Results: The measured peripheral defocus (D) increased significantly (all $p \leq 0.001$) with increasing incidence angle (IOL power adjusted mean of +0.27, +0.78, +1.85, +3.25, +5.54 and +8.60 at $\pm 5^\circ$, $\pm 10^\circ$, $\pm 15^\circ$, $\pm 20^\circ$, $\pm 25^\circ$ and $\pm 30^\circ$ respectively). The IOL power mean difference (D) between the measured and predicted peripheral defocus (Figure 2) was +0.03, -0.21, -0.24, -0.74, -0.76 and -0.59 at $\pm 5^\circ$, $\pm 10^\circ$, $\pm 15^\circ$, $\pm 20^\circ$, $\pm 25^\circ$ and $\pm 30^\circ$ respectively.

Conclusions: The IOL power increases with increasing field angle corresponding to a shift towards myopic peripheral defocus. The LRT-OCT system accurately measures the peripheral power.

TITLE: Identifying gene interaction effects in Adipor1 and Mfrp double mutant mice

SESSION TITLE: Genetics of Retinal dystrophies and Functional Genomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Gogna, S. Weatherly, J. Pinkney, P.M. Nishina, The Jackson Laboratory, Bar Harbor, Maine, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Navdeep Gogna: Commercial Relationship: Code N (No Commercial Relationship) | Sonia Weatherly: Commercial Relationship: Code N (No Commercial Relationship) | Jai Pinkney: Commercial Relationship: Code N (No Commercial Relationship) | Patsy Nishina: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Adipor1^{-/-} and Mfrp^{rd6} mutant mice share similar disease characteristics such as photoreceptor (PR) degeneration, hyperopia, and uniformly flecked retina. Further, Adipor1 expression in RPE is lost in Mfrp mutant mice. Currently, MFRP function and its association with the ADIPOR1 protein are not well understood. The aim of this study was to identify individual gene contributions and digenic epistatic interactions between Adipor1 and Mfrp genes, in order to have a better understanding about their functional relationship and shared or individual pathways that lead to the shared common phenotypes.

Methods: Adipor1 and Mfrp mutant mice were outcrossed and resulting F1 offspring were intercrossed to produce Adipor1/Mfrp double mutant mice with nine possible genotypic combinations. Mice (n = 10-16/genotype, both genders) were analyzed for PR degeneration by histology and axial length measured by calipers. Two-way ANOVA and post-hoc analysis was used to study gene interaction effects.

Results: For PR degeneration, both the single (Adipor1^{-/-}/Mfrp^{+/+}, Adipor1^{+/+}/Mfrp^{rd6/rd6}) and double (Adipor1^{-/-}/Mfrp^{rd6/rd6}) mutants showed significant (p< 0.0001) degeneration as compared to wild type (Adipor1^{+/+}/Mfrp^{+/+}) mice. Both genes showed significant main effects and significant gene interaction effects confirming that PR degeneration due to one gene is dependent on the PR degeneration caused by the other gene. For axial length, while both genes showed significant main effects, no gene interaction effects were seen (p = 0.267). This confirms that while both the genes individually contribute to decrease in axial length, they do not interact to decrease the axial length and the decrease due to one gene is independent of the decrease due to another gene.

Conclusions: The observation of an interaction between two mutations is the first step towards uncovering the mechanism through which the genes of interest affect the measured phenotype. Our study confirms that both Adipor1 and Mfrp genes interact and are possibly part of the same pathway that lead to PR degeneration. On the other hand, our study suggests that even though a decrease in axial length is observed in both mutant strains, the genes do not interact and don't contribute to axial length changes via the same pathway. This study therefore provides important insight into the complexity of interactions between ADIPOR1 and MRFP that govern different disease characteristics.

TITLE: Promoting axon growth in human iPSC derived retinal ganglion cells by membrane-bound magnetic nanoparticles

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. CHU, C. Chiao, Life science, National Tsing Hua University, Hsinchu, TAIWAN|

Commercial Relationships Disclosure (Abstract): TINGYU CHU: Commercial Relationship: Code N (No Commercial Relationship) | Chuan-Chin Chiao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Axon growth of implanted retinal ganglion cells (RGCs) is an important step in restoring vision for glaucoma and retinal degenerated patients. Magnetic composite materials which can be manipulated non-invasively and functionalized easily have been reported to enhance filopodial elongation of RGCs by exerting mechanical tension.

Methods: Magnetic nanoparticles (MNPs) were added in isolated human iPSC derived RGCs, and magnetic field was applied continuously for 3 days to observe RGC axon growth length and direction in vitro. These isolated human iPSC derived RGCs with membrane-bound MNPs were injected into mouse retinas, and the elongation of transplanted RGC axons was assessed in vivo.

Results: The data shows that MNPs promoted RGC axon regeneration and guided RGC axon growth toward the direction of magnetic field significantly in vitro (Fig 1). When the magnetic field was applied in vivo, transplanted RGCs showed increased axon elongation and directed growth.

Conclusions: The present study demonstrates that MNPs are a potential therapeutic strategy in promoting axon regeneration and growth in RGCs. Future application of this approach may be using MNPs coated with growth factors to further facilitate RGC axon growth.

ABSTRACT BODY:

Purpose: A prominent aging change in human retinal pigment epithelium (RPE) under investigation for its role in age-related macular degeneration (AMD) is the accumulation of lipofuscin. Prior compositional analyses of lipofuscin revealed the fluorescent bisretinoid A2E, yet imaging mass spectrometry results suggest the presence of additional fluorophores of unknown origin. The purpose of this study is to identify and characterize new retinal fluorophores.

Methods: Human eyes (n=3) (white donors > 80 years of age) were obtained from the Advancing Sight Network. The retina was carefully removed, extracted using Folch extraction solvent, and fluorophores were separated using high performance thin layer chromatography (HPTLC) RP-18 plates using chloroform: methanol 1:1(v/v) with TFA as mobile phase. After visualization with UV absorbance and autofluorescence microscopy, fluorescent bands were separated manually and subjected to MALDI analysis using a solariX 9.4T FT ICR mass spectrometer (Bruker Daltonics) and LC-MS/MS using a Q-Exactive HF instrument (Thermo Scientific).

Results: Seven well-separated bands having UV absorbance and fluorescence properties were detected by TLC. A2E was identified in band 5 based on accurate mass measurement but was not located in the most fluorescent band. Mass spectra obtained from MALDI revealed the presence of high molecular weight species ranging from m/z 700-1100 in the intensely fluorescent bands (bands 3, 6 and 7). The molecular identity of m/z 782.557, 828.531, 711.980, 758.490 and 797.888 obtained from the most intensely fluorescent bands is currently under investigation using tandem mass spectrometry.

Conclusions: A TLC method was developed to separate retina extracts with separated bands having differing absorbance and fluorescence properties compared to A2E. The strategy will help us in the identification of fluorophores of unknown origin which may have implications in the onset of AMD.

ABSTRACT BODY:

Purpose: To assess the distribution of intraocular pressure (IOP) and its determinants in a very old population.

Methods: The population-based Ural Very Old Study (UVOS) was performed in a rural and urban region of Bashkortostan/Russia and consisted of 1526 (81.1%) out of 1882 eligible individuals aged 85+ years. As part of a series of medical and ophthalmological examinations, we measured IOP upon non-contact tonometry.

Results: The study included 1042 (68.3%) individuals with available IOP readings (mean age:88.1±2.7 years). Mean IOP was 14.6±5.3 mmHg (median:14 mmHg; range:6-60mmHg; 95%confidence interval (CI): 14.3,15.0) and 15.1±5.1mmHg (median:14mmHg; range:5-49mmHg; 95%CI: 14.8,15.4) in the right eyes and left eyes, respectively. In multivariable analysis, higher IOP was associated (regression coefficient r:0.35) with the systemic parameters of younger age (standardized regression coefficient beta:-0.08; non-standardized regression coefficient B:-0.13; 95%CI: -0.26, -0.01; P=0.04), female sex (beta:0.15; B:1.26; 95%CI:0.57,1.94; P=0.001) and higher systolic blood pressure (beta:0.18; B:0.03;95%CI:0.02,0.04; P<0.001), and the ocular parameters of thicker central corneal thickness (beta:0.18; B:0.02; 95%CI:0.01,0.03; P<0.001), longer axial length (beta:0.09; B:0.32;95%CI:0.05,0.60; P=0.02) and status after cataract surgery (beta:-0.13; B:-0.26; 95%CI:-1.59,-0.37;P=0.002). In that model, the IOP measurements increased by 0.19 mmHg (95%CI: 0.10,0.27) for each increase in central corneal thickness by 10 µm. In an univariate analysis, the IOP readings increased by 0.21 mmHg (95%CI: 0.13,0.29) for each increase in central corneal thickness by 10 µm.

Conclusions: In this population-based recruited study population aged 85+ years, IOP decreased with older age and increased with blood pressure and was higher in females. As in younger populations, the IOP readings were dependent on central corneal thickness, increased with longer axial length and were lower in eyes after cataract surgery.

ABSTRACT BODY:

Purpose: Corneal opacity is a leading cause of sight impairment worldwide. Gellan gum is a water soluble, anionic polysaccharide that, may be used to form optically clear fluid gel eyedrops. Previously, it has been shown that gellan fluid gel (FG) significantly reduces markers of corneal scarring in a murine model of microbial keratitis. This study looks into why gellan FG is so effective at preventing fibrosis and scarring.

Methods: Cultured human primary corneal fibroblasts were treated with 5 ng/ml Transforming Growth Factor b1 (TGFb1) with or without 27.5% v/v gellan FG. Samples were analysed for changes in expression of mRNA after 24 and 80 hours by RT-PCR. Cultured human dermal primary fibroblasts were treated with 10 ng/ml TGFb1 with or without 20% v/v gellan FG. Samples were analysed for total collagen content using a hydroxyproline assay. Data analysed using unpaired t-test.

Affinity of different proteins for quiescent and fluid gels was compared by incubating equal volumes of hydrogel and phosphate buffered saline (PBS) contain protein. Rate of absorption for each protein was determined by measuring the amount of protein remaining in the PBS was measured using a total protein assay or ELISA at multiple time points.

Results: Gellan FG significantly inhibited TGFb1 mediated upregulation of smooth muscle actin a, fibronectin, collagen 1A1 and collagen 3A1 mRNA expression in human corneal fibroblasts ($p < 0.05$), indicating an anti-scarring effect. Gellan FG also prevented TGFb1 stimulated collagen production in human dermal fibroblasts ($p < 0.01$).

Proteins with a net positive charge under physiological conditions (isoelectric point (pI) > 7) have a significantly higher affinity for gellan than those with a neutral or net negative charge (pI = or < 7). Gellan eye drop absorbed 80% of fibrogenic TGFb1 (pI = 8.6), but only 22% of Epidermal Growth Factor (pI = 4.5). Hydrogel made from agarose, an uncharged polysaccharide, did not preferentially absorb proteins depending upon their net charge.

Conclusions: In addition to mechanically protecting the wound bed and providing lubrication, gellan FG absorbs and sequesters proteins from the wound bed by diffusion coupled with electrostatic association. The gellan dressing alters the trophic profile of the wound and reprograms the extracellular signalling microenvironment by selectively absorbing proteins.

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) degeneration is a primary characteristic of glaucoma, although non-cell autonomous mechanisms have been implicated in RGC dysfunction. Astrocytes associate with RGCs in the nerve fiber layer of the retina and optic nerve, where they can contribute to RGC neurodegeneration. However, the mechanisms by which astrocytes promote neurotoxicity and contribute to glaucoma remain unknown.

Methods: Human pluripotent stem cells (hPSCs) can serve as powerful tools for the in vitro study of neurodegenerative diseases, including neuron-glia interactions. Using hPSC-derived cells from a glaucoma patient with an Optineurin (OPTN) E50K mutation (linked to inherited forms of glaucoma) as well as isogenic control cells obtained by CRISPR/Cas9 gene editing, we explored how the OPTN(E50K) mutation affects RGC-astrocyte interactions leading to neurodegeneration.

Results: hPSC-derived OPTN(E50K) astrocytes exhibited a hypertrophic shape and increased branching, as well as autophagy dysfunction and altered mitochondrial dynamics. Transcriptional analysis showed upregulation of the inflammatory pathway and downregulated axonal guidance in OPTN(E50K) astrocytes, suggesting they confer neurotoxicity and/or a lack of neurosupportive roles. Therefore, the contribution of astrocytes to RGC neurodegeneration was determined through co-cultures. Importantly, compared to the effect promoted by isogenic control astrocytes, OPTN(E50K)-astrocytes induced degenerative phenotypes in RGCs, including decreased neurite length and complexity, together with increased excitability, in both OPTN(E50K) and isogenic control RGCs. Conversely, isogenic control astrocytes were capable of rescuing degenerative phenotypes observed in OPTN(E50K) RGCs. Glaucomatous astrocytes secrete reduced levels of certain growth factors, suggesting a deficit in their neurosupportive role. In accordance, the incubation of OPTN(E50K) RGCs with these factors increased neurite branching and synaptic protein expression, highlighting the role of astrocyte-derived factors in RGC support.

Conclusions: These results are the first of its kind to identify a neurotoxic phenotype in hPSC-derived astrocytes from a glaucomatous source, as well as to identify a role for astrocytes in the neurodegenerative process through non-cell autonomous mechanisms, highlighting these glial cells as novel potential therapeutic targets in glaucoma.

TITLE: Interleukin-6 is necessary and sufficient for choroidal angiogenesis

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Lavine, S. Droho, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jeremy Lavine: Commercial Relationship: Code N (No Commercial Relationship) | Steven Droho: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Despite monthly intravitreal injection therapy, 15% of neovascular age-related macular degeneration (nAMD) patients lose vision. Interleukin-6 (IL6) is a pro-inflammatory and pro-angiogenic cytokine that is correlated with AMD progression and nAMD activity. We hypothesize that anti-IL6 therapy is a potential therapeutic for nAMD.

Methods: All experiments were performed on 10-12 week-old C57BL6/J mice. Wildtype (WT) and Il6^{-/-} mice underwent laser injury. Choroidal neovascularization (CNV) area was measured on choroidal flatmounts by ICAM-2 immunofluorescence on Day 14. Choroidal explants were cultured from WT mice for 7 days in Matrigel with and without exogenous IL6 (10 ng/ml) addition on Day 2, 4, and 6. IL6 levels were measured from posterior eye cups via ELISA on Day 3 after laser in WT and Ccr2^{-/-} mice. IL6 receptor expression was detected by immunofluorescence staining of whole eye frozen sections with IBA1 and lectin. Wildtype and Il6^{-/-} mice underwent laser injury followed by multiparameter flow cytometry on Day 3 to investigate macrophage infiltration.

Results: Male and female Il6^{-/-} mice demonstrated a 42% reduction (p<0.01, N=24-25 mice per group) in CNV area without sex-specific effects. Exogenous IL6 stimulated ex vivo choroidal angiogenesis by 131% (p<0.001, N=5 per group). Since IL6 is a pro-inflammatory cytokine produced by macrophages, which are essential for laser-induced CNV, we measured IL6 levels in WT and Ccr2^{-/-} mice. IL6 levels increased 1.15-fold (p<0.001, N=4-5 per group) in both genotypes, suggesting that classical monocyte-derived macrophages are dispensable for the increased IL6 production after laser. Next, we found that the IL6 receptor is expressed in choroidal endothelial cells and macrophages after laser injury. Due to IL6 receptor expression in macrophages, we investigated the effects of IL6-deficiency on macrophage recruitment using multiparameter flow cytometry. We found that laser injury increased the number of MHCII⁻ (13.0 to 15.0-fold, p<0.05), MHCII⁺CD11c⁻ (4.9 to 8.4-fold, p<0.05), and MHCII⁺CD11c⁺ (5.9 to 6.5-fold, p<0.01) macrophages (N=5-10 per group), with no differences between wildtype and Il6^{-/-} mice.

Conclusions: IL6 is both necessary and sufficient for choroidal angiogenesis. IL6 is not produced by classical monocyte-derived macrophages and signals to endothelial cells and/or macrophages to stimulate choroidal angiogenesis without affecting macrophage numbers.

ABSTRACT BODY:

Purpose: The IL-2 receptor (IL-2R) is composed of three different chains, α (CD25), β , and γ . CD25 is the binding arm of the receptor and critical for IL-2 signaling. CD25 is expressed primarily on immune cells, but an epithelial expression of CD25 has been reported in epithelia, including the cornea. We showed that CD25 null mice develop a Sjögren-like Syndrome, with ocular alterations, including loss of intraepithelial corneal nerves and decreased corneal mechanosensitivity. However, the role of epithelial CD25/IL-2 signaling has not been thoroughly investigated.

Methods: Corneal epithelium from 14-week old female C57BL/6 mice were collected and subjected to real-time PCR. Tear washings were collected and assayed for IL-2 and IL-1 β . Laser scanning confocal microscopy evaluated the expression of CD25 within the corneal epithelium in wild-type C57BL/6 mice. Tet-On Krt12^{rtTA} (Keratin 12-reverse tetracycline-trans-activator knock-in), tet-O-Cre, and CD25^{flox} lines were mated to create a conditional, doxycycline-inducible Krt12^{rtTA/rtTA}/tet-O-Cre/CD25^{flox/flox} ternary mouse line (hereafter named CD25 ^{Δ/Δ CEpi}) where CD25 is ablated only in the corneal epithelium after administration of doxycycline in chow. Offspring of both sexes were subjected to a doxycycline diet for four weeks, and corneal sensitivity was measured with a Cochet-Bonnet esthesiometer at eight weeks of age.

Results: In wild-type mice, mRNA expression of CD25, IL-2R β , and IL-2R γ was present in the corneal epithelium. IL-2 was detected in tears of naïve mice, while IL-1 β was below the level of detection. Confocal microscopy showed that CD25 immunoreactivity is present in the cell membrane of apical and subapical epithelial cells but not in basal cells or intraepithelial nerves. A significant decrease in corneal sensitivity was observed in the induced-CD25 ^{Δ/Δ CEpi} mice compared to doxycycline-fed binary littermates Cre⁽⁻⁾, non-induced CD25 ^{Δ/Δ CEpi} mice, and binary littermates Cre⁽⁻⁾ mice on a regular diet.

Conclusions: All three chains of the IL-2R are expressed in the corneal epithelium. IL-2 is present in tears, bathing the ocular surface. Our results indicate that CD25/IL-2 epithelial signaling is important for corneal nerve homeostasis. Future studies are needed to delineate the mechanisms of how IL-2 preserves corneal nerves.

TITLE: A20 may alter the fibrotic response within the trabecular meshwork by attenuating TGF β 2-TLR4 signaling crosstalk

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: P. Mzyk, C.M. McDowell, Department of Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Philip Mzyk: Commercial Relationship: Code N (No Commercial Relationship) | Colleen McDowell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although the ECM in TM cells is known to be important in IOP regulation, the molecular mechanisms involved in generating a glaucomatous environment in the TM are not completely understood. Recently we identified a molecular pathway, TGF β 2-TLR4 signaling crosstalk, as an important regulator of glaucomatous damage in the TM which contributes to fibrosis. Here we continued our studies on a novel molecular target, A20 (also known as TNFAIP3), within this pathway which may help to block pathological TGF β 2-TLR4 signaling, ultimately leading to new treatments to prevent the development and progression of glaucoma.

Methods: Primary human trabecular meshwork (TM) cells were grown to confluence, switched to serum free media, and then treated for 48hrs with TGF β 2 (5ng/mL), TLR4 inhibitor (TAK-242, 15 μ M), A20 inducer (Vitamin E, 100 μ M), TGF β 2 and TLR4 inhibitor, TGF β 2 and Vitamin E, or PBS as a control. Lysates were either collected and immunoblotted for A20 and fibronectin expression, or for A20 analysis by RT-PCR.

Results: RT-PCR and immunoblotting showed that A20 is expressed in primary human TM cells. A20 message increased ($p=0.0052$) when the TLR4 pathway was inhibited. Immunoblotting of cell lysates from primary TM cell strains showed that TGF β 2, a known inducer of fibrosis, increases fibronectin expression ($p=0.0035$), while at the same time decreasing the expression of A20 ($p=0.0019$). Both direct inhibition of TLR4 (with TAK-242) and direct induction of A20 (with Vitamin E) showed a trending increase in A20 expression on immunoblots. Concurrent treatment with both TGF β 2 and Vitamin E also showed an increase in A20 levels.

Conclusions: This ongoing study reports the expression of A20 in primary cells as it relates to the TGF β 2-TLR4 crosstalk pathway. A20 was easily detectable by PCR analysis and increased with TLR4 inhibition. Low basal expression of A20 was detected at the protein level, which has also been reported in other cell types. However, treatment with TGF β 2, TLR4 inhibitor, or Vitamin E did modulate A20 protein expression. Therefore, TGF β 2-TLR4 crosstalk may be an important mechanistic pathway in the development of fibrotic TM damage and A20 may be able to alleviate some fibrotic responses by attenuating the TLR4 pathways ability to induce fibrosis.

TITLE: Conforming versus nonconforming meshes in the finite element modeling of the human lamina cribrosa

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H.G. Kollech, Computational Modeling and Simulation, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|J.P. Vande Geest, Bioengineering, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hirut Kollech: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Vande Geest: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The biomechanics of the optic nerve head region including the lamina cribrosa (LC) and sclera is fundamental for the development of glaucoma. Several finite element (FE) approaches have been utilized to investigate the material properties of this region. Although both subdomain and full geometries are used to model the LC, the difference between conforming mesh (based on the geometry & structure) and nonconforming mesh has not been quantified. The purpose of this study is to investigate the differences between a conforming and nonconforming mesh on a small region of a human LC.

Methods: A nonglaucomatous human eye was imaged using a multiphoton microscope during a pressure inflation experiment. Second-harmonic generation images were collected and utilized to generate a 3D segmentation geometry. A small subdomain region was created from the segmented LC and meshed using a conforming tetrahedral mesh, a nonconforming hexahedral mesh, and a nonconforming tetrahedral mesh (shown in each panel where red indicates collagen in the LC). Element sizes were varied in each of the groups and FE simulations were run using identical boundary conditions, load, and material parameters. A few locations were selected to output displacement.

Results: The mesh convergence study within each of the three groups is shown in the Figure where Panels A, B and C display the conforming tetrahedral, nonconforming hexahedral, and nonconforming tetrahedral meshes. The percent error was calculated using the conforming finest mesh as a reference. The conforming mesh showed a maximum of 6.2 ± 0.3 % error variation and the error was smaller than 1% for element sizes greater than 1 million. The hexahedral mesh had a maximum error of $69.8 \pm 8.2\%$ at the coarse mesh and that of the nonconforming tetrahedral mesh was $57.8 \pm 4.2\%$.

Conclusions: The non-conforming mesh simulations result in $< 5\%$ error at finer mesh sizes. While the geometry in this study was small and the conforming mesh simulations were not computationally demanding, generating conforming FE simulations for complex structures such as the LC require large computational resources. Therefore, mesh-converged nonconforming models that result in small errors can be a great alternative. We are currently using these results to estimate the size of FE problems in our full LC.

ABSTRACT BODY:

Purpose: Nephrocystin (NPHP1) is a ciliary transition zone protein and its ablation causes nephronophthisis (NPHP) with partially penetrant retinal dystrophy. This study is to determine the roles of NPHP1 in photoreceptors and uncover the molecular/genetic basis of the incomplete penetrance of retinal dystrophy in NPHP1-associated nephronophthisis.

Methods: Nphp1 gene-trap (Nphp1^{gt}) and Cep290^{fl} mice were obtained from the Jax lab (Nphp1^{tm1Jgg}/J; #013169 and Cep290^{tm1Jgg}/J; #013701). Nphp1 expression from normal and Nphp1^{gt/gt} mice was examined by immunoblotting, immunohistochemistry, and RT-PCR. Localization of various inner segment and outer segment proteins was examined by immunohistochemistry. Retinal functions were examined by electroretinography (ERG). Physical interactions of NPHP1 mutant variants with other NPHP proteins were tested by immunoprecipitation.

Results: In Nphp1^{gt/gt} retinas, inner segment plasma membrane proteins including STX3, SNAP25, and IMPG2 accumulate in the outer segment when outer segments are actively elongating. This phenotype, however, is spontaneously ameliorated after the outer segment elongation is completed. Retinal degeneration also occurs temporarily during the photoreceptor maturation but stops afterward. We found that the Nphp1^{gt} allele, which was previously described as null, was hypomorphic due to the production of a small quantity of functional mRNAs derived from nonsense-associated altered splicing and the consequent production of near-full-length, internal deletion mutant proteins. The mutant protein appears to retain most, if not all, functions of full-length NPHP1 as determined by in vitro studies. We further show that Nphp1 genetically interacts with Cep290, another NPHP gene, and that a reduction of Cep290 gene dose results in retinal degeneration that continues until adulthood in Nphp1^{gt/gt} mice.

Conclusions: Our data show that NPHP1 is essential to prevent infiltration of inner segment plasma membrane proteins into the outer segment during the outer segment development, but its requirement diminishes as photoreceptors mature. Our study also suggests that additional mutations in other NPHP genes may influence the penetrance of retinal dystrophy in human NPHP1 patients.

ABSTRACT BODY:

Purpose: The Joslin 50-Year Medalist Study identified elevated concentrations of retinal specific protein, Retinol Binding Protein 3 (RBP3) in people with 50 years or longer duration of type 1 diabetes and no to mild non-proliferative diabetic retinopathy (NPDR), suggesting potential to neutralize toxic effects of hyperglycemia on the vascular and neuronal retina. This study correlated RBP3 levels in the vitreous with diabetic retinopathy (DR) severity and progression in a large group of people with type 1 and type 2 diabetes.

Methods: Vitreous samples (n=213) were obtained during vitreoretinal surgery at the Joslin Beetham Eye Institute (n=58) and from post-mortem eyes (n=155) of Medalists. RBP3 concentration was measured by two self-developed ELISAs using either colorimetric or luminescent assays with a linear detection range of 10 pM to 15 nM and inter-experimental variation of <5%.

Results: Elevated vitreous RBP3 concentration was associated with less severe DR in all eyes ($p<0.0001$), post-mortem Medalist specimens ($p<0.0001$) and surgical samples from type 1 and type 2 diabetic patients with shorter diabetes duration (mean \pm SD 26.5 \pm 12.7 yrs, $p=0.03$). RBP3 concentration in subjects with no diabetes (NDM, median: 22.4 nM) and no to mild NPDR (15.7 nM) were increased compared to moderate-severe NPDR (8.2 nM, $p<0.01$ and $p=0.01$, respectively), active proliferative DR (PDR, 8.4 nM, $p<0.0001$ and $p=0.0003$, respectively) and quiescent PDR (3.5 nM, $p<0.0001$, both). Vitreous RBP3 concentration was associated with age (point estimate 0.06, $p=0.008$), diabetes duration (0.04, $p=0.05$), triglycerides (-0.01, $p<0.05$), neuropathy (-0.07, $p=0.02$), albumin/creatinine ratio (-0.01, $p<0.0001$), and panretinal laser (-1.06, $p=0.01$), but not with A1c ($p=0.68$). There was no difference in RBP3 concentration between people with type 1 and type 2 diabetes ($p=0.44$). Vitreous RBP3 concentrations were highly correlated between fellow eyes ($r=0.86$, $p<0.0001$). Further, in participants with longitudinal follow up, higher RBP3 concentrations were associated with reduced risk of PDR development over time ($n=34$, $p<0.001$).

Conclusions: These data suggest that higher RBP3 concentration in the vitreous is associated with less severe DR and slower rates of progression to PDR, supporting its therapeutic potential for prevention of DR worsening in people with diabetes.

TITLE: A Prospective study of type 1 and type 2 Diabetics examining the correlation between antioxidant levels and neuronal layer loss. (DECAN study)- An exploratory Study

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. NORTH, G.V. Menon, M. Chandran, Frimley Health NHS Foundation Trust, Frimley, Surrey, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): LORRAINE NORTH: Commercial Relationship: Code N (No Commercial Relationship) | Geeta Menon: Commercial Relationship: Code N (No Commercial Relationship) | Manju Chandran: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this study was to examine the relationship between retinal neuronal layer changes assessed using spectral domain optical coherence tomography (SD-OCT) with dietary intake of foods in patients with type 1 and type 2 diabetes with or without diabetic retinopathy.

Methods: Patients with type 1 and type 2 diabetes patients were recruited from the diabetic eye clinics at Frimley Park Hospital. A cross sectional study with a longitudinal element was carried out, 204 participants were recruited to the DECAN study. Outcome measures were dietary intake assessed using a food frequency questionnaire (FFQ), and optical coherence tomography (OCT).

Results: The results of the study showed that both outer nuclear layer (ONL) and the inner nuclear layer (INL) showed statistically significant associations with Vitamin B12, Pantothenic acid, copper and selenium. Selenium was seen to be associated with a thinner INL. The ONL showed a statistically significant association with vitamin B12, indicating that an increase in Vitamin B12 results in a thicker ONL whereas an increase in pantothenic acid is also associated with a thinner ONL.

Conclusions: This study has added to the growing evidence that oxidative stress, antioxidants and neurodegeneration are critical factors in the pathogenesis of diabetic retinopathy early on.

The study showed promising results for further research that could lead to an interventional trial using a supplementation of selenium which has not been previously reported.

TITLE: Limited Hyperoxia Induced Retinopathy Alters Retinal Vasculature, Pericyte Count, and Gene Expression

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Lee, T. Tedeschi, A. Fawzi, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kendal Lee: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Tedeschi: Commercial Relationship: Code N (No Commercial Relationship) | Amani A Fawzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While the Oxygen Induced Retinopathy (OIR) model is the most widely studied animal model used to mimic Retinopathy of Prematurity (ROP), the more recent Limited Hyperoxia Induced Retinopathy (LHIPR) model reflects more advanced pathological phenotypes seen in ROP. In this study, we expand upon the findings of the LHIPR model to show vascular changes that mimic other retinopathies.

Methods: Wild type C57Bl/6J mouse pups were exposed to 65% oxygen from P0 until P7 to model LHIPR. After P7, pups were returned to room air oxygen levels and allowed to recover until endpoints of P21 or P30. LHIPR pups were euthanized along with their age-matched control room air (RA) pups and eyes were harvested. For each mouse, one eye was fixed and prepared for flatmount immunolabeling of retinas and RNA was collected from the other for qPCR analysis. For the flatmounts, endothelial cells were labeled with CD31 antibody and pericytes were labeled with NG2 antibody. NG2 positive pericyte counts were scored by two masked readers. For qPCR experiments, a CD31 antibody/magnetic bead complex was used to isolate endothelial cells from dissociated retinas to purify RNA and perform first strand cDNA synthesis. Relative fold gene expression of endothelial PDGFB, an endothelial-derived pericyte growth factor, was quantified in the endothelial fraction.

Results: We found that LHIPR retina displayed a decrease of vessel density in P21 and P30 flatmounts (P21 $p < 0.05$, P30 $p < 0.001$). The P21 LHIPR flatmounts showed no relative difference in the number of pericytes. In contrast, P30 LHIPR flatmounts had a 34% pericyte loss relative to RA (P30 RA: 1.00 ± 0.05 , P30 LHIPR: 0.66 ± 0.07 , $p < 0.001$). The qPCR data showed a decrease (P21 $p > 0.05$, P30 $p < 0.001$) in PDGFB in P30 LHIPR endothelial samples, and not in P21.

Conclusions: Our study expands on the LHIPR model where we observe decreased vessel density, pericyte loss, and changes in gene expression involving endothelial-derived pericyte growth factors. These retinal vascular alterations mimic a spectrum of clinical retinopathies, including diabetic retinopathy.

SUBMITTER (NAME ONLY): Brenda Brankin

TITLE: Blood retinal barrier tight junction expression modulation by NRF2 agonists

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Brankin, C. McCormack, S. Meaney, Biological and Health Sciences, Technological University Dublin, Dublin, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Brenda Brankin: Commercial Relationship: Code N (No Commercial Relationship) | Conor McCormack: Commercial Relationship: Code N (No Commercial Relationship) | Steve Meaney: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress may contribute to RPE cell damage in progressive degenerative diseases such as age-related macular degeneration (AMD). Nuclear factor erythroid 2-related factor 2 (NRF2) is a key modulator of the antioxidant response and represents a potential modifying factor to limit the extent of oxidative stress in the eye. We examined how modulation of NRF2 activation influenced the expression of tight junctional genes, trans-epithelial electrical resistance (TEER) and barrier permeability in an ARPE-19 cell model.

Methods: ARPE-19 cells were treated with varying concentrations sulforaphane (SFN) or brusatol (BRL), or a combination, for 24 hours. Cell viability was assessed via resazurin reduction. Gene expression was determined by quantitative RT-PCR, using the comparative threshold cycle method and PPIA as the endogenous control. TEER and barrier permeability experiments were carried out on confluent monolayers cultured for up to four weeks in TransWell plates. Comparative studies with histone deacetylase inhibitors (HDACi) were used to assess the contribution of the known HDACi effect of SFN on the experimental readouts. The student's t-test was used for statistical comparisons, with $P < 0.05$ considered significant.

Results: SFN and BRL appear well tolerated by ARPE-19 cells and modify the expression of classic antioxidant response genes (superoxide dismutase (SOD), thioredoxin-1 (TRX1)). The effects of BRL were only apparent at 100-200 nM, concentrations while those of SFN were concentration dependent (peak induction at 10 mM). SFN modulated the expression of several tight junction genes including Claudin-1 (CLDN1), occludin (OCCLDN) and zona occludens-1 (ZO1), again in a dose dependent manner. TEER was modestly, but significantly, reduced under these conditions. Analogous experiments with BRL resulted in a suppression of gene expression and an increase in TEER. Computational analysis identified potential antioxidant response elements (ARE) in the CLDN1 gene that may explain the observed effects on mRNA expression.

Conclusions: We show that the natural compounds SFN and BRL can modulate tight junction proteins in ARPE-19 cells at low doses. The functional effects of SFN on TEER appear to be driven by the HDACi activity of SFN rather than the NRF2 effect, as the effects of other HDACi and SFN on TEER are consistent despite variable changes in gene expression.

ABSTRACT BODY:

Purpose: Nod2 (nucleotide-binding oligomerization domain-containing 2) is an important anti-microbial receptor. However, mutations in NOD2 result in Blau Syndrome, typified by uveitis. We recently uncovered a T cell-intrinsic mechanism for Nod2 in suppression of Th17-immunity and experimental autoimmune uveitis (EAU). Nod2 is induced upon antigen-recognition in CD4⁺ T cells; hence we examined how Nod2 disruption controls T cell receptor (TCR)-triggered responses under homeostatic conditions in Nod2^{-/-} mice as well as in patients with Blau Syndrome.

Methods: Naive (CD62L^{hi}CD44^{lo}) CD4⁺ T cells purified from WT vs. Nod2^{-/-} mice were differentiated under Th17 polarizing conditions (CellXVivo) and Th17 cells quantified by flow cytometry. For TCR-ligation, purified memory (CD62L^{lo}CD44^{hi}) CD4⁺ T cells from naive mice were stimulated with anti-CD3/CD28 antibodies, and activation state (CD69) and cytokine production were measured by flow cytometry (n=4 mice/genotype x 3 experiments). Data were analyzed by two-tailed Mann-Whitney U test, and p<0.05 was considered significant. Peripheral blood mononuclear cells from Blau Syndrome patients (heterozygote NOD2 1147G->A mutation, n=2) or healthy controls (n=3) were stimulated with PMA/ionomycin.

Results: Nod2 was dispensable for conventional Th17 differentiation of naïve, mouse T cells. Rather, Nod2 functioned within memory (antigen-experienced) CD4⁺ T cells, with Nod2^{-/-} memory cells producing significantly greater amounts of IL-17, RORγt and CD69 after continued TCR-stimulation. Transcriptional analysis of early TCR-signaling events revealed a unique profile involving IL23r, Ccl25, Ccr7, and Cxcl2 regulation by Nod2 in memory cells. Importantly, continued TCR-stimulation of CD4⁺ T cells from Blau Syndrome patients recapitulated the exacerbated IL-17 phenotype. Further immunoprofiling indicated enhanced cell surface expression of CCR7 in Blau patients vs. controls, which was further increased upon TCR-ligation; whereas production of cytokines IL-2, IFNγ and TNF was impaired based on kinetics of TCR-activation.

Conclusions: Our data support Nod2 as a homeostatic factor in T cells, which suppresses responses of antigen-experienced Th17 cells and uveitis. Thus, loss of proper Nod2 function within T cells could be involved in the pathology of Blau Syndrome; thereby presenting new therapeutic options for patients.

SUBMITTER (NAME ONLY): Parisah Moghaddampour

TITLE: Acuity of Emergency Room and Inpatient Ophthalmology Consultations at a Level 1 Trauma Center

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Moghaddampour, J.A. Dunbar, L. Khazaeni, Ophthalmology, Loma Linda University Medical Center, Loma Linda, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Parisah Moghaddampour: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Dunbar: Commercial Relationship: Code N (No Commercial Relationship) | Leila Khazaeni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to investigate the acuity of all ophthalmology consults from the emergency department and inpatient ophthalmology consultations at a level 1 trauma center in Southern California.

Methods: This was a retrospective chart review of patients evaluated by the ophthalmology consultation service at Loma Linda University Medical Center from June 2016 to May 2017. Age, gender, consulting service, reason for consult, diagnosis, and recommended follow up were recorded. The level of acuity of pre-consult was defined based on the reason for the consult and was stratified to three levels: acute, chronic, and screening exams. The post-consult acuity level was updated based on the result of the consult: emergent, acute, chronic, and other. Eleven diagnosis were labeled as emergent. Ophthalmology procedures and surgeries performed within 48 hours were recorded.

Results: A total of 2043 charts were reviewed with an average of 170 new consults per month. Pre consult acuity included 69% acute consults, 4.3% chronic, and 25% screening exams. Post consult acuity included 24% emergent, 51% acute, 15% chronic, not urgent, or negative, and 10% were considered other. Of those with pre-consult acuity considered acute, 25% were updated to emergent after ophthalmologic exam with 30% requiring emergent surgery. Roughly 25% of all consults were screening exams, and of those two-thirds were negative screens or chronic diagnoses.

Conclusions: Acuity stratification of reasons for ophthalmology consultation may be useful in designing guidelines for emergency department and inpatient ophthalmologic exams. Further studies at other medical centers are needed to customize such guidelines.

ZAPATA-DIAZ: Commercial Relationship(s);Cristalens Industrie:Code E (Employment) | María de los Remedios Ortega-García: Commercial Relationship: Code N (No Commercial Relationship) | Jerónimo Lajara-Blesa: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the clinical outcomes and the complementarity of the new set of multifocal intraocular lenses (IOLs) Artis Symbiose (Cristalens Industrie, France).

Methods: Twenty patients were implanted with the Artis Symbiose Mid IOL in the dominant eye, and the Artis Symbiose Plus IOL in the contralateral eye after phacoemulsification. Inclusion criteria were: age over 50 years, cataract or refractive lens exchange patients, pupil diameter between 2 and 4 mm in photopic conditions, DEWS ≤ 2 in the scale of dry eye severity. Exclusion criteria were any pathology or condition that could affect the outcomes and the performance of the measurements and expected postoperative residual astigmatism ≤ 0.75 D. Monocular and binocular defocus curves were assessed at 1-2 months with ETDRS charts at 4 m. Distance, intermediate (90 and 70 cm), and near (40 cm) visual acuity, contrast sensitivity (CSV-1000, VectorVision, USA), light disturbances (LDA, Binary Target, Portugal), and patient satisfaction (VF-14 questionnaire) were assessed at least 6 months after surgery.

Results: Mean monocular defocus curves of both eyes met at 2.00 D of defocus. The binocular defocus curve showed a visual acuity of 0.10 logMAR or better from 0 to 3.00 D of defocus (Figure 1). Uncorrected distance, intermediate (90 cm and 70 cm), and near visual acuity were -0.03 ± 0.08 , 0.03 ± 0.13 , 0.03 ± 0.11 , and 0.06 ± 0.10 (mean \pm SD) logMAR respectively. Contrast sensitivity was within normal values for patients age. Binocular light distortion index was 9.93 ± 5.30 % and patient satisfaction 93.37 ± 7.31 %.

Conclusions: Monocular defocus curves demonstrated the complementarity of the Artis Symbiose Mid & Plus IOLs. The mean binocular defocus curve showed a depth-of-field of 3.00 D with visual acuity 0.1 logMAR or better. Uncorrected visual acuity was good at all evaluated distances. Contrast sensitivity was normal and patient satisfaction was very high.

ABSTRACT BODY:

Purpose: The Unfolded Protein Response (UPR) is a conserved regulatory mechanism of the Endoplasmic Reticulum (ER) initiated to maintain protein homeostasis. Dysregulation of the UPR is implicated in the pathology of many human diseases associated with ER stress. Inactivating genetic variants in the UPR regulator Activating Transcription Factor 6 (ATF6) cause severe congenital heritable vision loss, presented as impaired visual acuity and loss of color vision. Cone photoreceptors are dysfunctional in this disease, but the pathomechanisms involving the lack of functional ATF6 is unknown. Furthermore, there are no treatments for people carrying these mutations.

Methods: To investigate the functional role of ATF6 during photoreceptor development, we generated retinal organoids from patient iPSCs carrying ATF6 disease-causing variants and ATF6 null hESCs generated by CRISPR. Retinal organoids underwent surface-scanning live imaging to examine morphology of WT and ATF6 mutant rods and cones, and confocal immunofluorescent microscopy of sectioned retinal organoids. In parallel, adaptive optics laser-scanning confocal ophthalmoscopy (AOSLO) was performed to visualize photoreceptor morphology from the ATF6 mutant patient stem cell donors used in this study. RNAseq analysis was performed to establish rod and cone gene expression profiles of WT and ATF6 mutant retinal organoids. Rescue of cone photoreceptor cells in ATF6 mutant retinal organoids was investigated using a small molecule ATF6 agonist.

Results: Cone photoreceptor cells in ATF6 mutant retinal organoids lacked inner and outer segments concomitant with absence of cone phototransduction gene expression; while rod photoreceptors developed normally. Adaptive optics retinal imaging of patients with disease-causing variants in ATF6 also showed absence of cone inner/outer segment structures but preserved rod structures, mirroring the phenotypes observed in our retinal organoids. We

further show that the ATF6 agonist activates ATF6 to restores the transcriptional activity of ATF6 disease-causing variants and stimulates the growth of cone photoreceptors in patient retinal organoids.

Conclusions: These results reveal that ATF6 is essential for the formation of functional human cone photoreceptors, demonstrating that pharmacologic targeting of ATF6 signaling is a therapeutic strategy that needs to be further explored for blinding retinal diseases.

TITLE: Exercise promotes retinal astrocyte plasticity and protects against retinal degeneration

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Bales, M.T. Pardue, J.H. Boatright, Atlanta VA Medical Center, Decatur, Georgia, UNITED STATES|K. Bales, J.H. Boatright, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|A. Chacko, M.T. Pardue, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Katie Bales: Commercial Relationship: Code N (No Commercial Relationship) | Alicia Chacko: Commercial Relationship: Code N (No Commercial Relationship) | Machelie Pardue: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Boatright: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The neuroprotective effects of exercise in regions of the central nervous system have been well documented, although the underlying molecular mechanisms remain elusive. We previously demonstrated that exercise is also protective to the degenerating retina. Here we explore the potential role of retinal astrocytes as mediators of exercise-induced retinal neuroprotection using a light-induced retinal degeneration model (LIRD) that exhibits phenotypes found in patients with retinal degenerations.

Methods: Male adult BALB/c mice (n=48) were assigned to active(A)-dim, inactive(I)-dim, inactive (I)-LIRD and active (A)-LIRD groups. Active mice were exercised on a treadmill (1 hr/d at 10 m/min) for two weeks, then LIRD was induced with bright light exposure (4000 lux for 4 hrs). Active groups were exercised an additional week. Inactive controls were placed on static treadmills for the same duration and schedule. At week three, retinal function was assessed using electroretinography (ERG). One week after LIRD, retinal flat mounts were stained for astrocytes using GFAP and quantitatively assessed using Skeletonize analyses (ImageJ) for population density, and GFAP expression and Sholl analyses for astrocytic branching and dendritic arborization. A proximity ligase assay (PLA) was used to detect astrocyte and brain-derived neurotrophic factor (BDNF) interaction in active groups compared to inactive groups. Data were analyzed by 2-way ANOVA (mean±SEM).

Results: LIRD diminished retinal function as measured by ERG. Importantly, retinal function in A-LIRD groups were significantly preserved compared to I-LIRD groups based on a-wave (p=0.041) and b-wave (p=0.003) amplitudes. Retinal flat mounts from A-LIRD mice had more astrocytes (A-LIRD: 9.00±0.35; I-LIRD: 4.00±0.29 # of cells per image) and cellular branching (A-LIRD: 93.4±3.47; I-LIRD: 40.95±4.40[PM1] # branches per cell; p<0.0001). PLA showed increased cellular interaction between GFAP and BDNF in retinas from active groups compared to inactive groups.

Conclusions: Our results suggest that the protective effects of exercise on retinal degeneration may be due to BDNF signaling mediated by astrocytes. These studies provide important insights into the molecular mechanisms that govern exercise-induced retinal neuroprotection. This information may be useful in optimizing exercise interventions for patients with progressive retinal degenerations.

ABSTRACT BODY:

Purpose: Pathogenic T cells in the vitreous of patients are a hallmark of autoimmune uveitis. Characterizing intravitreal phenotypes and T cell receptor (TCR) sequences at the single cell level would enable downstream tests to identify the cognate antigens recognized by intravitreal T cells. Typically, too few viable T cells from vitreous biopsies are available to allow direct single cell sequencing (scSEQ) technologies to be applied. Thus, we developed a novel ex vivo rapid T cell expansion culture method on vitreous biopsies to enable scSEQ for TCR identification.

Methods: Vitreous biopsies were collected at the time of steroid-eluting implant replacement. Samples were centrifuged at 4° C to concentrate cells and reduce the volume of vitreous fluid, which inhibits T cell proliferation in culture. The pellets were transferred to tissue culture wells containing irradiated PBMC feeder cells separated from vitreous cells by a well insert that is permeable to growth factors produced by feeder cells while maintaining a physical barrier between feeder and vitreous cells. The media contained supportive T cell cytokines (IL-7, IL-15, IL-2) and the T cell stimulus anti-CD3 antibody (OKT3 clone). Although T cell stimulants were provided, the culture also supported B and NK cells during the 7-day culture period. After 7 days, total cultured vitreous cells were collected and applied to the 10X Genomics Chromium single cell capture and parallel whole genome transcriptome and TCR sequencing.

Results: We first expanded vitreous T cells from a patient with sarcoidosis-related intraocular immune infiltration. Following 7-day expansion and scSEQ analysis, we observed that 675 out of 681 cells expressed CD3. A unique TCR alpha and beta chain was detected in 547 CD3+ cells with a total of 34 clonotypes. Among the top 12 most frequent clonotypes, the number of cells sharing the same clonotype ranged from 5 to 172. These expanded cells were comprised of both CD4 and CD8+ T cells. TCR clonality analysis revealed that T cells from both subsets were clonally expanded.

Conclusions: Using a novel ex vivo rapid expansion protocol for fresh vitreous biopsies, we found that T cells can be analyzed by single cell methods. This approach allows sensitive and in-depth profiling of T cells and provides T cell subtype and clonotype information from auto-immune uveal diseases.

ABSTRACT BODY:

Purpose: Human stem cell derived in vitro models of cornea tissue can aid our understanding of the process of wound healing and may be useful for pharmacological screening, in a cost effective manner, while reducing the reliance on animal experiments. Previous reports of 3D corneal colonies demonstrate corneal features, but require a dissection step that may reduce scalability. Here, we report the generation of 3D eye organoids from human embryonic stem cells (hESCs), with cornea characteristics independent of dissection

Methods: H9 ESCs were seeded at 3000 cells/well in a 96 ultra-low bind well plate in mTeSR media with 2.5% matrigel and 2µM Thiazovivin (THIA). Differentiation into eye organoids were stimulated at day 2 by changing to differentiation media (DM): GMEM with 10% knockOut Serum Replacement, 1mM Sodium pyruvate, 1mM non-essential amino acids, 2mM L-glutamate, 1% penicillin-streptomycin solution and 55µM β-mercaptoethanol. Corneal specification was enhanced at day 32-46 by changing to DM:CnT-PR (1:1) with 10ng/mL keratinocyte growth factor (KGF) and 2µM THIA, before changing to maintenance media; DMEM:F12, 2% B-27 supplement, 10ng/ml KGF and 2µM THIA at day 48. Corneal features were characterized by immunohistochemistry (IHC).

Results: By day 20, ≈20% (N=3x96) of the organoids formed transparent blebs interpreted as pre-cornea formation. At day 28, organoids show pigmented regions (RPE or iris pigment cells). By day 48, organoids show transparent, opaque and pigmented regions, Figure 1. IHC revealed an organized outer layer consisting of tightly packed cells (epithelium) on top of a thin acellular structure reminiscent of Bowman's membrane (BM). The epithelial layer was positive for corneal markers: TP63α, PAX6, ZO-1, Keratin 15 and Keratin 12 (Figure 2). Cells found beneath the putative BM were vimentin positive and resemble keratocytes of the corneal stroma (Figure 2).

Conclusions: We report a method for culturing 3D eye organoids from hESCs exhibiting features resembling the three outer layers of the cornea; Epithelium, BM and stroma. These organoids may be useful to study wound healing and identification of therapeutic compounds.

ABSTRACT BODY:

Purpose: Subconjunctival (SC) administration of AAV vectors exhibit capsid serotype-dependent transduction in the cornea and broad transduction of ocular/peri-ocular tissues, demonstrating its suitability to treat ocular diseases. In addition to viral capsid serotype and physiological factors, administration volume affect AAV vector transduction efficiency. Herein, we explored the role of administration volume in AAV gene delivery, biodistribution, and transduction efficiency following SC injection.

Methods: The relationship between injection volume, vector transduction, and vector biodistribution was evaluated in wild type mice using multiple doses of self-complementary AAV8-CMV-GFP vectors. Sixty female C57BL/6J mice aged 6-8 weeks were randomly divided into no injection, low-volume (7 μ l containing either 5e8 vg or 5e9 vg or vehicle), and high-volume (70 μ l containing either 5e8 vg or 5e9 vg or vehicle) injection groups. Ocular clinical parameters were collected prior to and after the injections. Animals were sacrificed at 3 months following the injection and tissues were harvested for immunofluorescence staining, vector genome biodistribution and transgene expression analysis.

Results: A single SC injection of AAV8 (7 μ L), resulted in efficient transduction of the ocular muscles (Fig. 1); in contrast, a ten-fold higher injection volume of the same dose exhibited little to no detectable transduction in the ocular muscles, and trended towards higher transduction efficiency in the peripheral cornea (Fig. 2). The transduction pattern was a dose-independent phenomenon that correlated well with vector genome biodistribution.

Conclusions: Taken together, the collective data indicate that injection volume dramatically alters AAV8 tissue transduction and biodistribution in the ocular and peri-ocular compartments following SC injection. Specifically, low-volume SC injection of AAV8 vectors could be ideal for therapy of ocular muscular diseases such as oculopharyngeal muscular dystrophy; Alternatively, AAV8 vectors administered in a high volume have apparent relevance for the treatment of ocular surface diseases including limbal stem cell deficiency and/or dry eye disease. Therefore, optimization of multiple experimental factors is necessary to achieve maximal transduction efficiency and desired tissue targeting, while concurrently decreasing vector production burden and immunological concerns.

ABSTRACT BODY:

Purpose: To investigate the least variable sampling location for OCT retinal nerve fiber layer (RNFL) thickness measurements on rhesus macaque monkeys, for determining the preferred sampling location.

Methods: In vivo three-dimensional spectral-domain OCT scans (Leica, Chicago, IL) were obtained as raster scan data (400x400x1024) in a 5x5x1.6 mm region (human equivalent, not the actual size in the monkey eye) centered on the optic nerve head (ONH) of 33 healthy adult rhesus macaques (19 males, 14 females; ages 3.0-10.7 years). The ONH scans of 48 eyes were analyzed using OCT segmentation software of our own design to calculate point-by-point RNFL thickness measurements. Mean RNFL thickness was computed on consecutive concentric circles within the scan window, centered on the geometric ONH center and starting at the optic disc margin (between 64-119 circles). The least variable RNFL measurement area was identified in the vicinity of the RNFL peak within the 2 μ m deviation.

Results: The least variable RNFL was observed in between 98.88 ± 11.82 and 114.4 ± 11.32 pixels from the ONH center with the peak RNFL at 106.42 ± 11.55 pixels (Figure 1). Note that the number of available eyes in each sampling location varied as detailed in Figure 2. For comparison, the radius of the OCT scan circle conventionally used in humans is 1.7 mm, or 136 pixels, from the center of the ONH.

Conclusions: In order to obtain less variable circumpapillary RNFL thickness measurements on rhesus macaque monkey eyes, it is recommended to use a sampling circle with a radius of approximately 106 pixels from the ONH center, which is smaller than the human equivalent.

ABSTRACT BODY:

Purpose: Reducing intraocular pressure (IOP) remains the only treatment for Primary Open-Angle Glaucoma but damage can continue despite IOP reduction. Understanding the molecular mechanism underlying retinal ganglion cell (RGC) death remains elusive as a major challenge is the limited availability of human RGCs. Aim of this study is to use human stem cell differentiated RGCs (hRGCs) with a glaucoma causing mutation to investigate cellular mechanisms and identify potential therapeutic targets.

Methods: We used CRISPR engineered human pluripotent stem cell reporter lines to differentiate and immunopurify hRGCs. For glaucoma modeling, we used patient derived induced pluripotent stem cells (iPSCs) and CRISPR mutated human embryonic stem cells (hESCs) with the Optineurin-E50K (OPTN-E50K) mutation, a widely accepted cause for a subpopulation of normal tension glaucoma. We used western blot for measuring mitophagy by LC3B lipidation and qPCR for mitophagy gene expression. Mitochondrial metabolic defects were analyzed using the Seahorse analyzer and RGC viability/apoptosis was assessed by fluorescence/luminescence-based assay. Statistical comparison between two independent groups was done by student's t-test and among multiple groups by One-way Anova with Dunnett's correction.

Results: Our study shows the glaucomatous OPTN-E50K mutation causes mitophagy defects in hRGCs. OPTN belongs to the mitophagy adaptor protein group which shares LC3 interacting (LIR) domain and ubiquitin binding domain (UBD) through which the mitophagy process is initiated. E50K hRGCs showed activation of other adaptor genes such as P62 and NDP52, possibly as a response to overcome the mitophagy defects. Mitophagy defects lead to the accumulation of damaged mitochondria, causing mitochondrial metabolism defects and cellular toxicity. Indeed, we observed reduced mitochondrial activity in the E50K hRGCs when compared to wild-type (Wt) cells. Mitophagy defects should lead to cellular toxicity in E50K hRGCs in presence of mitochondrial stress. Indeed, we observed increased cell death for the E50K hRGCs in presence of the mitochondrial toxic drug CCCP.

Conclusions: Our study showed that the glaucomatous E50K mutation causes mitophagy defects leading to hRGC death and implicates mitophagy pathway proteins as possible therapeutic target for OPTN associated glaucoma.

ABSTRACT BODY:

Purpose: To determine the differences in optical coherence tomography (OCT) segmentation metrics between machine learning based assessment and an expert-reader corrected logic based algorithm in eyes with severe outer retinal diseases. A machine learning based segmentation model created from normal, diabetic retinopathy and age related macular degeneration eyes was assessed in this experiment. OCT images from severe outer retinal diseased eyes (uveitis patients with syphilitic retinitis and retinitis pigmentosa) were analyzed and compared to a manually corrected expert readers.

Methods: 21 eyes were included in this experiment (9 RP and 12 syphilitic). For this analysis, the inner limiting membrane (ILM), outer nuclear layer (ONL), ellipsoid zone (EZ), and retinal pigment epithelium (RPE) were segmented using both deep learning and a logic based algorithm (LBA) with expert reader (ER)-corrected segmentation. The intraclass correlation coefficients (ICC) for ER-corrected LBA and machine learning were calculated and compared using segmentation metrics for central subfield thickness and central subfield volume. Intraclass correlation coefficients were created (MS-Excel, RealStatistics 2020) with 95% confidence intervals.

Results: ICC scores were highest for total retinal thickness measurements including central subfield thickness (.619) and central foveal mean thickness (.826). Machine learning displayed poor correlation when compared to ER-corrected LBA for all EZ based measures including EZ/RPE central subfield thickness (ICC 0.062) and central subfield volume (ICC 0.059). Enface based measures including maps detailing zero micron thickness and less than 20 micron thickness also had poor correlations. When separating out by disease subtype, there were no differences between correlations in syphilis retinopathy nor in RP.

Conclusions: In this machine learning model created from normal, AMD and DR pathologies, there was poor correlation to expert readers when assessing EZ based metrics in eyes with severe outer retinal pathology. Though our numbers are small, specific models created from manually graded severe retinal pathology may be needed to improve performance when assessing these complicated eyes. When assessing severe EZ pathology, our results suggest that manual grading is still needed.

ABSTRACT BODY:

Purpose: RNA m⁶A methylation has been implicated in controlling the development and maintenance of neurons. However, an extensive in-depth analysis of its involvement and profile in the retina is still lacking. Here we systematically characterized m⁶A modification pattern on a genome-wide scale in mouse retina.

Methods: Global m⁶A assays determined RNA m⁶A modification levels in the retinas of newborn and 8-week-old mice. Quantitative RT-PCR analyses detected the expression levels of RNA Methyltransferase Complex genes- METTL3, METTL14, and WTAP. We performed genome-wide RNA m⁶A modification analyses of mouse retina using m⁶A RNA immunoprecipitation followed by high-throughput sequencing (MeRIP-Seq). Using bioinformatics, we analyzed genes affected by the m⁶A marks in mouse retina.

Results: Global m⁶A RNA modification levels were significantly decreased in adult mouse retina as compared to newborn mouse retina. METTL3, METTL14, and WTAP expression levels were significantly downregulated in adult mouse retina. MeRIP-Seq identified typical patterns of global m⁶A methylation exhibited at exons, introns, stop codons, 5'UTR, and 3'UTR regions. Bioinformatic analyses revealed a complex m⁶A-mRNA regulatory network in mouse retina.

Conclusions: Our genome-wide RNA m⁶A modification profile provides a comprehensive picture of epitranscriptomic regulatory mechanism in mouse retina.

TITLE: The neurite outgrowth response of cultured retina ganglion cells upon extrinsic stimulations

SESSION TITLE: Ganglion cells and beyond

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. liu, National Tsing Hua University, Hsinchu, TAIWAN|

Commercial Relationships Disclosure (Abstract): chia chun liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cells (RGCs) of postnatal mouse retinal explants can regenerate neurites by either light or electrical stimulation. However, previous studies focused on neurite outgrowth in the whole mount retina and less attention has been paid in discussing the effect on individual RGCs. In the present study, we aimed to examine the neurite outgrowth response of isolated RGCs upon different external stimulations.

Methods: The retinas from 18 to 24 mice of 2 days old were used to purify primary RGCs by immunopanning. For the electrical stimulation group, cultured RGCs were given 200 mV, 100 Hz, monophasic electrical stimulation for 100 ms and rest for 2 seconds, repeated for 30 mins, using the multielectrode array (MEA) at DIV2 (Days in vitro). The neurite outgrowth was stained with calcium AM (1:1000) for 10 minutes at 37 degrees at DIV3. For the blue light stimulation group, cultured RGCs were transfected with ChR2 proteins via AAV2, then applying 20 Hz (25-ms pulse width) blue light ($\sim 680 \text{ cd}/\text{m}^2$, 470 nm) to stimulate RGCs for 1 hour at DIV1, and observed the neurite outgrowth at DIV2 and DIV3.

Results: Despite the MEA substrate used in the present study was glass, which is not the optimal surface for neurite outgrowth of RGCs, and yet the extent of neurite outgrowth with electrical stimulation was significantly larger than the ones without electrical stimulation. Similarly, neurite outgrowth of RGCs with the presence of ChR2 upon blue light stimulation was significantly longer than the ones without the presence of ChR2 upon blue light stimulation.

Conclusions: The present study suggests that increased neural activity of RGCs upon light or electrical stimulation can significantly promote neurite outgrowth of cultured neurons at DIV2. In the future, it will be informative to analyze the RNA expression profile of RGCs after external stimulation in order to identify genes or a network of gene expression that are responsible for promoting RGC axon growth.

ABSTRACT BODY:

Purpose: We recently showed that dynasore protect ocular surface epithelial cells and their mucosal glycocalyx against oxidative stress by shifting the unfolded protein response (UPR) in the endoplasmic reticulum (ER) towards homeostasis via calcium dynamics (PMID 32791188). Dynasore is a cell-permeable small molecule inhibitor of dynamin family GTPases responsible for membrane fusion/fission events, discovered after screening a small molecule library for inhibition of DNM2 GTPase activity and endocytosis (PMID:16740485). Our goal is to identify molecular target(s) of dynasore that determine cytoprotective effect.

Methods: A cell culture model of human immortalized corneal limbal epithelial (HCLE) cells was used (PMID: 12766048). Cultures were stressed by application of t-butyl hydroperoxide (3mM) for 2 hrs while treating or not treating (control) with dynasore (Sigma). Cytoprotective effect was quantified using the WST-1 metabolic assay (Sigma). RNA was extracted with RNeasy kit (Qiagen). First strand cDNA was synthesized by reverse transcription. qPCR was performed with cDNA and specific primers using SYBR®Green. Western blot was performed with the total protein extracted using RIPA buffer.

Results: We determined in dose-response experiments (0.5-80 μ M) that dynasore protects cells with an EC50 of $6.0 \pm 0.8 \mu$ M (n=16). qPCR was performed to determine which members of the dynamin family are expressed by HCLE cells (Fig. 1). Of the 3 classic dynamins, DNM2 is dominant while DNM1 has low expression. Of the 3 ER-localized atlastins, ATL3 is dominant while ATL1 has low expression. Of the 2 mitochondria-localized mitofusins, MNF2 is dominant. By western blot, we observed ATL3 dimerization increased in stressed cells, however, this was not inhibited by dynasore.

Conclusions: We have identified, for the first time, dynamin family members expressed by ocular surface epithelia. Dimerization of ATL3, which brings two ER membranes into contact, increases in cells subjected to oxidative stress. This is consistent with UPR-mediate ER-phagy to eliminate misfolded proteins and restore metabolic homeostasis. ATL3 dimerization does not appear to be targeted by dynasore at the current condition.

ABSTRACT BODY:

Purpose: Enhanced detection of choroidal neovascularization (CNV) can lead to improved visual acuity in patients by providing targeted treatment and monitoring of disease progression. This study uses functionalized gold nanorods conjugated with targeting RGD peptides (GNR-RGD) as contrast agents in the presence of a custom-built photoacoustic microscopy (PAM) and OCT imaging system. This combination is used to optimally distinguish the margins of CNV in rabbits.

