degeneration including their transformation into an elongated “teardrop” shape, loss of some post-synaptic processes, changes in the geometry of the synaptic invagination with enlargement of the opening (hilus) through which post-synaptic processes pass, fragmentation of synaptic ribbons, the accumulation of large cytoplasmic vesicles, and a loss of branches from horizontal cell axon terminals within the synaptic invagination. In addition, Müller cells show many ultrastructural changes associated with their hypertrophy throughout the OPL. Within 1hr of RD there is minor restructuring of the synaptic invagination and postsynaptic processes, and a severe loss of synaptic vesicles. The degenerative phenotype becomes more severe as the length of the RD increases.

Conclusions: Our data indicate that RS undergo both pre- and post-synaptic changes that begin within 1hr after a RD. This is much earlier than previously thought. Clearly, it will now be critical to determine at what stage these early changes cease to be reversible, in order to understand the limitations of surgical reattachment for the return of vision in RD patients.

ABSTRACT BODY:

Purpose: To develop an artificial intelligence framework for detecting glaucoma progression using retinal nerve fiber layer (RNFL) thickness measurements obtained from optical coherence tomography (OCT) imaging of the optic disc.

Methods: We developed a deep archetypal analysis (DAA) framework and applied it to RNFL thickness measurements (circle scans with 768 A-scans) of 691 eyes of 691 patients and identified 16 prevalent patterns of RNFL loss. We then developed a framework to detect glaucoma progression using the deep archetypes discovered. We simulated a stable dataset by randomly shuffling the longitudinal visits of another dataset with 254 eyes of 127 subjects (Average of 9 visits). We selected the critical slopes of no-progression from this dataset at 95th percentile and subsequently used an independent longitudinal dataset with 254 eyes (mean 9 visits) to compare the detection rate of the proposed model against linear regression of RNFL summary parameters.

Results: Deep archetypal analysis discovered 16 patterns of RNFL loss which explained over 70% of the total variation in the RNFL data (Fig. 1). The critical slopes were selected in such a way to maintain 95% specificity for each model using the simulated stable dataset. The sensitivity of the overall DAA model was 54.7% while the detection rate of the linear regression of RNFL in global, superior, and inferior hemifields were 16.1%, 13.0% and 16.9%, respectively. Most of the eyes progressed across deep archetypes number 10 and 12 (Fig. 2).

Conclusions: The proposed deep archetypal analysis framework identifies major patterns of RNFL loss in patients with glaucoma. It also provides a more sensitive model in detecting glaucoma progression compared to linear regression of the summary parameters. This model may aid clinicians in detecting structural progression and identifying the corresponding pattern of RNFL loss, which in turn could improve disease monitoring and treatment planning.

ABSTRACT BODY:

Purpose: Transfer learning (TL) is a method in deep learning where knowledge is transferred from one model to another. It allows for generation of artificial intelligence (AI) by 1) limited amounts of data and 2) shortened time. We previously generated AI for analyzing guttae in a Fuchs endothelial corneal dystrophy (FECD) model mouse (Yamada, S, et al., ARVO, 2020). Here we report the use of TL to generate AI for analyzing human guttae from a mouse-model AI.

Methods: Of corneal endothelial images obtained from 20 patients with FECD via contact specular microscopy, 26 focused images were selected and the guttae area was manually annotated as ground truth. Our previously reported AI for analyzing mouse guttae, which was generated by using the FECD mouse-model data (n=2538), was then used to predict the area of human guttae. Next, training/testing was performed to accommodate the AI for mouse guttae to AI for human guttae via application of U-Net, a fully convolutional network architecture for biomedical image segmentation. TL AI was then evaluated by predicting the guttae areas of the human subjects and comparing it with the ground truth.

Results: The AI for mouse guttae severely underestimated the guttae of human subjects, and Pearson correlation coefficient showed no significant correlation between the guttae area predicted by AI and ground truth ($r = 0.21$, $p = 0.384$). Thought sensitivity, specificity, and F-measure of the mouse-model AI was 84.6%, 99.8% and 88.8%, respectively, for analyzing mouse guttae and 5.8%, 99.9% and 10.9%, respectively, for analyzing human guttae. However, the AI for human subjects, which was generated by TL from the mouse-model AI, successfully recognized human guttae, and sensitivity, specificity, and F-measure were 86.6%, 94.7%, and 81.5%, respectively. Pearson correlation coefficient showed that guttae area predicted by TL AI for human subjects was strongly associated with manually annotated ground truth ($r = 0.96$, $p = 1.60 \times 10^{-11}$). Brand Altman analysis showed that the mean systematic error of the TL AI was $-2.25 \pm 10.7\%$.

Conclusions: TL allowed for accommodation of AI for analyzing mouse guttae to AI for analyzing human-subject guttae. Our findings suggest that TL will be applicable in multiple ophthalmology fields; e.g., the generation of AI for device A from data set obtained by device B, C, and D.

TITLE: Ophthalmology resident on-call performance at a tertiary referral center in Texas

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Katuri, J. Wong, N. Tran, S. Lahoti, The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, Texas, UNITED STATES|H. Nguyen, R. Jones, Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joshua Katuri: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Wong: Commercial Relationship: Code N (No Commercial Relationship) | Nghi Tran: Commercial Relationship: Code N (No Commercial Relationship) | Sejal Lahoti: Commercial Relationship: Code N (No Commercial Relationship) | Huy Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Richard Jones: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Post-clinic emergency room and inpatient ophthalmic consultations ("on call") allow unique insights due to increased resident autonomy. We use these encounters to evaluate resident performance in relation to multiple systemic variables to help optimize training and patient care.

Methods: A retrospective study used electronic medical records to collect logistics, clinical data, and resident variables for resident on-call encounters between 7/2019 – 7/2020. Resident data was anonymized and initial encounters were compared with serial follow-up visits for accuracy. Performance was scored by a modified ACR RADPEER system of review. Diagnostic accuracy = 0/1. Diagnostic difficulty = 1/2/3. Management accuracy = 0/1. Management difficulty = 1/2/3, where 2 should involve a senior resident and 3 should involve faculty. Disposition appropriateness = 0/1. Adverse outcome = 0/1 if results were secondary to management and disposition appropriateness.

Results: 209 of 501 encounters had serial follow-up data to use for grading. 23/501 patients were triaged to a later clinic appointment without direct encounter. 9/209 patients followed up 7.1 ± 6.8 days after indirect encounters. Of the 200 direct encounters (difficulty 1.6 ± 0.7), 191 diagnoses were accurate (difficulty 1.6 ± 0.6). 9 were inaccurate (difficulty 2.2 ± 0.8) and encountered a late PGY-2 on average. 2/11 inaccurate diagnoses led to suboptimal management, although both had appropriate follow-up triage and no adverse outcomes. 194/200 had appropriate initial management (difficulty 1.7 ± 0.7). 6/200 were suboptimal (difficulty 1.8 ± 0.4) and encountered a late PGY-2 on average but had no adverse outcomes. 199/200 had appropriate disposition (location and duration). 3/209 were marked as adverse outcomes, one from each level of training: 2 were from delayed IOP management and 1 was a mistriage based on ED staff evaluation.

Conclusions: Sub-optimal performances occurred infrequently in our current redundancy-designed safety escalation system. Performance scores did not statistically vary with different residents, clinical difficulty, or call logistics. Due to appropriate follow-up, suboptimal performances were not associated with worse visual outcomes, but rare cases show the need for prudent high IOP management and reliable ED physician sign out of ocular vitals.

TITLE: Claudin 5 expression has distinct impacts on the Immune profiles of mouse models of AMD

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Byrne, N. Hudson, C. Delaney, A. Reddy, M. Campbell, Smurfit Institute of Genetics, The University of Dublin Trinity College, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Kieva Byrne: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Conor Delaney: Commercial Relationship: Code N (No Commercial Relationship) | Avril Reddy: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Campbell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The role of claudin-5 as a key mediator of the inner Blood Retinal Barrier (iBRB) and Blood Brain Barrier (BBB) are well established. However, the role of this Tight Junction (TJ) protein in diseases affecting retinal homeostasis, remains poorly understood. In this study we analyse the effects of Claudin-5 expression disruption on Age-Related Macular Degeneration (AMD) pathology through the analysis of the immune profiles of two novel mouse models of the disease.

Methods: The first model analysed is created through a Cldn5 flox Tie2cre system in which endothelial Cldn5 expression is heterozygosity is established. RNA samples were isolated from the retinas of these mice for qPCR analysis. Cre negative animals were used as controls.

The second model under investigation utilised AAV vectors expressing an shRNA targeting claudin-5 to decrease Cldn5 expression levels in the retinal endothelium. These mice were fed a high cholesterol diet (HCD) to further induce AMD pathogenesis. RNA samples were isolated from the RPE of these mice and subjected to a PCR array of 35 genes representing various inflammatory markers, markers of endoplasmic reticulum (ER) stress, and oxidative stress markers. Controls used were mice administered with non-targeting shRNA.

Results: Analysis of Cldn5 tie2-cre⁺ retinas show a significant decrease in expression of TJ genes, Marvel2 and Lsr concomitant to Cldn5 suppression, (*p=0.048, *p=0.0493, respectively). Numerous inflammatory markers also show downregulation including Il-1β (*p=0.0455) and macrophage markers such as Tmem119 (**p=0.0089).

Results from the RPE qPCR panel show that inflammatory markers are significantly upregulated in Cldn5 deficient mice. Such markers included cytokines such as Cxcl10 (**p=0.0038), components of the complement system, Traf6, (*p=0.0197) and Toll like receptor 2 (Tlr2, **p=0.0039).

Conclusions: The immune profile of these two disease models show trends towards two distinct inflammatory outcomes. This disparity in inflammatory phenotypes may be attributed to the synergistic effect of a HCD with decreased claudin 5 expression, resulting in the differential recruitment and activation of immune cells within the retina. Therefore, these results provide an interesting insight into the immunological implications of the disruption of claudin-5 expression in such disease contexts.

ABSTRACT BODY:

Purpose: To study the Impulse response functions (IRFs) to luminance and photoreceptor-isolating stimuli in mice expressing a human L*-opsin instead of M-opsin.

Methods: After dark adaptation over night, anesthetized animals were adapted for 2 min to the mean luminance (ML) of the following stimulus.

ERGs to temporal white noise modulation (wnERGs: containing all frequencies up to 20 Hz with equal amplitudes and random phases) were recorded. Both luminance and photoreceptor-isolating stimuli were used.

Responses were recorded at 7 mean luminances (MLs) between -0.7 and $1.2 \log \text{cd/m}^2$ with luminance and at 4 MLs (between -0.8 and $1 \log \text{cd/m}^2$) with rod and cone isolating stimuli.

For each stimulus condition, two recordings of 200 sweeps were performed. IRFs were calculated by a cross correlation of the recordings and the stimulus luminance or photoreceptor excitation. Amplitudes and latencies of the IRF trough and peak were measured at each ML.

Results: Recordings measured with equal stimulus conditions displayed similar time courses, indicating that wnERGs gave reproducible results. IRFs of luminance stimulation showed an initial (a-wave-like) trough followed by a positive (b-wave-like) peak for all MLs. Trough and trough-to-peak (T-P) amplitudes increased monotonously with increasing ML. Latencies of trough and peak decreased with increasing ML up to $0.3 \log \text{cd/m}^2$ and were constant for higher MLs. IRFs of L*-cone and S-cone isolating stimuli displayed similar time courses and dependency on ML. T-P amplitudes increased by a factor of 10^2 for L*-cones and by a factor of 2.5 for S-cones. Maximal S-cone-driven responses were 2.7 times smaller than maximal L*-cone-driven responses. In contrast to cone-driven responses, IRFs of rod-driven recordings decreased in amplitude with increasing ML by a factor of 1.7. In none of the recordings, oscillatory potentials were observed.

Conclusions: wnERGs can be reliably recorded in mice with luminance stimulation and photoreceptor-isolating stimuli. Cone-driven responses grow with increasing ML, whilst rod-driven responses were larger at low ML.

Luminance stimulation shows a rod-cone transition below $0.3 \log \text{cd/m}^2$. Although the IRFs resemble flash ERGs superficially, they are fundamentally different and offer a novel procedure to study retinal physiology.

ABSTRACT BODY:

Purpose: Dark fundus pigmentation (FP) can limit fundus photography quality in eyes being evaluated for retinopathy of prematurity. We sought to determine the impact of FP on retinal layer and choroid-scleral junction (CSJ) visibility and scan quality for investigational bedside swept source (SS) optical coherence tomography (OCT) imaging.

Methods: We analyzed investigational SS-OCT images captured between 30-42 weeks post menstrual age in 188 eyes of 94 preterm infants enrolled in BabySTEPS study (NCT02887157). Trained ophthalmologists, masked to OCT findings, determined FP (dark/medium/blond). Expert graders, masked to FP, evaluated OCT images for: 1) age-appropriate retinal layers visible (yes/no), 2) CSJ visible (yes/no), and 3) overall OCT quality (excellent/acceptable/poor/unusable). To assess the association of FP with retinal layer and CSJ visibility and OCT quality, we performed multivariable logistic regression modeling, adjusting for biologic and demographic confounders and correlations from repeated OCT scans and paired eyes.

Results: Mean gestational age was 27.8±2.6 (SD) weeks, mean birthweight was 964±283 grams; 51 (54%) infants were non-white, and 48 (51%) infants were male. FP was dark in 24 (13%) eyes, medium in 92 (49%), and blond in 72 (38%). All age-appropriate retinal layers were visible in 781 of 846 scans (92%), CSJ was visible in 701 (83%), and OCT quality was excellent/acceptable in 725 scans (86%). Compared to eyes with blond FP, eyes with medium and dark FP did not have higher odds of inability to see all age-appropriate retinal layers on OCT (adjusted OR 1.17 [95% CI 0.39-3.51] and 0.57 [95% CI 0.15-2.20], respectively) or poor/unusable OCT scan quality (adjusted OR 0.87 [95% CI 0.50-1.48] and 0.49 [95% CI 0.16-1.55], respectively). Conversely, eyes with medium and dark FP had higher odds of inability to visualize the CSJ (adjusted OR 2.8 [95% CI 1.49-5.31] and 4.8 [95% CI 1.48-15.48], respectively).

Conclusions: Medium and dark FP affected visibility of CSJ but did not affect overall scan quality or age-appropriate retinal layer visibility on investigational bedside OCT in preterm infants. This study supports the feasibility of using OCT to analyze retinal microanatomy in diverse populations of preterm infants with a range of fundus pigmentation. Further imaging methods/system enhancement could be pursued to improve CSJ imaging.

ABSTRACT BODY:

Purpose: to characterize a large cohort of patients with RPGR-related rod-cone dystrophy (RCD) and compare the phenotypes of patients with mutations on the RPGR-ORF15 isoform and on the RPGR(1-19) isoform.

Methods: male patients with RPGR-related RCD were recruited at the “Center of rare diseases” at “Quinze-Vingts” Hospital, Paris, France. Phenotypic data were collected retrospectively including age of onset, best corrected visual acuity (BCVA), presence of high myopia, kinetic visual field (VF), presence and size of a central hyper-reflective ring on short-wavelength fundus autofluorescence (SW-FAF), presence and width of central preserved ellipsoid zone (EZ) on optical coherence tomography (OCT). All available visits were considered for each patient and an estimation of the progression was done for each quantitative parameter through the analysis of the regression slopes which were then compared between the two genotypic groups. Finally, a correlation between BCVA and all other parameters was done using a linear regression analysis with the cross-sectional data from the last visit available.

Results: 28 patients (age: 42.73 ± 22.27 years) with RPGR(1-19)-related RCD and 84 (age: 37.57 ± 15.03 years) with mutations on the RPGR-ORF15 isoform were included. The age of onset was significantly earlier in the RPGR(1-19) group than the RPGR-ORF15 group (76.4% vs 50.8% in the 1st decade respectively). In both groups a progressive decline of all quantitative parameters was observed along the available follow-up (maximum 18 years for RPGR(1-19); maximum 14 years for RPGR-ORF15). When comparing the respective regression slopes for BCVA, VF, SW-FAF and OCT parameters, no significant differences were found between the two genotypic groups. In all the cohort (as well as in both RPGR(1-19) and RPGR-ORF15 cohorts separately), age was a strong predictor for BCVA (standardized β coefficient: 0.404, $p < 0.001$) as well as the preserved EZ on OCT (standardized β coefficient: -0.450, $p < 0.001$).

Conclusions: longitudinal data on a large cohort of RPGR-related RCD showed no differences in progression between patients carrying mutations on different isoforms of the gene. Overall, the comprehensive analysis of RPGR(1-19)- and RPGR-ORF15-related RCD will help clinicians in assessing the visual prognosis of these patients. This will also constitute an important guidance in the design of therapeutic clinical trials.

TITLE: Multiomic identification of genome-wide DNA binding sites and target genes identifies HIF1 α as a hypoxia-dependent master regulator of lens gene expression

SESSION TITLE: Lens Development and Differentiation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Disatham, L.A. Brennan, M. Kantorow, Biomedical Sciences, Florida Atlantic University, Boca Raton, Florida, UNITED STATES|D. Chauss, B. Afzali, NIDDK, National Institutes of Health, Bethesda, Maryland, UNITED STATES|J. Kantorow, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joshua Disatham: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Brennan: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Chauss: Commercial Relationship: Code N (No Commercial Relationship) | Jason Kantorow: Commercial Relationship: Code N (No Commercial Relationship) | Behdad Afzali: Commercial Relationship: Code N (No Commercial Relationship) | Marc Kantorow: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Hypoxia-inducible factor 1 (HIF1 α) is a critical transcription factor known to govern vascularization. The lens contains an oxygen gradient that parallels the surface to core differentiation of lens epithelial cells into fiber cells. The presence of this oxygen gradient suggests that HIF1 α could mediate gene expression events required for lens cell differentiation and fiber cell function. Consistently, we have recently identified HIF1 α to be an essential regulator of BNIP3L that we have shown initiates the hypoxia-dependent elimination of non-nuclear organelles during fiber cell maturation. Here, we employed a multiomics approach to map the genomic complement of HIF1 α DNA binding sites and target genes in the lens and identify HIF1 α as a novel master regulator of lens gene expression.

Methods: HIF1 α DNA binding was induced in embryonic primary chick lens cells through exposure to dimethylallyl glycine (DMOG). HIF1 α -DNA binding complexes were identified by CUT&RUN (Cleavage Under Targets and Release Under Nuclease). Expression levels of activated or repressed HIF1 α -target genes were identified by parallel RNA sequencing analysis. Sites were mapped to putative promoter or enhancer sequences and analyzed for chromatin configuration by analysis of ATAC sequencing data.

Results: CUT&RUN analysis revealed 8,375 HIF1 α -DNA binding complexes across the chick lens genome. 1,190 HIF1 α -DNA binding complexes were significantly clustered within open chromatin regions ($p < 1e-55$) identified by ATAC sequencing. Formation of the identified HIF1 α -DNA complexes parallels the direct activation or repression of 526 genes, 202 of which contained HIF1 α binding sites within 100kbp of the transcription start site. The identified genes were associated with multiple key cellular processes including glycolysis, cell cycle control, chromatin remodeling, Notch and Wnt signaling, lens cell differentiation, development, and cataract formation.

Conclusions: The data establish a functional genomic map of novel HIF1 α -regulated lens genes. They further support the hypothesis that hypoxia is critical for lens fiber cell differentiation, structure and function and they identify novel HIF1 α -dependent pathways and genetic components important for lens differentiation, homeostasis and cataract formation.

TITLE: Visual Outcomes and Complications of Corneal Transplant With and Without Previous Glaucoma Surgery

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Alawami, H. Liu, I. Kherani, F. Mostofian, S. Ziai, G. Mintsioulis, K. Baig, Ophthalmology, Ottawa Hospital, Ottawa, Ontario, CANADA]

Commercial Relationships Disclosure (Abstract): Adnan Alawami: Commercial Relationship: Code N (No Commercial Relationship) | Henry Liu: Commercial Relationship: Code N (No Commercial Relationship) | Irfan Kherani: Commercial Relationship: Code N (No Commercial Relationship) | Fargol Mostofian: Commercial Relationship: Code N (No Commercial Relationship) | Setareh Ziai: Commercial Relationship: Code N (No Commercial Relationship) | George Mintsioulis: Commercial Relationship: Code N (No Commercial Relationship) | Kashif Baig: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to assess change in visual outcomes and graft survival for patients undergoing corneal transplantation (PKP, DSAEK, UT-DSAEK, DMEK) with a previous history of glaucoma surgery compared to those with a history of glaucoma without glaucoma surgery.

Methods: This is a retrospective single center, case-control study. 71 consecutive patients (mean age = 72.3 ± 14.8 years, M:F = 1.1) who underwent corneal transplantation procedures with a history of glaucoma filtering surgery (trabeculectomy and/or tube shunt) compared to 83 controls (mean age = 72.1 ± 13.9 years, M:F = 0.89) at the University of Ottawa Eye Institute. Patient demographics, surgical technique for corneal transplantation, indication for transplantation, donor endothelial cell density (ECD), death to enucleation and graft times were recorded. The primary outcome of the study was number of letters gained from baseline to 12 months. Secondary outcome was incidence of graft failure and time to graft failure. Analysis was conducted using t-test and chi-squared test with a significance level of 0.05.

Results: Overall, the proportion of patients in each corneal transplant group was as follows: 23 (14.9%) PKP, 70 (45.5%) DSAEK, 9 (2.6%) UT-DSAEK and 52 (33.8%) DMEK. No difference was observed between the two groups with respect to graft status including donor and recipient age, donor ECD, and death to enucleation and graft times ($p > 0.05$). No difference was observed between the two groups with respect of IOP control at baseline ($p > 0.3$) and at 12 months follow up ($p > 0.05$). Baseline BCVAs were 1.56 ± 0.62 LogMAR and 1.26 ± 0.76 LogMAR for the case and control groups respectively ($p = 0.01$). BCVA was improved significantly from baseline to follow-up at 12 months in both case ($p = 0.02$) and control ($p < 0.01$) groups. There was no difference in the number of letters gained from baseline to 12 months between the two groups ($p > 0.05$). Average time to graft failure was 10.6 months, with better overall graft survival rates in the control group (78.3%) compared to the case group (59.2%) ($p = 0.01$).

Conclusions: Although there was no difference in the number of letters gained between the two groups at 1 year, patients with pre-existing glaucoma surgery had worse pre-operative BCVA and overall corneal graft survival rates compared to patients with pre-existing glaucoma on medical therapy.

TITLE: Monocarboxylate Transporters Facilitate Succinate Export, but not Import, in Ocular Tissues

SESSION TITLE: Metabolism and protein processing: retina, photoreceptors and RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Bisbach, D. Hass, J. Hurley, Biochemistry, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Celia Bisbach: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Hass: Commercial Relationship: Code N (No Commercial Relationship) | James Hurley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retina tissue exports succinate, while eyecup tissue (containing sclera, choroid, and retinal pigment epithelium) imports succinate. This study aims to determine which transporters facilitate export of succinate from the retina and import of succinate into the retinal pigment epithelium.

Methods: Retina and eyecup tissue from male and female C57Bl6/J mice was incubated in Krebs-Ringer Bicarbonate buffer with ^{12}C - and ^{13}C -labeled metabolites. Incubation medium was sampled at 0, 20, and 40 minutes, and gas chromatography-mass spectrometry was used to measure the rates of metabolite release into and depletion from the media. Experiments were conducted with a variety of transporter inhibitors and competing metabolic substrates to determine conditions under which succinate import or export was diminished.

Results: Succinate export by retinas was diminished by the MCT1 inhibitor AZD3965 and the MCT4 inhibitor bindarit. Although eyecups also express MCT1 (and MCT3), succinate import by eyecups was completely insensitive to the MCT1 inhibitor AZD3965 and was unaffected by including the MCT1 substrates lactate and pyruvate in the incubation medium. However, eyecup succinate import was severely diminished when assayed in sodium-free buffer, indicating that succinate import into eyecups might instead occur through a sodium-linked transporter, such as one of the SLC13 family members.

Conclusions: Both MCT1 and MCT4 contribute to export of succinate from retinas. Although MCT1 is present on the apical side of the RPE, inhibiting MCT1 does not affect import of succinate into eyecups. Import of succinate into the RPE instead appears to occur through a sodium-linked transporter. It is possible that the different role MCT1 plays in succinate export and uptake in our ex vivo system could be due to physiological differences between the cytoplasm of the retina and the incubation medium that eyecups are exposed to. Since transport of substrates by MCTs is proton-linked, the high rate of glycolysis in retinas could acidify the retinal cytosol to an extent which is sufficient to activate MCT-mediated succinate export. Further experiments to determine 1) the extent to which aerobic glycolysis and succinate export are linked in retinas, and 2) if lowering the pH of eyecup incubation media can cause MCT1 to participate in succinate import will be required to test this hypothesis.

ABSTRACT BODY:

Purpose: We compared fundus features in patients carrying mutations in ABCA4 (16 patients) and peripherin-2/RDS (PRPH2/RDS) (7), both of which are associated with fundus flecks; retinol dehydrogenase 5 (RDH5) (1) and retinaldehyde-binding protein 1 (RLBP1) (2) that display white-dot lesions and patients (9) manifesting reticular pseudodrusen (RPD) in association with age-related macular degeneration (AMD).

Methods: This retrospective study included spectral domain optical coherence tomography (SD-OCT); near infrared fundus autofluorescence (NIR-AF) that originates from melanin; short-wavelength fundus autofluorescence (SW-AF) originating in bisretinoid lipofuscin; and ultrawide-field pseudocolor fundus images.