Methods: CNV models were generated in two groups of New Zealand rabbits. 3 rabbits received laser-induced RVO with 50 mg/kg Rose Bengal and laser illumination. A pulse duration of 0.5 s and a laser spot size of 75 μ m were used with a power of 150 mW for the first 20 spots and 300 mW for an additional 20 spots. 3 other rabbits received subretinal injection of 750 ng human vascular endothelial growth factor (VEGF-165) at a concentration of 100 μ L/mL in 1% bovine serum albumin mixed with 20 μ L Matrigel. The models were monitored for 28 days until CNV had developed. All then received IV injection of 0.4 mL of targeting GNR-RGD (2.5 mg/mL). The injection was synchronously monitored with PAM and OCT and further imaged using fundus photography, OCT, PAM, FA, and ICGA at 2, 8, 24, and 72h and 5-14 days post-injection to provide visualization of GNR.

Results: IV administration of GNR-RGD into rabbit CNV models yielded a signal enhancement of 27.2-fold for PAM and 171.4% for OCT. The OCT and PAM signal peaked at 48 h post-injection. The PAM images were obtained at 578 and 700 nm, which permitted improved discernment of normal vasculature from CNV. Histological analysis and TUNEL assay showed no evidence of cell damage or death.

Conclusions: These images demonstrate that GNR-RGD can effectively localize to CNV regions to provide improved contrast and molecular imaging. For this reason, contrast-enhanced PAM and OCT provide a possible method of precise detection of CNV without harming ocular structures.

ABSTRACT BODY:

Purpose: Corneal sensitivity is an important factor in several ocular and systemic conditions, however, current measurement methods for corneal touch sensitivity are rather complicated and impractical to use. In a prospective clinical study, we evaluated a novel type of rebound technology based esthesiometry (RTE).

Methods: One hundred and eight subjects with mean age of 51,5 years (SD 18,2) were included in the study. The method used was a rebound technology-based prototype instrument employing a lightweight probe driven by a magnetic field. The corneal sensitivity of the subject was assessed by establishing the minimal perceivable kinetic energy probe velocity touching the center of the cornea for about 2 milliseconds. Test subjects used trigger button to report sensation. The stimuli were implemented in linear increments, starting with 0.67 μ J and ending with 26.01 μ J of energy (on average), in 10 steps, where velocity of the probe, the impact level, was linearly scaled. Thresholding algorithm was set to increase the stimulus intensity gradually, then to assess the final threshold by bracketing up and down. The final result was defined as the lowest intensity of the probe to which participants responded successfully twice. Classic Cochet – Bonnet (C–B) esthesiometer was used for comparison.

Results: All 216 eyes were successfully measured from which 26 exceeded the measuring range of the RTE and were excluded from the results. Average measured corneal sensitivity with the RTE was at the level of 3.4 μ J (SD 5.4 μ J) and with the C–B esthesiometer, 54.7 mm (SD 8.8 mm). The correlation of both types of measurements was $r = -0.70$ at significance level $p < 0.001$. The average within-subject deviation of the positive responses around the threshold obtained with RTE was 0.98 μ J. Dividing measurements to normal versus decreased corneal sensitivity using cut-off values of 56 mm (C-B) and 1.0 μ J (RTE) resulted in agreement between the two methods in 83 % of tested eyes.

Conclusions: We propose a novel method for corneal esthesiometry using rebound technology which could represent a practical and reliable way of measuring the corneal touch sensitivity in a clinical practice.

Hysi, King's College London Department of Twin Research and Genetic Epidemiology, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): ZIHE XU: Commercial Relationship: Code N (No Commercial Relationship) | Xiaofan Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Hammond: Commercial Relationship: Code N (No Commercial Relationship) | Omar Mahroo: Commercial Relationship: Code N (No Commercial Relationship) | Pirro Hysi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Numerous myopia risk loci have been identified, but underlying mechanisms remain unclear. Retinal signalling pathways are thought to be involved in controlling refractive development. The electrical responses of retinal neuronal populations can be recorded non-invasively in vivo from human subjects as the electroretinogram (ERG). We investigated associations between myopia risk loci and ERG parameters.

Methods: Adult twins from the TwinsUK cohort underwent ERG recordings incorporating the International Society for Clinical Electrophysiology of Vision (ISCEV) protocol. Recordings were made with conductive fibre electrodes in the lower conjunctival fornix. In participants with genotypic information, we explored associations between ISCEV ERG parameters and allelic dosages of 1361 exonic variants that were previously associated with refractive error. Genetic associations were quantified using univariate linear mixed models, adjusted for age and sex and genetic relatedness between family members. Secondary analyses, adjusting for the strongest known genetic effects in adjacent genomic regions associated with myopia, were used to explore the origin of the association signals in the respective loci.

Results: Genotypic information was available for 187 participants. One candidate risk locus (rs2840795) near the gene KCNQ5, showed the most significant association ($p = 7.84 \times 10^{-5}$) with an ISCEV parameter, namely the b-wave peak time elicited in the dark-adapted response to white flashes ($3 \text{ cd m}^{-2} \text{ s}$). The association remained significant even after adjustment for two additional common known polymorphisms (SNPs) at the KCNQ5 locus. The ERG b-wave response to this stimulus arises in bipolar cells driven by both rod and cone photoreceptors.

Conclusions: The association between the locus at KCNQ5 and ERG b-wave peak time suggest the possibility that changes in patterns of KCNQ5 expression or function might affect the timing of retinal bipolar cell signals generated in response to photoreceptor light-evoked responses. Immunohistochemistry studies in primate retina have shown KCNQ5 in the retinal pigment epithelium and neural retina, including in photoreceptor inner segments, which would be consistent with this effect. It is possible that alterations in bipolar cell responses are involved in conferring susceptibility to myopia.

TITLE: Pharmacokinetics of OTX-CSI, a Cyclosporine Intracanalicular Insert, in Surgically Induced Dry Eye Beagle Dogs

SESSION TITLE: Cornea, cytokines, anti-inflammatory

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Vanslette, C.D. Blizzard, A. Driscoll, M. Cheung, M.H. Goldstein, Ocular Therapeutix Inc, Bedford, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrew Vanslette: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Charles Blizzard: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Art Driscoll: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Matthew Cheung: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Michael Goldstein: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment)

ABSTRACT BODY:

Purpose: Cyclosporine and punctal plugs are used for the treatment of dry eye disease (DED) to increase tear production and tear conservation, respectively. OTX-CSI, a cyclosporine intracanalicular insert, combines the two modalities into a single treatment, and is designed to provide sustained release cyclosporine along with punctal occlusion. The objective of this study was to investigate the pharmacokinetics of cyclosporine drug released from OTX-CSI in a dry eye model following administration in beagle dogs.

Methods: Dry eye was surgically induced in the right eye of 12 beagle dogs by removal of lacrimal glands while the left eye was untreated (healthy). Ten days after surgery, OTX-CSI was administered in the canaliculus of both eyes on Day 0. Schirmer tears test were performed in both eyes pre-surgery (baseline prior to surgery on Day -10), post-surgery (Day -3, -2 and -1) and post-insertion of OTX-CSI (Days 11, 20 and 29) to monitor tear production. Tear fluid samples were collected using 10 mm Schirmer test strips at 3 hours, 1, 7, 14 and 28 days post-insertion and analyzed for cyclosporine concentrations by liquid chromatography tandem mass spectrometry.

Results: Mean Schirmer Tear Test Score was higher in healthy eyes at all timepoints post-baseline compared to dry eyes and was sustained through Day 29 showing successful induction of dry eye model (Figure 1). Mean tear fluid cyclosporine concentrations in the dry eye group were generally higher compared to concentrations in healthy eyes at most time points (Table 1) likely due to less dilution of the cyclosporine on the ocular surface with the reduced tear fluid production of surgically induced dry eyes. OTX-CSI was well tolerated and not associated with any substantial ocular findings and had no adverse effects on general, non-ocular health.

Conclusions: OTX-CSI successfully released cyclosporine into the tear fluid of surgically induced dry eyes of beagle dogs as demonstrated by cyclosporine concentrations greater than or equal to concentrations in healthy eyes. The reduction in tear fluid production (typically seen in dry eye subjects) does not appear to inhibit transport of cyclosporine to the tear fluid in beagle dry eyes. The insert is currently being evaluated for efficacy and safety in a Phase 2, randomized, masked, vehicle-controlled, multicenter clinical trial in subjects with dry eye (NCT04362670).

TITLE: Psychophysical Absolute Threshold in Mice is Inversely Related to Stimulus Duration

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. LaMagna, Y. Umino, Y. Guo, E.C. Solessio, Ophthalmology and Visual Sciences, State University of New York Upstate Medical University, Syracuse, New York, UNITED STATES|E.C. Solessio, Neuroscience and Physiology, State University of New York Upstate Medical University, Syracuse, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sam LaMagna: Commercial Relationship: Code N (No Commercial Relationship) | Yumiko Umino: Commercial Relationship: Code N (No Commercial Relationship) | Ying Guo: Commercial Relationship: Code N (No Commercial Relationship) | Eduardo Solessio: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Stimulus duration and psychophysical threshold have an inverse linear relationship up to a critical duration, beyond which thresholds approach a constant value. While the mechanism governing this phenomenon in the amphibian visual system is understood, the mechanism setting the critical duration in mammals is unknown. An obstacle to defining this process is that the threshold-duration relationship has yet to be characterized in a genetically modifiable mammalian model organism. This study seeks to characterize the psychophysical threshold-duration relation in wild type mouse. We expected mice to exhibit a similar inverse-linear relationship as observed in humans and amphibian (Barlow 1958; Haldin et al 2009).

Methods: Absolute visual threshold was measured in 3 male C57 BL6/J mice using a modified 1-alternative forced choice task (Umino et al 2018). Dark adapted mice were trained, via operant conditioning, to visit one of two ports depending on whether a brief, dim stimulus was presented. Hit and False Alarm rates were calculated to determine a sensitivity index (d') value for each stimulus intensity to construct psychometric functions. Mice first learned the task with a bright, 2s stimulus under light adapted conditions. Mice were then slowly introduced to briefer stimuli and dimmer conditions. After achieving a stable d' value for a dim 60msec stimulus, multi-intensity trials for data collection began. Radiometric measures of stimulus intensity were converted to $R^*/\text{rod/s}$ (Lyubarsky et al 2004).

Results: Average d' values were well fit to stimulus intensity with log-linear models ($R^2 \geq 0.75$; $\alpha = 0.05$ ANOVA) at each duration (30ms-2s). At 30ms the absolute threshold, the intensity at the predicted $d' = 1$, was $0.27 R^*/\text{rod/s}$ ($SE = +/ - 0.11$). Assuming total temporal summation, this is $\sim 0.008 R^*/\text{rod}$. Each mouse exhibited an inverse linear relation between log-threshold and log-duration up to 250-500ms, below which, data is well fit with a linear equation on log-log axes, with slopes of -1.7, -2.0, and -2.9.

Conclusions: In wild type mice, absolute visual thresholds have an inverse relationship with stimulus duration. Unexpectedly, mice exhibit a supra-linear relation between stimulus duration and threshold. This study establishes a foundation to further study threshold-duration relationships in transgenic mouse lines, allowing us to dissect the neural circuits underlying temporal summation in the visual system.

TITLE: Vanishing optotype reading test in non-advanced age-related macular degeneration

SESSION TITLE: AMD: Clinical and translational research II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Welch, J.D. Rodriguez, D. Narayanan, M.B. Abelson, Ora, Inc, Andover, Massachusetts, UNITED STATES|M.B. Abelson, Ophthalmology, Harvard University, Cambridge, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Donna Welch: Commercial Relationship(s);Ora:Code E (Employment) | John Rodriguez: Commercial Relationship(s);Ora:Code E (Employment) | Divya Narayanan: Commercial Relationship(s);Ora:Code E (Employment) | Mark Abelson: Commercial Relationship(s);Ora:Code E (Employment)

ABSTRACT BODY:

Purpose:

During early stages of age-related macular degeneration (AMD), patients experience difficulty in everyday tasks including reading under low luminance (mesopic) and low contrast conditions. In this study, vanishing optotypes reading test using nine levels of contrast was used to assess visual function in AMD.

Methods:

Subjects with non-advanced AMD N=11 (grade 1 to 4 on AREDS simplified scale) and normal controls N=24 (AREDS grade 0) with best visual acuity (VA) 20/25 or better during their baseline visit were included. Vanishing optotype reading test was done using a computerized system. Testing was done for the study eye, with best correction in place and non-tested eye occluded. Passages comprising of a series of pepper words was presented on the screen. Each passage was of the same length and same font size but reduced in contrast as the test progressed. Nine different contrast levels ranging from high to low (0.29 to 0.02) were tested. A practice session was given prior to the actual test to get the subject acclimated with the test process. For each passage, reading speed and accuracy was documented. The time taken to read each passage accurately was recorded in words per minute (wpm).

Results: Both non-advanced AMD and normal subjects showed a clear trend of reduced reading performance with reduced contrast levels, although statistical significance was not reached. For example, mean (\pm SD) reading speed in normals and AMD subjects was 93.1 ± 21.3 and 89.5 ± 22.4 wpm at high contrast level (0.23), 84.4 ± 23.4 and 76.8 ± 24.0 wpm in mid contrast level (0.13) and was 10.4 ± 16.6 and 12.2 ± 12.3 wpm in low contrast level (0.02), respectively. The difference between normal and AMD groups showed a clear separation at mid and low contrast levels with AMD subjects showing reduced reading performance than normal group. Reading speed (wpm) at 0.09 contrast was 68.4 ± 26.4 in AMD and 77.8 ± 20.9 in normal group ($p=0.23$) and at 0.04 level was 18.7 ± 23.7 in AMD group and 28.4 ± 21.2 in normal group ($p=0.20$). Reading performance was similar in normals and AMD subjects for high contrast levels (0.29) (95.0 ± 19.3 wpm in normals and 95.2 ± 16.8 in AMD, $p=0.98$).

Conclusions: Reading test using vanishing optotype with varying contrast as a target shows promise to assess visual performance in AMD subjects and could be useful in clinical trials.

ABSTRACT BODY:

Purpose: Recombinant human erythropoietin is increasingly being used to treat or prevent anemia in preterm infants, but its association with retinopathy of prematurity (ROP) is complex. rHuEPO may reduce the risk of retinal hypoxia and neovascularization that anemia poses, but rHuEPO itself is known to trigger angiogenic pathways. We tested the hypothesis that rHuEPO administration would rescue retinal inflammatory and angiogenic transcriptomic pathways in a preclinical model of OIR and anemia.

Methods: Retinopathy was induced with the 50/10 oxygen-induced-retinopathy (OIR) model in Sprague Dawley rat pups. Anemia was induced by phlebotomy to a hematocrit of 18-20%, a 50% reduction from baseline hematocrit. rHuEPO was administered to 50% of the pups in the anemic and non-anemic groups from P10 to P20. Rats were euthanized at P20, RNA was isolated from whole retinal lysates, next generation sequencing was performed, and differentially expressed genes were mapped onto disease or function pathways by Ingenuity Pathway Analysis. Differentially expressed genes (DEG) were identified using absolute \log_2 fold change $\geq 1.5x$ with corrected-p value <0.05 and false discovery rate <0.05 .

Results: Anemia activated the transcriptomic pathway infection of mammalia (Z-score 1.5) and weakly activated pathways of vasculogenesis and angiogenesis (Z-score 0.6, 0.3 respectively) ($p<0.01$ for all). rHuEPO in the anemic, OIR pups resulted in no differentially expressed pathways related to vasculogenesis, angiogenesis, or inflammation. rHuEPO in the OIR pup without anemia inhibited multiple pathways involved in vascular development, e.g. cell movement, endothelial cell migration, vasculogenesis, angiogenesis, development of vasculature and inflammatory response, and activated pathways of apoptosis and infarction (Table 1).

Conclusions: At the time point of peak neovascularization, late rHuEPO administration inhibits multiple pathways important in vascular development in the non-anemic retinal transcriptome. Administering rHuEPO to the anemic rat pup rescued pathways of infection, suggesting an anti-inflammatory effect, and angiogenesis and vasculogenesis. rHuEPO may provide a protective effect against abnormal retinal vascularization in the at-risk retina.

TITLE: IGFBP-3 mediates mitochondrial homeostasis during hyperosmolar stress

SESSION TITLE: Corneal epithelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W. Stuard, D.M. Robertson, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Whitney Stuard: Commercial Relationship: Code N (No Commercial Relationship) | Danielle Robertson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose: The insulin like growth factor binding protein 3 (IGFBP-3) is a pleiotropic protein with known roles in cell growth and survival. Our prior findings suggest that IGFBP-3 may play a novel role in mitochondrial homeostasis in corneal epithelial cells (CECs). The purpose of this study was to determine expression levels of IGFBP-3 in CECs exposed to hyperosmolar stress and in a mouse dry eye model.

Methods: Methods: Telomerase-immortalized human corneal epithelial (hTCEpi) cells were cultured in serum-free keratinocyte basal media (330 mOsm, isotonic control). To induce hyperosmolar stress, cells were cultured in 450 mOsm media with or without recombinant human (rh)IGFBP-3 for 2, 6 or 24 hours. Mitochondrial respiration, morphology and polarization were assessed using Seahorse, transmission electron microscopy, MitoTracker and TMRE staining, respectively. Mitophagy was examined by live cell fluorescent imaging, immunofluorescence and western blotting. ROS levels were quantified using Amplex red. Dry eye was induced in C57BL6/N mice by injecting the extraorbital lacrimal gland with 20 milliunits of botulinum toxin. Mice were assessed for dry eye using phenol red thread and corneal staining using fluorescein at baseline, 7, 14 and 28 days. IGFBP-3 expression was quantified in both models at all time points using an IGFBP-3 sandwich ELISA.

Results: Results: Intra- and extracellular levels of IGFBP-3 were decreased in hTCEpi cells exposed to hyperosmolar stress. Intracellular levels of IGFBP-3 were also decreased in the corneal epithelium of mice with clinical signs of dry eye. hTCEpi cells in hyperosmolar culture further showed a loss in mitochondrial membrane polarization. This was associated with a shift towards a glycolytic phenotype and an increase in mitophagy. Mitochondria in cells exposed to hyperosmolar stress were small and irregular with a balloon-like morphology and loss of cristae. Cells co-treated with rhIGFBP-3 had a metabolic profile similar to control cells. There was a corresponding reduction in mitophagy. Mitochondrial morphology were elongated with intact cristae.

Conclusions: Conclusions: Taken together, these data confirm an important role for IGFBP-3 in the regulation of mitochondrial homeostasis in CECs exposed to hyperosmolar stress. Further studies are needed to determine the mechanism by which IGFBP-3 regulates these mitochondrial changes and metabolism.

ABSTRACT BODY:

Purpose: Mini-chaperones derived from α A-crystallin, with their inherent anti-aggregation and anti-apoptotic properties, have therapeutic properties. A second generation mini-chaperone peptide, having cell-penetrating and protease-resistant properties (CPPRMC), was synthesized using L- and D- amino acids. This study aimed to evaluate the therapeutic efficacy of CPPRMC and unravel the mechanism of peptide action using cell culture and *C. elegans* model systems.

Methods: The anti-oxidant and anti-apoptotic properties of the CPPRMC was evaluated in sodium iodate-treated ARPE-19 cells. The effect of peptide treatment (50 μ g every two days along with *E. coli* OP50 food source) on the wild-type (N2) worm lifespan was tested at 20°C. Tolerance to chemical-stimulated oxidative stress (50 mM Paraquat, 50 μ M Juglone, and 40 mM glucose) was evaluated using peptide-fed N2 worms (Day-5). The CPPRMC's ability to attenuate beta-amyloid aggregation-induced paralysis and survival was tested in the CL4176 strain expressing β -amyloid peptide. RNA sequencing and high-throughput untargeted metabolic profiling (polar and non-polar) were also performed to compare differentially expressed genes and metabolites across experimental conditions.

Results: The Sodium iodate-induced (1 mM) oxidative stress and cytotoxicity were suppressed entirely in CPPRMC treated (5 μ M) ARPE-19 cells. Peptide treatment increased the lifespan of N2 worms by 18%. N2 worms pretreated with 50 μ g CPPRMC for 24h at 20°C and then subjected to thermal stress at 35°C showed a 43% increase in survival as equated to vehicle control. Peptide treatment delayed AD-related paralysis and extended worm's survival (17%) after temperature up-shift in CL4176. RNA-seq analysis showed the upregulation of genes responsible for lifespan increase, and the polar and non-polar metabolic profiling revealed altered metabolites involved in the lifespan.

Conclusions: The increased worm lifespan and alleviation of A β -induced toxicity up on CPPRMC treatment are likely mediated by the activation of molecules involved in stress response pathways. Our findings signify the therapeutic prospective of CPPRMC against aging and age-concerned AD.

ABSTRACT BODY:

Purpose: Lens thickness is an important risk factor for cataract, myopia and glaucoma. Identifying genes contributing to this quantitative trait may effectively identify genetic risk factors predisposing to related complex diseases. Previously we performed genome-wide linkage analyses in 16 consanguineous pedigrees from South India and identified 3 novel genetic loci (3p22.3, 5q31.1 and 6q27) for lens thickness. The purpose of this study is to refine the candidate genes in these loci using whole genome sequencing.

Methods: 279 individuals of 23 consanguineous pedigrees from South India were measured for lens thickness using Pentacam (Oculus, Inc., Lynnwood, WA). Whole genome sequencing was performed using the Standard Coverage PCR-Free WGS platform (read length: 2 x 150bp; coverage: 30x) at the Broad Institute. Homozygosity mapping was conducted using PLINK (v1.9) and detectRUNS (v0.9.6). Gene-based association test was performed for both rare and common variants using famSKAT-RC (v1.1.0). Age and sex were included as covariates. Multiple testings were corrected using the Bonferroni method.

Results: Homozygosity mapping revealed 4, 22 and 3 candidate genes in the 3p22.3, 5q31.1 and 6q27 loci, respectively. Gene-based association test further refined the candidate genes to CLASP2 ($P = 1.43 \times 10^{-6}$) and FBXL2 ($P = 1.41 \times 10^{-6}$) in the 3p22.3 locus, CXXC5 ($P = 1.04 \times 10^{-8}$), CYSTM1 ($P = 2.93 \times 10^{-6}$), ECSCR ($P = 7.76 \times 10^{-8}$), MATR3 ($P = 4.28 \times 10^{-8}$), PAIP2 ($P = 1.15 \times 10^{-7}$), PSD2 ($P = 1.69 \times 10^{-8}$), SIL1 ($P = 8.93 \times 10^{-8}$) and UBE2D2 ($P = 4.34 \times 10^{-8}$) in the 5q31.1 locus, and PACRG ($P = 1.07 \times 10^{-6}$) in the 6q27 locus.

Conclusions: We identified 11 candidate genes for lens thickness. Among these genes, MATR3 and PAIP2 are highly expressed in the mouse lens. Mutations in SIL1 are known to cause Marinesco-Sjögren syndrome, an autosomal recessive cerebellar ataxia complicated by cataracts, developmental delay and myopathy. These findings provide new insights into the genetic etiologies of lens thickness and related diseases.

ABSTRACT BODY:

Purpose: Our goal is to understand how loss of the membrane protein Slc4a11 produces Congenital Hereditary Endothelial Dystrophy. In the current study, we ask if autophagy flux and lysosomal function are affected in Slc4a11 KO cells and determine whether mitochondrial ROS is responsible for any dysfunctions.

Methods: All experiments were conducted in 8 week old Slc4a11 WT and KO mice or in immortalized mouse WT and KO cell lines. Western Blot analyses were conducted using traditional (SDS-PAGE) or Simple Protein Wes® system. In order to quench mitochondrial ROS, cells were treated with 2mM MitoQ for 16 hours and animals were subject to i.p injections of 0.068mg on alternate days for four weeks.

Results: In Slc4a11 KO tissue, we observed an increase in autophagy substrate P62 (2.5 ± 0.5) and reduced lysosomal proteins; vATPase (0.2 ± 0.08), Cathepsin B (0.1 ± 0.02), Cathepsin D (0.1 ± 0.01), TFEB (0.1 ± 0.01) relative to WT. With MitoQ treatment, we observed a significant improvement in lysosomal protein expression and decrease in P62 levels. MitoQ treatment in Slc4a11 KO animals also showed improvement in two main disease characteristics, corneal endothelial cell density ($20 \pm 2.2\%$ improvement) and decreased corneal edema ($35 \pm 1.9\%$ reduction).

Conclusions: We show that mitochondrial ROS induced lysosomal dysfunction in Slc4a11 KO corneal endothelia. MitoQ treatment improved lysosomal function, autophagy, decreased corneal edema and improved corneal endothelial cell density.

ABSTRACT BODY:

Purpose: We evaluated the potential of super-resolution ultrasound localization microscopy (ULM) as a method to measure perfusion velocity in absolute metrics within the posterior ciliary arteries and their anastomoses.

Methods: Porcine ocular tissue from a local abattoir was dissected immediately following the sacrifice of the animal. The ophthalmic artery was further dissected and cannulated with micro-tubing attached to a microvolume syringe pump and in-line pressure transducer. A dilute microbubble (MB) ultrasound contrast agent (Vevo Micromarker) in 10% dextran and heparin was used to perfuse the whole globe. The anterior chamber was cannulated to manometrically maintain IOP at 25 mm Hg. Using a 50-MHz ultrasound transducer (Vevo2100, FUJIFILM VisualSonics) at a frame rate of 100 Hz, 3 sec of continuous image data was recorded with a mean arterial pressure of 60 mm Hg. Singular value decomposition was applied to separate tissue signal from the microbubble flow signals. A sparse recovery process was used to estimate the center position of the MB onto a high-resolution grid using knowledge of the MB point spread function and signal intensity. Multi-Hypothesis tracking in combination with Kalman filtering were used to incorporate the position and velocity information from prior frames to predict the position of each microbubble in each frame. The accuracy of the algorithm was validated using controlled velocity experiments in a 230 μ m inner diameter tubing system and by manually tracking MBs in the long posterior ciliary arteries (figure 1).

Results: Validation studies in controlled velocity tube experiments resulted in a root-mean-square error of 0.28 mm/s (controlled velocity range of 1.0 to 10.0 mm/s). The mean velocity within the long posterior ciliary artery was 4.18 mm/s using the tracking algorithm and 4.06 mm/s with manual MB tracking.

Conclusions: Super-resolution ULM provides spatial resolution beyond the acoustic diffraction limit. This technique has the potential to measure vascular perfusion in absolute metrics within regions of the globe that cannot currently be measured using conventional optical techniques.

TITLE: Long-term follow-up of chronic central serous chorioretinopathy patients after primary treatment of oral eplerenone or half-dose photodynamic therapy and crossover treatment: SPECTRA trial report No. 3

SESSION TITLE: Macular diseases excluding AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Feenstra, T.J. van Rijssen, E. van Dijk, C.J. Boon, Ophthalmology, Leids Universitair Medisch Centrum, Leiden, Zuid-Holland, NETHERLANDS|R. Diederens, R. Schlingemann, Amsterdam UMC Locatie AMC, Amsterdam, North Holland, NETHERLANDS|C. Hoyng, Radboudumc, Nijmegen, Gelderland, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Helena Feenstra: Commercial Relationship: Code N (No Commercial Relationship) | Thomas van Rijssen: Commercial Relationship: Code N (No Commercial Relationship) | Roselie Diederens: Commercial Relationship: Code N (No Commercial Relationship) | Carel Hoyng: Commercial Relationship: Code N (No Commercial Relationship) | Reinier Schlingemann: Commercial Relationship: Code N (No Commercial Relationship) | Elon van Dijk: Commercial Relationship: Code N (No Commercial Relationship) | Camiel Boon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We performed an open-label, multicenter, randomized controlled trial to compare the anatomic and functional efficacy and safety of primary treatment with either half-dose photodynamic therapy (PDT) or oral eplerenone treatment, with or without crossover treatment in patients with chronic central serous chorioretinopathy (cCSC).

Methods: After the baseline visit of the SPECTRA trial, eligible patients were randomized in a 1:1 allocation ratio. Treatments involved indocyanine green angiography (ICGA)-guided half-dose PDT versus oral eplerenone for 12 weeks. Crossover treatment was performed in patients with persistent subretinal fluid (SRF) on optical coherence tomography (OCT) scanning at the first follow-up visit. The 2 crossover groups included 38/46 patients (82.6%) of the patients who received primary oral eplerenone, and 11/50 patients (22.0%) of the patients who received primary half-dose PDT. The presence of SRF on OCT, best-corrected visual acuity (BCVA), and both retinal and foveal sensitivity on microperimetry were evaluated during a final follow-up visit at 12 months after baseline.

Results: Out of the 96 patients who were evaluated at first follow-up visit, 49 patients had persistent SRF on OCT (38 in the eplerenone group and 11 in the half-dose PDT group). Out of 90 the patients who had a final follow-up visit, 38/39 (97.4%) in the group with primary resolution after half-dose PDT, 7/7 (100%) in the group with primary resolution after eplerenone, 30/35 (85.7%) in the group who received crossover from eplerenone to half-dose PDT, and 5/9 (55.5%) in the group who received crossover from half-dose PDT to eplerenone group, had a complete resolution of SRF on OCT. There were no differences in BCVA and retinal or foveal sensitivity between the groups at final visit.

Conclusions: Half-dose PDT is the treatment of choice for achieving complete resolution of SRF in cCSC, even after previous eplerenone treatment. Twelve months after baseline visit, most patients treated with half-dose PDT (either primary or crossover treatment) still had a complete resolution of SRF. Crossover after half-dose PDT to eplerenone is less likely to result in complete SRF resolution at long-term follow-up.

ABSTRACT BODY:

Purpose: To describe the spectrum of retinal dystrophies associated with GUCY2D, and to identify potential clinical endpoints and optimal patient selection for future (gene) therapy.

Methods: This multicenter retrospective study reviewed medical records of 52 affected patients from 30 unrelated families for medical history, symptoms, best-corrected visual acuity (BCVA), ophthalmoscopy, visual field, full-field electroretinography and retinal imaging (fundus photography, spectral-domain optical coherence tomography (SD-OCT), fundus autofluorescence).

Results: Patients had autosomal dominant cone-rod dystrophy (CORD; n=39; 75%) and autosomal recessive Leber congenital amaurosis (LCA; n=13; 25%). The mean follow-up time was 11.4±11.8 years for CORD and 5.7±4.4 years for LCA. The mean age at onset was 21.5±18.7 years and 0.4±1.0 years, respectively. For CORD, the mean Snellen BCVA at first visit was 0.25±0.22 (0.60±0.65 logMAR), and on average decreased with 0.07 (1.15 logMAR) per 10 years (p<0.003). In LCA patients, Snellen BCVA ranged from no light perception to 0.10 (1.00 logMAR). In CORD patients, the integrity of the ellipsoid zone (EZ) and external limiting membrane (ELM) on SD-OCT were significantly correlated with BCVA (Spearman's r=-0.685 p=0.001 and r=-0.61 p=0.004, respectively).

Conclusions: LCA associated with GUCY2D mutations resulted in severe congenital visual impairment. GUCY2D-associated CORD showed a later onset and a relatively slow decrease of visual acuity, possibly suggesting a relatively large window of opportunity for future (gene) therapy. Severe visual impairment in the CORD group was generally reached in the 5th decade of life. The integrity of ELM and EZ may be suitable structural endpoints for future gene therapeutic studies in CORD.

Commercial Relationships Disclosure (Abstract): Laura Valdez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal pigmented epithelium (RPE) cells are located between the choroid and photoreceptors within the eye and are essential to provide nutrients from blood to rods and cones, as well retinoids of the visual cycle. Vision loss and ocular diseases are attributable to the degeneration or dysfunction of the RPE cells, leading to blindness. One of the major ocular problem from RPE dysfunction is macular degeneration. Age-related macular degeneration (AMD) can be frequently diagnosed in elderly patients. The purpose of this study is to provide important information on the molecular pathway on RPE survival to minimize rejection of RPE cell in transplantation to restore vision in AMD patients. This study poses as a cell model for iPSC-RPE in either 5.5 or 30mM glucose conditions in proinflammatory or hypoxic environments to determine if IL8 can act as possible cell protectants against different glucose concentrations in proinflammatory and hypoxic conditions.

Methods: iPSC-RPE were seeded in fetal RPE media of MEM, N1 supplement, glutamine, nonessential amino acids, taurine .25mg/mL, hydrocortisone 10ng/mL, triiodothyronine 13ng/mL, 15%FBS, 1%pen/strep, in a humidified 5%CO₂ incubator with a temperature of 37°C. In order to determine the iPSC-RPE cell proliferation/viability, cell viability prior to treatment, 12hrs after treatment and 72hrs after treatment was determined using the Trypan Blue Method. Cells were treated with LPS 10µg/mL, Cobalt Chloride 1mM/mL, IL8 12.5ng/mL or 25ng/mL, 0mM/mL, 5.5mM/mL, or 30mM/mL of glucose. Cell culture media supernatants was collected and stored in -80°C. MCP-1 and RANTES were identified using a multiplex ELISA.

Results: Wells treated with 12.5ng/mL of IL8 in 30mM of glucose went from 11,700 cells at 12hrs to 2,060,000 cells at 72hrs. In comparison, wells treated with 25ng/mL of IL8 and increased from 11,700 cells at 12hrs to 258,000 at the end of treatment at 72hrs. RANTES showed a significant increase at 72hrs whereas MCP-1 expressed significant increase at 12hrs. The results from a Two Way ANOVA calculated the interaction effect and identified RANTES expression was significant at 72hrs comparable to MCP-1 expression at 12hrs.

Conclusions: Increased viable cell number in response to IL8 treatment suggest IL8 may provide protection for iPSC-RPE and MCP-1/RANTES expression. This study was essential in understanding possible therapeutic treatment models for AMD.

ABSTRACT BODY:

Purpose: To explore preoperative features of multimodal retinal imaging that may correlate with postoperative visual outcomes following pars plana vitrectomy with epiretinal membrane peeling (PPV/MP) in pediatric patients with combined hamartoma of the retina and retinal pigment epithelium (CHRRPE) associated with epiretinal membrane (ERM) and decreased visual acuity.

Methods: A retrospective chart review was performed of pre- and post-operative visual acuity, fundus photographs, fluorescein angiograms, and spectral-domain optical coherence tomography (OCT) images among children with CHRRPE (diagnosed by a pediatric retinal surgeon at the Duke Eye Center between 2010 and 2020) with associated ERM who underwent a single PPV/MP, with at least 3 months of postoperative follow-up.

Results: Among 8 included patients, mean age at time of surgery was 7.69 years (range, 3 months to 13 years). 5 children were male. 5 lesions were peripapillary with or without macular involvement, 2 were localized to the macula, and one was peripheral with associated macular dragging. After a mean 26.38 months of postoperative follow-up, 3 patients had improved vision, 3 lost up to 2 lines of vision, 1 had stable fix and follow vision, and 1 had no wince to light (and questionable wince to light preoperatively). Among 6 patients with Heidelberg Spectralis OCT scans, mean preoperative central foveal thickness (CFT) was $725 \pm 279 \mu\text{m}$, with a mean decrease in CFT of $161 \pm 151 \mu\text{m}$ at last follow-up. For 2 patients, OCT scans were available but not retinal thickness measurements. Patients with the greatest improvement in vision postoperatively had preoperative CFT $< 700 \mu\text{m}$, absence of fovea-involving leakage on fluorescein angiography, and intact outer retinal layers on OCT. Patients with decreased or minimally improved vision postoperatively had fovea-involving leakage on fluorescein angiography and irregular or disrupted subfoveal outer retinal layers.

Conclusions: A combination of fluorescein angiography and OCT structural features may identify children who will have the greatest visual acuity gains after PPV/MP for CHRRPE associated with ERM.

ABSTRACT BODY:

Purpose: Accurately segmenting OCT images requires both a high-resolution understanding of the specific boundary between medically significant regions, as well as an understanding of the broader context of the imaging boundary. Our group has developed an approach which uses a combination of low-magnification (low-mag) convolutional models to detect regions of interest where the specific retinal boundary is likely to be located, as well as high-magnification (high-mag) models which create high-resolution annotations within those regions of interest. The goal of this project was to measure segmentation performance improvements resulting from multi-scale approaches in images that require both large-scale contextual information and precision.

Methods: A total of 111,000 annotated OCT images were used in training and testing. For this analysis, a single retinal layer, the internal limiting membrane (ILM), was utilized for evaluation purposes. Three training methodologies were tested. One method processed OCT images using a high-resolution patch system and divided images into 128x128 patches. A second method utilized a low-mag model where training images were compressed into 128x128 patches. A third high-mag model was trained leveraging the low-mag model to center a 128x128 patch around where the low-mag model indicated the location of the retinal boundary of interest. The performance of these models was compared by measuring the average pixel distance away from manual ground truth.

Results: The patch-diced model had an average offset of 12 pixels (stdev 15 pixels) which demonstrated high resolution but poor regional context. The low-mag model had an average offset of 4.9 pixels (stdev 0.92 pixels), and the highmag-lowmag combination had an average offset of 2.6 pixels (stdev 0.93 pixels). The differences between each of the populations average distance from ground truth were statistically significant (p values less than 0.025).

Conclusions: These results demonstrate the potential for enhanced retinal layer segmentation performance through a multi-model approach using both low and high-mag system. The combined model approach provides assessment of both regional contextual information and subsequent high-resolution modeling for improved segmentation precision.

ABSTRACT BODY:

Purpose: Retinal venous loops (RVLs) are rare findings in diabetic retinopathy (DR). Bek reported 7.7% prevalence of RVLs in patients with proliferative DR (PDR) using color fundus photography (CFP). However, previously reported prevalence of RVLs may be underestimated due to limited detection of vascular abnormalities on CFP. This study aimed to determine RVL prevalence, distribution and associated microvascular changes using WF SS-OCTA.

Methods: Retrospective, observational study including diabetic patients with proliferative DR (PDR), non-proliferative DR (NPDR) and no DR. All patients were imaged with WF SS-OCTA using Angio 6×6mm and Montage 15×15mm scan protocols centered on the fovea. Images were independently evaluated by two graders for the presence of RVLs and other DR lesions including nonperfusion areas (NPAs) and neovascularization (NV). RVLs were classified as type I or type II according to the branching level of the feeder vessel. Type I RVLs emerge from larger veins encompassing the first and second branching level from the central retinal vein; type II RVLs emerge from the third or higher branching level. A binary logistic regression model (outcome: presence of RVLs) was used for statistical analyses.

Results: One hundred and ninety-five eyes of 132 diabetic patients (n = 31 without DR; 57 NPDR and 107 PDR) were included. Among them, 22 eyes (11%) had RVLs on WF SS-OCTA. The prevalence of RVLs was higher in PDR eyes compared to NPDR eyes (18% vs. 5%, p<0.05, Chi-square test). Type II RVLs were more prevalent than type I RVLs (p<0.001, Chi-square test). In terms of distribution, RVLs were more likely to originate from superior (vs. inferior) and temporal (vs. nasal) veins (p<0.05, Chi-square test). More advanced severity of DR (OR = 4.495, 95% CI: 1.177-17.161, p = 0.028) and younger age (OR = 0.961, 95% CI: 0.926-0.998, p = 0.037) were associated with the presence of RVLs. NPAs and NV area/number were not significantly correlated with the presence of RVLs.

Conclusions: WF SS-OCTA is useful for the identification of RVLs in patients with DR. Severity of DR, but not ischemia-related imaging biomarkers, was associated with the presence of RVLs in our cohort. Further longitudinal studies may be needed to identify the role of RVLs in DR progression and retinal ischemia.

ABSTRACT BODY:

Purpose: Despite success with retinal gene therapy using adeno-associated viruses (AAVs), many disease-causing genes, like ABCA4 or USH2A, are too large for packaging into a single AAV. One option for delivery of large retinal genes is helper-dependent adenoviruses (HDAd5). However, we recently showed that HDAd5 primarily targets Müller cells, not photoreceptors and elicits an inflammatory response. The purpose of this project is to evaluate the tropism and photoreceptor transduction efficiency of two chimeric HDAd5s.

Methods: Chimeric HDAd5s carrying eGFP under the control of the cytomegalovirus promoter (CMVp) were purchased from Creative Biolabs: HDAd5 constructed with the adenovirus 5 (Ad5) backbone and either an Ad3 or Ad35 fiber [HDAd5/3-CMVp-eGFP (HDAd5/3) and HDAd5/35-CMVp-eGFP (HDAd5/35)]. For testing in vitro, hTERT-immortalized human induced pluripotent stem cell (iPSC)-derived retinal progenitor cells were transduced with 10 μ L of HDAd5, HDAd5/3 or HDAd5/35 (1×10^6 vg/ μ L per well) and assessed via fluorescent microscopy at 72-hours post-transduction. For in vivo analysis, we utilized Sprague Dawley and RNU^{+/-} rat lines and subretinally injected 10 μ L of HDAd5/3 or HDAd5/35 viral particles (1×10^6 vg/ μ L per eye) or sterile buffer and assessed injected eyes at 3- and 7-days post-injection via immunohistochemistry and confocal microscopy.

Results: EGFP-positive retinal progenitor cells were observed at 72-hours post-transduction in wells treated with HDAd5, HDAd5/3 or HDAd5/35. There were noticeably more eGFP-positive cells in HDAd5/3- and HDAd5/35-treated cultures compared to HDAd5-treated wells. Fundus photography demonstrated that both HDAd5/3 and HDAd5/35 produced a speckled eGFP expression pattern, suggestive of photoreceptor cell transduction at 3- and 7-days post-injection in each Sprague Dawley and RNU^{+/-} rats. Confocal microscopy showed prominent eGFP expression within the retinal pigmented epithelium and neural retina.

Conclusions: Compared to HDAd5, chimeric HDAd5/3 and HDAd5/35 produced more eGFP-positive cells when delivered to human iPSC-derived retinal progenitor cells. Subretinal injection of HDAd5/3 and HDAd5/35 also produced eGFP expression in the retinal pigmented epithelium and neural retina of Sprague Dawley and RNU^{+/-} rats. Future studies will further characterize the tropism and transduction efficiency of chimeric HDAd-mediated gene transfer in the neural retina.

ABSTRACT BODY:

Purpose: The impact over visual tasks of a simulated central scotoma in healthy subjects overcomes interfering complications associated with retinal diseases or aging. Patients with age-related macular degeneration (AMD), do not benefit from a head-unrestrained viewing in a smooth pursuit task. The current study investigates the role of a head-unrestrained setting over a simulated and enhanced scotoma applied to healthy participants in a smooth-pursuit task to look for similar head-movement strategies.

Methods: Participants were asked to pursue a moving target with unrestricted head movement while playing a 2D Pong game in VR. The moving target consisted of a 3° ball moving with an average velocity of 21.74°/s (SD: ±0.63) from one side to the other of the screen following a randomised triangular trajectory. The subjects controlled both paddles to keep the moving ball inside the playing area. Five participants were tested in 3 conditions: normal, scotoma, and augmented scotoma simulation. In the 2nd condition, eye-tracking was used to simulate a 12° circular scotoma occluding the central visual field (VF). In the 3rd condition, a 2° circular augmentation, with a diameter of 27° was implemented around the simulated scotoma. Figure 1 shows an example of a target trajectory in the 3rd condition. Each condition was tested for 15 minutes within 5 min blocks. Head velocity was calculated as the head position vector's velocity changes across subsequent frames. Velocity was averaged across each condition for each subject. A Kruskal–Wallis test investigated the effect of condition type over median head velocity.

Results: Individuals with no simulation, simulated and augmented simulated scotoma have similar head velocities with no effect across the three conditions over the head movement strategy, $\chi^2(2) = 0.38$, $p = .83$.

Conclusions: As previous studies using patients showed, head velocity was not affected in head-unrestrained VR gaming smooth pursuit task in normal, scotoma simulated, and augmented simulated scotoma conditions. The congruence of the results with the literature indicates that these new VR simulations can be further utilised to investigate oculomotor control under common eye disorders for future patient use.

ABSTRACT BODY:

Purpose: To identify risk factors for endophthalmitis and poor visual outcomes in cases of retained intraocular foreign body (IOFB) and management strategies for these cases.

Methods: A retrospective chart review was conducted in 88 eyes of 88 patients suffering traumatic injury with retained IOFB at the University of Michigan between January 2000 and December 2019. Medical records were reviewed to identify the nature of the injury, IOFB composition, and presenting characteristics of each eye as well as the surgical and antimicrobial strategies employed. Details of the injury, IOFBs, and clinical presentation were utilized to identify factors associated with clinical outcomes. Visual outcomes and development of endophthalmitis were additionally evaluated for association with treatment modalities.

Results: This cohort developed endophthalmitis at a rate of 11.4% (4.5% presented with endophthalmitis, 7.1% of the remaining eyes developed endophthalmitis after initial intervention). Delayed presentation and organic IOFB were significantly associated with development of endophthalmitis. Retinal detachment, wound length greater than 5 mm, and poor presenting visual acuity were associated with poor final visual outcome. Antibiotic prophylaxis was given to all patients, though agents and routes of delivery varied. Primary and deferred removal of posterior segment IOFBs were associated with similar rates of endophthalmitis.

Conclusions: Poor presenting visual acuity and severity of injury as measured by large wound and retinal detachment correlate with poor visual outcome. Prompt globe closure and antimicrobial prophylaxis is critical for infection prevention. Deferred IOFB removal may carry similar risk of endophthalmitis as primary removal.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a degenerative disorder of the macula, the region of central retina responsible for the greatest visual acuity. Oxidative stress and aging of retinal pigment epithelial (RPE) cells are the major reason of AMD. 4-Hydroxynonenal (4-HNE) is a major product of lipid peroxidation which takes part in ferroptosis of cells. Also, 4-HNE is accumulated in aging cells and could be related to several age-related diseases. The mechanism of RPE cell death under oxidative stress is still controversial. The goal of the current study is to determine RPE cell death mechanisms using 4-HNE and RSL3 treatment models.

Methods: ARPE-19 or human primary RPE cells were treated with 4-HNE or RSL3, and cell viability was tested 24 hours later. The effect of apoptosis, necroptosis, pyroptosis and ferroptosis pathways on cell survival was tested using specific inhibitors. Cellular ATP and ROS levels were measured. Cell morphology was observed under a light microscopy, PYCARD and RIPK3 expression was used to visualize inflammasomes and necrosomes that are involved in pyroptosis and necroptosis, respectively. Lipid ROS, a ferroptosis marker, was tested using BODIPY reagent.

Results: 1. 4-HNE induces RPE cell death in a concentration-dependent manner which can be rescued by ferroptosis inhibitors (Lip-1 and Fer-1) and both upstream and downstream necroptosis inhibitors (RIPK1 inhibitor Nec-1 and MLKL inhibitor NSA respectively), but not apoptosis or pyroptosis inhibitors; 2. Ferroptosis inducer RSL3 induces RPE cell death in a concentration-dependent manner which can be rescued by Lip-1, Fer-1, and Nec-1, but not NSA; 3. Both 4-HNE and RSL3 induce RIPK3 activation in RPE cells which can be inhibited by Lip-1, Fer-1, and Nec-1; 4. Both 4-HNE and RSL3 induce lipid ROS accumulation in RPE cells which can be inhibited by Lip-1, Fer-1, and Nec-1 but not NSA.

Conclusions: Both RSL3 and 4-HNE can induce RPE ferroptosis. Ferroptosis is associated with RIPK3 activation, therefore representing one type of necroptosis. However, 4-HNE but not RSL3-induced RPE death can be inhibited by MLKL inhibitor NSA. RIPK1 inhibitor Nec-1 is likely a better inhibitor for RPE ferroptosis compared to MLKL inhibitor NSA, possibly because RIPK1/3 activation can induce other types of cell death when MLKL is inhibited.

ABSTRACT BODY:

Purpose: Lamina cribrosa (LC) deformation is hypothesized to be a major cause of glaucoma. The LC undergoes different forms of stress both anteriorly from intraocular pressure (IOP), as well as posteriorly and circumferentially from subarachnoid cerebrospinal fluid pressure (CSFP) and the sclera. The purpose of this study was to determine possible in vivo changes in the path of the lamina pores under different IOP settings while maintaining fixed CSFP.

Methods: Spectral-domain OCT scans (Leica, Chicago, IL) of the optic nerve head (ONH) were acquired in vivo under different pressure settings from healthy rhesus monkeys. IOP was controlled using a gravity-based perfusion system through a needle inserted into the anterior chamber. CSFP was maintained at the baseline opening pressure via gravity-based perfusion system through cannulation of the brain's lateral ventricle (range 8-12mmHg). Scans were acquired at baseline IOP (15mmHg), high (30 mmHg) and very high IOP (40-50 mmHg) and registered in 3D. Pores from shared regions were automatically segmented using a previously described segmentation algorithm. The path of each pore was tracked based on the calculated geometric centroid of each pore. The tortuosity of each pore path was defined as the total actual distance of the centroid path divided by the minimal distance between the first (most anterior) and last (most posterior) pore centroids.

Results: 7 eyes from 6 healthy adult Rhesus macaque were analyzed. The mean value of the pore path tortuosity varies between eyes at baseline IOP levels (range: 1.16-1.68; Table). Two main overall patterns of pore path tortuosity were detected in response to increased IOP at fixed CSFP: 4 eyes became more tortuous (M2, M5, M8, M11); in the rest of the eyes (M6 OD, M6 OS, M10) the pore paths remained either unchanged or showed a variable response. No statistically significant change ($p > 0.05$) was observed in this small sample in either the subject-specific analysis or the analysis of the pooled combined values of the pore path tortuosity.

Conclusions: Baseline pore tortuosity as well as the response of the pores to acute IOP increase varies between eyes. Further investigation is warranted to determine if these differences are associated with glaucoma susceptibility.

ABSTRACT BODY:

Purpose: Blinding retinopathy in sickle cell disease is usually associated with vitreous hemorrhage or tractional retinal detachment, which are preceded by neovascularization (NVE) of the retina. There is currently no widely accepted framework for predicting progression to proliferative sickle retinopathy (PSR). We evaluated serial fluorescein angiograms (FA) to identify variables associated with PSR in this descriptive retrospective qualitative study.

Methods: Serial FA's of 7 patients with sickle cell disease (4/7 SC, 1/7 SS, 1/7 SB, 1/7 S-O Arab) with progression of retinopathy to PSR were reviewed. All patients were seen at Montefiore Medical Center in Bronx, New York. Progression was defined as new NVE or increase in size or fluorescence of persistent NVE. FA were reviewed by 3 medical students trained by 2 retina specialists. Agreement on variables was obtained at time of grading. Variables included distance of retina visualized, capillary dropout (CD), arteriovenous loops at vascular border (AV Loop), arborization with and without staining, and CD posterior to vascular border (CDPB). Variables were evaluated by clock hour ± 0.5 centered on the temporal ON. Clock hours without visible border due to hemorrhage, blurred image, or lack of image were excluded from analysis. Distance of variables from temporal ON was calculated with unit of distance, X, equal to the distance between temporal optic disc and fovea. Student's T-test and chi-square test of independence were used to analyze the data.

Results: 288 total clock hours were analyzed, 163 contained visualizable border, and 18 contained NVE. CDPB and arborization with and without staining were significantly more common in clock hours with NVE. There was also significantly less distance captured in the images of clock hours with NVE. CD and AV loops trended towards being more common in clock hours with NVE.

Conclusions: It is important to perform routine serial FA's in patients with sickle cell disease to better evaluate the risk of developing NVE. Patients who have FA's with CDPB and/or arborization should be followed more closely as these characteristics may indicate a higher chance of developing proliferative disease.

ABSTRACT BODY:

Purpose: KIF21A and TUBB3 are two common pathogenic genes identified by congenital fibrosis of extraocular muscles (CFEOM) which is an inherited nonprogressive neuromyopathy. This study aims to explore the phenotype-genotype correlations in Chinese CFEOM patients with KIF21A and TUBB3 mutations, and to discover further understanding of gene functional.

Methods: Thirty-nine subjects from familial or sporadic CFEOM cases with clinical examinations, MRI findings and positive genetic test results were enrolled for retrospective case series study. MRI was used to evaluate orbital, encephalic, and intracranial nerve integrity. Ocular motor nerves diameters and extraocular muscle (EOM) volumes were measured.

Results: Genetic testing indicated that 53.8% patients harbored KIF21A mutations (p.R954W, p.R954Q, p.F355S), 30.8% with TUBB3 mutations (p.R262C, p.R262H, p.R380C, p.E410K, p.S78T), and 15.4% with others. All familial patients were detected with pathogenic mutations in KIF21A (68.4%) or TUBB3 (31.6%). Among subjects with KIF21A and TUBB3 mutations, all subjects showed typical ocular manifestation; two subjects (9.5%) with KIF21A mutations and 4 subjects (33.3%) with TUBB3 mutations showed other systemic malformations (e.g., congenital finger contractures, funnel chest etc.). MRI revealed hypoplasia of oculomotor nerve (CN3) and the atrophy of corresponding extraocular muscles. Mean±SD CN3 diameter in TUBB3 group was 1.03±0.45 mm, slightly but not significantly smaller than the diameter in KIF21A group, which measured 1.11±0.39 mm. Fifteen subjects (71.4%) with KIF21A mutations had unilateral or bilateral abducens nerve (CN6) absence and one subject (6.3%) with TUBB3 mutations had bilateral absence. Meanwhile, SR, IR and LR volumes in subjects with KIF21A were significantly smaller than those in TUBB3 group ($p < 0.001$). Besides, the phenotypes of TUBB3 mutations were notably differ from each other. Five patients (66.7%) in TUBB3 had intellectual disabilities with dysplasia of the midline commissural structures (anterior commissure, corpus callosum etc.).

Conclusions: KIF21A and TUBB3 are hotspot mutation genes and KIF21A is the main pathogenic gene in Chinese CFEOM. CN3 and its innervated extraocular muscles are most often affected. TUBB3 group had more systemic malformations and brain developmental defects. Moreover, TUBB3 group had a better correspondence between genotype and phenotype.

ABSTRACT BODY:

Purpose: Mechanisms of axonal insult within the ONH in glaucoma are not fully understood. This study aimed to delineate ONH molecular alterations in chronic stages of glaucoma, in an inherited feline model with ONH structure comparable to humans.

Methods: ONH tissues from 10 LTBP2^{mut/mut} cats with glaucoma and 5 wt control cats (age 1-3 yrs) were used to generate cDNA libraries for RNAseq. Weekly intraocular pressure (IOP) data and optic nerve axon counts were available for all subjects. Differentially expressed genes (DEGs) were identified using DESeq2 (false discovery rate < 0.05), and g:Profiler was used for functional enrichment analysis. DEGs in chronic glaucoma were compared to DEGs in an RNA-seq dataset generated by our lab from ONH tissues of LTBP2^{mut/mut} cats prior to axon degeneration. Transcriptomic findings were validated by RNAscope in situ hybridization (ISH) and by immunolabeling (IF) of archived ONH tissue sections. For confirmatory studies, data were compared between groups by two-tailed unpaired t-test or ANOVA (p < 0.05 considered significant).

Results: Mean and cumulative IOP over 10mths prior to tissue collection were consistently higher in LTBP2^{mut/mut} than in wt cats. Stratifying subjects by optic nerve damage based on histological evaluation (mild [MLD], moderate [MOD] and severe [SEV] damage), 77, 882 and 1878 DEGs were identified, respectively, in glaucoma relative to age-matched controls. Functional analysis of DEGs in chronic, established glaucoma (MOD and SEV groups) identified upregulated DEGs ascribed to cell adhesion, immune/inflammatory responses, and MAPK cascade, and downregulated DEGs associated with metabolism, fatty acid synthesis, actin cytoskeleton and myelination. Comparing these DEGs in established chronic glaucoma to those in pre-degenerative, early-stage disease, 111 DEGs were shared between stages, including significant upregulation of HP and TNC. ISH confirmed expression of HP and TNC in the ONH, but with sub-regional differences in expression. TNC was highly expressed in the prelaminar - laminar regions and HP in the laminar and retrolaminar regions. ISH and IF identified astrocytes as the predominant ONH cell-type expressing these gene products.

Conclusions: Early and chronic stages of glaucoma share a reactive astrocyte molecular signature. Gene expression changes are more complex and enhanced in chronic glaucoma.

ABSTRACT BODY:

Purpose: Endothelial keratoplasty has become the gold standard for treating corneal endothelial dysfunction, but little is known yet about the long-term outcomes. Therefore, this study was designed to evaluate 15-year outcomes of Descemet stripping endothelial keratoplasty (DSEK).

Methods: This retrospective, observational study assessed postoperative outcomes through 15 years in an initial consecutive series of 360 DSEK cases performed between December 2003 and December 2005 at a single center. The main outcomes were graft survival and immunologic rejection rates determined by Kaplan-Meier and proportional hazards analysis, central corneal thickness (CCT) measured with ultrasonic pachymetry, and best spectacle-corrected visual acuity (BSCVA) assessed with a Snellen chart.

Results: The transplant indications were Fuchs dystrophy (n=301, 84%), bullous keratopathy (n=34, 9%), and previous keratoplasty failure (n=25, 7%), and the mean age at the time of DSEK was 69 ± 12 years. At 15 years, 50 grafts were replaced or failed (14%), 136 (38%) were in patients known to have died, and 55 of the remaining 174 grafts (32%) were examined. The 15-year graft failure/replacement rate was 22%, taking loss to follow up into consideration. Fifteen grafts were replaced within the first year because of early failure to clear (n=9) or unsatisfactory vision associated with excessive graft thickness or wrinkles (n=6), and 35 experienced late endothelial failure (11 after clinically evident immunologic rejection and 24 without evidence of rejection). Glaucoma filtration surgery (present in 34 eyes, 9%) was associated with a 4-fold increased risk of graft failure (p<0.0001). The median CCT remained stable at 650 to 660 microns from 6 months to 15 years. The median BCVA among all examined eyes was 20/40 from 3 to 12 months and 20/30 from 2 to 15 years.

Conclusions: DSEK provided superior long-term visual rehabilitation and had a 15-year survival rate comparable to that of the previous standard, penetrating keratoplasty, when performed for similar indications. The DSEK failures that occurred within the first year were mostly associated with the learning curve at a time when techniques and instrumentation were still being developed and refined.

ABSTRACT BODY:

Purpose: SUN (Standard Uveitis Nomenclature) scoring is subjective, hence its use to characterize the severity of inflammation in mild-to-moderate uveitis is clinically challenging. By leveraging objective measurements of the intensity of light scatter (ILS; as a measure of aqueous flare), we intend to achieve a robust prediction of the severity of inflammation by machine learning (ML) for enhanced clinical management of uveitis through consistent grading and granular indexing of the inflammation.

Methods: Patients diagnosed with uveitis were graded by SUN scores, and their ILS were recorded using a laser flaremeter (Kowa FM700). Normal subjects with no pathology served as controls. Ensemble method classifiers were used to predict the severity of inflammation based on ILS and first-order patient characteristics, which included the type of uveitis, status of iris/lens/pupil/cornea, and comorbidities such as diabetes.

Results: Fig. 1 is the summary of ILS in uveitis patients and normals. Regression showed a weak correlation between ILS and the SUN grade ($p < 0.0001$, $r^2 = 0.41$ on \log_2 of ILS). To train supervised ML classifiers, SUN scoring by one expert clinician was treated as the ground truth. Since our challenge is to distinguish mild-to-moderate uveitis, we focused only on data of patients with SUN scores of 0 and 1+. The dataset was imbalanced as the # of eyes w/SUN grade of 1+ was smaller compared to the # of eyes w/grade 0. Therefore, we explored data balancing approaches. The approach of the balanced bagging classifier, which incorporates under-sampling of the data, produced an F1 score of 0.92 with an accuracy of 90%. Another approach relied on SMOTE for data oversampling. The resulting balanced dataset was used to train the Random Forrest classifier, resulting in an F1 score of 0.88, with an accuracy of 83%. The classifier also identified the mean and SD of ILS as the top features of importance, thereby validating the significance of ILS measurements for grading the severity.

Conclusions: The aqueous flare is reliable for objective quantification of the intraocular inflammation. Our analysis has shown that ILS and its SD can reliably train ML models to grade uveitis on par with expert clinicians. Further optimization of the ML models and additional data on patients with Grade 1+ can be expected to enhance the performance of the ensemble methods.

ABSTRACT BODY:

Purpose: Elevated TGF β 2 in the aqueous humor is one of the most studied biomarkers of glaucoma. TGF β 2 induces excessive extracellular matrix proteins as well as the formation of cross-linked actin networks (CLANs) in trabecular meshwork (TM) cells. CLANs are complex web-like structures. Our previous studies identified four actin-associated proteins including caldesmon, calponin, tropomyosin and myosin light chain which are enriched in CLANs. In this study, we determined if these proteins promote CLAN formation in the TM.

Methods: Lentiviral vectors were constructed to express fusion proteins of caldesmon/calponin/ myosin light chain/tropomyosin+GFP. Primary human TM (HTM) cells were cultured close to confluency and transduced with different lentiviral vectors or a control vector (GFP only) at an MOI of 1:125 in triplicates (N=3) in 24-well plates. The cells were cultured up to 2 months. Some HTM cells were treated with 5ng/ml TGF β 2 as a positive control. At the end of the study, the cells were fixed and stained with phalloidin-Alexa-568 and DAPI for actin filaments and nuclei, respectively. To quantitate the number of CLAN-positive cells, ten fluorescent images per well were captured. The total number of fluorescent positive cells per image was counted and the percentage of CLAN-positive cells over total cell numbers per image (PCPC) per well was determined. PCPCs were compared using one-way ANOVA and post-hoc tests.

Results: The baseline level of PCPC in the GFP overexpression group was 4.3% \pm 0.2%. In comparison, there was a 7-fold increase in PCPC (38.0% \pm 2.0%; P<0.001) in TGF β 2 treated cells. There was about 2-fold increase of PCPC in the myosin light chain group (7.3% \pm 1.5%; P>0.05) and tropomyosin group (8.5% \pm 3.8%, P>>0.05), about 4-fold increase in the caldesmon group (19.3% \pm 2.5%; P<0.05), and about 6-fold increase in calponin (26.0% \pm 4.0%; P<0.01). The greatest increase was observed in the cells overexpressing all four proteins with about 11-fold increase in PCPC (51.0% \pm 14.2%; P<0.001), and this increase was higher than that in TGF β 2-treated cells (P<0.01).

Conclusions: Caldesmon, calponin, tropomyosin and myosin light chain work individually or synergistically to promote CLAN formation in primary HTM cells.

ABSTRACT BODY:

Purpose: The retinal microvasculature is remodeled in hypertension and in diabetes but little is known about the actual remodeling that occurs in human in vivo small arterioles ($<50\text{ }\mu\text{m}$) due to limitations in imaging techniques. High-resolution retinal imaging allows us to visualize and measure the fine structure of small retinal arterioles non-invasively. We used adaptive optics scanning laser ophthalmoscopy (AOSLO) to investigate the differences in arteriolar remodeling in retinal arterioles with diameters under $50\text{ }\mu\text{m}$ in diabetes and hypertension.

Methods: The posterior pole of 52 participants was imaged with the Indiana AOSLO sampled at $1\text{ }\mu\text{m/pixel}$ or less with a video rate of 28 frames/s. After the imaging session, MATLAB (Mathworks Inc., Natick, Ma) was used to correct for eye movements to create averaged images. Custom MATLAB software was used to measure the vessel wall structure of arteriole segments less than $50\text{ }\mu\text{m}$ in diameter from the imaging sessions. 72 arteriole segments from control participants, 156 arteriole segments from participants with diabetes, and 41 arteriole segments from participants with hypertension were measured. The differences the wall thicknesses, wall-to-lumen ratios (WLR), wall-cross sectional area (WCSA), and the retinal arteriole index (a ratio of the actual to predicted lumen diameter based on the outer diameter to actual inner diameter from control data) were analyzed in SPSS (IBM SPSS Statistics for Windows, Chicago, IL) using Welch's ANOVA and the Games-Howell post hoc test.

Results: A statistically significant difference was present for the arteriole index, wall-to-lumen ratio, and wall thickness between the control group and the group with diabetes ($p<.001$) and between the control group and hypertension group ($p<.001$). There was no difference between any groups for the wall cross-sectional area. For all parameters there was no difference between the groups with hypertension and diabetes

Conclusions: Our results suggest that despite the loss of myogenic control in diabetes, there is similar vascular remodeling occurring in the two diseases in small retinal arterioles. Most of our sample of participants with diabetes were also hypertensive suggesting that hypertension is driving the remodeling observed. In addition, the similarity of WCSA between all three groups suggest that the remodeling occurring in the vessels maintains wall volume, which is consistent with eutrophic remodeling.

TITLE: Nonsense suppression therapy in an animal model of Usher 1D syndrome

SESSION TITLE: Retinal Degenerations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Nizamudheen, K. Gregory-Evans, C.Y. Gregory-Evans, Ophthalmology, The University of British Columbia, Vancouver, British Columbia, CANADA|A. Yanai, The University of British Columbia, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure (Abstract): Vahitha Shameem Nizamudheen: Commercial Relationship: Code N (No Commercial Relationship) | Anat Yanai: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Gregory-Evans: Commercial Relationship: Code N (No Commercial Relationship) | Cheryl Gregory-Evans: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Usher syndrome 1D (USH1D) is an autosomal recessive condition characterized by severe deafness, vestibular dysfunction and progressive vision loss. Cadherin 23(CDH23) is a structural protein present in stereo cilia of mechanosensory hair cells of the cochlea. In photoreceptors CDH23 is thought to mediate membrane–membrane adhesion between the inner segment membranes of neighboring photoreceptor cells and at synapses, to keep the synaptic cleft in close proximity. We have obtained a mouse model Y2209X line (Cdh23) which has a nonsense mutation in Cdh23. Homozygous Cdh23 mice exhibited head shaking, circling behavior and a reduction in the ERG response. In this study, we hypothesized that manipulation of Cdh23 dosage by a nonsense suppression strategy could rescue the disease phenotype in this animal model.

Methods: Two drug treatment protocols was performed (i) Prenatal: time-mated pregnant mice received daily subcutaneous injections of 30 µg/g Ataluren® and then the offspring received the same daily injections from P4 to P90. (ii) Postnatal: mice from P4-P90 received daily injections of 30 µg/g Ataluren®. ERGs were measured at P45 and P90 and P120. After treatment, IHC was performed to confirm Cdh23 protein expression and the trafficking of photoreceptors proteins. Structural benefits in photoreceptors were studied by immunohistochemistry and by transmission electronmicroscopy.

Results: We characterised this mouse model of USH1D (Cdh23) that had a nonsense mutation in Cdh23. The Cdh23 mouse was significantly smaller than wildtype mice and did not survive past 60 days of age. As with other models of USH1D, we did not find any structural abnormalities in the Cdh23 retinal structure. However, we found abnormalities in light-induced trafficking of proteins including rhodopsin, arrestin, α -transducin and recoverin. When Cdh23 mice were treated with Ataluren®, Cdh23 protein was expressed in the connecting cilium, the trafficking defects were rescued and electrical response to light were improved. The mice survival rate was increased to P120 and the circling behaviour was reduced.

Conclusions: These data show for the first time that nonsense suppression in a mouse model of USH1D was able to rescue the major phenotypic features observed in the homozygous mutant mice. We conclude that translational readthrough by the small molecule Ataluren® improved the disease phenotype in this mouse model.

ABSTRACT BODY:

Purpose: Stargardt disease (STGD1) associated with mutations in ABCA4 is genetically and phenotypically heterogeneous. Phenotypes range from yellow-white flecks in the macula with varying degrees of atrophy, some with more extensive distribution; bull's eye maculopathy, to a more severe chorioretinal atrophy. In this study, we report novel variants in the ABCA4 gene and describe their genotype-phenotype correlation.

Methods: Patients with novel sequence variants were identified from a large cohort of clinically diagnosed STGD1 patients with at least two variants in ABCA4, by the Oxford Medical Genetics Laboratories. Phenotyping included: visual acuity, Goldmann visual field and electrophysiology testing, optical coherence tomography (OCT), false-color ultra-widefield and fundus autofluorescence (AF) imaging. This study was carried out in accordance with the tenets of the declaration of Helsinki, with ethics approval.

Results: In this cohort of 20 patients, we identified 19 novel variants in ABCA4 of which 7 were missense mutations, 7 frameshift mutations, 1 whole exon deletion, 1 nonsense mutation, and 3 splice site mutations. The phenotypes in this cohort included the typical flecks seen in STGD1, macular atrophy and peripapillary sparing disease. Other features identified in these patients included; foveal sparing disease, a region of reduced foveal AF surrounded by a ring of raised AF, and widespread chorioretinal atrophy.

Conclusions: We describe 19 novel variants in ABCA4 and their associated phenotypes in a cohort of STGD1 patients. The identification of novel variants is important, as defining ABCA4 variants as pathogenic underpins genetic counselling, helps to confirm the diagnosis and in the future identify potential candidates for recruitment to therapeutic trials.

TITLE: An experimental model of Escherichia coli-induced endophthalmitis in rodents

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Tsoka, M.K. Tsilimbaris, Laboratory of Optics and Vision, University of Crete Medical School, Heraklion, GREECE|E. Scoulica, E. Magkafouraki, Laboratory of Clinical Microbiology and Molecular Microbiology, University of Crete Medical School, GREECE|

Commercial Relationships Disclosure (Abstract): Pavlina Tsoka: Commercial Relationship: Code N (No Commercial Relationship) | Effie Scoulica: Commercial Relationship: Code N (No Commercial Relationship) | Eleni Magkafouraki: Commercial Relationship: Code N (No Commercial Relationship) | Miltiadis Tsilimbaris: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Bacterial endophthalmitis can lead to significant vision loss even after prompt and proper treatment. So far, there are only a handful of studies on experimental models of bacterial endophthalmitis due to gram-negative organisms in small rodents. The purpose of this study was to establish an Escherichia coli-induced experimental model of endophthalmitis in rats suitable for potential pharmaceutical intervention.

Methods: Bacterial endophthalmitis was induced in both male and female Sprague-Dawley rats. Animals received an intravitreal injection of viable Escherichia coli (E. coli) of two different strains; U13 which is susceptible to moxifloxacin and U27 which has an inducible resistance to moxifloxacin. Several inocula were tested in a range from 10.000 colony – forming units (CFUs)/eye to 840.000 CFUs/eye. Clinical scores were evaluated in vivo with slit lamp biomicroscopy and direct ophthalmoscopy and animals were euthanized at 0, 24, 48 and 72 hours post intravitreal injection, eyes were enucleated, and bacterial growth rate was assessed.

Results: An inoculum of 10.000 CFUs/eye of E. coli U13 resulted in conjunctival hyperemia, purulent exudations, iritis and miosed pupils (posterior synechiae) at 24 hours with mild to moderate average inflammatory scores in the two-thirds of the animals. The signs of clinical inflammation were not progressed at 48 or 72 hours, while the bacterial load remained stable with an average of 10^5 CFUs/eye. However, in all experiments, one-third of the animals demonstrated significantly lower clinical scores. On the contrary, higher inocula (> 70.000 CFUs/eye) of E. coli U13 resulted in moderate to severe inflammatory signs even at 24 hours. In addition to E. coli U13, an inoculum of even 100 CFUs/eye of E. coli U27, resulted in severe inflammation and particularly high clinical scores within the 72-hours timeframe.

Conclusions: Escherichia coli-induced experimental endophthalmitis can be achieved in rats and is a highly reproducible model of gram-negative bacterial endophthalmitis. Low inocula of E. coli strain U13 result in mild to moderate progress of the inflammatory signs, thus allowing pharmaceutical intervention. Further experimentation is currently ongoing in order to evaluate novel liposomal formulations that are specifically designed for sustained intraocular release of moxifloxacin.

TITLE: The impact of neighborhood factors on physical activity in older adults with glaucoma

SESSION TITLE: Visual Impairment - Driving and Mobility

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Garzon, A. Mihailovic, J. E. S.K. West, P.Y. Ramulu, Wilmer Eye Institute, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|D.S. Friedman, Massachusetts Eye and Ear, Harvard Medical School, Boston, Massachusetts, UNITED STATES|L.N. Gitlin, College of Nursing and Health Professions, Drexel University, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Catalina Garzon: Commercial Relationship: Code N (No Commercial Relationship) | Aleksandra Mihailovic: Commercial Relationship: Code N (No Commercial Relationship) | Jian-Yu E: Commercial Relationship: Code N (No Commercial Relationship) | Sheila West: Commercial Relationship: Code N (No Commercial Relationship) | David Friedman: Commercial Relationship: Code N (No Commercial Relationship) | Laura Gitlin: Commercial Relationship: Code N (No Commercial Relationship) | Pradeep Ramulu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate if neighborhood factors are associated with physical activity in older adults with visual impairment.

Methods: Persons with glaucoma or suspected glaucoma had accelerometer-defined physical activity collected over 7-days and summarized as average daily steps and non-sedentary minutes. Census block and tract numbers were utilized to collect the following neighborhood characteristics: Area Deprivation Index, fraction of residents living below the federal poverty line, and average crime rate per 100k people, categorized as low (<2,500), medium (2,500-5,000) and high (>5,000). Based on the integrated visual field (VF) sensitivity, participants were categorized to mild, moderate or severe VF loss from glaucoma. Multivariable negative binomial regression models evaluated the effect of neighborhood factors on physical activity for all participants, and participants stratified by severity of the VF loss.

Results: The 230 study participants were on average 70 years old; about half were female, and about third Black. Average daily steps and non-sedentary minutes were lower with higher area deprivation index (rate ratio [RR]=0.96 per 1 decile, 95%CI=0.93 to 0.99, p=0.007 and RR=0.96 per 1 decile, 95% CI=0.94 to 0.98, p=0.001, respectively). Average non-sedentary minutes were also lower for those living in areas with higher fraction of residents below the federal poverty line (RR=0.92 per 10% increase, 95% CI=0.85 to 0.98, p=0.02). Both, average daily steps and non-sedentary minutes, also decreased significantly in those with severe VF loss who lived in the areas with higher fraction of residents below the federal poverty line (RR=0.78 per 10% increase, 95% CI=0.63 to 0.96, p=0.02, and RR=0.76 per 10% increase, 95% CI=0.66 to 0.88, p<0.001, respectively). Neither average daily steps nor non-sedentary minutes were associated with crime rates (p>0.11 for all) for the whole group, though much less activity was noted in those living in higher vs. lower crime rate areas amongst participants with severe VF loss (RR=0.32, 95% CI=0.17 to 0.58, p<0.001, and RR=0.36, 95% CI=0.23 to 0.57, p<0.001, respectively).

Conclusions: Neighborhood characteristics might be important drivers of mobility in glaucoma patients, especially in those with the severe VF loss. Interventions to overcome activity limitations may be particularly important in this group.

ABSTRACT BODY:

Purpose: To perform a systematic review and network meta-analysis (NMA) of ocular adverse events (OAE) including endophthalmitis, inflammatory events and retinal vascular occlusive events secondary to anti-VEGFs for the treatment of neovascular age-related macular degeneration (nAMD).

Methods: A comprehensive search of Pubmed was conducted of all studies from inception until June 2020. Eligible publications included ≥ 50 patients and reported OAE of interest including endophthalmitis, uveitis, iritis, vitritis, vasculitis and ocular vascular occlusions.

Results: The search identified 7303 articles. 95 studies involving 302978 eyes were included in the systematic review and 23 comparator studies involving 261995 eyes in the NMA.

Incidence rates (IR) (total number of events n/total number of study eyes N) for endophthalmitis, inflammatory OAE and vascular occlusions were reported for each agent. Denominators for IR were based on total number of eyes across all studies that examined each complication. IR of endophthalmitis ranged from 0.27% (336/124,299) for ranibizumab to 1.2% (15/1251) for abicipar. IR of inflammatory OAE ranged from 0.9% (164/18153) for ranibizumab to 16.2% (203/1251) for abicipar. IR of vascular occlusions ranged from 0.085% (8/9460) for ranibizumab to 0.95% (8/841) for bevacizumab. Only abicipar reported retinal vasculitis at an IR of 1.8% (22/1251).

A NMA comparing the agents showed that the odds ratios (OR) (95% confidence intervals) for endophthalmitis from least to most likely with abicipar as reference were bevacizumab OR 0.097 (0.0075, 1.25), ranibizumab OR 0.13 (0.012-1.51), aflibercept OR 0.24 (0.018, 3.07), abicipar 1.00 (1.00, 1.00) and brolucizumab OR 1.12 (0.031, 40.1). For inflammatory OAE, the OR were: ranibizumab OR 0.008 (0.0011-0.59), bevacizumab 0.013 (0.0015, 1.09), aflibercept 0.096 (0.0069, 1.32), brolucizumab 0.44 (0.026, 7.24) and abicipar 1.00 (1.00, 1.00). Finally, the OR for vascular occlusive events were aflibercept OR 0.008 (0.00014, 0.55), brolucizumab OR 0.035 (0.00034-3.69), ranibizumab OR 0.044 (0.0026, 0.72), bevacizumab OR 0.15 (0.0065, 3.49) and abicipar 1.00 (1.00, 1.00).

Conclusions: The reported rates of OAE are generally low across the different anti-VEGFs but appear higher for newer agents brolucizumab and especially, abicipar. Further trials are needed to adequately assess their safety profile.

TITLE: Effect of Rho-kinase Inhibition on a Patient-Derived Model of Proliferative Vitreoretinopathy

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Ramos, D. Amarnani, L.A. Kim, Retina, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|N. Singh, L.A. Kim, Retina, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Leslie Ramos: Commercial Relationship: Code N (No Commercial Relationship) | Dhanesh Amarnani: Commercial Relationship: Code N (No Commercial Relationship) | Nakul Singh: Commercial Relationship: Code N (No Commercial Relationship) | Leo Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is a common complication of open globe trauma and recurrent retinal detachment currently lacking medical treatment. Migration and proliferation of retinal cells, the formation of contractile membranes, and subsequent retinal detachment are hallmarks of PVR. This study aims to investigate the effect of Rho-kinase inhibition using an in vitro patient-derived cell and ex vivo explant model of PVR.

Methods: PVR membranes from human donors were cultured into a single cell suspension after digestion with enzymes creating primary PVR cell cultures. Explants were made from fragments of PVR membranes embedded into Matrigel. The effect of Rho-kinase inhibition using ROCK1 and ROCK2 inhibitors: ripasudil, netarsudil, fasudil and Y-2762 were tested. We examined the response of these inhibitors on cell proliferation of PVR cell cultures at two concentrations, selected from the IC50. The effects of ripasudil (150 nM and 300 nM), netarsudil (30 nM and 60 nM), fasudil (500 nM and 1 µM), and Y-2762 (500 nM and 1 µM) were evaluated at 24 hours. The effect of Rho-kinase inhibitors at 1 µM was tested on our PVR explant. Phase contrast images were taken at 7 and 14 days, and outgrowths were measured.

Results: At 24 hours, ripasudil (300 nM) and netarsudil (60 nM) revealed a 11% and 13% reduction in proliferation in PVR cells, whereas fasudil showed a 39% reduction in proliferation at 500 nM and a 87% reduction at 1 µM concentration. Similarly, Y-2762 showed a significant 80% reduction at 500 nM and an almost complete (94%) reduction in the proliferation of PVR cells. Robust outgrowths were observed growing from the freshly isolated PVR explant samples at 7 and 14 days (28.58 mm and 207 mm respectively) post embedding in Matrigel in culture. Ripasudil (0.8 mm and 15 mm), and netarsudil (4.2 mm and 37 mm) successfully inhibited and reduced explant growth at 7 and 14 days. The explants treated with fasudil (1 µM) and Y-2762 (1 µM) showed no outgrowths and almost complete inhibition of migration at all time points.

Conclusions: Currently, there are no specific therapeutic agents to prevent PVR. Common in vitro models of PVR rely primarily on RPE cell cultures to mimic early PVR, whereas our model relies on patient-derived PVR membranes. Our assays, when used in drug screens, may be beneficial at identifying potential therapies likely to work in preclinical and clinical trials for PVR.

ABSTRACT BODY:

Purpose: To determine whether handheld optical coherence tomography (OCT) is feasible in children with craniosynostosis.

Methods: This was a single-centre, prospective observational study. Fifty patients with syndromic and non-syndromic craniosynostosis were approached between February 13th 2020 and October 1st 2020. Patients were excluded if they could not cooperate with handheld OCT imaging or were aged over 18 years old. Main outcome measures included feasibility, including patient recruitment and handheld OCT image acquisition success rates. Main secondary outcome measures included visual acuity (VA), fundoscopic examinations and 48-hour intracranial pressure (ICP) assessments.

Results: All 50 children were successfully recruited (100%). At least one ONH image was obtained in 43 children (86%), while bilateral ONH imaging was successful in 37 children (74%). Of the 43 included children, median age was 66.3 months (range: 1.9-156.9 months; IQR: 37.8-44.9). LogMAR chart VA was available in 31 of 43 patients. Median VA was 0.1 logMAR (range: -0.06 – 1.30; IQR 0.02 – 0.2). Fundoscopy was successful in 40 of 43 patients. ICP assessments were available in five patients, demonstrating normal ICP in two, reduced intracranial compliance in one and raised ICP in two – these were not identified on fundoscopy but correctly identified on handheld OCT.

Conclusions: Handheld OCT is feasible in children with craniosynostosis. This represents the first study of its kind. Further work is required to determine whether handheld OCT represents an effective screening tool for intracranial hypertension in this patient population.

TITLE: Racial Disparities in Cataract Surgery Outcomes

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Singh, S. Bal, A.C. Lorch, Massachusetts Eye and Ear Infirmary Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nakul Singh: Commercial Relationship: Code N (No Commercial Relationship) | Sila Bal: Commercial Relationship: Code N (No Commercial Relationship) | Alice Lorch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess differences in cataract surgery outcomes by race in order to better understand delivery of surgical care to diverse patient populations.

Methods: Massachusetts Eye and Ear surgical outcomes were assessed between January 1, 2019 and December 31, 2019. Patient's self-identified race/ethnicity were extracted from the medical record and collapsed into broader categories of White, Black, Hispanic, Asian, declined/unavailable, and other for race. Cataract surgery outcomes were intraoperative complications(Descemet's tear, posterior capsule tear, vitreous loss, anterior vitrectomy, dropped lens, and zonular dialysis), final refractive error within 1 diopter of target refraction, and loss to follow up. Logistic regression was performed to estimate the odds ratios between categories.

Results: A total of 2,874 patients underwent cataract surgery and were included in the analysis (White=2,121, Asian=212, Black=202). Patients reporting their race as Asian had increased odds of an intra-operative complication (OR 3.29, CI 1.46-7.38, p-value <0.001) compared to self-reported White patients. Patients reporting their race as Black (OR 0.65, CI 0.46- 0.93) or other (OR 0.66, CI 0.46-0.94) were less likely than self-reported White patients to be within 1 diopter of target refraction. Patients reporting their race as Black (OR 1.91, CI 1.33-2.76) or other (OR 1.79, CI 1.22-2.60) had increased odds of loss to follow up.

Conclusions: There were racial disparities in cataract surgery outcomes in intraoperative complications, target refraction, and loss to follow up. These findings warrant further investigation into these disparities and development of programs that improve equity of cataract care.

TITLE: Ocular Distribution of Pegcetacoplan in Rabbits Following a Single Intravitreal Injection.

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.J. Reid, Research and Translational Medicine, Apellis Pharmaceuticals Inc, Watertown, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Reid: Commercial Relationship(s);Apellis Pharma:Code E (Employment)

ABSTRACT BODY:

Purpose: Geographic Atrophy (GA) is an advanced stage of age-related macular degeneration (AMD); a major cause of blindness affecting almost 1 million people in the US alone. GA is characterized by a loss of RPE, photoreceptors, and atrophy of the choriocapillaris. Dysregulation of the complement system is a contributor to the pathogenesis of AMD. Polymorphisms in C3, factor H and factor B are associated with risk of AMD and upregulation of the complement pathway leads to C3 opsonization of photoreceptors and RPE. Since C3 is the central component of all three complement pathways, inhibition of C3 represents a promising approach to treat GA. Pegcetacoplan (APL-2), a PEGylated cyclic peptide inhibitor of C3, slowed GA lesion growth in a Phase II (FILLY) study and is being investigated in ongoing Phase III trials (DERBY and OAKS). Intravitreal (IVT) injection remains the most efficient route to reach the diseased tissues in the posterior section of the eye. However, therapeutics delivered from the vitreous to the retina must traverse multiple biological barriers; including the inner limiting membrane (ILM) which is considered the main filtration barrier between the retina and vitreous.

Methods: An ocular distribution study of pegcetacoplan in New Zealand white rabbits was conducted to measure concentrations in aqueous humor (AH), iris-ciliary body, vitreous humor (VH) and the retina/RPE/choroid. Pegcetacoplan was administered as a single IVT dose of 12 mg and animals were euthanized for tissue/fluid compartment collection on Days 1, 3, 7, 14 and 28. Isolated tissues were analyzed by LC-MS/MS methods specific for each matrix.

Results: Peak concentrations in each ocular compartment were reached 24 hours with the exception of VH which plateaued between 24 and 96 hours. Exposure in the retina/RPE/choroid and AH was generally 3- and 6-fold lower than VH, respectively. Elimination half-life was ~5 days in each ocular compartment in rabbits compared to 3 days in cynomolgus monkeys.

Conclusions: Pegcetacoplan has rabbit vitreal kinetics in the range of marketed anti-VEGF biologics and does traverse the ILM in adequate concentrations supporting the posology in the clinical studies.

ABSTRACT BODY:

Purpose: The lens microcirculation system is required to maintain transparency; however, how this system is established and maintained as a function of age is not well understood. Aquaporin-0 (AQP0) plays important roles in lens fiber cell adhesion and water permeability. The purpose of this study is to structurally characterize AQP0 through Native mass spectrometry (Native MS) and to develop a method to analyze AQP0-protein interactions via hydrogen deuterium exchange-mass spectrometry (HDX-MS) using AQP0-calmodulin interactions as a model.

Methods: Bovine lens membranes were solubilized in 1% octylglucoside and AQP0 was purified via anion exchange chromatography. HDX-MS: After incubation in D₂O, the HDX process was quenched, proteins were digested using pepsin, and resulting peptides separated and analyzed via liquid-chromatography mass spectrometry on a Waters Xevo G2-XS QToF. Data were analyzed using Waters PLGS and DynamX software. Native MS: Purified AQP0 was buffer exchanged into C₈E₄ detergent in 200 mM ammonium acetate, introduced into a Thermo Exactive Plus EMR Orbitrap or a Thermo Q Exactive Plus UHMR mass spectrometer using nanoelectrospray ionization and dissociated by collision induced dissociation (CID) or by surface induced dissociation (SID).

Results: HDX-MS: After optimization, significant sequence coverage was obtained for both AQP0 (75%) and calmodulin (90%) that includes coverage of the C-terminal tail of AQP0. As expected, AQP0 loop and C-terminal tail peptides displayed greater deuterium incorporation relative to transmembrane regions. Native MS: Multiple AQP0 proteoforms of intact tetrameric AQP0 were identified in isolated AQP0 fractions including phosphorylated and lipidated AQP0. Chromatographic separation allowed enrichment of un-, mono-, and di-phosphorylated forms.

Conclusions: HDX-MS methodology was optimized to yield good sequence coverage for lens membrane protein AQP0 which sets the stage for examining AQP0-protein interactions. Deuterium uptake data suggest AQP0 loop and C-terminal tail regions to be dynamic and solvent exposed whereas transmembrane regions remain largely solvent protected. Multiple proteoforms of tetrameric AQP0 were identified via Native MS which will allow us to compare unphosphorylated and phosphorylated AQP0 to understand the effects of phosphorylation on AQP0 function. Native MS data show di-phosphorylation to be the highest degree of phosphorylation of intact tetrameric AQP0.

TITLE: Numerous Protein Mutations Detected in FEVR Patients Using a New Custom Ampliseq Targeted-Sequencing Panel

SESSION TITLE: Genetics, (gen)omics, systems and computational biology in ocular health and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Petrelli Cicerone, W.A. Dailey, M. Sun, N. Haque, A. Guzman, K. Mellert, K.A. Drenser, K.P. Mitton, Eye Research Institute, Oakland University, Rochester, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amanda Petrelli Cicerone: Commercial Relationship: Code N (No Commercial Relationship) | Wendy Dailey: Commercial Relationship: Code N (No Commercial Relationship) | Michael Sun: Commercial Relationship: Code N (No Commercial Relationship) | Naomi Haque: Commercial Relationship: Code N (No Commercial Relationship) | Alvaro Guzman: Commercial Relationship: Code N (No Commercial Relationship) | Kendra Mellert: Commercial Relationship: Code N (No Commercial Relationship) | Kimberly Drenser: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Mitton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Analyze the first subset of 69 patients with Familial Exudative Vitreo Retinopathy (FEVR) who were sequenced using a custom Ampliseq targeted gene panel that includes 7 genes (NDP, CTNNB1, TSPAN12, KIF11, FZD4, LRP5, ZNF408) that are potentially involved in FEVR.

Methods: A custom Ampliseq targeted-panel (180 amplicons) for 8 genes was designed with illumina's DesignStudio Sequencing Assay Design for complete coverage of 83 exons with 25 bp adjacent intron sequence. Seven of the genes are applicable to FEVR: NDP (ChrX), CTNNB1 (Chr3); TSPAN12 (Chr7); KIF11 (Chr10), FZD4 (Chr11), LRP5 (Chr11), ZNF408 (Chr11). Ampliseq libraries were pooled and sequenced using the Illumina iSeq-100 platform. Variant impacts and allele frequency data were determined from ClinVar and The Genome Aggregation Databases (gnomAD).

Results: For the seven genes that are applicable to FEVR, a total of 35 variants were found that alter protein sequence, with the following relative distribution: NDP 1/35 (2.9%), CTNNB1 1/35 (2.9%), TSPAN12 1/35 (2.9%), KIF11 3/35 (8.6%), FZD4 10/35 (28.6%), LRP5 13/35 (37.1%), ZNF408 6/35 (17.1%). Types of protein changes were: single amino acid change (77.1%), amino acid deletion (8.6 %), and amino acid insertion (2.9%).

Conclusions: A custom Ampliseq targeted-sequencing Orphan Pediatric Retinal Disease panel (version 2, 8 genes) developed by our lab provided extensive sequencing coverage of all exons and detected 35 protein-altering variants in a set of 69 FEVR patients. 76% of the variants were found in three genes: FZD4, LRP5, and ZNF408. The testing format greatly reduces associated costs and now facilitates greater access to genetic testing for Families with this very rare inherited retinal disease.

Commercial Relationships Disclosure (Abstract): Nai-Wen Fan: Commercial Relationship: Code N (No Commercial Relationship) | Yihe Chen: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship(s);Aramis Biosciences:Code I (Personal Financial Interest) | Reza Dana: Commercial Relationship(s);Aramis Biosciences:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: Our previous work has identified two CD44^{low} effector Th17 subsets that contribute to acute inflammation in dry eye disease (DED): CD4⁺IFN γ ⁻IL-17⁺ ("single-positive" eTh17) and CD4⁺IFN γ ⁺IL-17⁺ ("double-positive" eTh17/1). Subsequently, memory Th17 cells (mTh17; CD4⁺CD44^{hi}IL17⁺IFN γ ⁻) become the principle mediators sustaining the chronic inflammation in DED. We have further demonstrated linear generation of mTh17 from effector T precursors driven by IL-23. This study aims to determine the differential contribution of eTh17 vs. eTh17/1 subsets to mTh17 in DED.

Methods: Six- to eight-week old female C57BL/6 mice were exposed to desiccating stress in a controlled environment chamber for 14 days to induce acute DED. Draining lymph nodes (DLNs) were collected, and eTh17 and eTh17/1 were isolated using IL-17 and IFN- γ cytokine secretion assay kits combined with FACS sorting, and then were individually adoptively transferred to Rag1 knockout (KO) mice that had been exposed to desiccating stress for 14 days. Immediately after transfer, Rag1 KO recipients were removed from desiccating stress and received intraperitoneal injection of anti-IL23 receptor antibody or control IgG. Disease severity was evaluated by corneal fluorescein staining, and T cell response was assessed at day 12 after cell transfer.

Results: Rag1 KO mice subjected to desiccating stress did not develop DED. Upon receiving acute DED-derived eTh17 or eTh17/1, both groups of Rag1 KO recipients developed disease at day 3 post-cell transfer, however, only eTh17/1 group, but not eTh17 group, showed persisting disease by day 12 along with the development of mTh17 cells in DLN (P<0.05). Blockade of IL-23 signaling significantly reduced disease severity in eTh17/1 recipients at day 12, as well as prevented the generation of mTh17 cells (P<0.05).

Conclusions: eTh17/1 cells generated in acute inflammation are the principle precursors of mTh17 cells that persist for long term and sustain the chronicity of inflammation in DED.

TITLE: Histopathological and immunohistochemical study of metastatic orbital tumors

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Ito, G. Nassrallah, S. Bergeron, J. Coblentz, A.A. Goyeneche, M.N. Burnier, The MUHC-McGill University Ocular Pathology & Translational Research Laboratory, McGill University, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Hiroaki Ito: Commercial Relationship: Code N (No Commercial Relationship) | Georges Nassrallah: Commercial Relationship: Code N (No Commercial Relationship) | Sabrina Bergeron: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Coblentz: Commercial Relationship: Code N (No Commercial Relationship) | Alicia Goyeneche: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Metastatic orbital tumors are rare and account for 3% of orbital lesions. It can be the initial manifestation of a systemic metastatic disease, and accurate pathological diagnosis is crucial. The objective of this study is to report 10 orbital metastases and to further understand these histopathological and immunohistochemical (IHC) characteristics.

Methods: From 8018 cases reviewed, 203 orbital lesions including 28 malignant tumors were collected at the MUHC-McGill University Ocular Pathology & Translational Research Laboratory from 2006 to 2020. Among the malignant tumors, 11 cases were metastatic. Ten of the metastatic cases were selected based on complete clinical history and available slides.

Results: Of the 10 patients with metastatic orbital tumors, 6 were women and 4 were men. The mean age was 68 years (range 52-83). Pathological examination revealed 70% (7/10) of carcinomas: metastatic breast carcinoma (3/10); adenocarcinoma consistent with metastasis of a prior cutaneous carcinoma (2/10) prostatic carcinoma (1/10); poorly differentiated carcinoma with a past history of skin squamous cell carcinoma (SCC) (1/10). The other three cases were plasmacytoma (2/10) and mucosal melanoma (1/10). All cases of breast carcinoma were positive for Estrogen Receptors (ER). Prostatic carcinoma was confirmed by PSA and NKX3.1. The two adenocarcinomas of the skin showed IHC findings which cannot exclude the possibility of breast origin: one case was 70-year-old female mucinous carcinoma, positive for ER, CK7, GATA3; the other was 53-year-old male signet-ring adenocarcinoma, positive for CK7, CK20, GATA3, BRST2. In both cases, no breast primary lesion was found, and the prior skin lesions showed similar morphology and IHC profile. Poorly differentiated carcinoma with a past skin SCC was positive for CK7 and negative for CK20, p40. The findings are consistent with metastasis from skin. In plasmacytoma, monoclonality was confirmed by light chain restriction with kappa and lambda. Melanoma was positive for HMB45 and Melan A.

Conclusions: The use of a panel of immunohistochemical markers is crucial for the final diagnosis of orbital metastasis. The histopathological and immunohistochemical findings may be inconclusive particularly in cases of cutaneous carcinoma. Careful interpretation and clinicopathological correlation are essential for final diagnosis.

TITLE: Iodine-125 Plaque Radiotherapy for Retinoblastoma Recurrence following Intra-arterial Chemotherapy

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Ruben, M. Eiger-Moscovich, A. Yaghy, S. Tadepalli, C. Shields, Wills Eye Hospital Ocular Oncology Service, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Megan Ruben: Commercial Relationship: Code N (No Commercial Relationship) | Maya Eiger-Moscovich: Commercial Relationship: Code N (No Commercial Relationship) | Antonio Yaghy: Commercial Relationship: Code N (No Commercial Relationship) | Sameeksha Tadepalli: Commercial Relationship: Code N (No Commercial Relationship) | Carol Shields: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the efficacy and toxicity of Iodine-125 (I-125) plaque radiotherapy for residual or recurrent retinoblastoma following intra-arterial chemotherapy (IAC).

Methods: In a retrospective review, clinical records of all children with retinoblastoma that received I-125 plaque radiotherapy after IAC on the Ocular Oncology Service at Wills Eye Hospital between December 1, 2009 and April 30, 2020 were reviewed.

Results: There were 41 retinoblastomas in 41 eyes of 41 patients treated with I-125 plaque radiotherapy after IAC, including 21 females (51%) and 20 males (49%) with a median age at plaque treatment of 32 months (range 9-71 months). The most common indication for I-125 plaque radiotherapy was recurrence of solid tumor with or without overlying subretinal/vitreous seeds (n=33, 80%), subretinal seeds alone (n=6, 15%), and vitreous seeds alone (n=2, 5%). The median irradiated basal diameter was 9 millimeters (mm) (range 2-16 mm) and median thickness was 4 mm (range 1-7 mm). Mean radiation dose to tumor apex was 3483 centigray. There was complete tumor control at the target site in 39 eyes (95%) at median follow-up of 20 months (range 1-109 months) after plaque radiotherapy. This included control within the target site for solid tumor (31/33, 94%), subretinal seeds (6/6, 100%), and vitreous seeds (2/2, 100%). A subgroup of solid tumor and/or subretinal seeds was identified, which occurred within an ischemic retinal/choroidal field, confirmed on fluorescein angiography and associated with highly calcified mass (n=24 cases). This select group demonstrated tumor control in 22/24 (92%). Visual acuity at last follow-up was 'fix and follow' in 13/14 (93%) of pre-verbal patients and 20/400 or better in 10/22 (45%) of verbal patients. Using Kaplan-Meier analysis, radiation complications at 2 years included vitreous hemorrhage (37%), retinopathy (28%), papillopathy (18%), and cataract (18%). Enucleation was necessary in 5 eyes (12%) for recurrence outside of the irradiated area, chronic vitreous hemorrhage, and/or total retinal detachment.

Conclusions: In this analysis, Iodine-125 plaque radiotherapy provided 95% tumor control for selected retinoblastomas that failed IAC, including those in an ischemic field, untreatable with further chemotherapy. Radiation-related side effects should be anticipated in these eyes already exposed to substantial chemotherapy.

ABSTRACT BODY:

Purpose: Neuronal ceroid lipofuscinosis (NCL) is a family of neurodegenerative lysosomal storage diseases. NCL type 11 (CLN11) is caused by biallelic mutations to the progranulin gene, leading to seizures, ataxia and vision loss. Patients and a murine model (PGRN^{-/-}) show retinal thinning, accumulation of autofluorescent lipofuscin, and increase in microglial activation. As a recessive neurodegenerative disease, CLN11 is an ideal candidate for gene replacement therapy; however, both brain and retina require AAV gene delivery. This study aimed to deliver two different AAV constructs, 7m8-scCAG-PGRN and AAV92YF-scCAG-PGRN, to the retinas of PGRN^{-/-} mice at four different timepoints, with the objective of stalling retinal degeneration.

Methods: Plasmids were packaged into two different capsids (7m8 and AAV92YF) using the triple transfection method and titered via qPCR. PGRN^{-/-} cohorts received intravitreal injections of 7m8-scCAG-PGRN in one eye and PBS in the contralateral eye at different timepoints: 1, 6, and 12 months old. Mice that received AAV92YF-scCAG-PGRN were intravenously injected at post-natal day 3 or 4 (P3-4). At 12 months old, cohorts injected at P3-4, 1 and 6 months old had their retinas imaged by optical coherence tomography (OCT) and were enucleated. The cohort injected at 12 months old were imaged and enucleated at 18 months old. Retinal thickness was measured using OCT cross-sections. Retinas were cryosectioned and immunohistochemistry was performed. Lipofuscin was quantified through fluorescent imaging.

Results: Animals that received AAV92YF-scCAG-PGRN showed a statistically significant improvement in overall retinal thickness and in photoreceptor layer thickness. However, animals injected with 7m8-scCAG-PGRN at month 1 and 6 showed no improvement in retinal thickness, while animals injected at 12 months old showed retinal thinning in comparison to contralateral controls. All cohorts show improvements in lipofuscin deposits when expressing PGRN.

Conclusions: Animals receiving PGRN at the earliest timepoint (P3-4) show improvement in retinal thickness, while the oldest cohort (12 months old) show retinal thinning when expressing PGRN. This points to a potentially toxic effect of PGRN delivery in elderly animals, which are reportedly more immune-reactive than age-matched wild-type mice. However, reduction in lipofuscin deposits indicate an improvement in lysosomal function, regardless of cell loss.

ABSTRACT BODY:

Purpose: Chloroquine has been linked to retinopathy for decades in humans, characterized by central visual loss and bull's eye maculopathy. We have developed a mouse model of chloroquine retinopathy to identify key steps in disease progression. The association of chloroquine induced retinal toxicity with oxidative stress and lipid peroxidation of RPE cells was examined.

Methods: Chloroquine retinopathy was induced by injecting chloroquine (50mg/kg) intraperitoneally into adult C57BL/6J mice 3x/week for 6-8 weeks. Retinal and/or RPE material was analyzed by histology, TUNEL staining, protein immunoblot, ELISA, and qPCR. Electroretinography (ERG) was used to monitor retinal function. ARPE-19 cells were used for in vitro experiments.

Results: ERG analysis detected a moderate reduction in both the a-wave and b-wave, with increases in implicit time. Spider graphs indicated a corresponding loss of outer nuclear layer cells in chloroquine treated retinae. TUNEL analysis detected increased apoptotic DNA fragmentation in photoreceptor nuclei; no corresponding signal was detected in RPE cells. RPE/choroid material from chloroquine-treated mice displayed an increase in HNE-adducted proteins detected with both Elisa and immunoblots. Chloroquine treatment increased the number and size of lysosomes, the amount of mitochondrial staining and expression of mitochondrial biogenesis genes in vitro.

Conclusions: This study suggests that the loss of photoreceptors accompanying moderate chloroquine treatment is associated with lysosomal stress, mitochondrial biogenesis and oxidative stress in RPE cells. How these stresses in the RPE lead to photoreceptor death requires further investigation.

TITLE: Determining the Utility of Epithelial Thickness Mapping in Refractive Surgery Evaluations

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Randleman, L. Asroui, W.J. Dupps, Ophthalmology, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): James Randleman: Commercial Relationship: Code N (No Commercial Relationship) | Lara Asroui: Commercial Relationship: Code N (No Commercial Relationship) | William Dupps: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine how the addition of corneal epithelial thickness maps impacts patient screening for refractive surgery candidacy.

Methods: A retrospective evaluation of 100 consecutive patients who were screened for refractive surgery candidacy was conducted. For each patient, screening based on Scheimpflug tomography, clinical data, and patient history was done and a decision on eligibility for corneal refractive surgery, and choice of surgery, was made by two masked reviewers. The reviewers were then shown the patient's epithelial thickness maps derived from OCT. The percentage of screenings that changed after evaluating the epithelial thickness maps, with regards to candidacy for surgery, surgery of choice, and ranking of surgical procedures from most favorable to least favorable, was determined.

Results: Candidacy for corneal refractive surgery changed in 17% of patients after evaluation of the epithelial thickness maps, with 41.18% of the changes resulting in screening out patients, and 58.82% screening in patients. In the subset of patients that remained eligible candidates for surgery, the surgery of choice changed in 20.83% of cases after evaluating the epithelial thickness maps. In that same subset, the ranking of surgical procedures, from most favorable to least favorable, changed in 36.11% of cases, with 13.89% of patients losing eligibility, and 11.11% gaining eligibility, for one or more surgical procedure. In the subset of patients in which eligibility for surgery, surgery of choice, and ranking of surgical procedures from most to least favorable did not change, the epithelial thickness maps increased the reviewers' confidence in their decision in 49.12% of cases, decreased their confidence in 17.54% of cases, and had no impact on their level of confidence in 33.33% of cases.

Conclusions: Epithelial thickness mapping derived from OCT imaging of the cornea alters candidacy for corneal refractive surgery, as well as choice of surgery, in a substantial percentage of patients, and is thus a valuable tool for screening evaluations. Overall, the use of epithelial thickness maps results in screening in a slightly larger percentage of patients for corneal refractive surgery.

ABSTRACT BODY:

Purpose: Electronic displays of randomized Snellen acuity charts are common; however, the accuracy of a forced-choice visual acuity (FCVA) test has not been explored. The purpose of this study is to assess the test-retest reliability (TRR), criterion validity (CV), and discriminant validity (DV) of the Early Treatment Diabetic Retinopathy (ETDRS) and FCVA test in a prospective comparative clinical study. We predict that there will be no difference between the logarithm of the minimal angle of resolution (logMAR) results of both exams.

Methods: Data of the right eye (69 healthy, 59 disease) from subjects 18-85 years, VA better than counting fingers, and no central vision loss were included. VA testing was done at 4 meters and repeated at least 1 hour later. Subjects were separated by primary ophthalmic diagnosis. Results were recorded in logMAR. All subjects ETDRS and FCVA results and TRR were analyzed with paired t-test, DV by independent t-test, and CV by Pearson correlation. All subject ETDRS and FCVA results were further analyzed by Bland-Altman (B-A) analysis.

Results: A paired sample t-test of all subjects between ETDRS and FCVA showed significant differences at the first visit (95% CI -.07 to -.02, $p < .01$), B-A analysis showed that 43% of subjects had at least 0.1 difference in logMAR between testing modalities. CV analysis demonstrated $r=0.836$ with p value less than .01. TRR analysis showed insignificant differences at two different time points. DV analysis showed significant differences amongst disease and healthy subjects within each test.

Conclusions: ETDRS and FCVA exams showed high TRR, but a significant difference was detected between ETDRS and FCVA. Though FCVA may solve issues such as crowding and memorization, the significant difference between logMAR results suggests that FCVA cannot replace ETDRS at this time.

ABSTRACT BODY:

Purpose: Glucose metabolism has been central in the study of photoreceptor cell physiology. However, recent evidence shows that fuel sources besides glucose can be utilized to meet the metabolic needs of photoreceptors. Therefore, we sought fundamental insight into the contribution of glutamine (Gln) as a potential alternative fuel source to photoreceptor metabolism, function, and survival.

Methods: Targeted metabolomic analyses was performed in 661W cells grown in uniformly labeled ¹³C-Gln in the presence or absence of the glutaminase (GLS) inhibitor, CB-839. 661W cell viability and redox status were measured with luminescent-based assays (Promega). To study the role of Gln catabolism in vivo in photoreceptors, GLS was deleted from rod photoreceptors (Gls cKO) in animals expressing cre-recombinase under the control of the rhodopsin promoter and a floxed Glis gene. The effect of GLS deletion on the survival of the photoreceptors was examined using in vivo and ex vivo analyses.

Results: Glis expression was over 20 times greater than its paralog, Glis2, in 661W cells and predominantly segregated to mitochondria. Treatment with CB-839 in 661W cells increased cellular Gln and decreased Gln-derived Glu. Furthermore, α-ketoglutarate, succinate, aspartate and malate were severely depleted underscoring that Gln contributes to TCA cycle. Additionally, inhibiting GLS reduced the biosynthesis of glutathione (GSH), altered redox homeostasis (GSH/GSSG ratio) and increased reactive oxygen species. Concomitantly, GLS inhibition reduced cell survival. In the mouse retina IHC, RT-PCR, and western blot analyses demonstrated that GLS is the predominant isoenzyme, enriched in photoreceptor inner segments, and segregated more to the mitochondrial than cytosolic fraction. IHC and western blot validated the rod-specific knockdown of GLS protein levels of the Glis cKO mouse. Glis cKO mice demonstrated comparable outer retinal thickness to wild-type animals at P14 with rapid photoreceptor degeneration evident by P21.

Conclusions: This study demonstrates that Gln catabolism via GLS is critical for redox balance, mitochondrial metabolism, and photoreceptor survival. Insight into the contribution of Gln to photoreceptor metabolism, function and survival may provide a framework for developing novel therapeutic approaches to prevent blindness in retinal degenerations.

ABSTRACT BODY:

Purpose: To classify the different grades of age-related macular degeneration (AMD) using optical coherence tomography (OCT) images, we propose an automated computer-aided diagnostic (CAD) system capable of identifying clinically meaningful OCT features. The proposed CAD system differentiates between normal eyes and two different grades of AMD: 1) early AMD, and 2) intermediate AMD.

Methods: The proposed CAD system started with segmenting OCT layers. Then, the system performed an estimation calculation for global biomarkers from the segmented OCT images. These biomarkers are first- and second-order reflectivity, thickness, and curvature. Those features were fed into an artificial neural network (ANN) to classify these images. The extracted image-derived markers are represented using cumulative distribution function (CDF) descriptors. The constructed CDFs are then described using their statistical measures, i.e., the 10th through 90th percentiles with a 10% increment.

Results: The performance of the proposed CAD system was evaluated on 300 OCT images. Clinical grades were determined based on multi-modal imaging including OCT. The differentiation between normal eyes, and those with early or intermediate AMD using the fusion of the extracted features achieved an accuracy of 96% using the leave-one-subject-out cross-validation technique. The ANN feature fusion showed better performance compared with individual markers.

Conclusions: The proposed CAD system demonstrated a high capability to distinguish between normal eyes and two other grades of dry AMD using multiple biomarkers derived from OCT images.

ABSTRACT BODY:

Purpose: To evaluate the agreement between different commercially available instruments and UltraSound Pachymetry(USP) on measurements of Central Corneal Thickness (CCT).

Methods: An observational, cross-sectional study. Two-hundred and eighteen eyes of 109 healthy patients were enrolled, and sequentially examined by means of USP, Swept-Source Optical Coherence Tomography (SS-OCT Casia), Spectral-Domain Optical Coherence Tomography (SD-OCT Optovue), Non-Contact Specular Microscopy (NCSM) and Rotating Scheimpflug Camera (RSC). The sequence of examination was randomized, except for USP, the last to be performed. With each instrument, the same examiner acquired 3 consecutive CCT measurements per eye, and the average value was used for the analysis. Linear correlations between CCT values acquired with different instruments and USP were computed, to test the strength of measurement associations. Bland-Altman plots were drawn to describe measurement agreement between optical instruments and USP.

Results: Mean CCT values (\pm SD) were 549.82 ± 29.95 , 552.34 ± 27.74 , 538.28 ± 26.88 , 525.18 ± 29.02 , and 563.58 ± 52.73 μ m, respectively for USP, RSC, SS-OCT Casia, SD-OCT Optovue and NCSM. Figure 1 shows the correlation coefficients (r) of SS-OCT Casia, SD-OCT Optovue, RSC, NCSM vs. UPS were 0.914, 0.882, 0.902 and 0.398, respectively ($p < 0.001$ for all the correlations). When evaluating the Bland-Altman plots, as illustrated in Figure 2, SD-OCT Optovue showed the highest mean difference of CCT measurements against USP ($+24.63$ μ m), while the lowest mean difference was achieved by RSC (-2.53 μ m). Intermediate values were obtained by NCSM and SS-OCT Casia (-13.77 , $+11.54$ μ m respectively).

Conclusions: The results support the use of optical methods as a viable alternative to USP pachymetry. Of the tested instruments, RSC proved as the best alternative to USP, with a strong correlation of measurements ($r=0.902$) and a good agreement (mean difference with USP: -2.53 μ m). Furthermore, SS-OCT Casia showed a good correlation with the USP gold standard.

TITLE: Theoretical Comparison of Peripheral Defocus between Object Space and Image Space by Optical Modeling

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Wei, Medennium Inc., California, UNITED STATES|P.S. Kollbaum, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|J. Dong, Aier Eye Hospital Group, Changsha, Hubei, CHINA|

Commercial Relationships Disclosure (Abstract): Xin Wei: Commercial Relationship(s);Medennium Inc.:Code E (Employment) | Pete Kollbaum: Commercial Relationship: Code N (No Commercial Relationship) | Jun Dong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As the retina is a tilted image plane in the peripheral visual field to the incident beam, the perceived defocus on the peripheral retina in image space is different from the measured peripheral defocus in object space, where the incident beam is normal to the instrument's detection plane. This study investigates the theoretical difference between the object-space defocus and image-space defocus in the peripheral visual field.

Methods: A wide-angle model eye was constructed to match published measures of peripheral defocus in object space (Atchison et al. 2006). The measured object-space defocus was modeled by minimizing the blur size on the autorefractor's detection plane through tracing rays from the retina to the object space along the peripheral line of sight. The image-space defocus was estimated by minimizing the blur size on the tilted retina through tracing parallel rays reversely along the same lines of sight. The differences between and object-space defocus and image-space defocus were compared at 0°, 10°, 20°, and 30° for 3.75, 5.0, and 6.5 mm-diameter pupils.

Results: Along the foveal line of sight, the object-space defocus is the same as the image-space defocus. In the periphery, a significant amount of the dioptric difference is observed. In particular, for myopic eyes, the measured object-space defocus underestimates the image-space defocus. For 3.75-mm pupil, the differences are 0.3 D and 0.4 D along 20° and 30° lines of sight. The gap becomes larger as the pupil size increases. Specifically, along the 30° line of sight, the defocus difference increases to 0.6 D for a 6.5-mm pupil.

Conclusions: In the peripheral visual field, the object-space defocus and image-space defocus are different. Unlike foveal vision, to interpret image-space defocus on the peripheral retina from defocus measurements in object space, optical analysis using a wide-angle eye model is required. This step is crucial for designing wide-angle-viewing optics for the eye.

TITLE: Inhibition of ischemia/reperfusion-induced retinal capillary degeneration in mice by peptain-1

SESSION TITLE: Diabetic retinopathy/retinal pharmacology/physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.B. Nahomi, M. Nam, C. Hougen, N. Carrillo, R.H. Nagaraj, Ophthalmology, University of Colorado, Denver, Colorado, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rooban Nahomi: Commercial Relationship: Code N (No Commercial Relationship) | Mi-Hyun Nam: Commercial Relationship: Code N (No Commercial Relationship) | Clarinda Hougen: Commercial Relationship: Code N (No Commercial Relationship) | Noelle Carrillo: Commercial Relationship: Code N (No Commercial Relationship) | Ram Nagaraj: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal capillary endothelial cells undergo apoptosis in diabetic retinopathy (DR). Peptain-1 is a cell-permeable α B-crystallin-derived peptide and it exhibits strong antiapoptotic properties. Here, we investigated the ability of peptain-1 to inhibit apoptosis in cultured retinal endothelial cells and in retinal capillaries of mice subjected to retinal ischemia/reperfusion (I/R) injury.

Methods: Human retinal endothelial cells (HRECs) were treated with peptain-1 or scrambled peptides (200 μ g/ml) for 3 h, and a combination of pro-inflammatory cytokines [IFN- γ (50 U/ml) + TNF- α (20 ng/ml) + IL-1 β (20 ng/ml)] for 48 h. Twelve-week-old C57BL/6J mice were subjected to I/R injury by elevating the intraocular pressure to 120 mmHg for 60 min followed by reperfusion. Peptain-1 or scrambled peptide (500ng/ μ l of PBS) was injected intravitreally immediately after and one week after I/R injury. The PBS injected eyes were used as vehicle controls and the animals were euthanized on day 14 post-I/R injury. Abnormalities in the retinal capillaries were evaluated by staining the elastase-digested retinal blood vessels using Periodic acid–Schiff stain.

Results: Our results suggest that peptain-1 entered HRECs and blocked the pro-inflammatory cytokine-mediated apoptosis. Intravitreally injected peptain-1 was distributed throughout the retina after 4 h. The I/R injury caused a significant increase in acellular capillaries in the retina (3.5-fold when compared to controls), while intravitreally injected peptain-1, but not scrambled peptide, protected those cells from I/R injury (1.5-fold increase when compared to the control group).

Conclusions: Our study demonstrated that peptain-1 protects retinal capillary cells from I/R injury and suggests that it could be used as a therapeutic agent to prevent capillary cell death in DR.

ABSTRACT BODY:

Purpose: Although surgical glaucoma intervention has made significant progress over the past few decades, advances in stemming postoperative fibrosis have lagged. To assess the utility of novel anti-fibrotic drugs for glaucoma filtration surgery (GFS), cell culture-based models are initially employed. Currently, these models do not recapitulate the perfusion of aqueous humor (AH) through subconjunctival tissues. We engineered a perfused three-dimensional collagen-based cell culture system containing human Tenon's capsule fibroblasts (HTCFs) that continuously record afferent perfusion line pressure as an analog for intraocular pressure. Elevated transforming growth factor-beta 1 (TGFβ1) in the AH is associated with GFS failure. We evaluated the effects of perfusing exogenous TGFβ1 with or without verteporfin – a TGFβ1 pathway inhibitor – on afferent perfusion line pressure within this novel culture system.

Methods: HTCFs were cultured within 3D collagen matrices that were covalently bonded to the edges of a flow chamber slide. Cell culture media was perfused through the HTCF-containing collagen matrix at the rate of physiological AH production. Continuous afferent perfusion line pressure was recorded over a 72-hour period, and light and fluorescent microscopy were used to assess 3D cell morphology and tissue architecture within the collagen matrix and cell lysate was probed for alpha-smooth muscle actin (α-SMA) via western blot.

Results: HTCF collagen cultures perfused with TGFβ1 showed significantly elevated afferent line pressure compared to vehicle control over 72hrs, with an average pressure of 35mmHg and 17mmHg respectively (p<0.05). Confocal microscopy confirmed the presence of a 3D matrix containing HTCFs within the chamber slides. HTCFs treated with TGFβ1 demonstrated increased proliferation and organization within the chamber. Western blot revealed elevated α-SMA in TGFβ1 compared to vehicle-treated replicates. Verteporfin co-perfusion ameliorated elevated afferent line pressures and decreased α-SMA.

Conclusions: Perfused 3D collagen matrices containing HTCFs can generate outflow resistance in vitro. Addition of exogenous TGFβ1 to the perfusate causes increased outflow resistance, and inhibition of TGFβ1 through verteporfin mitigated this effect. These findings support this culture system as a platform for the discovery of anti-fibrotic drugs for glaucoma surgery.

TITLE: Ocular Pharmacokinetics of OTX-DED, a Sustained-release Intracanalicular Insert Delivering Dexamethasone, in a Canine Model

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.D. Blizzard, A. Desai, A. Driscoll, M. Cheung, M.H. Goldstein, Ocular Therapeutix Inc, Bedford, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Charles Blizzard: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Ankita Desai: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Art Driscoll: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Matthew Cheung: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment) | Michael Goldstein: Commercial Relationship(s);Ocular Therapeutix:Code E (Employment)

ABSTRACT BODY:

Purpose: Ocular surface inflammation plays a key role in all types of dry eye disease (DED) and corticosteroids are well-established as a fast-acting and effective treatment for signs and symptoms of DED. OTX-DED is an intracanalicular insert containing 0.2 mg of dexamethasone entrapped in a hydrogel matrix designed to provide sustained-release dexamethasone to the ocular surface. OTX-DED is similar to DEXTENZA (dexamethasone ophthalmic insert) 0.4 mg (indicated to treat post-ophthalmic surgery inflammation and pain) but contains lower doses of dexamethasone and a shorter intended duration of therapy. The objective of the study was to characterize the pharmacokinetics of the 0.2 mg dose of OTX-DED in a beagle model.

Methods: OTX-DED inserts containing 0.2 mg dexamethasone were placed into the canaliculus of beagle dogs. Beagle dogs were selected as the animal model since the morphometry of the nasolacrimal system provides an appropriate sized puncta and canaliculus. Tear fluid samples were collected using 10 mm Schirmer test strips from beagle dog eyes throughout the study duration after insertion of OTX-DED into the canaliculus and concentrations of dexamethasone in tear fluid were measured using liquid chromatography with tandem mass spectrometry.

Results: The average dexamethasone concentration in the beagle tear fluid of the 0.2 mg dexamethasone insert is presented in Figure 1. Results demonstrated sustained drug release into the tear fluid with concentrations declining over the study duration as the dexamethasone became depleted from the insert. This decrease in tear fluid concentration is evidenced in the 0.2 mg dose after 14 days. The profile demonstrates sustained levels of dexamethasone in the tear fluid through 7 days followed by a tapering from day 7 to 14 days with a complete release of dexamethasone from the insert by 17 days.

Conclusions: OTX-DED at a dose of 0.2 mg delivered dexamethasone to the ocular surface for approximately 14 days. Comparatively, DEXTENZA (0.4 mg) delivered dexamethasone to the ocular surface up to 28 days. In vivo dexamethasone release data indicates a shorter duration of drug release for the 0.2 mg dose compared to the 0.4 mg from the hydrogel insert in the beagle model.

ABSTRACT BODY:

Purpose: Primary congenital glaucoma (PCG) is an important cause of irreversible childhood blindness. LTBP2 mutations have been identified as causative for both human and feline PCG, but mechanisms of intraocular pressure (IOP) elevation remain unknown. We hypothesized that LTBP2 mutation causes pathology in the conventional aqueous outflow pathway. Ultrastructure of the trabecular meshwork (TM) was studied by transmission electron microscopy (TEM) and aqueous angiography (AA) evaluated more distal components of the outflow pathway in feline eyes, prior to and at the onset of significant IOP elevation.

Methods: Eyes from 11 LTBP2^{-/-} cats (2 neonates and 9 at 10- 12wks) and 6 age-matched control eyes (1 neonate and 5 at 10-12wks) were paraformaldehyde fixed, anterior segments dissected, and sectors post-fixed in glutaraldehyde, osmicated and processed and sectioned for TEM. To evaluate distal aqueous outflow pathways, indocyanine green AA was performed in 1 PCG (10- 12 wks) and 5 aged-matched control eyes <2hrs post-mortem, imaged by Spectralis HRA+OCT (Heidelberg Engineering).

Results: The angle appeared open and TM and angular aqueous plexus (AAP; analogous to Schlemm's canal) were visualized by TEM in both normal and mutant cats. In neonates, the still immature TM and AAP were morphologically comparable between PCG and control eyes. However, at 10-12wks, differences were evident between the two groups. In eyes of PCG cats, TM cells had an elongated, attenuated appearance and the inter-trabecular spaces of the corneoscleral TM appeared collapsed, with lower percentage of open space (P= 0.0006) relative to controls. Subjectively, TM beams appeared similar between groups, with regular collagen bundles and elastin cores, but less fibrillar material surrounding the core structure of the more proximal TM beams in PCG. The AAP and distal outflow channels still appeared patent in the juvenile PCG cats as supported by AA and OCT. All 10-12 wk-old cats regardless of disease status had nearly 360° circum-limbal AA signal, visible within <5 mins of commencing tracer perfusion.

Conclusions: In this model of PCG related to LTBP2 mutation, TM, inter-trabecular spaces, AAP and more distal outflow pathways appear normal at birth. Subsequent development of TM cellular pathology and TM and JCT ECM pathology coincides with onset of IOP elevation.

TITLE: Phase resolved OCT to measure laser induced refractive index change (LIRIC) in hydrogel

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Michalko, L. Zheleznyak, Clerio Vision, Inc., Rochester, New York, UNITED STATES|V. Pandiyan, R. Sabesan, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aaron Michalko: Commercial Relationship(s);Clerio Vision, Inc.:Code E (Employment) | Vimal Prabhu Pandiyan: Commercial Relationship(s);University of Washington:Code P (Patent) | Ramkumar Sabesan: Commercial Relationship(s);University of Washington:Code P (Patent) | Len Zheleznyak: Commercial Relationship(s);Clerio Vision, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: LIRIC is a non-invasive method for correcting aberrations in hydrogels, IOLs and the cornea. As such, the need exists for non-destructive metrology of LIRIC-induced optical phase change. Here we demonstrate the feasibility and validation of parallel phase resolved OCT for measurements of optical phase change induced by LIRIC in hydrogel.

Methods: To produce the LIRIC sample, a femtosecond laser was focused inside a 0.5 mm thick hydrogel button (Contamac, Acofilcon A) and scanned throughout a single layer. Seven rectangular regions (0.1 x 0.4 mm each) of LIRIC piston wavefronts were induced. Each region was written at a distinct laser power (0.7 to 1.0 W, in 0.05 W steps). The LIRIC-induced phase shift was subsequently measured in two methods: (a) phase-resolved line-scan OCT and (b) phase-shifting interferometry (PSI). The line-scan, spectral domain OCT ($\lambda=820$ nm, $\Delta\lambda=80$ nm) was used to image a 3.5x2.5 mm field-of-view on the hydrogel. The 3D phase distribution was obtained in the reconstructed complex volume after segmenting the LIRIC layer in depth. The PSI consisted of a Mach-Zehnder interferometer ($\lambda=632$ nm) with a piezo-driven phase-shifting mirror in the reference arm. LIRIC was quantified from both OCT and PSI by computing the difference in optical phase between written and unwritten regions of the hydrogel.

Results: The intended spatial profile of the LIRIC-induced wavefront was readily reproduced in both measurements. Both measurement techniques (OCT and PSI) showed a predictable increase in the magnitude of phase change with increasing laser power. With OCT, it ranged from 76 ± 58 to 376 ± 91 nm at 0.7 and 1.0 W, respectively. With PSI, it ranged from 61 ± 29 to 334 ± 40 nm. The OCT and PSI measurements were highly correlated (R-squared = 0.99).

Conclusions: Phase resolved OCT was shown to accurately measure optical phase change in hydrogels induced via femtosecond laser processing (LIRIC).

SUBMITTER (NAME ONLY): Heather Chandler

TITLE: Platelet-Derived Growth Factor Receptor β Promotes Cataract Formation

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H.L. Chandler, J.A. Geisler, G.M. Sizemore, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Heather Chandler: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Geisler: Commercial Relationship: Code N (No Commercial Relationship) | Gina Sizemore: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate how in vivo hyperactivation of platelet-derived growth factor receptor (PDGFR) β alters lens homeostasis and induces epithelial-mesenchymal transition (EMT) in lens epithelial cells (LEC).

Methods: In a mouse model of mesenchymal-specific PDGFR β activation using the Fsp-cre transgene (herein referred to as β KI mice), lens phenotype was monitored over time. Standard histologic processing and immunohistochemistry (IHC) were used to evaluate morphologic changes and expression of PDGFR β and α -smooth muscle actin (SMA) in the lens.

Results: β KI mice began to develop spontaneous cataracts at 16 weeks of age while control mice did not (n=6). Histologic evaluation of lenses from β KI mice at approximately 26 weeks of age (n=6) demonstrated LEC proliferation and EMT with extracellular matrix deposition and fibrosis. By comparison, lenses from control mice were histologically normal. Expression of Fsp1-cre in LEC was confirmed using a Rosa reporter and expression of PDGFR β in LEC was confirmed with IHC. As mice continued to age (up to 67-72 weeks; n=8), cataracts advanced and became hypermature in the β KI mice, while control lenses remained transparent. Cataractous lenses were positive for α SMA expression, as observed with IHC, while control lenses were negative. No differences in outcome measures were observed when comparing males and females.