Results: At positions of flecks, dots and RPD in en face images, hyperreflective lesions were detected in SD-OCT scans. These lesions presented as corrugated thickenings of interdigitation zone (IZ) and ellipsoid zone (EZ) or in later stages as rectangular or pyramidal shaped foci that extended radially through photoreceptor cell-attributable bands interrupting the IZ, EZ in association with a thinned outer nuclear layer (ONL). Hypertransmission of OCT signal, a sign of non-intact retinal pigment epithelium (RPE) was observed with dot-lesions and RPD. Dots, flecks and RPD were typically (but not always) hypoautofluorescent in NIR-AF images, and hyperautofluorescent (flecks, dots) or hypoautofluorescent (RPD) relative to the surround in SW-AF images. Flecks profiles were larger in NIR-AF than in SW-AF images. In wide-field pseudocolor images acquired from an RLBP1-patient, depigmented dot-like foci were organized into peripheral radial arrays resembling patterns in ocular albinism indicative of RPE clones. Target configurations were observed in NIR-AF images associated with dots (RDH5, RLBP1) and RPD.

Conclusions: Common to these disorders are hyperreflective lesions that extend anteriorly and progressively incorporate photoreceptor-attributable OCT bands. We suggest that these deposits may be left by degenerative processes in groups of photoreceptor cells, the degeneration beginning in inner and outer segments and being preceded by RPE dysfunctioning, thinning or atrophy. Differences in en face appearances of these lesions may be accounted for by disease-associated levels of retinoids and bisretinoid, melanin, sensitivity settings and image normalization.

ABSTRACT BODY:

Purpose: We previously reported that retinal pigment epithelial cells (RPE) through melanocortin pathways suppress phagosome maturation within antigen presenting cells (APC). This suppression would significantly affect APC activation of CD4⁺ T cells. Therefore, we assayed for suppression of APC antigen-activation of CD4⁺ T cells by RPE from mice with experimental autoimmune uveitis (EAU) and treated with alpha-melanocortin stimulating hormone (α -MSH).

Methods: Experimental autoimmune uveitis (EAU) was induced in C57BL/6 mice immunized with IRBP peptide in adjuvant, and the mice were treated with α -MSH when EAU reached the chronic phase. At clearance of uveitis, RPE-eyecups were made by making a circumferential cut just under the ciliary body, and discarding the anterior chamber, lens, and neuroretina leaving the RPE monolayer, choroid, and sclera. The RPE-eyecups were incubated in serum-free media for 24 hrs. The conditioned media was removed and used to treat the naive peritoneal macrophages with opsonized ovalbumin for 24 hours. Opsonized rat serum albumin was used as irrelevant antigen control. The APC were washed, and CD4⁺ T cells isolated from draining lymph-nodes of mice immunized to OVA were added. After 48 hrs incubation, the culture supernatant was assayed by ELISA for IFN- γ , IL-17, and IL-10, and the T cells assayed by flow cytometry for Treg cell markers CD25 and FoxP3.

Results: APC treated with the conditioned media of RPE-eyecups from naive and α -MSH-treated EAU mice, but not from untreated-EAU mice significantly suppressed IL-17, while significantly enhancing IL-10 production by CD4⁺ T cells with all RPE-eyecup conditioned media suppressing APC-stimulation of IFN- γ production. While APC treated with the conditioned media of RPE-eyecups from EAU mice significantly enhanced by 2.5-fold the number of CD25⁺ FoxP3⁺ T cells, it was 80% suppressed by RPE-eyecup conditioned media from α -MSH-treated EAU mice that were neither statistically different from the effects of EAU or naive RPE-eyecup conditioned media on APC. None of the RPE-eyecup conditioned media induced APC to expand the population of CD25⁺ FoxP3⁺ Treg cells.

Conclusions: The results demonstrated that APC are influenced by RPE soluble molecules and demonstrated that RPE promote APC maintenance of Treg cells while suppressing expansion of effector T cells. Treatment of EAU with α -MSH supports recovery of RPE regulation of immune cell activity.

TITLE: Cost Comparison of Reusable versus Disposable Equipment for Retinopathy of Prematurity Screening Rounds

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Chang-Wolf, S.F. Freedman, S.G. Prkalapakorn, Department of Ophthalmology, Duke University, Durham, North Carolina, UNITED STATES|S.F. Freedman, Department of Pediatrics, Duke University, Durham, North Carolina, UNITED STATES|E.R. Commercial Relationships Disclosure (Abstract): Jennifer Chang-Wolf: Commercial Relationship: Code N (No Commercial Relationship) | Evan Myers: Commercial Relationship: Code N (No Commercial Relationship) | Sharon Freedman: Commercial Relationship: Code N (No Commercial Relationship) | S. Prkalapakorn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of Prematurity (ROP) screening rounds have been linked to infection transmission and serious adverse outcomes in the neonatal intensive care unit (NICU). The purpose of this study is to compare the cost of using reusable versus disposable equipment (i.e. indirect lenses, eyelid speculums, and scleral depressors) and identify the least costly strategy for maintaining sterile equipment for use on ROP rounds based on the gestational age (GA) distribution of a NICU.

Methods: Based on institutional data of infants examined on ROP screening rounds (2015-2019) and published data from a neonatal network on United States NICU admissions by GA category and NICU type (2015-2019), we modeled cost estimates of maintaining sterile equipment for use on ROP rounds over a 5-year (yr) period. Cost considerations included purchasing enough equipment/day and processing/autoclaving equipment (assuming 5-yr equipment lifetime). We performed separate Monte Carlo microsimulations for per-infant (1) lenses and (2) speculum/depressor sets to quantify uncertainty about whether using reusable or disposable equipment is least expensive.

Results: Over 5 yrs, the median cost of using reusable versus disposable lenses was less (Figure 1A) and the median cost of using reusable speculum/depressor sets was less than the first quartile cost of using disposable speculum/depressor sets regardless of NICU level (Figure 1B). Using Monte Carlo simulations, in level I-IV NICUs, using reusable versus disposable lenses was cheaper in 65.7%, 60.5%, 63.1%, and 63.3% of scenarios, respectively, and using reusable versus disposable speculum/depressor sets was cheaper in 74.8%, 77.2%, 80.4%, and 81.4% of scenarios, respectively. At our academic institution (a level IV NICU), using reusable versus disposable lenses became and remained cheaper after ~2.08 yrs, or 1960 examinations.

Conclusions: Using reusable versus disposable equipment is more likely less expensive for maintaining sterile equipment at all level NICUs for ROP rounds, assuming ≥ 5 yr instrument longevity. Our findings help inform those choosing between these strategies, taking into consideration cost, infection control, and efficiency.

TITLE: Efficacy of netarsudil in veterans with severe glaucoma on maximally tolerated medical therapy

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Kianian, S.W. Hulbert, E.G. Villalpando, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|S.K. Law, J. Giaconi, Ophthalmology, Ronald Reagan UCLA Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Reza Kianian: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Hulbert: Commercial Relationship: Code N (No Commercial Relationship) | Emmanuel Villalpando: Commercial Relationship: Code N (No Commercial Relationship) | Simon Law: Commercial Relationship: Code N (No Commercial Relationship) | JoAnn Giaconi: Commercial Relationship(s);Allergan:Code C (Consultant)

ABSTRACT BODY:

Purpose: Netarsudil is a newly approved intraocular pressure (IOP) lowering agent with a novel mechanism of action. Although the efficacy of netarsudil has been shown in clinical trials, its real-world effectiveness is uncertain. This study assesses netarsudil's effectiveness in reducing IOP in patients with advanced glaucoma already on maximally tolerated medical therapy.

Methods: Medical records of all patients who received netarsudil between 6/1/2018 and 4/30/2020 from the West Los Angeles Veterans Administration Medical Center were retrospectively reviewed. Exclusion criteria included laser trabeculoplasty and glaucoma surgery within 6 months of initiation of netarsudil, ocular conditions interfering with reliable IOP measurement, documented noncompliance with baseline medical therapy, initiation of netarsudil prior to first visit, or if netarsudil was discontinued due to intolerability prior to first post-treatment visit. One eye per patient was enrolled. If both eyes were qualified, the more severely affected eye based on visual field was selected. Baseline average IOP was compared to average IOP within 4 months and more than 4 months after initiation of netarsudil with paired t-tests. Intolerability was reported.

Results: Sixty-six out of the 202 patients that were prescribed netarsudil met the inclusion criteria. Mean age (\pm SEM) was 74.6 ± 1.1 years. 98.5% were male, 65.2% were black, and 80.3% had open angle glaucoma. The mean LogMAR acuity score was 0.78 ± 0.10 (equivalent to 20/120), cup/disc ratio was 0.87 ± 0.01 , the central corneal thickness was 527.4 ± 6.2 μ m, and the total number of medications at baseline was 3.6 ± 0.1 . Mean IOP was reduced from 17.2 ± 0.4 at baseline to 15.0 ± 0.5 within 4 months ($n=66$) and 15.0 ± 0.5 mmHg between 4-18 months ($n=40$) after netarsudil initiation ($p<0.0001$). Thirty-three patients (50%) within 4 months and 18 patients (45%) between 4-18 months had $\geq 15\%$ IOP reduction. There was no significant difference in absolute or percent IOP reduction between patients on ≤ 2 and >2 baseline glaucoma medications. Three patients could not tolerate and stopped netarsudil during follow-up, and 18 of the 136 excluded patients discontinued netarsudil before the first post-treatment visit. Total discontinuation rate was 10.4% (21/202).

Conclusions: Netarsudil is moderately effective in lowering IOP even among patients who have exhausted all other pharmacologic options.

TITLE: Monitoring corneal change in a murine dry eye disease model using in vivo confocal microscopy

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Seo, M. Chen, S.C. Yiu, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|W. Schubert, Bayer AG, Leverkusen, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Stefanie Seo: Commercial Relationship: Code N (No Commercial Relationship) | Minjie Chen: Commercial Relationship: Code N (No Commercial Relationship) | William Schubert: Commercial Relationship(s);Bayer AG:Code E (Employment) | Samuel Yiu: Commercial Relationship(s);Bayer AG:Code F (Financial Support)

ABSTRACT BODY:

Purpose: While dacryoadenectomy is a commonly employed method to establish animal dry eye disease model, there is limited research in systematically monitoring its development longitudinally. In vivo confocal microscopy (IVCM) is a powerful tool to examine the cornea in vivo. Here we applied the Heidelberg Retina Tomograph III with Rostock Cornea Module (HRT III-RCM) to a murine double dacryoadenectomy model to examine the effect of dry eye disease on the cornea.

Methods: Five (5) Sprague-Dawley rats (aged 8-9 weeks, male) underwent double dacryoadenectomy to remove the intraorbital and extraorbital lacrimal glands. Male rats were chosen in this study due to a lesser influence of hormone cycle. A modified Schirmer's tear test, blink tests and IVCM images were acquired pre-surgery and at 1, 2 and 4 weeks post-surgery. Location and depth of up to three nerves per eye were randomly selected in the sub-basal nerve plexus (SNP). Same areas were identified by locating them in SNP layer and re-imaged as volume acquisition in subsequent weeks. Data were presented as Mean+SEM, and p values were calculated by Student's t test.

Results: After double dacryoadenectomy, aqueous tear production measured by Schirmer's test were reduced by 45% ($1.03 \pm .04$ vs. $1.88 \pm .19$ mm/5 min, $*p=0.024$) and blink rate increased to 237% (24.9 ± 3.5 vs. 10.5 ± 2.2 blinks/5 min, $**p<0.001$) compared to pre-surgery value. We observed distinct differences between pre- and post-surgery corneal morphologies using IVCM. Starting from 1 week after surgery, massive inflammatory cell infiltration was observed throughout the SNP which peaked at week 1 and subsided at week 2. Nerve branches swelled and showed noticeable nerve sprouting. These trends were also seen in nerve trunks located in the stroma. Furthermore, in the stroma, we noticed that activated keratocytes were present through week 4. Blood vessels and fibrous elements were also more prominent in post-surgery than pre-surgery corneas.

Conclusions: Here we demonstrated that the HRT III-RCM could be employed to non-invasively monitor pathophysiological changes of dry eye disease. It revealed that differential changes in corneal nerves as well as corneal epithelia and stroma.

TITLE: Objectively Measured Near Work and Light Exposure in Adults

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.R. Bhandari, H. Mirhajianmoghadam, L.A. Ostrin, Optometry, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Khob Bhandari: Commercial Relationship: Code N (No Commercial Relationship) | Hanieh Mirhajianmoghadam: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Ostrin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Evidence supporting a role for near work in myopia prevalence and progression is conflicting, likely due to the subjective nature in which behaviors are traditionally quantified. Additionally, potential mechanisms have not been elucidated. Animal studies suggest that temporal patterns of myopiagenic stimuli may be significant. Continuous objective measurement of viewing behavior and light exposure may help to better understand contributing factors. Here, a novel sensor, the Clouclip, is further validated in adults.

Methods: Five adults wore a spectacle-mounted Clouclip during waking hours and wrist-worn Actiwatch Spectrum continuously for 7 days. Working distance and illuminance were recorded by the Clouclip every 5 seconds (s) and 2 minutes (min), respectively. Activity and illuminance were recorded by the Actiwatch every 1 min. Subjects maintained a log of activities. Data were analyzed in MATLAB. Near work was defined as viewing distances of 10 to <60 cm, and intermediate work 60 to <100 cm. Near work episodes were defined as >1 min near viewing with no interruption >20 s. Continuous near work was defined as 30 min with no interruptions >60 s. Clouclip- and Actiwatch-measured illuminances were compared, and shifts from indoors to outdoors were quantified.

Results: Clouclip wear time was 14.4 ± 0.6 hours (h) per day. Activities noted in subject logs correlated well to Clouclip-measured distance and illuminance. Mean daily duration of near work was 5.0 ± 2.8 h, and intermediate work was 2.1 ± 1.5 h. Mean daily number of near work episodes was 57.1 ± 31.7 with duration of 4.6 ± 1.2 min each and distance of 33.0 ± 4.2 cm. Mean daily number of continuous near work episodes was 1.7 ± 1.2 . Clouclip-measured mean daily light exposure (281 ± 210 lux) was not significantly different than Actiwatch-measured light exposure (125.1 ± 119.8 lux, $P=.09$). Mean daily wake time spent in illuminance <30 lux, 30 to <1000 lux, >1000 lux, >2000, and >3000 lux were 6.1 ± 2.2 h, 6.6 ± 2.1 h, 0.8 ± 0.8 h, 0.5 ± 0.6 h, and 0.4 ± 0.5 h respectively. The number of shifts between indoors and outdoors was 4.9 ± 4.5 (range: 0-15).

Conclusions: The Clouclip provided continuous, objective data for viewing distance and illuminance that correlated well with subject logs and with the Actiwatch, a widely used light sensor. These findings suggest that the Clouclip will be a valuable tool for quantifying behaviors that have been linked to myopia.

ABSTRACT BODY:

Purpose: To evaluate the response of type 1 and type 2 choroidal neovascularization (CNV) components under anti-vascular endothelial growth factor (VEGF) treatment in age-related macular degeneration (AMD) using projection-resolved optical coherence tomography angiography (PR-OCTA).

Methods: Eyes with treatment naïve exudative AMD were enrolled in a prospective, year-long longitudinal cohort study while under PRN anti-VEGF injections. Macular PR-OCTA was obtained at baseline, 6-month, and 1-year visit. PR-OCTA signal between outer plexiform layer to Bruch's membrane generated total CNV angiogram. PR-OCTA signal was further separated by RPE and projected onto type 1 (above RPE) and type 2 (below RPE) CNV angiograms. CNV vascular area was segmented and measured by a convolutional neural network (CNN) based algorithm. Individual CNV were classified as pure type 1 CNV, all vascular area was type 1 CNV component; predominantly type 2 CNV, at least 75% of the vascular area was type 2 CNV component; or mixed type CNV, with type 2 component accounting for 75% or less of the lesion. Change in CNV vascular area between visits were assessed with Friedman's analysis of variance (ANOVA).

Results: Of 18 total eyes, 13 eyes (72%) were pure type 1 CNV, 2 eyes (11%) were predominantly type 2 CNV, and 3 eyes (16%) were mixed type CNV at baseline. Total CNV vascular area did not change over the 1-year follow-up ($P=0.45$). CNV vascular area of type 1 increased ($P=0.0034$), whereas CNV vascular area of type 2 decreased during the 1-year follow-up ($P=0.0015$). At 6-month and 12-month visit, type 2 CNV was undetectable and all cases were graded as pure type 1 CNV. Of 5 eyes with type 2 CNV component at baseline, 4 eyes (80%) had RPE envelopment which converted type 2 CNV component into a type 1 pattern. CNV vascular area of pure type 1 CNV increased, but not significantly ($P=0.0753$).

Conclusions: PR-OCTA with CNN based algorithm demonstrated after one year of treatment, all Mixed type CNV and predominantly type 2 CNV converted to pure type 1 CNV. In these eyes, type 1 CNV vascular area increased at one year. Pure type 1 at baseline had non-significant increase in CNV vascular area at one year.

TITLE: Increased DISC1 expression restores mitochondrial axonal transport and rescues RGC function in glaucoma

SESSION TITLE: Hot Topics in Glaucoma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Quintero, N. Belforte, L. Alarcon-Martinez, F. Dotigny, S. El Hajji, A. Di Polo, Neuroscience, Centre Hospitalier de l'Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Heberto Quintero: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Belforte: Commercial Relationship: Code N (No Commercial Relationship) | Luis Alarcon-Martinez: Commercial Relationship: Code N (No Commercial Relationship) | Florence Dotigny: Commercial Relationship: Code N (No Commercial Relationship) | Sana El Hajji: Commercial Relationship: Code N (No Commercial Relationship) | Adriana Di Polo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Adequate distribution of mitochondria in retinal ganglion cells (RGCs) is crucial for energy balance and synaptic function. Here, we tested the hypotheses that: i) early deficits in mitochondrial transport in glaucoma contributes to RGC loss, ii) the adaptor protein Disrupted in Schizophrenia 1 (DISC1) is an essential regulator of mitochondrial trafficking along RGC axons, and iii) restoring mitochondrial transport is beneficial for RGCs survival and function.

Methods: Ocular hypertension was induced by intracameral injection of magnetic microbeads in Thy1-CFP-MitoS mice, a strain that allows mitochondria visualization in RGCs. Two-photon laser scanning microscopy (TPLSM) was used to image mitochondrial transport along RGC axons, followed by kymograph analysis. Levels of transport adaptor proteins were analyzed by qPCR using mRNA from FACS-sorted RGCs. DISC1 levels in RGCs were modulated using siRNA or recombinant adeno-associated virus serotype 2 (AAV2.DISC1). RGC function was assessed by measuring positive scotopic threshold responses (pSTR).

Results: Live imaging using TPLSM revealed a selective reduction of anterograde mitochondrial transport along RGC axons soon after glaucoma induction (50% decrease vs. sham control, Student's t-test $p < 0.001$, $n = 35$ axons/group, $N = 12-14$ mice/group). Analysis of mitochondrial trafficking genes in RGCs showed reduced DISC1 transcript levels after glaucoma (Student's t-test, $p \leq 0.01$, $n = 4$ /group). DISC1 protein, which is abundantly expressed by naïve RGCs, was also downregulated by ocular hypertension (Student's t-test $p \leq 0.05$, $n = 6$ /group). siRNA-mediated silencing of DISC1 further reduced mitochondrial transport and exacerbated RGC death (14% reduction vs. control siRNA, ANOVA $p < 0.05$, $n = 6$ /group). In contrast, AAV2.DISC1 fully restored mitochondrial mobility and promoted RGC survival in glaucomatous eyes (30% increase vs. control AAV, ANOVA $p < 0.001$, $n = 6$ /group). AAV2.DISC1 also restored light-evoked pSTR amplitudes, indicative of RGC functional recovery.

Conclusions: Ocular hypertension triggers mitochondria axonal transport deficits and limits the availability of trafficking proteins, notably DISC1. Restoration of DISC1 levels is sufficient to rescue mitochondrial mobility, enhance RGC survival and light-evoked responses. These findings suggest that mitochondrial transport recovery is beneficial to improve RGC viability and function in glaucoma.

ABSTRACT BODY:

Purpose: Inherited retinal degenerations (IRD) are rare genetic eye diseases with >300 implicated genes, many manifesting as progressive visual loss in children/young adults. The IRD population was historically underserved and disillusioned with healthcare services due to lack of interventions. Many novel therapies (e.g., gene and cell-based therapies) will require accurate genetic/clinical diagnosis, thus an efficient and effective pathway for assessment and management of IRDs is required. Here we describe the development of a national pathway for the management of the Irish IRD population.

Methods: Surveys of past Irish practice and international experts advice were used to design an all-Ireland IRD service (Target 5000). Assessment included clinical phenotyping (history, examination, multimodal imaging, perimetry, and electrophysiology) and next generation genetic sequencing in research-grade and accredited laboratories. Unresolved pedigrees underwent further studies (whole gene/whole exome/whole genome sequencing). Novel variants were interrogated for pathogenicity (cascade screening, in silico analysis, functional studies). Weekly multidisciplinary team (MDT; ophthalmologists, physicians, clinical and molecular geneticists, genetic counsellors) meetings reconciled phenotype with genotype. Bespoke care plans were created for each patient comprising supports, existing interventions, and novel therapies/clinical trials.

Results: The survey revealed that, prior to Target 5000, a significant cohort of patients were not engaging with healthcare and support services due to lack of effective interventions. Pathogenic/likely-pathogenic genetic variants in IRD-implicated genes were confirmed in 62.3% of cases, with 11.6% had variants of unknown significance. The genotyping strategy (research grade testing with validation in an accredited laboratory) of Target 5000 saved 42.73% vs independent testing, not accounting for MDT expertise access, which is unavailable outside the program. This has leveraged funding from government resources, where previously this was largely charitably sourced.

Conclusions: The Target 5000 program has demonstrated a move toward a more efficacious & efficient model of care. This enables harmonized clinical & genetic diagnosis while investigating novel genes/variants, disease mechanisms and therapies. This template could be helpful in developing similar IRD program in small/medium nations.

AUTHORS/INSTITUTIONS: P. Patel, J. Zhao, K.E. Bollinger, Ophthalmology, Augusta University Medical College of Georgia, Augusta, Georgia, UNITED STATES|J. Zhao, K.E. Bollinger, B.A. Mysona, James and Jean Culver Vision Discovery Institute, Augusta, Georgia, UNITED STATES|B.A. Mysona, Cell Biology and Anatomy, Augusta University, Augusta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Parth Patel: Commercial Relationship: Code N (No Commercial Relationship) | Jing Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Kathryn Bollinger: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Mysona: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is the leading cause of irreversible blindness in the world. Two risk factors are elevated intraocular pressure and increased age. The Brown Norway (BN) rat has emerged as an important pre-clinical model to study glaucoma. Here, we investigated changes in ON structure and function with age. We hypothesized that in vivo screening of the visual system would correlate with ON morphology.

Methods: Male and female BN rats, 11 (average age 15.5 months) and 11 (average age 2.8 months) were used. Prior to sacrifice, pattern electroretinography (PERG), optokinetic response (OKR), and optical coherence tomography (OCT) were assessed. ONs harvested 1.5 mm posterior to the globe, were fixed (4% paraformaldehyde, 2% glutaraldehyde in 0.1-M sodium cacodylate buffer), postfixed (2% osmium tetroxide), and embedded. Semithin (0.5–1 μ m) sections stained with 1% toluidine blue were imaged by light microscopy (63x oil). QuPath software was used for automated analysis of axon numbers, densities, and size distributions, percent gliotic area, and ON cross sectional area. Statistical significance ($P < 0.05$) was determined by two-way ANOVA followed by Sidak's multiple comparison test or two-tailed Student's t-test.

Results: Overall, ON axon numbers in old and young rats were not statistically different although young female rats had fewer numbers of detected axons. Old rats had significantly lower axon densities and higher ON cross sectional areas than young rats. Old rats had significantly increased NFL thickness but smaller total retinal thickness than young rats. Old rat axon distributions had more small (0.25 μ m) and large (>2 μ m) diameter axons than young rats. Functional analyses showed significant increases in N2 wave timing in old rat PERGs. Old and young rats had similar visual acuity assessed by OKR but contrast sensitivity trended lower in old rats. Correlations of axon numbers and densities with PERG, OKR, and OCT parameters did not show significant trends.

Conclusions: Old and young rats have subtle but significant differences in ON structure and function. Lack of correlation between in vivo screening and ON morphology suggest that PERG, OKR, and OCT did not predict variations in axon numbers or axon densities at baseline. Examination of other biochemical markers of aging and neurodegeneration may offer a clearer picture of how age affects the propensity to develop glaucoma.

ABSTRACT BODY:

Purpose: Usher syndrome Type 1C (USH1C) is an inherited deaf-blinding disease that affects Acadian populations in the United States and Canada. Specifically, the USH1C c.216G>A mutation encodes a truncated harmonin protein that disrupts photoreceptor and hair cell function. The goal of this study was to develop genetic approaches for long-term vision improvements in a murine model of USH1C. We hypothesized that AAV-mediated gene therapy and gene-editing approaches would increase full-length Ush1c expression and restore visual function in USH1C mice.

Methods: An AAV vector co-expressing Ush1c-a1 and GFP was delivered via subretinal injection to USH1C mice at different postnatal (P) ages (P17, P22, P98). Transgene expression was determined by confocal scanning laser ophthalmoscopy (cSLO), immunohistochemistry (IHC), and polyacrylamide gel electrophoresis (PAGE). Changes in retinal structure, function, and visual behavior were assessed using optical coherence tomography (OCT), electroretinography (ERG), and a visual cliff assay, respectively. As an alternative approach, multiple gene-editing systems targeting the 216A mutation were developed and introduced into 293T cells alongside an USH1C minigene or into USH1C murine fibroblasts. Editing efficiency was determined by restriction fragment length polymorphism (RFLP) and sequencing analyses.

Results: AAV-treated retinas showed increased full-length Ush1c mRNA and GFP fluorescence localized to the outer nuclear layer (ONL) and photoreceptor inner/outer segments (IS/OS) up to 6 months of age. Although cSLO showed GFP in approximately 20% of the fundus, these molecular changes did not correlate with improvements in retinal structure, function, or visual behavior. Multiple combinations of gene-editing plasmids yielded high rates of on-target editing (up to 46% in sorted 293T cells) with minimal off-target effects in the protospacer region.