Conclusions: Overall, the pronounced spontaneous cataract formation in β KI mice compared to age-matched control mice, and resultant histologic changes, indicate that PDGFR β activation is important for induction of EMT in LEC. Further, hyperactivation of PDGFR β is a primary contributor of cataract formation.

ABSTRACT BODY:

Purpose: Prostaglandin analogues and beta-blockers are effective intraocular pressure (IOP) lowering drugs commonly used for glaucoma. However, there remain a sizeable number of nonresponders to these treatments. This study used both iCare and pneumatonometry to identify the IOP response to latanoprost and timolol under monotherapy.

Methods: We examined 212 eyes from 106 ocular normotensive, non-glaucomatous volunteers (76% female, 55.5 ± 8.9 years of age) from the EDEN consortium. At baseline, IOP was measured by iCare at 9AM and 11AM, and pneumatonometry at 11AM. Subjects were randomized and treated in both eyes (OU) with either 0.005% latanoprost once daily or 0.5% timolol twice daily for 7 days, with measurements repeated on day 8 of each treatment. After a 6-week washout, subjects switched drug arms. IOP-responders were those having an IOP reduction of $>15\%$ OU, while mixed responders had an IOP reduction of $>15\%$ in one eye (OD or OS). Treatment effects and intereye correlations on IOP were analyzed using Spearman's rho, two-tailed paired t-tests and Fisher's Exact Test.

Results: As compared to baseline, timolol and latanoprost effectively lowered IOP by 13% OD (14% OS) and 17% OD (18% OS), respectively ($p < 0.0001$, pneumatonometry). Twenty-two subjects (21%) failed to respond to either latanoprost or timolol OU. IOP response to timolol did not predict IOP response to latanoprost, however, latanoprost responders tended to also respond to timolol. More subjects were IOP-responders OU when taking latanoprost compared to timolol ($p < 0.007$), with 54% responding to latanoprost and 28% responding to timolol (pneumatometry) (Figure 1). In patients given timolol, a higher non-response rate was found when measuring with pneumatonometry as opposed to iCare ($p = 0.037$) (Figure 1).

Conclusions: In this group of healthy subjects, a significant amount did not respond to either timolol or latanoprost. Even though the drugs represent two different mechanisms of action (timolol decreasing aqueous flow and latanoprost increasing uveoscleral outflow), non-response to one drug did not predict response to another. A new study is underway to determine if this pattern persists in patients with ocular hypertension.

ABSTRACT BODY:

Purpose: To compare the odds of glaucoma surgery in minority racial/ethnic groups against that of white patients in the American Academy of Ophthalmology (AAO) Intelligent Research in Sight (IRIS) Registry database.

Methods: This was a cross-sectional study using 2015-2017 IRIS Registry public use data of glaucoma patients from over 3,000 practices across the United States. The outcome of interest was three-year prevalence of glaucoma surgery by type, including incisional surgery (IS) (trabeculectomy, tube shunts), minimally invasive glaucoma surgery (MIGS) (canaloplasty, trabecular/suprachoroidal bypass, transscleral cyclophotocoagulation), and laser surgery (LS) (laser trabeculoplasty). The primary exposure was race/ethnicity, including American Indian/Alaska Native (AI/AN), Asian, Black, Latino, Multi, Native Hawaiian/Pacific Islander (NH/PI), white, and unknown. Logistic regression modeling was performed to estimate odds of IS, MIGS, and LS by racial/ethnic group, controlling for age, sex, insurance type, geographic region, and glaucoma severity.

Results: The study sample included a total of 7,566,572 unique patients, of whom 74,028 (0.98%) received IS, 119,410 (1.58%) MIGS, 236,902 (3.13%) LS, and 7,172,833 (94.80%) received no surgery. Racial/ethnic groups with decreased odds of all glaucoma surgery types compared to white patients included Asians (IS odds ratio [OR]: 0.80, 95% confidence interval [95% CI]: 0.76-0.84; MIGS OR: 0.79, 95% CI: 0.76-0.82, LS OR: 0.88, 95% CI: 0.81-0.95), Latinos (IS OR: 0.97, 95% CI: 0.94-0.99; MIGS OR: 0.92, 95% CI: 0.90-0.94; LS OR: 0.95, 95% CI: 0.94-0.97), NH/PI (IS OR: 0.52, 95% CI: 0.40-0.69; MIGS OR: 0.66, 95% CI: 0.55-0.80; LS OR: 0.75, 95% CI: 0.66-0.86), and unknown race (IS OR: 0.65, 95% CI: 0.64-0.67; MIGS OR: 0.81, 95% CI: 0.79-0.82; LS OR: 0.73, 95% CI: 0.72-0.75). Compared to white patients, Black patients had increased odds of IS (OR: 1.26, 95% CI: 1.23-1.28), decreased odds of LS (OR: 0.96, 95% CI: 0.95-0.98), and no difference in odds of MIGS (OR: 1.01, 95% CI: 0.99-1.03).

Conclusions: In the 2015-2017 AAO IRIS Registry sample, most minority racial/ethnic groups (Asians, Latinos, NH/PI, unknown race) were found to have decreased odds of all glaucoma surgery types when compared to white patients, after adjusting for covariates. Additional population-based studies are necessary to further examine differences in rates of glaucoma surgery across racial/ethnic groups.

ABSTRACT BODY:

Purpose: Transforming Growth Factor beta 2 (TGF- β 2) has been widely described as a key cytokine involved in the pathophysiology of ocular disease. ISTH0036 is a 14-mer modified antisense oligodeoxynucleotide selectively targeting TGF- β 2 mRNA. It exhibits potent activity in murine models of choroidal neovascularization (CNV). ISTH0036 induced a decrease in neovascularization, vascular leakage, fibrotic development, as well as blockage of epithelial-to-mesenchymal transition. The presented studies explored pharmacokinetics (PK), pharmacodynamics (PD), and toxicity in rabbits and non-human primates (NHP) and long-term safety in a first-in human Phase1 trial to support further developments.

Methods: Long-term safety in Phase 1 was assessed after single ITV injection up to 12mo. PK, ocular tissue distribution, PD (target engagement), and long-term toxicity were studied upon single and repeated IVT administration(s) in rabbits and Cynomolgus monkeys. Results were compared with observations in the CNV model to support development in retinal diseases.

Results: In the Phase 1 study, single ITV injection of ISTH0036 in patients after Trabeculectomy was well tolerated and safe out to 12-months. One subject with several (preexisting) risk factors developed cataract. Rabbits and NHPs were treated with single or repeated IVT administration(s) for up to 9mo. Toxicology profile was established and pointed at lens opacification as dose-limiting toxicity in both species. Long-lasting target engagement was observed in relevant eye tissues in animals; with TGF- β 2 mRNA downregulation in retina and lens, and TGF- β 2 protein reduction in vitreous humor (VH). Interestingly, evidence of much longer target engagement (up to 4 months, after single drug administration) was observed in NHPs.

Conclusions: Compared tests of ISTH0036 in rabbits and NHPs resulted in similar toxicity profile, although with higher dose-dependent sensitivity observed in Rabbits. Pronounced and long-lasting time- and dose-dependent ocular tissue distribution and target engagement in retina and VH was observed, with longer effects observed in NHPs. Aligned with biological efficacy demonstrated in preclinical models, and preliminary evidence of safety in a first-in-human study, these results strongly support the planned Phase 2 development of ISTH0036 in wAMD and DME.

ABSTRACT BODY:

Purpose: The Port Delivery System with ranibizumab (PDS) is an investigational drug delivery system for the continuous intravitreal release of ranibizumab (RBZ) via a permanent indwelling intraocular implant. The phase 2 Ladder and phase 3 Archway trials demonstrated that treatment with PDS with a customized formulation of RBZ 100 mg/mL (PDS 100 mg/mL) was generally well tolerated and had comparable efficacy to monthly intravitreal RBZ. Immunogenicity is important in assessing safety and efficacy of recombinant therapeutics and was monitored in both trials.

Methods: Ladder (NCT02510794) patients (pts) were randomized to PDS with RBZ 10, 40, or 100 mg/mL, or monthly intravitreal RBZ 0.5 mg (monthly RBZ). Archway (NCT03677934) pts were randomized to treatment with PDS 100 mg/mL with fixed 24-week refill exchanges (Q24W) or monthly RBZ (Q4W). As both trials enrolled pts with nAMD responsive to anti-VEGF treatment, immunogenicity analyses focused on incidence of treatment-emergent (TE) anti-drug antibodies (ADAs) and neutralizing antibodies (NAbs). We report ADA status in Ladder (end of study) and Archway (primary analysis) and the impact of ADA status on serum PK at week 24, and on visual and safety outcomes at week 40 in Archway.

Results: In Ladder, there was no apparent dose response on incidence of TE-ADAs across PDS arms (6.9%-15.3%). Incidences of TE-ADAs with PDS 100 mg/mL were relatively low in Ladder (15.3% [9/59]) and Archway (11.7% [29/247]), and comparable or slightly higher than monthly RBZ (Ladder: 14.6% [6/41]; Archway: 5.5% [9/164]). Overall incidences of TE-NAbs were low with both monthly RBZ and PDS 100 mg/mL (Ladder: 0%-3.4%; Archway: 2.4%-5.3%). In Archway, over 40 weeks, presence of ADAs in PDS 100 mg/mL pts did not appear to impact mean (95% CI) change from baseline in BCVA versus ADA negative pts (0.0 [-2.8, 2.8] vs 0.2 [-1.0, 1.5] ETDRS letters, respectively) or postoperative (>37 days) incidence of ocular AEs (41.2% [14/34] vs 38.0% [81/213]), intraocular inflammation (including endophthalmitis; 2.9% [1/34] vs 5.6% [12/213]), or iritis (0% [0/34] vs 1.4% [3/213]); there was no apparent trend for an effect of ADA status on serum PK or incidence of non-ocular AEs.

Conclusions: The immunogenicity profile of PDS 100 mg/mL was comparable to that of monthly RBZ, with no apparent impact of ADAs on outcomes. These data further support the efficacy and tolerability of PDS 100 mg/mL Q24W in nAMD.

ABSTRACT BODY:

Purpose: Self-Examination Low-Cost Full-Field Optical Coherence Tomography (SELFF-OCT) is a novel OCT technology that was specifically designed for home monitoring of age-related macular degeneration (AMD). First clinical findings have been reported before [1]. This trial investigates an improved prototype for AMD patients and focusses on device operability and diagnostic accuracy compared with established spectral-domain OCT (SD-OCT). [1] von der Burchard C et al. Self-examination low-cost full-field OCT (SELFF-OCT) for patients with various macular diseases. Graefes Arch Clin Exp Ophthalmol, 2020, DOI: 10.1007/s00417-020-05035-6.

Methods: We performed a cross-sectional study in patients with age-related macular degeneration. Patients received short training in device handling and then performed multiple self-scans with the SELFF-OCT according to a predefined protocol. Additionally, all eyes were examined with standard SD-OCT, performed by medical personnel. All images were graded in a reading center by at least 2 blinded investigators for different biomarkers and the necessity of anti-VEGF treatment.

Results: In total, 85 eyes of 45 patients with AMD were measured with SELFF-OCT. Compared to prior prototypes, advancements in technology and an improved patient interface enhanced image quality and reduced motion artifacts. In 86% of all examined eyes, OCT self-acquisition resulted in interpretable retinal OCT volume scans. In these patients, the sensitivity for detection of anti-VEGF treatment indication was 0.94 [confidence interval 0.79-0.99] and specificity 0.95 [0.82-0.99]. Sensitivity and specificity for the detection of single biomarkers were 0.9/0.98 for subretinal fluid, 0.57/0.95 for intraretinal fluid and 0.76/0.95 for pigment epithelium detachment.

Conclusions: SELFF-OCT was used successfully for retinal self-examination in most patients, and it could become a valuable tool for retinal home-monitoring in the future. Improvements are in progress to reduce device size and to improve handling, image quality and success rates.

TITLE: Ex vivo ophthalmic surgical guidance using intraoperative spectrally encoded coherence tomography and reflectometry (iSECTR)

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Ringel, E. Tang, Y. Tao, Vanderbilt University, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Morgan Ringel: Commercial Relationship: Code N (No Commercial Relationship) | Eric Tang: Commercial Relationship: Code N (No Commercial Relationship) | Yuankai Tao: Commercial Relationship(s);Vanderbilt University:Code P (Patent);Leica Microsystems:Code R (Recipient)

ABSTRACT BODY:

Purpose: Intraoperative optical coherence tomography (iOCT) during ophthalmic surgeries provides high-resolution, volumetric imaging, which benefits surgical decision-making. However, live 4D visualization of surgical maneuvers remains challenging due to the OCT field-of-view (FOV) requiring manual adjustment and tracking. Here, we demonstrate a multimodal, intraoperative spectrally encoded coherence tomography and reflectometry (iSECTR) imaging system that combines OCT and en face reflectance imaging. We believe that this system addresses current limitations in iOCT imaging by enabling registration and tracking of serial OCT volumes with surgical regions-of-interest using high-speed en face images of the surgical field.

Methods: The spectrally encoded reflectometry (SER) and OCT imaging relays were designed to share the objective lens of a Zeiss VISU 200 surgical microscope and a binocular indirect ophthalmomicroscope (Oculus BIOM 3). A custom scan-head was designed to contain the iSECTR optics, scanning galvanometers, fold mirrors, and optomechanics (Fig. 1(A)). iSECTR was folded into the surgical microscope imaging path using a dichroic mirror and a custom 400 kHz 1060 nm swept-source (Axsun) engine with a 2 GS/s per channel digitizer was used to simultaneously acquire en face SER and cross-sectional OCT images.

Results: Retinal surgery was simulated in ex vivo porcine eyes using 25G forceps. SER and OCT projection images show FOV co-registration with the surgical microscope FOV captured with a documentation camera. iSECTR volumes were acquired with 2560x500x2500 pix. (spectral x lateral x lateral). All three images show the surgical forceps and a prominent retinal vessel. The cross-sectional OCT view shows the forceps and surrounding retinal layers (Fig. 1(B)-(E)).

Conclusions: An iSECTR system featuring a custom scan-head enclosure was integrated with a Zeiss VISU 200 surgical microscope, and the system was used to image simulated retinal surgery in ex vivo porcine eyes. Clinical translation of iSECTR will benefit ophthalmic surgical guidance by enabling region-of-interest tracking iOCT imaging of surgical maneuvers and tissue dynamics.

ABSTRACT BODY:

Purpose: We sought to analyze the changes in clinical care following the restrictions that were implemented in Massachusetts in response to COVID-19 pandemic as well as to depict the visual outcomes in patients receiving intravitreal injections as part of a treatment regimen for either exudative age-related macular degeneration (AMD), diabetic retinopathy (DR), central or branch retinal vein occlusion (CRVO, BRVO).

Methods: A retrospective analysis of the intravitreal injection clinics of three retina specialists at Massachusetts Eye and Ear from December 2019 to June 2020 was performed. Demographic data of patients with either wet AMD, DR, CRVO or BRVO were collected. Descriptive statistics were used to quantitatively summarize the features of our cohort and box plots to illustrate the spread and differences of visual acuity among groups over time.

Results: A total of 1,086 visits were scheduled within this period and more than a quarter of these visits were not completed [801 (74%) completed vs 285 (26%) cancel or no show; $p=0.000$]. The mean age of our cohort was 72.5 ± 13.2 years (males: 72.48 ± 13.2 ; females: 74 ± 12.4 ; $p=0.0524$). Out of 259 cancel visits, 240 visits (93%) were canceled by the patients and 19 visits (7%) by the provider/institution ($p=0.000$). There was no significant difference in the appointment status (completed, cancel, no show) among males and females, among different providers, or diagnoses ($p=0.225$, $p=0.131$ and $p=0.234$ respectively). Asians and Caucasians were more likely to complete their visits (80% and 74% respectively) compared to patients of Hispanic, African American and American Indian ethnicities where more cancel/no show visits were observed (40%, 29% and 29% respectively; $p=0.002$). The highest numbers of cancel/no show appointments were reported in March (48.8%) and April (45.6%) and were significantly different when compared to the other months ($p=0.000$).

Conclusions: Intravitreal therapy is the standard care for a variety of retinal disorders and adherence to the proposed treatment regimen is important to maximize the visual acuity benefits and maintain the gains in the long term. In this cohort it was noted that vast majority of visits were canceled by the patients whereas underrepresented minorities were more likely not to complete their scheduled visits which could be partially explained by the fact that these groups are also disproportionately affected by COVID-19.

TITLE: TRPML1 channels activation facilitates lysosomal exocytosis and reduces autofluorescent lysosomal accumulations, opsin retention and lipid peroxidation in RPE cells compromised by chloroquine

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Mas Gomez, W. Lu, C.H. Mitchell, Department of Basic & Translational Sciences, University of Pennsylvania School of Dental Medicine, Philadelphia, Pennsylvania, UNITED STATES|C.H. Mitchell, Department of Ophthalmology, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nestor Mas Gomez: Commercial Relationship: Code N (No Commercial Relationship) | Wennan Lu: Commercial Relationship: Code N (No Commercial Relationship) | Claire Mitchell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Excessive lysosomal accumulations are associated with multiple neurodegenerations including age-related macular degeneration. Treatment to reduce these accumulations is of broad interest. Lysosomes store calcium, and the regulated efflux through TRPML1 channels contributes to the fusion of lysosomal membranes with the plasma membrane during lysosomal exocytosis. We previously identified functional TRPML1 channels on RPE lysosomes. Here we ask whether TRPML1 activation can facilitate lysosomal exocytosis and clearance of accumulations in RPE cells

Methods: Experiments were performed on confluent aged ARPE-19 cells. Autofluorescence (AF) at 488 ex/560 em was determined in a Fluoroskan plate reader and microscopically. Extracellular acid phosphatase (AP) was measured with a standard colorimetric kit. Cells were fed with bovine photoreceptor outer segments (POS) using a pulse chase protocol to minimize interference in phagocytosis; cells were fed 1×10^6 POS/ml for 2 h (pulse), medium alone for 2 h (chase), then 20 h in control or chloroquine (CHQ) medium. Opsin levels were determined with immunoblots. Lipid peroxidation were determined from measurements of Bodipy-C11

Results: Cellular accumulations were induced by exposing ARPE-19 cells to CHQ for 7 days followed by 24 hr exposure to U18666A (U18). CHQ/U18 treatment increased AF accumulations. Exposure of these cells to TRPML1 agonist ML-SA1 reduced AF levels. To determine whether ML-SA1 increased lysosomal exocytosis, extracellular levels of lysosomal AP were determined. ML-SA1 increased extracellular levels of AP in both control and CHQ-treated cells, suggesting ML-SA1 triggered lysosomal exocytosis. Furthermore, the effect of TRPML1 on opsin turnover was investigated. RPE treated with CHQ and loaded with POS showed a significant rise in opsin on immunoblots. Critically, ML-SA1 decreased retention of opsin in CHQ-treated cells.

Conclusions: Activation of TRPML1 in compromised RPE cells increased lysosomal exocytosis and decreased lysosomal autofluorescence. In cells loaded with POS, CHQ treatment increased opsin retention and lipid peroxidation, while TRPML1 activation decreased both. Further investigation is needed to identify how TRPML1 activation enhances lysosomal clearance in compromised RPE cells

ABSTRACT BODY:

Purpose: Health seeking behaviour is influenced by driving factors and barriers to action. It has been suggested that such behaviour may have been linked to the negative impact of the COVID-19 pandemic on health care service provision and delivery. This study aimed to explore the health seeking beliefs held by the British public in relation to eye symptoms, and assess how these were influenced by the first COVID-19 lockdown.

Methods: Methods: An anonymous web-based survey was made publicly available and disseminated through mailing lists and social media between June and August 2020. In addition to baseline demographics (including postcode-derived indices of deprivation), the survey sought respondents views on the severity and urgency of the need for medical review for four ophthalmic (dry eye disease, conjunctivitis, microbial keratitis and painless vision loss) scenarios on a five-point scale. Regarding urgency of medical review, respondents were asked to answer questions twice: once ignoring the COVID-19 pandemic, and once taking this into account.

Results: A total of 402 respondents completed the survey, with a mean age of 61.6 years, and of whom 253 (63.1%) were female and 348 (87.7%) of white ethnicity. Scores for symptom severity and urgency of medical review increased significantly with the severity of the clinical scenario (both $p < 0.001$). However, respondents gave significantly lower scores for urgency of medical attention when accounting for the COVID-19 pandemic (compared to no pandemic) for all scenarios (all $p < 0.001$). Younger age, greater deprivation and non-white ethnicity were correlated with a lower perception of seriousness and urgency of medical attention.

Conclusions: During the first UK lockdown of the COVID-19 pandemic, reduced urgency of medical review for ocular and systemic pathologies was reported in response to the pandemic, and represents a barrier to health seeking behaviour. This has the potential to critically delay medical review and timely management, negatively impacting patient outcomes. Younger individuals with higher deprivation and non-white ethnic backgrounds may be at greater risk of this.

ABSTRACT BODY:

Purpose: Congenital ocular malformations, such as microphthalmia, anophthalmia, and coloboma (MAC), are responsible for 25% of childhood blindness. Focal Dermal Hypoplasia is an x-linked dominant disorder that is often associated with MAC and caused by mutations in Porcn, a membrane bound O-acyl transferase that is required for the palmitoylation of Wnt ligands. Previous studies in frogs and zebrafish have demonstrated that the non-canonical Wnt pathway is essential for early eye formation. However, little about the role of non-canonical Wnt signaling in eye development is known in mammals. Here, we inactivate Porcn in mouse to interfere with non-canonical Wnt signaling and examine its effect on early eye formation and tissue patterning.

Methods: PORCN is inactivated in mouse embryos at embryonic day (E)6.5-E7.5 by tamoxifen-inducible, ubiquitous ROSA26^{CreER}. Affected male embryos with conditional deletion of Porcn are analyzed by immunohistochemistry (minimum n=3) using antibodies for eye field developmental markers PAX6, SIX3, LHX2, RX, OTX2 and the optic vesicle markers MITF and VSX2.

Results: Porcn mutants show a range of defects, depending on the time of inactivation. Tamoxifen treatment at E7.5 results in arrested eye morphogenesis in less severely affected Porcn mutants; the optic vesicle is reduced and does not invaginate to form an optic cup. At E10.5, MITF and VSX2 labeling reveals lack of expression in the RPE and neural retina, respectively. Similarly, OTX2 is not detectable in the optic vesicle. The pan-ocular marker PAX6 is expressed at slightly lower level in the mutant optic vesicle and lens ectoderm. Surprisingly, Six3 expression is detectable in the retina and lens ectoderm of Porcn mutants, indicative of eye field formation. Currently, we are investigating expression of additional ocular genes critical for ocular morphogenesis and patterning (e.g. LHX2, RX, COUPTF2, PAX2), including at earlier stages. In addition, our goal is to rescue ocular defects in Porcn mutants in vitro by non-canonical Wnt activation.

Conclusions: Porcn is required for proper formation of the optic vesicle and differentiation into retina and RPE, possibly to regulate transition from the eye field to optic vesicle stage. We predict that this occurs via non-canonical Wnt signaling.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity and many other pediatric retinal diseases have a vascular etiology. However, most commercial OCT angiography (OCTA) systems are large table systems that cannot be used to image pediatric or other non-cooperative subjects. Even if they could be brought to the bed side, OCTA image acquisition with these systems takes tens of seconds as they use relatively slow 100 kHz engines. To address this need we have previously reported a 200 kHz handheld OCTA (HH-OCTA) system, allowing for capture of OCTA images from infants at the bedside in 3 to 6 seconds. This work describes the continued development of the HH-OCTA system via the integration of 400 kHz OCT engine

Methods: We developed a 400 kHz OCT engine based on a 400 kHz VCSEL laser (Thorlabs inc.) and used our previously reported HH-OCTA scanner that has an ergonomic grip optimized for supine imaging, $\pm 10D$ refractive error correction, and a $30 \times 30^\circ$ degree field of view. OCT and OCTA images were taken from consented, healthy volunteers lying in a supine position. OCT images were taken over an $\sim 10 \times 10$ mm field of view using a 950 A-scan/B-scan, 128 B-scan/volume scan protocol (0.374s), and a 950 A-scan/B-scan and 4x averaged 128 B-scan protocol (1.495s). OCTA images were acquired over an $\sim 6 \times 3$ mm field of view with 500 A-scans/ B-scan, 250 lateral locations sampled with 4 repeated B-scans (1.8s). OCTA images were generated in post processing using speckle variance and graph cut based segmentation was used to create projections of the vasculature. Optical power was set in accordance with the ANSI Z80.36 standard Light Hazard Protection for Ophthalmic Instruments and all human subjects research was performed under protocols approved by the Duke University institutional review board in accordance with the Declaration of Helsinki.

Results: Representative HH-OCT and OCTA images from normal subjects are shown in fig. 1.

Conclusions: We demonstrated a 400 kHz HH-OCT probe capable of acquisition of OCTA images from supine subjects in 1.8s. We believe that the increase in speed for both structural OCT and OCTA images will facilitate bedside imaging in infants.

ABSTRACT BODY:

Purpose: To quantify and compare the clinical evaluation of intra- and subretinal fluid (IRF, SRF) change between eye care professionals with different degrees of experience in retinal diseases in spectral-domain optical coherence tomography (SD-OCT) images of neovascular age-related macular degeneration (nAMD) patients.

Methods: We included SD-OCT data of patients who were diagnosed with nAMD and treated at our retina department and are part of the Vienna Imaging Biomarker Eye Study (VIBES) registry. There were 28 to 120 days between two visits and anti-VEGF injections were either given between the two visits or on the day of the second visit. A fully automated algorithm based on deep learning was used to quantify the change in IRF/SRF between visits. Firstly, the segmentation performance and clinical utility of each scan was determined by manual inspection. Secondly, retina specialists, ophthalmology residents, ophthalmologists working in private practice and orthoptists were asked to grade the IRF/SRF change between visits, following a standardized questionnaire.

Results: SD-OCT volumes of 230 visit pairs were included in our analysis. Manual inspection of all scans revealed a detectable fluid change of approximately 5nl. We therefore excluded scans with a fluid volume of <5nl at the first visit and fluid change of <5nl to the follow-up visit.

Conclusions: Artificial intelligence allows a precise assessment of fluid change over time, and thus an optimized management of macular edema. Our study determines the variability in the clinical assessment of retinal fluid change and the significance of retina- and OCT related experience for an accurate clinical evaluation of macular edema.

ABSTRACT BODY:

Purpose: Sulfur mustard (SM) exposure to the eye causes many keratopathies and vision loss. The damage to various corneal components and underlying mechanisms are still largely unknown. This study investigated the effects of SM on the corneal epithelial basement membrane and epithelial-stromal attachment using a human corneal ex vivo organ culture model.

Methods: An ex vivo human cornea organ culture model available in the lab was used. Thirty donor healthy human corneas suitable for research were purchased from various Eye Banks. Corneas were placed into a well of a standard 6-well tissue culture dishes on a sterile customized corneal conformer to maintain in culture for long durations. Each well was fed with MEM medium having 10% FBS (4.5-5.5ml), allowing corneal endothelium to continually bathed in medium with an air-lift environment. The axial cornea air-exposed received one drop of medium every 8h to prevent corneal desiccation. Cultures were maintained in a humidified 5% CO₂ incubator at 37°C for 2-4 weeks in +/- SM analog (200µM of Nitrogen Mustard). An eight mm circular filter disc was used for SM exposure to the cornea. Standard H&E staining, real-time quantitative RT-PCR (qRT-PCR), western blotting, and Immunofluorescence (IFC) techniques were used to study cellular and molecular parameters.

Results: The vehicle-treated human cornea revealed normal corneal epithelium, epithelial basement membrane, epithelial-stromal association, stromal arrangement, and endothelium in H&E staining. Conversely, SM exposure to cornea demonstrated varying levels of damage to the corneal epithelium, epithelial basement membrane, epithelial-stromal association, stromal arrangement, and endothelium under similar culture conditions in H&E staining. The IFC and qRT-PCR data showed a significant change in the level of integrin β 4 ($p<0.001$), Collagen XVII ($p<0.01$), and Col IV ($p<0.001$) compared to vehicle-treated control. Tested proteins play a crucial role in the maintenance of normal corneal architecture and function. The Western blot analyses validated findings of the IHC and qRT-PCR.

Conclusions: Mustard gas exposure to the human eye compromises corneal basement membrane and epithelial-stromal attachment crucial for maintaining refraction.

ABSTRACT BODY:

Purpose: Previous studies have established that convergence insufficiency and accommodative dysfunction are diagnosed more frequently following concussion as compared to the general population. However, conclusions are limited due to inconsistent diagnostic criteria and a lack of non-concussed control data. We compare the frequency of vergence deficits (VD, i.e., convergence insufficiency, convergence excess, and fusional vergence deficit) and accommodation deficits (AD) in concussed individuals to control participants using both established clinical criteria (ECC) and the distribution of normal clinical data.

Methods: Retrospective cohort study at Boston Children's Hospital. Non-concussed control group: n = 30 (median age: 9.2 years, IQR: 8.1 -10.6.), evaluated in 2016, Concussed group: n = 256 (median age: 15.2 years, IQR: 13.6 - 16.8) evaluated from 2012 to 2020. Both groups had visual acuity 20/30 or better in each eye; complete clinical assessment of vergence and accommodation; no strabismus, amblyopia, or other ocular pathology. Normal accommodation was determined by Hofstetter's formula ($15 - 0.25 \times \text{age}$). VD and AD were identified using both of the following methods: 1) ECC and 2) clinical findings falling outside the 95th percentile of control group criteria (CGC). Fischer's exact test and Chi-square Test assessed group differences.

Results: In the ECC in control data, 67% failed near point of convergence (NPC) (≥ 6 cms) and 33% failed monocular accommodative facility (MAF) (≥ 6 cycles per minute (cpm)). There was a difference in frequency of AD (33 vs 13%, $p=0.02$), but no change in VD (7 vs 7%, $p>0.05$) between ECC vs CGC respectively in controls. In the concussed group, the failure rate was higher for NPC (79 vs 52%, $p=0.001$), convergence amplitude (48 vs 59%, $p<0.01$) and MAF (64 vs 35%, $p<0.001$) using ECC vs CGC respectively. There was a difference in frequency of AD (81 vs 72%, $p=0.015$), but no change in VD (51 vs 50%) between ECC and CGC respectively in the concussed group.

Conclusions: We found using ECC for NPC ≥ 6 cm and accommodative facility ≥ 6 cpm resulted in higher failure rates in the control and concussed groups than would be expected. The differences between ECC and CGC emphasize the need for a larger sample of normative data and careful consideration of criteria used for diagnosis of visual deficits in concussion.

ABSTRACT BODY:

Purpose: Growth/differentiation factor 15 (GDF-15), which belongs to the TGF-beta superfamily of growth factors, is recognized as an all-cause mortality/stress marker and prognostic protein of various diseases. GDF-15 also serves as a key regulator of various cellular pathways. Having detected the presence of GDF-15 in human and mouse aqueous humor (AH) samples and secretion of GDF-15 by trabecular meshwork (TM) cells, in this study we evaluated the levels of GDF-15 in both AH and serum samples obtained from primary open-angle glaucoma patients.

Methods: AH and blood samples were collected following informed consent from glaucoma and cataract patients who underwent surgery at the Duke Eye Center. Serum samples and cell/tissue debris free AH samples were analyzed for GDF-15 content by ELISA. Data were compared between age and gender matched glaucoma and cataract patients.

Results: GDF-15 levels in AH (n=50) and serum (n=54) samples derived from the same patients were significantly elevated in POAG patients ($P<0.001$; Wilcoxon rank sum test of difference between medians equal to zero) by ~10-fold and 79%, respectively, compared to samples from cataract patients (n=33-39). Moreover, analysis of a larger set (n=117) of AH samples from POAG patients also showed a significant ($P<0.001$; by ~9 fold) elevation in the levels of GDF-15 relative to AH from cataract patients (n=113). GDF-15 levels were elevated in both male and female glaucoma patients, with no apparent gender differences. Similarly, both African American and Caucasian glaucoma patients exhibited elevated levels of GDF-15 with no significant racial differences.

Conclusions: In support of a previous report, this large sample size study not only reveals significantly elevated levels of GDF-15 in the AH but also in the serum of POAG patients compared to non-glaucoma patients. These findings indicate that serum GDF-15 levels might serve as a biomarker for the diagnosis of POAG. Additionally, the robustly elevated levels of GDF-15 detected in the AH of glaucoma patients warrants studies to investigate the role of GDF-15 in the pathobiology of ocular hypertension and glaucoma.

TITLE: Miotic-assisted Rotational Extraction of Incarcerated Iris at the Slit Lamp

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.E. Sponsel, Vision Sciences, University of the Incarnate Word, San Antonio, Texas, UNITED STATES|W.E. Sponsel, Ophthalmology, WESMDPA, San Antonio, Texas, UNITED STATES|G. Slagle, Clinical Research, Sponsel Foundation, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Grant Slagle: Commercial Relationship: Code N (No Commercial Relationship) | William Sponsel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Iris incarceration as a complication of glaucoma filtering surgery generally requires surgical intervention. We describe a novel technique for removal of incarcerated iris and restoration of bleb filtering capacity that can be safely performed at the slit lamp, dubbed rotational extraction of incarcerated iris (REII). A retrospective analysis of visual function and intraocular pressure (IOP) control was done in eyes treated with REII.

Methods: The patient is positioned at a securely locked slit lamp with two assistants. One drop of 0.5% proparacaine hydrochloride ophthalmic solution is administered to the affected eye. The eye is cleansed with betadine 5% sterile ophthalmic prep solution. Using sterile technique, 0.7mL of carbachol 0.01% intraocular solution is drawn into a 30G needle. With the bevel facing up, the needle is bent to 45° before inserting it using the dominant hand (at 11:00 or 2:00) tangentially into the anterior chamber (AC) via a peripheral corneal approach. 0.2mL carbachol is injected into the AC before the needle engages the iris over the zonule near the incarceration site. The needle is rotated downward using the cornea as a fulcrum, freeing the iris. Then the remaining 0.5mL carbachol is injected into the AC.

We retrospectively evaluated all patients who received REII between 1/1/2015 and 1/1/2021. IOP (Goldman applanation tonometry) and LogMAR visual acuity (VA) were measured at the time of REII, and at 1 month and 3 months post-procedure. Paired, two tailed t-tests with Bonferroni correction were used for all comparisons using Microsoft Excel (Redmond, Washington, USA).

Results: Forty-one eyes (46% left) of 41 patients (44% female, mean age \pm SD 64.7 \pm 10.7) were treated with REII. Median time to iris incarceration from surgery date was 50 days (range 1- 1906). Mean pre-REII IOP \pm SD was 33.1 \pm 14.4 mmHg, which reduced to 11.4 \pm 6.0 mmHg (66% reduction) day-of procedure ($P<0.01$) and remained reduced to 14.6 \pm 7.2 mmHg (56%, $P<0.01$) and 18.6 \pm 9.0 mmHg (44%, $P<0.01$) at 1 and 3 months, respectively. LogMAR VA was 0.78 \pm 0.8 log units at baseline, was unchanged at 1 month (0.70 \pm 0.8 log units, $P=0.14$), and improved at 3 months (0.50 \pm 0.6 log units, $P<0.01$).

Conclusions: Iris incarceration can be effectively managed at the slit lamp by REII, which can restore bleb filtering capacity and provide sustained reduction in IOP.

ABSTRACT BODY:

Purpose: To present 5-year post-injection results for the multi-luminance mobility test (MLMT) and full field light sensitivity threshold test (FST) endpoints in the original intervention and delayed intervention groups of the phase 3 voretigene neparvovec-rzyl (VN) study in biallelic RPE65 mutation-associated inherited retinal disease.

Methods: Patients were randomized to either original intervention (OI:bilateral subretinal VN at baseline; n=20) or delayed intervention (DI:VN after 1 year; n=9). The primary endpoint was Multi-Luminance Mobility Test (MLMT) at 7 standard light levels as measured by a change score. The first secondary endpoint was full-field light sensitivity threshold (FST). The five-year timepoint was analyzed for OI and DI groups individually and combined OI group plus DI group.

Results: For OI patients at Year 5 (n=18) and DI patients at Year 5 (n=7), the MLMT mean (SD) bilateral light level change score was 1.6 levels (1.2) and 2.4 levels (1.6), respectively compared to baseline. The combined (OI plus the DI groups) mean bilateral light level change score was 1.8 (1.3) (N=25). Mean change in white light FST in \log_{10} (cd.s/m²) was -2.02 (1.45) \log_{10} at Year 5 for OI patients (n=17) and -2.57 (1.21) \log_{10} at Year 5 for DI patients (n=7). The mean change in white light FST in \log_{10} (cd.s/m²) was -2.18 (1.38) for the combined OI and DI group (N=24).

Conclusions: Visual improvements are maintained for at least 5 years after VN administration for both the OI and DI patients.

ABSTRACT BODY:

Purpose: Pseudoexfoliation glaucoma (PEXG) is an ocular manifestation of the systemic elastotic disease pseudoexfoliation syndrome (PEX), and can be diagnosed by fibrillary deposits in the anterior chamber and significantly increased intraocular pressure (IOP). PEX-related extracellular matrix dysregulation can manifest as pelvic organ prolapse, inguinal hernia, aortic aneurism, or COPD. Consistent with these pathologies, polymorphisms in the lysyl oxidase-like 1 (LOXL1) gene, which codes for an elastin crosslinking and assembly enzyme, impart significant risk for PEX. Thus, changes in LOXL1 expression may lead to elevated IOP in PEXG, as the outflow tissues that regulate IOP are highly elastic. Here, we use a Loxl1 knockout mouse model to investigate genetic susceptibility to the elastotic phenotypes associated with Loxl1 depletion.

Methods: 129S.C57Bl/6.Loxl1^{+/-} mice were backcrossed onto the C57Bl/6 background for 6 generations (N6). Two month old N6 and mixed background 129S/N6 (N1) Loxl1^{+/+}, ^{+/-} and ^{-/-} mice were analyzed for systemic phenotypes including anal prolapse, skin elasticity, total weight, and morphological changes in major organs. Ocular phenotypes monitored include IOPs and histology of anterior and posterior segments.

Results: Prolapse prevalence was significantly higher in N6 C57Bl/6 mice in comparison to mixed background mice ($p < 0.0001$). In mixed 129S/N6 (N1) Loxl1^{-/-} mice, significant increases in skin tiring ($p = 0.0235$) and reduction in elastic recovery ($p = 0.0294$) were observed. The tiring effects of skin after repeated stretch were significantly higher in Loxl1^{-/-} animals versus Loxl1^{+/+} and ^{+/-} littermates ($p = 0.0010$). Knockout of Loxl1 in the N6 C57Bl/6 mice led to significant weight loss ($p < 0.05$), and systemic and ocular tissues exhibited enlarged luminal spaces histologically. Knockout of Loxl1 in mixed background mice lead to significantly increased IOP ($p < 0.0001$), but no significant IOP increase was observed in the N6 C57Bl/6 mice.

Conclusions: Genetic background significantly affects the systemic and ocular phenotypes of elastosis associated with Loxl1 knockout. This data shows for the first time that susceptibility to Loxl1 knockout-induced elastosis depends upon genetic modifiers that may contribute to phenotypic severity of PEX, providing a foundation for studying gene targets associated with this susceptibility that are relevant in human patients.

ABSTRACT BODY:

Purpose: It has been shown that nuclear distribution protein C (NUDC) modulates F-actin dynamics through F-actin severing protein cofilin1 (CFL1). We have shown NUDC is critical in the morphogenesis of rod photoreceptor disks in *X. laevis* tadpoles as well as in mice. We hypothesize that NUDC regulates F-actin through CFL1 in rods as it does in other cell types. Since CFL1 is regulated in other cell types upon phosphorylation at the serine at position 3 in the protein, we hypothesize that expression of phospho-mimics or phosphonull mutants of CFL1 will affect F-actin levels and outer segment (OS) disk formation. Here we seek to uncover the regulatory action of CFL1 and the molecular mechanisms governing F-actin architecture in rod OS by generating transgenic *X.laevis* expressing mutants of CFL1 and shRNAs against CFL1.

Methods: We are preparing transgenic *X. laevis* tadpoles expressing wild type CFL1 (CFL1), constitutively active phospho-null CFL1 (CFL1^{S3A}), dominant negative phospho-mimic CFL1 (CFL1^{S3D}) as well as shRNA directed against CFL1, under the rod opsin promoter. Immunohistochemistry (IHC), proximity ligation assays and dot blot analysis using solubilized retinas of key proteins are being performed WT *X. laevis* tadpoles, as well as those expressing CFL1, CFL1^{S3A}, CFL1^{S3D} and shRNA against CFL1. We will use fluorescent microscopy to visualize key proteins such as NUDC, CFL1, rhodopsin, actin, transducin, arrestin and others to uncover their localization within the rod cell. We will utilize transmission electron microscopy (TEM) images of photoreceptor ultrastructure using ultrathin sections of 2wk old *X. laevis* tadpoles.

Results: We have found CFL1 is expressed in the inner segment (IS) of *X. laevis* and mouse photoreceptors. Through the proximity ligation assay we found CFL1 is < 40nm to NUDC in the IS and at the base of the OS in rods of mouse and *X. laevis*. We have prepared transgenic *X. laevis* tadpoles and are currently analyzing the localization of key proteins and ultrastructure of photoreceptors in these animals.

Conclusions: We have demonstrated that CFL1 is expressed in rod photoreceptors and is near NUDC in at the base of the OS, supporting our hypothesis that NUDC is working through CFL1 to regulate F-actin levels. Further analysis is ongoing. This work critical to further our understanding of the molecular mechanism of disk regulation and morphogenesis.

TITLE: The strength of center-surround antagonism in retinal ganglion cell receptive fields is light-dependent and affects stimulus-response filtering in the spatial and temporal domains

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Ingram, F. Rieke, Physiology and Biophysics, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Norianne Ingram: Commercial Relationship: Code N (No Commercial Relationship) | Fred Rieke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Contemporary studies in visual neuroscience look to understand how adaptive modulations and circuit routing affect stimulus encoding across layers of the retina. At the output of the retina, retinal ganglion cells (RGCs) are able to encode rapid stimulus fluctuations despite the relatively slow input they receive from upstream photoreceptors. They also have receptive fields that display center-surround antagonism, in which lateral inhibition driven by the surround inhibits responses generated from stimulating the center (Barlow, 1957). Previous studies in mouse show that the spatial dimensions of center versus surround change with background light conditions (Hoggarth et al., 2015; Farrow et al., 2013). It is not known if all RGC subtypes undergo similar shifts, to what degree circuit mechanisms like changes in rod-cone signal routing are responsible, and if other receptive field features such as surround-dependent temporal filtering are similarly dependent on light level.

Methods: To answer these questions in the primate retina, we make electrophysiological recordings from primate RGCs with stimuli that span 8 orders in magnitude in light intensity. We measure light-dependent shifts in spatial and temporal receptive fields through this entire range of stimuli and in multiple RGC subtypes.

Results: Both parasol and midget RGC receptive field spatial dimensions show similar trends in light dependence. In addition, we show for the first time, that the strength of surround-mediated temporal filtering also depends on the background light intensity. Interestingly in ON-parasol RGS, the effects of surround-mediated temporal filtering are greater in dim light, a condition in which the surround contributes little to the spatial receptive field.

Conclusions: The light-dependent changes in these receptive field features demonstrated in this study are likely to have large effects stimulus tuning and encoding in both the spatial and temporal domains. Adaptation of receptive field characteristics should play an important role in an organism's ability to perform complex visual tasks which depend on correlations between space and time (e.g. motion detection) as well as modulate circuit-defined limitations in perception.

ABSTRACT BODY:

Purpose: Pseudoexfoliation syndrome is a connective tissue disorder first described in the eye in 1917. It has a genetic component associated with mutations in the lysyl oxidase-like 1 gene (LOXL1) at the locus 15q22. More commonly seen in Scandinavian and Northern European populations, its prevalence in all populations increases with age. Characterized by deposition of fluffy “dandruff-like” material composed of amyloid, laminin, elastic fibers, collagen and basement membrane on ocular structures, diagnosis is made on slit-lamp examination where gray-white flakes are evident at the pupillary margin and on the anterior lens capsule. The purpose of this study is to evaluate the utility of ultrasound biomicroscopy (UBM) in delineating capsular and zonular enhancement.

Methods: Retrospective review of 98 UBM consecutive patients over the past year was conducted. Examinations were performed using Quantel Aviso UBM system with 50 MHz probe with ClearScan standoff to place anterior segment in focal zone. Cineloop data were obtained in all four quadrants as well as centrally in horizontal and vertical orientations. Pseudoexfoliation (PEX) was evident as enhancement of the zonular fibers, presence of echogenic debris on the anterior lens capsule and/or secondary atrophic changes in the iris (“moth-eaten” appearance of iris stroma). Data was analyzed for relationship to sex and age.

Results: UBM consistent with PEX was observed in 10 of 98 patients. Results showed no significant relationship with sex (Chi-square =.527, p=.468). PEX patients were, on average, approximately 10 years older than non-PEX subjects (65.4±14.0 versus 54.8±21.6 years), but this did not reach statistical significance (t=-1.52, p=.132).

Conclusions: Pseudoexfoliation syndrome is a major risk factor for complications during cataract surgery related to weakened capsule and zonular apparatus. It is also the most common form of secondary glaucoma as pigment and exfoliative material in the trabecular meshwork and Schlemm’s canal results in increased outflow resistance and elevation of intraocular pressure. Ultrasound biomicroscopy can be a useful adjunct in delineation of the disease, especially because retroiridal structures are unable to be visualized with anterior segment OCT.

TITLE: Mining the BXD Family of Mice to Better Model the Natural Progression of Glaucoma

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.M. Jablonski, R. Simpson, X. Wang, W. White, T. Hollingsworth, The University of Tennessee Health Science Center Department of Ophthalmology Hamilton Eye Institute, Memphis, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Monica Jablonski: Commercial Relationship: Code N (No Commercial Relationship) | Raven Simpson: Commercial Relationship: Code N (No Commercial Relationship) | XiangDi Wang: Commercial Relationship: Code N (No Commercial Relationship) | William White: Commercial Relationship: Code N (No Commercial Relationship) | TJ Hollingsworth: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is the leading cause of irreversible blindness worldwide. Despite this, a complete understanding of the disease and its pathogenesis remains a struggle due to the lack of high fidelity spontaneous polygenetic models that recapitulate the human phenotype. In recent years, the BXD mouse family has emerged as a source of spontaneous models of ocular disease. It is the purpose of this study to identify natural polygenetic mouse models of primary open angle (POAG), primary angle closure (PACG), and normotensive (NTG) glaucoma by mining the BXD family and provide them as a valuable resource for the vision research community.

Methods: BXD strains were selected by evaluating data from previous studies that include the density of dead axons, ON damage scorings, and IOP. Eight strains were selected for further study. Functional/anatomical analyses including optical coherence tomography (OCT), optokinetic nystagmus (OKN), full field and pattern electroretinograms (ERG/PERG), and IOP measurements were performed every 3 months from the age of 1 month to 12 months. Gonioscopy was performed at 12 months to determine if the angle was open or closed. Histological and ultrastructural analyses of the eye/optic nerve will be performed after euthanasia at 12 months.

Results: Although this study is still in progress, preliminary data highlight BXD50 and BXD51 as possible models of POAG. Both strains exhibit open angles, decreased ERG and PERG amplitudes, and loss of contrast sensitivity by 12 months. Interestingly, the two strains vary greatly in IOP over their lifetimes with BXD50 reaching a maximum IOP of 28 mmHg, while the maximum IOP of BXD51 was 41 mmHg.

Histological analysis of the eye/optic nerve is in progress to evaluate optic nerve damage and RGC health.

Conclusions: The BXD family of mice offers valuable insights into ocular disease pathogenesis. Of the strains we selected, BXD50 and BXD51 present POAG-like phenotypes. Ongoing studies are being performed to better characterize plausible spontaneous models of PACG and NTG, thereby providing additional valuable tools for the future study of glaucoma.

ABSTRACT BODY:

Purpose: The purpose of this study was to investigate the role of Lsd1 in retinal development by deleting Lsd1 in all retinal progenitor cells. Lysine specific demethylase 1 (Lsd1) is the only histone demethylase that is able to demethylate mono- and di-methyl groups on H3K4 and H3K9. Previously, we have shown that Lsd1 is ubiquitously expressed throughout the developing retinoblast and in the majority of mature retinal neurons (Ferdous et. al IOVS 2019 PMID: PMC6827424) . Using a Chx10-Cre driver line, we generated a transgenic mouse line to delete Lsd1 through the entire retinoblast lineage. Chx10 is a transcription factor that is expressed in all retinal progenitor cells (RPCs) starting about embryonic day 14.5 (E14.5) and is critical to progenitor cell proliferation and specifically bipolar cell determination. We hypothesize that deletion of Lsd1 early in retinal development will result in either 1) a failure of RPCs to proliferate or 2) the death of RPCs due to transcriptional abnormalities which could result in a reduction in retinal thickness and subsequently visual function defects.

Methods: After generating Chx10-Cre Lsd1 lox/lox mice, we tested mice at P30 and P45 for visual function, using electroretinograms (ERGs), and in vivo imaging to obtain SD-OCT and cSLO images. Afterwards, eyes were enucleated and fixed for H&E staining and immunocytochemistry staining.

Results: We have observed a marked reduction in ERGs a- and b- waves in both scotopic and photopic conditions as well as cone flicker responses at P30 and P45 compared to littermate Cre negative controls. This decrease in visual function is corroborated with reductions in total retinal thickness and ONL thickness as measured from SD-OCT images at both ages. H&E stained sagittal sections indicate the same retinal thinning. Additionally, there is an increase in TUNEL positive cells in the Chx10-Cre Lsd1 loxlox compared to controls.

Conclusions: Our data supports the notion that Lsd1 is necessary for neuronal development specifically in the retina. Adult Chx10-Cre Lsd1 lox/lox mice show impaired visual function and retinal morphology and future experiments will continue to characterize the timeline of morphological defects during embryonic development as well as investigate epigenome and transcriptome abnormalities leading to these defects.

ABSTRACT BODY:

Purpose: Animal models of human retinal degenerations (RDs) have been of interest to the vision community for decades. Generating high fidelity models has been hit-or-miss and is often dependent upon the disease itself. Of the RDs, age-related macular degeneration (AMD) is one the most elusive phenotypes to mirror due to numerous genetic polymorphisms and environmental factors associated with it. Recently, the BXD family of mice has become a valuable tool for modeling various ocular diseases. This study's purpose is to apply a systems genetics approach to the BXD mouse family to better model human AMD, providing the vision community with polygenetic pre-clinical models of AMD.

Methods: We identified 27 genes associated with human AMD and, of these, 11 have polymorphisms in the BXD family of mice that are predicted to change gene function in a similar manner to that seen in humans. We chose 6 strains of mice with various combinations of the 11 genes with the goal of selecting mice with various presentations of AMD. The 6 BXD strains and C57B/6J controls are aging from 6 to 18 months. Optical coherence tomography (OCT), full field electroretinogram (ERG), funduscopy/fluorescein angiography (FA) and optokinetic nystagmus (OKN) measurements are performed every 3 months. Histological and ultrastructural analyses will be performed upon euthanasia at 18 months.

Results: Preliminary data indicates BXD34 as a possible AMD model due to drusen-like deposits observed by funduscopy along with degeneration near the central retina by OCT. It also exhibits vascular leakage and a loss of both contrast sensitivity and a- and b-wave amplitudes of the ERG. We have excluded the BXD32 and BXD79 strains as plausible AMD models. BXD32 exhibits markedly rapid degeneration similar to recessive retinitis pigmentosa (RP). BXD79 has phenotypes of high blood glucose, obesity, vascular leakage, and early onset retinal degeneration occurring between 6 months and 9 months of age making it a possible model of diabetic retinopathy (DR).

Conclusions: Currently, BXD34 exhibits the most AMD-like phenotype among the 6 strains chosen for characterization by exhibiting drusen-like deposits and both anatomical and physiological declines in retinal health. BXD32 and BXD79 may better serve as spontaneous models of RP and DR, respectively. Further investigation into these strains is necessary to confirm them as true models of the respective diseases.

ABSTRACT BODY:

Purpose: Angiogenesis of the retina is mediated in part by cell-cell signaling through the NOTCH1 receptor and its ligands Jagged1 (JAG1) and Delta-Like ligand 4 (DLL4). O-Fucosylation of Ser/Thr residues in the Epidermal Growth Factor-like (EGF) repeats by Protein O-fucosyltransferase 1 (POFUT1) is necessary for receptor activation by both ligands, and addition of b1,3-GlcNAc to O-fucose by Fringe glycosyltransferases reduces NOTCH1 activation during interaction with JAG1 while enhancing NOTCH1 activation during interaction with DLL4. We generated a mouse model to study the regulatory contributions by Fringe glycosyltransferases during angiogenic development of the mouse retina.

Methods: Using CRISPR/Cas9 to knock in a three base pair change from ACC to GTG, we made a T/V substitution at Thr₂₃₂ of the NOTCH1 protein in a C57BL/6J mouse. This mutation excludes the O-fucose site at EGF6 as a substrate for POFUT1 and Fringe, and previous in vitro studies show that this mutation rescues the inhibitory effect of JAG1 signaling through Fringe-modified NOTCH1 with no changes to the enhancing effect of DLL4 signaling through Fringe-modified NOTCH1. Retinas from P5-P6 and adult mice were stained with Isolectin B4 to visualize the endothelial vasculature, and a Mask Sholl Analysis was performed to quantify the vascular density of the retina.

Results: Preliminary data from P5-P6 mutant retinas show decreased vascular density compared to wildtype as well as a growth delay from the inner retina to the outer retina. This phenotype extends into the adult stage with reduced endothelial staining and a less severe growth delay.

Conclusions: A loss of vascular density is consistent with published mouse models showing hyperactivation of NOTCH1 through knockdown of Jag1 or with the opposite gain of vascular density from treatment with the λ -secretase inhibitor DAPT, which is an established inhibitor of Notch signaling. These data suggest that we uncoupled Fringe-mediated regulation of NOTCH1-JAG1 signaling from Fringe-mediated enhancement of NOTCH1-DLL4 during angiogenic development of the mouse retina. We are currently immunostaining and measuring transcript levels of components in the NOTCH1 pathway to confirm the genetic mechanism by which we observe this phenotype.

ABSTRACT BODY:

Purpose: Synapses—the basic unit of neuron function—are a central challenge of retinal cell replacement therapies for blinding eye disorders. Synapse formation within human pluripotent stem cell (hPSC)-derived retinal organoids (ROs) has been observed by electron microscopy, but the capacity for de novo synaptogenesis among hPSC-derived retinal neurons (RNs) following isolation from ROs has not been definitively established. In this study, we validated a synaptic tracing assay to screen for functional synapses in vitro among dissociated hPSC-RN cultures.

Methods: A monosynaptic retrograde tracing assay using a GFP-encoding lentivirus (lenti-GFP) and mCherry-encoding pseudotyped rabies virus (RaV) was modified to assess hPSC-RN synapse formation. Stage 2 (D80) ROs were dissociated and plated onto 96 well plates. 10 days post-plating, cultures were treated with lentiviral constructs to label a subset of RNs. After 5 days, cultures were infected with RaV, which enters only lenti-GFP-transduced cells. Synaptic tracing cultures were fixed 5 days post RaV transduction (D100) to screen for the presence of potentially postsynaptic (GFP+ and mCherry+) and presynaptic RNs (GFP-, mCherry+). To control for material transfer, a glycoprotein-null, RaV transmission-incompetent lentivirus was used. Confocal and high-content images were taken for qualitative and quantitative analysis.

Results: RaV-mCherry and lenti-GFP vectors labeled pre- and potentially postsynaptic RNs in dissociated hPSC-RN cultures. RaV transmission to presynaptic RNs was significantly greater ($p < 0.0001$) in experimental cultures (~6.3% of all cells) relative to control cultures (<1.5%), validating the assay for presynaptic RN identification. Functional synapses, as demonstrated by RaV transmission, were identified in post-dissociation cultures. Major classes of hPSC-RNs, including photoreceptors (PRs), ganglion cells (GCs), and interneurons were detected among traced presynaptic cells. PRs and GCs—neurons of particular importance for cell replacement—represented ~40% and ~28% of traced presynaptic cells, respectively.

Conclusions: This study successfully demonstrates the use of a synaptic tracing assay to identify de novo synapse formation among hPSC-RNs isolated from ROs in vitro. While overall synaptic formation rates were expectedly low, this system represents a platform for high-throughput testing of methods to improve hPSC-RN synapse formation in vitro.

ABSTRACT BODY:

Purpose: To report on the outcomes of patients with RPE65-associated retinopathy treated with FDA-approved voretigene gene replacement therapy at a single treatment site.

Methods: This is a retrospective study on patients with RPE65-associated retinopathy treated with voretigene neparvovec-rzyl. Records, imaging, and diagnostics were reviewed including fundus autofluorescence (FAF), optical coherence tomography (OCT), full-field stimulus threshold (FST), kinetic visual fields, dark-adapted two color visual fields (2cDAP), full-field ERG (ffERG). FST was performed and analyzed on Espion ColorDome LED full-field stimulator system and Diagnosys software, and dark-adapted two color perimetry on the Octopus 900 Haag-Streit perimeter.

Results: A subretinal injection of voretigene was administered into 19 eyes from 11 patients (pt) with an average age of 20.82 YO (range 4-38 YO). FST was performed for 11 eyes (from 6 pts) with improvements seen in 10 eyes. There was an average gain in FST of 13.3 dB (range 4.9-17.6, SD 8.92 dB) with the short-wavelength stimulus (blue), and 8.1 dB (range 2.5-15.0, SD 5.43 dB) with the long-wavelength stimulus (red). When 1 year or longer follow-up data was available (10 eyes from 5 pts), gains in sensitivity were maintained in all treated eyes. 2cDAP field was performed for 10 eyes (from 6 pts) with all eyes showing an improvement in mean sensitivity to the blue stimulus, with an average improvement of 10.91 dB (range 2.0-22.2, SD 4.98 dB). 9 out of 10 eyes (from 6 pts) showed an improvement to the red stimulus, with average improvement of 4.73 dB (range 0.8-10.0, SD 2.37 dB). Gains in 2cDAP was sustained in all patients with follow-up at 1 year. ffERG was performed in 14 eyes (from 8 pts) with a greater than 50% improvement in 5 eyes (from 3 pts). Improved OCT findings were observed in 7 eyes (from 4 pts). Patients also reported moderate to significant subjective improvement in nyctalopia (9 pts), overall vision (6 pts), color vision (3 pts), and nystagmus (2 pts).

Conclusions: A majority of patients with RPE65-associated retinopathy treated with voretigene showed improvements in FST and dark-adapted perimetry. Dark-adapted perimetry may be a sensitive outcome that provides topographical information in relation to the treatment area. Several patients reported significant subjective improvement in color vision, a potential outcome measure to systematically evaluate in the future.

ABSTRACT BODY:

Purpose: Stereoacuity deterioration following keratorefractive surgeries is attributed to an increase in the magnitude and interocular differences in post-operative higher-order aberrations (HOAs) (Sarkar et al, 2020). This study modeled the contributions of interocular HOA differences induced by refractive surgery to disparity visibility and binocular matching using cross-correlation analyses.

Methods: We recruited subjects (n=99) with myopia and astigmatism ≤ 1.5 D who underwent Femtosecond Laser-Assisted In situ Keratomileusis (FS-LASIK, n=38), PhotoRefractive Keratectomy (PRK, n=26) or SMAll-Incision Lenticule Extraction (SMILE, n=35). Post-cycloplegic HOAs and stereoacuities were measured for 6mm diameter pupils pre-operatively, and 1, 4, 12 and 24 weeks post-operatively. Left and right eye retinal image pairs were convolved with respective HOA-derived point spread functions. Optical effects on disparity signal quality were modeled computationally using four metrics derived from binocular cross-correlation functions, namely, signal width, signal height, signal-to-noise ratio, and height-to-width ratio (Metlapally et al, 2019). We assessed covariation of cross-correlation metrics with corresponding psychophysical measures of stereoacuity. We also compared the three refractive surgeries for their binocular outcomes using analyses of variance.

Results: Increased interocular average and difference in the magnitude of HOAs caused sustained worsening of stereoacuity (Sarkar et al, 2020). Stereoacuity strongly covaried with the four cross-correlation metrics ($p < 0.001$, $r = 0.725$, -0.630 , -0.732 and -0.786 , respectively, for the four metrics above). The changes from the pre-operative to the 24-week time point for each of the cross-correlation metrics differ significantly among the three refractive surgeries. Altogether, SMILE showed better binocular outcomes than LASIK or PRK ($p < 0.001$).

Conclusions: Mismatched HOAs add disparity noise by differentially altering the properties of the retinal images of the two eyes, and negatively affect binocular matching and disparity visibility. Computational analyses point to disparity noise as a possible mechanism through which HOAs induced following refractive surgery make extracting stereoacuity difficult. They also suggest better binocular outcomes for SMILE than LASIK or PRK.

ABSTRACT BODY:

Purpose: We wished to compare the ability to human observers (retinal doctors) to co-localize pathological structures from different platforms. We compared traditional co-localization techniques (side-by-side with human observers) to an AI technique which overlaid the images with AI algorithms and then alternated the images using the previously described automated alternation flicker method. We determined time to localize the lesions and accuracy of both methods.

Methods: Images taken with a Topcon color fundus camera showing diabetic retinopathy (4 eyes), AMD (5 eyes) and central vein occlusion (2 eyes) were analyzed for a masked clinician, lesions of interest were identified and marked with a circle. Infrared SLO images of the same fundus showing the corresponding area were then also selected. For the side-by-side (SBS) method, two retina specialists identified the corresponding lesion on the unmarked IR image and drew it digitally with the color image in the side. For the AI overlaid images, the same specialists identified the lesion on the unmarked IR and drew it digitally as it was being presented by automated alternating flicker along with the color image. A total of 53 lesions from 11 fundus image pairs were analyzed 2 times, one time for each method, in different days, for each specialist. Image analysis was done in random order. Time to find each lesion in each method was measured and recorded for the same person in all attempts.

Results: The time to find the lesions was faster in the overlay method ($p < 0.01$). Out of 106 (combined total between both observers) gradings 19 lesions were missed in the SBS method and zero missed lesion in the overlay method. The average decentration (difference in lesion center normalized to lesion radius) was 22% and 27% for observers 1 and 2 in the overlay study. No significant difference between the graders ($p = 0.127$). The average decentration was 59% and 56% for observers in the SBS method. No significant difference between the graders ($p = 0.265$). However, there is a statistic difference when we compare SBS and overlay methods pooled for both graders ($p = 0.0000607$).

Conclusions: The overlay method permits more rapid and accurate co-localization of lesions from different imaging platforms. It is easier and more accurate than the side-by-side method, which is closer to the "normal" approach to analyze different images in clinical and image reading settings.

TITLE: Mitochondrial dysfunction causes retraction of Müller cell lateral processes.

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.J. Allingham, S. Cousins, P.S. Mettu, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Allingham: Commercial Relationship: Code N (No Commercial Relationship) | Scott Cousins: Commercial Relationship: Code N (No Commercial Relationship) | Priyatham Mettu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Müller cell perisynaptic lateral processes provide support to retinal synapses and are critical for vision. Currently, the mechanisms regulating Müller cell lateral process maintenance and retraction are poorly understood, particularly in vivo. We tested the hypothesis that Müller cell mitochondrial dysfunction causes retraction of lateral processes using a model of retinal vein occlusion (RVO).

Methods: RVO was induced after intravenous injection of rose bengal (66mg/kg) using a 532nm laser to place 3-7 applications at 80 mW and 50 micron spot size directed at two retinal veins 1 disc diameter from the nerve. Negative control consisted of placing an equal number of laser spots without targeting the retinal vein. Male and female C57BL/6J mice aged 7-9 months with confirmed absence of *Crb1*^{rd8}, GLAST-CreER and Rosa26 mTmG mice were obtained from Jackson Labs. Elamipretide, a mitochondrial protective drug, was administered intraperitoneally (2mg/kg/day) using prevention and intervention strategies. Retinal histology and Müller cell lateral process morphology was evaluated on day 7 following induction of RVO. Mitochondria dysfunction was evaluated by quantifying superoxide and flavoprotein autofluorescence. Significance was determined using nonparametric statistical testing with $p < 0.05$ considered significant.

Results: After RVO, mitochondria dysfunction was induced within the retinal plexiform layers where lateral processes are located, seen as increased superoxide and flavoprotein autofluorescence. This was prevented by treatment with mitochondria protective compound, elamipretide. RVO resulted in retraction of Müller cell perisynaptic lateral processes in the inner and outer plexiform layers. Lateral process length and the diameter of the lateral process arbor were quantified and reductions found to be statistically significant ($p < 0.05$). Markers of lateral processes including GLAST, GluR3, AQP6 and T567 phospho-ezrin were quantified by confocal microscopy and found to be greatly reduced following RVO ($p < 0.05$). Elamipretide treatment using either intervention or prevention approaches significantly preserved Müller cell lateral processes and markers ($p < 0.05$).

Conclusions: RVO causes retraction of Müller lateral processes. Treatment with elamipretide, a mitochondria protective drug, prevents and reverses these changes. This suggests that mitochondrial function is required for maintenance of lateral processes.

ABSTRACT BODY:

Purpose: Baseball has long been called America's pastime. As the first professional sport in the US, baseball has been a source of great pleasure and leisure; however, the sport is also associated with occurrence of ocular trauma. We performed a retrospective analysis assessing baseball-related ocular injury incidence and trends across the US.

Methods: We analyzed ten years of emergency department (ED) data from the US Consumer Product Safety Commission's National Electronic Injury Surveillance System (2009-2018). We identified baseball- and softball-related ocular trauma (BOT, collectively) presenting to EDs. We grouped patients by age in years (y): Pediatric, ≤ 17 y; Adult, ≥ 18 y. We analyzed normality with both Shapiro-Wilk tests and Q-Q plots and variances with Levene's tests. We performed Student's t-, Welch's t-, and Mann-Whitney U tests and calculated 95% confidence intervals (CI).

Results: From 2009-2018, an estimated 25816 (CI [21780-29852]) patients presented to US EDs with BOTs. Pediatric patients experienced 67.6% (n=17442) of BOTs; Adults, 32.4% (n=8375). Median patient age was 14y (interquartile range, 10-23y). Patients age 0-4y experienced 1.3% (n=342) of BOTs; 5-9y, 18.6% (n=4799); 10-14y, 35.4% (n=9149); 15-19y, 15.5% (n=3989); 20-24y, 7.0% (n=1797); 25-34y, 8.6% (n=2209); 35-44y, 6.6% (n=1706); 45-54y, 4.5% (n=1173); ≥ 55 y, 2.5% (n=656).

Primary diagnoses were contusion/abrasion (51.2%, n=13230), other (34.8%, n=8994), laceration (3.3%, n=844), conjunctivitis (3.0%, n=782), foreign body (2.9%, n=750), hematoma (2.4%, n=621), or hemorrhage (2.3%, n=595). Mean annual BOT incidence decreased by 630 ± 336 (CI [5.91- ∞]; p=.0487) in 2014-2018 compared to 2009-2013. Annual BOT incidence decreased by 32.0% from 2009 (n=2909; CI [1918-3901]) to 2018 (n=1998; CI [941-3056]) and peaked in 2012 (n=4040; CI [2919-5160]), yielding a decrease of mean annual incidence from 2897 ± 717 in 2009-2013 to 2267 ± 222 in 2014-2018.

Conclusions: Nearly 2600 patients presented to US EDs with BOTs annually. Pediatric patients presented with BOTs more frequently than adults. Incidence of BOTs has decreased in recent years, which may suggest an increase in the use or efficacy of protective sporting equipment. We encourage the use of protective eyewear when playing baseball and softball.

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) produces alterations in the tear film (TF) lipid layer that causes excessive evaporation of tears from the ocular surface and subsequent increased osmolarity leading to dry eye disease. However, the molecular mechanism underlying TF evaporation has yet to be understood. This study aimed to investigate the association between (o-acyl)-omega-hydroxy fatty acids (OAHFAs) derived from TF and meibum and TF evaporation in a cohort of healthy and MGD subjects.

Methods: Of 195 eligible subjects (18–84 years, 62.6% female), 178 and 170 subjects provided both TF optical coherence tomography (OCT) imaging and mass spectrometry data for tears (n = 178) and meibum (n = 170). The rate of TF thinning (μm/min) was measured in the right eye of each subject using an ultra-high-resolution, custom-built OCT. Tear and meibum samples from the right eye of each subject were infused into the SCIEX 5600 TripleTOF mass spectrometer in the negative ion mode. Intensities (m/z) of pre-identified OAHFAs were measured with Analyst 1.7TF and LipidView 1.3 (SCIEX) and normalized by internal standards, and then correlated with TF thinning rate using Spearman's correlations.

Results: Out of 76 OAHFAs detected in meibum samples, intensities of 28 OAHFAs had statistically significant negative correlations with TF thinning rate (all p < 0.05). These OAHFAs were: 18:2/16:2, 18:0/22:1, 18:0/23:0, 18:2/24:1, 18:1/24:1, 18:0/24:1, 18:0/24:0, 18:1/25:0, 18:1/26:1, 18:0/26:1, 18:1/28:1, 18:0/28:0, 18:0/28:1, 18:2/30:1, 18:1/30:1, 18:0/30:1, 18:0/31:2, 18:1/31:0, 18:2/32:2, 18:2/32:1, 18:1/32:1, 18:0/32:1, 18:1/33:0, 18:2/34:2, 18:2/34:1, 18:1/34:1, 18:2/36:1, 18:1/36:1. In contrast, there were statistically significant positive correlations between intensities of two meibum-derived OAHFAs (18:2/18:1, 16:1/28:3) and TF thinning rate (both p < 0.05). Of 78 OAHFAs detected in tear samples, intensities of six OAHFAs (18:0/24:0, 18:0/26:0, 18:2/27:2, 18:2/27:0, 18:2/28:2, and 18:2/29:2) were positively correlated with TF thinning rate, while one OAHFA (18:0/22:1) was negatively correlated (all p < 0.05).

Conclusions: Several OAHFAs derived from the human tear film and meibum showed significant associations with alterations in TF thinning. These findings suggest that OAHFAs could be implicated in the mechanism underlying the stabilization and evaporation (or thinning) of TF in health and MGD.

ABSTRACT BODY:

Purpose: Appropriate care of ocular injuries is vital to the preservation of vision. Full-thickness injuries are especially challenging in low-resource or emergency settings as current standards of care involve high surgical skill, equipment, and complex drug regimens. Nanoparticle (NP) based drug delivery systems (DDS) allow for localized tissue targeting with controlled drug release and dosages. Many anti-inflammatory ophthalmic drugs are class II compounds with low bioavailability due to their hydrophobic nature. Herein, we demonstrate a novel DDS by loading drug-laden micelles into a visible light photopolymerizable hydrogel patch with the potential to seal ocular injuries and elute a hydrophobic anti-inflammatory drug.

Methods: Micelle building blocks were synthesized via radical polymerization to create poly(ethylene glycol)-b-(N-(2-hydroxypropyl) methacrylamide-co-oligolactate (PEG-b-(pHPMAm-co-Lac_n)). Micelle characterization utilized gel permeation chromatography (GPC) to obtain the polydispersity index (PDI), and proton nuclear magnetic resonance (¹H NMR) to measure molecular weight (Mw). Micelle physicochemical properties were obtained with dynamic light scattering (DLS) and zetasizer analysis. Loteprednol Etabonate (LE) was encapsulated into micelles and loading efficiency and in vitro drug release were measured using high performance liquid chromatography (HPLC). Lastly, LE loaded micelles were incorporated into the patch composed of methacrylated biopolymers with varying concentrations.

Results: Synthesized micelle characterization showed a block co-polymer with Mw of ~20 kDa and a PDI of 1.46. LE was successfully loaded into micelles with a size of 100-120 nm and loading efficiency of ~ 30%. Micelles were stable for up to five days of incubation in buffer solution at 37°C. A first order (sustained) release of LE was demonstrated for 10 days, with 98% drug released on day 10. Micelles loaded into the patch showed complete and sustained release of LE within 10 days. DLS analysis of release media showed retention of micelles within the hydrogel network.

Conclusions: The adhesive patch successfully loads a hydrophobic drug and allows for sustained release for up to 10 days. Our NP DDS can address critical factors in ocular injury care by its potential use in ocular injury sealing and drug delivery which can increase drug bioavailability without need for complicated and high frequency drug regimen.

TITLE: Cystathionine β -synthase as novel regulator of lymphangiogenesis

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Hatami, F. Bock, S. Simfors, C. Cursiefen, T. Clahsen, Klinikum der Universität zu Köln Zentrum für Augenheilkunde, Köln, Nordrhein-Westfalen, GERMANY|C. Büttner, A. Reis, Universitätsklinikum Erlangen Institut für Humangenetik, Erlangen, Bayern, GERMANY|

Commercial Relationships Disclosure (Abstract): Niloofar Hatami: Commercial Relationship: Code N (No Commercial Relationship) | Christian Büttner: Commercial Relationship: Code N (No Commercial Relationship) | Felix Bock: Commercial Relationship: Code N (No Commercial Relationship) | Sara Simfors: Commercial Relationship: Code N (No Commercial Relationship) | André Reis: Commercial Relationship: Code N (No Commercial Relationship) | Claus Cursiefen: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Clahsen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lymphangiogenesis is critically involved in tissue fluid balance, immune responses, corneal graft rejection, and dry eye disease. The healthy cornea is an avascular and alymphatic tissue with a distinct limbal lymphatic vascular arcade. The genetic background significantly influences the architecture of this limbal lymphatic arcade and corneal lymphangiogenesis. By using the BALB/c x C57BL/6 intercross for QTL analysis we identified and functionally characterized a novel potential candidate gene responsible for the differences in the limbal lymphatic vessel architecture on chromosome 17, the cystathionine β -synthase (CBS) gene.

Methods: To analyze the effect of CBS on human dermal lymphatic endothelial cells (HDLECs) aminooxyacetic acid (AOAA), a pharmacological inhibitor for CBS, was used in vitro. Proliferation and migration of HDLEC after treatment with AOAA was measured by using IncuCyte Zoom and the expression of lymphangiogenic factors was quantified by using qRT-PCR.

In vivo, three 11-0 nylon sutures were placed into the cornea stroma of C57BL/6 mice for 14 days. The treatment group received AOAA as eye drops three times per day for 14 days. Control mice received an equal amount of PBS. Vessel area was analyzed by using cellF software.

Results: In vitro experiments showed that the inhibition of CBS with the inhibitor AOAA in HDLECs resulted in a significant dose-dependent decrease in proliferation compared with control HDLECs. HDLECs treated with the inhibitor show also significantly delayed wound closure compared to the control. In addition, qRT-PCR revealed that the treatment with AOAA influences the expression of lymphangiogenic factors and their receptors. Fourteen days after the inflammatory insult in vivo, the total surface area of the vessel ingrowth into the cornea of AOAA treated and control treated C57BL/6 mice was assessed and the AOAA treated C57BL/6 mice showed a significantly lower lymphatic surface area compared to control treated C57BL/6 mice, indicating that CBS is also involved in inflammation-induced lymphangiogenesis in vivo.

Conclusions: In this study we identified cystathionine β -synthase as a novel endogenous regulator of lymphangiogenesis. CBS reduces not only proliferation and migration, but it also influences the expression of lymphangiogenic factors and their receptors. This opens new treatment avenues in diseases associated with pathologic lymphangiogenesis, such as corneal graft rejection.

ABSTRACT BODY:

Purpose: ONH astrocyte reactivity is an early response to elevated IOP, a key risk factor in glaucomatous optic neuropathy. To better understand astrocyte mechanobiology, we have developed a 3D hydrogel cell culture system to mimic the in situ ONH environment. Here our goals were: (i) to quantify morphology of astrocytes cultured in this system, as assessed by semi-automated image analysis, and (ii) compare to in situ morphology.

Methods: Primary astrocytes isolated from rat ONH were cultured in a synthetic hydrogel based on 4-arm polyethylene glycol norbornene (PEG-4NB) macromer functionalized with 1.0 mM RGD for 2 to 14 days. Astrocytes within hydrogels were stained with DAPI and phalloidin and imaged using a Leica DM6 fluorescent microscope at post-seeding day 5. Images were skeletonized (AnalyzeSkeleton plugin in ImageJ/FIJI), and individual astrocytes were isolated (n=11). The number and length of astrocytic processes were then quantified from each astrocyte and used to calculate branching frequency (number of processes emanating directly from the cell body divided by total number of processes), a measure of branching complexity. This morphometric quantity was then compared to data in the literature (Butt et al., J Neurocytology, 1994).

Results: We successfully identified, segmented, and analyzed astrocytes from hydrogel cultures. Branching patterns were qualitatively similar to astrocytes in situ; however, quantitative analysis showed that cultured astrocytes had higher branch frequency than cells in situ (Fig. 2, chi-squared test, χ^2 (df=8) = 116.68, p < 0.001).

Conclusions: Qualitative morphological similarities of astrocytes in situ vs. those cultured in 3D hydrogels suggest that the PEG-4NB hydrogel system is a viable model for studying ONH astrocyte mechanobiology. However, astrocytes grown in 3D hydrogels are less elongated and branch more frequently than in situ, possibly explained by the additional constraints imposed in situ on the astrocytes by the cylindrical optic nerve shape. Ongoing efforts seek to develop this 3D hydrogel cell culture system, along with image analysis tools, as a novel platform for studying the mechanobiology of astrocytes in glaucoma.

ABSTRACT BODY:

Purpose: Deep neural networks have been used for choroidal segmentation using OCT images. However, the complexities of choroidal structure require the use of a large amount of data and computational time for training a model. We hypothesize that integration of transfer learning to an encoder-decoder network can enable latent features to be detected under the constraint of limited data. We tested this hypothesis with a computational framework that adapts geometrical transformations, spatially adaptive augmentation, and variance scaling weight initialization.

Methods: We used 120 OCT image-mask pairs of the choroid and randomly assigned 96 of them for training and 24 for validation. We augmented the training set to 1248 images using rotation and flipping. All images were resized to 128×128 pixels using bilinear interpolation and then masks were binarized. We built U-Net and UNet++ (encoder-decoder network) models on a VGG-19 backbone for allowing pretrained (PT) ImageNet weights in the encoder. We adapted a Glorot uniform initialization otherwise. We experimented with freezing (FR) the first 30% of the backbone layers when using transfer learning while using the final layer outputs for U-Net and UNet++. The models were trained for 10 epochs using Dice-score loss as a quantitative measure, and a model performance was evaluated using an average precision as a qualitative measure.

Results: We obtained average precision scores of 0.92 for U-Net and UNet++. The integration of transfer learning yielded an average increase of 2% in U-Net and 4% in UNet++. A subjective (visual) evaluation confirmed that the segmented choroidal regions are meaningful (Fig. 1) with respect to the increase in precision values. Freezing of the initial layers slightly reduced the precision value.

Conclusions: The transfer learning approach can significantly help to improve encoder-decoder networks for choroidal segmentation in OCT scans. Our computational framework comprises U-Net and UNet++ on a VGG-19 backbone and uses the PT encoder to perform choroidal segmentation. Our future research will include more rigorous subjective evaluation with choroidal OCT images of unhealthy eyes to develop a fully automated choroidal segmentation system.

ABSTRACT BODY:

Purpose: Pulmonary arterial hypertension (PAH) is characterized by systemic inflammation, endothelial dysfunction, and smooth muscle cell hypertrophy. PAH is classically considered an isolated small vessel vasculopathy of the lungs with peripheral pulmonary vascular obliteration. Diagnosis and monitoring of PAH patients require frequent procedures, including invasive hemodynamics with an average time to diagnosis of over two years after symptom onset. Systemic manifestations of PAH are increasingly acknowledged, but data remains limited. We hypothesized that retinal vascular changes could be associated with markers of PAH severity.

Methods: Using VESSEL GENERational Analysis (VESGEN), a non-invasive, user-interactive computer software that assigns branching generation of large (1) to small (9) vessel.

Results: We examined fluorescein angiograms from controls (n=6) and group 1 PAH subjects (n=9) and correlated retinal vessel parameters with pulmonary hemodynamic endpoints from right heart catheterization. The tortuosity of PAH retinal vessels increased compared to controls ($P<0.001$). Retinal vessel area density, a vascularity indicator, correlated negatively with right heart catheterization hemodynamics (right atrial pressure, ($p=0.04$, $r=-0.50$; mean pulmonary arterial pressure, $p=0.02$, $r=-0.55$; pulmonary capillary wedge pressure, PCWP, $p=0.0017$, $r=-0.72$. PCWP also negatively correlated with arterial density ($p=0.04$, $r=-0.51$). Smaller, more fragile vessels (generations 6-9) correlated positively with vessel area density, superior vena cava oxygen saturation (SVCO₂) ($p=0.04$, $r=0.53$), and pulmonary arterial oxygen saturation (PAO₂) ($p=0.01$; $r=0.70$). Normal vessel tortuosity that typically ranges from 1 to 1.15 pixel/pixel was greater in PAH arteries (1.17 ± 0.041) and veins (1.17 ± 0.040).

Conclusions: In conclusion, we show that 1) reduced retinal vascularity (density) was associated with worsening pulmonary hemodynamics and 2) higher than normal tortuosity in PAH subjects. This investigation suggests that retinal changes may be associated with PAH severity. Use of FA and VESGEN in PAH is feasible and may facilitate early, non-invasive detection of PAH by careful determination of changes in retinal vessel tortuosity.

ABSTRACT BODY:

Purpose: .To measure the effect of nursery school light intensity on refraction and pupil size

Methods: A total of 1260 children age 4-5 years from 27 nursery school were examined. Light intensity was tested by Luxmeter device (Lux) inside and outside the nursery school. Pupil size, corneal reflex and non cycloplegic refraction were measured by the Plusoptix vision screening device. Data analysis was performed using Pearson coefficient and Chi-square tests

Results: The mean age of included children was 4.8 ± 0.22 years ($N=1184$). Light intensities of the low, medium and high intensity nursery schools were 343, 461, 602 lux, respectively (ANOVA, $P<0.01$) with mean refraction of $+0.54 \pm 0.9$, $+0.74 \pm 0.6$, and $+0.84 \pm 0.6$ diopters, respectively. (ANOVA, $P<0.0001$) Pupil size was larger as light intensity increased.

Conclusions: In the nursery school, the higher the indoor light intensity the greater the refraction. Light dependent pupil diameter is less likely to be involves in refractive development. Monitoring the nursery school light intensity should be part of the child safety.

ABSTRACT BODY:

Purpose: Using deep learning (DL), this pilot study aimed to demonstrate that function in the form of visual acuity can be predicted from pathologic structural alterations due to neovascular age-related macular degeneration (nAMD) in optical coherence tomography (OCT) images.

Methods: This retrospective analysis included 2443 OCT volumes from 341 eyes of 294 patients with nAMD. Only the foveal line scan from each OCT volume was used. We train a deep convolutional neural network using transfer learning for the binary task of predicting better or worse than 20/40 BCVA. A cut off VA of $\geq 20/40$ was chosen, as it is the accepted cut-off value for driving in most states in the US and $\geq 20/40$ has been used in several large clinical trials to characterize good visual outcomes in nAMD patients. The BCVA recorded at each corresponding clinic visit was used as ground truth. The entire dataset (BCVA $\geq 20/40$ 1097 images; BCVA $< 20/40$ 1346 images) was split randomly at the patient level into training (82.8%), validation (12.3%) and testing (4.9%).

Results: For the binary classification task of distinguishing between better and worse than BCVA 20/40, our DL algorithm achieved an accuracy of 80.0%, precision of 80.0%, recall of 79.0%, with the area under the ROC of 86.2%.

Conclusions: We have developed a DL algorithm that is capable of predicting function (BCVA) from structure (OCT images) in nAMD. As the next step, we plan to collect more training data and refine our algorithm for more fine-grained BCVA predictions, which if successful, could lead to the development of a novel DL-based OCT metric that can be used to monitor treatment efficacy in nAMD.

TITLE: Optic nerve head astrocyte mechanotransduction in congenital glaucoma

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Liu, North Texas Eye Research Institute, Pharmacology & Neuroscience, University of North Texas Health Science Center, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yang Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In congenital glaucoma, the ocular developmental abnormalities cause high intraocular pressure which places mechanical stress on the optic nerve head (ONH) and leads to optic nerve degeneration. Untreated or treated late children develop irreversible blindness. Astrocytes are the major glial cells in the ONH. Astrocytic mechanotransduction transduces mechanical stress to biological signals and regulates cell activity. In this study, we investigated the mechanosensing channels involved in ONH astrocyte mechanotransduction in an early-onset glaucoma mouse model.

Methods: Homozygous *egl1* mutant mice were obtained from the Jackson Laboratory. Intraocular pressure (IOP) was measured in conscious mice using the TonoLab tonometer. Mice were sacrificed and the ONH were collected before, 1 and 4 weeks after IOP elevation. Primary mouse ONH astrocytes were also cultured from the *egl1* mice and subjected to mechanical stretch of 10% strain for 2 hours using a FlexCell Tension System. Real time quantitative PCR was performed to assess the expression levels of mechanosensing channels in the ONH tissue. The astrocytic location of significantly regulated genes in the ONH was further validated by immunohistochemistry staining co-labeling with astrocyte marker glial fibrillary acidic protein (GFAP).

Results: The *egl1* mutant mice developed elevated IOP starting from 4 weeks of age (22.1 ± 3.7 mmHg vs. 16.5 ± 1.7 mmHg in age-matched wild type animals, Mean \pm S.D., $n=10-14$, $p<0.01$). Gene expression levels of mechanically activated ion channels of Piezo, transient receptor potential and potassium mechanosensing channel families were assessed. Expression levels of Piezo1 and Pkd2 in the ONH were upregulated in response to IOP elevation. Immunohistochemistry staining showed astrocytic location of elevated Piezo1 and Pkd2 in the ONH. After 2 hours of stretch, the morphology of astrocytes did not show significant changes; however, there was a significantly increased expression of Piezo1 and Pkd2 in stretch stimulated cells.

Conclusions: Mechanosensing channels Piezo1 and Pkd2 respond to mechanical stretch and IOP elevation. Piezo1's activity is regulated by Pkd2. The Piezo1 and Pkd2 interaction may play a role in ONH astrocyte reactivity in response to IOP elevation and contribute to pathogenesis of congenital glaucoma.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is a sight-threatening complication of retinal detachment and its surgical repair with no effective treatment. The aim of this study is to identify promising drug combinations with a potential synergistic effect by carrying out a screen in our primary culture model and an explant model of PVR.

Methods: Twelve candidate drugs were tested at 2 concentrations at 72 hours for their effects on proliferation and cytotoxicity in C-PVR cells. The most significant hits were tested in combination with other compounds to study combinatorial effects on proliferation. This effect was further evaluated in an ex vivo explant model, and total branch lengths were measured.

Results: At 5 μ M concentration 6 out of 12 drugs, bendamustine, semagacestat, daclatsvir, marbofloxacin, stavudine, and resveratrol significantly inhibited cell proliferation (20%, 30%, 16%, 30%, 19%, and 28% inhibition respectively). At 1 μ M concentration, 2 out of 12 drugs, bendamustine (25%) and semagacestat (28%) significantly inhibited proliferation. 30 μ M melphalan induced 74% inhibition, and a 60 μ M concentration reduced cell proliferation by 83%. Topotecan at 40 nM induced a 54% decrease in proliferation, and a 53% decrease was noted with 80 nM. Daunorubicin, 15 nM treatment resulted in a 50% reduction, while the 30 nM treatment resulted in a 53% reduction in proliferation. Likewise, with lenalidomide, 24% inhibition of proliferation was observed. The combination of melphalan or topotecan with other drugs showed a dramatic effect on the proliferation of C-PVR cells. Melphalan showed synergistic effect with all 10 drugs. In comparison, with topotecan, 6 out of 10 showed a synergistic effect in combination. No significant cell death was observed. Melphalan at 30 μ M (27.5 mm total branch length) and topotecan at 40 nM (34 mm total branch length) alone reduced the distance covered by outgrowths compared to vehicle (167 mm total branch length) in the explants. Explants treated with combination therapy showed an almost complete inhibition of any growth suggesting synergistic effect.

Conclusions: The majority of our candidate drugs showed dose dependent effects on C-PVR cell proliferation. Melphalan and topotecan in combination with other drugs successfully inhibited proliferation in vitro, and in an explant model of PVR suggesting synergistic effects of these agents when used as combination therapy.

TITLE: Role of Plasmacytoid Dendritic Cells in the Homeostasis of Retinal Blood Flow

SESSION TITLE: CNV

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Ortiz, A. Jamali, D.L. Harris, P. Hamrah, Ophthalmology, Tufts Medical Center, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gustavo Ortiz: Commercial Relationship: Code N (No Commercial Relationship) | Arsia Jamali: Commercial Relationship: Code N (No Commercial Relationship) | Deshea Harris: Commercial Relationship: Code N (No Commercial Relationship) | Pedram Hamrah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have recently demonstrated the presence of plasmacytoid dendritic cells (pDCs) in murine retina. In particular we have shown that pDCs are in close proximity to retinal vessels. Thus, we aimed to evaluate whether resident pDCs may mediate the homeostasis of retinal vasculature in the laser-induced choroidal neovascularization (CNV) mice model of age-related macular degeneration.

Methods: Six- to 8-week-old, BDCA2-DTR mice were intraperitoneally injected with 200 mg/ml of diphtheria toxin or PBS as pDC-depleted and sham-depleted animals respectively. pDC-depletion was corroborated by flow cytometry. Both naïve and laser-induced CNV depleted animals were evaluated in this study. CNV was performed on the same day of depletion. Three and 7 days after CNV induction, fluorescein angiography was conducted in sham and pDC-depleted animals. Fundus images were obtained; abnormal vascular leakage and scar size were quantified as fluorescence intensity and scar area (as normalized to optic disc) respectively. Further, we used our transgenic DPE-GFP^x RAG-1^{-/-} mice in which only pDCs express GFP, to quantify retinal GFP cells in naïve and after laser-induced CNV.

Results: Fluorescein angiography in naïve animals showed that vascular leakage was 1.5-fold ($p < 0.001$) and 1.4-fold ($p = 0.042$) increased after 3 and 7 days of pDC-depletion, respectively, compared with sham depleted. At 7 days after CNV induction, vascular leakage and scar area increased 4-fold ($p = 0.040$) and 2-fold ($p = 0.046$), respectively, in pDC-depleted animals. Additionally, retinal eGFP cells were CD11c^{low}, PDCA-1⁺, Ly6C⁺, Ly49Q⁺ and CD19⁻, CD3⁻, F4/80⁻, CD11b⁻. This population was increased 4-fold after laser-induced CNV as measured by flow cytometry and epi-fluorescent microscopy ($p < 0.001$).

Conclusions: pDCs are required to preserve vasculature homeostasis in naïve retinas. Moreover, pDC depletion in a clinically relevant model of AMD exhibits worse outcomes, including increased vascular leakage and scar size, indicating that pDCs may be necessary to limit disease.

Rosenfeld, Department of Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zhongdi Chu: Commercial Relationship: Code N (No Commercial Relationship) | yingying shi: Commercial Relationship: Code N (No Commercial Relationship) | Xiao Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Yuxuan Cheng: Commercial Relationship: Code N (No Commercial Relationship) | Rita Laiginhas: Commercial Relationship: Code N (No Commercial Relationship) | Giovanni Gregori: Commercial Relationship(s); Carl Zeiss Meditec: Code R (Recipient) | Philip Rosenfeld: Commercial Relationship(s); Carl Zeiss Meditec: Code R (Recipient); Carl Zeiss Meditec: Code C (Consultant) | Ruikang Wang: Commercial Relationship(s); Carl Zeiss Meditec: Code R (Recipient); Carl Zeiss Meditec: Code C (Consultant)

ABSTRACT BODY:

Purpose: To develop an algorithm to segment pigment deposits and to identify their axial positions relative to the retinal pigment epithelium (RPE) using swept source OCT (SS-OCT) data based on the appearance of hypo-transmission defects (hypoTDs).

Methods: A three-step algorithm was developed. Firstly, optical attenuation coefficient (OAC) was evaluated on a linear scale 3D SS-OCT. Bruch's membrane (BM), RPE, and inner limiting membrane (ILM) were segmented on the 3D SS-OCT cube. En face images from the slab of ILM to BM from the 3D OAC data were generated using sum projection as well as maximum projection. Axial positions of the pixels with the highest OAC along each A-scan were also calculated and their distances to BM were recorded as an elevation map. A composite RGB image (Figure 1) was generated using the OAC sum, max en face images, and the elevation map. Secondly, a deep learning model with the Unet configuration was trained to segment retinal pigment deposits from the RGB images generated in step one. Target labels were manually outlined by professional graders. Thirdly, the axial positions of pigment deposits segmented by the model were identified using the elevation map and compared to the RPE segmentation. Pigment deposits with a distance larger than 30 μm from the RPE were classified as intraretinal pigment deposits and otherwise RPE pigment deposits.

Results: A total of 152 scans from 52 eyes were collected for this study. 41 eyes were diagnosed with age-related macular degeneration (AMD) and 11 eyes showed no ocular pathology upon recruitment with long term plaquenil use in 1 eye, but no obvious retinopathy present. 132 scans were used for training (with an 80/20 split between training and validation) and 20 scans were used for testing. In the testing dataset, the model achieved an intersection over union (IoU) score of 0.75. Figure 2 shows an example of the final output of intraretinal pigment deposits and pigment deposits associated with the RPE as segmented by the proposed algorithm.

Conclusions: The proposed algorithm demonstrated a satisfactory performance for automatically segmenting pigment deposits and identifying their axial positions using SS-OCT data. This strategy could be potentially useful for tracking the appearance, size, and position of retinal pigment deposits in AMD patients as indicators of disease progression and for assessing the effect of therapies in clinical trials.

ABSTRACT BODY:

Purpose: Automated quantification of ocular inflammation provides continuous measurements of inflammation and improves the ability to differentiate activity in uveitis management. This subgroup analysis evaluates the utility of automated imaging-based measures of ocular inflammation in sarcoid uveitis (SU) and birdshot chorioretinopathy (BC).

Methods: This is a subgroup analysis of the prospective imaging of inflammation study (IQI). Recently active uveitis patients were prospectively imaged using ultra-wide field fluorescein angiography (UWFA), spectral domain optical coherence tomography (SD-OCT), and anterior segment optical coherence tomography (AS-OCT) at baseline and follow-up visits. Patients were identified as active based on clinical exam with physician interpretation of imaging. A masked grader performed automated software analysis to measure total retinal leakage (TRL) measured on UWFA, OCT central subfield thickness (CST) and AS-OCT identification of cells. Activity was met based on one or more of the following criteria: TRL > 4%, CST > 350 microns, and AS-OCT > 8 cells/mm³. In this analysis, patients with SU and BC are analyzed. Central 3-disc diameter (3DD) leakage on UWFA and intraretinal fluid percentage on OCT were also analyzed.

Results: A total of 40 eyes from 20 patients (13 SU, 7 BC) with a total of 164 visits were evaluated. BC patients met activity threshold based on AS-OCT, SD-OCT, AND UWFA in, 19.5%, 10.7%, and 2%, respectively. In SU patients, activity was noted in 20% of UWFA, 16.2% of AS-OCT, and 5.8% of SD-OCT images. In SU patients, when determined active by any imaging modality, TRL, 3DD, CST, AS-OCT were increased compared to inactive visits. In BC, when FA and AS-OCT identified activity, there was an increase in TRL and AS-OCT compared to inactive visits. When SD-OCT determined activity, CST and 3DD were higher compared to inactive visits.

Conclusions: Patients with BC and SU are identified active more often based on AS-OCT and TRL on FA, respectively. An increase in all TRL, 3DD, CST, and AS-OCT in patients with active SU validates our automated

imaging software in detecting disease activity objectively. Based on our limited number of patients with BC, further investigation will be conducted to improve our ability to differentiate imaging activity in BC patients.

ABSTRACT BODY:

Purpose: To characterize age-related changes in anterior vitreous with 3-D high-resolution Swept Source Optical Coherence Tomography (SS-OCT) and evaluate associations with vision.

Methods: This cross-sectional observational study included 49 phakic eyes of 49 patients (25 men and 24 women, mean age: 40.0 ± 19.3 yrs, range: 9-78 yrs). The anterior vitreous and the crystalline lens were imaged with a prototype SS-OCT operating at 1 μm in an enhanced vitreous imaging mode. OCT-derived parameters were: Vitreous Optical Density (VOD), Vitreous Opacification Ratio (VOR), and Lens Optical Density (LOD). Axial eye length (AL) was measured with optical biometry. Retinal point spread function was measured with a double-pass system to obtain objective scatter index (OSI). Contrast sensitivity was measured using a visual simulator, and area under log-log contrast sensitivity function (AULCSF) was calculated.

Results: The high sensitivity SS-OCT instrument allowed for visualization of the anatomy of the anterior vitreous body including gel vitreous, lacunae of liquefied vitreous, Berger's space, retrolental laminar structures, and fibrous opacified structures. VOD, VOR, and LOD showed high reproducibility (intraclass correlation coefficients 0.968, 0.975, and 0.998, respectively). VOD was highly correlated with VOR (Pearson's $R=0.96$, $p<0.000001$). VOD, VOR and LOD correlated with age ($R=0.48$, 0.58 , and 0.85 ; $p<0.001$ for each). VOR and LOD correlated with OSI ($R=0.36$; $p=0.0094$, and $R=0.3630$, $p=0.0096$, respectively). Furthermore, VOR negatively correlated with AULCSF ($R=-0.53$, $p<0.00009$). Multivariable regression confirmed a strong independent association between age and LOD, which seemed to mediate the relationships between age and VOD or VOR. AULCSF was linked to OSI.

Conclusions: SS-OCT enables visualization of age-related microstructural changes of the anterior human vitreous. Opacification of the anterior vitreous is associated with increased heterogeneity, and more scattering with degradation in contrast sensitivity function. While anterior vitreous opacities might induce CSF degradation, this more likely reflects central and posterior vitreous opacification, and can thus serve as a useful index for management of vision degrading myodesopsia.

ABSTRACT BODY:

Purpose: Stem cell-derived retinal organoids (RO) constitute powerful in-vitro tools to study human development, model disease, or test potential therapeutic drugs for retinal degenerative conditions. However, current protocols for retinal organoid generation present limitations such as variability in quantity, quality and reproducibility within and between batches, as well as extensive culture times. Such shortcomings limit the usefulness of these models and can confound outcome interpretation. Thus, establishing robust protocols to overcome the challenges of retinal organoid generation is essential for their application to drug screening and validation, as well as to the study of retinal development and disease.

Methods: We tested 5 different RO culture supplementation protocols, including different concentrations of retinoic acid (RA) or 9 cis retinal (9CisRal) as well as no supplement. Several parameters (yield, quality, development of photoreceptor outer segments) were longitudinally quantified over a 6-month time period to assess the outcomes of each condition. Additionally, we optimized the timing of implementation of a 96-well plate culture format more amenable to quantitative applications. Retinal integrity and structure were evaluated using immunostaining and TEM.

Results: Retinal organoid cultures supplemented with 9CisRal were remarkably superior in yield and photoreceptor outer segment elongation compared to all other conditions. Interestingly, this supplementation protocol also accelerated the timing of outer segment development by at least one month. Finally, we determined the optimal conditions to increase reproducibility in 96-well plate RO cultures.

Conclusions: This study compares the performance of different protocols for RO generation and highlights the conditions that lead to the most reproducible, high-quality retinal organoids. Although culture supplementation with RA or 9CisRal was confirmed to be far superior to lack of supplement, all conditions generated organoids with photoreceptor outer segments, albeit at different efficiency levels and times. Depending on the focus of interest, the addition of one supplement over the other may be more suitable. By optimizing the concentration and type of supplement, we have designed a robust protocol that will reliably produce retinal organoids for quantitative applications.

ABSTRACT BODY:

Purpose: It is not known whether different pathogens induce distinct neuronal responses and how nociceptors affect infection outcomes.

Methods: To monitor nociceptor responses during bacterial infection, C57BL6/N mice were either infected or sham treated, corneal whole mounts harvested at 24h and 48h post-infection, and stained for bIII tubulin and CGRP. To chemically ablate TRPV1⁺ nociceptors, C57BL6/N mice were treated with three consecutive doses of RTX: 30 ug/kg, 70 ug/kg, and 100 ug/kg subcutaneously. The capsaicin eye wipe test was performed to evaluate functional deficiency of nociceptors. To quantify blink reflexes, mice were monitored using Cochet-Bonnet aesthesiometer. To determine the impact of TRPV1- positive neurons on keratitis susceptibility, RTX-treated mice and vehicle-treated control mice were infected with *P. aeruginosa* strain 6294 at 5×10^5 CFU/ml and bacterial burdens were quantified. Myeloid cellular infiltrates were evaluated using CD45, CD11b, Ly6G, ICAM-1 markers using flow cytometry and ImageStream analysis.

Results: Infection induced rapid loss of blink reflexes and collapse of subbasal plexus neuronal fibers. Resiniferatoxin (RTX)-treated mice showed significantly ablated corneal sensory neurons and a temporary mild decrease in blink reflexes, which was recovered. Infected RTX-treated mice exhibited decreased bacterial corneal burdens in the first 24h of infection, elevated myeloid trafficking of CD45⁺CD11b⁺Ly6G⁺ICAM-1⁻ neutrophils and reduced CD45⁺CD11b⁺Ly6G⁺ICAM-1⁺ neutrophils. Mechanistically, increased frequencies of CGRP-induced ICAM-1⁺ neutrophils in the infected vehicle-treated mice showed reduced neutrophil bactericidal activities.

Infected NaV1.8Cre DTA⁺ mice, lacking the NaV1.8 channel, showed decreased bacterial burdens at 24h and 48h post-infection, a phenotype which was stronger and more sustained when compared to the RTX-treated mice.

Conclusions: These data showed that sensory neurons can regulate corneal neutrophil responses in a tissue-specific manner affecting disease progression during *P. aeruginosa* keratitis. Hence, therapeutic modalities that control nociceptor activation could impact anti-infective therapies.

ABSTRACT BODY:

Purpose: The molecular basis of AMD is only partly understood. Photoreceptor death and vision loss has been linked to extracellular deposits on apical and basal aspects of the retinal pigment epithelium (RPE). The purpose of this study is to use high spatial and mass resolution imaging mass spectrometry (IMS) to molecularly characterize regions of pathology observed in the neural retina, drusen, subretinal drusenoid deposit (SDD), and between photoreceptors and RPE).

Methods: Human donor eyes were either frozen or fixed following ex vivo imaging to assess AMD pathology. Tissue sections of macular and peripheral regions were analyzed using a multimodal imaging strategy which includes MALDI IMS as well as DIC, autofluorescence, and stained tissue microscopy. Adjacent sections were stained with Periodic acid-Schiff-hematoxylin and hematoxylin-eosin for morphological analysis. IMS was performed at 10-15 μ m spatial resolution in both positive and negative ion modes on a Bruker Solarix 9.4T FTICR instrument with a modified MALDI source designed for high spatial resolution and a Bruker timsTOF flex instrument at 10 μ m spatial resolution. To enable high-precision registration of IMS and optical signals, tissue autofluorescence and reflectance images were acquired from sections before and after IMS experiments. Lipid identifications were performed via LC-MS/MS in negative and positive ion modes using a Q Executive HF instrument.

Results: High spatial resolution IMS combined with registration to tissue images enabled detection of distinct lipid signals in drusen and SDD. Lipid signals observed in IMS images display heterogeneity in deposits and differences between drusen and large numbers of signals in SDD. Both unesterified cholesterol and esterified cholesterol, previously seen by histochemistry, were observed surrounding and within drusen while sphingomyelin species were abundant within drusen and basal laminar deposits. Autofluorescence and DIC imaging allowed for visualization of SDD while MALDI IMS displayed a high number of signals relating to lipid and high mass signals possibly indicating glycolipids accumulating in these regions. Inner retina internal to SDD and pathology in the RPE layer were also found to have abnormal lipid signatures.

Conclusions: IMS technology provides spatially-resolved molecular analysis of retinal pathology and extracellular deposits in human donor eyes with AMD.

TITLE: Computational modeling of the impact of corneal surgical procedures on regional stress distribution within the stroma

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Hassaniardekani, M. Petroll, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|V. Varner, Bioengineering, The University of Texas at Dallas, Richardson, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hajar Hassaniardekani: Commercial Relationship: Code N (No Commercial Relationship) | Victor Varner: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Petroll: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have demonstrated that corneal keratocyte differentiation, motility and mechanical behavior are influenced by extracellular matrix (ECM) stiffness and mechanical stress. Most biomechanical models of the surgical techniques used to treat keratoconus or to correct for refractive errors focus on predicting corneal shape. Here, we have created finite element (FE) models to predict how these procedures impact the spatial distributions of mechanical stress to which keratocytes are exposed.

Methods: A 2D axisymmetric FE model was developed in ANSYS to simulate the re-distribution of mechanical stress within the cornea following corneal cross-linking (CXL), photorefractive keratectomy (PRK) or phototherapeutic keratectomy (PTK). The cornea was modeled as a Mooney-Rivlin hyperelastic material, as described previously. To simulate CXL, the stiffness of the anterior 50% of the cornea was doubled in a central, circular region (8 mm diameter). For PTK and PRK, standard clinical ablation profiles were incorporated. We also evaluated how altering the surgical parameters (e.g. size and stiffness of CXL area, PRK ablation depth), IOP or stromal material properties impacted the stress distribution in the cornea.

Results: We found that each surgical procedure substantially re-distributes mechanical stresses within the cornea (Figure 1). In the central cornea, following CXL, the stress in the anterior cornea increases, whereas the stress in the posterior cornea decreases. In contrast, stress in both the anterior and posterior cornea increase following PTK or PRK. In the corneal periphery, the stress distribution generally remained similar to the control (unoperated) cornea. Altering the simulated surgical parameters, IOP or material properties changed the magnitude of the responses, but the overall patterns of stress were similar. Because of the nonlinear stress-strain relationship, increases in stress also increase the effective tissue stiffness.

Conclusions: In addition to altering corneal shape, corneal surgical procedures can have a profound impact on the regional stress distribution within the stroma and its response to fluctuations in IOP. These factors may influence keratocyte wound healing responses and long term stromal physiology.

ABSTRACT BODY:

Purpose: Mutations in the ABCA4 gene are the most frequent cause of inherited macular disease, with phenotypes ranging from early onset fast progressing retinal degeneration to late onset mild cases of central atrophy. Phenotypic variability is caused by extensive genetic variation in the ABCA4 gene, and correlated with the combined effect of the two disease alleles on the ABCA4 function. In genetic screening, 5-10% of the Stargardt patients remain with only one ABCA4 disease allele identified after sequencing the ABCA4 gene. The aim of this study was to identify missing causal variants in ABCA4 monoallelic STGD1 patients from a large, well-characterized ABCA4 disease cohort.

Methods: Sequencing was performed on Illumina TruSeq platform. Pathogenicity of variants was assessed according to ACMG guidelines, combining information from allele frequency data in patients vs the general population, predictive algorithms (e.g., CADD), previous publications, and segregation analysis in families. Patient phenotypes were assessed from clinical and retinal imaging data.

Results: In 61/706 (8.6%) patients only one definitely pathogenic ABCA4 variant was identified in screening of the ABCA4 coding sequences. Subsequent sequencing of the non-coding intronic sequences has revealed several rare deep-intronic candidate variants in about half of the monoallelic STGD1 patients, while many cases remain genetically 'unsolved' without plausible candidate variants. Several rare ABCA4 missense variants (p.I1562T, p.V643G, p.V643M, p.G1591R, p.T897I) have been classified as benign or of uncertain significance despite moderate pathogenicity predictions, because they are not enriched in STGD1 patients. In our cohort, four 'unsolved' monoallelic STGD1 patients harbored the c.4685T>C (p.I1562T) variant opposite from a functionally deleterious ABCA4 mutation. They were diagnosed in 5th-7th decade and showed mild macular lesions with foveal sparing. We suggest that the rare p.I1562T variant shared between these 4 patients exhibiting similar mild late onset STGD1 phenotype, might be causal when in combination with a null allele. We do not exclude the role of other possible yet to be identified cis or trans modifying variants.

Conclusions: Rare missense variants previously considered benign or of uncertain significance may contribute to late-onset ABCA4 disease with mild macular symptoms and foveal sparing.

ABSTRACT BODY:

Purpose: Apical-basal polarity (ABP) is essential to establish the apical barrier function in many epithelial tissues in the body including the cornea. Previously, we demonstrated that the corneal epithelial (CE) maturation and homeostasis depend on Krüppel-like transcription factor 4 (Klf4) that promotes epithelial identity and suppresses mesenchymal gene expression. We also demonstrated that the mature CE ABP is disrupted in the absence of Klf4. Here we evaluate the expression of ABP-determinants during CE stratification and maturation.

Methods: We employed 8 mm thick cryosections from postnatal day-8 (PN-8), PN-12, PN-14, and PN-90 wild type mouse eyes to evaluate the expression of ABP determinants Pals1, Par3, Scribble and Cdc42 during CE stratification and maturation by immunofluorescent staining.

Results: Immunofluorescent staining of sections from mature (PN90) mouse eyes revealed that Klf4 is most intensely expressed in the central CE, and gradually tapered off towards the periphery. ABP markers Pals1, Par3 and Cdc42 were prominently membrane-associated in the central and peripheral mature CE, while faint or no immunostaining was observed in the limbal region or the adjoining conjunctiva. Coincident with the mouse CE stratification, ABP markers Par3, Scribble and Cdc42 were more cortically organized in the PN-12 and PN-14 corneas compared with their diffuse expression in the unstratified PN-8 CE. As the CE matured (PN-90), immunostaining for these markers became more prominently organized in the cortical regions of the CE cells. We also observed that the basal CE has more Yap1 (a nuclear effector of Hippo signaling pathway involved in development, growth, repair, and homeostasis) expression during stratification (PN-12 to PN-14), compared with either the unstratified (PN-8) or fully mature CE (PN-90).

Conclusions: These results demonstrate dynamic changes in expression of ABP-determinants during CE stratification and their sub-cellular re-organization from being diffusely expressed at PN-8 to being cortically organized at PN-14 and PN-90. Based on these results, we suggest that Klf4 plays a key role in CE stratification by promoting relative enrichment of ABP-determinants in the central CE compared with the limbus or the conjunctiva.

TITLE: Aryl hydrocarbon receptor (AHR): potential link between autophagy and inflammation in retinal pigment epithelial (RPE) cells.

SESSION TITLE: RPE pathology in AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Choudhary, G. Malek, Ophthalmology, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|G. Malek, Pathology, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mayur Choudhary: Commercial Relationship: Code N (No Commercial Relationship) | Goldis Malek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Increasing evidence suggests an association between autophagy, and age-related degenerative disorders. AHR is a transcription factor mainly known for its role in toxin metabolism. Recently however, it has also been shown to regulate inflammation and autophagy. Aged $Ahr^{-/-}$ mice exhibit several phenotypic features of dry AMD including increased expression of inflammatory markers in the RPE/choroid, as shown by RNAseq and morphological flatmount analyses. Herein, we further investigated the role of AHR expression and function in regulating inflammation and autophagy in RPE cells.

Methods: In vivo, aged $Ahr^{-/-}$ and $Ahr^{+/+}$ mice were used to (1) study inflammation in the sub-retinal space by staining RPE-choroid flatmounts for F4/80 (macrophages) and phalloidin (RPE cell borders); (2) generate a cytokine profile of the posterior retina; and (3) measure levels of autophagy proteins (LC3B, SQSTM1/p62, Beclin1, Atg5, Atg7) in the posterior retina. In vitro, human and mouse primary RPE cultures were used to study the effect of AHR knockdown and modulation of AHR activity (Agonists: n=4, Antagonists: n=2) on autophagy. Finally, we tested the therapeutic potential of modulating AHR activity (chronic/acute), on autophagy and inflammation in RPE cells exposed to oxidative insults.

Results: $Ahr^{-/-}$ mice displayed a significant upregulation of F4/80⁺ sub-retinal cells in aged mice as compared to $Ahr^{+/+}$ mice (3.5-fold in 12-14 month old, 3-fold in 18-22 month old, n=4, p<0.04). RPE-choroid protein lysates exhibited significant upregulation of LC3B in 12-14 month old (2.5-fold) as well as 18-22 month old (2-fold) in $Ahr^{-/-}$ mice as compared to $Ahr^{+/+}$ mice (n=4, p<0.05). Interestingly, RPE/choroid samples from a 12-14 month old cohort, showed significant downregulation of p62/SQSTM1 protein levels (2-fold, n=4, p<0.05). In vitro results, consistent with the in vivo findings, showed an induction of autophagosome formation in RPE cells as measured by LC3B II/ LC3B I ratio, with AHR knockdown (4.5-fold, n=3, p<0.05).

Conclusions: The absence of Ahr is associated with an increase in inflammation and autophagosome formation in the RPE-choroid milieu. These finding along with our previous reports of RPE cell dystrophy and accumulation of extracellular sub-RPE deposits in aged $Ahr^{-/-}$ mice, support the premise that targeting the AHR signaling pathway may improve RPE cellular turnover and health.

ABSTRACT BODY:

Purpose: In humans, the long and middle wavelength-sensing cone opsins (LWS/MWS) are encoded in a tandemly replicated array. Zebrafish possess an orthologous tandemly replicated long wavelength-sensitive (lws) array. The differential regulation of human LWS vs. MWS is viewed as a stochastic mechanism, while there is evidence for trans-regulatory mechanisms in zebrafish. Our lab demonstrated thyroid hormone (TH) promotes *lws1* at the expense of *lws2* (Mackin et al., 2019, PNAS). The present work aims to identify additional transcriptional differences in the LWS1 vs. LWS2 cone populations, toward elucidating the genetic mechanisms underlying the differential regulation of LWS cone opsin expression.

Methods: We isolated GFP+ (LWS1) cones and RFP+ (LWS2) cones from dissociated retinas of adult male *lws:PAC(H)* zebrafish, using established FACS methods (Sun et al., 2018, Exp Eye Res). Bulk RNA-Seq was performed to identify differentially expressed (DE) transcripts of interest in these two cone populations. A separate, single cell RNA-Seq dataset obtained from adult retinas was used to complement this DE list with transcripts enriched in identified *lws1*- or *lws2*-expressing cones. Larval zebrafish were treated with TH, and qPCR and multiplex in situ hybridization of DE transcripts were performed.

Results: Based on a false discovery rate (FDR)<0.05, ~130 transcripts were enriched in LWS1 cones (~1.6 [AF1] % of LWS1 transcriptome), and ~93 transcripts were enriched in LWS2 cones (1.2% of LWS2 transcriptome), suggesting that these cone types are highly similar yet with a subset of distinct transcripts. Among the DE transcripts [SD(2) [AF3] were phototransduction components [*gngt2b*], transcriptional regulators [*hmgb1b*, *sox4a*, *meis2a*], and synaptic/cell adhesion molecules [*syt2*, *syph*, *adrm1*], and regulators of circadian rhythm [*cry1ba*, *aanat2*]. Preliminary qPCR and in situ data show some transcripts may also be DE in control vs TH-treated larvae, including *gngt2b* (qPCR: p<0.05, n=6).

Conclusions: This study identified several transcripts that were DE in LWS1 vs. LWS2 cones, which have been presumed identical aside from opsin expression. The DE transcripts include some involved in cone function. Some of those DE transcripts appear to be regulated by TH. This dataset provides foundations to investigate the mechanism by which *lws1* and *lws2* are differentially regulated, including candidates for functional testing.

Jane Farrar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the clinical features of adRP due to a novel heterozygous deletion of PRPF31 identified in an Irish family following whole genome sequencing (WGS).

Methods: Clinical tests performed included: ETDRS visual acuity, Goldmann perimetry, Full-field electroretinography (ERG), colour and autofluorescent fundus photography and optical coherence tomography. DNA samples underwent target capture next generation sequencing (NGS) of the exons of a panel of 260 inherited retinal disease-associated genes and WGS.

Results: The proband is one of 4 siblings. Her mother, deceased at age 80, had no vision problems. Her maternal grandmother was known to have had low luminance and independent mobility issues by her 5th decade. The proband had poor night vision at age 17 years and problems with steps, pavement edges etc, suggestive of visual field loss at age 25. Best-corrected visual acuities were 6/15 (0.4) right eye and 6/12 (0.5) left eye at age 52 and 1/25 (0.04) right eye and 1/30 (0.03) by age 66, despite bilateral, technically successful, cataract surgery. Peripheral visual fields were concentrically constricted to within 10° of fixation, with preservation of small temporal islands bilaterally, at age 54 years. She retained the same central field in each eye over subsequent assessments, despite loss of the peripheral islands. At age 54 no convincing rod or cone full-field ERG responses were recordable. Target panel NGS failed to detect any convincing pathogenic sequence variants. However, subsequent WGS identified a large (c. 28kb) heterozygous deletion on chromosome 19, encompassing the whole of PRPF31. Cross deletion polymerase chain reaction and Sanger sequencing confirmed presence of this deletion in her unaffected mother and absence in her 3 unaffected siblings.

Conclusions: Mutations in PRPF31 account for approximately 5% of adRP. Most are single base changes or deletions. Total deletion of the gene has been uncommonly reported. PRPF31 is an important component of the spliceosome, involved in pre-RNA splicing in RPE and photoreceptors. PRPF31 adRP is marked by reduced penetrance, as exemplified in this family. Total deletion of PRPF31 suggests haploinsufficiency as the causative mechanism and raises the possibility that gene replacement alone may be a therapeutic option, in contrast to a dominant-negative scenario where replacement alone is unlikely to result in benefit.

ABSTRACT BODY:

Purpose: Traumatic eye injuries often pose a significant risk for blindness in military personnel. The injured eye needs immediate attention and should be temporary stabilized until soldiers are evacuated to operating facilities. For this purpose, we have developed OcuPairTM hydrogel sealant, a novel dendrimer-hyaluronic acid adhesive for temporary corneal repair and wound stabilization.

Methods: Photo-crosslinkable components of OcuPair, methacrylated dendrimer (D-MA) and methacrylated hyaluronic acid (HA-MA) were synthesized using scale-up amenable protocols and their stability was assessed at different storage temperatures. The gelation kinetics of OcuPair were evaluated using rheology. The performance of OcuPair in sealing different full thickness corneal wounds was evaluated ex vivo in porcine and rabbit eyes. In vivo (non-GLP) performance of OcuPair was evaluated in a rabbit model of corneal injury. GLP toxicity of OcuPair was evaluated in healthy rabbits by using scaled-up engineering batches.

Results: he OcuPair was designed and optimized to form a transparent and flexible hydrogel sealant within 90 seconds of exposure to blue light (365nm, 4W). OcuPair seals full thickness corneal and corneo-scleral wounds (collectively mimicking battlefield injuries) and withstood burst pressures up to 70mmHg in porcine eyes. OcuPair secured different corneal wounds (n=12 each) in rabbits. OCT and seidel test analysis of rabbit eyes demonstrate that OcuPair maintained good anterior chamber structure and normotensive IOP up to 5 days. Clinical assessment indicated the OcuPair is biocompatible with no signs of significant inflammation to corneal tissue. In contrast, cyanoacrylate group demonstrated significant leakage, inflammation, and corneal toxicity. A 28-day GLP ocular toxicity study demonstrated that OcuPair and its components are well tolerated by ocular tissues and do not induce toxicity to the cornea or other ocular tissues. No signs of genotoxicity, pyrogenicity or bacterial reverse mutations were observed with OcuPair.

Conclusions: During medical evacuation of critically injured soldiers, lifesaving efforts are focused on treating other injuries. Unfortunately, this increases the likelihood of enucleation or permanent vision loss. OcuPair is designed to be applied easily and stabilizes the eye during the evacuation. OcuPair may provide the eye a better chance of rehabilitation and preservation of vision.

TITLE: In vivo OCT and OCTA monitoring of all retinal quadrants in the neurodegenerative mouse model

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kim, D. Klatt, X. Yao, Richard and Loan Hill Department of Bioengineering, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|X. Yao, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tae-Hoon Kim: Commercial Relationship: Code N (No Commercial Relationship) | Dieter Klatt: Commercial Relationship: Code N (No Commercial Relationship) | Xincheng Yao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As one part of the central nervous system, the retina manifests neuronal dysfunction and vascular abnormality in neurodegenerative diseases, such as Alzheimer's disease (AD). Early studies demonstrated that the pathological hallmarks appear selective to the retinal quadrant. This study aims to demonstrate in vivo optical coherence tomography (OCT) and OCT angiography (OCTA) monitoring of all quadrants of the neurodegenerative mouse retina.

Methods: Six-month-old 5xFAD (TG, N = 5) and wild-type mice (WT, N = 6) were used in this study. A custom-built OCT system ($\lambda = 810$ nm) was used for retinal imaging. Volumetric raster scans were acquired in 4 retinal quadrants (nasal, dorsal, temporal, ventral) per mouse. Each volume consisted of $4 \times 500 \times 500$ A-scans. Four repeated B-scans at each slow scan position were collected for OCTA construction. For quantitative analysis, we measured retinal thickness, vascular width, and vascular density. The artery and vein around the ONH were classified for width measurement. Retinal vascular layers were segmented into superficial vascular plexus (SVP), intermediate capillary plexus (ICP), and deep capillary plexus (DCP) for density measurement.

Results: Wide-field OCT and OCTA images were constructed by stitching 4 retinal volumes obtained from 4 different quadrants (Fig. 1), and each OCT/OCTA volume was individually analyzed for quantitative assessment. Inner retinal and outer retinal thickness were notably reduced in the dorsal and temporal quadrants of TG mice. Accordingly, whole retinal thickness was significantly lower in TG mice compared to WT mice (TG: 223.8 ± 5.3 μm ; WT: 229.5 ± 4.7 μm ; $P < 0.001$). A significant arterial narrowing in TG mice was also found (TG: 28.3 ± 4.8 μm ; WT: 33.6 ± 4.7 μm ; $P < 0.0001$). In addition, vessel densities in three plexuses were consistently low in TG mice. Especially, the ICP density reduction in TG mice was close to being statistically significant (TG: $13.7 \pm 2.6\%$; WT: $14.8 \pm 2.3\%$; $P = 0.056$), which suggests a tight correlation between neuronal and vascular degeneration.

Conclusions: In this study, we demonstrated wide-field OCT/OCTA monitoring of all retinal quadrants, which allowed to examine regional changes in the retina due to neurodegeneration. The wide field OCT/OCTA provides an imaging platform for longitudinal monitoring of AD-associated retinal degeneration and noninvasive assessment of therapy protocols.

TITLE: Engineering models to replicate RPE cell detachment in vitro

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Paterson, J. Cannon, E. Vargis, Utah State University, Logan, Utah, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chase Paterson: Commercial Relationship: Code N (No Commercial Relationship) | Jamen Cannon: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Vargis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) affected approximately 2 million Americans in 2010, and this number is expected to more than double by 2050 (National Eye Institute). In diseases like AMD, abnormal angiogenesis can lead to vision loss or blindness. While the cause of angiogenesis is unknown, previous work suggests that retinal pigment epithelial (RPE) cell detachment contributes through the imbalanced secretion of angiogenic proteins. Increased expression of pro-angiogenic proteins, like vascular endothelial growth factor (VEGF), and decreased expression of anti-angiogenic proteins, such as pigment epithelium-derived factor (PEDF), both contribute to angiogenesis. To see how RPE cell detachment affects angiogenic protein expression, we used micropatterning methods to control cell growth patterns. This method created affordable stencils that can be tuned to various stages of RPE degeneration and control cell detachment in vitro.

Methods: Real fundus images were analyzed with ImageJ software to isolate areas of retinal degeneration. These areas were combined using AutoCAD into a single shape for easier manipulation in culture while maintaining the total area of detachment. Soft lithography, a technique to fabricate shapes using a flexible mold, was used to create polydimethylsiloxane (PDMS) stencils. These stencils were placed in culture plates and seeded with primary porcine RPE cells that grew until confluency. The stencils were then removed, which introduced an area void of cell growth. Enzyme-linked immunosorbent assays and immunocytochemical staining will be used to determine how angiogenic protein expression changes with RPE cell detachment.

Results: Patterns with an area of approximately 47.6 mm^2 were created in AutoCAD. These patterns were formed into stencils that represented areas of RPE cell detachment and effectively controlled the growth of primary porcine RPE cells. One day after stencil removal, RPE cells began growing in the open spaces and angiogenic protein secretion of the RPE cells changed.

Conclusions: Engineered models of RPE cell detachment can be created from analyzed fundus images. The results of this research will elucidate relationships between varying stages of detachment and angiogenic protein expression. This understanding may increase the efficacy of current treatments and lead to additional therapeutics for retinal pathologies.

ABSTRACT BODY:

Purpose: To measure the effect of short-term exposure to dissociation enzyme on the mechanical response of the optic nerve head (ONH) in explanted mouse eyes.

Methods: The ONH was imaged with two-photon laser scanning microscopy (Zeiss LSM 710) in explanted mouse eyes using previously-published inflation testing methods (FVB/N-Tg(GFAP-GFP)14Mes mice, both sexes, 3-8 months of age). Inflation tests were performed before and again after 60 minutes exposure to TrypLE Express (Gibco 12604013), a non-animal-derived recombinant enzyme and a purified trypsin alternative. These (n=8) were compared to sequential inflation of explants exposed only to buffer (n=8). Deformation of the astrocytic lamina (AL) and of connective tissues of the peripapillary sclera (PPS) was analyzed by digital volume correlation (Korneva et al., 2020). After inflation-testing, treated specimens were prepared either for transmission electron microscopy or for fluorescent immunolabeling with phalloidin to quantify changes in the actin network (Ling et al., 2020).