Conclusions: This study demonstrated successful AAV-mediated transgene expression in USH1C murine retina and successful gene editing of the human USH1C c.216G>A mutation, in vitro. Future studies will modify viral dose, Ush1c variant, gene promoter, and capsid structure to optimize long-term improvements in retinal structure, function, and visual behavior. We are currently optimizing the transfection protocol for murine fibroblasts to determine editing efficiency at the genomic 216A site.

TITLE: The anti-inflammatory and neuroprotective activity of novel hybrid molecule SA-10 in in vitro ischemic models

SESSION TITLE: Blood flow, ischemia, reperfusion

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Acharya, S. Gondi, A. Dibas, C. Amankwa, North Texas Eye Research Institute, University of North Texas Health Science Center, Fort Worth, Texas, UNITED STATES|L. Acha, S. Roth, B. Mathew, Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Suchismita Acharya: Commercial Relationship: Code N (No Commercial Relationship) | Lorea Gamboa Acha: Commercial Relationship: Code N (No Commercial Relationship) | Sudershan Gondi: Commercial Relationship: Code N (No Commercial Relationship) | Adnan Dibas: Commercial Relationship: Code N (No Commercial Relationship) | Charles Amankwa: Commercial Relationship: Code N (No Commercial Relationship) | Steven Roth: Commercial Relationship: Code N (No Commercial Relationship) | Biji Mathew: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Embolism and/or high intraocular pressure lead to poor retinal circulation, reactive oxygen species (ROS) production, microglial activation and retinal ganglion cell (RGC) death. Previously we reported, a small hybrid molecule, SA-10 with both anti-oxidant and nitric oxide donating activity protect retina in a mouse model of ischemia/reperfusion (I/R) injury. Here, we determined the anti-inflammatory and angiogenic effects of SA-10 using in vitro primary human endothelial and rat retinal neuronal cells.

Methods:

Tube formation assay: Human umbilical vascular endothelial cells (HUVECs) were seeded on Matrigel with H_2O_2 (200 μM) and with or without SA-10. Formation of microtubules were captured at 12h and analyzed by Angiogenesis analyzer on ImageJ. I/R cell assays: Primary and immortalized (R28) rat retinal mixed neurons (Oxygen Glucose Deprivation model) and primary rat retinal microglial cells (activated with TII: TNF- α IL- β and IFN- γ) were used with or without SA-10 (1.0, 10, 100 μM). ROS scavenging (DCFDA) and cytoprotective (LDH) activities were measured at 24h. Inhibition of microglial activation by SA-10 was evaluated by measuring inflammatory cytokines from cell supernatant using multiplex ELISA. Data represented as Mean \pm SEM. N = 4.

Results: In HUVECs, SA-10 dose dependently increased microtubule formation with an EC_{50} of 0.125 μM . SA-10 (10 μM) significantly attenuated cell death in both microglia and R28 cells (43% vs 13% and 52 % vs 17% respectively) and decreased ROS (68% to 38%) production in retinal microglial cells. OGD induced cell death is attenuated in primary retinal neurons (66% vs 10%) by SA-10. In microglia after TII insult, there was significant increase in inflammatory cytokines IL-4, IL-1 β , IL-6, TNF- α and decrease in anti-inflammatory cytokine IL-10 as compared to control. SA-10 (10 μM) significantly decreased (2-3-fold) all inflammatory cytokines and increased IL-10 (2.5-fold).

Conclusions: Our results are consistent with our hypothesis that the compound SA-10 is protective to retinal neurons and microglia by decreasing oxidative stress, inflammation with possibility to improve retinal blood perfusion by forming new blood vessels. We predict SA-10 as a possible therapeutic candidate in treating I/R injury in retina and diseases associated with microglia activation and inflammation.

ABSTRACT BODY:

Purpose: The cadherin-related family member 1 is a transmembrane photoreceptor protein encoded by CDHR1 (OMIM 609502). Mutations in CDHR1 are associated with cone-rod dystrophy (CRD 15), retinitis pigmentosa (RP 65) and late-onset macular dystrophy. This work aims to:

1. Describe the clinical and molecular findings in a retinal dystrophy cohort attributed to autosomal recessive CDHR1 variants.
2. Report novel pathogenic CDHR1 variants in ethnic/racial groups not previously known to be affected by disease associated with this gene.

Methods: Ten retinal dystrophy patients harboring biallelic CDHR1 variants were identified from the National Eye Institute clinic records. Pertinent demographic and historical data as well as genetic testing results were collected. Initial visit and follow-up data were analyzed including visual acuity, color vision, Goldman visual field (GVF) testing, color fundus photography (CFP), fundus autofluorescence (FAF), optical coherence tomography (OCT), electroretinography (ERG).

Results: Six males and four females (mean age at the most recent clinic visit 49.0 ± 13.7 years) from nine families of African American, Asian, and European (including Greek) origins were identified. Age at the time of initial symptoms showed a bimodal distribution with peaks in the second (for RP patients) and fifth (for CRD patients) decades of life. Vision loss was the most common presenting symptom. Best corrected visual acuity at last visit ranged from 20/20 to 20/2000 (average LogMAR 0.8 or 20/125). Notable asymmetry of the degree of macular atrophy was present in two patients. Color vision deficits were more severe in patients with larger areas of macular atrophy. GVF testing revealed constriction of visual fields in three patients diagnosed with RP, while seven patients with maculopathy or CRD had central scotoma that mirrored the degree of macular atrophy. Macular involvement was noted in all patients on CFP, FAF, and OCT. Unrecordable scotopic ERG responses distinguished the RP patients. Novel pathogenic variants included a 7-bp deletion common to three patients of Greek origin.

Conclusions: Despite the variable phenotype of CDHR1-associated retinal dystrophies, an involvement of the macula is a common manifestation in this patient cohort. Notable asymmetry in macular involvement is highlighted in two patients. Novel mutations affecting patients of African American and Greek background are reported.

TITLE: Expression and localization of exon-skipping RGR-d protein in cultured RPE cells

SESSION TITLE: Retinal diseases: molecular and biochemical mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Bao, H. Xu, H. Cui, M. Zhao, Department of Ophthalmology, Peking University People's Hospital, Beijing, CHINA|H.K. Fong, USC Roski Eye Institute, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Xuan Bao: Commercial Relationship: Code N (No Commercial Relationship) | Hui Xu: Commercial Relationship: Code N (No Commercial Relationship) | Haoran Cui: Commercial Relationship: Code N (No Commercial Relationship) | Henry Fong: Commercial Relationship: Code N (No Commercial Relationship) | Mingwei Zhao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The exon-skipping isoform of RGR opsin (NM_001012722.1, RGR-d) has been reported to be associated with human age-related macular degeneration (AMD) and AMD-like pathology in gene-editing mouse models. RGR-d is considered an abnormal protein that undergoes different intracellular processing from the normal RGR protein. Here, we studied the expression and subcellular localization of RGR and RGR-d protein.

Methods: ARPE-19 cells were transfected with FLAG labeled lentiviral vectors expressing RGR or RGR-d and cell lines with stable expression were selected by puromycin. Cells were treated with 4 μ M MG132, a 26S proteasome inhibitor, for 0, 4, 12, and 20 h. The expression of RGR and RGR-d was detected by real-time PCR and western blot. After the cells were treated with 2 μ M MG132 for 10 h, double-labeling immunofluorescence was used to detect the co-localization of RGR/RGR-d and the markers of organelles or autophagy-lysosomal pathway, including calnexin, GM130, LAMP-2, and Rab7.

Results: After the transfection, the mRNA expression of both RGR and RGR-d were hundreds of times higher than that of the negative control. The protein expression of RGR was significantly elevated. But inconsistent with the mRNA expression, RGR-d expression was barely detected by western blot. After the cells were treated with MG132, the protein expression of RGR-d was detected after 4 h, and gradually increased after 12 h and 20 h, indicating an intracellular proteasome degradation of RGR-d. MG132 of a low concentration was then used for the enrichment of intracellular RGR and RGR-d protein. Double-labeling immunofluorescence showed that compared with RGR, RGR-d had less co-localization with calnexin, a marker of the endoplasmic reticulum (ER), and better co-localization with LAMP-2 and Rab7, markers of the autophagy-lysosomal pathway. Neither RGR nor RGR-d had significant co-localization with GM130, a marker of the Golgi apparatus.

Conclusions: In transfected cells, RGR-d was normally transcribed but was almost completely degraded through the ubiquitin-proteasome pathway after translation, while the full-length RGR was normally expressed at both mRNA and protein levels. With the treatment of MG132, RGR-d was less likely to undergo the post-translational modification in the ER and Golgi apparatus and was prone to lysosomal degradation. The findings may provide insights into the processing of abnormal RGR-d protein in the aged population.

TITLE: Mesenchymal stem cells enhance suppressive function of T regulatory cells and promote corneal graft survival

SESSION TITLE: Corneal immunology and neovascularization I

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Mittal, W. Cho, E. Elbasiony, S. Chauhan, Department of Ophthalmology, Harvard Medical School, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sharad Mittal: Commercial Relationship: Code N (No Commercial Relationship) | WonKyung Cho: Commercial Relationship: Code N (No Commercial Relationship) | Elsayed Elbasiony: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mesenchymal stem cells (MSCs) regulate adaptive immune responses in various inflammatory disorders. Here, we investigate whether MSCs directly interact with T regulatory cells (Tregs) to promote their suppressive function in corneal transplantation.

Methods: Bone marrow MSCs (CD45⁻CD34⁻SCA1⁺CD29⁺) and CD4⁺CD25⁺ Tregs (purity: >95% Foxp3⁺) from spleen and lymph nodes (LNs) of Balb/c mice were used. MSC-Treg co-cultures were set up in the presence or absence of Transwells (1 µm pore size) for 48h. Flow cytometry was performed to assess (i) Tregs for Foxp3 levels and frequencies of Foxp3^{high} Tregs and (ii) MSCs for CD80 expression. Results were calculated as fold change from normal controls. To evaluate the contribution of MSC-expressed CD80 on Treg function, MSC-Treg co-cultures were neutralized with anti-CD80 antibody (1 mg/ml), and CD80-silenced MSCs were intravenously administered to transplanted allogeneic mice (Balb/c grafted with B6 corneas). Corneal opacity was evaluated to assess graft survival.

Results: A significant increase was observed in frequencies of Foxp3^{high} Tregs (fold change: 4.8 ± 0.6; p<0.01) and their FoxP3 expression (fold change in MFI: 3.4 ± 0.7; p<0.01) in direct co-cultures of MSCs and Tregs compared to Tregs cultured alone. Inhibition of cell-cell contact via Transwell mitigated this effect (p<0.05). Data showed significant expression of CD80 on MSCs, and neutralization of CD80 in the co-cultures resulted in a decrease of Foxp3^{high} Treg frequencies (fold change: 2.8 ± 0.8; p<0.04) and levels of Foxp3 in Tregs (fold change in MFI: 1.6 ± 0.6; p<0.05). Mice treated with CD80-silenced MSCs did not show augmented frequencies of Tregs with high Foxp3 levels (fold change: 1.3 ± 0.3) and enhanced graft survival (p<0.02) compared to control shRNA/MSC-treated controls (fold change: 2.4 ± 0.3; p<0.03).

Conclusions: MSC-expressed CD80 directly amplifies function of regulatory T cells and promotes corneal graft survival.

ABSTRACT BODY:

Purpose: The most common ophthalmic surgery performed in the world is cataract surgery, as cataracts affect the aging population and is an inevitable part of life. Standard post-operative care after all ophthalmic surgery involve the use of eye drops to prevent infection. One of the major challenges including the postoperative infection prevention after ophthalmic surgery is the difficulty in administering topical medications into the patients' eyes. Studies have shown that up to 50% of prescribed drops are incorrectly instilled or not used at all. When used correctly, only a minor fraction of the instilled medication can effectively get into eyes. In this study, we examine the safety and efficacy of an in vitro safe sustained release formulation of antibiotics in prevention and treatment of ocular infections. This could revolutionize infection control and treatment regimens, and significantly improve patient's outcomes and quality of life, while also reducing the cost of care.

Methods: Hyaluronic acid conjugated polymers of ciprofloxacin and vancomycin were created using biocompatible chemical linkers with stable release profile and safety in vitro. 10,000 colony forming units of bacteria were injected into the anterior chamber of New Zealand white rabbit eyes to simulate potential inoculation from bacteria during surgery and compared to standard topical antibiotic therapy using ciprofloxacin and vancomycin. Daily clinical anterior segment and fundus exams were performed. Animals were followed daily for 2 weeks or until any evidence of endophthalmitis.

Results: Hyaluronic acid-antibiotic polymers provide effective prophylaxis and treatment of potential bacterial inoculation of *Staphylococcus aureus* and *Pseudomonas aeruginosa* in a rabbit model for ophthalmic surgery that is non-inferior to current standard of care using topical antibiotics. Rabbit eyes are able to clear the infection at similar rates in both groups.

Conclusions: The hyaluronic acid and antibiotic polymers provide effective and predictable release of antibiotics that are safe and effective in vitro and in vivo. These particles provide a novel way to deliver drugs in an ophthalmic setting that could replace the need for post-operative drops and make surgery dropless. These sustained release particles could also be used to treat corneal keratitis, removing the need for hourly drops, improving both efficacy and patient quality of life.

ABSTRACT BODY:

Purpose: The optic nerve and the brain share anatomy and pathophysiology of the neurodegenerative process. This study investigates if genetic risk scores (GRS) for large optic nerve cupping (CDR) mediates the association between CDR and cognitive function.

Methods: We used data from the Women's Health Initiative (WHI)-Sight Exam and WHI-Memory Study, excluding women with ocular hypertension (intraocular pressure > 23 mmHg) or glaucoma medication use. Large CDR was defined as > 0.6 in either eye. To form the GRS, we used the log odds ratio (OR) estimated from a previously identified single nucleotide polymorphisms (SNP) logistic regression model adjusted for age and two principle components. Cognitive function was measured by the Modified Mini-Mental State Examination (3MSE). We used multiple logistic regression to evaluate the association of the weighted GRS with large CDR, then a generalized linear model to assess the association between weighted GRS and 3MSE scores, and between weighted GRS, CDR, and 3MSE scores, adjusted for age, education, smoking, diabetes, body mass index, cardiovascular disease, diabetic retinopathy, and hormone therapy randomization. As 3MSE scores were non-normally distributed, a log-transformed function of scores, $\log(102-3MSE)$, was used.

Results: Final analyses included 1201 White women; mean age (\pm SD) was 69.59 ± 3.62 years. Of those, 7.24% had large CDR. The mean GRS in women with and without a large CDR was 1.51 ± 0.31 vs. 1.41 ± 0.36 , $p = 0.004$, and the odds of large CDR for a one unit increase in GRS is 2.29 (95% CI: (1.21, 4.34), $p = 0.011$). There was no association between weighted GRS and 3MSE scores ($p = 0.964$). The final adjusted model showed that women without large CDR had significantly lower 3MSE scores than those with large CDR, yielding a predicted mean difference in 3MSE of 0.838 (p -value=0.0071). Adding GRS in the model, women with large CDR still had statistically significantly lower 3MSE scores than those without large CDR, yielding a predicted mean difference in 3MSE scores of 0.844 ($p = 0.0069$).

Conclusions: Prior work showed a mean difference of 0.21 3MSE units was associated with a 76% increased hazard for dementia. This analysis suggests independent of the GRS, women who had large CDR, without glaucoma or ocular hypertension had a lower cognitive function. Further investigation is warranted.

ABSTRACT BODY:

Purpose: To characterize macular neovascularization (MNV) developing in eyes affected by geographic atrophy (GA).

Methods: In this multicentric longitudinal study, patients previously affected by GA that developed an active MNV were included in 3 retina referral centers. Patients were investigated using structural optical coherence tomography (OCT), fundus autofluorescence, OCT-angiography, and dye angiographies. Patients were treated with ProReNata (PRN) anti-vascular endothelial growth factor (VEGF) injections and were reevaluated after treatment.

Results: Among 512 patients previously diagnosed with GA, 40 eyes of 40 patients (mean age 80.8 ± 7.9 years, mean GA area $8.73 \pm 7.39 \text{ mm}^2$) presented with treatment-naïve exudative MNV (accounting for an estimated prevalence of 7.81%; 5.49 - 10.13, 95% confidence intervals) and thus were included in the analysis. 67.5% of MNVs were classified as type 2 MNV, 25% as type 1, 2.5% as type 3, and 5% as mixed phenotype. In 92.5% of cases, active MNV in GA showed subretinal hyperreflective material (SHRM) with or without evidence of sub-/intra-retinal hyporefective exudation. During a mean follow-up of 28 ± 25 months, patients were treated with 6.6 ± 6.3 anti-VEGF injections, with 2.9 ± 1.4 injections in the first year of treatment. No patient developed GA enlargement in the area of MNV.

Conclusions: MNVs in GA showed different multimodal imaging features and therapeutic response in comparison to previously reported features of MNV in age-related macular degeneration (AMD) without GA. For these reasons, the combined phenotype (i.e. GA with neovascular AMD) should be considered as a distinct entity in the research and clinical setting.

TITLE: Fixation Eye Movements in Amblyopia during Binocular and Dichoptic viewing conditions

SESSION TITLE: Amblyopia: Translational Studies and Trials

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F.F. Ghasia, J. Murray, K. Garg, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Fatema Ghasia: Commercial Relationship: Code N (No Commercial Relationship) | Jordan Murray: Commercial Relationship: Code N (No Commercial Relationship) | Kiran Garg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patching and dichoptic amblyopia therapies aid recovery of vision through distinct mechanisms and require different viewing conditions. We have previously characterized abnormalities of fixation eye movements of the fellow and amblyopic eye during monocular and binocular viewing conditions. The purpose of the study was to assess the fixation stability of the fellow and amblyopic eye and quantify eye misalignment in dichoptic environment when the contrast of the fellow eye was rebalanced to facilitate reduction in the inter-ocular suppression.

Methods: We recruited 20 amblyopic and 10 control subjects. Fixation eye movements were measured with high-resolution video-oculography during A) binocular and B) dichoptic viewing as the brightness of the fellow eye fixation target varied from full to low contrast. Fixation eye movements and BCEA of fellow and amblyopic eye and vergence BCEA were analyzed.

Results: We found increased instability of the amblyopic eye during both eye viewing conditions. We also found increased instability in both controls and amblyopes under dichoptic viewing especially at low fellow eye contrasts. BCEA values increased from -0.12 ± 0.07 at full contrast to -0.07 ± 0.12 at low contrast in the dichoptic environment in controls. Amblyopes responded more dramatically, with mean BCEA values increasing from 0.02 ± 0.38 at full contrast to 0.1 ± 0.36 at low contrast for the fellow eye and from 0.32 ± 0.29 at full contrast to 0.54 ± 0.45 at low contrast for the amblyopic eye. Dichoptic viewing also affected eye alignment, with 4 of the 6 strabismic subjects experiencing pronounced increases in strabismus angle as compared with binocular viewing. Vergence BCEA increased from 1.93 ± 0.925 to 3.15 ± 2.99 at 100% contrast in amblyopes, rising to 4.84 ± 3.31 at low contrast. There was no such increase in controls.

Conclusions: Even for simple stimuli, dichoptic presentation presents challenges for amblyopes. Although, the contrast rebalance to the fellow eye is likely reducing the inter-ocular suppression, the eye misalignment and disconjugacy are increased in the dichoptic environment for amblyopic subjects. This could account for the variability of treatment outcomes seen with dichoptic therapies.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic began in the United States in early 2020, affecting day to day life for adults and children. Secondary to quarantine and lockdown measures, many people have had to spend more time in their home and carry out activities virtually, not only for work, but also for social interactions and daily tasks, such as grocery shopping. Increased time indoors and electronic device use may ultimately impact sleep/wake patterns and, in younger adults, potentially eye growth and myopia progression. Our goal was to compare subjective measures of daily behaviors in myopic and non-myopic adults during the summer COVID-19 pandemic to their behaviors prior to the pandemic.

Methods: Adults (ages 40.5 ± 5.5 years, $n=66$) completed a questionnaire regarding their demographics, ocular history, and behaviors for summer 2020, as well as for before the COVID-19 pandemic. Subjects were asked to estimate the time spent per day on various activities, such as hand held and traditional electronic device use, time spent outdoors, and sleep. Data were analyzed with repeated measures ANOVA for session (COVID-19 vs pre-COVID-19), day of week (weekdays vs weekends), and refractive error group (myopic vs non-myopic).

Results: During the COVID-19 pandemic, participants spent more time doing near work compared to pre-COVID-19 (4.5 ± 0.4 vs 4.1 ± 0.3 hours per day, respectively, $P=.026$). Additionally, on weekdays, participants demonstrated increased electronic device use during COVID-19 compared to pre-COVID-19 (9.9 ± 0.5 vs 8.9 ± 0.5 hours per day, respectively, $P=.008$). On weekdays, sleep duration significantly increased by 36 minutes during COVID-19 ($P<.001$). Time spent outdoors and in physical activities were not significantly different between sessions ($P>.05$ for all). For all metrics, there were no significant differences by refractive error group.

Conclusions: COVID-19-related quarantine measures changed adults' behaviors compared to before the COVID-19 pandemic. Based on self-report, near work and use of electronic devices increased during COVID-19, whereas physical activity and time outdoors were not significantly different compared to pre-COVID-19. There were no differences in behaviors between myopes and non-myopes. Depending on temporal characteristics of artificial light exposure from the reported increase in electronic device use, sleep/wake patterns and circadian rhythm may ultimately be affected.

ABSTRACT BODY:

Purpose: Vascular leakage and aberrant neovascularization in eyes are major causes of blindness affecting diverse patient groups. Current treatments require regular intravitreal injections of anti-VEGF biologics. Here, we demonstrated the therapeutic benefits of a topically administered inhibitor of End-Binding protein 3 (EB3), herein EBIN, in treating leaky choroidal neovessels.

Methods: The efficacy of topical administration of EBIN was evaluated in a CNV model of AMD in African green monkeys compared to topical vehicle and single IVT administration of aflibercept. Six laser spots were symmetrically placed within the perimacular region employing an Iridex Oculight TX 532 nm laser with laser duration of 100 ms, with a spot size of 50 μm and power of 750 mW. All animals received 30 μL topical instillation of vehicle or 150 μg EBIN twice daily on days 1-7 and once a day on days 8-21. An additional cohort received IVT injections of 2 mg Eylea® per eye. Fluorescein leakage was graded using angiograms of CNV lesions. The CNV complex area was measured using Optical Coherence Tomography images.

Results: The incidences of clinically relevant grade IV CNV was 23.08% and 16.42% of the total lesions from the vehicle treated group and 11.94% and 7.35% in EBIN treated group at days 14 and 21, respectively. The Fisher's Exact Probability Test revealed significantly lower incidence of grade IV lesions in EBIN versus vehicle groups at day 14 ($p=0.0288$). No significant difference was observed between vehicle and EBIN groups on day 21, and EBIN and aflibercept treated groups on days 14 and 21. The mean CNV lesion size was 50,471, 39,512 and 23,838 μm^2 at day 14, and 34,621, 33,884 and 19,739 μm^2 at day 21 for vehicle, EBIN, and aflibercept groups, respectively. Compared to the vehicle group, the mean CNV complex area was significantly smaller in EBIN-treated eyes at day 14 ($p=0.0146$), but not at day 21 ($p=0.9791$). The mean CNV complex area was smaller in the aflibercept group compared to EBIN group at days 14 ($p=0.0003$) and 21 ($p=0.0014$).

Conclusions: Mean CNV complex size was significantly smaller in the EBIN group at day 14 and aflibercept group on days 14 and 21 when compared with the vehicle-treated animals. This was consistent and aligned with observed reduction in incidence of grade IV lesions.

ABSTRACT BODY:

Purpose: Several growth factors, lipids and microRNAs can influence the regeneration of corneal nerves after injury. However, they have been primarily used as single entities with variable results. Here we propose the use of exosomes, which carry as “cargo” many of these regenerative factors, as a multitarget approach to enhance nerve growth.

Methods: Exosomes from cultured human corneal mesenchymal stem cells (cMSCs) and bone marrow mesenchymal stem cells (BM-MSCs) were isolated using ultracentrifugation. Trigeminal ganglia neurons from adult mice were cultured in neurobasal A media alone (negative control), supplemented with nerve growth factor (NGF) as a positive control, or supplemented with exosomes derived from cMSCs or BM-MSCs. Neurons were observed for four days and subsequently fixed with paraformaldehyde (PFA) and stained with beta-tubulin to evaluate neurite growth. Treatment conditions were masked to prevent bias and neurons were imaged and traced using Neurolucida software. Finally, branched-length and Sholl analysis were performed. Experiments were repeated for each treatment condition (n=3).

Results: Neurons treated with exosomes derived from BM-MSCs had an average neurite length of 576 um, while those in the control and NGF group had an average length of 288 and 529 um respectively. Additionally, Sholl analysis indicated that neurons from the BM-MSC exosome group had greater complexity than controls. Exosomes derived from cMSCs did not show as strong of an effect, with an average neurite length of 433 um.

Conclusions: Our results indicate a possible neurotrophic effect of exosomes. Neurons treated with exosomes displayed greater neurite growth and complexity than controls. Additional work will evaluate the effects of stem cell derived exosomes on in-vivo models of corneal nerve injury.

ABSTRACT BODY:

Purpose: Two-photon vision is associated with the perception of short pulses of near-infrared (NIR) laser radiation as a visible (VIS) light. It is caused by the nonlinear process of two-photon absorption by visual pigments. The longer wavelength of the stimulating radiation suggests that this phenomenon may be beneficial for functional visual examination in cataract patients compared to normal, one-photon based, perception of light. To verify this hypothesis, we performed measurements of the one-photon (VIS) and two-photon (IR) visual thresholds for a group of cataract patients before and 6 months after the intraocular lens (IOL) implantation.