Results: AL nasal-temporal strain (Exx) increased significantly post TrypLE treatment (post: $3.59 \pm 1.10\%$, pre: $2.52 \pm 0.73\%$, $p=0.01$). AL superior-inferior strain (Eyy) also significantly increased post TrypLE treatment (post: $2.50 \pm 0.64\%$, pre: $0.86 \pm 0.75\%$, $p=0.002$). The change in AL strain after treatment with buffer was insignificant (Exx post: $2.77 \pm 1.17\%$, pre: $2.92 \pm 1.41\%$, $p=0.64$). The effect of TrypLE on PPS strain response was insignificant (Exx post: $0.00 \pm 0.34\%$, pre: $0.06 \pm 0.41\%$, $p=0.93$). The differences in PPS strain after TrypLE and buffer were similar (Δ Exx $p=0.99$, Δ Eyy $p=0.81$). The PPS maximum principal strain after TrypLE significantly increased from before treatment ($p=0.01$) but not compared to after buffer ($p=0.67$). Quantitative morphological analysis of astrocyte processes in these eyes will be presented.

Conclusions: TrypLe treatment led to greater strain of the AL but similar strain of the PPS in inflation testing of explanted mouse eyes. Morphological studies suggest that astrocyte junctional complexes to the PPS are disrupted in experimental mouse glaucoma eyes (Quillen et al., 2020). Comparisons of experimental alterations of mouse model tissue may elucidate the underlying mechanisms of optic nerve head remodeling.

TITLE: A robust approach to assess cellular yield from simple non-cultured endothelial cells (SNEC) harvesting technique for corneal endothelial cell-injection therapy

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G.S. Peh, K. Adnan, D. Neo, H. Ong, J.S. Mehta, Singapore Eye Research Institute, Singapore, SINGAPORE]

Commercial Relationships Disclosure (Abstract): Gary Peh: Commercial Relationship: Code N (No Commercial Relationship) | Khadijah Adnan: Commercial Relationship: Code N (No Commercial Relationship) | Dawn Neo: Commercial Relationship: Code N (No Commercial Relationship) | Hon Shing Ong: Commercial Relationship: Code N (No Commercial Relationship) | Jodhbir Mehta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of the study is to establish a robust approach in determining the corneal endothelial cell yield following a recently described simple non-cultured endothelial cells (SNEC) harvesting approach for cell-injection therapy.

Methods: Pairs of donor corneas deemed unsuitable for transplantation were procured for this study. Optimization studies were initially performed using primary human corneal endothelial cells (CECs) isolated and cultured to the second or third passage using a dual media approach. Propagated CECs (n=3) were dissociated where 2×10^6 cells were obtained, before being serially diluted into 4 concentrations, where a manual cell count together with two automated cell counts using 2 different cell counters (BioRad TC-20 & NucleoCounter NC-250) were compared. Remaining cells from each dilution were seeded, stabilized (48hrs) and assessed morphologically. Subsequent validation was performed on CECs isolated from independent donor pairs (n=3) via the SNEC harvesting approach as previously described. The isolated CECs were strain-filtered, spun down and resuspended in 1mL where 50uL were used for cell counting and the rest seeded onto FNC-coated WillCo-Dish, and stabilized for 48hrs before morphometric analysis were performed.

Results: Initial optimization experiments using cultivated primary CECs showed that the consistency of the cell counts by the two cell counters were comparable to that of manual cell counting across the various dilutions. These results could be corroborated by the respective morphological assessments. More importantly, these automated cell counts were accurate down to the range of approximately 1×10^5 cells, which was the estimated cell yield from the SNEC harvesting technique from a single donor cornea. Subsequent validation studies using 3 sets of paired donor corneas, and 1 single donor corneas showed consistency in overall cell yield for the paired corneas of $2.7 \pm 0.4 \times 10^5$, $3.1 \pm 0.1 \times 10^5$, $3.2 \pm 0.3 \times 10^5$; and for the single donor: $1.7 \pm 0.1 \times 10^5$.

Conclusions: With regulatory consideration in mind, the capacity to robustly and accurately determine the cellular yield of isolated single-celled CECs from SNEC harvesting technique for cell-injection therapy - as shown in this study, is essential for its translation towards clinical practice.

ABSTRACT BODY:

Purpose: Even though VEGF inhibition is effective, there is a crucial need for longer-acting anti-VEGF agents to reduce the burden of repeated IVT injections and alternative therapeutic approaches to improve outcomes in wet AMD patients. Here, we evaluate a non-viral gene therapy approach to deliver aflibercept, a potent anti-VEGF inhibitor, or Decorin (DCN), an endogenous TGF-beta inhibitor with known anti-angiogenic and anti-fibrotic properties, to reduce choroidal neovascularization (CNV) in rats. Finally, we designed EYS809, a dual-gene plasmid, to deliver sustained concentrations of both proteins.

Methods: Aflibercept- or DCN-coding plasmids (30 µg/eye) were electrotransferred in the rat ciliary muscle 3 days prior laser-induced CNV. IVT injection of a human equivalent dose of aflibercept (15 mg/eye) or recombinant DCN (1 mg/eye) at disease induction served as positive controls, respectively. CNV leakage was assessed by fluorescein angiography (FA). Different dual gene expression cassettes delivering intraocular concentrations of aflibercept and DCN in rats were compared.

Results: Electrotransfection of plasmids resulted in sustained intravitreal production of aflibercept or DCN in the vitreous during the 2 week-study while aflibercept or DCN were quickly eliminated following IVT. Following both plasmid or IVT administration aflibercept reduced incidence of Grade 3 CNV lesions to 11% and 29%, respectively, vs. 59% in untreated rats. The percentage of eyes with at least one clinically relevant lesion was also reduced in both treatment groups (39% and 63%, respectively vs. 97% in untreated). Similarly, plasmid- or IVT-administered DCN reduced the incidence of Grade 3 CNV lesions to 36% and 24%, respectively vs. 59% in untreated rats with 60% and 66% of eyes having at least one clinically relevant lesion compared to 75% in untreated rats. The dual gene expression cassette expressing the highest concentrations of both proteins in rat pharmacokinetic assessments was designated as EYS809.

Conclusions: Our non-viral gene therapy sustained drug delivery approach to deliver anti-VEGF proteins to the eye could be a viable alternative to repeated IVT injections that have been associated with poor visual outcomes in wet AMD patients. The combined effect of aflibercept and DCN, expressed from the EYS809 dual-gene plasmid, is expected to provide benefits over aflibercept alone by also reducing CNV and subretinal fibrosis.

TITLE: Pediatric Refractive Error Profile 2 (PREP2) Validation Study

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.E. Dougherty, L. Jordan, D.O. Mutti, E. Galko, J.J. Walline, The Ohio State University, Columbus, Ohio, UNITED STATES|D.A. Berntsen, L. Cardenas, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bradley Dougherty: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Jordan: Commercial Relationship: Code N (No Commercial Relationship) | David Berntsen: Commercial Relationship: Code N (No Commercial Relationship) | Donald Mutti: Commercial Relationship: Code N (No Commercial Relationship) | Laura Cardenas: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Galko: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Walline: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Pediatric Refractive Error Profile 2 (PREP2) is a survey to measure aspects of the vision-related quality of life of children with refractive error. The purpose of this study was to assess the validity of the survey and examine relationships between PREP2 scores and baseline characteristics of children enrolled in the BLINK Study, a randomized clinical trial to examine the effects of multifocal versus single vision soft contact lenses on myopia progression.

Methods: Subjects completed the survey after wearing their randomly assigned contact lenses for two weeks, and data were analyzed using Rasch analysis to assess measurement precision (person separation statistic), response category functioning, and unidimensionality. Additionally, Rasch analysis was used to estimate interval-level person scores for each scale. The relationships between the scale scores and age, gender, cycloplegic spherical equivalent, and treatment group were analyzed using ANOVA and Spearman correlation.

Results: 289 subjects were enrolled with mean \pm SD age of 10 \pm 1 years (range = 7 to 11). Mean cycloplegic spherical equivalent refractive error OD was -2.38 \pm 1.01 D (range = -0.82 to -5.49 D). Response category function and item fit to the Rasch model were good for all scales. There was no evidence of multidimensionality in the measures by principal component analysis of model residuals. Measurement precision, assessed by the Rasch person separation statistic, was less than ideal for most scales. The Symptoms scale performed best, with good person separation and no evidence of multidimensionality. There were gender differences in scores on the Symptoms ($P=.006$), Appearance ($P=.014$), and Handling ($P=.003$) scales. Scores on the Vision subscale differed by treatment assignment ($P=.03$), with lowest scores for the +2.50D add group. There were low but significant correlations between age and the Appearance ($p=.16$, $P=.007$), Handling ($p=.14$, $P=.02$), Peer ($p=.17$, $P=.003$), and Overall ($p=.13$, $P=.032$) scales. OD spherical equivalent refractive error was correlated with Peer scale score ($p=.17$, $P=.004$).

Conclusions: The PREP2 survey scales showed generally good fit to the Rasch model but could be improved with better measurement precision. Scores on several scales showed relationships with characteristics of myopic children including age, gender, and refractive error. Future studies could examine survey performance in a more heterogeneous sample.

ABSTRACT BODY:

Purpose: Glaucoma drainage devices and minimally invasive glaucoma surgeries (MIGS) often present with tradeoffs in safety and durability of efficacy. Using a rabbit model, we examined the biocompatibility and feasibility of VisiPlate, a novel, ultrathin, tubeless subconjunctival shunt comprised of a network of microchannels.

Methods: Six naïve female New Zealand White rabbits received a total of nine implants, each composed of a 400 nm thick aluminum oxide core and coated with 2 µm of parylene-C. Three rabbits were implanted in the right eye with the contralateral eye untreated and monitored for 93 days. Another three rabbits received devices in both eyes and were monitored for 180 days, with 100 µL of 0.2 mg/mL mitomycin-C (MMC) application in the right eye. The surgical procedure involved a 60-90° peritomy and a stab incision through the sclera into the anterior chamber, 2 mm from the limbus. Tonometry, slit-lamp exam, clinical exam, fluorescein patency testing, and histopathology were performed.

Results: VisiPlate demonstrated statistically significant ($p<0.05$) intraocular pressure (IOP) lowering of 20-40% compared to baseline at each timepoint over the course of three months in the nine implanted eyes. All eyes developed blebs over the implant, and fluorescein testing demonstrated fluid patency at 22 days post-implantation. Slit lamp and clinical observations showed that VisiPlate was well tolerated, with low levels of conjunctival congestion, conjunctival swelling, aqueous flare, hyphema, and iris involvement from surgery that resolved over time. At sacrifice time points of 93 days and 180 days, the only notable observations were mild levels of conjunctival congestion in implanted eyes. Histopathology showed minimal tissue response and no obvious inflammation, fibrosis, or necrosis around the implant.

Conclusions: The results of this in vivo study demonstrate the biocompatibility and IOP-lowering effect of a multichannel, ultrathin subconjunctival shunt in a rabbit model. The data suggest that VisiPlate may safely enhance aqueous outflow and significantly reduce intraocular pressure.

TITLE: Elucidating endothelial caspase-9 signaling pathways in retinal vein occlusion.

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.M. Potenski, Pharmacology, Columbia University, New York, New York, UNITED STATES|C. Troy, Neurology, Columbia University, New York, New York, UNITED STATES|C. Troy, Pathology, Columbia University, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Anna Potenski: Commercial Relationship: Code N (No Commercial Relationship) | Carol Troy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Non-apoptotic induction of endothelial caspase-9 by retinal vein occlusion (RVO) sets off a signaling pathway causing edema, BRB breakdown, and eventual neuronal loss, however the exact mechanism of this pathway is still unknown. Previous studies by our lab have shown that knocking out endothelial caspase-9 diminishes the amount of edema and neuronal damage after RVO, suggesting that the endothelial caspase-9 is motivating the signaling pathway. Since this large induction of caspase-9 seems to be non-apoptotic which is atypical of the normal function, we are determining if the upstream activation of caspase-9 by Apaf-1 is the driving force behind the non-apoptotic signaling. These experiments will be carried out using inducible endothelial cell Apaf-1 knock out mice (Apaf-1 iECKO) and WT littermates who are injured with retinal vein occlusions.

Methods: 2-month-old Apaf-1 iECKO and WT littermate mice will undergo the RVO procedure previously described in Avrutsky, et al. Live imaging readouts will be used to track the pathology of the animals and compare to previous data from the caspase-9 iECKO mice. Immunohistochemistry and western blotting will be used to determine the presence of a known downstream target caspase-7 and to track the alteration in other proteins relevant to edema, BRB breakdown, and neuronal loss between injured vs. non-injured mice as well as the Apaf-1 iECKO vs. WT.

Results: This model has previously shown that the deletion of caspase-9 protects from edema and neuronal injury after RVO. Co-staining with TUNEL (marker for cell death) shows that endothelial cells aren't dying but neurons are. We know that this activation of caspase-9 within endothelial cells is non-apoptotic and will explore the activation of endothelial caspase-9 to determine why it is not carrying out its normal death signaling in the endothelial cells themselves but instead setting off a signaling cascade leading to neuronal death.

Conclusions: Endothelial caspase-9 sets off a signaling cascade leading to neuronal death and by eliminating the induction of endothelial caspase-9, we are able to prevent edema and BRB breakdown while preserving the neurons. The activation of caspase-9 specifically in endothelial cells seems to be different than its canonical function. Apaf-1 activation may be altered in this system and can be driving how caspase-9 is behaving in different cell types.

ABSTRACT BODY:

Purpose: Individuals born moderate-to-late preterm (MLP), defined as 32–36 weeks of gestation, have an elevated morbidity risk compared with full-term individuals, including neurodevelopmental disorders and cognitive impairment. However, little is known of their ophthalmological development. Our previous studies have shown impaired ocular motility, heterophoria, abnormal retinal vascularization, and lower visual evoked potential amplitudes in MLP children. In the present ongoing study, MLP adolescents at 15–18 years of age were compared with full-term adolescents regarding visual and orthoptic status.

Methods: The MLP group consisted of 50 adolescents (26 girls; mean gestational age (GA) 35.0 weeks; mean age 16.5 years). Exclusion criteria were chromosomal abnormalities, severe malformations, syndromes, or being born to mothers with severe chronic diseases. Presently, the age-matched controls consisted of 35 adolescents (mean GA 40.4 weeks; mean age 16.6 years). Visual acuity (VA), refraction, motility, strabismus, convergence, accommodation, stereoacuity, and total axial length (TAL) were examined. Statistical analyses were performed using Fisher's exact test and Mann Whitney U-test.

Results: Mild ($\geq +0.5$ diopter (D) spherical equivalent (SE)) and moderate ($\geq +2.0$ D SE) hyperopia were more commonly found in the MLP group compared with controls (mild: 39/47 vs 19/34, $p=0.012$; moderate: 9/47 vs 1/34, $p=0.039$). Mild (≤ -0.5 D SE) and moderate (≤ -1.0 D SE) myopia were more frequently seen in the control group (mild: 2/47 vs 8/34, $p=0.015$; moderate: 1/47 vs 6/34, $p=0.038$). The TAL was shorter in the MLP group (right eye: mean \pm standard deviation (SD) 23.0 ± 1.2 mm vs 23.6 ± 0.8 mm, $p=0.024$; left eye: 22.9 ± 1.3 mm vs 23.6 ± 0.8 mm, $p=0.027$). Stereoacuity >60 seconds of arc was more commonly shown in the MLP group (17/50 vs 4/34, $p=0.023$). There was no significant difference between the groups regarding VA, strabismus, motility, convergence, or accommodation.

Conclusions: In the present study, both mild and moderate hyperopia were more commonly found in the MLP group at 15–18 years of age. Accordingly, myopia was more frequently shown in full-term adolescents. This was also reflected by the shorter TAL in the MLP group. Furthermore, subnormal stereoacuity was more commonly found in MLP adolescents. There was no significant difference concerning VA, strabismus, motility, convergence, or accommodation.

TITLE: Association of Age-related Macular Degeneration with Exfoliation Syndrome: The Utah Project on Exfoliation Syndrome

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Taylor, C. Paulson, C.J. Pompoco, K. Curtin, B.C. Stagg, B.M. Wirostko, Moran Eye Center, University of Utah Health, Salt Lake City, Utah, UNITED STATES|R. Ritch, New York Eye and Ear Infirmary of Mount Sinai, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Samuel Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Chase Paulson: Commercial Relationship: Code N (No Commercial Relationship) | Christian Pompoco: Commercial Relationship: Code N (No Commercial Relationship) | Karen Curtin: Commercial Relationship: Code N (No Commercial Relationship) | Brian Stagg: Commercial Relationship: Code N (No Commercial Relationship) | Robert Ritch: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Wirostko: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Exfoliation syndrome (XFS) is associated with COPD, obstructive sleep apnea, hernias, and atrial fibrillation. Studies suggest XFS may share pathogenetic relationships with age-related macular degeneration (AMD) due to underlying elastin and basement membrane dysfunction and repair. A retrospective analysis was conducted to assess the association between XFS and AMD.

Methods: Subjects were identified in the University of Utah Healthcare System (UUHCS) with an XFS diagnosis (ICD-9 codes 365.52 and 366.11) from 1996-2015. A conditional logistic regression accounting for individual matching on age and sex and adjusted for race, ethnicity, obesity, smoking history, and hypertension history was performed. The risk of AMD was estimated in patients age ≥ 60 y on 1/1/1996 (when electronic records became available) with an ICD-9 AMD diagnosis: 362.50 (unspecified/presumed nonexudative ('dry') if no history of exudative ('wet') AMD, 362.51 (dry AMD), 362.52 (wet AMD), 362.57 (drusen). Random non-XFS UUHCS controls matched 5:1 on age and sex comprised the comparison group for assessing AMD risk in this cross-sectional analysis.

Results: Of 3,082 UUHCS patients with an XFS diagnosis, 562 (18.2%) were positive for a diagnosis of any type of AMD. Of 15,418 controls, 1,160 had a history of any type of AMD (7.5%) (OR= 2.79; 95% CI= 2.47-3.10; $P<0.0001$). 245 (8.0%) of XFS patients and 347 (2.3%) of controls had a diagnosis history of wet AMD (OR=3.76; 95% CI= 3.16-4.47; $P<0.0001$). 300 (9.7%) XFS patients and 765 (5.0%) controls had a diagnosis of dry AMD (OR= 2.03; 95% CI= 1.76-2.34; $P<0.0001$). In XFS patients, increased risk of a wet AMD diagnosis was significantly higher than that of dry AMD (non-overlapping confidence intervals). Drusen, a very small group, was not analyzed separately.

Conclusions: XFS patients may have an increased risk of both wet and dry AMD compared to those without XFS. The increased risk of AMD associated with XFS was greater for wet AMD than dry AMD. XFS patients need to be followed closely for both AMD and glaucoma. Continued data analysis will explore associations at an individual eye level.

TITLE: Suprachoroidally delivered DNA nanoparticles produce human Myosin7A protein in RPE-choroid in rabbits

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Kansara, L. Muya, T.A. Ciulla, Clearside Biomedical Inc, Alpharetta, Georgia, UNITED STATES|M.J. Cooper, R. Moen, Copernicus Therapeutics Inc., Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Viral Kansara: Commercial Relationship(s);Clearside Biomedical:Code E (Employment) | Mark Cooper: Commercial Relationship(s);Copernicus Therapeutics:Code E (Employment) | Leroy Muya: Commercial Relationship(s);Clearside Biomedical:Code E (Employment) | Robert Moen: Commercial Relationship(s);Copernicus Therapeutics:Code E (Employment) | Thomas Ciulla: Commercial Relationship(s);Clearside Biomedical:Code E (Employment)

ABSTRACT BODY:

Purpose: Adeno-associated viral vectors (AAV) cannot accommodate large genes such as Myosin7A, limiting investigational gene therapy for Usher syndrome. A prior preclinical study demonstrated that non-viral DNA nanoparticles (DNPs), which can accommodate large genes, yield similar marker gene activity when administered suprachoroidally or subretinally, suggesting the potential for office-based gene therapy. This study evaluated ocular tolerability and transfectability of DNPs encoding human Myosin7A (hMyo7A) after either suprachoroidal (SC) or intravitreal (IVT) injection in rabbits.

Methods: The DNPs consisted of a single copy of plasmid DNA encoding hMyo7A. Dutch-Belted pigmented rabbits (N=4 per group) received a single SC (0.1 mL) or IVT injection (0.05 mL) of DNPs (either 4 or 8 mg/mL of DNA). Ocular tolerability, with or without prophylactic steroids, was assessed via slit lamp, indirect ophthalmoscopy, intraocular pressure (IOP), optical coherent tomography (OCT), electroretinography (ERG) and fundus photography (FP) for up to 3 months. Protein and RNA levels were measured in ocular tissues via ELISA and qRT-PCR, respectively at 3 months.

Results: OCT imaging confirmed reversible opening of the suprachoroidal space after SC injection of DNPs. The SC injection of DNPs was much better tolerated than IVT injection of DNPs. During the 3- month study, IVT injected DNPs resulted in signs of severe ocular inflammation as assessed by slit lamp, indirect ophthalmoscopy, OCT, FP, and ERG testing. Prophylactic steroid treatment showed no clinically meaningful improvement in ocular inflammation after IVT injections. The hMyo7A protein was detected in the RPE-choroid (68-105 ng/gm) at 3 months after SC or IVT injection with no statistically significant difference between the routes of administration. The hMyo7A protein levels were detected in sporadic retina samples. The RT-PCR data indicate that DNPs produce mRNA levels in the RPE-choroid that is in the range of 45%-160% of the endogenous rabbit Myo7A.

Conclusions: Suprachoroidally administered DNPs produced hMyo7 protein in RPE-choroid in rabbits. Given the potential for repeatable office-based large gene therapy, further studies are warranted to improve transfection of photoreceptor cells, and to evaluate efficacy and safety in higher species

TITLE: A modified AAV2/6 enhances retinal microglial transduction in a layer-specific manner

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Maes, G. Wögenstein, G. Colombo, S. Siegert, Institute of Science and Technology Austria, Klosterneuburg, Niederösterreich, AUSTRIA|

Commercial Relationships Disclosure (Abstract): Margaret Maes: Commercial Relationship: Code N (No Commercial Relationship) | Gabriele Wögenstein: Commercial Relationship: Code N (No Commercial Relationship) | Gloria Colombo: Commercial Relationship: Code N (No Commercial Relationship) | Sandra Siegert: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Microglia are a critical component to retinal homeostasis and disease progression, yet we still lack an effective strategy to manipulate them in vivo. Adeno-associated viruses (AAVs) are a widely used tool for transducing cells in the retina, and can also be translated to the clinic for targeted gene therapy approaches. So far, targeting microglia with AAV in the retina has not been explicitly addressed, since microglia transduction in other CNS regions has proven to be challenging.

Methods: We performed intravitreal and subretinal injections in adult C57Bl6/J mice using a self-complementary capsid-modified AAV2/6^{TYF} harboring the GFP transgene under the microglia-specific CD68 promoter (scAAV2/6^{TYF}-CD68-GFP). Then, we modified the viral capsid to reduce interaction with heparin-binding sites, and finally, we inserted a double-floxed inverted open reading frame (DIO) into the AAV2 transfer vector (scAAV2/6^{d4}-CD68-DIO-GFP) to increase specificity. Two weeks post-injection, we performed immunostaining for GFP and the ionized calcium binding adaptor molecule 1 (Iba1), which labels the entire microglial population. We quantified the ratio of GFP/Iba1 double-positive cells to total Iba1-positive cells within each plexiform layer to determine microglial transduction efficiency.

Results: Subretinal or intravitreal injection of scAAV2/6^{TYF}-CD68-GFP showed greater microglial transduction efficiency in the plexiform layer closest to AAV delivery location. However, the overall transduction efficiency was low regardless of injection method, and non-specific transgene expression was prominent, especially in photoreceptors and Müller glial cells. Subretinal injection of our modified scAAV2/6^{d4}-CD68-DIO-GFP resulted in microglia-specific transgene expression and moderately increased transduction efficiency in the outer plexiform layer (OPL). Strikingly, we observed up to a three-fold increase in microglial transduction efficiencies under conditions that stimulate microglia.

Conclusions: We show that AAV-mediated microglial transduction in the retina is feasible, yet remains a challenge. Our modified AAV2/6^{d4} was microglia-specific and increased microglial transduction in the OPL, however our results suggest that additional factors contribute to substantial increases in transduction efficiency. Future work will need to identify how the retinal environment impacts AAV-mediated microglial transduction.

ABSTRACT BODY:

Purpose: Our overall objective is to develop a femtosecond laser system designed to deliver pulses aimed at preventing and treating vitreoretinal disease. Here, we sought to determine the feasibility of delivering our laser to in vitro retinal surfaces, detect pulse energy-dependent changes in laser-induced burn patterns, and measure how vitreous degenerates pulse morphology.

Methods: In Experiment 1, equatorially bisected pig eyes (n=2) were mounted in our laser system. Single-shot ultra-short laser pulses (800nm; 10mm diameter spot size; 28fs pulse duration) were delivered from a Ti:Sapphire chirped-pulse-amplification laser system. Pulse duration was measured by a Frequency-Resolved Optical Gating (FROG) system and compressed by optimizing diffraction-grating optical compressor spatial parameters. Laser-induced retinal burns were imaged using scanning-electron microscopy. Total burn area was measured using ImageJ. One-way analysis of variance (ANOVA) was used to assess effects of pulse energy on burn area. In Experiment 2, laser pulses were passed through: (1) empty glass container; (2) glass container filled with pig vitreous to 20mm depth; and (3) same condition as (2) with compensated pulse parameters. Full-width half maximum (FWHM) of the pulse temporal and spectral profiles were extracted from FROG measurements.

Results: In Experiment 1, femtosecond laser-induced burns were observed in retinae. Total burn area ($\text{mm}^2 \pm \text{SD}$) was measured across four energy levels: 12nJ ($2,346.7 \pm 378.8$; n=4), 115nJ ($4,968.1 \pm 347.1$; n=2), 12mJ ($15,220.4 \pm 6974.3$; n=5), 21mJ ($7,174.1 \pm 2388.9$; n=5). One-way ANOVA revealed an effect of laser energy on total burn area ($F(3,12)=7.52$, $p=.0043$). In Experiment 2, vitreous degenerated pulse morphology. Relative to the empty glass container, 20mm of vitreous introduced a 78% increase in temporal FWHM and a 4% increase in spectral FWHM. Compensating for pulse morphology degeneration, by contrast, produced a 4% decrease in temporal FWHM and a 16% decrease in spectral FWHM relative to empty glass container.

Conclusions: Our femtosecond laser delivers ablative pulses that scale with pulse energy. Vitreous imposes non-zero degenerative effects on laser pulse morphology that can be corrected. These results will be informative for further developing this system to deliver therapeutic laser pulses aimed at preventing and treating vitreoretinal disease.

ABSTRACT BODY:

Purpose: The human Usher syndrome (USH) is the most frequent cause of inherited combined deaf-blindness. USH1C encodes for the scaffold protein harmonin organizing the USH protein interactome. We aimed to decipher the expression profiles of harmonin isoforms and analyzed harmonin's subcellular localization in the cells of the human retina.

Methods: We analyzed and quantified the expression of harmonin isoforms in human retina by RT-PCR, RNAseq and Western blotting. Harmonin localization was studied in human and non-human primate retinas by immunofluorescence (LM) and immunoelectron (EM) microscopy. Protein-protein interactions were analyzed by co-immunoprecipitations and in situ proximity ligation assays.

Results: Although at least 20 harmonin isoforms were identified in the human retina, harmonin-a1 is the most frequently expressed variant. Bulk RNAseq of retinal cell populations revealed not only abundant expression in Müller glia cells, but also in retinal neurons including photoreceptor cells. LM and EM revealed harmonin localization in endfeet and apical microvilli of Müller glia cells. In photoreceptor cells, we found harmonin at adhesion complexes in the outer limiting membrane and calyceal processes of the inner segment. In addition, harmonin was detected in the synaptic pedicles of cones. In contrast, in rods, it was most abundant in the outer segments (ROS).

Conclusions: Our data are valuable for both gene therapy development and retinal cell biology. We identified harmonin-a1 as the most abundant harmonin isoform in human Müller glial and photoreceptor cells. Therefore, for gene therapy, we propose retinal delivery of harmonin-a1 using a vector that transduces both cell types. We hypothesize that harmonin organizes protein networks associated with the actin cytoskeleton in those cells. Of note, harmonin in ROS may participate in disk staking by interacting with actin and rhodopsin. Defects in harmonin might cause disruption of these protein networks and thus of retinal cell maintenance, leading to the retinal pathophysiology phenotype of USH1C.

ABSTRACT BODY:

Purpose: CRISPR-Cas9 genome editing has revolutionized basic and translational vision research. The ability to select for corrected disease-causing variants provides an effective strategy in disease modelling and development of cell therapy for inherited retinal diseases. However, in some cases the placement of the selection cassette interferes with expression from the target locus. We hypothesized that delivering CRISPR-Cas9 reagents, a donor template targeting the locus of interest, and a donor template carrying the selection cassette targeting a separate locus would address selection-based transcriptional interference at the intended locus. The purpose of this study was to develop a co-targeting strategy employing the AAVS1 safe harbor site as a selection locus.

Methods: We created a plasmid carrying a *S. pyogenes* Cas9 expression cassette and single guide RNA expression cassettes targeting both the locus of interest and the AAVS1 site. The CRISPR-Cas9 expression plasmid, a donor template carrying homologous sequence to the locus of interest, and a donor template carrying a puromycin selection cassette flanked by AAVS1 homology sequence were delivered to human cells via cationic lipid transfection and cultured under puromycin selection for 10-14 days. Genomic DNA was isolated from puromycin resistant clones and screened for modification at the locus of interest via PCR.

Results: We cloned and screened single guide RNAs targeting five loci: CRX, GRK1, VSX2, USH2A, and CEP290. We achieved successful co-targeting at all five loci as revealed by amplification of donor-target junctions and RFLP analysis. Clonal analysis at three loci – CRX, GRK1, and VSX2 – indicated co-targeting in 5%, 20%, and 35% of puromycin-resistant clones, respectively.

Conclusions: This work may accelerate the development of CRISPR-Cas9 therapies for inherited retinal dystrophies.

TITLE: Analyzing lubricant eyedrop touchdown and motion on dry ocular surface

SESSION TITLE: Corneal disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Abdulrazik, Innovative Therapeutic Algorithms, East Jerusalem Biomedical Institute, East Jerusalem, PALESTINE, STATE OF

Commercial Relationships Disclosure (Abstract): Muhammad Abdulrazik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Effective biotribological lubrication of dry ocular surface was reported as correlating with ocular comfort score and needs a minimum lubricant film thickness to be sustained significantly above thickness of natural tear film. This study aimed to analyze the dynamic interactions between lubricant droplet and ocular surface and to introduce the rate of droplet thinning, while droplet is spreading, as a benchmark for predicting lubricant biotribological merits.

Methods: Droplet touchdown on ocular surface triggered the recording of droplet motion. Ten frames per second were captured from AVI movie, framing a 40 microliter lubricant droplet above a face-up placed ocular surface of freshly excised rabbit eyeglobe at induced dry eye condition. Droplet boundaries, its contact angle and droplet cross-section width were auto-determined from captured frames by FTA-188 algorithm (First Ten Angstroms Inc.) allowing the extraction of droplet central-height (h) and base-area radius (r). Studied lubricants were cationic (CEM) and anionic (AEM) nanoemulsions (core oil, emulsifier, surfactant, and cationic or anionic entity) and polyanionic hyaluronate 0.1% (SH).

Results: Spreading of CEM droplet was swift and its height (h[CEM]) fell sharply. Between 0.1 and 0.3 seconds after touchdown, h[CEM] went from 0.5 ± 0.1 mm to 0.3 ± 0.1 mm ($p = .0291$) and then down to an approaching-zero plateau after 2 seconds. In contrast, the droplet height of AEM and SH went down moderately. In the 1-10 seconds interval, h[AEM] went down from 1.7 ± 0.3 to 1.2 ± 0.2 mm ($p = .0715$), and h[SH] went down from 2 ± 0.8 to 1.2 ± 0.6 mm ($p = .2321$). Regression analysis of h and r relationship returned $h = 0.4658e[-0.063r]$ ($R^2 = 0.9655$) for CEM, $h = 5.9312e[-0.354r]$ ($R^2 = 0.9993$) for AEM and $h = 3.9905e[-0.217r]$ ($R^2 = 0.9692$) for SH.

Conclusions: CEM droplet swift spreading reflects, in part, the electrostatic attraction of the cationic CEM to the anionic entities that dwell at ocular surface. Yet, the associated swift thinning of CEM droplet is not corresponding with favorable biotribological merits. In contrast, biotribological features can still be realized for the anionic AEM and SH, as both sustained a minimum film thickness significantly above thickness of natural tear film. The results showcase the merits of lubricant droplet motion imaging after topically applying a droplet on ocular surface and introduce the thinning rate of lubricant droplet as a biotribological benchmark.

Light Technologies, Inc.:Code P (Patent)

ABSTRACT BODY:

Purpose: To quantify inter & intra-day variability of microsaccades in a cohort of young, healthy controls.

Methods: We used a custom-built retinal tracker, the TSLO, to record microsaccades in a cohort of 14 healthy controls, ages < 40 years, at 9 different time points (3x a day (morning, afternoon & evening), for 3 days). Each session had 3 videos recorded per eye (6 traces per subject per session). Individuals were instructed to fixate for 10s on the upper right-hand corner of a 5°x5° imaging raster. Microsaccade characteristics of frequency, amplitude, peak velocity, & peak acceleration were calculated & compared for all time points to determine inter & intra-day variability & overall variation between subjects. Descriptive statistics were used to characterize measures of central tendency & variation for each of the microsaccade metrics.

Results: Our sample consisted of 14 participants, 121 sessions, & 608 traces. Participants had an average (std) microsaccade frequency of 0.84 Hz (0.52), average amplitude of 0.32° (0.11), average peak velocity of 43.68 °/s (14.02), & average peak acceleration of 13,920.04 °/s² (4,186.84). In general, we found only modest evidence of variability between traces, with consistently higher peak velocity &/or acceleration values for the 1st trace of each session. Trace 2 had a significantly lower average peak velocity of 3.93 °/s (p=0.02) & lower peak acceleration of 1,312.30 °/s² (p=0.023) than trace 1. Additionally, trace 3 had a significantly lower average peak acceleration than trace 1 by 1,657.14 °/s² (p=0.009). We detected a negligibly higher vertical velocity of 1.75 °/s (p=0.017) in trace 3 when compared to trace 2. Microsaccade frequency was the only metric to have a significant time of day difference, with evening values being slightly higher than morning recordings (0.098 Hz, p=0.007). We found no statistically significant differences in day-to-day measurements & no significant learning effect from session to session was observed in the metrics.

Conclusions: Utilizing our fixation stimuli & a 10 second recording paradigm, trace 1 showed statistical differences when compared to subsequent traces within a session. We saw a modest increase in the number of microsaccades between morning & evening sessions. No statistically significant differences in day-to-day measurements of microsaccades were observed, revealing no significant learning effect.

TITLE: Measuring the Volume of the Limbal Crypts with visible-light Optical Coherence Tomography

SESSION TITLE: Keratoconus and biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Fang, L. Beckmann, H. Zhang, Northwestern University, Evanston, Illinois, UNITED STATES|A.R. Djalilian, Illinois Eye and Ear Infirmary, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Raymond Fang: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Beckmann: Commercial Relationship: Code N (No Commercial Relationship) | Ali Djalilian: Commercial Relationship: Code N (No Commercial Relationship) | Hao Zhang: Commercial Relationship(s);Opticent Health:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: Structural changes of the limbal stem cell niche are unknown in many ocular pathologies. Although studies have characterized the shape of the focal stromal projections of the palisades of Vogt, there is a dearth of studies examining the macroscopic structure of the limbal crypts. Consequently, a method for measuring the volume of the limbal crypts using visible-light optical coherence tomography (vis-OCT) imaging was developed.

Methods: One ex vivo human eye, positioned in a region where the palisades were most visible, was imaged with vis-OCT. A raster scan pattern with a field of view of 1 mm by 1 mm was used to acquire two images of the eye at different times and slightly different locations. For volume calculation, the first step was to identify the surface of the limbus. A combination of thresholding, outlier removal, and 3D parabola fitting was used to determine this surface. Next, the boundary of the stromal projections was identified. The inverse gradient was calculated and a fast marching scheme using the inverse gradient found the boundary of the stromal projections. An initial mask found from a threshold that under segmented the limbal crypts was used as a seed for the marching algorithm. An alternate method based on manual thresholding to find the stromal projection surface was implemented for comparison. The volume of the limbal crypts is the volume between the limbal surface and stromal projections.

Results: Repeated measurements of limbal crypt volume at slightly different locations yielded volume measurements of 3.5×10^7 cubic microns and 2.7×10^7 cubic microns. Volume changed by less than 2% as parameters differed when the fast marching scheme was used to determine the stromal projection boundary. However, volume changed by up to 27% when different manual thresholds were used.

Conclusions: We developed a method that is robust to changes in parameters for measuring the volume of limbal crypts. Such measurement has the potential to serve as a parameter for monitoring the health of the stem cell niche. However, additional investigation is needed to examine the consistency and capability in identifying pathological alterations.

ABSTRACT BODY:

Purpose: FOXC1 is a transcription factor involved in heart, craniofacial and ocular development in vertebrates. Mutations in FOXC1, along with mutations in PITX2, cause Axenfeld-Rieger syndrome (ARS) and explain approximately half of the ARS cases. However, there is still a significant number of patients with an unknown genetic cause. Expression and activity of transcription factors involved in development are finely controlled by their regulatory elements that are often evolutionarily conserved. It has been shown that mutations in those regulatory elements could be also pathogenic. The goal of this project is to discover regulatory elements for FOXC1 using zebrafish as a vertebrate model and relate this information to human eye development and disease.

Methods: BLAST alignments involving regions surrounding human FOXC1 and two orthologous zebrafish genes foxc1a and foxc1b were carried out to identify conserved sequences. CRISPR-Cas9 was used to generate zebrafish lines carrying deletions for the identified conserved elements. The obtained lines were characterized by gross morphology examination, OCT and histology analysis. Expression of foxc1a and foxc1b genes and encoded proteins was assessed by RT-qPCR, in situ hybridization with RNAscope probes and immunohistochemistry.

Results: We identified 3 elements downstream of human FOXC1 and 1 element upstream of FOXC1 that were conserved in zebrafish foxc1a or in both foxc1a and foxc1b. The deletion of a 152kb intergenic region comprising all 3 downstream elements (Δ CED1-3) resulted in a downregulation of both the foxc1a transcript and protein in developing zebrafish embryos. Homozygous Δ CED1-3 larvae die at 1 month post fertilization and present with enlarged anterior chambers of the eye and a significant pericardial and other organs' edema. Deletion of an 82.7Kb region containing only 2 out of the 3 downstream conserved elements (Δ CED2-3) produced a similar but milder phenotype. Deletion of elements upstream either foxc1a (Δ CEU1a) and foxc1b (Δ CEU1b) did not produce a visible phenotype.

Conclusions: The identified downstream conserved elements are essential for normal foxc1a expression and their deletion results in a phenotype consistent with foxc1/FOXC1 deficiency in zebrafish and humans. Further studies of these regions in human patients is likely to explain additional ARS cases.

TITLE: c-TBI Induced Ocular Dysfunction and its Mitigation by RIC

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Singh, A.K. George, R.P. Homme, D. Stanisic, J. Behera, N. Tyagi, S.C. Tyagi, Physiology, University of Louisville School of Medicine, Louisville, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mahavir Singh: Commercial Relationship: Code N (No Commercial Relationship) | Akash George: Commercial Relationship: Code N (No Commercial Relationship) | Rubens Homme: Commercial Relationship: Code N (No Commercial Relationship) | Dragana Stanisic: Commercial Relationship: Code N (No Commercial Relationship) | Jyoti Behera: Commercial Relationship: Code N (No Commercial Relationship) | Neetu Tyagi: Commercial Relationship: Code N (No Commercial Relationship) | Suresh Tyagi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While cortical traumatic brain injury (c-TBI) is a leading cause of mortality, and morbidity worldwide, there are no effective pharmaceutical interventions for this condition. It is induced by a combination of complex primary, and secondary mechanisms that give rise to cellular death, inflammation, and neurological dysfunction in c-TBI patients. Furthermore, hyperhomocysteinemia (HHcy) led metabolic malfunctioning is a significant biological variable that could further contribute, and add to c-TBI heterogeneity, and related pathophysiology. Since remote ischemic conditioning (RIC) exerts endogenous protective effects that has the potential to become a therapeutic treatment in such complex medical conditions. Therefore, to understand the mechanisms of c-TBI derived neurological damage during HHcy, as well as the approaches that might promote its mitigation could help guide the development of therapeutic modalities for c-TBI patients that suffer from ocular dysfunction.

Methods: To study neurological injury to the eye in c-TBI patients, we used experimental groups of mice as follows: (i) Wild type C57BL/6J (WT), (ii) WT+ c-TBI, (iii) WT+RIC, (iv) WT + c-TBI + RIC, (v) CBS⁺/-, (vi) CBS⁺/- +c-TBI, (vii) CBS⁺/- + RIC, and (viii) CBS⁺/- + c-TBI + RIC. Retinal layers architecture, and intraocular pressure (IOP) were measured by optical coherence tomography (OCT), and tonometry. Vision guided behavior was tested in a light-dark chamber along with measurement of retinal functions via electroretinography (ERG). In addition, immunohistochemistry fluorescent antibody analysis was performed by confocal microscopy, and the retinal fluorescent angiography analysis was also carried out employing funduscopy. Our further investigations employing chromatin immunoprecipitation (ChIP) assay, creatine kinase (CK) analysis, zymography, western blotting, and Immunohistochemistry analyses aided in understanding the mechanistic of neurological injury to the eye.

Results: Interestingly, RIC was found to alleviate some of the detrimental effects to the eye in the HHcy mice that underwent experimental c-TBI manipulations.

Conclusions: This work highlights therapeutic potential of RIC towards reversing the harmful effects of c-TBI on vision especially during HHcy metabolic malfunctioning.

ABSTRACT BODY:

Purpose: To compare thickness of different retinal segmentations between dyslexic individuals and controls at the macula, including the fovea, the parafovea and the perifovea.

Methods: Twenty dyslexic volunteers and twenty age- and sex-matched non-dyslexic controls underwent macular optical coherence tomography (OCT) scans in both eyes using the Early Treatment Diabetic Retinopathy Study protocol. The thickness of the fovea, 4 sectors of the parafovea and 4 sectors of the perifovea (temporal, nasal, superior and inferior sectors) were considered in the following segmentations: complete retina, outer retina, inner retina, outer nuclear layer + outer plexiform layer + inner nuclear layer (ONL+OPL+INL) and ganglion cell complex (GCC). The results of the right and left eyes were independently compared between groups.

Results: Significantly higher thickness in all the sectors of the parafovea and some sectors of the perifovea, but not the fovea, was found in right and left eyes in complete retina and inner retina in the dyslexic group. Plus, all sectors of the macula of ONL+OPL+INL in both eyes (including the fovea) were significantly thicker in the dyslexic group. In contrast, no thickness differences between both groups were found in any of the sectors of GCC or outer retina in any eye.

Conclusions: Middle retinal segmentation (ONL+OPL+INL) at the macula is thickened in dyslexia in both eyes as measured by OCT. This fact seems to induce thickening in inner retina and complete retina results at the macula in the context of this disorder. Considering that a certain degree of integration of visual stimuli takes place at middle retinal layers our results suggest that the retina could play a role in the development of the dyslexia.

ABSTRACT BODY:

Purpose: Clinical investigations associate hypothyroidism with an increased risk for microvascular complications, yet the role of thyroid hormone in the development of diabetic retinopathy is not clearly understood. The purpose of the current study is to investigate 1) thyroid hormone activating enzyme iodothyronine deiodinase 2 (Dio2) levels ex vivo in the retinas of diabetic and non-diabetic mice, 2) Dio2 expression in vitro in retinal cells grown in high glucose conditions, 3) effect of thyroid hormone supplementation on high glucose-mediated cell death in primary mouse retinal microvascular endothelial cells (mREC).

Methods: Dio2 gene expression was measured in control and 12-week streptozotocin-induced diabetic mouse retina by RNA sequencing and Real-time PCR. Mouse retinal microvascular astrocytes and mREC were cultured in normal (5 mM) or high glucose (25 mM) and Dio2 protein level was quantified in cell lysates by western blotting. Cell death was measured by trypan blue exclusion assay.

Results: Diabetes caused a significant decrease in Dio2 transcripts in the retina ($P=0.004$) and an overall 50% decrease ($p=0.0001$) in Dio2 gene expression in the retinas of diabetic mouse compared to non-diabetic mice. Retinal cells grown in high glucose demonstrated a significant reduction of Dio2 protein level in both mouse retinal astrocytes ($p=0.002$) and endothelial cells ($p=0.02$). Moreover, a significant protective effect of thyroid hormone supplementation on high glucose-induced endothelial cell death was observed with active hormone (T3) ($P=0.0079$) but not with prohormone (T4), supporting a loss of Dio2 activity in the presence of high glucose conditions.

Conclusions: Decreased intraretinal, active thyroid hormone level due to diabetes-induced loss of Dio2 may lead to apoptosis of both vascular and neuronal cells in the retina, a contributing factor to the pathogenesis of early diabetic retinopathy.

ABSTRACT BODY:

Purpose: Choroidal macrophages (cMΦ) are the predominant resident immune population in the choroid, and our goal is to characterize cMΦ heterogeneity and transcriptomic states in health and disease.

Methods: We reanalyzed publicly available bulk and single-cell RNA-sequencing (scRNA-seq) data from the choroids of 150 non-diseased and AMD donors (scRNA-seq: 7 controls, 2 AMD; bulk RNA-seq: 115 controls, 26 AMD).

Results: We identified 5 predominant myeloid populations including classical monocytes, nonclassical monocytes, conventional dendritic cells, monocyte-like macrophages, and cMΦ. cMΦ displayed a unique transcriptomic profile that was enriched for genes/pathways involved in phagocytosis, lipid metabolism, and immunosuppression. Of note, cMΦ contained uniquely high levels of TREM2 expression, a lipoprotein receptor that regulates the phagocytosis and removal of excess lipid. In macular AMD samples, cMΦ displayed a reduction in relative abundance and a transcriptomic shift that included upregulation of MHCII and NF-κB target genes and downregulation of TREM2 signaling modules. To expand our findings, we used bulk RNA-seq deconvolution and found a significant decrease in cMΦ in macular AMD samples (macular control=4.4%, macular AMD=1.6%, $p=0.006$). We confirmed that mouse cMΦ express TREM2 at baseline using publicly available scRNA-seq, immunofluorescence, western blot, and RT-qPCR. To test the hypothesis that TREM2 expression in cMΦ regulates vascular maintenance and lipid removal, we challenged TREM2 knock-out mice (TREM2KO) with 15wk of high-fat diet (HFD). Compared to WT mice on HFD, TREM2KO HFD mice showed an accelerated loss of visual function, assessed using optokinetic nystagmus (percent change from baseline at 10wk HFD: WT=-2.9% [$p=0.24$], TREM2KO=-20.9% [$p=0.0004$]). At 15wk of HFD, TREM2KO mice showed significantly decreased choroidal thickness on OCT (WT=49.5μm, TREM2KO=45.9 μm, $p=0.009$), significantly decreased choroidal vascular density in whole mount stains (vascular to avascular ratio: WT=1.6, TREM2KO=1.3 [$p=0.04$]) and significantly increased neutral lipid droplets (mean pixel intensity: WT=21.0, TREM2KO=25.9 [$p=0.04$]).

Conclusions: Together, these findings expand our understanding of cMΦ heterogeneity, abundance, and expression profiles in health and AMD, and identify TREM2 as a novel regulator of choroidal homeostasis that is lost in disease.

ABSTRACT BODY:

Purpose: Mifepristone is an antiglucocorticoid and antiprogesterone drug that has emerged as a promising anti-cancer therapeutic agent. Our laboratory has previously shown mifepristone as a potent growth inhibitor of uveal melanoma (UM) cell lines. However, the mechanism of how mifepristone works on UM cells is still unclear. This work aimed to investigate the receptors possibly responsible for the observed actions of MF on UM.

Methods: Human MP41, MEL270 and OMM2.5 UM cell lines were used to analyze the mRNA expression of progesterone receptor (PR), progesterin and adipoQ receptor family member 8 (PAQR8), membrane-associated progesterone receptor component 1 (PGRMC1) and component 2 (PGRMC2), as well as the glucocorticoid receptor, receptor subfamily 3 group C member 1 (NR3C1). β -Actin was used as a reference gene. Gene expression was quantified using SybrGreen-based Real Time PCR. UM cells were exposed to vehicle (DMSO) and IC_{50} of mifepristone for 72 H. IC_{50} was detected by the CCK8 assay. RNA was extracted using the RNeasy Plus Micro kit. cDNA was synthesized using iScript. A breast cancer cell line (MCF7) was used as a positive control.

Results: According to gene expression analysis by qPCR, primary MP41 and MEL270 as well as metastatic OMM2.5 cells express the glucocorticoid receptor (NR3C1). UM cells also express the non-classical progesterone receptors: PAQR8, PGRMC1, PGRMC2, while classical nuclear PR appears to be absent. To evaluate the expression of the receptors in the absence and presence of mifepristone, the expression of receptors was quantified after cells were exposed to either vehicle or IC_{50} concentration of mifepristone (20 μ M). We found the expression of NR3C1, PAQR8, PGRMC1, PGRMC2 receptors to be downregulated compared to control conditions. The mRNA levels were normalized using β -Actin.

Conclusions: While non-classical progesterone receptors (PAQR8, PGRMC1 and PGRMC2) and a glucocorticoid receptor (NR3C1) were detected, classical nuclear PR was not found by qPCR in UM cells. Given the lack of PR in UM, the antiproliferative action of mifepristone on UM appears to be independent of classical nuclear PR expression. The cytostatic effect of mifepristone may be through an agonist action of NR3C1 and/or membrane PR such as PGRMC1 and C2. A better understanding of the mechanism of action of mifepristone in UM will help determine its therapeutic potential.

ABSTRACT BODY:

Purpose: Mucopolysaccharidosis VI (MPS VI) is a rare, autosomal recessive lysosomal storage disease caused by mutations in the ArsB gene encoding arylsulfatase B. Corneal blindness in MPS VI remains an important factor compromising quality of life and there is no effective treatment. The purpose of this study is to examine the efficacy, toxicity, and immune response to a single and sequential (opposite eye) intracorneal injection of AAV8-ArsB.

Methods: A MPS VI feline, homozygous for a null ArsB mutation and a second, asymptomatic heterozygote, were acquired at 75 days of age. AAV8 vectors packaged with optimized human ArsB cDNA were validated and characterized in vitro (UNC Gene Therapy Center) and injected unilaterally intracorneally (1e9 viral genomes (vg) / 50 uL volume) at 152 days, while the other eye was injected with PBS. Eight weeks following the initial injection, the opposite cornea was injected with AAV8-ArsB (1e9 vg/50 uL). Ophthalmic examinations (slit lamp biomicroscopy, tonometry, pachymetry, ophthalmoscopy, OCT) were performed prior to and following each injection. Corneal confocal microscopy was performed (endothelial cell counts) at 242 days, followed by euthanasia and histological and molecular tissue analyses.

Results: The homozygote MPS VI feline had diffuse mild corneal opacity and peripheral corneal vascularization that progressed until dosing, while the heterozygote had clear corneas. Following both initial and sequential dosing with AAV8-ARSB, the majority of corneal opacity in the homozygote cleared in AAV8-ArsB corneas within 3 weeks of dosing either cornea and remained clear and without signs of inflammation or immune response through the end of the study (90 days after initial injection). No signs of inflammation or toxicity was noted in either eye in the heterozygote following AAV-ArsB dosing.

Conclusions: Results after intracorneal AAV8-ArsB injections in MPS VI felines demonstrate that corneal intrastromal AAV gene therapy is safe and effective to reverse corneal opacity. Importantly, sequential dosing of the opposite eye with intrastromal AAV8-ArsB was clinically effective to clear corneal opacity with no clinical evidence of an inhibitory capsid antibody response or other adverse effects. These results generate optimism for the efficacy and safety for single dose treatments of corneal abnormalities associated with lysosomal storage disorders.

ABSTRACT BODY:

Purpose: Exfoliation syndrome (XFS) is an age-related systemic disorder involving the accumulation of amorphous protein aggregates within the extracellular matrix of many tissues, especially on the surface of the ciliary body, iris and lens. The autophagy dysfunction that causes a decrease in degradation of both denatured proteins and aging cellular organelles, may be thought to give rise to those aggregates in XFS. The aim of our study is to investigate different autophagy pathways and mitochondrial dysfunction in XFS.

Methods: Anterior lens capsules derived from microincision cataract surgery with XFS (n=13) were collected and compared to anterior lens capsules of age-matched healthy controls (n=17). The samples were placed in RNAlater and stored at -80 °C until they were used. RNA isolation was done and measured with the NanoDrop. The reverse transcription- polymerase chain reaction (RT- PCR) was performed for PTEN- putative kinase 1 (PINK1), PARKIN, BNIP3, NIX and LC3A, LC3B, p62 gene expressions.

Results: The mRNA expressions of PINK1, PARKIN and BNIP3 increased significantly in the lens epithelial cells with XFS compared to healthy controls ($p<0.05$), while the expression of NIX decreased significantly ($p<0.05$). The mRNA expressions of LC3A, LC3B and p62 were not significantly different in the samples with XFS compared to controls ($p>0.05$).

Conclusions: In this study, we found that mitophagy pathways are impaired in the lens epithelial cells with XFS compared to controls. This deterioration may shed light on the pathogenesis of the disease in the light of the impairment of degradative process in specific autophagy pathways and mitochondrial dysfunction. Further studies are needed to evaluate the protein expressions of the above-mentioned genes.

ABSTRACT BODY:

Purpose: Uveal melanomas (UM) can be divided into prognostic groups based on gene expression profile (GEP) class 1 versus class 2, class 1A versus 1B, and preferentially expressed antigen in melanoma (PRAME) - versus PRAME+. The purpose of this study was to evaluate gthese factors in young patients.

Methods: 1756 patients from 26 centers were enrolled into COOG2 prospective study, all patients had tumor biopsy for genetic analysis. We analyzed clinical and genetic data from 76 patients 18-35 years of age and excluded 7 primary iris lesions resulting in 69 analyzed patients.

Results: A total of 69 patients between 18-35 years were analyzed. Average age was 30 years, with 35 female and 34 male.

3 patients had ocular melanocytosis. 9 tumors involved ciliary body. Largest basal diameter varied from 3 to19.3mm (mean11.5 mm) and tumor thickness 1.2-15.3 mm (mean 5.1 mm).

Primary treatment was brachytherapy with radioactive iodine (I-125) in 56 patients, enucleation 8 in eyes, proton beam therapy in 4 patients and observation in 1 patient. All patients underwent tumor biopsy (transscleral 18 patients, transvitreal 43 and enucleation 8 patients). GEP analysis revealed Class 1A (31 tumors, of them 10 PRAME +), followed by Class1B (27, of them 7 PRAME +) and Class 2 (10 tumors, of them 3 PRAME +).

Follow-up period is 1-56 months (average 19 months). No tumor recurrence was documented. Metastatic disease developed in 1 patient with Class 1A PRAME + large tumor (16 months after treatment, patient died at 37 months follow up).

Conclusions: Most young patients with UM have genomic profile consistent with very favorable prognosis (Class 1A PRAME -), even when they have clinical features that are considered to be high risk. This suggests that endogenous factors, such as immune regulation, may favor the evolution of less aggressive molecular subtypes of UM in younger patients. Further investigation and longer follow up is warranted to elucidate the biological factors in young patients that predispose them to better survival prognosis.

ABSTRACT BODY:

Purpose: To diagnose and segment choroidal neovascularization (CNV) in a real-world multi-center clinical optical coherence tomographic angiography (OCTA) dataset.

Methods: In this study, a total of 10125 OCTA scans from 2497 eyes, including 4260 CNV scans and 5865 non-CNV scans, were collected from 5 eye clinics. Selected scans included 3×3-mm and 6×6-mm macular scans. All scans were included regardless of image quality. CNV scans were collected from multiple diseases, including neovascular age-related macular degeneration (AMD), pathological myopia, polypoidal choroidal vasculopathy (PCV), and other rare retinal diseases. The non-CNV dataset consisted of a heterogenous group including healthy controls, non-neovascular AMD, diabetic retinopathy, branch retinal vein/artery occlusion, and central serous chorioretinopathy. Two experts (JW and KT) graded projection resolved OCTA images and manually delineated CNV membrane area using both en face of outer retina and cross-sectional OCTA images. Multiple representations of both en face and volumetric OCT&OCTA were fed into a custom designed hybrid multi-task convolutional neural network (CNN) that produces a CNV diagnosis and membrane segmentation. 5-fold cross-validation was applied to evaluate the performance of the proposed method.

Results: For CNV diagnosis, the sensitivities were 96% and 91% on 3×3-mm and 6×6-mm scans with 95% specificity, respectively. Of all scans with CNV, 2% of CNV scans were incorrect due to segmentation error preventing CNV detection. Of low quality scans (n=993) with a signal strength less than 50, CNV was correctly detected 97.3% of the time. The method was able to accurately diagnose CNV and segment CNV membranes on both 3×3-mm and 6×6-mm in neovascular AMD (Fig.1) and also showed reliable performance on challenging scans in other retinal disease, e.g. PCV, and myopia (Fig.2).

Conclusions: The proposed method can accurately diagnose and segment CNV in a real-world clinical dataset. These results could enable automated CNV screening and quantification in clinic and lead to improved artificial intelligence-aided CNV diagnosis.

ABSTRACT BODY:

Purpose: To infect the eye, SARS-CoV 2 needs virus-specific receptors and coreceptors or proteases in the specific ocular tissue. The human angiotensin-converting enzyme-2 (ACE2) receptor represents the major gateway for SARS-CoV 2 to enter cells. Furthermore, the mammalian serine protease TMPRSS2 and the protease furin have been identified as relevant proteases for the interaction of the virus with ACE2. The expression status of these key receptors in ocular tissues is still not fully elucidated.

Methods: The expression profile ACE2, TMPRSS2, and furin were analyzed in fresh and fixed eyes from healthy donors, sections from eyes with other ocular diseases, and eyes from patients, who died from COVID-19. Protein expression was examined via immunohistochemical staining, mRNA expression was analyzed via quantitative real-time PCR.

Results: A relevant difference in the amount of expression of the receptors was observed between fixed and unfixed samples. Interestingly, the eyes from COVID-19 patients expressed a stronger signal than the tissues from non-infected patients. Noteworthy, the results were not consistent with all antibodies used. A pronounced mRNA expression of ACE2 was detected in fresh human cornea, 20 times stronger than in fresh human retina. In contrast, relevant protein expression of ACE2 was not found in fixed corneal samples, while the expression of ACE2 was detected in the retina in the same sections. TMPRSS2 was detected in fresh as well as fixed corneal and retinal samples.

Conclusions: ACE2 and TMPRSS2 were found in ocular tissue, although to a limited amount. The age of the sample, the method of preservation, the freshness of the tissue, and the selection of antibody/primer have an influence on the detection of the relevant receptor expression. In addition, COVID-19 patients might have a stronger expression of ACE2 in ocular tissue in comparison to non-infected patients. This effect will be investigated in further studies. In conclusion, the infestation of ocular tissue does likely not represent the main route of infection, due to the weak receptor expression.

ABSTRACT BODY:

Purpose: Fuchs endothelial corneal dystrophy (FECD) is a common degenerative disease predominantly caused by an expanded (≥ 50 copies) CTG repeat (termed CTG18.1) in an intron of the transcription factor encoding gene TCF4. CTG18.1-mediated FECD is unique among repeat expansion diseases in its high frequency among the general population and a pathophysiology limited to corneal endothelial cells (CECs). Here we generated transcriptome data from primary CEC cultures to identify the differentially expressed transcripts that may represent key biomarkers to enhance understanding of the pathophysiology of FECD.

Methods: We extracted total RNA from primary CEC cultures from 10 unrelated individuals including: 4 unaffected controls, 3 CTG18.1-expansion negative FECD (NE-FECD) and 3 CTG18.1 expansion-positive (E-FECD) patients. RNA-seq libraries were prepared using oligo(dT) beads to enrich for poly-A mRNA and sequenced in accordance with standard Illumina paired-end protocols. Differential gene expression was assessed via DeSeq2 and adjusted with independent hypothesis weighting, while differences in pre-mRNA splicing were analyzed via IsoformSwitchAnalyzerR to identify canonical isoform variants.

Results: Of the 4,497 genes significantly (adj. p-value ≤ 0.05) differentially expressed in E-FECD, 1,248 were unique to E-FECD when compared with NE-FECD with 486 having a log2-fold difference of at least 1. Among these 486 genes, ontology analysis revealed enrichment of genes involved in signaling pathways, cell structure, extracellular matrices, and protein synthesis. Isoform analysis revealed 303 genes with significant differences in isoform expression between E-FECD and controls, 205 of which are predicted to produce a functional difference due to the inclusion or exclusion of a functional exon. Included within this dataset are genes with known MBNL1 splicing regulation, suggesting that splicing dysregulation could be due to sequestration of splicing factors by the CTG18.1-expanded transcript.

Conclusions: A comparison of transcriptomic profiles of control, E-FECD and NE-FECD provides a dataset of differentially expressed transcripts and aberrantly regulated pre-mRNA splicing events that uniquely occur in E-FECD. These data provide insight into disease mechanisms and highlight targets for CTG18.1 expansion-specific translational interventions.

ABSTRACT BODY:

Purpose: Allergic conjunctivitis (AC) is a common ocular disease with a growing incidence rate. Novel topical therapies add to a physician's armamentarium. The aim of this work was to evaluate the efficacy of three concentrations of Bilastine Eye Drops, as a multi-dose, preservative-free formulation, for the treatment of the signs and symptoms of AC.

Methods: This was a single-center, double-masked, randomized, vehicle-controlled, phase 2, dose ranging study conducted to assess the efficacy of bilastine ophthalmic formulation for treatment of the signs and symptoms of AC. The Ora-CAC[®] Allergen Challenge Model was used to assess acute allergic responses. Subjects must have had a history of ocular allergies and a positive skin test reaction to a seasonal or perennial allergen. On Day 1, 121 subjects with AC were randomized to receive Bilastine 0.2% N=30, 0.4% N=30, 0.6% N=31 or vehicle N=30. Two duration-of-action (16 hours post drop on Day 1 and 8 hours post drop on Day 15) and one onset-of-action (15 minutes post drop on Day 22) visits were conducted. The primary efficacy analyses (ocular itching) were conducted using analysis of covariance (ANCOVA) models. Least square (LS) means were estimated for each treatment and for the difference between each active treatment and vehicle at each visit and time point.

Results: All three concentrations of bilastine showed efficacy controlling ocular itching at 15 minutes and 8 hours post treatment. Bilastine 0.6% was also effective at 16 hours post treatment, compared to vehicle. Mean treatment differences at all time points were ≥ 1 unit for bilastine 0.6% ($P < 0.0001$). Statistically significant ($P < 0.05$) treatment effects were observed for bilastine 0.6% compared to vehicle in the secondary endpoint of conjunctival redness at all 3 visits. For the exploratory endpoints of tearing, eyelid swelling and nasal symptoms, treatment differences were statistically significant ($P < 0.05$) for bilastine 0.6% compared to vehicle at all 3 treatment visits. All concentrations showed a good overall safety profile with comfort scores comparable to vehicle.

Conclusions: Bilastine ophthalmic formulation is an effective and safe treatment for AC, with the 0.6% concentration exhibiting the most efficacy in reducing signs and symptoms lasting at least 16 hours post treatment, making it suitable for once-daily administration. Bilastine was well tolerated.

ABSTRACT BODY:

Purpose: The murine ocular graft versus host disease (OGvHD) model is a well-established model of human OGvHD that develops following allogeneic hematopoietic stem cell transplantation (HSCT). The objective of this study was to optimize the total body irradiation (TBI) protocol in the murine OGvHD model when using X-RAD 320 irradiator to allow sufficient ablation of the recipient bone marrow (BM) while minimizing the ocular and systemic effects of acute radiation toxicity.

Methods: The major histocompatibility mismatch chronic OGvHD murine model was created, as described by Perez (2016; doi: 10.1016/j.bbmt.2016.07.012). Animal use was approved by the NC State University IACUC. BM from male C57BL/6 mice, 6-8 weeks of age, was collected from the femurs, tibias, and humeri then depleted of red blood cells and T cells. Splenocytes were collected, red blood cells were lysed, and remaining cells analyzed by flow cytometry. Female BALB/c mice, aged 6-8 weeks, were placed into an X-RAD irradiator (Accela, Inc.) programed at 320 Kv and 12.5 mA and administered 650 cGy (n=10), 700 cGy (n=4), or 750 cGy (n=10) x-ray TBI. Two hours after irradiation, mice were injected intravenously with 1×10^7 BM cells and 1×10^6 splenocytes. Following injection, body weights and tear production (phenol red test) were recorded, and scores (0-4) of the eyelid margins and corneal opacity were collected through day 42 after transplantation.

Results: By day 40 after TBI, mean body weight of the 650, 700, and 750 cGy groups decreased 19.27%, 8.66%, and 16.69% respectively. Mortality rates of these groups were 20%, 0%, and 50% respectively. Eyelid margins had immediate elevation in scores by day 1-3 in the 700 and 750 cGy groups, while corneal scores were elevated in the 700 and 750 cGy groups by day 8-9. Eyelid and corneal scores did not increase with 650 cGy until day 21. There was no significant difference in tear production between these groups.

Conclusions: OGvHD clinical findings appear to develop at approximately 21 days after TBI and HSCT, regardless of dose of TBI. However, TBI dose >650 cGy resulted in acute radiation induced ocular changes noted within the first week after TBI in addition to a higher body weight loss and mortality rate. To minimize TBI acute radiation ocular signs, which may confound interpretation of treatment effects, TBI x-ray radiation dose of less than 700 cGY is recommended.

ABSTRACT BODY:

Purpose: Reticular pseudodrusen (RPD) have been identified as an independent risk factor in the progression of age-related macular degeneration (AMD), particularly predictive of geographic atrophy. However, RPD characteristics are poorly defined in natural history studies. We determined the prevalence and morphological features of RPD using multimodal imaging and assessed associations with demographics, AMD status, and visual acuity in participants of CAREDS2, an ancillary study of the Women's Health Initiative.

Methods: Multimodal imaging included spectral domain optical coherence tomography (SD OCT) and infrared reflectance (IR) to identify RPD characteristics, such as presence, location (within or outside the ETDRS grid), peripapillary involvement, pattern, and RPD area. AMD features from SD OCT, IR, and color photographs were also assessed and AMD severity was categorized.

Results: In 927 eyes from 466 female participants (age 69 to 101), RPD were present in 130 eyes (14% of eyes, 16% of participants) and 76% participants with RPD had bilateral involvement. There was increasing prevalence with age; 7% in < 78 years, 14% in 78-83 years, and 30% in > 83 years. The AMD severity classification from the color photographs showed RPD in 2.4% of eyes with no AMD, 11.5% in early AMD, 25.1% in intermediate AMD and 51.1% in late AMD. Ribbon morphology (53%) was more common than dot morphology RPD (36%). RPD were mostly located both within and outside the ETDRS grid with primarily superior retinal distribution. Among eyes with RPD, 35% had peripapillary involvement which showed an increase with age. Mean RPD area was 17.4 (14.7) mm² and was not significantly associated with age (P = 0.10) or with AMD status (P=0.60). RPD were visualized with corresponding color fundus photography in only 38 eyes (4% of total eyes). Participants with and without RPD had a visual acuity ± standard error of 77.9 (1.4) and 81.3 (0.4) letters, respectively (P = 0.02).

Conclusions: The prevalence of RPD in the aging female population of CAREDS2 was associated with advancing age and AMD severity. RPD were also detected in eyes without other features of AMD which could represent an earlier disease state. Sensitivity for visualizing RPD was greatly enhanced using multimodal imaging with SD OCT and IR over color fundus photography.

ABSTRACT BODY:

Purpose: Our group has demonstrated the performance of the i-ROP Deep Learning (DL) system for retinopathy of prematurity (ROP) telemedicine screening programs in Nepal and Mongolia. The purpose of this study is to evaluate the performance of i-ROP DL in Nepal and Mongolia when increasing the number of infants included and conducting further analysis by country and fundus camera.

Methods: This retrospective study evaluated prospectively collected data from ROP screening programs in Nepal and Mongolia. Birth weight, gestational age, and ROP severity based on the International Classification of ROP (ICROP) guidelines were recorded. Fundus images were obtained with the Forus 3nethra neo in Nepal and the RetCam[®] Portable in Mongolia. The i-ROP DL system, previously trained on RetCam[®] images, was used to identify posterior pole images in the dataset and subsequently generated a mean vascular severity score (1-9). Analysis of variance was used to compare vascular severity scores to ROP categories by country. A p value ≤ 0.05 was considered statistically significant. Stata MP 13, SAS, and R statistical software programs were used.

Results: There were a total of 377 patients and 860 exams in Nepal and 321 patients and 917 exams in Mongolia. Average birth weight and gestational age were lower in Mongolia compared to Nepal (both $p < 0.001$). Overall disease prevalence of treatment-requiring ROP was 14% in Mongolia vs 2% in Nepal ($p < 0.001$). See Table 1. The ROP vascular severity score was higher in Mongolia compared to Nepal at the population level (3.5 vs. 2.5, $p < 0.002$).

Figure 1 displays the vascular severity scores overall and by category for Nepal and Mongolia.

Conclusions: In Mongolia and Nepal, the AI-generated vascular severity scores correspond to ICROP disease severity using two different camera systems, despite the i-ROP DL system not being previously trained on Forus 3nethra neo images. Vascular severity at the population level may be a useful tool for epidemiologic assessment of geographic and temporal variations in ROP severity.

ABSTRACT BODY:

Purpose: Uveitis and scleritis can cause a number of vision threatening complications if left untreated. Because the precise complications of each sub-type of uveitis can be relatively uncommon, it can be difficult to uncover clinically significant associations and risk factors for developing these complications. Here we employ a large national insurance claims database to conduct a retrospective case-control study of the long-term ocular sequelae of uveitis and scleritis.

Methods: The Optum Clinformatics Data Mart, a large national database, was used to obtain medical claims and demographic data. Patients with a diagnosis of uveitis/scleritis based on ophthalmologist or optometrist examination were included in the study. Medical claims data after 2007 was used and diagnosis codes were based on the International Classification of Diseases (ICD) 9th and 10th Revisions. Data was categorized on the basis of anatomic location/classification of uveitis – scleritis, anterior, intermediate, posterior, panuveitis. Multivariable logistic regression analysis was implemented to calculate odds ratios within each sequelae type on the basis of age, gender, ethnicity, socioeconomic status, education, smoking status, as well as numerous systemic medical comorbidities.

Results: Of the 115,876 patients with uveitis and scleritis identified in this study, 29.4% had scleritis, 51.7% had anterior uveitis, 0.6% had intermediate uveitis, 16.1% had posterior uveitis, and 2.3% had panuveitis. The most common sequelae were cataracts (18.8%), cystoid macular edema (2.9%), blindness (1.5%), chorioretinal scarring (1.5%), and choroidal neovascularization (1.0%). Multivariate analysis revealed that cataracts were more likely in panuveitis, cystoid macular edema was more likely in intermediate uveitis, blindness was more likely in panuveitis, and chorioretinal neovascularization and scarring were most likely in posterior uveitis. Multivariate analysis further demonstrated associations of each sequelae with various demographic parameters and medical co-morbidities.

Conclusions: This study demonstrates the utility of employing a large database and clinical informatics to study relatively uncommon ocular diseases and to elucidate key associations and risk factors for their vision threatening complications.

ABSTRACT BODY:

Purpose: E-ETDRS and FrACT are the two most popular electronic visual acuity (VA) tests. To improve the precision of VA threshold estimates from the tests, we re-analyzed the E-ETDRS and FrACT data from 14 eyes in four Bangerter foil conditions in Zhao et al. (2021) with the qVA method and a hierarchical Bayesian model (HBM) based on the qVA method (Lesmes & Dorr, 2019).

Methods: The HBM consisted of hyperparameters and parameters at the population and individual test levels, each of which is a 2-dimensional Gaussian distribution of VA threshold and range. The covariances were set up to capture the cross- and within-test regularities. We compared the average half width of the 68.2% credible interval (HWCI) of the VA threshold and range estimates from the qVA and HBM analyses.

Results: The HBM analysis recovered the correlations between VA threshold and range from the E-ETDRS (0.527 and 0.058) and FrACT (0.755 and 0.218) datasets at the population and individual test levels (Fig. 1). Table 1 shows the average HWCI of the VA threshold and range estimates. The average HWCI of the VA threshold estimates from the E-ETDRS dataset were 0.050 and 0.039 logMAR from the qVA and HBM analyses, respectively, with a 22% reduction by the HBM. The average HWCI of the VA threshold estimates from the FrACT dataset were 0.049 and 0.043 logMAR, with an 11% reduction by the HBM. Compared with the qVA analysis, the HBM also significantly reduced the average HWCI of the range estimates from the E-ETDRS (from 0.148 to 0.072 logMAR, a 51% reduction) and FrACT (from 0.214 to 0.096 logMAR, a 55% reduction) datasets. In comparison, HBM analysis of the qVA data from the same subjects in the same testing conditions resulted in average HWCIs of 0.019 and 0.048 logMAR for VA threshold and range (Table 1).

Conclusions: Incorporating both cross- and within-test regularities, the HBM analysis greatly improved the precision of VA threshold and range estimates in the E-ETDRS (30 optotypes) and FrACT (45 optotypes) datasets, although the combination of the HBM and qVA test is the best option.

ABSTRACT BODY:

Purpose: There has been demonstrated variability in plus disease diagnosis amongst ROP experts. There are subjective differences in the diagnostic cutoffs for pre-plus and plus disease. Features such as training, field of view, magnification, and tempo have been proposed as explanations. The purpose of this study is to assess changes in ROP diagnosis in single and serial retinal images.

Methods: 7 graders with expertise in ROP grading independently reviewed both single and 3 consecutive serial retinal images from 15 ROP cases on a secure web-based platform. Severity was assigned as plus, pre-plus, or none. A secondary analysis was performed using the previously validated i-ROP deep learning system to assign a vascular severity score (VSS) to each image, ranging from 1-9, with 9 being most severe disease. This score has been previously demonstrated to correlate with expert diagnosis and the ICROP. Mean plus disease severity was calculated by averaging 14 labels per image in both serial and single images.

Results: Assessment of serial retinal images changed the grading severity for >50% of the graders, though there was wide variability. Cohen's kappa ranged from 0.29 to 1.0. Changes in grading of serial retinal images was noted more commonly in cases of pre-plus disease, where the mean severity showed a borderline significant increase ($p=.08$). (Figure 1) The ROP VSS demonstrated good correlation with the range of expert classifications of plus disease, and overall agreement with the mode class ($p=0.001$) (Figure 2A). The VSS correlated with mean plus disease severity by expert diagnosis (correlation coefficient 0.89). (Figure 2B). The VSS also demonstrated agreement with disease progression across serial images which progressed to pre-plus and plus disease. (Figure 2C).

Conclusions: Clinicians demonstrated diagnostic variability with both single and serial images. However, the use of serial retinal images caused a change from pre-plus to plus disease, which represents a change in management. More aggressive graders tended to be influenced by serial images to increase the severity of their grading. The use of

deep learning as a quantitative assessment of plus disease can standardize diagnosis and treatment.

ABSTRACT BODY:

Purpose: A recent study in transgenic murine models of Alzheimer's disease (AD) described a unique microglial neurodegenerative phenotype (MGnD) that is triggered by amyloid- β plaque-mediated neuronal stress. The microRNA miR-155 was primarily characterized in relation to pro-inflammatory M1 microglia. However, recent research demonstrated regulatory role of miR-155 on neurodegenerative response in AD brain and its contribution to MGnD microglial phenotype differentiation. Our team identified the pathological hallmarks of AD in the neurosensory retina. We further found a tight correlation between the impacts of AD on brain and retinal pathology. Here, we sought to evaluate the roles of miR-155 depletion on microglial phenotypes associated with amyloidosis in the retina of transgenic murine models of AD.

Methods: The Cx3cr1-Cre^{ERT2} mice were used to specifically and transiently target miR-155 depletion in microglia (miR-155^{fl/fl}) and were further introduced into APP^{SWE}/PS1 ^{Δ E9} (ADtg) mice to generate Cx3cr1-Cre^{ERT2}:miR155^{fl/fl}:APP^{SWE}/PS1 ^{Δ E9} mice. Oral treatment of tamoxifen was applied to induce miR-155 deletion at 2 months of age. At 4 and 8 months, mice were sacrificed to extract retinas for different experimental measurements. These, included inflammatory marker assessment by meso scale discovery (MSD) analysis, global proteomic profiles by mass spectrometry (MS), and microglial phenotypes associated with retinal abluminal and vascular amyloidosis by histological examination.

Results: Our initial results demonstrate that miR-155 deletion decreased expression of multiple cytokines including IFN- γ , TNF α , IL-2, IL-6 and IL-12 in the retinas of ADtg mice, as well as reduced TNF- α in wild type mice. Retinal cross section showed deposition of A β ⁴² and A β ⁴⁰ in retinal parenchyma and blood vessels in ADtg mice at 8 months. The miR-155 deletion in microglia seems to enhance clearance of retinal A β deposition in 8-month-old ADtg mice. Intriguingly, distinct retinal proteome profiles were identified in the Cx3cr1-Cre^{ERT2}:miR155^{fl/fl}:APP^{SWE}/PS1 ^{Δ E9} mice.

Conclusions: Our data indicate that inhibiting miR-155 expression in CNS microglia may provide beneficial therapeutic effect in retinas of ADtg mice, including downregulating proinflammatory cytokines and enhanced A β clearance. These findings propose a potential new target for AD diagnosis and treatment.

TITLE: Bioinformatic Analysis reveals possible mechanisms of Aniridic Keratopathy

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Krishnan, A. Faranda, S.G. Novo, Y. Wang, M.K. Duncan, University of Delaware, Newark, Delaware, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aarthi Krishnan: Commercial Relationship: Code N (No Commercial Relationship) | Adam Faranda: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Novo: Commercial Relationship: Code N (No Commercial Relationship) | Yan Wang: Commercial Relationship: Code N (No Commercial Relationship) | Melinda Duncan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aniridic Keratopathy is a sight threatening manifestation of Aniridia, a genetic disease caused by Pax6 haploinsufficiency. However, the mechanisms underlying this keratopathy remain unclear. We performed unbiased transcriptome profiling of PAX6 mutant mouse corneas to understand the mechanisms involved in Aniridic Keratopathy.

Methods: RNA was isolated from PAX6 mutant (+/-) and wildtype corneas obtained from 20 week old mice (3 biological replicates of each) and transcriptome profiling performed by RNAseq. Differentially expressed genes (DEGs) were identified using bioinformatic pipelines and altered pathways identified via iPathway Guide (<https://advaitabio.com/>). DEGs in the Pax6 mutant cornea were compared to those obtained from prior corneal gene expression profiles including those differentially expressed between human cornea and conjunctiva (GEO Accession GSE38190). L1000CDS² analysis was performed on the LINCS server (<https://lincsproject.org/>)

Results: A total of 823 genes (514 upregulated and 309 downregulated) were differentially expressed in the 20-week-old PAX6 mutant mouse cornea. Inflammation, cytokine-cytokine receptors and angiogenesis were the most upregulated pathways in PAX6 mutant corneas. Conjunctival cytokeratins upregulate in the Pax6 mutant cornea, and while bioinformatics comparisons revealed that 95 genes that were upregulated in PAX6 mutant corneas normally are overexpressed in the conjunctiva compared to the cornea. Similarly, corneal cytokeratins are expressed at lower levels than normal in corneas from mice heterozygous for Pax6 mutations and a total of 33 genes that normally exhibit corneal preferred expression were downregulated in the Pax6 mutant cornea compared to wildtype. L1000CDS² analysis revealed histone deacetylase inhibitors as potential drugs capable of normalizing the mRNA transcriptome of Pax6 mutant corneas.

Conclusions: This analysis reveals the PAX6 mutant cornea expresses transcriptional signatures consistent with inflammation and angiogenesis. Further, transcriptome profiles are consistent with the Pax6 mutant corneal epithelium either being invaded by or transdifferentiating into, conjunctiva. Histone deacetylase inhibitors are potential drugs to reverse the corneal consequences of aniridia.

ABSTRACT BODY:

Purpose: The macular pigment is a yellowish pigment of nutritional origin, lying primarily at the macula. It is believed to play a protective role, shielding foveal photoreceptors from blue-light associated photochemical damage and oxidation from free-radicals. The purpose of this study was to collect macular pigment optical density (MPOD) values, measured with a new optical instrument in a healthy population.

Methods: The instrument uses two sources, a green and a blue, flickering at different frequencies and focusing a central disk of 3.5 degrees diameter and a concentric peripheral annulus of 1 degree on the ocular fundus. The reflected light from the fundus is collected by a high-speed, high sensitivity photodetector and the signal is then processed in the frequency domain. The value for the macular pigment optical density is subsequently computed from the processed signal and the appropriate mathematical equation based on a fundus light extinction model. The duration of the measurement is kept below 0.2 sec and it is done at a natural pupil. Our cohort consisted of 51 healthy volunteers with no known ocular pathology. Their age ranged between 19 and 61 years old with an average age 33.9 years. The demographic, lifestyle and dietary habits were recorded for all subjects, focusing mostly on the consumption of leafy green vegetables. The answers ranged from no consumption to everyday consumption. We grouped subjects based on their answers in frequent consumers (FC), those eating leafy vegetables every day or weekly, and in infrequent consumers (IC), those with monthly or no consumption.

Results: The measured MPOD values showed an age dependence ($p < 0.0005$) in both eyes, and therefore, the age-corrected sample was defined, where all MPOD values were normalised around a specific age value (35yo). The age corrected MPOD values for the FC group ranged from 0.29 to 0.54 D.U. with a mean of 0.39 D.U. while for the IC group ranged from 0.2 to 0.49 D.U. and a mean value of 0.35 D.U. The difference in MPOD between the two groups was small.

Conclusions: MPOD data were collected in a healthy population. The values were normalized according to age and were found to be slightly higher in the group that consumed vegetables frequently, that is on a daily or weekly basis. This finding is consistent with current bibliography stressing the positive effect of leafy green vegetables on macular pigment density values.

Commercial Relationships Disclosure (Abstract): Sushma Vishwakarma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Microglia, the resident immune cells that reside within the retina are involved in the maintenance of retinal homeostasis via surveying their microenvironment and communicating with other neurons. Microglia get activated under stress and depending on their phenotype, exert either neurotoxic or neuroprotective effects to other cells by secreting several cytokines and signaling molecules. Polymeric scaffolds have the ability to regulate cellular responses through precisely designed cues. The purpose of present study is to assess the effect of polymeric nanofibers on microglial polarization and immunomodulatory responses under hypoxia, and their potential for the treatment of retinal inflammatory conditions.

Methods: Human microglial CHME3 cells were grown on plain coverslips, as well as poly α -ester-based fibers possessing distinctly different topographies. Hypoxia was induced by the addition of CoCl_2 for 24 h. Cell viability was measured using Alamar blue assay, cell shape using immunofluorescence, gene expression using qPCR and protein expression using western blotting. Statistical significance was calculated using ANOVA with a p value < 0.05 considered significant.

Results: Microglial cells proliferated well on polymeric scaffolds, and followed the topographical cues. Under normoxia, microglia cultured on fibers with specific topographies displayed a predominantly pro-inflammatory phenotype. Specifically, IL-6, GM-CSF, TNF- α , and CXCL10 mRNA expression was significantly higher compared to the control group without nanofibers, and these trends largely reflected at the protein level too. Under hypoxia however, cells grown on fibers with different architectures showed a significantly higher viability, lower cell death and suppressed expression of the autophagy marker LC3 compared to the control group also cultured under hypoxia. Lysosomal proteins that protect the cells from apoptosis also showed higher expression when cultured on the scaffolds. Finally, expression of anti-inflammatory markers IL-4 and IL-10 was significantly higher on the scaffolds regardless of topography.

Conclusions: The regulation of microglial phenotype by using engineered nanofibers with tightly controlled properties provides new insights and a potential therapeutic approach for the development of immunomodulatory therapy for retinal inflammatory diseases.

ABSTRACT BODY:

Purpose: Cataract surgery in patients with age-related macular degeneration (AMD) alleviates vision loss from cataracts, but controversy exists whether it contributes to AMD progression. This study evaluated the risk of late AMD progression following incident cataract surgery in a prospective cohort within a controlled clinical trial of oral supplementation for the treatment of AMD – the Age-Related Eye Disease Study 2 (AREDS2).

Methods: Participants 50 to 85 years with bilateral large drusen or unilateral AMD were enrolled in the AREDS2 study from 82 retinal specialty clinics in the US between 2006 – 2008 and followed until the conclusion of the clinical trial in 2012. After the end of the trial, an additional 5-year of follow-up was conducted via telephone every 6 months until 2018. Clinical information obtained by telephone was verified by collecting medical records of treating physicians. A subset of the AREDS2 participants was also evaluated in a final in-clinic study visit. The incidence of late AMD in eyes that received cataract surgery after the baseline visit and before any evidence of late AMD was compared with those that remained phakic until the study completion. Eyes that had at least 2 years of follow-up after cataract surgery were included in the analysis. We used Generalized Estimating Equations (GEE) and Cox regression models that were adjusted for age, sex, smoking, education, and AMD severity. Late AMD was defined as the presence of geographic atrophy (macular atrophy ≥ 430 mm) or neovascularization on annual stereoscopic fundus photographs or medical record documentation.

Results: A total of 1229 eyes (30%), of the 4064 participants in the AREDS2 study, had cataract surgery at a mean (SD) of 5.7 (3) years from study enrollment. The risk of late AMD after a mean (SD) of 4.6 (2.8) years from cataract surgery was not significant, Risk Ratio from GEE: 0.92 (95% Confidence Interval [CI]: 0.56-1.49, $p=0.73$). The Cox regression model showed that there was no increased risk for progression to late AMD after cataract surgery: hazard ratios 0.96 (95% CI, 0.8 – 1.13, $p=0.60$) for the right eye and 1.05 (0.89–1.25, $p=0.56$) for the left eye.

Conclusions: Cataract surgery did not accelerate the rate of progression to late AMD among the AREDS2 participants with up to 10-year follow-up. This study provides data in counselling AMD patients who would benefit from cataract surgery.

ABSTRACT BODY:

Purpose: The wet form of age-related macular degeneration (AMD) is characterized by neovascular pathologies that can result in edemas, which can lead to rapid vision loss if untreated. Inhibition of vascular endothelial growth factor (VEGF) has been used to successfully treat neovascular pathologies of the eye. Nonetheless, some patients require frequent intraocular anti-VEGF injections, raising the risk of complications from the procedure and the burden to both, doctors and patients. rAAV-mediated expression of anti-VEGF proteins is an attractive alternative to reduce the risk to affected patients. However, controversy remains as to the safety of sustained VEGF inhibition in the eye. Here, we test the safety and efficacy of delivering the anti-VEGF drug Conbercept (KH902) with adeno-associated virus (AAV) vectors in two mouse models of vascular pathology.

Methods: To test the efficacy of rAAV-KH902, we used the oxygen-induced retinopathy of prematurity model, as well as the laser damage-induced choroidal neovascularization model. The same cassette expressing KH902 from a ubiquitous promoter was packaged into four different rAAV serotypes. To assess the efficacy of rAAV-KH902, we quantified the number of aneurysms in the oxygen-induced retinopathy model and the number of edemas, as well as the size of the neovascular lesions in the laser damage model.

Results: We found that intravitreal delivery of rAAVs expressing KH902 can successfully reduce the number of aneurysms, edemas, as well as the growth of the choroidal neovascular lesions. Serotypes with high transduction efficiencies were found to induce, in a dose dependent manner, a vascular sheathing pathology that is characterized by immune cell infiltrates, reminiscent of vasculitis. We found that this pathology is accompanied by increased expression in vascular cells adhesion molecule 1 (VCAM1), which promotes extravasation of immune cells from the vasculature. Importantly, low viral doses were still able to reduce edemas and lesion size without causing any vascular sheathing pathology.

Conclusions: The data suggest that rAAV-mediated expression of anti-VEGF drugs can be employed safely for the treatment of neovascular eye pathologies. However, vector design needs to be taken into consideration when determining the appropriate therapeutic dose.

TITLE: SARS-CoV2 Infection damages RPE Function and Survival

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Hultgren, B. Burgess, D.S. Williams, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nan Hultgren: Commercial Relationship: Code N (No Commercial Relationship) | Barry Burgess: Commercial Relationship: Code N (No Commercial Relationship) | David Williams: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: SARS-CoV2 infection affect a wide range of tissues in the human body. Viral presence has been reported in the ocular environment and alterations in the retina by Optical Coherence Tomography have been reported in COVID patients. However, it is unclear if and how retinal cells are directly affected by the virus. Using cell culture models along with pseudotyped virus, we tested the hypothesis that the presence of SARS-CoV2 negatively affects several critical functions of the retinal pigmented epithelial (RPE) cells, and could have long-term effects on retinal health.

Methods: Polarized human ARPE-19 cells and wild type iPS-RPE cells were cultured using recently published protocols from our lab. Two main steps of the viral life cycle were modeled: 1) viral entry, using lentivirus pseudotyped with SARS-CoV2 Spike protein; 2) viral replication, by testing expression of SARS-CoV2 protein E and 3a, following lentiviral transduction. Cells were maintained on Trans-well filters for up to 6-weeks. Barrier function was evaluated by measuring trans-epithelial resistance (TER) and immunofluorescence labeling of tight-junction proteins. Phagocytic capacity was evaluated by testing ingestion and degradation of photoreceptor outer segments (POSs). General RPE morphology was evaluated using transmission electron microscopy. Changes in gene expression was examined by qPCR and Western Blot analysis.

Results: We confirmed a previous finding that RPE cells express the receptor ACE2 and protease TMPRSS2 necessary for viral entry. Using Spike-protein pseudotyped lentivirus, we found that human RPE, but not fibroblasts, can be infected via a Spike-ACE2 mediated mechanism. This specific mechanism of viral-entry alone (as opposed to VSV-mediated entry) caused significant changes in cell physiology, including alterations in cell junction and protein trafficking. Using expression of lentiviral SARS-CoV2 components, we found that the presence of protein E induced expression of several pro-inflammatory cytokines in the RPE cell, while protein 3a activated apoptosis in the RPE cells. These data suggest that SARS-CoV2 can infect and cause serious damage to RPE function and survival.

Conclusions: Damage to the RPE cells often precedes photoreceptor degeneration. Given our findings that SARS-CoV2 can cause severe damage to the function and survival of RPE cells, COVID19 patients may be at increased risk of long-term RPE pathogenesis and associated visual impairment.

ABSTRACT BODY:

Purpose: Accurate data regarding prevalence of Inherited Retinal Diseases (IRDs), impact on individuals and families affected, and cost burden to the USA and Canadian economies was lacking. This hinders research, development and commissioning of clinical services, treatments, care pathways and clinical trials. Thus there is a need for a stronger evidence base to support value-for-money to regulatory bodies for treatments approved, and treatments progressing through clinical trials. To safeguard future research and service provision it was necessary to learn more about the IRD community.

Methods: The socioeconomic burden of IRDs in the USA and Canada was estimated using a cost of illness methodology applying a prevalence approach. Patient involvement was incorporated throughout project design and review. Analysis was based on targeted literature review and primary data collection (survey) of adults aged 18+, and parents of children (under 18) living with one of the following IRDs: Achromatopsia, Bardet-Biedl Syndrome, Best Disease, Blue Cone Monochromacy, Choroideremia, Cone Dystrophy, Cone-Rod Dystrophy, Leber Congenital Amaurosis (LCA), Leber Hereditary Optic Neuropathy (LHON), Retinitis Pigmentosa, Rod-Cone Dystrophy, Stargardt Disease, Usher Syndrome, and X-Linked Retinoschisis (n=687 USA; n=151 Canada).

Results: The greatest cost type in both countries was attributed to wellbeing and accounted for 63% (up to US\$20.043 billion), and 66% (CAN\$1.071 billion) of total IRD costs in the USA and Canada respectively. Productivity losses were the second highest burden in both the USA and Canada, amounting to US\$4.056 billion, and CAN\$205.1 million. Persons with an IRD in the USA and Canada were 28.8% and 24.4% less likely to be in paid employment than the general population. In the USA and Canada IRDs resulted in a 0.3% and 1.4% reduction in productivity while at work respectively. The health systems cost in both regions was low at US\$2.216 billion and CAN\$37.8 million respectively.

Conclusions: The highest costs incurred due to IRDs were attributed to well-being and loss of productivity, yet those affected by IRD do not regularly engage with health care systems. The data demonstrates clearly that the measurements used to assess the burden of vision loss need urgent review. The wellbeing of those living with an IRD is currently underserved and under resourced, and there is an urgent need for equality in accessing the workforce.

ABSTRACT BODY:

Purpose: Neuronal transplantation has emerged as a potential therapy to restore vision in advanced optic neuropathies by repopulating RGCs. However, successful engraftment is limited by poor donor survival. Dual leucine zipper kinase (DLK) and leucine zipper kinase (LZK) signaling pathways regulate endogenous RGC apoptosis. Here, we examined the neuroprotective effects of DLK and LZK inhibition on human embryonic stem cell (hES) derived RGC transplantation by using transgenic and pharmacologic approaches.

Methods: Organotypic retinal explants from 8-week-old C57BL/6J mice were co-cultured with hES-RGCs on the vitreous surface for 1 week. We compared transplanted RGC survival in wildtype (WT) hES-RGCs versus CRISPR-Cas9 engineered DLK^{-/-} and LZK^{-/-} hES-RGCs. In addition, we assessed survival and neurite integration of WT hES-RGCs on pronase-treated explants co-cultured in regular media or media containing 1μM VX-680 (a kinase inhibitor with strong activity against DLK). Cell survival was quantified using tiled retinal wholemount confocal images. Donor neurite integration, normalized to the number of RGCs in area measured, was assessed in high resolution 3D confocal reconstructions using Imaris software.

Results: DLK^{-/-} hES-RGC survival was significantly greater than WT hES-RGCs (16.1±2.8% vs 9.2±3.3%, p<0.001); LZK^{-/-} hES-RGCs did not show neuroprotection over WT cells (10.0±1.6%, p>0.05). On pronase-treated retinas, VX-680 enrichment conferred significantly increased survival of donor RGCs compared to control (20.20±4.66% vs 16.04±2.14%, p<0.05). The percentage of donor RGCs with neurite integration was similar between groups (1.69±0.38% in VX-680 vs 1.76±0.89% in control, p>0.05). However, the total length and dendritic complexity of integrated neurites localized to the recipient inner plexiform layer were significantly higher in the VX-680 treated group (98.9±37.7 μm/mm²/RGC vs 41.83±27.8 μm/mm²/RGC, p<0.005; 2.81±0.34 branches/mm²/RGC vs 1.25±0.86 branches/mm²/RGC, p<0.001).

Conclusions: Transgenic DLK deletion and pharmacologic kinase inhibition with VX-680 promoted survival of transplanted hES-RGCs on organotypic retinal explants. DLK inhibition also demonstrated significantly higher donor neurite integration and dendritic complexity. Ongoing studies aim to examine the neuroprotective effects of DLK inhibition on transplanted hES-RGC survival in vivo.

ABSTRACT BODY:

Purpose: Glucose is the major nutrient in the lens, which is taken up by the lens from the aqueous humor. This study aims to map glucose uptake and metabolism in cultured lenses, and correlate the pattern of glucose uptake to glucose transporter distributions and abundance.

Methods: Ex vivo bovine lenses were incubated in AAH containing normoglycaemic stable isotopically-labelled (SIL) glucose (5mM) for 5min-20h. Lenses were then fixed in 2%PFA for 72h for immunofluorescence microscopy analysis, frozen for MALDI imaging mass spectrometry (IMS) analysis, or manually dissected into epithelium flat mount and cortical fibre cells for either MALDI IMS or proteomic analysis. For MALDI-IMS studies, 20um thick axial lens tissue sections were analysed by a MALDI-MS. For proteomics studies, membrane protein preparations generated by centrifugation were separated by SDS-PAGE, gel bands digested by trypsin, and peptides analysed by LC-MS/MS. For immunohistochemistry studies, 16um thick axial lens sections were labelled with primary antibodies specific for GLUT 1 or GLUT 3. Fluorescent secondary antibodies, and cell membrane marker were added, and images collected by confocal microscopy.

Results: MALDI-IMS maps of SIL glucose showed uptake at 5min was concentrated in the peripheral epithelium. At later timepoints, glucose distributed throughout the epithelium and the cortical lens fibres. Proteomic analysis of central and peripheral regions of the lens epithelium detected GLUT1 and 3, with GLUT 3 in higher abundance than GLUT1 throughout the epithelium, but with GLUT1:GLUT3 ratio increased in the peripheral epithelium relative to central. Microscopy localized GLUT1 and GLUT3 to epithelial cell membranes and young fibre cells. SIL glucose metabolites found in glycolysis, the sorbitol pathway, and UDP-glucose formation were mapped to cortical lens fibres, with distinct signal changes relative to endogenous glucose metabolite signal up to 20h incubation.

Conclusions: Mass spectrometry and immunohistochemistry have spatially mapped the major uptake site of glucose in bovine lens to the peripheral epithelium and cortical fibres. SIL glucose is rapidly metabolized in epithelial and fibre cells to many metabolites, which are most abundant in the metabolically more active cortical fibre cells in comparison to central fibres.

ABSTRACT BODY:

Purpose: To assess cryopreserved (C-AM) versus sterilized chorion-free freeze-dried (FD-AM) amniotic membranes overlay transplantation for corneal epithelial defects in a French tertiary ophthalmology hospital

Methods: Between March and July 2020, when C-AM were not available due to the COVID-19 pandemic and to the national lockdown, 28 corneal ulcers underwent FD-AM overlay transplantation and were retrospectively compared to 22 corneal ulcers treated with C-AM during the same period in 2018. All patients had at least 3 months of follow-up and those who underwent combined surgeries were excluded. Ulcers were assessed at baseline and then at 1 and 3 months. Population demographics, follow-up time, ulcer etiologies, ulcer size, and complications were also recorded.

Results: Baseline characteristics and clinical features of both groups were comparable. There was no statistically significant difference in the number of overlay amniotic membrane transplantations ($p=0.52$) or early fall ($p=0.57$). At 3 months, the corneal healing rate was almost the same in both groups (89% and 91% for FD-AM and C-AM, respectively; $p=0.85$). Complications were evenly unusual (11% and 9% respectively; $p=0.92$). In logistic regression, the nature of the membrane did not influence corneal healing at 1 month ($p=0.42$) and 3 months ($p=0.99$) regardless of the depth of the ulcer. However, whatever the type of AM used, the deeper the ulcer was, the less likely it was to heal at 3 months ($p=0.02$).

Conclusions: This first study provides positive insight into the effectiveness of FD-AM as compared to C-AM when used as overlay transplantation for treating corneal ulcers.

ABSTRACT BODY:

Purpose: To develop and validate a machine learning algorithm for accurate estimation of the optic disc and fovea center position in infra-red SLO fundus images including cases outside of the field of view or apparent occlusions of the landmarks.

Methods: To detect the coordinates of obstructed or out-of-view optic disc or fovea, we reformulated the task as a regression problem where a machine learning algorithm learns to predict an anatomically plausible coordinate system centered on the fovea. The prediction was obtained by training a neural network with EfficientNet backbone. To this end, a dataset of 1226 grayscale OCT localizer images (Heidelberg Spectralis, average field of view: 8.75x8.75mm) affected with either Retinal Vein Occlusion related Macular Edema, Diabetic Macular Edema or Age-Related Macular Degeneration with choroidal neovascularization, was annotated and randomly split into a train (1106) and a test set (120). The test set included 46 images for which at least 50% of the optic disc was outside field-of-view. An outlier-robust estimation (RANSAC) was used to determine the final fovea and optic disc location in an anatomical coordinate system. The detection was evaluated by computing the average distance between manual annotation and predicted location.

Results: The presented methodology was able to estimate the location of the optic disc with an average error of 0.07 mm and the fovea with an average error of 0.2 mm, independent of the diseases (Fig. 1).

The method showed good performance also in cases where optic disc or fovea were only partially visible or fully-occluded due to existing lesion or artificial image cropping (Fig. 2 bottom). The goodness of fit was a good surrogate of the detection error (Fig. 2 top).

Conclusions: The automated detection algorithm could identify fovea and optic disc locations with a high level of accuracy. The addition of RANSAC increased the robustness of the model also in the presence of occlusions and enabled quantification of the localization accuracy. This method allows the registration of longitudinal scans, even if the optic disc is not or only partially visible, as it is often the case on fovea-centered OCT scans.

ABSTRACT BODY:

Purpose: 7,8-Dihydroxyflavone (7,8-DHF), a reported TrkB agonist, improves vision in the atp6v^{ucd6} zebrafish model of inherited blindness. Here, the mechanism by which 7,8-DHF restores vision is investigated and biodegradable nano/microparticles for 7,8-DHF ocular drug delivery are characterized.

Methods: 3 days post fertilized (dpf) sibling or atp6v^{ucd6} larvae (n=5, N=3) were treated with 20-40 µM 7,8-DHF or 0.1% DMSO. Visual behaviour was assessed at 5 dpf by the optokinetic response assay (OKR). For mechanistic analysis, 60 eyes of 5 dpf atp6v^{ucd6} treated with 0.1% DMSO or 20 µM 7,8-DHF were analysed by RNAseq and differentially expressed genes/pathways identified using Cytoscape and gProfiler. PLGA nano/micro-particles incorporating 7,8-DHF were produced by single emulsion solvent evaporation, encapsulation efficiency analyzed by HPLC, and particle size or shape analysed by dynamic light scattering or scanning electron microscope.

Results: 20 µM 7,8-DHF rescues atp6v^{ucd6} visual function (p= 0.04). RNAseq identified 15,662 genes of which 58 were down regulated and 213 up regulated by 7,8-DHF. Following gProfiler analyses, among the down-regulated processes are genes related to inflammation, among the up regulated processes are genes related to translation. 7,8-DHF PLGA nanoparticles show ~59% drug encapsulation, mean size of 314 nm; the spherical microparticles of 3-30 µm display drug encapsulation of ~72%.

Conclusions: 7,8-DHF may rescue vision by decreasing inflammation in the eye. The biodegradable PLGA nano/microparticles display appropriate drug encapsulation and physiochemical properties. Future directions include characterization of efficacy and safety in biological systems.

TITLE: Longitudinal analysis of the microbiome in ocular surface diseases

SESSION TITLE: Translational Immunology and Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Zilliox, C. Mores, P. de Bustros, C.S. Bouchard, Ophthalmology, Loyola University Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Zilliox: Commercial Relationship: Code N (No Commercial Relationship) | Carine Mores: Commercial Relationship: Code N (No Commercial Relationship) | Paul de Bustros: Commercial Relationship: Code N (No Commercial Relationship) | Charles Bouchard: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously found that the ocular surface microbiome (OSM) can differ between each eye in approximately half of patients and healthy controls. In addition, we observed that the OSM was less diverse in patients with several ocular surface diseases (OSDs) compared to controls. However, longitudinal data has been lacking in these OSDs to understand the stability of the microbiome. We performed prospective, longitudinal observational studies to characterize the ocular surface microbiome OSM in OSDs.

Methods: Sterile swabs were used to collect samples from each eye of patients. Sterile technique and multiple controls were used to assess contamination during DNA extraction, amplification and sequencing using V4 primers of the 16S rRNA gene. Concurrent use of topical antibiotics, steroids, and bandage contact lenses (BCLs) was documented.

Results: Despite the low biomass of the ocular surface, we can detect a microbiome in ~50% of eyes sampled using sequencing. We observed that approximately half of patients had distinct microbiomes in each eye despite the eyes having similar diversity measures. In Steven's Johnson Syndrome (SJS), there were 5 ocutypes (defined as distinct microbiome communities) with the ocutypes being dominated by *Corynebacterium*, *Achromobacter*, *Stenotrophomonas*, *Staphylococcus* or a diverse population with no dominant genera. The *Corynebacterium* and *Staphylococcus* ocutypes were observed in other OSDs as well. Human pathogens not previously associated with SJS that were found included *Achromobacter*, *Stenotrophomonas* and *Sphingobacterium*. Alpha diversity was lower in SJS and DED patients compared to healthy controls and GVHD patients. Next, we performed longitudinal analysis of SJS patients and observed several interesting patterns, however, only 14% of eyes showed a stable microbiome over several weeks.

Conclusions: About half of patients had similar microbiomes in each eye. Microbiomes from OSDs had lower alpha diversity compared to controls. Longitudinal analysis has found that only 14% of eyes had a stable microbiome over time, suggesting global measurements for the microbiome, such as alpha diversity, may be more useful to define the OSM.

TITLE: Likelihood of Germline Mutation with Solitary Retinoblastoma Based on Tumor Location at Presentation

SESSION TITLE: Advances in Diagnosis and Management of Retinoblastoma and Congenital Eye Diseases

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: P. Dockery, M. Ruben, A. Yaghy, C. Shields, Wills Eye Hospital Ocular Oncology Service, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Philip Dockery: Commercial Relationship: Code N (No Commercial Relationship) | Megan Ruben: Commercial Relationship: Code N (No Commercial Relationship) | Antonio Yaghy: Commercial Relationship: Code N (No Commercial Relationship) | Carol Shields: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the likelihood of germline mutation in patients presenting with solitary retinoblastoma, based on tumor location at presentation.

Methods: Retrospective analysis of 482 consecutive patients with solitary, unilateral, unifocal retinoblastoma for likelihood of germline mutation (family history of retinoblastoma and/or genetic testing germline Rb1 mutation present and/or development of additional new tumors) based on overall tumor location at presentation (macular vs. extramacular).

Results: Of the overall group (n=482 consecutive patients) with solitary retinoblastoma, macular tumors at presentation were more likely to have a smaller basal diameter (12.5 mm vs. 18.9 mm, $p<0.001$) and thinner (6.1 mm vs. 10.7 mm, $p<0.001$) than extramacular tumors. Patients with tumors located in the macula were more likely to have a family history of retinoblastoma (13% vs. 2%, $OR=4.89$ [1.85–12.97], $p<0.001$) and to develop new tumors (10% vs. 4%, $OR=3.17$ [1.27–7.93], $p=0.014$) compared to patients with tumor located outside the macula at presentation. There was no statistically significant difference in genetic testing for Rb1 mutation (25% vs. 16%, $p=0.078$) or likelihood of germline mutation (23% vs. 14%, $p=0.066$).

Conclusions: Patients with solitary unilateral macular retinoblastoma are more likely to express phenotypic outcomes of germline retinoblastoma, such as development of new tumors and family history of retinoblastoma, while trending toward increased risk of possessing germline Rb1 mutation.

ABSTRACT BODY:

Purpose: The high sensitivity of rod photoreceptors has led to the notion that they saturate when exposed to moderate light intensities, thus contributing little to vision in bright light. Recent studies have challenged this view and suggest that rods are able to avoid saturation under some conditions of bright persistent illumination. We tested the hypothesis that the light-dependent translocation of the G protein, transducin, causes a reduction in gain, allowing rods to escape saturation during prolonged illumination.

Methods: We recorded mouse rod photoresponses en masse using ex vivo electroretinogram (ERG) as well as single-cell suction electrode recording in the presence of steady, bright background light. Cone contributions were eliminated from ERGs by the use of $Gnat2^{-/-}$ mice. In addition, we recorded from $Gnat2^{-/-}$ $Gnat1^{-/-}$ $A3C^{+}$ mice in which the alpha subunit of transducin has an additional S-palmitoylation site that anchors it more tightly to cell membranes and thus impedes its translocation. The amount of pigment bleaching under experimental conditions was quantified using microspectrophotometry to measure spectral absorbance.

Results: During prolonged exposure to bright light ($10^4 - 10^6$ effective photons $\mu m^{-2} s^{-1}$) rods recovered responsiveness from initial saturation, increasing their response amplitude and sensitivity over a period of 30 - 90 minutes. In the $A3C^{+}$ mouse, responses in the presence of the background light were almost undetectable immediately after turning on background light and continued to be smaller, growing much more slowly in amplitude than in control retinas. In addition, control rods remained responsive even after light exposures that were calculated to bleach nearly all the rhodopsin. This finding was confirmed in both whole retina recording as well as single-cell recording, indicating that a mechanism of pigment regeneration within the rods themselves is required to sustain responsiveness during prolonged bright light exposure.

Conclusions: The reduction in outer-segment transducin and a novel mechanism of visual-pigment regeneration within the rod itself together enable rods to remain responsive over the whole of the physiological range of vision. In this way, rods are able to avoid an extended period of channel closure, which is known to cause photoreceptor death.

ABSTRACT BODY:

Purpose: Recent studies on VLC-PUFAs (C24-36) have revealed their specific presence and importance in retina. They are rarely consumed in diets and are specifically synthesized in vivo from long-chain PUFAs through the action of an enzyme known as ELOVL4. Genetic defects in ELOVL4 underlie the retinal pathology in Stargardt Type 3 (STGD3), a dominant, early-onset blinding disease with many symptoms that mirror dry age-related macular degeneration (dAMD). In a previous study, we chemically synthesized a VLC-PUFA (32:6 n-3) and measured its uptake in mouse retina and its beneficial effects on vision. In order to further study the role of VLC-PUFAs on photoreceptor development and maintenance, we supplemented 32:6 n-3 to ELOVL4 knockout retinal organoids.

Methods: We knocked out ELOVL4 in normal human iPSCs using CRIPR/Cas9 technology and generated retinal organoids using standard techniques. When the organoids had completed the phase of photoreceptor birth (17 weeks), the ELOVL4^{-/-} organoids were divided into two groups. One group was supplemented with 8 µM 32:6 n-3, while the control group received vehicle alone. Photoreceptor outer segment morphology and length were measured at 33 weeks of age.

Results: By 33 weeks of age, the vehicle-treated ELOVL4^{-/-} organoids had outer segments, but they appeared shorter and more disorganized than expected for normal human retinal organoids. The ELOVL4^{-/-} organoids supplemented with 32:6 n-3 had significantly longer outer segments (P<0.001) with normal morphology.

Conclusions: These results establish that ELOVL4^{-/-} organoids can be used as a model to study the pathophysiology and treatment of diseases associated with ELOVL4 dysfunction and that a synthetic VLC-PUFA can rescue abnormalities associated with absence of ELOVL4 activity. We are currently studying the ultrastructure of the outer segments of our treated and control organoids and the efficacies of n-3 versus n-6 VLC-PUFAs.

ABSTRACT BODY:

Purpose: This study will examine the practice patterns of long term management of keratoconus patients including follow up visit, frequency of topography and surgery.

Methods: An internet-based, 22 question, IRB approved RED-Cap survey of providers who managed at least one KC patient per week. Descriptive analyses are presented. Some responses allowed more than one answer.

Results: Of the 296 respondents, 245 providers with an average of 23.1 +12 years in practice met entry criteria. Respondents (n=220) averaged caring for 27.2 +35 KC patients each month. Respondents follow stable KC patients as follows: 6 month intervals (n=76) or 12 months (n=142). Stable patients were administered topography as follows (n=299): Initial visit (n=91), every follow up visit (n=43), only if progression suspected (n=31), every 6 months (n=26), every year (n=126),more than a year (n=25). Most practitioners (n=222) follow unstable KC patients at 3 month (n=78) or 6 month (n=134) intervals, while few follow them annually (n=10). Unstable KC is followed with topography as follows (n=299): at every follow up (n=101), only if indicated (n=27) every 6 months (n=99) every 12 months (n=29). Respondents recommend crosslinking in the following situations (n=221): All patients (n=16), documented diseases progression regardless of age (n= 118), documented progression under 40 (n=75), Other (n=12). Respondents were asked to estimate the percentage of patients who had undergone crosslinking. Results were as follows (n=212): 0-10% (n=86), 11-25% (n=82), 26-50% (n=38), 51-75% (n=13), 76-100% (n=3). Respondents (n=222) were asked to estimate the percentage of patients with KC who had undergone corneal transplantation. Results were as follows: 0-10% (n=104), 11-25% (n=90), 26-50% (n=26), 51-75% (n=2), greater than 75% (n=0).

Conclusions: Practice patterns for long term management of keratoconus show wide variability in terms of follow up care and assessment of progression with point of care testing. While respondents stated that they often recommend crosslinking, there are still few patients who have undergone the procedure. Results from this survey support the recent trend for fewer patients with corneal transplants. Better patient outcomes might be achieved with more defined algorithms for follow up care and point of care testing.

TITLE: Expression of axon guidance proteins in the cornea and trigeminal ganglia and their role in cornea neuro-epithelium regeneration.

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V.H. Guaiquil, G. Dimailig, C. Xiao, D. Lara, Q. Zhou, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Victor Guaiquil: Commercial Relationship: Code N (No Commercial Relationship) | Gregory Dimailig: Commercial Relationship: Code N (No Commercial Relationship) | Cissy Xiao: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Lara: Commercial Relationship: Code N (No Commercial Relationship) | Qiang Zhou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Determine the expression and neurogenic potential of axon guidance proteins in the cornea.

Methods: The expression of axon guidance proteins belonging to the Semaphorins, Ephrins and Netrins families of proteins, and their associated receptors were evaluated by RT-qPCR and immunofluorescence staining (IF) in mouse trigeminal ganglia and cornea tissues. Corneas (n=3 per condition) were subjected to epithelium debridement and the recovery of gene and protein expression was analyzed at 0, 1, 3, 5, 7 and 14 days post injury. Gene expression was evaluated using predesigned mouse TaqMan gene expression assays using validated internal controls. Protein expression was analyzed by immunofluorescence staining, tissue cryosections were incubated with antibodies against different members of axon guidance proteins and imaged under a fluorescent microscope. The epithelium and subbasal nerves regeneration of injured corneas were evaluated in mice treated with axon guidance recombinant proteins and compared to vehicle controls. Slit lamp, Von Frey filaments and B3 tubulin staining were used to determine the epithelium recovery, nerve sensation and nerve regeneration respectively.

Results: We found that all axon guidance proteins evaluated are expressed in the trigeminal ganglia and cornea epithelium. In the trigeminal ganglia all proteins were found in the neuronal cell body and few of them were expressed in the axons projecting to the cornea. The receptors that are usually associated with these proteins such as Neuropilins, Plexins and VEGFRs were also present in both tissues with certain degree of variation. After corneal epithelium injury there was a fast recovery of axon guidance proteins gene expression. They initially colocalized within the basal cells in the epithelium and remained in the first two epithelial cell layers after two weeks post injury. Two of the axon guidance proteins studied in vivo, significantly enhanced nerve regeneration and may have pleiotropic effects since they induce neuronal growth on isolated neurons and accelerate epithelium recovery in scratch assays.

Conclusions: Axon guidance proteins are crucial for axonal targeting in the eye. In the adult cornea they are highly expressed in the steady state and quickly upregulated after injury. Their trophic and neuro-regenerative effects indicate that they may be essential for cornea repair.

TITLE: Performance of the Spot Vision Screener in Children with Down Syndrome and Other Special Needs

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Mudie, E. McCourt, R. Enzenauer, Ophthalmology, University of Colorado Health, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lucy Mudie: Commercial Relationship(s);Welch Allyn:Code F (Financial Support) | Emily McCourt: Commercial Relationship: Code N (No Commercial Relationship) | Robert Enzenauer: Commercial Relationship(s);Welch Allyn:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Amblyopia is the most common cause of monocular blindness in adults and children, and disproportionately affects developmentally delayed children; being up to 3 times more common in one study. After the age of 9, amblyopia becomes irreversible, highlighting the importance of early detection. The Welch-Allyn Spot Vision Screener (Spot) is a commonly used device for detecting amblyogenic risk factors. The Spot takes a photograph of the child's eyes and determines approximately their refractive power, eye alignment and if there are any visual obstructions (such as ptosis or cataract). The test typically lasts 6 seconds and is without any known risks. Prior studies have reported good accuracy of Spot in the general population, however its performance in patients with Down Syndrome and special needs is not substantiated. Our study assessed the efficacy of Spot at detecting various amblyogenic risk factors in developmentally delayed children.

Methods: Children with various disabilities or delays were recruited from the Children's Hospital of Colorado Eye Clinic, Special Care Clinic and the Sie Center for Down Syndrome. Participants had their photograph taken with Spot pre and post pupillary dilation, and this was then compared to a comprehensive eye exam in the Ophthalmology clinic.

Results: One hundred children participated in the study. Twelve children were unable to get images with Spot and 5 did not attend for their exam in the eye clinic. The mean age was 5.9 years (standard deviation, SD, 3.4). 64% were male and 58% were non-Hispanic white. The overall sensitivity of Spot was 90% and the positive predictive value was 80% in undilated subjects. The area under the receiver operator curve (AUROC) was 0.68 (95% confidence interval, CI: 0.57-0.79), and this was not significantly different from the AUROC of Spot accuracy after dilation (0.68, 95% CI: 0.54-0.81).

Conclusions: The Spot Vision Screener performed well in this cohort of special needs children, the children did not need to be dilated in order for the Spot to have good accuracy. Spot could be used by primary care clinics and vision screening programs to better triage which patients need to be referred to Ophthalmology.

TITLE: Modulation of the acylation of the C-terminal segment of GRK1 drastically influences its solubility and membrane-binding properties

SESSION TITLE: Genetics, (gen)omics, systems and computational biology in ocular health and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Millette, C. Gagnon, C. Salesse, Universite Laval, Quebec, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Marc-Antoine Millette: Commercial Relationship: Code N (No Commercial Relationship) | Camille Gagnon: Commercial Relationship: Code N (No Commercial Relationship) | Christian Salesse: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: G-protein coupled receptors (GPCR) are key receptors in signal transduction. They are inactivated by G-protein coupled receptor kinases (GRK). GRK1 is the first member of the GRK family, which includes seven members. All GRK bind membranes via their C-terminal segment. Four GRKs are acylated at their C-terminus: GRK1 is farnesylated, GRK7 is geranylgeranylated, GRK4 and 6 are palmitoylated. The objective of this research work was to compare the extent of membrane binding of the 30 most C-terminus amino acid residues of GRK1 bearing three different acyl groups (palmitoyl, farnesyl and geranylgeranyl).

Methods: Infrared spectroscopy and circular dichroism measurements were performed to determine the secondary structure of the C-terminal segments. Fluorescence spectroscopy measurements were performed to gather information on the environment of tryptophan 531.

Results: Infrared and circular dichroism measurements showed these the acylated C-terminal segments adopt a random coil structure. Intrinsic fluorescence measurements suggest that the farnesylated segment of GRK1 is soluble in aqueous solution, whereas the palmitoylated segment is only partially soluble and the geranylgeranylated segment is aggregated. In addition, no significant increase in the fluorescence of the farnesylated segment was observed in the presence of sodium dodecyl sulfate (SDS). Moreover, measurements at increasing concentration of small unilamellar vesicles (SUVs) made of palmitoyl-oleoyl-phosphocholine (POPC) showed little modification in the position of the emission maximum, suggesting that this residue is not membrane embedded. In contrast, a drastic increase in fluorescence of the palmitoylated segment was observed in presence of SDS and SUVs, whereas an increase was only observed with SDS for the geranylgeranylated segment. Membrane binding to phospholipid monolayers shows a preferential binding of the farnesylated segment to unsaturated phospholipids, whereas a higher affinity to saturated phospholipids was observed for the palmitoylated segment.

Conclusions: The modification of the acylation of the C-terminal segment of GRK1 using either a farnesyl, a palmitoyl or a geranylgeranyl group drastically lowered its solubility. The preferential binding of the farnesylated segment for unsaturated phospholipids was modified in favor of saturated phospholipids with the palmitoylated segment.

TITLE: Aflibercept influences the immunocompetence of Dendritic Cells.

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Weindler, F. Bock, M. Hamdorf, C. Cursiefen, Ophthalmology, Uniklinik Köln, Köln, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Jasmin J Weindler: Commercial Relationship(s);Deutsche Forschungsgesellschaft (DFG):Code F (Financial Support) | Felix Bock: Commercial Relationship(s);Deutsche Forschungsgesellschaft (DFG):Code F (Financial Support) | Matthias Hamdorf: Commercial Relationship(s);Deutsche Forschungsgesellschaft (DFG):Code F (Financial Support) | Claus Cursiefen: Commercial Relationship(s);Deutsche Forschungsgesellschaft (DFG):Code F (Financial Support)

ABSTRACT BODY:

Purpose: In the course of keratoplasty, inflammatory processes may lead to a higher risk of graft rejection by changing the immunocompetence of dendritic cells (DCs). Therefore, in this experimental in-vitro study the effect of Aflibercept on the differentiation of DCs was investigated.

We hypothesize that administration of Aflibercept during maturation of DCs can influence the immunocompetence of mature DCs by neutralizing autocrine/paracrine VEGF-A.

Methods: Peripheral Blood Mononuclear Cells of human blood donors (N= 5-6) were differentiated in DC-Medium containing IL-4 and GM-CSF. At the beginning of maturation of immature DCs into mature DCs either 40µg/ml Aflibercept or 40µg/ml Fc-IgG-control was given to the cells. Maturation of DCs was performed with cytokines (CS; containing IL-1b, IL-6, TNFa and PGE) or Lipopolysaccharide (LPS).

After entering the stadium of mature DCs flow cytometry was performed with the focus on DC-specific surface markers (CD11c, CD40, MHC II), co-stimulatory receptors for T-cell stimulation (CD80, CD83, CD86) and the VEGF receptors VEGFR1 and VEGFR2.

Also, RNA was harvested of treated mature DCs and mRNA-levels of VEGF-A and VEGFR1 were investigated by using Realtime-PCR (RT-PCR).

Statistical analysis was performed with GraphPad Prism using a t-test or Man-Whitney-U-test.

Results: Aflibercept administrated during maturation of dendritic cells induced significant upregulation of the receptor CD11c (CS: p: 0.0145; 111.7%±44.1) and a significant downregulation of the co-stimulatory receptors CD83 (LPS: p: 0.032; 97.4%±16.8) and CD86 (LPS: p: 0.047; 94.01%±6.7) as well as VEGFR1 (CS: p: 0.0095; 47.1%±19.1). Furthermore, the frequency of VEGFR1-positive cells decreased significantly under Aflibercept treatment (CS: p: <0.0001; 21.4%±14.7; LPS: p: 0.0001; 36.1%±8.5).

No differences of the VEGF-A-mRNA-level or the VEGFR1-mRNA level was seen in the RT-PCR.

Conclusions: Aflibercept has a direct effect on dendritic cell maturation. Aflibercept modulates DC immunocompetence by downregulation of the receptors CD83 and CD86. The downregulation of the receptor VEGFR1 as well as the reduced expression of VEGFR1 on DCs treated with Aflibercept suggest that Aflibercept interacts with this receptor or could have an effect on the binding of VEGF-A on this receptor.

ABSTRACT BODY:

Purpose: Sickle cell disease (SCD) causes vascular occlusion associated with ischemia and increased mortality. SS genotype has been shown to have worse mortality than SC. Major complications of SCD that contribute to premature death include organ failure, acute sickle crisis, and stroke. Since these major complications of SCD are associated with increased vascular occlusion, we wanted to investigate if increased vascular occlusion in the retina could be a sign of worsening disease and therefore, a risk factor for increased mortality. There have not been studies looking at ophthalmic characteristics with SCD mortality. The goal of this study was to evaluate high risk ophthalmic characteristics that could be correlated more with deceased SCD patients.

Methods: This retrospective study included adult SCD patients seen routinely at Montefiore Medical Center (Bronx, NY) from January 2014 to June 2020. Patients were categorized as Deceased Patients (DP, n=57) and Living Patients (LP, n=985). Data on demographics, lab values, comorbidities, and ophthalmic care were obtained from Montefiore EMR (Epic, Verona, WI). Deceased patients were identified either from notification of the primary care provider or hospital records. Statistics were analyzed using R. Wilcoxon ranked sum test was used for continuous variables and Chi Square test was used for categorical variables unless the frequency counts were small (<10) in which case, a Fisher's exact test was used.

Results: The study included 1036 patients. 26 DP and 484 LP had at least one documented eye exam. Of these, DP were significantly older than LP ($p=0.003$). This difference was significant for SS patients ($p=0.004$) but not for SC ($p=0.81$). There were no significant differences between DP and LP in race or sex. DP were significantly more likely than LP to have had pars plana vitrectomy (PPV) ($p=0.007$). This significant difference was seen even when stratified for SS ($p=0.003$). There were no significant differences for diagnosis of proliferative sickle retinopathy (PSR) or laser retinopathy between DP and LP.

Conclusions: Higher rates of PPV in DP suggests that SCD patients requiring PPV may be at a higher risk of death. We recommend that SCD patients requiring PPV should be more carefully monitored regarding their general health.

TITLE: Accurate machine-learning estimation of axial length distribution in human populations from refraction, corneal curvature, age and gender

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Fitzpatrick, I. Flitcroft, J. Loughman, Centre for Eye Research Ireland, Technological University Dublin, Dublin, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Brian Fitzpatrick: Commercial Relationship: Code N (No Commercial Relationship) | Ian Flitcroft: Commercial Relationship(s);Ocumetra Ltd:Code I (Personal Financial Interest) | James Loughman: Commercial Relationship(s);Ocumetra Ltd:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: Human axial length (AL) is one of the most important ocular biometric parameters when it comes to understanding, tracking, and treating many ocular diseases. Ophthalmic datasets featuring AL are relatively small since AL measurements require specialized costly equipment. Datasets featuring simpler biometric parameters such as refraction but without AL can be very large in comparison since these variables are more straightforward to measure. We introduce a new machine learning technique that leverages refraction, corneal curvature, age and gender data to obtain estimates of the AL distribution in a population that can be at least as accurate as those given by direct measurement and kernel density estimation.

Methods: A regression-based machine-learning model was generated to predict AL from refraction, corneal curvature, age and gender (auxiliary data) based on a training dataset (n=383 records). Kernel density estimation (KDE) which incorporated this imputed AL information was then performed on a testing dataset (n=3809 records). On big datasets this approach is computationally intensive, so methods to accelerate the computations were explored.