Methods: We used custom-built two-photon perimeter with NIR pulsed laser ($\lambda_c = 1028.4$ nm, $\tau_p = 12.2$ ps, $F_{rep} = 19.17$ MHz) and VIS continuous wave laser ($\lambda = 520$ nm) as a source of stimulating light. Due to two-photon vision effect both sources are perceived as green. The sensitivity of central part of the macula (10 deg diameter) was tested in 32 patients aged 53-84 years, under scotopic conditions. The examined patients were qualified for IOL surgery because of cataract with no diagnose of diabetes and retinal diseases. 6 months after the surgery 25 patients were tested again. The retinal sensitivity assessment was the same as described in [1] except smaller number of tested locations (17) to shorten examination time. The visual function of the patients before and after IOL implantation was also tested by commercial MAIA microperimeter (photopic version) on the same retinal area. The study was approved by the Ethics Committee of the Collegium Medicum, NCU.

1. BOE 12(1) pp. 462-479 (2021)

Results: The mean difference of sensitivity after the cataract surgery was equal to: 6.6 ± 1.3 dB (SEM) for VIS laser, 2.8 ± 0.7 dB (SEM) for IR laser and 2.0 ± 0.6 dB (SEM) for MAIA. There is significant difference between VIS and IR result (p-value 0.014) and between VIS and MAIA result (p-value 0.004).

Conclusions: The obtained results indicate that presence of cataract stronger affects the sensitivity of retina as measured by VIS- than IR-laser-based perimetry under scotopic conditions. It supports the hypothesis that two-photon visual sensitivity of cataract patients is limited less by the changes that occur in the lens than normal visual sensitivity. Surprisingly, the photopic visual sensitivity measured by MAIA also has changed slightly, which may be explained by wide spectral range of stimulus used in the device.

TITLE: Ocular surface distribution of mast cells functionally contributes to asymmetrical angiogenic response

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Cho, S. Mittal, E. Elbasiony, S. Chauhan, Department of Ophthalmology, Harvard Medical School, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): WonKyung Cho: Commercial Relationship: Code N (No Commercial Relationship) | Sharad Mittal: Commercial Relationship: Code N (No Commercial Relationship) | Elsayed Elbasiony: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Asymmetrical neovascularization has been reported in the pathogenesis of multiple ocular conditions such as pterygium and pinguecula. Here, we investigated whether distribution of ocular surface mast cells are functionally associated with angiogenic response.

Methods: Corneal neovascularization was induced by placing a single figure-8 intrastromal suture on the nasal or temporal side of the cornea using 11-0 nylon suture. Growth of blood vessels were observed clinically using a slit-lamp biomicroscope and at the molecular level by immunohistochemistry (IHC) analysis of CD31+ vascular endothelial cells in harvested corneas on day 7 post-suture. Distribution and activation of mast cells in the nasal and temporal corneas were evaluated by IHC analysis of avidin stained corneas and by quantification of tryptase and β -hexosaminidase levels in tear and corneal lysates. Mast cell deficient cKitw-sh mice and cromolyn (2% in PBS) treated mice were used to study the effect of mast cell distribution on asymmetrical corneal angiogenesis.

Results: A nasally placed suture resulted in more extensive corneal neovascularization compared to one placed temporally, as evidenced by slit lamp ($p=0.01$) and IHC analysis ($p=0.04$). IHC analysis showed a 2-fold increase in number of avidin+ mast cells in the nasal cornea compared to the temporal cornea. Moreover, 4.3-fold increase in tryptase levels and 2.1-fold increase in β -hexosaminidase levels were observed following suture placement on the nasal side, compared to the naive cornea. Suture on the temporal side resulted in significantly less increase in tryptase (1.4-fold ($p=0.0002$)) and β -hexosaminidase levels (1.1-fold ($p=0.006$)). Mast cell deficiency and cromolyn-mediated inhibition of mast cell activation abrogated the disproportionate growth of blood vessels, resulting in comparable nasal and temporal neovascularization, as evidenced by slit-lamp and IHC.

Conclusions: Our novel findings demonstrate that the spatial distribution and function of mast cells regulate pathological angiogenesis.

TITLE: Hemodynamic retinal changes in diabetic macular edema after anti-vascular endothelial growth factor injection on optical coherence tomography angiography

SESSION TITLE: Diabetic macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Konopek, P.L. Nesper, A.A. Fawzi, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nicholas Konopek: Commercial Relationship: Code N (No Commercial Relationship) | Peter Nesper: Commercial Relationship: Code N (No Commercial Relationship) | Amani Fawzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate retinal hemodynamic response to anti-vascular endothelial growth factor (anti-VEGF) injection in diabetic macular edema (DME) eyes evaluated before and 1 month after the injection using optical coherence tomography angiography (OCTA).

Methods: We used a previously validated thresholding method based on the skeletonized deep capillary plexus (DCP) of each eye. We then analyzed the following parameters in the parafoveal area (3mm annulus with 1mm inner circle): Adjusted Flow Index (AFI), Vessel Density (VD), Skeletal Vessel Density (SVD) in addition to the Fovea Avascular Zone (FAZ), and Central Foveal Thickness (CFT). We assessed longitudinal changes using a generalized linear model correcting for image quality (SSI).

Results: Our pilot study examined 6 eyes (4 female, age 51 ± 15.7 years). Compared to baseline, follow up imaging revealed significantly reduced superficial capillary plexus (SCP) VD ($p=0.036$), FAZ area ($p=0.001$) and CFT ($p=0.001$). Although not significant, overall trends showed increased AFI in the full retina and middle capillary plexus (MCP), contrasted with reduced AFI in the SCP and DCP slabs.

Conclusions: FAZ and CFT decrease significantly after anti-VEGF injection, consistent with reduced DME. Only the VD in the SCP was significantly reduced on follow up. Ongoing active recruitment is underway to further confirm the results of this pilot study and will be reported at the ARVO 2021 Annual Meeting.

TITLE: Vitamin A aldehyde-aurine adduct and the visual cycle

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Kim, J. Zhao, J.R. Sparrow, Ophthalmology, Columbia University Irving Medical Center, New York, New York, UNITED STATES|J.R. Sparrow, Pathology and Cell Biology, Columbia University Irving Medical Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hye Jin Kim: Commercial Relationship: Code N (No Commercial Relationship) | Jin Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Janet Sparrow: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Continued light sensitivity necessitates the regeneration of 11-cis-retinal via a series of enzyme-catalyzed steps within the visual cycle. During this process vitamin A aldehyde is shepherded within photoreceptors and retinal pigment epithelial cells by retinoid-binding proteins and NRPE to facilitate retinoid trafficking, to prevent non-specific aldehyde reactivity and to conserve the 11-cis configuration. Least understood is a Schiff base adduct (A1T) that forms non-enzymatically and reversibly from reactions between taurine and vitamin A-aldehyde and is abundant in neural retina of humans and mice.

Methods: Retinoids (derivatized with O-ethylhydroxylamine (100 mM) in DPBS) and bisretinoids, taurine and β -alanine (derivatized with NBD-F) were quantified by HPLC and UPLC with reference to authentic standards. A1T was synthesized by reacting retinaldehyde with taurine (1:1 molar ratio of retinal isomers and taurine) in dehydrated methanol containing sodium methoxide. ONL area was calculated as the sum of the ONL thicknesses in superior and inferior retina (0.2–2.0 mm) multiplied by the measurement interval of 200 microns.

Results: Reduction in cellular taurine by treatment with the taurine transport inhibitor β -alanine (in drinking water, 2%; 2 months) accentuated the thinning of outer nuclear layer (ONL) expected in albino $Abca4^{-/-}$ mice. β -alanine-treatment reduced bisretinoid levels. When mice were treated with taurine (2.5% in drinking water for 2, 4 and 6 months) ONL thinning in albino $Abca4^{-/-}$ mice was reduced.

Conclusions: We previously observed that A1T is more abundant under conditions in which 11-cis-retinaldehyde is present at higher levels, including black versus albino mice, dark-adapted versus light-adapted mice and mice carrying the Rpe65-Leu450 versus Rpe65-450Met variant. The accentuated ONL thinning indicative of photoreceptor cell loss, is consistent with previous reports of photoreceptor cell death in the presence of taurine deficiency; perhaps the worsening of ONL thinning occurs due to inadequate 11-cis-retinal handling. The reduction in bisretinoid levels with β -alanine treatment suggests that the intent of A1T formation is not to protect against unwanted bisretinoid formation as might be supposed. Rather A1T may serve to preserve retinaldehyde.

ABSTRACT BODY:

Purpose: High intraocular levels of proinflammatory cytokines have been associated with low corneal endothelial cell density in pseudophakic bullous keratopathy (PBK). However, it is unknown which mechanism is involved in this interaction. The adaptor protein apoptosis-associated speck-like protein containing a caspase-recruitment domain (ASC) is part of the inflammasome, a protein complex responsible for triggering the activation of the pro-inflammatory cytokine IL-1 β and the inflammasome-mediated cell death process of pyroptosis. In the present study, we measured the intraocular levels of ASC among patients with PBK and Fuchs' dystrophy to assess the role of pyroptosis-mediated endothelial cell death and correlate them with clinical parameters such as central corneal thickness (CCT) and ocular surface inflammation.

Methods: Aqueous humor (AqH) samples from 17 patients were analyzed. These samples were collected at the beginning of surgery from patients with PBK (5) and Fuchs' dystrophy (4) who underwent cornea transplantation, and healthy patients undergoing cataract surgery (8). The presence of the inflammasome was assessed by measuring ASC levels of the AqH samples via Simple Plex technology (Protein Simple). Additionally, a correlation between ASC concentrations and clinical parameters (CCT measured by ultrasound pachymetry and ocular surface inflammation measured by InflammaDry[®] tear immunoassay) among the subjects was made.

Results: Protein levels of ASC were significantly higher in the AqH of patients with PBK compared with both Fuchs' dystrophy [Mann-Whitney U, or Wilcoxon, (MWW) test $p=0.016$] and the control group (MWW test $p=0.001$). Fuchs' dystrophy and controls did not show significance when compared to each other. Regarding clinical measurements, there was a positive correlation between the levels of ASC in AqH and the InflammaDry[®] assay severity (Kendall's tau correlation coefficient=0.55, $p=0.020$). Also, the CCT positively correlated with protein levels of ASC in the AqH (Spearman's rank correlation coefficient=0.53, $p=0.028$).

Conclusions: Significantly higher levels of ASC in the AqH of patients with PBK suggest that the inflammasome may play an important role in the disease and should be further studied for therapeutic purposes. Moreover, protein levels of ASC in the AqH could aid to a better management of the PBK patient population in combination with the parameters used during standard clinic visits.

ABSTRACT BODY:

Purpose: Usher syndrome type I (USH1) is characterized by congenital deafness, vestibular areflexia, and progressive retinal degeneration. The protein-truncating p.Arg245* founder variant of PCDH15 has ~2% carrier frequency among Ashkenazi Jews, accounting for nearly 60% of their USH1 cases. Here we will investigate the precise role of protocadherin-15 in light transduction and mechanism of visual deficits and rescue of vision in the Pcdh15^{KI/KI} mouse model (Pcdh15^{R250X}; equivalent to human p.Arg245*) by two different modalities.

Methods: Pcdh15^{KI} mice were generated using CRISPR/Cas9. Retinal function was assessed by electroretinography (ERG), structural integrity by optical coherence tomography (OCT). Light-dependent translocation of phototransduction cascade proteins was determined using immunostaining. RPE65 and CRALBP levels by immunoblot. Rescue strategies included exogenous retinoids delivery via intraperitoneal injections, and AAV mediated gene delivery via subretinal injections.

Results: Our results showed Pcdh15^{KI} mutants recapitulates human p.Arg245* visual deficit phenotype. ERG showed attenuated a- and b-wave amplitudes and OCT showed no gross retinal degeneration. We found light-dependent translocation of arrestin and transducin was perturbed in mutant mice, indicating protocadherin-15 has an important role in rapid shuttling of proteins from outer segments to inner segments and vice versa, under light adapted conditions. We found lower levels of visual retinal cycle proteins RPE65 and CRALBP. For the rescue of retinal phenotype, administration of exogenous 9-cis retinal, improved ERG amplitudes in these mutant mice. We evaluated dual AAV PCDH15 mediated expression of full length PCDH15 in Pcdh15^{KI/KI} MSC's (Mesenchymal stem cells). Currently, we are evaluating the impact of subretinal injections of dual AAV vector containing full length PCDH15 gene in Pcdh15^{KI} mutant mice. Results of these studies will be presented in the meeting.

Conclusions: Our current findings support a role for visual retinoid cycle dysfunction in Pcdh15^{R250X} mutant mice suggesting a basis for a clinical trial of exogenous FDA approved retinoids to preserve vision in USH1F patients. Finally, dual AAV PCDH15 vectors mediated gene replacement therapy is one of the treatment modalities to rescue vision function in USH1F patients at the early stage.

ABSTRACT BODY:

Purpose: Blue light in the evening phase-delays the dim light melatonin onset rhythm, and is associated with various pathologies. Blue-blocking lenses prevented the phase-delay in humans (2019 ARVO E-Abstract #5269). In chicks, while rearing in blue light inhibited ocular growth, brief daily exposures to blue light in the morning or evening stimulated ocular growth (2020 ARVO E-Abstract 3407), which, if translatable, might predispose children to myopia. We tested the effects of blue-green blocking lenses (Essilor: block 70% in the circadian band of 460-510nm; Tv(D65) = 77%) on ocular growth rates in chicks.

Methods: Experiments began at age 12-14 days. The light cycle was 12L/12D in all experiments. Lens Conditions: White light: Chicks wore binocular lenses for 4 hours in the morning (n=11) or evening (n=8) in white light (588 lux). Extra blue light: Chicks wore lenses for 4 hours in the evening, with the addition of 4 hours blue light (575 lux; 460 nm) in the morning (n=6). Control conditions: Blue light: chicks were exposed to 4 hours blue light (200 lux) in the morning (ZT0-ZT4; n=9) or evening (ZT8-ZT12; n=16). White light: chicks were not exposed to blue light (n=23). Growth rates ($\mu\text{m}/9\text{d}$) were determined using A-scan ultrasonography; rhythm parameters were determined by measures at 6-hr intervals over 24 hours on the last day of the experiment.

Results: Wearing lenses in the evening inhibited ocular growth relative to "white controls" (670 vs 766 $\mu\text{m}/9\text{d}$; ANOVA $p=0.025$; $p<0.05$); there was no significant effect of morning lens-wear (708 vs 766 $\mu\text{m}/9\text{d}$). The addition of blue light in the morning did not reduce the efficacy of the evening lens-wear: growth was inhibited relative both to white controls and to morning blue (no lens) controls (592 $\mu\text{m}/9\text{d}$ vs 766 μm and 830 $\mu\text{m}/9\text{d}$ respectively; $p<0.05$ for both comparisons). 4 hours of blue light in the evening (without lenses) increased the amplitude of the rhythm in choroidal thickness relative to white controls (71 μm vs 47 μm ; $p<0.05$); wearing lenses in the evening prevented this effect (34 μm ; $p<0.01$ for lens vs blue evening light).

Conclusions: The evening-wear of lenses that block light spectra in the circadian range inhibited eye growth in white light, and when "extra" blue light was added to the light cycle. These results suggest that such lenses may be beneficial in preventing the development of myopia in children.

ABSTRACT BODY:

Purpose: Oculomotor apraxia (OMA) is a rare disorder characterized by inability to initiate saccades. In children, OMA may be congenital and idiopathic or secondary to an underlying genetic or neurologic diagnosis. We describe clinical and radiographic findings and outcomes in children with OMA in the modern era of neuroimaging and genetic testing.

Methods: We conducted a retrospective chart review of all children (<18 years) diagnosed with OMA at our institution from 2010-2020. OMA was diagnosed in children with impaired horizontal and/or vertical saccade initiation during optokinetic nystagmus testing. Children with developmental delays underwent neuroimaging; those with additional medical comorbidities underwent genetic testing. OMA was considered improved if saccades could be generated in the affected direction with or without blinking. We compared children with congenital idiopathic OMA (CIOMA) to those with acquired or congenital OMA secondary to a genetic or neurologic disorder (SOMA).

Results: 37 patients were included. 17 (46%) were congenital and idiopathic, and 20 (54%) were secondary to a genetic or neurologic condition. Among SOMA cases, 17 (85%) had a genetic disorder (6 with Joubert syndrome), 2 had hypoxic-ischemic encephalopathy (10%), and 1 (5%) occurred after encephalitis. Neuroimaging abnormalities (90% vs. 18%, $p<0.001$) and developmental delays (100% vs. 59%, $p=0.002$) were more frequent in children with SOMA than CIOMA. Endocrine disorders (most commonly growth hormone deficiency) were diagnosed in 12% of CIOMA and 15% of SOMA cases ($p=0.77$). Strabismus (45% vs. 12%, $p=0.03$), nystagmus (30% vs. 0%, $p=0.02$), and vertical saccade involvement (25% vs. 0%, $p=0.05$) were significantly more common in SOMA than CIOMA. Improvement occurred more frequently in CIOMA than SOMA (77 vs. 35%, $p=0.02$). Follow-up time did not significantly differ (median 3.5 vs. 3.2 years in CIOMA and SOMA groups, respectively, $p=0.77$).

Conclusions: Consistent with prior literature, we report a high frequency of developmental delays, neuroimaging abnormalities, and genetic and neurologic disorders in children with OMA. Additionally, we found that children with both CIOMA and SOMA had a higher rate of endocrine disorders than the general pediatric population, which has not been previously reported. Compared to children with CIOMA, those with SOMA were more likely have vertical involvement, strabismus, nystagmus, and poor oculomotor outcomes.

TITLE: A possible link between age-dependent photoreceptor cone density and the onset of myopia driven by low luminance

SESSION TITLE: Refractive Error, Emmetropization and Ocular Development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Vohnsen, Physics, University College Dublin, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Brian Vohnsen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Time outdoor is a critical parameter for emmetropization and to prevent the onset of myopia. Here, the purpose is to analyze whether oblique ray angles at the retina may cause photoreceptor light leakage and contrast reduction in low luminance conditions. If so, this will give an optical understanding to mechanisms that halt myopia and why dim light may trigger excessive eye growth.

Methods: Reported age-dependent changes in axial length for emmetropes and myopes (Jones et al., IOVS 2005), cone inner and outer segments (Lee et al., IOVS 2015) and cone densities (Yuodelis and Hendrickson, Vision Res. 1986) are used to evaluate the degree of photoreceptor light leakage, as well as cross-coupling, in terms of visual contrast as a function of pupil size for typical outdoor and indoor conditions. The impact of age-dependent changes in axial length, cone photoreceptor density and geometry is evaluated using ray optics in a scalable eye model to determine which parameters matter most for infants, children and adolescents from 0 to 20 years.

Results: The analysis reveals two distinct phases: (i) In the infant, post-natal photoreceptor parameters change significantly in the first 4 years of life while the foveal pit matures with denser cone packing. (ii) For the child and adolescent, photoreceptor dimensions remain stable while axial length and foveal cone density increase at a balanced pace in the emmetropic eye. A typical outdoor pupil of 2.4 mm is small enough to ensure that rays cannot leak from foveal cones whereas a larger indoor pupil increases the likelihood of leakage before traversing the entire outer segment. For the infant eye, the reduction in calculated contrast is less than 20% when the pupil increases to 4 mm. In turn, the dropoff is faster for the adult eye with denser cone packing and a corresponding contrast reduction by up to 70%.

Conclusions: The study shows that leakage of light presents a serious challenge for emmetropization when foveal cone density reaches that of the adult eye. Myopia-induced eye growth reduces the ray angle in ideal conditions and lowers the foveal cone density thereby limiting leakage-associated contrast loss. The same concept may also explain why form-deprivation myopia with a diffuser stimulates open-loop eye growth as an ocular mechanism to search for improved contrast as the retina is moved further from the pupil.

ABSTRACT BODY:

Purpose: Factors associated with poor quality of life (QoL) in glaucoma are not well understood. In this study, we used the Glaucoma Computerized Adaptive Testing System (GlauCAT) to identify clinical and sociodemographic factors associated with lower scores in five QoL domains reported by patients with glaucoma.

Methods: 138 English-speaking adults presenting to an outpatient glaucoma clinic at a tertiary eye center were enrolled in this study. Patients with a history of intra-ocular surgery 90 days prior to enrollment, and/or who met criteria for cognitive impairment were excluded. GlauCAT is a tablet-administered survey that uses computerized adaptive testing and item banking to measure QoL in five domains (Table 1). Scores for each domain range from 0 to 100, with higher scores indicating better QoL. Multivariable linear regression analyses were used to identify clinical and sociodemographic factors associated with domain scores. Covariates associated with domain scores with a significance at p-value <0.1 on univariate analyses were included in the multivariable models.

Results: Low visual acuity was associated with lower scores on activity limitation (3.1 points lower with each 0.1 worse logMAR, 95% CI -4.8 to -1.4) and mobility (2.5 points lower with each 0.1 worse logMAR, 95% CI -4.1 to -0.9). Factors associated with lower emotional well-being scores were worse visual field mean defect (2.7 points lower with each 5 dB worse visual field mean defect, 95% CI -5.2 to -0.2), low visual acuity (1.9 points lower with each 0.1 worse logMAR, 95% CI -3.5 to -0.4), history of a glaucoma laser procedure and/or surgery (13.3 points lower vs no treatment, 95% CI -24.3 to -2.3) and female gender (6.8 points lower vs male, 95% CI -12.9 to -0.7). No significant clinical or demographic correlates of the ocular comfort symptoms and concerns domains were found.

Conclusions: Worse visual acuity was associated with greater self-reported activity limitation and worse mobility and emotional well-being. Worse visual field mean deviation, history of glaucoma laser and/or surgery and female gender were associated with worse emotional well-being.

TITLE: Myeloid deletion of AMPK α worsen the pathobiology of bacterial endophthalmitis by promoting inflammatory milieu

SESSION TITLE: Pathobiology of Ocular Infections

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Singh, P. Singh, A. Kumar, Ophthalmology, Visual and Anatomical Sciences, Wayne State University, Detroit, Michigan, UNITED STATES|S. Giri, Department of Neurology, Henry Ford Health System, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sukhvinder Singh: Commercial Relationship: Code N (No Commercial Relationship) | Pawan Kumar Singh: Commercial Relationship: Code N (No Commercial Relationship) | Shailendra Giri: Commercial Relationship: Code N (No Commercial Relationship) | Ashok Kumar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: AMP-activated protein kinase (AMPK) is a critical regulator of fundamental cellular processes such as growth, proliferation, and survival. Previously, using AMPK α knockout mice, we reported their increased susceptibility to endophthalmitis. To dissect the role of AMPK in residential versus infiltrating cells, in this study, we sought to determine the pathobiology of bacterial endophthalmitis in mice lacking AMPK α in myeloid cells.

Methods: Endophthalmitis was induced in wild-type (WT), C57BL/6, and myeloid deleted AMPK α (LysM AMPK α ^{-/-}) mice by intravitreal (IVT) injection of *S. aureus* strain RN6390 (500 CFU/eye). Disease progression was evaluated by both non-invasive (ophthalmoscopy exam, ERG analysis), and invasive (histology, bacterial burden) methods. In-vitro studies were performed using mouse bone marrow-derived macrophages (BMDMs). Activation of inflammatory mediators was measured using qPCR and ELISA.

Results: *S. aureus* endophthalmitis was resolved in WT mice, in contrast, the LysM AMPK α ^{-/-} mice showed a time-dependent increase in endophthalmitis severity. The intraocular bacterial burden was significantly higher in LysM AMPK α ^{-/-} vs WT mice at 24, 48, and 72h post-infection. The ERG analysis revealed a transient decline in retinal function in WT mice, whereas LysM AMPK α ^{-/-} mice exhibited a rapid decline. Analysis of inflammatory mediators showed significantly higher levels of IL-1 β , TNF- α , and IL-6 in the eyes of LysM AMPK α ^{-/-} mice as compared with WT mice at all-time points. Mechanistically, LysM AMPK α ^{-/-} mouse exhibited the inflammatory, M1 phenotype (Cox2, iNos, and IL12p40), whereas the WT mice retina showed the M2 phenotype (Arg1, Ym1, Fizz1, and IL10) during *S. aureus*-induced endophthalmitis resolution.

Conclusions: Our findings demonstrated that myeloid-specific AMPK α deficiency impairs the resolution of inflammation in endophthalmitis by skewing to M1 macrophage phenotype. Therefore, therapies directed to restore or enhance AMPK activity could be used to improve visual outcomes in endophthalmitis.

ABSTRACT BODY:

Purpose: Current Optical Coherence Tomography (OCT) denoising techniques mainly focus on denoising 2-dimensional (2D) B-scans, especially for deep learning (DL) methods, which assume spatial integrity among neighboring samplings. However, OCT signal is essentially one dimensional (1D), and eye movements during scanning often violate the assumption. The purpose of this study was to see if 1D denoising is a feasible approach for clinical OCT imaging.

Methods: 3D SD-OCT data within 6x6x2mm volumes centered on optic nerve head were obtained from 121 eyes (79 patients). Clean reference scans were constructed by registering and averaging 6 OCT scans obtained on the same day using ANTs software. As shown in Figure 1, we used a 5-layer U-shape net (UNet) for both 2D denoiser (Figure 1.(a)) and 1D denoiser (Figure1.(b)). In addition, both 2D and 1D approaches are combined by using the 2D denoised B-scan as a mask to selectively remove high signal peaks in the 1D denoised B-scan (Figure 1.(c)). Peak signal-to-noise ratio (PSNR) and contrast-to-noise ratio (CNR) were calculated to compare the performance.

Results: Subjectively, the 2D denoiser generated smoother edges but tended to over-smooth textual information within the retinal layers, while the 1D denoiser preserved more textual information but caused more jittering at retinal edges due to the lack of structural information from neighboring A-scans. Quantitatively, the 1D denoiser showed similar PSNR to the 2D denoiser, while outperforming in CNR (PSNR: 31.20 (1D) V.S. 31.20 dB (2D), $p=0.963$; CNR: 4.23 (1D) V.S. 3.90 dB (2D), $p<0.001$, paired t-test, Table 1). The combined denoiser further improved CNR (4.39 (combined) V.S. 3.90 dB (2D), $p<0.001$). Combining 1D and 2D denoisers, the denoised B-scan showed more continuous edges compared to the 1D denoiser and did not lose the texture information compared to the 2D denoiser (Figure 2).

Conclusions: Quantitatively, 1D denoiser performance is as good as 2D denoiser or even better. A combination of 1D and 2D approaches may provide well-balanced image enhancement in clinical applications.

ABSTRACT BODY:

Purpose: To test the efficacy of high-dose of AAV2(Y444,500,730F)-P1ND4v2 vector obtained from Children's Hospital of Philadelphia (CHOP) to rescue retinal ganglion cell (RGC) structure and function in a mouse model of LHON.

Methods: Thirty DBA/1J mice were separated into three groups: Naive Controls (NC, n=10); Mock LHON controls (MC, n=10) intravitreally injected in both eyes with ScAAV2-HSP-ND4(G11778A) (4.32×10^{12} vg/ml, 1 μ l) followed by a second injection ScAAV2-mCherry (4.32×10^{12} vg/ml, 1 μ l); Gene Therapy (GT, n=10) intravitreally injected in both eyes with ScAAV2-HSP-ND4(G11778A) (4.32×10^{12} vg/ml, 1 μ l) followed by a second injection with CHOP test article (TA) ScAAV2-(Y444,500,730F)-P1ND4v2 (High Dose, 4.5×10^{12} vg/ml, 1.5 μ l). Pattern electroretinograms (PERG) were recorded between 3- and 12-months post injections. At one-year post-injection, cell density in RGC layer (H&E staining) and axon density in the optic nerve (TEM) were determined (n=3 in each group).

Results: While in the MC group the mean PERG amplitude decreased by about 20 % over time (GEE, $p=0.01$) it did not change in the GT and NC groups (GEE, $p<0.05$: NC>MC; GT>MC). At endpoint, the mean RGC layer cell density and optic nerve axon densities were on average reduced in the MC group by about 9% and 10%, respectively, compared to NC and GT groups.

Conclusions: High titer CHOP TA appeared to have a protective role on RGC function and structure in mice with optic neuropathy induced by mutant ND4.

TITLE: Redundant functions of MLL1 and MLL2 in retinal development and cone cell maintenance

SESSION TITLE: Glial Cells

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. SUN, X. Zhang, S. Chen, Ophthalmology and Visual Sciences, Washington University in St Louis School of Medicine, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure (Abstract): CHI SUN: Commercial Relationship: Code N (No Commercial Relationship) | Xiaodong Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Shiming Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: MLL1 (KMT2A) and MLL2 (KMT2B) are closely related members in the mixed-lineage leukemia (MLL) family of histone methyltransferases. They form a core complex for epigenetic regulation of gene expression. The previous study showed MLL1 is essential for retinal neurogenesis and horizontal cell integrity. This research aimed to unveil MLL1/MLL2 collaboration, whether by distinct pathways or through redundancy, in the retinal development and maintenance.

Methods: Cre/loxP-mediated Mll2 and Mll1/Mll2 deletions were specifically targeted in retinal progenitors (Chx10-Cre), developing rods (Nrl-Cre) and cones (HRGP-Cre), respectively. Electroretinography (ERG) detected functional deficits caused by Mll1 and Mll2 deficiency. Hematoxylin and eosin (H&E) staining of retinal cross-sections showed morphological defects at various postnatal (P) ages. EdU labeling and immunostaining of cell-type specific markers reported changes in cell composition between mutant and control retinae. Quantitative PCR (qPCR) determined gene expression differences of cell type-specific markers, phototransduction cascade components and transcriptional factors.

Results: Mll2 knockout (KO) in progenitors produced similar retinal thinning and functional decline to Mll1KO retinae at all ages. Mll1/Mll2 double-KO mice showed severe flaws, including null ERG responses, retinal thinning at P14 and P30, reactive gliosis at 1 month old (MO), followed by rapid degeneration within 2MO. Progenitor cell proliferation was moderately affected in all mutants. In addition, double-KO retinae had decreased numbers of M-cones, horizontal and amacrine neurons. qPCR results confirmed the cellular changes in mutants and explained the ERG deficits. In contrast, rod-specific double-KO mice showed normal retinal morphology and function, suggesting that Mll1/Mll2 are not functionally required for rod development and survival. Cone-specific double-KO mice had M-cone number reduced by 50% and decreased cone ERG responses.

Conclusions: Our results identified the redundant roles of MLL1 and MLL2 in the retinal development and maintenance of M-cones. Mll1/Mll2 deficiency results in retinal degeneration and reactive gliosis as well as gene silencing at young adulthood. Future efforts are underway to determine the underlying molecular mechanisms.

TITLE: Accuracy and repeatability of net corneal astigmatism measured with a novel OCT topography algorithm compared to two commercial devices

SESSION TITLE: Keratoconus and biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Llorens Quintana, E. Pavlatos, O.C. Thaware, D. Huang, Y. Li, Department of Ophthalmology, Oregon Health & Science University Casey Eye Institute, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Clara Llorens Quintana: Commercial Relationship: Code N (No Commercial Relationship) | Elias Pavlatos: Commercial Relationship: Code N (No Commercial Relationship) | Omkar Thaware: Commercial Relationship: Code N (No Commercial Relationship) | David Huang: Commercial Relationship(s);I:Code F (Financial Support);I:Code P (Patent);I:Code I (Personal Financial Interest);I:Code R (Recipient) | Yan Li: Commercial Relationship(s);I:Code F (Financial Support);I:Code P (Patent)

ABSTRACT BODY:

Purpose: To assess the accuracy of net corneal astigmatism (NCA) measured with a spectral-domain optical coherence tomography (SD-OCT, Avanti, Optovue Inc), a Scheimpflug imaging device (Pentacam HR, Oculus Optikgerate GmbH) and a swept-source optical biometer (IOLMaster 700, Carl Zeiss Meditec AG) and to determine the repeatability for Avanti and Pentacam HR derived astigmatism.

Methods: Sixty pseudophakic eyes from 39 subjects (39 eyes post-LASIK, 16 eyes post-radial keratectomy and 5 eyes post-photorefractive keratectomy) with monofocal non-toric intraocular lens (IOL) were measured with Avanti, Pentacam HR and IOLMaster 700. Avanti topography was measured using a 16-meridian scan pattern that was repeated 10 times in less than 1.50 sec. Motion error was reduced by comparison of the 10 redundant scan sets and NCA was obtained by Zernike decomposition of the vertex-centered 4 mm diameter area of anterior and posterior corneal surfaces using a custom algorithm. For Pentacam HR and IOLMaster 700, true net and total keratometry readings were used, respectively. Vector analysis was used by decomposing astigmatism into cardinal and oblique components. Repeatability was assessed by means of the coefficient of repeatability ($CR = S_w * 2.77$, where S_w is the within-subject standard deviation of three repeated measures). To assess accuracy, NCA was compared to manifest refraction (MR) converted to the corneal plane. Vectors difference between NCA and MR were calculated and the average of the absolute magnitude of the difference vectors (mean absolute difference) and the mean difference vector reported.

Results: The repeatability of NCA measurement was significantly better (F test, $p < 0.01$) for Avanti (total vector CR = 0.29 D) than for Pentacam HR (total vector CR = 0.67 D). The accuracy of NCA measurement was best for Avanti compared to Pentacam HR and IOLMaster 700 (Fig. 1) – the mean absolute difference with MR was significantly lower ($p < 0.01$ by mixed effect model using gamma distribution).

Conclusions: In post refractive surgery patients, NCA measured by high-speed SD-OCT can achieve better accuracy than current commercial Scheimpflug and swept-sourct biometer devices. This may be useful in toric IOL selection.

ABSTRACT BODY:

Purpose: The lens of the eye undergoes a regulated differentiation process whereby organelle removal in the fiber cells is necessary for lens clarity. A critical step in this process is the removal of the fiber cell nucleus. The mechanisms by which this occurs are unclear. Previous work in our lab demonstrated that impaired lens fiber cell denucleation (LFCD) was associated with increased levels of the CDK inhibitor p27. Additionally, deletion of CDK1 in the lens impaired LFCD indicating that CDK activity is crucial for LFCD. In this study, we test CDK activators and inhibitors in the denucleation process.

Methods: We examined lens differentiation in the mouse and embryonic chick by histology and immunofluorescence. We used three different mouse models to ask whether increased p27 levels affects lens differentiation. The first model expresses a drug inducible p27 transgene. We induced expression of the transgene during pregnancy to increase p27 during a crucial phase of lens differentiation. The second model is a Skp2^{-/-}. Skp2 is part of a ubiquitin ligase complex that is known to ubiquitinate p27 and target it for proteasomal degradation; these mice constitutively express high levels of p27. The third model expresses a degradation resistant mutant p27. To determine how CDK1 regulators are involved in LFCD, we used an organ culture system and treated isolated chick lenses with small molecules that inhibit the activities of CDK1 and Cdc25, which activates CDK1. Additionally, we examined LFCD in lenses in which we inhibited CDK1 inhibitors, Wee1 and PP2A.

Results: Expression of increased levels of p27 led to impaired LFCD in all three mouse models. Inhibition of the CDK1 activator Cdc25 inhibits LFCD, whereas inhibition of the CDK1 inhibitors Wee1 and PP2A potentiate LFCD in chick lenses. PP2A inhibits CDK1 activity: activation of PP2A inhibits LFCD while inhibition of PP2A increases LFCD.

Conclusions:

Increasing p27 levels in lenses or inhibiting CDK1 in lenses by genetic and pharmacologic mechanisms results in impaired LFCD. CDK1 activity is a crucial regulator of LFCD in the chick as well as the mouse.

ABSTRACT BODY:

Purpose: To evaluate the agreement between Compass New Grid (NG) and Compass10-2 test protocols for detecting early glaucomatous defects in the central 10 degrees of the visual field (CVFD).

Methods: 123 eyes of 14 healthy individuals, 17 glaucoma suspects and 32 glaucoma patients performed NG and 10-2 automated perimetry measurements within one week and macular scans using Spectralis OCT within 12 months. For both test protocols total deviation (TD) or pattern deviation (PD) plot CVFDs were defined in either superior or inferior hemifields by three contiguous points with probabilities of <5%, <2%, <2% or <5%, <1%, <1%. Cohen's Kappa (k) statistic was used to assess agreement between NG and 10-2 for identifying CVFDs. The Spectralis GMPE Hood Glaucoma Report (investigational software version) macula deviation analysis was used to identify macular defects as areas of thickness with $p \leq 0.05$ covering three or more contiguous 10-2 test points in the superior and inferior hemiretina for calculating sensitivities and specificities of all test protocols.

Results: Low to moderate agreement was observed between NG and 10-2 protocols for detecting presence of superior CVFDs on TD ($k=0.566$) and PD ($k=0.256$) plots and for detecting inferior CVFDs on TD (0.487) and PD (0.272) plots. Specificity of NG and 10-2 TD plots for detecting superior CVFDs was 0.82 and 0.65, respectively. Specificity of NG and 10-2 TD plots for detecting inferior CVFDs was 0.92 and 0.84, respectively. Specificity of NG and 10-2 PD plots for detecting superior CVFDs was 0.81 and 0.36, respectively. Specificity of NG and 10-2 PD plots for detecting inferior CVFDs was 0.86 and 0.52, respectively. Sensitivity of NG and 10-2 plots ranged from 0.20 for NG PD plot inferior defects to 0.78 for 10-2 PD plot superior defects.

Conclusions: Because agreement between the detection of central visual fields defects using Compass New Grid and 10-2 is fair to moderate, the visual field test results may be complementary and are not interchangeable.

ABSTRACT BODY:

Purpose: To update estimates of the global vision loss burden due to glaucoma, presenting temporal change since the beginning of VISION 2020 and distribution by sex and region.

Methods: Data gathered from population-based surveys of eye disease from January, 1980, to October, 2018 were collated. We fitted hierarchical models to estimate prevalence (with 95% uncertainty intervals [UIs]) of moderate and severe vision impairment (MSVI; presenting visual acuity from <6/18 to 3/60) and blindness (<3/60) caused by glaucoma, by age, sex, region, and year.

Results: In 2020, 3.60 million (95% UI 2.80-4.41) people aged 50+ years were blind due to glaucoma, and a further 4.13 million (3.24-5.17) had MSVI, a 41.0% increase in cases of blindness and 91.9% increase in cases of MSVI since 2000. Over the same period, age-standardised prevalence of glaucoma blindness decreased by 23.3% but for MSVI it increased by 5.9%. The age-standardised ratio of women to men for glaucoma blindness was 0.71:1.00 in 2020 and 0.67:1.00 in 2000. For MSVI, this ratio was 0.87:1.00 in 2020 and 0.84:1.00 in 2000. Sub-Saharan Africa was the super-region with the highest 50+ age-standardised glaucoma blindness and MSVI rates in 2020 (blind: 0.66%; 0.52-0.81, MSVI: 0.46%; 0.36-0.57), followed by North African and Middle East (blind: 0.57%; 0.44-0.71, MSVI: 0.38%; 0.29-0.48) and Latin America and the Caribbean (blind: 0.26%; 0.20-0.32, MSVI: 0.39%; 0.30-0.48).

Conclusions: Raw prevalence of vision impairment from glaucoma has grown due to population aging since 2000. The decline in age-adjusted glaucoma blindness (compared to MSVI) suggests successful targeting of the most severe cases or earlier detection. Further reduction in the burden of VI from glaucoma can be realised by improved access and affordability of topical medications and laser, and a focus on high quality glaucoma surgery and postoperative care. Screening must be cost-effective and sustainable and this may be possible in some populations, but in most areas of the World there is a reliance on opportunistic case detection. Heightening awareness of glaucoma among family members of cases and in primary care and within existing eyecare programs such as cataract and

diabetic retinopathy screening may slow the rise in numbers of people with irreversible vision loss due to glaucoma.

ABSTRACT BODY:

Purpose: To investigate sensitive outcome measures based exclusively on abnormal points in microperimetry testing of eyes with intermediate age-related macular degeneration (iAMD)

Methods: 25 eyes of 25 subjects with iAMD had undergone 2 successive tests of mesopic microperimetry with the Macular Integrity Assessment Microperimeter (MAIA), using a custom grid of 33 points spanning the central 14 degrees of the macula. Each point was defined as abnormal if its threshold sensitivity was lower than 1.65 standard deviations (SD) (5%) or 2 SD (2.5%) than the expected threshold in healthy eyes according to the MAIA internal database. We analyzed the number of abnormal points in each test, their mean sensitivity and deviation from normal values, and compared the repeatability of these measures with those of all the points in the grid.

Results: Among the 25 eyes there were 11.8 ± 9 and 8.4 ± 8.2 abnormal points at $<5\%$ and $<2.5\%$, with mean deviation of thresholds from normal -4.9 ± 1.2 dB and -5.8 ± 1.5 dB, respectively. These deviations were greater, and their SD smaller, compared with the mean deviation of all points in the microperimetry grid which was -2.3 ± 2.0 dB. The number of eyes with at least 5 abnormal points was 19 (76%) and 14 (56%) using the two criteria. The 95% limits of agreement for average threshold between the 2 successive tests were smaller when only abnormal points were included compared with the complete grid, 3.2 vs 4.2 dB, implying better repeatability.

Conclusions: We propose a framework for the construction of an outcome measure for clinical trials of visual function improvement in iAMD that consists only of microperimetry points that are abnormal at baseline. Despite limiting the analysis to a particular subset of points, most subjects in this iAMD cohort could be enrolled. Advantages include a greater average deviation allowing more ample opportunity for observable effect of any intervention, a more homogenous dataset, and excellent test-retest variability.

ABSTRACT BODY:

Purpose: The blood retinal barrier (BRB) breakdown in diabetic retinopathy (DR) is induced in part by increased paracellular permeability. Interleukin-6 (IL-6) plays an important role in the regulation of paracellular permeability in human retinal endothelial cells (HRECs). This pleiotropic cytokine acts via two distinct mechanisms, including “classical” signaling through a membrane-bound IL-6 receptor and “trans-signaling” through a soluble IL-6 receptor. The purpose of this study was to compare the effects of these two IL-6 pathways on paracellular permeability in HRECs.

Methods: To activate IL-6 classical signaling, HRECs were treated with IL-6 (50 ng/mL), and to activate IL-6 trans-signaling, cells were treated with IL-6 (50 ng/mL) and sIL-6R (150 ng/mL) overnight. Trans-endothelial electrical resistance (TEER) was measured using electrical cell impedance sensing (ECIS). Gene expression changes were determined using RNA-Seq.

Results: IL-6 trans-signaling activation caused a significant drop in TEER, while there was no effect of classical signaling. Among the 3 parameters of endothelial barrier function, paracellular resistance was significantly decreased, cell membrane capacitance was significantly increased, and no change was observed in basal adhesion. We found distinct effects on gene expression with each treatment, with more genes significantly altered following trans-signaling activation. Significant changes in the expression of 7 tight junctions were observed after trans-signaling activation: CLDN1 (-3.27-fold), CLDN3 (-4.44-fold), CLDN11 (-1.85-fold), CLDN12 (1.25-fold), CLDN14 (-1.36-fold), TJP1 (1.17-fold) and TJP2 (-1.31-fold). Among the adherens junctions, genes which showed significant changes were CDH6 (-1.66-fold), CDH11 (1.74-fold), CDH12 (1.97-fold), CDH24 (-1.67-fold), CTNNAL1 (-1.21-fold), and CTNNBIP1 (-1.29-fold). The 3 differentially expressed gap junctions included GJA1 (1.49-fold), GJA4 (-2.41-fold) and GJC1 (-1.19-fold). Only CLDN15 (1.48-fold) was significantly upregulated by classical signaling.

Conclusions: IL-6 trans-signaling caused a significant increase in paracellular permeability in HRECs, while classical signaling had no significant effect. Specific gene expression changes in intercellular junctions were identified that will aid our future understanding of the molecular mechanisms of IL-6 trans-signaling mediated BRB breakdown in HRECs.

Commercial Relationships Disclosure (Abstract): Mohammad Sharifian Gh.: Commercial Relationship: Code N (No Commercial Relationship) | Mihaela Gadjeva: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Laurie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lacritin C-terminal proteoform 'N-104' is a main source of tear bactericidal activity. By screening for N-104 resistance, we recently discovered the importance of respective putrescine and iron transporters PotH and FeoB as likely virulence factors for *P. aeruginosa* (PA14) ocular pathogenesis. PotH and FeoB are constituents of the inner bacterial membrane, whereas N-104 is in tears and not membrane disruptive. How then does N-104 bactericidal activity involve PotH and FeoB? Here we search for N-104 binding proteins in the outer membrane of PA14.

Methods: N-104, and negative control lacritin peptide C-95, synthesized with cysteine added to the N-terminus, were coupled to beads of SulfoLink® Coupling Resin with an efficiency of 0.7 mmole peptide to ml resin, and then blocked with L-cysteine. Overnight cultures of PA14, either without or with prior surface biotinylation, were washed in PBS, resuspended in lysis buffer containing 200 mM octyl β -D-glucopyranoside ('OG') with rocking overnight at 4°C to allow membrane proteins to insert into OG vesicles, and centrifuged. Supernatant was passed through PierceTM Agarose Resin precolumns and then onto N-104 or C-95 columns with rocking overnight at 4°C. After washing with 20 ml of running buffer containing 20 mM KCl, proteins were eluted by progressive addition of 50, 75, 100, 125, 150, 300, 500 or 1000 mM KCl. 500 mM KCl eluted proteins from N-104 and C-95 columns were subjected to mass spectrometry.

Results: 'YaiW' was the sole outer membrane protein hit with 7.4x higher enrichment from N-104 vs negative control C-95 columns, and mutants lacking YaiW resistant to N-104 with a slope ratio threshold of 0.7. YaiW contributes to the transport of proline-rich Bac7 peptides across the outer membrane. No hits were obtained from biotinylated cells, in keeping with amine-reactive interference.

Conclusions: YaiW is a candidate outer membrane receptor for N-104 with the potential capability to transport N-104 into the periplasm, and thus in proximity to inner membrane PotH and FeoB.

ABSTRACT BODY:

Purpose: Interleukin 6 (IL-6) plays a role in the endothelial barrier dysfunction seen in diabetic retinopathy (DR). Our recent studies have shown that the primary IL-6 signaling modality in retinal endothelial cells is IL-6 “trans-signaling”, which utilizes a soluble form of the IL-6 receptor (sIL-6R). The molecular mechanisms underlying this dysfunction, however, have not been fully elucidated. Adherens junctions play a critical role in the formation of cellular barriers, and the purpose of this study is to evaluate the contribution of adherens junction components to IL-6 trans-signaling induced barrier dysfunction.

Methods: Expression of VE-cadherin, β -catenin, α -catenin, and p120-catenin were measured in human retinal endothelial cells (HRECs) by RT-PCR following overnight treatment with IL-6 (50 ng/mL) \pm sIL-6R (150 ng/mL). Protein expression was measured by western blotting and immunofluorescence (IF). β -catenin gene knockdown in HRECs was performed using siRNA, and endothelial barrier function was measured using electric cell-substrate impedance sensing (ECIS).

Results: IL-6 trans-signaling significantly decreased expression of VE-cadherin (0.7-fold) and β -catenin (0.6-fold), but not α -catenin or p120-catenin. IF showed that β -catenin was primarily junctional, and trans-signaling led to gaps in membrane coverage. Activation of IL-6 trans-signaling significantly decreased endothelial barrier function (0.76-fold vs. untreated). β -catenin knockdown with siRNA resulted in a baseline decrease in barrier function (0.85-fold vs. wildtype), and IL-6 trans-signaling activation further reduced barrier function (0.73-fold vs. wildtype untreated), suggesting that β -catenin loss can partially explain IL-6 trans-signaling induced barrier dysfunction. Furthermore, β -catenin knockdown did not alter expression of β -catenin-regulated genes involved in tight junctions and the formation of capillary fenestrae. IL-6 trans-signaling, however, induced changes in expression of several permeability-associated genes, including CLDN1 (0.28-fold), CLDN3 (0.58-fold), OCLN (0.69-fold), and PLVAP (1.4-fold).

Conclusions: Our findings suggest that loss of β -catenin and adherens junctions partially explain the mechanism of IL-6 trans-signaling-induced endothelial barrier dysfunction and provide further support for the role of IL-6 trans-signaling in the pathology of diabetic retinopathy.

ABSTRACT BODY:

Purpose:

Three-year evaluation and comparison in microvascular and neuronal macular parameters in patients with type 1 and 2 diabetes mellitus (DM1/DM2) and no clinical signs of diabetic retinopathy(DR).

Methods:

Ninety-two eyes/patients(20 with DM1, 48 with DM2, 24 healthy controls) were included in this prospective longitudinal study. Main inclusion criteria were: absence of any sign of DR in both eyes, good image quality. The right eye was chosen for analysis unless poor quality of imaging. OCT/OCT-angiography (OCT-A) images of the macula were taken using DRI swept source-OCT Triton plus. Following OCT parameters were evaluated: thickness of retinal nerve fiber layer(NFL), ganglion cell layer(GCL+) and NFL + GCL+ (GCL++). On 3x3 mm OCT-A images: foveal avascular zone(FAZ) parameters, perfusion/vessel density(PD/VD), fractal dimension(FD) at the superficial and deep capillary plexus (SCP/DCP); choriocapillaris flow voids(CC-FV) using MATLAB, version 2017b. Changes over time were evaluated by means of repeated measures ANOVA.

Results: At baseline, in DM1 in the SCP a decrease in FAZ circularity index(CI, $p<0.001$), PD($p=0.05$) and FD($p<0.001$) vs controls was detected; in the DCP a decrease in FAZ CI and FD($p<0.001$) and an increase in FAZ perimeter($p=0.03$) vs controls; and in the CC a decrease in FV($p=0.02$) vs DM2 were documented. In DM2, central subfield-GCL++ and GCL+ and inner ring-GCL+ thickness were reduced vs DM1($p\leq 0.01$); in the SCP a decrease in FAZ CI and FD($p\leq 0.001$) and an increase in FAZ area and perimeter($p\leq 0.01$) vs controls were detected; in the DCP a decrease in FAZ CI and FD($p<0.001$) vs controls and an increase in FAZ area and perimeter vs controls and DM1($p\leq 0.02$) were detected. During the follow-up 14 eyes(20.6%) developed mild DR. After 3 years, no significant changes were observed in OCT parameters; FAZ area and perimeter in the DCP and FV($p<0.05$ for all) significantly increased in DM2.

Conclusions: Specific microvascular changes in SCP, DCP and CC were documented in both DM1&2 without clinical signs of DR. GCL thickness was more reduced in DM2 vs DM1. FAZ parameters in the DCP and FV in the CC significantly increased in DM2 in patients that progressed to mild DR vs those who remained stable(no clinical signs of DR). Further longitudinal studies should evaluate the role of DCP and CC in development of clinical signs of DR.

ABSTRACT BODY:

Purpose: Glaucoma is a lifelong disease that requires treatment adherence and active patient engagement. Poor patient adherence is associated with lower levels of understanding of the disease. However, little is known about the relationship between patient glaucoma knowledge and level of glaucoma severity. The purpose of this study is to evaluate a correlation between glaucoma knowledge scores and disease severity among veterans with glaucoma who had poor adherence enrolled in a randomized controlled trial.

Methods: Patients treated for glaucoma who had poor adherence at the Durham Veterans Affairs Eye Clinic were recruited to participate in the medication adherence in glaucoma to improve care (MAGIC) study, which measured adherence following an educational intervention (NCT03052257). As part of that study, participants completed a glaucoma knowledge assessment using the 10-question Eye-Q glaucoma knowledge test. Glaucoma severity was assessed using visual field criteria. Demographics and clinical history were recorded. Comparisons were made between glaucoma severity levels, categorized as mild, moderate, severe, and indeterminate. Continuous variables were compared using analysis of variance and categorical characteristics using the chi-square statistic; alpha was 0.05.

Results: Two hundred participants were included with a mean age of 68 ± 8 years and representation across all glaucoma severity categories (53 mild, 56 moderate, 74 severe, and 17 indeterminant). The majority (57%) reported a glaucoma duration of 5 years or more. The mean Eye-Q score was poor across all categories and did not differ based on severity (6.0 ± 1.6 , 6.2 ± 1.5 , 6.3 ± 1.8 , and 5.9 ± 1.9 for mild, moderate, severe, and indeterminate visual field severity, respectively; $p=0.779$).

Conclusions: Glaucoma knowledge did not differ across disease severity categories in this population of glaucoma patients with poor adherence. Glaucoma knowledge was generally poor, supporting the need for interventions to educate glaucoma patients about their disease.

ABSTRACT BODY:

Purpose: Polymorphisms at the Cav1/2 gene loci impart increased risk for ocular hypertension and primary open-angle glaucoma (POAG). Caveolae are specialized cellular domains that form invaginations in the plasma membrane, and Cav1 is required for caveolae biosynthesis. The mechanism by which Cav1 contributes to intraocular pressure (IOP) homeostasis is unknown. Interestingly, protein kinase C (PKC) interacts with Cav1 and plays a key role in trabecular meshwork (TM) contractility; an important mediator of conventional outflow resistance, and subsequently IOP. Thus, we used pharmacological modulators of PKC to test the hypothesis that caveolae serve as mechanosensors in the TM, which respond to changes in IOP by modulating PKC signaling.

Methods: Experiments were conducted using cultures of 8 different human TM cell strains. Adenoviruses encoding shRNA targeted to Cav1 were used to silence expression. Western blotting was used to determine relative protein levels, phosphorylation status, and PKC activity. Gö6983 (1 micromolar) was used as a selective PKC inhibitor. For cyclic stretch experiments, TM cells were plated on type IV collagen-coated flexible silicone bottom plates and subjected to 20% stretch, 1 Hz for 24 h. Data are expressed as mean \pm SEM.

Results: Using phosphorylated myosin light chain (pMLC) as a surrogate indicator for Rho/ROCK activity and contractile tone, we found that pMLC/MLC levels in TM cells were reduced in stretched versus unstretched conditions ($58.2 \pm 12\%$ vs. $100 \pm 19\%$, $n=8$, $p=0.005$). When Cav1 expression was decreased by knockdown (efficiency= $56 \pm 5.7\%$), pMLC/MLC levels were unaffected in stretched versus unstretched conditions ($81.5 \pm 16\%$ vs. $100 \pm 19\%$, $n=8$, $p=0.28$). Levels of pMLC/MLC were also lower in TM cells treated with the PKC inhibitor, Gö6983, for 24 h compared to control ($74.1 \pm 5.6\%$ vs. 100% , $n=7$, $p<0.004$). Interestingly, PKC activity trended downward in 24 h stretched, Cav1-competent TM cells ($90.3 \pm 9.5\%$ vs. $100 \pm 9.3\%$, $n=7$, $p=0.057$). This effect was not present in Cav1-deficient cells ($94.5 \pm 4.8\%$ vs. $100 \pm 9.7\%$, $n=7$, $p=0.55$), likely because PKC colocalizes with Cav1 at plasma membrane in TM cells.

Conclusions: Caveolae act as scaffolds that compartmentalize PKC at the membrane in TM cells, enabling signal transduction to downstream effectors in response to chronic stretch (Figure 1).

ABSTRACT BODY:

Purpose: Eye disease analysis using en-face maps over predefined retinal vascular slabs in optical coherence tomography angiography (OCTA) has been a popular approach. However, such approach relies on high lateral resolution and is rather insensitive to decrease of OCTA signal (flow density) axially due to diseases. In contrast, axial profiles are averaged over the flow density in lateral directions which are then analyzed in depth and may be more sensitive to detect changes of microvasculature with diseases. The purpose of this pilot study is to compare axial profiles in healthy eyes and eyes with age-related macular degeneration (AMD).

Methods: The study cohort includes 19 eyes of young adults, 11 eyes of elderly adults, and 33 eyes of AMD patients. Among the 33 AMD eyes, 7 has intermediate AMD; 6 has geographic atrophy (GA); and 20 has macular neovascularization (MNV). OCTA macular images were captured with Spectralis OCT2 (Heidelberg Eng.) using scan pattern 3mm x 3mm (10° x 10°; 512 x 512 pixels). Axial signals were quantified from specific retinal layers (NF - nerve fiber, GC - ganglion cell, IP - inner plexiform, IN - inner nuclear, OP - outer plexiform) within fovea-centered concentric rings in radii 1.5° - 2° (paracentral) , 3° - 3.5° (pericentral), and 4.5° - 5° (peripheral).

Results: Fig.1 shows comparison of axial profiles in eyes from healthy young and elderly adults, and AMD patients. Fig. 2 shows that from AMD sub-category eyes. Blunting of axial signal peaks in GCL in paracentral ring and in IPL-INL (intermediate capillary plexus) in pericentral ring was observed in elderly and AMD eyes compared to young eyes. Both intermediate and deep (INL-OPL) peaks were blunted in AMD eyes compared to elderly eyes in paracentral ring. Significant differences were not observed in eyes with different AMD stages.

Conclusions: Axial profile analysis may reveal differences between healthy and diseased eyes, providing new insights into disease pathophysiology. AMD eyes show a reduction in parafoveal OCTA signal in intermediate and deep flow layers. These findings require replication in larger studies.

ABSTRACT BODY:

Purpose: Technical skills are critical to the practice of ophthalmology and other surgical fields. Visuospatial ability is associated with technical competency and outcome quality in spatially complex surgeries. While surgical instruction and practice improve technical skills, medical education does not provide explicit training to improve visuospatial abilities. Dance training has been associated with improved visuospatial abilities. We sought to evaluate the effects of formal ballet training on the technical surgical competence of medical students.

Methods: Twenty pre-clinical medical students naive to dance or surgical training were divided 1:1 into dance-training and control groups. Students in the dance-training group received six 1.5-hour ballet lessons over a 2-month period at Koresh Dance Studio in Philadelphia. All subjects completed pre- and posttesting, in which they performed a wet lab bovine extraocular muscle recession. Procedure videos were graded by two ophthalmologists using a modified version of a previously validated surgical skills assessment tool, the Objective Structured Assessment of Technical Skill, and masked to group assignment and pretesting/posttesting status.

Results: Technical surgical ability, as measured by wet lab skills lab testing, improved significantly in the dance group (mean change +12.6 points) compared to the control group (mean change +5.2 points), $p=0.042$. In a poststudy questionnaire, students in the dance group reported improvement in awareness of their body positioning in space as well as control over their own movements.

Conclusions: Dance training for pre-clinical medical students can improve ophthalmology technical surgical ability. Principles from the field of dance, which focus on body awareness and intention, can successfully be applied to surgical training. Further studies can examine the extent of impact of dance training on surgical ability.

ABSTRACT BODY:

Purpose: Prior studies of schizophrenia (SZ), schizoaffective (SZA) and bipolar disorder (BD) patients have identified retinal layer abnormalities, but none have closely investigated their choroidal vasculature. We compared choroidal vascularity in patients with SZ, SZA, BD, and healthy controls using swept-source optical coherence tomography angiography (SS-OCTA) in a cross-sectional pilot study.

Methods: 51 subjects were recruited, including 19 healthy controls (HCs) and 18 SZ, 9 SZA, and 5 BD patients. SS-OCTA images were obtained using Triton DRI OCT-1 Atlantis. Choroidal thickness (CT) was obtained using native device software (Topcon Fastmap). Choroid vascular enface images (12mm x 9mm) were exported every 2.6 μ m from Bruch's membrane to the choroid-scleral interface from Topcon to ImageJ. Images were binarized using Otsu's method, signal from the optic disk and retinal vasculature was removed, and average choroid vascular density (CVD) was calculated as the average of percent area occupied by choroidal vasculature across images in the stack. Choroid vascular volume (CVV) was calculated as the CVD multiplied by maximum CT and image area. Data was analyzed in R, with mixed-effect linear regression modeling to test for group differences and post-hoc multivariate analysis to test for group-by-sex interactions. Tukey's HSD test was used to adjust for multiple comparisons.

Results: Among patients with a psychiatric diagnosis, 64% were male, median age was 34 years, and median body mass index (BMI) was 29.4. Compared with same-sex controls, male psychiatric patients had significantly lower CVD. Compared with same-sex controls, female psychiatric patients had significantly lower maximum CT with correspondingly decreased CVV, after adjusting for age. When all psychiatric patients were compared with all healthy controls, no significant differences in CT, CVD, or CVV were noted. Neither race nor BMI were predictors of maximum CT, CVD, or CVV.

Conclusions: We report sex-specific changes in choroid thickness and choroid vascularity among patients with SZ, SZA, and BD. Further investigation of sex-specific pathologic differences in these patients is needed, as similar sex-specific changes in SZ and BD patients' cortical imaging have also been reported.

ABSTRACT BODY:

Purpose: To characterize the spatial patterns of microvascular dropout in glaucoma using an unsupervised artificial intelligence approach.

Methods: This retrospective cohort study included a total of 1899 Angiovue optic nerve head optical coherence tomography angiography (OCTA) scans of 707 eyes of 397 healthy, glaucoma suspect and glaucoma patients from the Diagnostic Innovations in Glaucoma Study. An unsupervised artificial intelligence technique "Archetypal Analysis" was applied to pre-processed en-face OCTA images obtained at the level of the retinal peripapillary capillary density network. Correlations of OCTA derived spatial patterns with 24-2 visual field (VF) mean deviation (MD), 24-2 VF pattern standard deviation (PSD), 10-2 VF-MD, and 10-2 VF-PSD were evaluated. Diagnostic accuracy of spatial patterns to detect past glaucoma progression was calculated and compared with those of circumferential capillary density (cpCD) and retinal nerve fiber layer thickness (cpRNFLT) using 310 eyes (of 195 glaucoma suspect and glaucoma patients) with a minimum of 3 years of follow-up and 5 reliable 24-2 VF tests before their last OCTA image. Progression was defined based on an event-based glaucoma progression analysis (GPA) criterion. Generalized mixed-effects model was used to adjust for correlations of different metrics at the patient and eye levels.

Results: Eleven distinct spatial patterns were identified across the spectrum of disease severity (Figure 1). Notably, 10 of the 11 patterns of microvascular loss preserved the less vulnerable papillomacular area. Eight (1,5,6,7,8,9,10,11), 5 (1,7,8,10,11), 5 (1,8,9,10,11) and 5 (1,3,8,10,11) spatial patterns were significantly associated with 24-2 MD, 24-2 PSD, 10-2 MD and 10-2 PSD, respectively ($P < 0.05$ for all). The archetypal model (area under the receiver operating characteristic curve [AUC]=0.75) outperformed cpCD (AUC=0.66) and cpRNFLT (AUC=0.65) in detecting past glaucoma progression ($P=0.017$).

Conclusions: Unsupervised artificial intelligence techniques are capable of identifying patterns of microvascular dropout in glaucoma using OCTA images. These patterns show promise not only in qualitative evaluation but also in the quantitative assessment of glaucomatous microvascular dropout associated with VF damage and VF progression.

TITLE: Differences in gene expression and metabolism among AMD and non-AMD patients arise only after iPSC are differentiated into RPE

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Cai, J. Gong, L.J. Rizzolo, L.V. Del Priore, M.A. Fields, Department of Ophthalmology and Visual Sciences, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Huey Cai: Commercial Relationship: Code N (No Commercial Relationship) | Jie Gong: Commercial Relationship: Code N (No Commercial Relationship) | Lawrence Rizzolo: Commercial Relationship: Code N (No Commercial Relationship) | Lucian Del Priore: Commercial Relationship: Code N (No Commercial Relationship) | Mark Fields: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have reported previously that retinal pigment epithelium (RPE) differentiated from induced pluripotent stem cells (iPSC) generated from fibroblasts of patients with age-related macular degeneration (AMD) exhibit a retinal degenerative phenotype and a distinct transcriptome compared to age-matched controls. Since the genetic composition of the iPSC and RPE are inherited from fibroblasts we investigated whether differential behavior was present in the parental fibroblasts and iPSC prior to differentiation of the cell lines into RPE.

Methods: Induced pluripotent stem cells (iPSCs) were generated from fibroblasts isolated from AMD patients or age-matched (normal) controls. Fibroblast, iPSC and iPSC-derived RPE cells from normal and AMD patient donors were studied with DNA microarrays and Seahorse analysis for mitochondrial functions.

Results: Principal component analyses revealed no significant differences in the transcriptome of fibroblasts harvested from skin biopsies of AMD patients versus controls. After reprogramming, there was no significant difference in the transcriptome of iPSC generated from AMD versus normal donors. In contrast, hierarchical clustering analysis reveals that the transcriptome of iPSC-derived RPE segregated into two distinct clusters of AMD-derived cells versus controls. Interestingly, mitochondrial dysfunction in AMD-derived RPE was evident after approximately two months in culture. Moreover, these differences in mitochondrial dysfunction were not evident in the parental fibroblasts and iPSC. This study demonstrates an altered transcriptome and impaired mitochondrial function in RPE derived from AMD patients versus controls, and demonstrates these differences are not present in the original fibroblasts or iPSC.

Conclusions: These results suggest that the initial pathological changes in RPE seen in AMD may develop only after fibroblasts and the subsequent iPSC are differentiated into RPE, and that mitochondrial function is significantly affected in these cells. Additional study is required to advance the current understandings of the etiology of AMD and the development of novel therapeutic targets.

ABSTRACT BODY:

Purpose: Oxidative stress is a potent contributor to the loss of retinal pigment epithelial (RPE) cell function observed with age-related macular degeneration (AMD). ST266 is the biological secretome produced by a novel population of amnion-derived multipotent progenitor cells. ST266 has been previously reported to improve retinal ganglion cell survival and cellular function in optic neuritis and optic nerve crush mouse models. Herein, we investigated the effect of ST266 on RPE cell survival and mitochondrial function after cells were treated with hydroquinone (HQ) and hydrogen peroxide (H_2O_2), oxidants related to cigarette smoke, and all-trans Retinal (atRal), a pro-oxidant component of the retinoid cycle.

Methods: Cultured human RPE cells were labeled with 10 μ M JC-1 dye (a mitochondrial membrane potential, $\Delta\psi$ m, indicator) for 30 minutes followed by treatment with HQ (175-250 μ M), H_2O_2 (1000-1200 μ M), or atRal (17.5-30 μ M) for 90 minutes. Media were then replaced with ST266 or STM100 (control) for 24 hours at 37°C. A fluorescent plate reader was used to determine the ratio of red JC-1 aggregate/ green JC-1 monomer. Cell viability was measured with WST-1 reagent.

Results: ST266 significantly improved cell viability on average by 20%, 23.2%, and 18.6% for HQ, H_2O_2 , and atRal treated cells, respectively, compared to control ($P<0.05$). Additionally, ST266 significantly reduced the percent decrease of $\Delta\psi$ m after 24 hours, on average, by 14.7% for atRal treated cells compared to control ($P<0.05$).

Conclusions: RPE cells subjected to varied sources of oxidative stress had reduced cell viability and mitochondrial membrane potential. ST266 inhibited these deleterious effects caused by atRal; however, it did not similarly impact the reduction in mitochondrial membrane potential induced by HQ and H_2O_2 . Therefore, the mechanism through which ST266 acts may be oxidant-specific and requires further study.

ABSTRACT BODY:

Purpose: We aim to characterize the pathways required for autofluorescent granule (AFG) formation by retinal pigment epithelium (RPE) cells using cultured monolayers.

Methods: We fed RPE monolayers in culture with a single pulse of photoreceptor outer segments (POS). After 24h the cells started accumulating AFGs similar to lipofuscin in vivo. Using this model, we used a variety of light and electron microscopical techniques, flow cytometry and western blot to analyze the formation of AFGs. We also generated a mutant RPE line lacking Cathepsin D by gene editing.

Results: AFGs appear to derive from incompletely digested POS-containing phagosomes and after 72h are surrounded by a single membrane containing lysosome markers. We show by various methods that lysosome-phagosome fusion is required for AF granule formation but that impairment of lysosomal pH or catalytic activity, particularly Cathepsin D activity, enhances AF intensity.

Conclusions: We conclude that lysosomal dysfunction results in incomplete POS degradation and AFG accumulation.

ABSTRACT BODY:

Purpose: Retinal progenitor cell (RPC) specification into appropriate retinal cell types is temporally and spatially coordinated by well-characterized intrinsic signals endowing RPCs with neurogenic or gliogenic potential. The cellular communication network 2 (CCN2), also known as connective tissue growth factor or CTGF, is a secreted extracellular matrix protein with regulatory functions in vasoproliferative and fibrotic diseases. Although CCN2 expression extends to developmental processes in the central nervous system, the role of such extrinsic signal in retinogenesis is unknown. Herein, we used mouse genetics and omic approaches to determine the functional importance of CCN2 in retinogenesis.

Methods: A CCN2-green fluorescent protein bacterial artificial chromosome transgenic mouse was used as a proxy to analyze CCN2 expression pattern during retinogenesis. Moreover, mice with global deletion of CCN2 were generated by crossing CCN2 floxed and cytomegalovirus promoter-driven Cre mice. RPC growth and differentiation were analyzed in transverse cryosections of retinas by immunohistochemical methods at embryonic stages E11, E14, E16, and E18. Transcriptomic changes were determined by RNA-sequencing analysis of retinas from CCN2-deficient and control littermate mice at E18.

Results: At E11, CCN2 was expressed in the outer neuroblastic layer, which consists of RPCs and differentiating photoreceptors (PRs). At E14, 45 and 23% of CCN2 producing cells were positive for the RPC markers Sox2 and CHX10, respectively. From P1 onwards, CCN2 expression was restricted to Müller glia and vascular cells. Meanwhile, CCN2 deficiency in mice resulted in retinal hypocellularity with reduced RPC pool and impaired competence of remaining RPCs to generate immediate-early and late-born retinal cell types. CCN2 deficiency induced a dramatic reduction of Sox2 to Pax6 ratio, which is key to the maintenance of RPC neurogenic competence and multipotency. CCN2 gene inactivation caused down-regulation of marker and transcription regulator genes of retinal ganglion cells, PRs, and Müller glia.

Conclusions: CCN2 expression is required for the generation of neuronal and glial diversity in the retina. Understanding the regulation and function of CCN2 in retinal neurogenesis is of key importance toward optimization of cellular replacement therapy in congenital retinal diseases.

TITLE: Parthanatos operates intraocularly during murine cytomegalovirus (MCMV) retinitis in mice with acquired immunodeficiency syndrome (MAIDS): An investigation of possible cell-type specificity

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Oh, Biology, Georgia State University, Atlanta, Georgia, UNITED STATES|R.D. Dix, Biology, Georgia State University, Atlanta, Georgia, UNITED STATES|R.D. Dix, Ophthalmology, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jay Oh: Commercial Relationship: Code N (No Commercial Relationship) | Richard Dix: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Parthanatos is a caspase-independent cell death pathway whose contributions to retinal tissue destruction during the progression of AIDS-related human cytomegalovirus retinitis have yet to be explored. We have previously shown that key parthanatos proteins are stimulated within MCMV-infected eyes of retinitis-susceptible mice with MAIDS of 10-weeks duration (MAIDS-10) (Oh et al, J Med Virol, 2019) but not within MCMV-infected eyes of retinitis-resistant mice with MAIDS of 4-weeks duration (MAIDS-4) (unpublished data). That stimulation of parthanatos during MCMV-related MCMV retinitis might be cell-type specific prompted us to perform a pilot study to test this hypothesis using mouse embryo fibroblasts (MEF) and mouse lung fibroblasts (MLg), both non-ocular cells known to be susceptible to MCMV infection.

Methods: Monolayers of MEF and MLg were inoculated with MCMV (moi = 1) or maintenance medium (control). Cell lysates of MCMV-infected and mock-infected cells were harvested at 24, 36, and 72 hrs after infection and subjected to western blot analysis for detection of parthanatos-associated PARP-1, PAR, and PARG proteins.

Results: Whereas MCMV-infected MEF showed stimulation of PAR and PARG when compared with mock-infected cells, stimulation of these two key parthanatos-associated proteins was not observed within MCMV-infected MLg at all times investigated. In comparison, PARP-1 protein showed significantly reduced stimulation within MCMV-infected MLg when compared with MCMV-infected MEF, but equivalent amounts of PARP-1 protein production were also observed within mock-infected MEF at all times investigated suggesting its stimulation was due to trauma associated with the inoculation procedure.

Conclusions: Our findings support the hypothesis that stimulation of the parthanatos cell death pathway during MCMV infection is cell-type specific. This proof-of-principle finding supports further investigations by us to determine if parthanatos operates within individual cell types of the retina during MAIDS-related MCMV retinitis with a focus on the retinal pigmented epithelium.

ABSTRACT BODY:

Purpose: To compare gradient boosting classifier model (GBM) machine learning analysis of instrument-based OCTA vessel density measurements with deep learning convolutional neural network (CNN) classifier analysis of radial peripapillary capillary (RPC) enface vessel density images for classifying healthy and glaucomatous eyes.

Methods: 100 eyes from 51 healthy participants and 264 glaucomatous eyes from 185 patients from the Diagnostic Innovations in Glaucoma Study who underwent OCTA imaging of the optic nerve head (ONH) were enrolled in this observational cross-sectional study. Classification performance of a GBM trained and tested on standard OCTA ONH measurements was compared to performance of a pre-trained ResNet-50 CNN trained and tested on enface OCTA high density (HD) and non-HD optic nerve head 4.5 mm x 4.5 mm images. Images from 69 healthy eyes (of 35 subject) and 188 glaucomatous eyes (of 130 subjects) were used to train both models and an independent test set containing images from 31 healthy eyes (of 16 subjects) and 76 glaucomatous eyes (of 55 subjects), with no patient overlap between training and test sets, were used to compare model performance. Areas under the receiver operating characteristic (AUROC) curves adjusted for age and the inclusion of both eyes per subject were calculated.

Results: The glaucoma test subjects were significantly older (mean [95% CI], 71.9 [68.7, 75.1] years and 59.5 [53.4, 65.6] years; $P < 0.001$) and glaucoma test eyes had a significantly worse visual field MD (-6.9 [-8.5, -5.2] dB and -0.53 [-0.2, 0.8] dB; $P < 0.001$) compared to the healthy test eyes. The adjusted AUROC using GBM was 0.82 (0.77, 0.84) for RPC vessel density measurements, 0.85 (0.80, 0.87) for RPC capillary density measurements and 0.86 (0.81, 0.87) for combined vessel and capillary RPC density measurements. The adjusted AUROC using CNN analysis of RPC enface vessel density images was 0.91 (0.88, 0.94) resulting in improved classification compared to all GBM results ($P < 0.05$ for all comparisons). Two randomly selected images from the test set with associated probabilities of glaucoma by CNN analysis are shown below .

Conclusions: Deep learning enface OCTA measured vessel density image analysis can improve on instrument-based GBM models for classifying healthy and glaucoma eyes.

TITLE: Membrane affinity of different segments of lecithin retinol acyltransferase

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Roy, O. Gosselin, S. Gagne, C. Salesse, Universite Laval, Quebec, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Sarah Roy: Commercial Relationship: Code N (No Commercial Relationship) | Olivier Gosselin: Commercial Relationship: Code N (No Commercial Relationship) | Stephane Gagne: Commercial Relationship: Code N (No Commercial Relationship) | Christian Salesse: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lecithin retinol acyltransferase (LRAT) is responsible for transforming all-trans retinol into all-trans retinyl ester in the visual cycle. Our preliminary nuclear magnetic resonance data of a truncated form of LRAT (residues 30-196) suggests the presence of an amphiphilic segment (residues 96-107) which could bind membranes. In addition, other authors have postulated that a segment near this amphiphilic segment (residues 71-103), which is found uniquely in LRAT, could be involved in its membrane binding. However, no evidence was shown to support their hypothesis. The objectives of this study are therefore to determine the secondary structure and the membrane binding of these segments of LRAT.

Methods: The amphiphilic segment of LRAT was synthesized commercially. In addition, the human and murine forms of the unique segment were synthesized by the Plateforme de Chimie Médicinale du Centre de Recherche du CHU de Québec. The secondary structure of these peptides was determined by circular dichroism (CD) and their membrane binding was studied using Langmuir monolayers.

Results: The CD spectra show that all segments have a predominantly α -helical structure in methanol. However, in an aqueous medium, the secondary structure of the amphiphilic segment and the murine unique segment is mostly in random coil, whereas the human unique segment is insoluble. All segments bind strongly to monolayers of different types of phospholipids. Indeed, maximum insertion pressure (MIP) values of 44 ± 2 , 47 ± 3 and 57 ± 5 mN/m were obtained for the amphiphilic segment in the presence of dioleoylphosphocholine, dioleoylphosphoethanolamine and distearoylphosphocholine, respectively. MIP values of 36 ± 2 , 40 ± 1 , 35 ± 1 and 40 ± 2 mN/m were obtained for the murine unique segment in the presence of dioléoylphosphocholine, dioléoylphosphoéthanolamine, palmitoyl-arachidonoyl phosphocholine and palmitoyl-arachidonoyl phosphoethanolamine, respectively.

Conclusions: The amphiphilic segment and the murine unique segment both have a high affinity for membranes since all the MIP values obtained are superior to the estimated lateral pressure of membranes (30 mN/m). This suggests that these segments could be involved in the membrane binding of LRAT. This study gives a better understanding of the role of these segments in the function of LRAT. Langmuir monolayer measurements of the human unique segment are in progress.

ABSTRACT BODY:

Purpose: Aberrant tonic and oscillatory spike activity emerges in retinal ganglion cells (RGCs) during the progression of inherited photoreceptor degenerations. This aberrant activity degrades residual vision and may impede the success of vision restoration. In this study, we tested whether the rod pathway drives aberrant activity in All amacrine cells (All-ACs) and RGCs during early degeneration in the rd10 mouse.

Methods: We used rd10 mice at postnatal (P) day 21-60, an age range when rod bipolar cells (RBCs) undergo morphological and functional changes. Age-matched C57BL6/J mice (WT) were used as controls. Whole-cell recordings were made from All-ACs in retinal slices and spike recordings were made from alpha-like RGCs in wholemount. Two-photon imaging was used to record spontaneous calcium signals from RGCs after bulk-loading of Cal520 AM. The Ca^{2+} -permeable AMPA receptor blocker, IEM1460 (IEM, 50 μM), was used to block RBC input to All-ACs, while sparing cone-driven input. Paired and unpaired t-tests were used for statistical analyses.

Results: We observed periodic voltage fluctuations (frequency: ~3-12 Hz) in 14/20 All-ACs in rd10 retina as early as P21-25, which were rarely seen in WT (1/10 All-ACs). These fluctuations were suppressed by IEM in 6/9 rd10All-ACs, suggesting they were driven in part by the rod pathway. Since All-ACs relay signals to RGCs, we tested whether IEM could suppress aberrant RGC activity in the rd10 retina at a timepoint after complete rod degeneration (P44-55). On-type RGCs had higher spontaneous spike rates in rd10 compared to WT (rd10, 31.3 Hz \pm 19.3, n=12 cells; vs WT, 3.6 Hz \pm 3.7, n=10 cells; mean \pm S.D., p=0.003). IEM significantly reduced spontaneous firing in rd10 On-RGCs (~62% suppression; n=12 cells, p=0.001) and unmasked residual cone-driven light-evoked activity. Ca^{2+} imaging in the rd10 (n=2 mice; P45-55) revealed spontaneous sustained Ca^{2+} events lasting >30s (~7.5% of 293 imaged cells), which were blocked by IEM. Similar spontaneous Ca^{2+} events were absent from WT retina (n=2327 cells, 3 mice; P30-60).

Conclusions: Our results suggest that the rod pathway drives aberrant spontaneous excitatory activity in a sub-population of RGCs in the rd10 retina. Blocking the rod bipolar to All-AC synapse may improve detection of residual cone signals in the degenerating retina by silencing much of the aberrant spontaneous activity.

ABSTRACT BODY:

Purpose: Retinal vascular endothelial cells (VECs) are critical for maintaining retinal-homeostasis and play a key role in mediating vascular permeability, tone and contractility. Dysfunction of the vascular endothelium negatively affects the integrity of the blood-retinal barrier and underlies pathogenesis in vascular diseases affecting the eye, such as diabetic retinopathy (DR) and exudative age-related macular degeneration (AMD). As such, VECs represent a promising therapeutic target for the development of future gene therapy treatments, but remain particularly challenging to transduce using existing viral vectors. In this study, we investigate whether the incorporation of endothelial targeting peptides into the rAAV capsid increases VEC transduction efficiency in an ex vivo primary culture model.

Methods: rAAV2/2, 2/2[QuadYF-TV] and rAAV2/9 serotype vectors (n=10 capsid mutants per serotype) packaging a ubiquitously expressing GFP reporter construct were generated by inserting heptameric peptides (7AA) at position 588 (2/2 and 2/2[QuadYF-TV] or 589 (2/9) of the virus protein (VP1-3). The packaging and transduction efficiency of the VEC targeting vectors was first assessed on HEK293T cells using a picogreen dsDNA quantitation assay, fluorescence microscopy, and flow cytometry. After isolating and culturing primary bovine VECs, all vectors were subsequently applied at MOI=75,000. After 72 hours, cells were stained with CD31, and transduction efficiency quantified using flow cytometry.

Results: All VEC targeting mutants packaged successfully and vectors at MOI=10,000 were found to be infectious in HEK293T cells, resulting in widespread GFP expression. Flow cytometry revealed that capsid mutant 5 demonstrated significantly increased normalized GFP expression in CD31+ primary bovine VECs in all serotypes, with 1.7-fold, 2.7-fold and 3.6-fold higher transduction efficiency in rAAV2/9, 2/2 and 2/2[QuadYF-TV], respectively.

Conclusions: Generating rAAV vectors capable of efficiently targeting retinal VECs is an essential first step towards the development of a successful gene therapy treatment for ocular diseases such as DR and AMD. Our initial findings indicate that incorporation of endothelial targeting peptides in the rAAV capsid is well tolerated and able to significantly alter vector tropism, leading to increased VEC transduction efficiency.

TITLE: Differences in the management of scleritis among ophthalmologists and non-ophthalmologists

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Abdel-Aty, N. Kombo, Department of Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ahmad Abdel-Aty: Commercial Relationship: Code N (No Commercial Relationship) | Ninani Kombo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We performed a retrospective, observational clinical study to identify differences in treatment utilization for acute scleritis across medical specialties.

Methods: The records of 256 patients (302 eyes) with scleritis who presented to the Yale New Haven Health System between January 1, 2013 to January 1, 2018 were retrospectively reviewed. Data was collected on treatments utilized and the specialty of the provider caring for the patient. The primary outcome was quiescence of inflammation at three months. The study was approved by the Institutional Review Board (IRB).

Results: We identified 256 patients (302 eyes), including 232 patients (90.6%) with diffuse anterior scleritis, 10 (3.9%) with nodular anterior scleritis, 5 (2%) with necrotizing scleritis, and 9 (3.5%) with posterior scleritis. 173 patients (67.2%) had an ophthalmologist involved in their care, 19 (4.6%) were managed by their rheumatologist alone, 16 (6.3%) were managed by their primary care physician, and 15 (5.9%) were managed by an emergency medicine physician. Patients seen by ophthalmologists were overall more likely to receive acute treatment than those not seen by ophthalmologists (91.9% compared to 50.6%, $p<0.05$). Patients seen by an ophthalmologist were more likely to receive topical steroids (61.3% compared to 10.8%, $p<0.05$), systemic non-steroidal anti-inflammatory drugs (NSAIDs) (43.4% compared to 14.5%, $p<0.05$), or systemic steroids (38.7% compared to 24.1%, $p<0.05$). Patients seen by an ophthalmologist were more likely to resolve within three months (49.5% compared to 10.0%, $p<0.05$). All patients with necrotizing or posterior scleritis were seen and managed by an ophthalmologist, as were the majority of those with systemic disease (61.1%).

Conclusions: There were differences in medication utilization among specialty types, and patients with an ophthalmologist involved with their care were more likely to have resolution of symptoms. Patients with scleritis may benefit from ophthalmologic consultation.

ABSTRACT BODY:

Purpose: *Tupaia belangeri* [tree shrew (Ts)] is a small para-primate mammal that have been successfully used as an animal model for progressive myopia and glaucoma due to the close resemblance of their eye to human. Having a large eye size with low lens-to-vitreous ratio, a cone-dominant retina, and an optic nerve head with collagenous lamina cribrosa, Ts is an excellent model to study retina ganglion cell (RGC) replacement. To enable allotransplantation in Ts retina, we explored a 3D differentiation approach for deriving RGCs from Ts induced pluripotent stem cells (iPSCs).

Methods: Ts iPSC were derived from Ts neural progenitor cells (Kandoi et. al 2021). Prior to differentiation, Ts iPSCs were first enriched for cells with the highest self-renewal capacity through transient glutamine starvation. Ts iPSC lines were then assessed for alkaline phosphatase (ALP) activity and pluripotency markers by immunofluorescence (IF). To derive RGCs, Ts iPSCs were aggregated to form embryoid bodies and subsequently differentiated into retinal organoids (ORs) using matrigel and sequential inhibition of WNT signaling pathway by IWR1e and activation of hedgehog signaling pathway by SAG. On day 35 of differentiation, Ts ORs were analyzed for RGC markers using IF. RGCs were then isolated using L1CAM-conjugated magnetic microbeads and plated onto PDL and laminin coated glass cover slips for further analysis.

Results: Ts iPSCs treated with transient glutamine starvation maintained rounded dome shaped colony morphology showing high ALP activity and are positive for pluripotency markers, OCT3/4, SOX2, and KLF4 after >50 passages. In contrast, untreated cells displayed rapid differentiation \leq 3 passages. On day 9 of differentiation, Ts neuro-retinal organoids were positive for neuroectoderm marker, PAX6, and neuroretina marker, SIX6. By day 35, RGC markers, RBPMS and THY1 were spatially detected within the organoids. Cultured cells of L1CAM specific RGCs extend neurite outgrowth by day 2 in culture and display typical morphology similar to that of mouse and human RGCs.

Conclusions: Ts RGCs expressing surface marker L1CAM were successfully derived from Ts iPSCs using 3D differentiation strategy. Our success in the generation and isolation of Ts iPSC-derived RGCs enables allotransplantation study and could potentially help to overcome challenges relating to acute rejection of donor RGCs in tree shrew model of glaucoma.

TITLE: Fixational Eye Movements depend on Fixation Task

SESSION TITLE: Aspects of Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Lin, N. Bowers, J. Gautier, A.J. Roorda, School of Optometry and Vision Science Graduate Group, University of California Berkeley, Berkeley, California, UNITED STATES|J. Gautier, Paris Eye Imaging, Quinze-Vingts National Hospital, INSERM, Paris, Île-de-France, FRANCE|

Commercial Relationships Disclosure (Abstract): Samantha Lin: Commercial Relationship: Code N (No Commercial Relationship) | Norick Bowers: Commercial Relationship: Code N (No Commercial Relationship) | Josselin Gautier: Commercial Relationship: Code N (No Commercial Relationship) | Austin Roorda: Commercial Relationship(s);C. Light Technologies:Code I (Personal Financial Interest);Rochester:Code P (Patent);University of Houston:Code P (Patent)

ABSTRACT BODY:

Purpose: Even when fixating on a stationary target, the eye is in constant motion. These fixational eye movements (FEM) consist primarily of drifts (slow, random-walk-like movements) and microsaccades (fast, ballistic movements). Understanding these movements is important for two reasons (i) determining their role in normal vision and (ii) to learn optimal strategies for maintaining stable fixation for imaging and/or vision testing. Here we compare FEMs during active and passive fixation tasks. Five fixation targets were selected: Maltese cross, Annular disk, Dynamic concentric circles, a two-bar Vernier target, and an E-letter. The Maltese cross and disk targets were stationary (passive) while the Vernier and E-letter targets varied in presentation and time, requiring subject response (active). The concentric circle target was an attention-grabbing task with continual inward moving rings but required no subject response.

Methods: An Adaptive Optics Scanning Laser Ophthalmoscope system (AOSLO) was used to present the fixation target and to collect retinal videos for subsequent retrieval of eye motion and fixated image position on the retina. This instrument provides high spatial (~ 0.1 arcmin) and temporal (960Hz) resolution. Data was collected on 8 subjects with normal. Five 30-second videos of the fixated target moving on the retina were collected for each condition. FEMs were extracted from the videos and analyzed using custom software. Saccades and drifts were automatically marked and any missed or mislabelled saccades were manually amended.

Results: Important differences between passive and active fixation targets were observed. FEMs were overall larger for active tasks, marked with larger saccades but lower saccade rate, larger and longer drifts, and a larger ISOA. Conversely, passive tasks had smaller FEMs, with more saccades and faster/shorter/smaller drifts. Furthermore, each subject consistently used the same preferred retinal locus for all targets.

Conclusions: The lower saccade rate for active tasks suggests saccadic suppression. This suppression, in turn, leads to longer drift segments, larger saccade magnitudes and an overall larger distribution (ISOA) for fixation. Passive fixation targets (eg Maltese cross or disk) are recommended if minimal FEMs are desired. This study emphasizes that the choice of fixation target is important when studying the fine structure and functional role of eye movements for human vision.

ABSTRACT BODY:

Purpose: Identify candidate inherited retinal disorder (IRD) genes through International Mouse Phenotyping Consortium (IMPC) generated single gene knockout mouse strains with retinal abnormalities, with particular interest in Usher Syndrome and heritable retinal vascular disorders such as Familial Exudative Vitreoretinopathy (FEVR).

Methods: The IMPC database currently contains phenotypic data for approximately 7,000 mice with targeted single gene knockouts. We investigated all strains with abnormal retinal phenotypes and further enriched our search for strains with concomitant hearing or retinal vascular abnormalities. Candidate genes were then analyzed for potential protein-protein interactions via bioinformatic analysis with STRING and PANTHER proteomics databases and cross-referenced against established IRD-causative genes as presented by the RETNET database.

Results: Initial interrogation revealed 182 knockout strains with retinal abnormalities, 153 of which have not been associated with retinal pathology to date. Of these 182 knockout strains, 15 had concomitant impaired auditory function, none of which have been implicated with Usher syndrome to date. Furthermore, 108 strains had vascular phenotypes, 106 of which were novel for retinal vascular anomalies based on search of literature. Bioinformatic analysis revealed two clusters of predicted protein-protein interactions between the 108 candidate vascular disorder genes from IMPC mice and established angiogenesis/vascular pathology genes. These clusters presented 13 candidate genes for retinal vascular disorders, 12 of which have not been implicated in retinal disorders. Analysis of gene clusters revealed evidence for involvement of Wnt/Notch/PDGFR/Rac1 signaling pathways.

Conclusions: We present 153 targeted gene deletions previously unknown to cause retinal pathology. Fifteen of these 153 are candidate Usher Syndrome genes. Thirteen of these 153 are candidates for heritable retinal vascular disorders such as FEVR. These genes are of interest not only for improving screening of human IRD patients, but also for elucidating novel biological mechanisms involved in retinal development.

ABSTRACT BODY:

Purpose: Ocular graft-versus-host disease (oGVHD) is a rapidly progressing, sight-threatening condition of the eye following allogeneic hematopoietic stem cell transplantation (aSCT). Previously we reported in a small case-series that adverse environmental stress (AES) during allogeneic hematopoietic stem cell transplantation (aSCT) may be a risk factor for chronic oGVHD. To strengthen these findings and to identify pathomechanisms, consecutive retrospective analysis of all clinical files of our clinic since 2014 was performed in addition to experimental simulation of AES in a mouse model of oGVHD.

Methods: Comprehensive review of all files from all patients undergoing aSCT between 2014-2018 was performed. Collected data included Schirmer test scores, corneal fluorescein staining, onset of GVHD of the eyes, skin and gut. Statistical analysis included Pearson's Chi2 and Kruskal-Wallis Test.

A minor mismatch-mouse model (129S2->C57BL/6) was used where mice either remained in standard housing or were subjected to AES (35% humidity, constant air flow) for 18 days after bone marrow transplantation (BMT). Systemic and ocular GVHD was monitored for up to 28 days and histological and flow-cytometry analyses of ocular tissue, lacrimal gland, ocular draining-lymph nodes and spleen were performed.

Results: From 444 patients (n=181 female, n=263 male) undergoing aSCT, 211 surviving patients presented with systemic GVHD and n=126 (53 %) developed chronic oGVHD. Humidity of less than 30% during aSCT was significantly higher correlated with oGVHD (73%), whereas humidity above 50% lead to a lower rate of oGVHD (30%). Acute skin GVHD, but not gut GVHD was an AES-independent risk factor for oGVHD.

In the mouse GVHD model, AES led to a significant higher systemic and ocular GVHD score than in the GVHD without AES at days 7 and days 14 after BMT. Corneal staining and blepharitis remained significant elevated after discontinuation of AES until day 28.

Conclusions: Both clinical and experimental data confirm the hypothesis that AES is an independent risk factor for ocular GvHD. In particular humidity below 30% during aSCT increases the risk for oGVHD significantly. Low humidity conditions after aSCT in the mouse model worsened the severity of systemic GVHD in the mouse model, implicating that AES has not only a local effect. In general, AES could be an avoidable risk factor for oGVHD.

ABSTRACT BODY:

Purpose: To assess the effect of an increase in the lateral resolution of the OCT beam, on the retinal and choriocapillaris optical coherence tomography angiography (OCTA) en face images .

Methods: Prototype software was used on the PLEX® Elite 9000 Swept-Source OCT instrument (ZEISS, Dublin, CA) in combination with the beam expander (BE) module in the OCT path, which produces a wider beam at the pupil plane. This configuration provides a 17 μm optical resolution at the retina compared to the standard 24 μm resolution. This retrospective study involved 23 healthy subjects imaged with 3 \times 3 mm and 2.25 \times 2.25 mm OCTA scans repeated at least 3 times for each subject. The 3x3 mm and 2.25x2.25 mm scans were acquired without and with the BE respectively.

The angiograms were aligned and cropped to keep the part common to both images. Two graders analyzed the images. Perfusion density (PD), vessel density (VD), and foveal avascular zone (FAZ) measurements were also compared.

Results: Qualitative analysis of retinal angiograms acquired with the BE showed significantly better vessel sharpness ($p=0.0005$), better peripheral image quality ($p=0.0001$) and a decrease in segmentation errors ($p=0.04$) compared to scans acquired without the BE.

Mean VD was significantly higher for BE angiograms compared to classic angiograms ($25.86 \pm 1.12 \text{ mm}^{-1}$ and $21.5 \pm 1.13 \text{ mm}^{-1}$, respectively, $p<0.0001$), whereas mean PD was not significantly different between the 2 groups.

Mean FAZ circularity was found to be significantly lower in BE angiograms ($0.65 \pm 0.14 \text{ mm}^{-1}$ and 0.69 ± 0.08 , $p=0.0067$) whereas mean FAZ area was not significantly different between the 2 groups.

Repeatability of VD, PD and FAZ measurements were higher for BE angiograms (ICC : 0.662 ; 0.536 and 0.874 with BE, vs 0.439; 0.435 and 0.804 without BE).

Choriocapillaris image quality was found to be significantly superior with BE, and flow deficits were more visible in all BE scans compared to “classic” scans.

Conclusions: An increase in lateral resolution of the OCT beam resulted in higher quality of retinal and choriocapillaris OCTA images. Improved vessel sharpness and higher mean VD were significant in the scans acquired with the BE.

The improvement was also very significant for choriocapillaris definition, particularly in the visualization of flow deficits

ABSTRACT BODY:

Purpose: To present long-term follow-up in autosomal dominant gyrate atrophy-like choroidal dystrophy (adGALCD) in two distantly related families and propose a possible genotype/phenotype correlation.

Methods: Clinical findings from two families, each with three affected patients, are presented. One of the families had been reported in part previously (Kellner et al 1997, doi: 10.1097/00006982-199709000-00008). Visual field testing, multifocal and full-field ERG recording according to ISCEV standards, as well as non-invasive retinal imaging (fundus photography, near-infrared reflection, fundus autofluorescence, optical coherence tomography) were performed in most patients. Diagnostic genetic testing was performed in two patients of each family using whole genome sequencing. Haplotype analysis was performed by genotyping SNPs and microsatellites in order to establish whether both families were distantly related.

Results: All affected patients presented with large confluent areas of choroidal atrophy beginning in the far periphery as well as peripapillary. Peripheral atrophy was first observed in the second decade of life. During progression, these areas continued to grow towards the foveal area, reaching the fovea at about 60 years of age. The fundus findings resemble gyrate atrophy, no or minimal pigmentary alterations were seen. In addition, subretinal lesions or choroidal neovascularization were not detected in these patients. Diagnostic genetic testing revealed a novel missense variant in a known gene in the heterozygous state in all affected family members. Haplotype analysis showed that the variant found in both families is identical by descent.

Conclusions: adGALCD presents a distinct phenotype with gyrate atrophy-like choroidal dystrophy, with early onset in the second decade of life and slow progression with preservation of the foveal area until late adulthood.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRD) are important causes of blindness in humans and animals. Non-human primates (NHP) are useful animal models for human retinal disease due to similar retinal morphology and function. Identification of spontaneous disease models in NHP colonies requires quick screening tools due to the laborious, expensive nature of individual examination. Chromatic pupillometry is a noninvasive method of identifying IRD in humans; however, standard protocols employ time-consuming dark adaptation. We used this tool to compare chromatic pupillary light reflex characteristics utilizing a shortened dark adaptation protocol as well as standard dark-adaptation in rhesus macaques with PDE6C associated achromatopsia to controls with normal retinal function.

Methods: This prospective study evaluated red-, blue-, and white-light chromatic pupillometry following a shortened 1-minute versus standard 20-minute dark adaptation in rhesus macaques with PDE6C associated achromatopsia and sex- and age-matched controls without IRD. Pupil latency, degree of pupil constriction, pupil constriction time, and average constriction velocity were measured and compared between groups.

Results: Nine rhesus macaques (7 females and 2 males) homozygous for the PDE6C mutation and nine age-, sex-matched normal controls were used in this study. Pupil constriction latency was significantly longer in achromats versus controls with red- and blue-light stimulation ($P<0.05$); but did not differ between groups with white-light stimulation ($P=0.2$). Degree of pupil constriction was significantly less in achromats compared to controls with red-, blue-, and white-light stimulation ($P<0.0001$). Pupil constriction time was significantly shorter in achromats versus controls with red- and white-light stimulation ($P<0.05$), but did not significantly differ between groups following blue-light stimulation ($P=0.9$). Pupil constriction velocity was significantly slower in achromats versus controls with red-, blue-, and white-light stimulation ($P<0.001$). Dark adaption time was only a significant factor for degree of pupil constriction ($P=0.008$) and pupil constriction time ($P=0.02$) following blue-light stimulation.

Conclusions: Chromatic pupillometry is an effective tool for screening NHPs for achromatopsia. A 1-minute dark adaptation protocol was sufficient to discern NHPs with and without achromatopsia.

ABSTRACT BODY:

Purpose: Optimization of corneal collagen cross-linking (CXL) is hindered by the inability to immediately measure treatment effects. Inverse spectroscopic optical coherence tomography (IS-OCT) is an emerging technique capable of non-invasively detecting nanoscale ultrastructural changes. The IS-OCT output measure D was previously found to increase with increased collagen cross-linking in vitro. We performed a pilot study to measure changes in keratoconus patient eyes before and after CXL by IS-OCT in vivo.

Methods: With IRB approval, keratoconus patients scheduled to undergo CXL were consented and enrolled. Standard epi-off CXL was performed in one eye (Glaukos, San Clemente, CA). Immediately preceding, and one month after unilateral CXL, both central corneas were imaged with dual channel visible and near-infrared light OCT. D was calculated and compared between eyes. A two-tailed paired Students t-test was used for statistical analysis.

Results: The change in corneal D before and after CXL was $+1.78 \pm 0.36$ ($n = 3$), compared to -0.22 ± 0.34 ($n = 3$) in the contra-lateral non-CXL cornea ($p = 0.03$). Delta D in the anterior half of the cornea was $+1.83 \pm 0.12$ in CXL eyes vs. -0.21 ± 0.68 in non-CXL eyes ($p=0.047$). Delta D in the posterior half of the cornea was $+1.68 \pm 0.47$ in CXL eyes vs. -0.19 ± 0.37 in non-CXL eyes ($p=0.03$). The increase in D after CXL appeared more consistently higher in the anterior corneal stroma and diminished in the posterior-most region (Figure 1).

Conclusions: In this preliminary study, we found that IS-OCT can be used to image corneas quickly and non-invasively in patients. D was increased in corneas following CXL. IS-OCT could help quantitate CXL in vivo, but further study with additional patients and methods for improved data normalization are needed to validate these preliminary results.

TITLE: Evaluation of the novel Foraging Interactive D-prime (FInD) CSF Test

SESSION TITLE: Assessing human vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Liu, A. Jnawali, F.A. Vera-Diaz, New England College of Optometry, Boston, Massachusetts, UNITED STATES|P. Bex, Northeastern University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jade Liu: Commercial Relationship: Code N (No Commercial Relationship) | Peter Bex: Commercial Relationship(s);Adaptive Sensory Technology LLC:Code I (Personal Financial Interest);Massachusetts Eye and Ear Infirmary:Code P (Patent);Northeastern University:Code P (Patent) | Ashutosh Jnawali: Commercial Relationship: Code N (No Commercial Relationship) | Fuensanta Vera-Diaz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the repeatability and reliability of the novel Foraging Interactive D-prime (FInD) test for the contrast sensitivity function (CSF) against a standard Two-Alternative Forced Choice (2AFC) method. Compared to other tests, FInD is self-administered, generalizable, and user-friendly for patients of all ages, cognitive status, language backgrounds, and literacy levels.

Methods: FInD was used to present three charts of 4*4 cells, a random subset of which contain band-pass filtered noise targets (peak spatial frequency 0.5, 1, 2, 4, 8, and 16 cpd) that observers are required to mouse-click. The contrast of each target is selected from a range spanning difficult ($d'=0.1$) to easy ($d'=4.5$), that is adaptively updated after each chart based on a decision function fit to Hit/Miss/Correct_Rejection/False_Alarm scores for each cell. Fourteen adult observers with varying visual acuities performed the FInD CSF and 2AFC CSF in random order at 40 cm and at 4 m. The FInD CSF test was repeated twice at both viewing distances. Repeatability was assessed using mixed linear models and Bland-Altman analysis. Reliability was assessed using mixed linear models.

Results: The FInD CSF test was completed significantly more quickly than the 2AFC (4.98 ± 1.52 min vs 10.86 ± 0.91 min at 40 cm; 4.93 ± 2.00 min vs 12.69 ± 2.11 min at 4 m). A mixed linear model repeated measures ANOVA with Huynh-Feldt correction showed good repeatability for the FInD CSF test at 4 m ($F=0.044$, $p=0.877$, $\eta^2=0.002$) and 40 cm ($F=0.633$, $p=0.498$, $\eta^2=0.024$). Posthoc analysis showed a significant difference in test-retest repeatability for 0.5 cpd only at 4 m. Bland-Altman analysis showed proportional biases for 0.5 cpd at 40 cm ($p=0.003$), and 16 cpd at 4 m and 40 cm ($p=0.008$, $p=0.002$). The mixed linear model showed no overall significant difference between the FInD CSF and 2AFC CSF tests at 4 m ($F=0.913$, $p=0.366$, $\eta^2=0.034$) and 40 cm ($F=2.130$, $p=0.123$, $\eta^2=0.098$). Posthoc analysis showed significant differences at 0.5 cpd ($p<0.001$), 1 cpd ($p=0.001$), and 2 cpd ($p=0.025$) at 4 m. At 40 cm, posthoc analysis showed differences for 4 cpd ($p=0.032$), and 8 cpd ($p=0.002$).

Conclusions: Good repeatability and reliability were found for the FInD CSF test at 4 m and 40 cm viewing distances. Completion of data collection (aim is $n=50$) will conclude whether the FInD CSF test is indicated for use in clinical practice.

ABSTRACT BODY:

Purpose: Protein citrullination is catalyzed by the peptidyl arginine deiminases (PADs). PAD4 has emerged as an important biomarker in mouse and human wet-AMD (IOVS June 2020, Vol.61, 3689). Here we have investigated the contribution of PAD4 to pathological citrullination in the mouse model of wet-AMD, as well as in human wet-AMD maculae.

Methods: PAD4 homozygous deficient (PAD4 KO) mice were generated by breeding PAD4^{flox/flox} mice with GFAP-Cre^{ERT2} mice and progeny treated with tamoxifen. PAD4 KO mice and litter mates were subjected to focal laser burns of the retinal pigment epithelium using the Meridian Merilas 532 nm laser coupled to the Micron III fundus imaging system. Mouse eyes were cryosectioned and stained with antibodies against F95 antibody (citrullination) and glial fibrillary acidic protein (GFAP). Mouse retino-choroidal tissue was lysed in RIPA buffer for western blot (WB) analyses. Human donor AMD eyes (n=2) and age-matched normal eyes (n=2; male and female) were subjected to SD-OCT, as described (Pang et al., Ophthalmology 2015). A circular 8 mm retino-choroidal button centered at the macula was cryosectioned and stained with antibodies to PAD4, GFAP and citrullinated GFAP (CTGF-1221) and analyzed by confocal microscopy.

Results: PAD4 KO 7-day-laser injured mice showed decreased citrullination of specific species, as well as high molecular weight species compared to injured litter mates in WB analysis. PAD4 KO mice also showed reduced filamentous citrullinated protein in Muller glia compared to wildtype mice. In human female AMD maculae, the CTGF-1221 antibody recognizing citrullinated arginine (R270 and R416) on GFAP showed increased positive staining in the astrocyte layer, as well the inner nuclear layer. The male AMD retina also showed modest increase of citrullinated-GFAP. The citrullinated-GFAP species are in the cell body in both layers and have decreased filamentous structure compared to age matched controls.

Conclusions: Increased retinal citrullination in the mouse AMD model is driven by Muller cell expression of PAD4. Providing proof of the importance of this enzyme, PAD4 genetic ablation results in reduced citrullination. Human wet-AMD maculae that show increased PAD4 expression revealed corresponding increased citrullinated GFAP species. These findings illuminate PAD4 as an important druggable target in AMD and its attenuation for pathological citrullination.

ABSTRACT BODY:

Purpose: To demonstrate automated capillary segmentation in adaptive optics – optical coherence tomography (AO-OCT) images.

Methods: AO-OCT volumes were acquired from the FDA multimodal AO imager focused on the inner retina. A trained grader generated the vessel plexus projections from the averaged AO-OCT volumes. We trained a UNet-based convolutional neural network to segment retinal capillaries in en face projections of the superficial vascular plexus (SVP), intermediate capillary plexus (ICP), and deep capillary plexus (DCP). The network was trained with random 128x128 pixel patches from 177 automatically contrast-corrected projections of each plexus from 18 eyes in 18 subjects with a 20% validation split. We trained four models: one with all-plexus images and three with plexus-specific images only. The models' results were compared with a trained grader's manual capillary segmentation. We evaluated segmentation performance based on Dice coefficient (DC), pixel-wise precision, recall, and accuracy on a held-out 20% test split.

Results: Our all-plexus model achieved good segmentation results with an overall DC of 0.701, precision of 0.686, recall of 0.749, and accuracy of 0.929. All-plexus and plexus-specific model performance had comparable results for each plexus, with slightly better DC in the all-plexus model in SVP and ICP, but worse in DCP projections.

Conclusions: This is the first application of deep learning techniques for automated vessel segmentation in AO-OCT projections, achieving a good DC, precision, recall, and accuracy and demonstrating the applicability of segmentation techniques to this imaging modality. Difference in results across plexus-specific models may reflect a trade-off in training sample size and task-relevance; however, statistical significance of these results is not determined from this study. Future work is needed to further understand whether automated segmentation should be optimized for each plexus.

ABSTRACT BODY:

Purpose: The strength of visual responses in primary visual cortex varies with stimulus luminance and size. However, the relative contribution of ON and OFF cortical pathways to signaling luminance remains poorly understood. Here, we investigated how the responses from ON and OFF cortical neurons change with the spatial structure and brightness of the stimulus.

Methods: We measured the responses from ON and OFF neurons in cat visual cortex to light-dark pattern stimuli (white noise, gratings) and light or dark homogenous surfaces. Cortical neurons were classified as ON or OFF based on the contrast polarity ratio of their maximum response to light and dark small features, $CP = (light - dark) / (light + dark)$, where $CP < 0$ indicates OFF pathway dominance and $CP > 0$ indicates ON pathway dominance.

Results: When stimulated with patterns, ON and OFF neurons had similar response strength (42.9 ± 1.1 vs. 41.9 ± 1.0 spk/s, $p=0.30$, Wilcoxon test). OFF neurons responded to small dark stimuli aligned with their receptive field centers, and were suppressed by small light stimuli, and the opposite was found for ON neurons. As stimulus luminance increased, the responses from ON and OFF neurons became stronger ($R^2=0.84$, $p<0.001$) and ON neurons increased their ON dominance while OFF neurons increased their OFF dominance, a change that may help to distinguish better small dark stimuli from small light stimuli. Surprisingly, both ON and OFF neurons showed strong spatial summation to large bright surfaces and strong spatial suppression to large dark surfaces (dark vs. light size suppression ratio; OFF: 0.46 ± 0.03 vs. 0.16 ± 0.03 ; ON: 0.39 ± 0.05 vs. 0.08 ± 0.04 ; $p<0.001$, Wilcoxon tests). Additionally, as stimulus luminance increased, cortical responses from both ON and OFF neurons, and the combined ON-OFF response, became stronger.

Conclusions: Our results reveal a cortical mechanism for stimulus size-luminance interactions that may underlie brightness perception. Brightness of small features is signaled with an increase in ON pathway strength but brightness of large surfaces is associated with a strong ON-OFF combined response. This is explained if both ON and OFF neurons have opposite receptive field centers but the same ON extended surrounds. With this structure, small features drive opposite ON and OFF center responses while large surfaces drive the same extended surround, increasing response to light surfaces and suppressing response to dark surfaces.

TITLE: Expression of immune checkpoint LAG3 is associated with high risk uveal melanoma

SESSION TITLE: Advances in Diagnosis and Treatment of Uveal Melanoma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. Souri, G. Luyten, M.J. Jager, Ophthalmology, Leids Universitair Medisch Centrum, Leiden, Zuid-Holland, NL, academic/hospital, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Zahra Souri: Commercial Relationship: Code N (No Commercial Relationship) | Gre Luyten: Commercial Relationship: Code N (No Commercial Relationship) | Martine Jager: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Uveal melanoma is a rare malignancy of the eye originating from the uveal tract. While treatment with immune checkpoint inhibitors such as anti-PD1 is often effective in the treatment of cutaneous melanoma metastases, no effective treatment for UM metastases has as yet been developed. A potential new target for immune checkpoint inhibitors is Lymphocyte-activation gene 3 (LAG3). LAG3 is an immune inhibitory receptor which is expressed on T cells and shows a great affinity for MHC Class II. Another ligand of LAG3 is Galectin-3. As LAG3 is known as an indicator of T cell exhaustion in tumors, we set out to investigate which Uveal Melanoma express this immune checkpoint and its ligands, MHC Class II and Galectin-3, in order to get a better insight in possible immunotherapeutic approaches.

Methods: The mRNA expression of LAG3, MHC II, Galectin-3, PD1, markers of tumor-infiltrating lymphocytes (TIL) and tumor-associated macrophages (TAM) was determined using an Illumina HT12V4 array in 64 primary UM. In order to confirm our analysis, the mRNA expression of the same markers was studied using 80 UM samples from the TCGA cohort.

Results: When comparing the level of LAG3 expression with clinic-pathological characteristics in the Leiden set of 64 tumors, a higher expression was associated with the presence of epithelioid cells ($P=0.05$), ciliary body involvement ($P=0.05$) and loss of BAP1 staining ($P=0.001$); the level of LAG3 expression was significantly higher in monosomy 3 tumors compared to disomy 3 ($P=0.004$). Furthermore, LAG3 showed a positive correlation with TILs and TAMs (CD3, CD4, CD8, CD68, all $P<0.001$). LAG3 expression correlated positively with expression of HLA-DP ($P<0.001$), HLA-DQ ($P<0.001$), two probes for HLA-DR ($P<0.001$; $P<0.001$), Galectin3 ($P<0.001$) and PD1 ($P<0.001$). When looking at the TCGA data, similarly, LAG3 ($P<0.001$), HLA-DP ($P=0.001$), HLA-DQ ($P<0.001$), HLA-DR ($P=0.001$), and Galectin3 ($P<0.001$) were significantly higher in M3 compared to D3 UM tumors.

Conclusions: We show that LAG3 is highly expressed in M3 UM tumors; LAG3 is strongly associated with expression of its ligand MHC Class II, and with the presence of TILs and TAMs. We suggest that LAG3 might have a potential role for the exhaustion of T cells present in the UM tumor environment and propose that due to its association with high risk tumor characteristics, LAG3 may be a good target for immunotherapy in UM.

ABSTRACT BODY:

Purpose: The eye is the most susceptible part of the body to the effects of chemical warfare agents, nitrogen and sulfur mustard (NM and SM). Steroidal and/or non-steroidal anti-inflammatory drugs are the accepted treatments for the acute and prolonged phases of mustard injury. However, there have been warnings against the use of topical steroids in SM ocular injuries. Thus, additional therapies to prevent the SM-induced ocular deterioration is a major unmet need.

Methods: Mouse corneas were exposed to NM (2%, 5 min) an analogue of SM. After exposure, corneas were topically treated with high-density lipoprotein like nanoparticles (HDL NPs), or Vitamin D3 (Vit D3, 5 ng i.p.) that was systemically injected. Cy3-labeled HDL NPs were used to determine penetration of HDL NPs through corneal epithelium. To evaluate corneal clarity, mouse corneas were imaged for haze scoring. To determine epithelial integrity, corneas were stained with fluorescein and imaged. Immunostaining and qPCR were performed to examine gene expression.

Results: After NM exposure, Vit D3 treatment significantly (>60%) reduced: (i) the amount of corneal fluorescein staining; (ii) degree of haze; (iii) pro-inflammatory cytokine and chemokine expression; and (iv) angiogenic signaling. This indicates that Vit D3 treatment results in marked alleviation of NM-induced corneal damage. Furthermore, we have demonstrated that following topical treatment, HDL NPs can penetrate into corneal epithelial cells. After NM injury, topical treatment of HDL NPs (1 μ M) significantly attenuated the expression of several inflammatory factors including Il6, Il1b, Cox2, and Ccl2. Additionally, factors that affect the stroma and normal repair process were reduced including Mmp9, Mmp12, Vegfa, Tgfb, and Pdgfb.

Conclusions: Collectively, our findings strongly suggest that systemic delivery of Vit D3 or topical delivery of HDL NPs to the cornea and limbus have vast treatment potential for corneal mustard keratopathy. Furthermore, the beneficial properties of HDL NPs as well as Vit D3 argues for the development of a "super" HDL NP-Vit D3 eye drop in order to reduce inflammation in the anterior segment.

ABSTRACT BODY:

Purpose: In response to neurodegenerative diseases and injury to the retina, astrocytes and Müller glia (MG) undergo reactive gliosis. Chronic reactive gliosis exacerbates neurodegeneration by promoting inflammation and scar formation. Studies report that Notch signaling enhances gliosis and neuronal death. Current compounds that target this pathway, including non-specific inhibitors of presenilin-dependent γ -secretase, do not effectively treat central nervous system (CNS) disease and injuries. Recently, PEAK1 Related, Kinase-Activating Pseudokinase 1 (PRAG1) was identified as a novel Notch transcriptional coactivator (and given the alternate name Notch Activation Complex Kinase [NACK]). Our team identified a first-in-class PRAG1 inhibitor to target Notch1 activity directly and specifically. Given the activation of Notch1 signaling upon CNS injury and the critical role of PRAG1 in the activation of this signaling pathway, we hypothesize that directly modulating Notch1 transcriptional activity via PRAG1 inhibition will mitigate reactive gliosis and neuropathic progression.

Methods: Human and mouse MG were stimulated with Notch ligands then treated with the PRAG1 inhibitor UM74 for Western blot and real-time PCR. We also studied changes in Notch signaling and the effects of UM74 following ischemia/reperfusion (IR) injury in 2-month-old C57BL/6J mice. Retinal ischemia was induced for 1 hour by elevating intraocular pressure above systolic blood pressure with normal saline (to 120 mmHg). Intravitreal injection of UM74 was performed immediately after IR injury. Mice were sacrificed 7 days after injury and their eyes were enucleated for Western blot, real-time PCR, and immunofluorescence staining.

Results: Notch-1 signaling was upregulated in human and mouse MG after Notch ligand treatment as confirmed by an increase in activated Notch-1 and Hes1. Notch-1 signaling was also upregulated after 7 days post IR-mediated retinal gliosis. Blockade of Notch signaling with PRAG1 inhibitor UM74 attenuated astrocytic and MG hypertrophy and GFAP expression as assessed by immunofluorescence staining and Western blot, respectively. Longitudinal retinal ganglion cell functional studies are underway.

Conclusions: Notch-1 signaling is induced after IR-mediated reactive gliosis, and its direct blockage by PRAG1 inhibition may be a potential therapeutic strategy.

ABSTRACT BODY:

Purpose: To introduce a novel method to map the mechanical stiffness of healthy and keratoconic corneas.

Methods: Numerical modelling based on the finite element method was used to carry out inverse analysis of simulated healthy and keratoconic corneas to determine the regional variation of mechanical stiffness across the corneal surface based on established trends in collagen fibril distribution. The Stress-Strain Index (SSI), developed and validated in an earlier study and presented as a parameter that can estimate the overall stress-strain behavior of corneal tissue, was adopted in this research as a measure of corneal stiffness. The regional variation of SSI across the corneal surface was obtained using inverse analysis while referring to the common features of collagen fibrils' distribution obtained from earlier x-ray scattering studies. Additionally, for keratoconic corneas, a method relating keratoconic cone features and cornea's refractive power to the reduction in collagen fibril density inside the cone was implemented in the development of SSI maps.

Results: SSI values varied slightly across the corneal surface in healthy eyes. In contrast, keratoconic corneas demonstrated substantial reductions in SSI values inside the cone, Figure 1. These SSI reductions depended on the extent of the disease and increased with more considerable simulated losses in fibril density in the cone area. SSI values and their regional variation showed little change with changes in IOP, corneal thickness and curvature.

Conclusions: SSI maps provide an estimation of the regional variation of biomechanical stiffness across the corneal surface. The maps could be particularly useful in keratoconic corneas, demonstrating the dependence of corneal biomechanical behavior on the tissue's microstructure and offering a tool to fundamentally understand the mechanics of keratoconus progression in individual patients.

ABSTRACT BODY:

Purpose: Current paradigm for therapy of immune mediated ocular surface diseases (i OSD) consists of targeting innate or adaptive immune system pathways in a sequential, step-up treatment approach. A combinatorial topical therapy (anti-inflammatory/immunosuppressive pharmaceutical [steroid] with immunomodulatory [pooled human immune globulin] and tear substitute [serum] biologics) that simultaneously targets several immunological pathways may be more efficacious. This combinatorial therapy targets distinct albeit overlapping pathways of the immune system to affect several inflammatory mediators (eicosanoids, autoantibodies, complement system and cytokines/chemokines).

Methods: We performed a retrospective, case study of patients receiving topical formulations of methylprednisolone, pooled human immune globulin, and serum tears to evaluate if the 'triple play' therapy resulted in clinical benefit in recalcitrant OSD cases (n=10). Patients included one male and nine females ranging in age from 27 to 87 years old. Patients were included if they suffered from recalcitrant OSD, received the three therapies, and had slit lamp photographs prior to starting the 'Triple Play' therapy and a subsequent photograph following at least a month of treatment. Outcome measures were individualized by case and included visual acuity, ocular surface disease index (OSDI), ocular discomfort score, subjective global assessment (SGA), and slit lamp photographs.

Results: Pathologies included ocular graft-versus-host disease, Sjögren's syndrome, ocular cicatricial pemphigoid, neurotrophic keratitis, pemphigus vulgaris, peripheral ulcerative keratitis, Stevens-Johnson syndrome, and giant papillary conjunctivitis. All patients were 'much improved' on SGA after 'Triple Play' therapy. Additionally, three patients had improvement in their visual acuity (one from 20/400 to 20/20). All patients had clinically meaningful improvement in signs (reduction in bulbar redness and corneal staining).

Conclusions: Combinatorial 'Triple Play' therapy provides a clinical benefit by reducing the symptoms and signs in recalcitrant i OSD. Our study provides the rationale for performing prospective clinical trials to evaluate the efficacy of combinatorial 'Triple Play' therapy for treating i OSD.

ABSTRACT BODY:

Purpose: To develop a computational biomechanical model of the mouse astrocytic lamina (AL) and investigate the effect of the AL network structure on the local stress and strain response to increased intraocular pressure (IOP).

Methods: An unmyelinated optic nerve section of a 6-month old GFP-GLT1 mouse was immunolabeled for GFAP and stained for actin and nuclei(Ling et al. 2020, Fig 1a). The non-GFAP and non-actin regions in the acquired confocal image were segmented as axonal compartments(ACs). A finite element model(FEM) was created using the GFAP, actin and AC labels in Gibbon Toolbox(Fig 1b). Nodal displacements were applied to the side surface of the AL using average of measured boundary displacements from 7 mouse eye explants that were inflated from 10 to 30 mmHg(Korneva et al. 2020). A pressure of 20 mmHg was applied on the anterior surface of the model to simulate the inflation test(Fig 1c). The GFAP, actin and ACs were assumed to be incompressible Neo-Hookean materials with shear moduli of 2.4MPa(Guzman et al. 2006), 21.2MPa(Janmey et al. 1991) and 1.9kPa(Budday et al. 2015), respectively. Bulk modulus for each material was assumed to be 100 times larger than the shear modulus. The effect of axonal area on strains simulated in FEBio was analyzed using a linear regression model in MATLAB.

Results: Preliminary results showed that the average nasal-temporal strain($E_{xx}=0.033$, Fig 2a) in the AL was higher than the inferior-superior strain($E_{yy}=0.026$), while the anterior-posterior strain was compressive($E_{zz}=-0.021$). This agreed with the inflation test results. The maximum principal strain(E_{max}) was larger in the ACs(0.03 ± 0.10) compared to that experienced by GFAP and actin structures in the astrocyte processes(0.01 ± 0.02 and 0.02 ± 0.01 , $p<0.01$, Fig 2b&d). However, the maximum principal stress(σ_{max}) was lower in the ACs (0.0058 MPa) when compared to that in GFAP(0.77 MPa) and actin(1.64 MPa, $p<0.01$, Fig 2c). Greater tensile strains E_{xx} and E_{yy} and greater compressive strains E_{zz} were obtained for larger ACs(Fig 2e&f, $p<0.05$). The model will be applied to examine the effects of fiber tortuosity and aspect ratio on the stress and strain response in the astrocyte processes and AC.

Conclusions: A specimen-specific FEM of the AL suggested that larger ACs experienced higher strain magnitudes. Variations in AL network structure may be related to the susceptibility of axonal damage in glaucoma.

ABSTRACT BODY:

Purpose: To compare the incidence of postoperative hemorrhagic complications in patients on antithrombotic therapy (ATT), including antiplatelet (AP) or anticoagulant (AC) therapy, and controls following combined trabecular stent implantation and phacoemulsification.

Methods: This single center, retrospective, case-control study included patients on chronic ATT who underwent iStent/iStent inject (Glaukos Corp., Laguna Hills, CA) or Hydrus (Ivantis Inc., Irvine, CA) with phacoemulsification between 2013-2019 and had ≥ 3 -month follow-up. The primary outcome measure was hemorrhagic complications within the 3-month postoperative period. Changes were not made to ATT therapy during this time. Secondary measures included visual acuity (VA), intraocular pressure (IOP), and number of glaucoma medications.

Results: Of 333 patients (435 eyes), 161 patients (211 eyes) were on ATT, and 172 patients (224 eyes) were controls. Baseline characteristics including age, sex, VA, IOP, cup-to-disc ratio, and number of glaucoma medications were similar between groups. Hyphema, the only hemorrhagic complication, was seen in 94 eyes (21.6%). Hyphema incidence differed by stent type (21.8% in iStent, 11.8% in iStent inject, and 42.4% in Hydrus ($P=0.002$)).

Incidence and duration of hyphema did not vary between ATT and control groups ($P=0.827$) (Figure 1). Of 35 ATT eyes with hyphema, 7 eyes (20.0%) were on AC therapy, 29 eyes (82.9%) were on AP therapy, and 1 eye was on combined therapy. Of the 102 patients who had two eyes included, hyphema was present in both eyes in 18 patients (17.6%). Hyphema was associated with an IOP increase of ≥ 10 mmHg from baseline in 22 ATT eyes (10.4%) and 25 control eyes (11.2%) ($P=0.878$). Reoperations were not required for hyphema or associated IOP spike. At month 3, VA improvement, reduction of IOP, and number of glaucoma medications were similar between the ATT and control groups ($P<0.001$ for all).

Conclusions: Hyphema was present in 21.6% of eyes, and was most common following Hydrus microstent and least common following iStent inject. ATT was not identified as a risk factor for the presence or prolonged duration of hyphema. Although hyphema was associated with an IOP increase of ≥ 10 mmHg from baseline in approximately one-tenth of eyes, reoperations were not required for this indication, and nearly all hyphemas resolved by postoperative month 1.

ABSTRACT BODY:

Purpose: Increasing use of optical methods for controlling myopia progression has raised questions regarding the potential long-term effects of these treatments on peripheral vision; however, there is currently no available clinical methodology for measuring peripheral visual acuity. We examined the ability to measure peripheral visual acuity in myopic children using standard spectacle lenses over a 12-month period in a prospective clinical trial using a novel measurement system.

Methods: Sixty-three myopic subjects aged 6 to 10 years old were evaluated using a novel, electronic system to measure peripheral acuity over two study visits, baseline (BL) and 12 months (12M). Subjects were seated 40 cm from a computer display wearing standard spectacle lenses, with the non-test eye patched. The test eye fixated on a numerical target while HOTV optotypes were presented at 25° eccentricity in 4 quadrants: Superior Temporal (ST), Superior Nasal (SN), Inferior Temporal (IT) & Inferior Nasal (IN). Varying optotype sizes were presented using a staircase method and responses recorded until threshold acuity was determined.

Results: Mean BL age and spherical equivalent refraction (\pm SD) were 8.1 ± 1.21 years and $-2.05 \pm 0.80D$ (range: -0.75 to -4.25). Mean BL peripheral visual acuity (\pm SD) in logMAR were: ST 0.99 ± 0.30 , SN 0.94 ± 0.30 , IT 1.06 ± 0.30 and IN 0.99 ± 0.25 . Mean 12M logMAR peripheral visual acuity were: ST 0.88 ± 0.27 , SN 0.88 ± 0.29 , IT 0.89 ± 0.28 and IN 0.87 ± 0.27 . Statistically significant differences in logMAR acuity between BL and 12M (paired t-test) were observed for the ST ($p = 0.015$), IT ($p = 0.002$) and IN ($p = 0.006$) quadrants. No difference was observed in the SN quadrant ($p = 0.20$).

Conclusions: Peripheral visual acuity in children wearing standard spectacle lenses can be measured effectively with this novel peripheral acuity system. While approximate 1-line improvements in mean logMAR peripheral visual acuity were observed in 3 of 4 visual field quadrants and may reflect increased subject familiarity with the test procedure and increasing subject age, these differences are not clinically significant and should be considered clinically stable. This measurement methodology may be an effective tool to monitor for changes in peripheral visual acuity over time in children in a clinical setting.

ABSTRACT BODY:

Purpose: There are no FDA-approved treatments for blepharitis due to Demodex infestation. We performed a prospective, randomized, vehicle-controlled Phase IIb clinical trial to evaluate the safety and efficacy of topical lotilaner ophthalmic solution 0.25% (TP-03, Tarsus Pharmaceuticals, Inc.) in patients with Demodex blepharitis.

Methods: Fifty-four adult participants were randomized 1:1 to the active (A) or vehicle (V) groups. One eye of each patient was defined as the analysis eye. To be included, participants had to have >10 collarettes (cylindrical dandruff) on the upper lid, at least mild upper lid margin erythema, and ≥ 1.5 mites per lash on the upper and lower lids combined. Lid hygiene treatment and topical antibacterial, antiparasitic or anti-inflammatory agents were not permitted during or 2 weeks before the study. Participants applied 1 drop of TP-03 in both eyes twice daily for 42 days. Primary outcome measures were the percentage of eyes achieving collarette cure (≤ 2 lashes with collarettes on the upper eyelid), mite eradication (mite density of 0), and a composite of collarette cure and grade 0 erythema. A one-sided Fisher's exact test with an α of 0.025 was used to compare the proportions between treatment groups.

Results: Collarette cure (Fig 1) was achieved in 72% of the A group and 11% of the V group at 28 days ($p < 0.001$) and 80% of the A group vs. 16% of the V group at 42 days ($p < 0.001$). Mites were eradicated in 56% of the A group and 11% of the V group at 28 days ($p = 0.006$) and in 73% of the A group and 21% of the V group at 42 days ($p = 0.003$). A composite collarette/erythema cure was achieved in 67% of the A group and 11% of the V group at 28 days ($p < 0.001$) and in 73% of the A group and 11% of the V group at 42 days ($p < 0.001$). There were no serious adverse events and no discontinuations due to adverse events. There was little to no change in mean CDVA or mean IOP in either group. In a post hoc analysis, 93% of the A group had collarette density of Grade 1 (2-10 total collarettes) or less by Day 42. Reduction in mite density by > 50% was seen in 87% of the A group by Day 14.

Conclusions: Treatment with TP-03 for 42 days is safe and shows promising efficacy for the treatment of blepharitis due to Demodex infestation.