Results: Comparison of the imputed AL distribution with conventional kernel density estimation of measured AL in the testing dataset showed no significant difference on the KS test at the 0.05 level. A Fast Gauss Transform (FGT) based algorithm significantly shortened computational time. The FGT algorithm accelerated the process 321-fold for a dataset of 800 eyes and 2087-fold for 4000 eyes (figure 1). Mathematical modelling demonstrated that the bias and variance of the estimator depend primarily on the number of input AL observations, the number of auxiliary data observations, and the properties of the auxiliary data. As a sample of AL measurements only estimates the true population AL distribution, a large sample of auxiliary data using this algorithm can match or exceed the accuracy of a smaller sample of AL measurements (figure 2).

Conclusions: The machine learning technique introduced in this work can accurately estimate the population distribution of AL by using refraction, corneal curvature, age and gender auxiliary data. This allows for the development of improved population centile data for AL from a wide range of epidemiological sources, which may be applied clinically in areas such as myopia control.

TITLE: Fixational Performance and Visual Function changes underwater in normal eyes

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Radhakrishnan, V.S. Ramasubramanian, Department of Optometry, SRM Institute of Science and Technology, Kattankulathur, Tamil Nadu, INDIA|

Commercial Relationships Disclosure (Abstract): Aiswaryah Radhakrishnan: Commercial Relationship: Code N (No Commercial Relationship) | Vivek Ramasubramanian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vision underwater is suboptimal and the human eye is poorly adapted to the aquatic environment. Differences in refractive index, illumination levels and image blur by the dynamic water environment contributes to altered vision underwater. In this study, we investigated changes in fixational eye movements, refractive error and vernier acuity with and without underwater blur in young normal eyes.

Methods: Fifteen young subjects (Age: 20 years to 35 years) with refractive error and otherwise normal ocular health participated in the measurements. None of the subjects had astigmatism $> 1D$ or any other ocular pathology. Fixational eye movements (FEM) were recorded while the subjects viewed a dynamic video target displayed on Display++ monitor using LiveTrack FM. Using an NVision-K 5001 openfield autorefractor, changes in spherical equivalent of refractive error (SEQ) during a reading task was measured every 30 seconds for 5 minutes. Vernier Acuity (VER) was measured using FrACT®. The reading task and the stimulus for VER were also presented on Display++ with the subject seated about 2m from the monitor. Underwater blur was simulated by generating turbulence and waves in water using mechanical motors, in a transparent tank placed between the subject and the monitor. All measurements were performed in a dim room illumination without and with underwater blur under binocular viewing conditions for each eye and for both eyes together. Overall the measurement lasted about 1.5 hours.

Results: FEM with and without underwater blur was significantly different ($p < 0.0001$, Fig.1). The mean increase in pupil size underwater was $0.2\text{mm} \pm 0.04$ ($p < 0.05$). The change in refraction was mostly hyperopic (64%) with maximum shift of $-0.10D \pm 0.25$ ($p = 0.6$, $U = 420.5$). On an average across subjects and eye, the difference in refractive error with and without underwater blur was $-0.02D \pm 0.34$ and was not statistically significantly different ($p = 0.26$, $U = 431$). The average VER with underwater blur ($18 \text{ arcsec} \pm 11$) was significantly lesser ($p = 0.0001$) than without underwater blur ($31 \text{ arcsec} \pm 20$).

Conclusions: No significant changes were observed in fixational eye movements and refractive status with underwater blur. A significant decrease in Vernier Acuity was observed with underwater blur. Our results imply that the subjects could probably experience difficulties in depth judgement in an aquatic environment.

ABSTRACT BODY:

Purpose: Many growth factors and cytokines are involved in the onset of diabetic retinopathy (DR), some promoting increased vascular permeability and neovascularization and contributing to disease progression. Previous investigations into the proteomic signature of Diabetic Macular Edema (DME) have characterized a number of factors; however, many consist of circulating cytokines and chemokines. We hypothesized a model of DME progression, vascular breakdown and edema could be strengthened by comparing known and putative permeability associated markers in the aqueous of diabetic subjects with or without a diagnosis of DME.

Methods: Aqueous humor samples (AH) were collected from 3 sources: Healthy non-diabetic control subjects at cataract surgery (CTL), non-proliferative diabetic retinopathy with absence of DME (NPDR), and NPDR with DME (DME). Samples were collected at Advanced Eye Centers, Dartmouth, MA, and delivered to Allergan/AbbVie, Irvine, CA for analysis. Three multiplex panels (Luminex) spanning 47 soluble protein markers were used to detect protein levels in 108 subject samples (CTL: 42, NPDR: 35, DME: 31).

Results: Of the 47 markers surveyed in DME subject samples, 13 were significantly upregulated when compared to control or NPDR following age-corrected univariate ANCOVA with Dunnett's correction for multiple comparisons. Upregulated factors included angiopoietin 2, angiostatin, endothelin 1, hepatocyte growth factor, placental growth factor 1, stem cell factor, soluble epidermal growth factor receptor, soluble hepatocyte growth factor receptor, soluble urokinase plasminogen activator surface receptor, and thrombospondin 2 (p values < 0.001). Platelet-derived growth factor B dimer (PDGF AB/BB) was downregulated compared to CTL (p< 0.01).

Conclusions: The strength and potential predictive value of the prospective markers modeled here are demonstrated by principal components analysis (PCA), showing that >70% of variance could be preserved by only two components. These markers were strongly associated with DME when grouped by PCA and >87% of DME subjects could be sorted by a single component (+PC1). Further, >90% of CTL subjects were sorted by PC2 and showed strong positive correlation with expression of a single marker (PDGF AA/BB; 0.624). In summary, these data provide a focused examination of permeability factors in addition to VEGF and present a robust model of AH disease markers highly associated with DME.

ABSTRACT BODY:

Purpose: The comparison of wide field eye fundus images (WFI) and functional tests is of great interest in a number of diseases of the retina. The purpose of this study was to evaluate a new technique for the comparison of WFI and wide field perimetry results (WFP).

Methods: WFI and WFP are both projections on a plane surface of the retina which can be approximated to a spherical shape. However, the projection of a retinal scotoma is different in the stereographic projection used in WFI and in the azimuthal equidistant projection used for perimetry. This results in differences in the localization and quantification of scotoma.

In a first study, a simulation software was used to evaluate the errors produced by these two projection modes for the position, shape and surface area of a scotoma of circular shape and constant surface area on the retina.

In a second study, we evaluated on 7 clinical cases with peripheral alterations the benefit of converting the representation of the WFP to WFI coordinates to allow the comparison of Goldmann perimetry results obtained with the MonCvONE perimeter (Metrovision) with wide field eye fundus images imported from OPTOS. Superposition was obtained by matching the positions of the fovea and optic disk.

Results: The following table summarizes the errors obtained with the two projection solutions.

When eccentricity to the fovea increases:

- measures of distances along meridians increase with WFI (+33% at 60d) and are constant with WFP,
- shapes of scotoma are preserved with WFI and become deformed with WFP (+21% at 60d)
- surface area is altered more significantly with WFI (+78%) than with WFP (+21%).

The following images show the results from a retinitis pigmentosa case with superposition of the eye fundus and Goldmann perimetry.

It shows that the discrepancy found with the WFP projection is corrected when using the WFI projection. The same is found for other cases when peripheral alterations are involved.

WFP projection WFI projection

Conclusions: The new method allows the comparison of eye fundus images and perimetry results at large eccentricities (over 20 degrees) and this is important to avoid significant errors in the position and quantification of scotoma.

ABSTRACT BODY:

Purpose: Glaucoma is one of the leading causes of blindness across the world, and elevated intraocular pressure is the most risky factor of the glaucoma. The equator sclera plays a pivotal role in vision as it provides stable mechanical support to the fragile optic nerve and retina under dynamic force loading condition. Previous research mainly focused on the mathematical modeling to predict its anisotropy property to the response of elevated IOP. In this study, we aim to use the high frequency ultrasonic array based elastography to investigate the anisotropy property of equator sclera experimentally in the superior, temporal, nasal and inferior locations under different IOP conditions.

Methods: A piezoelectric shaker was used to induce tissue motion instead of acoustic radiation force. The unscaled pig eye was connected with infusion line and IOP sensor. A mechanical shaker (mini-shaker type 4810; Bruel & Kjaer) was positioned at the anterior sclera to initiate elastic wave. An ultrasonic array (L22-14v; Verasonics Inc.) was positioned above the equator sclera and its beam was aligned to be parallel with the shaker.

Results: Fig. 1 shows one example in the superior location of the B-mode images and the corresponding spatial-temporal maps in different IOP in two different directions. The elastic wave speed can be acquired using liner regression algorithm of each wavefront with its corresponding lateral position (indicated by red lines). In the equator direction, from 10 mmHg to 30 mmHg, the elastic wave speed is 6.1 m/s, 11.83 m/s, 13.70 m/s, 14.35 m/s and 15.16 m/s respectively. The reconstructed Young's modulus is 111.63 KPa, 419.85 KPa, 563.07 KPa, 617.77 KPa and 689.48 KPa respectively. In the anterior to posterior direction, elastic wave velocities are 3.7 m/s, 4.26 m/s, 4.75 m/s, 5.46 m/s and 6.18 m/s, and the Young's modulus are 32.08 KPa, 54.44 KPa, 67.69 KPa, 89.43 KPa, 114.58 KPa correspondingly.

Conclusions: The equator sclera has the anisotropy property, it is stiffer along with the equator direction. These results demonstrate the feasibility of our system to investigate the anisotropy property in equator sclera with elevated IOP.

ABSTRACT BODY:

Purpose: Teprotumumab was recently approved in January of 2020 to treat thyroid eye disease (TED). The purpose of this study was to evaluate the safety profile and Graves' ophthalmopathy quality of life questionnaire (GO-QOL) for a group of patients in which compassionate use of teprotumumab was deemed appropriate, prior to U.S. Food and Drug Administration (FDA) approval.

Methods: Adults with active, moderate-to-severe TED were scheduled to receive 8 infusions (10 mg/kg first infusion, 20 mg/kg thereafter) of teprotumumab over 21 weeks. Adverse events (AEs), lab assessments, vitals and GO-QOL (max QOL=100) were assessed.

Results: 22 patients (52.4±16.2 years, 64% female, 91% non-smokers, 7.2±3.0 months TED duration) from 8 sites were treated. 19/22 (86%) received 8 infusions (3 discontinued treatment due to COVID-19, personal choice, and hyperglycemia). Baseline Total GO-QOL was 47.8±21.4 (appearance [AP]: 42.9±26.7, visual function [VF]: 52.9±24.6). At Week 21, Total GO-QOL improved from baseline by 24.9±21.0 points (AP improved by 23.8±26.2, VF improved by 25.7±25.8), all large changes. All patients reported an AE. One patient suffered from appendicitis, which was deemed unrelated. Other AEs (>2 patients) included muscle spasms (n=11), fatigue (n=10), hypoacusis (n=5), headache (n=5), nausea (n=5), extremity pain (n=4), alopecia (n=4), hypertension (n=4), dry skin (n=3), diarrhea (n=3), tinnitus (n=3), myalgia (n=3), increased lacrimation (n=3), and hypogeusia (n=3). No new safety concerns were identified.

Conclusions: Teprotumumab resulted in large QOL improvements as demonstrated previously in controlled clinical trials. Safety findings were consistent with the previously established teprotumumab profile.

ABSTRACT BODY:

Purpose: To quantitatively evaluate and compare the retinal microvasculature in patients with cystoid macular edema (CME) secondary to diabetes (DME), central retinal vein occlusion (CRVO), branch retinal vein occlusion (BRVO) and post-cataract surgery (pseudophakic CME; PCME) using optical coherence tomography angiography (OCTA).

Methods: In this observational study, 91 eyes (51 patients) with CME and their fellow eyes serving as controls underwent ophthalmologic examination and imaging using OCTA (Optovue XR Avanti, USA). The 3x3 en face angiograms (automatically segmented) of superficial capillary plexus (SCP) and deep capillary plexus (DCP) were analyzed using ImageJ program. Parameters analyzed were the foveal avascular zone (FAZ) size in the SCP, and vessel density (VD), vessel skeleton density (VSD) in the SCP and DCP. Descriptive statistics and mixed-effects multiple regression model accounting for inclusion of two eyes of same patient were used to quantitatively summarize the features of our cohort. The statistical analysis was performed using the statistics software SPSS (v 19; IBM Corp., Chicago, IL, USA). Results with a p value < 0.05 were considered significant.

Results: Ninety-one eyes (37 DME, 10 CRVO, 10 PCME, 9 BRVO and 25 control) were included in the analysis. Total mean age was 63.5±10.5 years (p=0.136) and no significant differences in other demographic characteristics were noted. Best corrected visual acuity (BCVA, measured in logMAR) was significantly different among groups (0.25±0.19, DME; 0.5±0.4, CRVO; 0.53±0.5, PCME; 0.67±0.53, BRVO; 0.05±0.09, controls; p<0.001). No significant differences were observed in FAZ size (p=0.17), VD (p=0.15) and VSD (p=0.18) in SCP using mixed-effects multiple linear regression analysis. Furthermore, VD (2.8±0.25, DME; 2.7±0.22, CRVO; 2.8±0.4, PCME; 2.8±0.21, 3.2±0.36, controls) and VSD (7.7±0.12, DME; 7.75±0.13, CRVO; 7.67±0.22, PCME; 7.73±0.15, BRVO; 7.52±0.14, controls) in DCP were significantly different among groups (p<0.001 and p<0.001 respectively).

Conclusions: To our knowledge this is the first study comparing the retinal microvasculature in patients with CME secondary to diabetes, CRVO, BRVO, post-cataract surgery and their fellow eyes. Our results revealed that fellow eyes of those patients had statistically significant higher VD and lower VSD measurements in DCP when compared to any CME group but not between groups.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a vasoproliferative retinal disease that has a multifactorial origin and can cause serious vision disturbances. Our goal is to identify possible maternal risk factors (RF) and those associated with pregnancy for the development of ROP in newborns at risk examined in our center, between January 2015 and December 2019.

Methods: A descriptive and retrospective study was carried out analyzing maternal and pregnancy-related risk factors in newborns with a birth weight less than 1500 grams and a gestational age less than 32 weeks in a 4-year period (2015 - 2019). Subsequently, a comparative study was carried out between a group of patients who developed ROP and a control group without signs of ROP who presented similar characteristics in terms of weight and gestational age. Finally, the statistical analysis of the data was carried out using SPSS Statistics 22.0.

Results: 88 newborns were evaluated (15 of them affected by ROP and 73 healthy children) as well as maternal and pregnancy-related risk factors of their mothers. The mean age among the mothers of children with ROP was 32.8 +/- 5.49 years, while the mean age of the control group was 31.93 +/- 6.64 years.

Different maternal RF that may influence the development of ROP were studied. Among these, those that occurred most frequently in the group of mothers of children with ROP were cesarean delivery (73.3%), multiple pregnancy (53.3%), infections during pregnancy (40%), and premature rupture of membranes (33.3%). However, we only found statistically significant differences in the presence of multiple pregnancy for the development of the disease, with a confidence interval of 95% ($p = 0.037$).

Conclusions: The mothers of the newborns with ROP evaluated in our center presented various risk factors with relative frequency, such as cesarean delivery or infections during pregnancy. However, multiple pregnancy was the only factor that showed statistically significant differences compared to the control group ($p = 0.037$). Finally, it is necessary to emphasize the importance of maternal and pregnancy-related risk factors in the evolution of the newborns and in the development of ROP.

ABSTRACT BODY:

Purpose: Long term outcomes and risk of reactivation of myopic choroidal neovascularisation (mCNV) are poorly understood. This study describes the treatment patterns, risk of reactivation and visual outcomes over ten years in a large cohort of patients.

Methods: Treatment-naïve eyes receiving at least one intravitreal anti-vascular endothelial growth factor (VEGF) injections for mCNV were included in the study. Data were generated during routine clinical care) between 09/2008 and 12/2018 utilising Medisoft Electronic Patient Record (EPR) data from 27 NHS sites in the UK. Main outcome measures included visual acuity (VA), number of injections, number of reactivations and number of visits.

Reactivations were defined as between 95 to 97.5 centile of distribution of injection interval in this study cohort.

Results: A total of 385 eyes of 380 patients receiving 1,822 injections were included. The mean age was 61.7 years old and the Female:Male was 2.25:1. Loess regression of Visual Acuity (VA) vs times 0, 6, 12, 24, 36, 48, and 60 months was 61, 64, 66, 66, 64, 61, and 59 (letters) . The end of an mCNV activity "reactivation" was determined to be 12 weeks (just below 97.5 centile of distribution of injection interval in this study cohort).

The mean number of injections was 3.12 injections during their first reactivation episode, which reduces to 2.04, 2.27, 2.36, 1.95, and 1.6 at their 2nd, 3rd, 4th, 5th, and 6th reactivation episode, respectively.

Conclusions: Our findings show that in the first four years of treatment, the VA is shown to have improved. However, past the fourth year, the VA steadily reduces. The data guides the temporal definition of the end of an mCNV reactivation and the number of treatments and the likelihood of further reactivations of disease activity occurring. These data will guide the counselling of patients and follow up intervals scheduling.

ABSTRACT BODY:

Purpose: Genetic Leukoencephalopathies (gLEs) are white matter disorders affecting the central nervous system, causing progressive abnormalities in the visual and motor systems. A mutation in Vacuolar Protein Sorting 11 (VPS11) has been identified as a causative allele of gLE in Ashkenazi Jewish individuals, with a carrier rate of 1:250. VPS11 forms membrane-tethering complexes with three additional VPS proteins to control crucial cellular processes in the endolysosomal and autophagy pathways. Here, we are characterizing two zebrafish vps11 mutant lines, vps11(plt) and vps11(KO), as potential models for gLE.

Methods: The DanioVision tracking system was used to monitor the movement of wild-type and mutant larvae at 5 and 7 days post-fertilization (dpf) (N>50 larva per time point per genotype). Two startle responses were utilized: a visual stimulus of alternating light and dark periods and an acoustic/mechanical stimulus of a loud tap. Output measurements included the distance travelled and velocity of movement. In addition, optokinetic response (OKR) analysis was performed using VisioTracker at 5dpf to test visual acuity (N>5 larva per genotype). One-way ANOVA with post-hoc Tukey's test was used to determine statistical differences between the groups.

Results: Behavioral analysis showed that vps11(plt) and vps11(KO) mutant fish could visualize changes in light and dark backgrounds, but OKR analysis indicated the animals were functionally blind and unable to make out an image at 5dpf. With regard to motor movement, no difference in response to alternating light-dark backgrounds was observed between the mutant and wild-type larvae at 5 dpf, but a significant reduction in movement and velocity of the mutants at 7 dpf ($p<0.01$; $p<0.01$) was observed. vps11(plt) and vps11(KO) mutants also showed significant reduction in movement to acoustic/mechanical stimuli at low ($p<0.01$; $p<0.01$) and high intensity ($p<0.01$; $p<0.05$). Together, these results suggest that loss of Vps11 function has a progressive defect on visual sensory and motor systems in zebrafish larvae.

Conclusions: Our findings support the use of zebrafish to further characterize the vision and motor defects associated with loss of Vps11 function.

ABSTRACT BODY:

Purpose: Lacritin is a human tear protein with preclinical basal tear and corneal epithelial restorative properties encapsulated in the potent C-terminal synthetic peptide 'LacripepTM', (also known as 'N-94/C-6'). LacripepTM and natural C-terminal LacripepTM-like tear fragments also stabilize the tear film by interacting with the meibum fatty acid 'OAHFA'. Lacritin and fragments are selectively deficient or absent in almost all dry eye tears, particularly those from primary Sjögren's Syndrome. Here we test topical LacripepTM at two concentrations versus placebo as a natural replacement therapy in primary Sjögren's Syndrome - the first in human trial.

Methods: A double-masked, randomized, thirty-five center, first-in-human phase 2 study to evaluate the efficacy and safety of 0.005% and 0.01% LacripepTM in 204 subjects with dry eye associated with primary Sjögren's Syndrome was performed (ClinicalTrials.gov Identifier: NCT03226444) with both signs and symptoms assessed using NEI Workshop fluorescein corneal staining scoring and specific standardized patient symptomatology. Visit one initiated a two-week washout, followed by randomization at visit two, topical treatment TID for four weeks and a two-week washout. Endpoints were monitored after two and four weeks of treatment, and after treatment washout.

Results: After two weeks, 0.005% LacripepTM demonstrated a -0.4 reduction in inferior corneal staining (p value vs placebo 0.0055) - that segment of the cornea recognized as the most relevant in dry eye disease, as well as a -14.5 point reduction in complaints of burning and stinging (p value vs placebo 0.0024). LacripepTM was well tolerated and there were no serious treatment related adverse events. The results are consistent with a bell-shaped dose response (as seen in both preclinical and cell culture studies) and suggest the need for lower dose optimization.

Conclusions: LacripepTM appears to be rapidly efficacious for both sign and symptom in primary Sjögren's syndrome, the most severe form of dry eye. This is the largest ophthalmic trial to date in primary Sjögren's Syndrome dry eye and was the first-in-human clinical study conducted with LacripepTM as the active ingredient.

ABSTRACT BODY:

Purpose: To correlate the presence of age-related macular degeneration (AMD) associated geographic atrophy (GA) and reticular pseudodrusen (RPD) with results of the night/dim light vision function captured on a night vision questionnaire (NVQ-10).

Methods: In a cross-sectional study of participants of the Age-Related Eye Diseases Study 2, AMD status was documented at the 5-year close-out study on ultrawide-field images divided into 3 zones: posterior pole (zone 1), peripheral (zone 2), and far periphery (zone 3). Zones 1 and 2 were divided into 4 quadrants: superonasal (SN), superotemporal (ST), inferonasal (IN), and inferotemporal (IT). Zone 3 was divided into superior and inferior. The reading center (Queens' University, Belfast) graded for presence of GA and RPD. The NVQ was administered. Specifically, the questions regarding driving at night and visual function in dim light/night were analyzed. Association between the presence of GA and RPD (analyzed separately) and two composite variables for driving and night/dim light vision were assessed using frequency tables and chi-square/Fisher's exact P-values.

Results: 889 eyes (450 participants) (mean age 72.5±8.1, female 58%) were analyzed. Comparing eyes with/without GA or RPD, statistically significant differences ($P < .001$ to $.01$) for % with difficulty in night/dim light vision were found for zone 1. In zones 2 and 3, higher differences were seen in the temporal regions with GA but not RPD. Comparing eyes with or without GA, significant differences were found for the % with moderate/extreme difficulty driving for zone 1 and the inferior regions of zone 2 ($P < .001$ to $.01$). No significant association was found between the presence of RPD in any zone and driving difficulty. Visual acuity was significantly lower for persons with low luminance difficulty and for eyes with GA in zone 1 ($P < .0001$).

Conclusions: Interestingly, the association was strongest with the GA or RPD located in the posterior pole or zone 1. This may be explained by rod distribution in the retina tend to be the highest around the paracentral area, located in zone 1. Despite having lesions in the more peripheral fields (zones 2 and 3), there is less of an impact on the function in dim light or at night. This provides further data to suggest the importance of patient reported outcome in our studies of disease progression/intervention.

ABSTRACT BODY:

Purpose: Ptosis is an eye condition where the upper eyelid droops. The current diagnosis for ptosis involves cumbersome manual measurements that are time-consuming and prone to human error. This work presents a fully automated and interpretable dual model system for rapid detection of ptosis that can help save the clinics and patients valuable resources.

Methods: The data for this study were queried from the Illinois Ophthalmic Database Atlas (I-ODA) that was developed by the Department of Ophthalmology at the University of Illinois Chicago. The dataset consisted of 820 facial images collected in a clinical setting and was augmented by 43 Flickr-Faces-HQ images. A subset of 100 images was hand-selected by an expert oculoplastic surgeon to create a held-out test set. All values reported in the results were derived from this test set.

The eye regions were extracted from the facial images and were fed into two pipelines, Deep Learning (DL) and Feature & Rule (FR). The DL used a 5-layer uni-eye convolutional neural network to learn data characteristics to predict ptosis likelihood and the FR extracted features to determine the marginal reflex distance (MRD1) and the iris visibility ratio (IR). AutoPtosis was a combination of both these pipelines, where a predictive model was trained using MRD1, IR, and DL's likelihood to predict ptosis.

Results: The DL performed well giving a 0.91 accuracy, 0.89 precision, 0.93 recall, and 0.95 AUC while FR gave 0.63 accuracy, 0.60 precision, 0.80 recall, and 0.77 AUC. When both pipelines were combined there was an improvement in accuracy to 0.95, precision to 0.96, recall to 0.96, and AUC to 0.98. We noticed an improvement especially in FR results when only clinical data was used. We also created class activation maps and direct feature visualization to interpret the most contributing eye regions for DL and iris, eye contours used for calculating MRD1 and IR respectively, that helps with error assessment.

Conclusions: AutoPtosis combined the preferable aspects of both DL and FR to create a rapid and automatic system for detection of ptosis all while achieving results almost as good as an expert physician. The models performed optimally under clinical settings and can be deployed there as a helping tool to generate results which can then be verified by physicians, saving the healthcare system and patients valuable resources.

ABSTRACT BODY:

Purpose: Aging is associated with a general decline in mitochondrial function and an increased accumulation of mitochondrial mutations. Retinas from age-related macular degeneration (AMD) patients have a higher incidence of mitochondrial mutations in their retina pigmented epithelium (RPE) layer than non-AMD controls. Polymerase subunit gamma 1 (POLG1) gene encodes the catalytic subunit of mitochondrial DNA (mtDNA). Expression of a dominant point mutant of this gene (POLG1(D1134A)) increases mitochondrial mutations and mitochondrial DNA depletion. This work aims to characterize the effects of POLG1(D1134A) expression in vitro using the RPE-like cell line ARPE-19.

Methods: We replaced the wild-type sequence of POLG1 for POLG1D1134A in a plasmid containing the AAV2 terminal repeats (pTR-POLG1(D1134A)). We transfected HEK293T cells with either pTR-POLG1, pTR-POLG1(D1134A), or pTR-GFP and quantified the differences in total mitochondrial DNA in these cells. The level of oxidative stress in these cells was also measured by MitoSox staining and flow cytometry. These plasmids were also electroporated in the RPE-like human cell line ARPE-19, followed by their growth in a glucose-free medium for four days. We used the Random Mutation Capture (RMC) assay to quantify the number of mutant mitochondrial genomes in each group by PCR.

Results: Transient transfection of HEK293T cells with pTR-POLG1(D1134A) plasmid led to a significant decrease in viability at 72 hours post-transfection compared to the wild type pTR-POLG1 transfected cells. We did not detect a significant difference in oxidative stress by flow cytometry between these groups. Electroporation of pTR-POLG1(D1134A) in ARPE-19 cells caused a significant accumulation of mutated mtDNA compared to either GFP or wild type POLG1 control groups.

Conclusions: The overexpression of POLG1(D1134A) decreases cell viability independent of oxidative damage. Furthermore, overexpression of this mutant gene also increases the accumulation of mtDNA mutations in a human RPE-like cell line. Thus, pTR-POLG1(D1134A) is a tool to study accelerated aging features due to mitochondria crisis.

TITLE: BAP1 status and response to radiation in melanoma

SESSION TITLE: Recent Advances in Uveal Melanoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Hanpude, J.B. Massengill, C.M. Cebulla, F. Davidorf, M.H. Abdel-Rahman, Ophthalmology, The Ohio State University Wexner Medical Center, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Pranita Hanpude: Commercial Relationship: Code N (No Commercial Relationship) | James Massengill: Commercial Relationship: Code N (No Commercial Relationship) | Colleen Cebulla: Commercial Relationship: Code N (No Commercial Relationship) | Frederick Davidorf: Commercial Relationship: Code N (No Commercial Relationship) | Mohamed Abdel-Rahman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The majority of uveal melanomas (UM) is managed using radiation based procedures. However, radiation retinopathy lead to irreversible vision loss within few years after treatment. BAP1 tumor suppressor gene is inactivated in up to 45% of UM patients. BAP1 is important in DNA repair and it could modify the tumor response to radiation. Here, we investigated the effect of BAP1 inactivation on response to radiation in a melanoma in-vitro model.

Methods: To assess the BAP1 role in response to treatment of melanoma cells we used CRISPR-Cas9 to knock out (KO) BAP1 in mouse melanoma cell line B16F10 and two UM cell lines 92.1 and Mel202. B16F10 cell line was selected as it has low mutation burden similar to UM cells and it could be used in-vivo tumor models in syngeneic C57BL6 mice without immunosuppression. We used RS-2000 irradiator to deliver various doses of ionizing radiation (IR) ranging from 10-80 Gy. For PARP inhibitor we used rucaparib at the average IC50 dose within 1h of IR. After 5 days, surviving cells were washed with PBS and fixed with 3% PFA and stained with 0.2% crystal violet then stain was extracted with 10% acetic acid and the optical density (OD) was determined by spectrophotometer at 600nm. The population survival rate was determined by the average ratio between the OD of the treated and untreated cells.

Results: The two UM cell lines Mel202 and 92.1 did not survive BAP1 knock down. B16F10 cells survived and multiple different clones of homozygous and heterozygous BAP1 KO cells were generated. BAP1 deletion and loss of expression were confirmed by sequencing and Western blot, respectively. Two B16F10 BAP1 KO clones in addition to the wild type were used for assessment. We observed increased cell death at different doses of radiation in BAP1 KO cell lines compared to BAP1 WT cells. Moreover, loss of BAP1 minimally increased the sensitivity of B16F10 cell line towards rucaparib.

Conclusions: Our results suggest that combination therapy of PARP inhibitor with IR could help to reduce the IR dosage in BAP1 mutant melanoma cells. Further studies on naturally occurring BAP1 mutant and wild type UM cell lines are ongoing.

TITLE: Biometric parameters and myopia in a canine model of open-angle glaucoma (OAG)

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.M. Komaromy, Michigan State University, East Lansing, Michigan, UNITED STATES|

C. Harman, Michigan State University, East Lansing, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Christine Harman: Commercial Relationship: Code N (No Commercial Relationship) | Andras Komaromy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess biometric parameters and refractive errors in beagle-derived dogs with Weill-Marchesani syndrome (WMS)-related OAG due to a G661R missense mutation in ADAMTS10.

Methods: A-scan parameters were measured in pre- and post-glaucomatous ADAMTS10-mutant (n=78) and normal control dogs (n=24) between 0.4 and 10.8 years of age (median ages: 25.6 and 31.1 respectively): anterior chamber depth (ACD), lens thickness (LT), vitreal chamber depth (VCD), and axial length (AXL). Refractive errors were measured in a subset of dogs (27 mutants, 11 normals) by streak retinoscopy. A total of 589 A-scans and 78 refractions were performed. Parameters were compared between groups by Student t-test with significance set at $p \leq 0.05$. Spearman's correlation coefficients were calculated between A-scan parameters and refractive errors and age, respectively.

Results: Regardless of age, A-scan parameters differed significantly between ADAMTS10-mutant and normal control dogs: AXL ($21.22 \pm 0.88\text{mm}$ vs. $20.62 \pm 0.52\text{mm}$; $p \leq 0.001$), LT ($7.21 \pm 0.31\text{mm}$ vs. $6.93 \pm 0.27\text{mm}$; $p \leq 0.001$), and VCD ($9.56 \pm 0.56\text{mm}$ vs. $9.34 \pm 0.31\text{mm}$; $p \leq 0.001$). AXL, LT, and VCD are significantly larger in ADAMTS10-mutant vs. normal dogs already at 1-2 years of age, before the increase in intraocular pressure (IOP) and development of OAG in mutants: AXL ($21.13 \pm 0.52\text{mm}$ vs. $20.79 \pm 0.58\text{mm}$; $p = 0.003$), LT ($7.14 \pm 0.30\text{mm}$ vs. $7.06 \pm 0.20\text{mm}$; $p = 0.013$), and VCD ($9.59 \pm 0.57\text{mm}$ vs. $9.34 \pm 0.24\text{mm}$; $p \leq 0.001$). ACD does not become significantly larger in mutant dogs until >4 years of age ($4.91 \pm 0.77\text{mm}$ vs. $4.37 \pm 0.35\text{mm}$; $p = 0.009$), when clinical detectable OAG is present. There was a significant difference in refractive errors between mutant and normal dogs ($-5.4 \pm 1.48\text{D}$ vs. $-0.2 \pm 0.63\text{D}$; $p \leq 0.001$) with mutant eyes being highly myopic. Age correlated to refractive error weakly in mutant (0.11) and moderately negative in normal dogs (-0.55). In contrast, correlation between AXL and age was much weaker in normal (0.08) vs. mutant dogs (0.49).

Conclusions: Mutant eyes are significantly longer than normal eyes due to a deeper VCD resulting in high degree of myopia even before the increase in IOP. Weak correlation between refractive error and biometric parameters suggest that lens position may have an important role in myopia. The increased LT may be due to ADAMTS10-mutation-related lens zonular dysplasia and weakness.

ABSTRACT BODY:

Purpose: To determine if the addition of novel Sjogren syndrome (SS) autoantibody data improves the performance of a previously reported algorithm to screen dry eye patients for SS.

Methods: Inclusion criteria were age ≥ 18 years, no history of autoimmune disease, and dry eye complaints for ≥ 3 months. Ocular and systemic symptoms were assessed using a questionnaire. Subjects underwent an ocular surface exam, measurement of unstimulated whole salivary rate, serological testing, and a lip biopsy if indicated to diagnose SS. A participant was diagnosed with SS if they met the 2016 American College of Rheumatology/European League Against Rheumatism criteria. The screening algorithm score was originally determined using questionnaire responses, assessment of tear film break-up time and conjunctival staining with lissamine green (Bunya et al Cornea 2021). The presence or absence of IgG, IgM, or IgA isotypes of the novel SS antibodies (anti-salivary protein (SP), anti-parotid secretory protein (PSP), and anti-carbonic anhydrase isoenzyme VI (CA-VI)) was compared between patients with and without SS, and incorporated into the algorithm.

Results: 89 patients (18 SS, 71 no SS) were enrolled, 82% of them female with a mean age (\pm SD) of 57 (\pm 17.6) years. There was no significant association between the presence of any one novel antibody and a positive SS diagnosis (Table 1). The percent of positive subjects in the following specific immunoglobulin groups: SP IgA, PSP IgM or CA-VI IgM, was higher in those with SS than those without SS (61.1% vs. 25.4%, $p=0.0009$, Table 1). The area under the ROC curve (95% CI) for SS screening was 0.68 (0.55-0.81) with the likelihood score alone, and significantly ($p=0.04$) improved to 0.77 (0.65-0.89) when using both the novel antibodies and the likelihood score (Figure 1).

Conclusions: We found that the inclusion of specific novel autoantibodies (SP IgA, PSP IgM and CA-VI IgM) significantly improved the performance of our previously reported SS screening tool. This likelihood scoring system can be implemented using the brief series of questions alone, or combined with standard ocular surface signs and novel SS antibody testing for improved performance. Once validated, the algorithm may serve as an effective screening tool to determine the likelihood of SS in dry eye patients, potentially allowing for earlier diagnosis and treatment.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRDs) are frequently associated with refractive error, usually resulting from an abnormally long or short axial length (AL). We investigated AL distributions in patients with particular IRD subtypes.

Methods: We analyzed axial lengths measured by partial coherence interferometry (IOLMaster optical biometer, Carl Zeiss Meditec AG, Jena, Germany) from patients recruited from the IRD clinics of Moorfields Eye Hospital London as part of a wider imaging study. Patients had a clinical IRD diagnosis with molecular confirmation in most cases. Distributions of AL for each IRD (where measurements >10 patients were available) were examined and comparison made against a normative database of AL from a cohort with a similar median age (Raine Study, Australia). Firth's logistic regression models for an AL greater than or equal to 26mm and less than or equal to 21mm were constructed with adjustment for age and sex in unrelated individuals, and only inclusive of males in the case of X-linked IRDs.

Results: 342 patients from 51 families with sixteen different IRDs were examined (median age 19.2yrs IQR 13.1-30.5; 63% male; mean AL 24.11mm SD 1.94). For 7 IRDs, we had data on >10 individuals: ABCA4 (n=74, mean AL 23.68mm), Blue Cone Monochromatism (BCM) (n=12, mean AL=26.02), Bornholm Eye Disease (BED) (n=13, mean AL = 26.54), CNGA3 (n=23, mean AL =23.91), CNGB3 (n=39, mean AL =23.19), RPE65 (n=25, mean AL = 23.27), and RPGR(n=58, mean AL = 24.75). The Raine Study included 1335 unrelated individuals (median age 19.9yrs IQR 19.7-20.3; 51% male; mean AL 23.60mm SD 0.93). Compared with this cohort, significantly increased odds for longer AL were observed for BCM (OR 34.7 p<0.001), BED (OR 80.4 p<0.001), RPGR (OR 6.1 p<0.001) and RPE65 (OR 6.7 p=0.004). Patients with variants in RPE65 also had increased odds for short AL (OR 12.5 p<0.001).

Conclusions: We identified longer mean ALs in patients with BED, BCM and RPGR-associated disease. Interestingly patients with RPE65-associated disease had increased odds for both longer and shorter AL (although the average AL of these patients was shorter than that for the reference cohort). Exploration of axial lengths in patients with specific defects in retinal signaling can shed light on processes driving development of refractive error as well as yielding a more complete description of disease phenotypes and visual impairment.

TITLE: Deep-learning based sequence modelling of the dark adaptation curve for noise reduction and parameter prediction in patients with AMD

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. de silva, P. Grisso, S. Mukherjee, B.G. Jeffrey, H. Wiley, T.D. Keenan, E.Y. Chew, C. Cukras, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tharindu de silva: Commercial Relationship: Code N (No Commercial Relationship) | Peyton Grisso: Commercial Relationship: Code N (No Commercial Relationship) | Souvick Mukherjee: Commercial Relationship: Code N (No Commercial Relationship) | Brett Jeffrey: Commercial Relationship: Code N (No Commercial Relationship) | Henry Wiley: Commercial Relationship: Code N (No Commercial Relationship) | Tiarnan Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Emily Chew: Commercial Relationship: Code N (No Commercial Relationship) | Catherine A. Cukras: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dark adaptation (DA) has shown to reveal early functional changes in eyes with age-related macular degeneration (AMD). This work aims to translate recent advances in deep learning sequence modelling to robustly estimate DA curves from sparse, noisy measurements and forecast late phase of the curve to reliably estimate parameters in shorter test times.

Methods: The data was collected in a clinical study involving AMD patients (NCT01352975). The DA test involved 82% focal bleach and recordings of log thresholds using a 3-down/1-up modified staircase threshold estimate procedure. 1496 DA curves were acquired from multiple annual study visits from 207 patients. During analysis, the sparse data points were interpolated within a 1.5 log unit reduction (Δ LU) and 3.1 Δ LU range using isotonic regression to obtain a monotonically-decreasing fit to the data. A recurrent neural network with long-short term memory (LSTM) autoencoder model was then devised to estimate the DA curve minimizing the curve fluctuations due to noise. The same model was then trained to forecast the latter part of the curve using the sequence of measurements up to different early portions of the curve ranging from 2 Δ LU – 2.9 Δ LU. The models were developed using 1271 train, 150 validation, 75 test curves. In each model, rod intercept time (RIT) was measured as the time required to reach 3 Δ LU and evaluated by comparing the model predicted RIT to ground truth.

Results: RIT measurements in the acquired data set varied between 3.6–39.9 min. When the entire curve was estimated from the model, the model successfully mitigated noisy fluctuations and the measured RIT had error (mean \pm stdev) = 0.3 ± 0.4 min (range=0.0–2.8 min) compared to ground truth. When the curve was forecasted at 2.5 Δ LU the predicted RIT had error = 1.2 ± 1.3 min whereas at 2 Δ LU the predicted RIT error degraded to 3.1 ± 3.1 min. Even at 2 Δ LU, 78.7% cases reported error < 5 min.

Conclusions: LSTM autoencoder modelling provides a useful method to estimate and predict DA curve utilizing patterns of variation and mitigating noise. The ability to forecast from early phase of the DA curve suggests that the trends in the curve could help estimate the parameters from patients who are unable to complete the test and could lead to the development of shorter tests and identification of additional curve parameters to serve as useful endpoints.

ABSTRACT BODY:

Purpose: To report the clinical features, antibiotic sensitivities, and outcomes of Burkholderia cepacia associated endophthalmitis in three patients.

Methods: The study design was a retrospective, observational case series.

Clinical and microbiology records were reviewed for patients evaluated at the Bascom Palmer Eye Institute and diagnosed with culture confirmed endophthalmitis due to B. cepacia. Antibiotic susceptibility profiles were generated using standard microbiologic protocols via an automated VITEK system.

Results: Of 3 patients identified, endophthalmitis occurred in the setting of post penetrating keratoplasty (P1), following cataract surgery (P3), and after glaucoma filtering surgery (P2). Time from surgical procedure to presentation with endophthalmitis occurred on post-operative day 14 (P1) and month 5 (P2). In P3, infection occurred several years after cataract surgery but in the context of a possible direct orbital trauma. Presenting visual acuity (VA) ranged from hand motion to light perception. Initial treatment strategies were intravitreal ceftazidime and vancomycin injection together with fortified topical antibiotics (n = 2), and surgical repair of corneal defect and fortified topical antibiotics (n = 1). VA outcomes ranged from hand motion to no light perception, with two eyes ultimately requiring enucleation (P1 and P2), and P3 developing early phthisis bulbi at last follow up.

Conclusions: Endophthalmitis caused by B. cepacia is a rare clinical entity with generally poor visual outcomes.

TITLE: Intergenerational utility in parents of children with amblyopia

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. van der Sterre, H. van der Meulen-Schot, H.J. Simonsz, Ophthalmology, Erasmus MC, Rotterdam, Zuid-Holland, NETHERLANDS|E. Abma-Buistraan, Reinier de Graaf Gasthuis, Delft, Zuid-Holland, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Geertje van der Sterre: Commercial Relationship: Code N (No Commercial Relationship) | H.M. van der Meulen-Schot: Commercial Relationship: Code N (No Commercial Relationship) | Ellen Abma-Buistraan: Commercial Relationship: Code N (No Commercial Relationship) | Huibert Simonsz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The cost-effectiveness of screening and treatment for amblyopia is uncertain. Gain of quality of life in adulthood is experienced long after amblyopia has been detected and treated. Possible functional loss of the only good eye occurs even later in life. There are few immediate benefits for the child when its amblyopia is treated. Yet the detection and treatment of amblyopia is not abolished because the parents decide on this. We think that the reduction of quality of life of the parents because of the amblyopia of their child, should be included in the cost-utility analysis.

We measured the loss of disease-related quality of life in parents whose child was treated for amblyopia.

Methods: In our study we ask the parents of a child who has had occlusion therapy for six weeks two questions. Two questions that measure their loss of utility. First, how many years of their life they are willing to give up (Time Trade-Off), and secondly, how much risk of unilateral blindness they are willing to take (Standard Gamble) in exchange for their child having good vision in both eyes.

Results: So far we have been able to interview 10 parents.

Against expectations, the responses to the Time Trade-Off question showed parents were willing to give up the maximum of 5 years of their life in exchange for the amblyopic eye of their child to be healthy. Clearly a ceiling effect had occurred.

This result was the reason to expand the options in the Time Trade-Off method by 10 years, 20 years and 30 years.

As we initially had not included the Standard Gamble question, only three parents have been interviewed with this question. One parent who was willing to risk 10% had amblyopia himself.

Conclusions: These highly surprising results necessitate an inventory of possible confounders.

We are considering:

- desire to give socially acceptable answers
- innate striving for reproductive success
- religious beliefs about sacrificing your own life
- social context and family structure: can others care for the child
- co-morbidity of the child

ABSTRACT BODY:

Purpose: Pathogenic variants in the RS1 gene cause X-linked retinoschisis (XLRS), a rare inherited disease that results in childhood vision loss. Variants may be transmitted through multiple generations of unaffected carrier females before an affected male is discovered. Notably, certain RS1 variants are repeatedly reported in seemingly unrelated probands. Here, we investigate recurrent pathogenic variants to determine whether this phenomenon represents founder alleles or multiple mutation events.

Methods: Patients were consented and blood-derived DNA was obtained for analysis. Three polymorphic short tandem repeat (STR) markers and four single nucleotide polymorphism (SNP) markers surrounding the RS1 gene (~2 cM) were selected. Custom STR primers were designed with 5'6 FAM. Proband DNA was amplified with STR primers by Polymerase Chain Reaction (PCR) and analyzed by capillary electrophoresis. Alleles were called based on marker sizes. SNP markers were analyzed by Sanger sequencing. Visualization of haplotype geographical distribution was mapped by Zone Improvement Plan (ZIP) code using Python.

Results: XLRS probands (n=114) with one of the 13 most prevalent RS1 variants were analyzed. Nine variants (69%) had at least two probands with common variant-specific haplotypes over 7/7 markers (~2 cM). Twelve variants (92%) had two or more probands with shared alleles across at least 3/7 markers bilaterally adjacent to RS1 (~0.4 cM). Eleven variants (85%) demonstrated one or more geographic clusters for probands sharing variant-specific haplotypes. Recurrent variants with shared haplotype showed varying degrees of geographic clustering. Overall, 19 unique haplotypes of at least ~0.4 cM surrounding the RS1 gene comprised 87/114 (76%) of reportedly unrelated probands. Additionally, 65/87 (75%) probands with shared haplotypes of ~0.4 cM or more clustered in specific regions of the United States.

Conclusions: Examination of this large XLRS cohort for common RS1 haplotypes supports that the majority are explained by founder effect rather than multiple equivalent mutation events. This is beneficial for clinical variant classification and may be generalizable to other X-linked disorders.

ABSTRACT BODY:

Purpose: Pigment dispersion syndrome (PDS) affects 2.45% of people of European ancestry and is highly correlated with myopia. In some cases, PDS can progress to pigmentary glaucoma (PG) leading to irreversible loss of vision with a relatively young average age of onset. The purpose of this study was to identify genetic variants associated with PDS risk, providing greater understanding of its genetic aetiology, and subsequently investigate whether myopia plays an active role in PDS and PG development.

Methods: GWAS was performed by meta-analysing four cohorts with a total of 574 PDS cases, and 52,627 controls all of European ancestry. Two-sample Mendelian randomisation was utilised to determine a causal relationship between myopia and PDS; uncorrelated variants, significantly associated ($p < 5 \times 10^{-8}$) with myopia in an independent analysis were selected as instrumental variables.

Results: Variants clustered at two distinct genomic loci were associated with PDS with genome-wide significance ($p < 5 \times 10^{-8}$). Associations at these loci implicate two previously unreported genes involved in human PDS development. The strongest association was within the gamma-secretase activator protein (GSAP) ($p = 6.0 \times 10^{-10}$), which participates in the same pigmentation pathways as PDS associated genes previously identified in familial studies. Significantly associated SNPs account for 3.1% of PG risk ($p = 1.9 \times 10^{-7}$), which is 6.9% of the total PG SNP heritability (0.45). Two-sample Mendelian randomisation analyses indicated that myopia exerts direct, causal effects over PDS risk ($p = 8.9 \times 10^{-7}$) with each decrease in spherical equivalent by one dioptre translating to an odds ratio of 1.4 for PDS risk.

Conclusions: Common genetic variants account for a considerable proportion of risk for PDS and PG. This is the first study to identify specific genetic risk factors for these conditions among unrelated cases outside of familial studies and provides insight into the genetic pathways of these conditions. Though myopia is known to correlate with PDS and PG, this study provides strong evidence that this correlation is a consequence of myopia exerting causal effects over PDS.

ABSTRACT BODY:

Purpose: To evaluate the risks and impact of COVID-19, SARS-CoV-2, on a private ophthalmology practice in Ohio and analyze the fluctuation in patient visits and surgeries before and during the COVID-19 pandemic.

Methods: A retrospective analysis was performed using outpatient clinic logs for patients seen during the first 10 weeks of 2020 and compared to outpatient clinic logs for 10 weeks during the COVID-19 pandemic. During the twenty-week period, the number of appointments, intravitreal injections, and surgeries, most commonly retinal detachments, epiretinal membrane (ERM), and vitreous hemorrhages, were compared. Additionally, consideration was given to potential measures to reduce the spread and maintain pre-pandemic clinical care levels. The number of appointments, injections administered, and surgeries completed or postponed were analyzed before and during the COVID-19 pandemic. The practice implemented additional precautions for patients and staff. These included, but were not limited to, temperature checks, hand sanitizer availability, required use of face masks, and asking patients to come alone to appointments; with the exception of patients that were wheelchair bound, suffered from dementia, were under the age of 18, or required a translator.

Results: During the first 10 weeks of 2020, the practice saw an average of 2,205 visits a week. In week one of the pandemic, the average was 1,147 patients per week, a 54% drop. An overall 40% drop was seen in surgical cases; vitreous hemorrhage surgeries decreased by 35%, retinal detachment surgeries decreased 25%, and ERM peels reduced by 60%. The drop in ERM's were mostly due to rescheduling. Intravitreal injections during the first 10 weeks averaged 1,025 (SD±112) per week. During the start of the 10 COVID-19 weeks, intravitreal injections averaged 852 (SD±122) per week and by the last weeks injections averaged 972 (SD±142) per week.

Conclusions: In the early stages, the initial number of outpatient visits declined by 54%, the average number of intravitreal injections did not change in a similar pattern. This represents the importance of patients' triage and prioritizing urgent cases.

TITLE: Characterization of early eye developmental defects in a new Rbm24 conditional knockout mouse model

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Patel, S. Dash, S.A. Lachke, Department of Biological Sciences, University of Delaware, Newark, Delaware, UNITED STATES|S.A. Lachke, Center for Bioinformatics and Computational Biology, University of Delaware, Newark, Delaware, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Shaili Patel: Commercial Relationship: Code N (No Commercial Relationship) | Soma Dash: Commercial Relationship: Code N (No Commercial Relationship) | Salil Lachke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Early eye development involves regulatory interactions between the optic vesicle and the overlying surface ectoderm that are necessary for formation of the lens and the correct placement of the retina. While signaling and transcriptional regulation in early eye development is well characterized, the significance of RBPs and post-transcriptional gene expression control, is less clear. Germline deletion of the RNA-binding protein (RBP) gene, Rbm24, in mice (Rbm24^{-/-}) perturbs these regulatory events, resulting in severe early eye defects such as microphthalmia (small eye) and anophthalmia (absence of eye). Rbm24 is expressed in both the optic vesicle and the presumptive lens ectoderm and how its activities in these tissues impacts eye development. Therefore, as a first step toward dissecting the tissue-specific role of Rbm24, Rbm24 compound conditional knockout mice were generated and characterized.

Methods: Rbm24^{cKO} (Rbm24^{+/-}-Rax-CreER^{T2}:Rbm24^{flox/flox}; termed Rbm24^{cKO}) mice were generated by crossing Rbm24^{flox/flox} mice with the tamoxifen-inducible Rax-Cre line that supports Cre expression in optic vesicle. Phenotypic characterization of the ocular defects was performed by marker analysis using immunofluorescence and confocal microscopy.

Results: Rbm24^{cKO} mice exhibit fully penetrant early eye defects exhibiting features of microphthalmia and anophthalmia, similar to that of Rbm24^{-/-} mice. The lens tissue in Rbm24^{cKO} mice appears abnormal from early stage at E10.5. Further, Rbm24^{cKO} mouse exhibit abnormal expression of key ocular transcription factor-encoding genes such as Sox2, Pax6, and Lhx2 in early eye development.

Conclusions: This work reports the development of a new Rbm24 compound conditional knockout mouse line. Phenotypic characterization of these mice show that Rbm24 is required in the optic vesicle for early eye and lens development. Further, these findings define a new layer of regulatory mechanism in early eye development, that involving Rbm24 and its downstream targets the key ocular transcription factors Pax6, Sox2, and Lhx2. Because these transcription factors are linked to anophthalmia/microphthalmia, this work also uncovers a potential mechanism for the eye defects observed in Rbm24 deficient mice.

ABSTRACT BODY:

Purpose: To evaluate the effect on retinopathy, hypertension (HTN) and kidney disease in sickle cell disease (SCD) patients with an added diagnosis of Diabetes Mellitus (DM).

Methods: This is a cross-sectional study of 743 adult patients with SCD seen at Montefiore Medical Center (Bronx, NY) from January 2014 to June 2020. Patients were categorized as having SCD without DM (n=703) or having SCD and DM (SCD-DM, n=40). Demographics, genotype of SCD (HbSS (SS) or HbSC (SC)) lab values, comorbidities, and ophthalmic complications were collected from the Montefiore electronic medical record (Epic, Verona, WI). Presence of DM, ophthalmic diagnoses and HTN were based on clinical diagnosis in the EMR. Ophthalmic diagnoses were collected in patients who had at least one ophthalmology visit (n= 434). A Chi-Squared test was used for total categorical data, while a Fisher's Exact test was used for genotype categorical data. A Wilcoxon Two-Sample test was used for continuous variables.

Results: While there was an increased percentage of retinopathy and proliferative disease in SCD-DM compared to SCD, this relationship was not statistically significant, as seen in Table 1. Increased retinopathy was also noted in patients with SS + DM and in patients with SC + DM compared to the SS and SC group, respectively. While there was an increase in proliferative disease in SS + DM, there was a decrease in proliferative disease in SC + DM, as compared to SS or SC, respectively.

SCD-DM was significantly correlated to increased rate of HTN, higher BMI, and lower GFR in both genotypes, as seen in Table 2. Comparing SS + DM and SS patients, SS + DM had a significantly significant increase in HTN, higher BMI, and lower GFR. A similar statistically significant relationship was seen in patients with SC + DM who had increased rates of HTN, increased BMI, and lower GFR, compared to SC.

Conclusions: SCD patients with DM were more likely to have a higher BMI, increased rates of HTN and lower GFR than those with SCD alone. While retinopathy remains an important complication in both SCD and DM, there appears to be no statistical difference in retinopathy in SCD-DM versus SCD patients.

TITLE: Higher protein concentrations are toxic for photoreceptors and correlate with lower functional recovery after rhegmatogenous retinal detachment

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Daruich, F.F. Behar-Cohen, Universite de Paris, Paris, Île-de-France, FRANCE|A. Daruich, E. Picard, F.F. Behar-Cohen, Centre de Recherche des Cordeliers, Paris, Île-de-France, FRANCE|J.H. Boatright, Emory University, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alejandra Daruich: Commercial Relationship: Code N (No Commercial Relationship) | Emilie Picard: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Boatright: Commercial Relationship: Code N (No Commercial Relationship) | Francine Behar-Cohen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Rhegmatogenous retinal detachment (RRD) is a threatening visual condition. Despite successful reattachment surgery, vision does not fully recover, due to subretinal fluid (SRF) accumulation and subsequent photoreceptor cell death. Various molecular components of SRF could exert toxicity on retinal neurons. With increased RRD duration, SRF protein concentration increases and visual prognosis worsens, but the direct effect of proteins on photoreceptors has not been evaluated. The aim of this study is to analyze the effect of proteins on photoreceptors as well as the role of protein concentration in SRF on functional outcome in RRD patients.

Methods: First, human cones cell line were treated by albumin from 2.5 to 40 g/L and cultured during 24 hours. Cell Titer was assessed to determine viable cells. Secondly, SRF from 21 consecutive patients underwent vitrectomy for RRD repair were collected and protein concentration was measured by Micro BCA protein assay. Clinical data was recorded at baseline and at 6 months after surgery. Finally, rat retinal explants were created to mimic retinal detachment and treated by albumin at 12 mg/ml. LDH release was measured in medium after 6 hours of culture.

Results: Albumin reduced cone viability in dose-dependent manner. Albumin concentrations higher than 5g/L significantly reduced viability of cone cells, when compared to the control ($p < 0.05$, Mann-Whitney test). At 20 mg/ml, albumin reduced 40% of cone cells viability.

Mean protein concentration in SRF from patients with RRD was 3.1 ± 2.9 mg/ml (range: 0.6-12.1 mg/ml). The protein concentration, measured in the SRF at the time of surgery correlated with lower best-corrected visual acuity (BCVA) at baseline ($r = 0.5$, $p = 0.0004$, Spearman correlation), as well as with lower BCVA recovery 6 months after surgery ($r = 0.6$, $p = 0.0001$, Spearman correlation).

Rat retinal explants treated by albumin, at concentration ranges found in SRF of patients, showed significantly higher LDH release in culture medium compared to control retinas ($p = 0.01$, Mann-Whitney test).

Conclusions: Lower visual outcome in RRD patients is associated with higher protein concentration in SRF that could be explained by a direct toxic effect of albumin on photoreceptors.

TITLE: Enhanced Hammerhead Ribozymes as Synthetic Nucleic Acid Ocular Therapeutics

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Myers, J.M. Sullivan, Ophthalmology, University at Buffalo, Buffalo, New York, UNITED STATES|J. Myers, J.M. Sullivan, Medical Research, VA Western New York Healthcare System Buffalo VA Medical Center, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jason Myers: Commercial Relationship(s);Research Foundation of SUNY:Code P (Patent);Veterans Administration:Code P (Patent) | Jack Sullivan: Commercial Relationship(s);Research Foundation of SUNY:Code P (Patent);Veterans Administration:Code P (Patent)

ABSTRACT BODY:

Purpose: We are investigating structure/function potential with enhanced hammerhead ribozymes (EhhRzs), discovered in this lab, that exceed the turnover rate of historical minimal hhRzs (mhhRzs) (1/min) by at least two log-orders. Therapeutic potential is enhanced because less EhhRz is needed to affect strong levels of target mRNA cleavage vs. a mhhRz. Gene and/or synthetic nucleic acid therapeutics become feasible. Synthetic RNA therapeutics require stabilization against nucleases for intraocular injection.

Methods: Substrate RHO-266 RNA is 15 nt long with 5' FAM and 3' BHQ1 (IDT); cleavage at CUC 266 results in liberation of quenched fluorescence which is quantified optically in real time. EhhRzs are transcribed (MegaShortScript) from PCR templates or generated synthetically (IDT). RNA Thermostability Enhancer Set (TriLink) was utilized to evaluate modified nucleotides. Anti-Reverse Cap Analog (ARCA) and poly(A) tailed transcripts were transcribed with mMESSAGE mMACHINE T7 Ultra (ThermoFisher). Reactions are initiated by mixing EhhRz with substrate RNA in buffer (10 mM Tris-HCl, pH 7.5) at 0.5 mM Mg^{2+} and optically measured at 37°C in a qRT/PCR machine. Data are analyzed in Origin 8.

Results: Site-specific chemical modifications (2'-O-Methyl) of the antisense flanks and the first three residues of the stem-II loop allow enhanced turnover activity (Model 1: 712/min vs unmodified 282/min $p=9.4E-17$, Model 2: 882/min vs unmodified 746/min $p=7.1E-5$), whereas modifications in the enzyme core are not tolerated (ANOVA $F=386.9$, $p\approx 0$). ARCA and addition of poly(A) tail to a model EhhRz supports enhanced turnover activity (ANOVA $F=363.2$, $p=2.07E-11$). Replacement of all A residues (2-aminoadenosine-5'ppp) obviates activity, whereas replacement of all U residues (5-methyridine-5'ppp) or replacement of all C residues (5-methylcytidine-5'ppp) permits strong enhanced turnover rate of the model EhhRz (U=389/min, C=206/min).

Conclusions: Efforts to stabilize EhhRz RNA with established synthetic chemistries by modifications of the antisense flanks and parts of the stabilizing stem-II loop region, or 5' capping and 3' polyadenylation has shown preservation of strong turnover rate activity, under substrate excess conditions and physiological Mg^{2+} levels. Certain enzyme core modifications are tolerable, but other residues critically involved in the reaction mechanism will require alternative chemistries from those already evaluated.

SUBMITTER (NAME ONLY): Maryam Mousavi

TITLE: Evaluation of Tear Film Surface Quality Non-Invasively During Soft Contact Lens Wear

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Mousavi, K.K. Nichols, The University of Alabama at Birmingham, Alabama, UNITED STATES|M. Mousavi, I. Garaszczuk, D. Iskander, The Wroclaw University of Science and Technology, POLAND|

Commercial Relationships Disclosure (Abstract): Maryam Mousavi: Commercial Relationship: Code N (No Commercial Relationship) | Izabela K. Garaszczuk: Commercial Relationship: Code N (No Commercial Relationship) | Kelly Nichols: Commercial Relationship: Code N (No Commercial Relationship) | D Robert Iskander: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate tear film surface quality (TFSQ) over 12 months of soft daily disposable contact lens (CL) wear using non-invasive method.

Methods: Fifty healthy subjects aged (mean \pm standard deviation) 25.7 ± 4.3 years were prescribed with silicone hydrogel (SiHy) or hydrogel (Hy). The protocol consisted of baseline visit including first(F)/mean(M) non-invasive keratometry break-up times (F/MNIKBT, K5M, Oculus Optikgeräte GmbH, Wetzlar, Germany), fluorescein tear film break-up time (FBUT), and corneal and conjunctival staining. At the end of the fitting day (day 2), the preferred lens was chosen based on objective measurements of contact lens fit, reported subjective comfort after four hours of wear and pre-lens TFSQ measurements. Thereafter, visits occurred at 2 weeks (CL check) and at 3, 6, and 12 months. TFSQ was measured over this period and differences between SiHy (n = 34) and Hy (n=16) fitted group were assessed.

Results: FNIKBT showed statistically significant differences between baseline (pre-fitting) and other visits: ($P < 0.001$ for Day 2 and at 3, 6, and 12-month visit, $P < 0.001$ for Day 2 and at 3, 6, and 12-month visit, respectively) and in MNIKBT between baseline (pre-fitting) and other visits ($P=0.004$, $P<0.001$, $P<0.001$, $P<0.001$ for Day 2 and at 3, 6, and 12-month visit, respectively). Across all visits, there were no significant differences in the measurements associated with both lens types for FBUT, corneal staining, conjunctival staining, FNIKBT, and MNIKBT. Measurements with F/M NIKBT were found to be the same and stable from Day 2, which indicates that TFSQ can be assessed and monitored reliably with NIKBT.

Conclusions: Throughout the course of the study, TFSQ was unaffected during CL wear and NIKBT showed to be the same after a four-hour and 12-month period. Therefore, NIKBT can be a promising indicator to evaluate TFSQ and furthermore improving CL wear success rate.

TITLE: HK2 and PKM2 deletion leads to outer segment shortening and photoreceptor degeneration

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Weh, K.X. Li, H. Hager, S. Sheskey, T.J. Wubben, C.G. Besirli, Ophthalmology and Visual Sciences, University of Michigan Michigan Medicine, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eric Weh: Commercial Relationship: Code N (No Commercial Relationship) | Katie Li: Commercial Relationship: Code N (No Commercial Relationship) | Heather Hager: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Sheskey: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Wubben: Commercial Relationship: Code N (No Commercial Relationship) | Cagri Besirli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Photoreceptor (PR) metabolism is unique among other neurons in that they primarily process glucose into lactate via aerobic glycolysis. This unique adaptation allows maintenance of the highly-specialized PR cell structure under basal conditions and provides a survival advantage during prolonged nutrient deprivation. The main drivers of aerobic glycolysis, HK2 and PKM2, are expressed primarily in PRs in the retina. We have previously demonstrated that the conditional knockout (cKO) of HK2 from rods sensitizes PRs to cell death following retinal detachment whereas cKO of PKM2 protects PRs from cell death during acute nutrient deprivation. Here we present data from animals lacking both HK2 and PKM2 in rod PRs.

Methods: Mice harboring a floxed Hk2 allele were crossed to mice carrying a floxed Pkm2 allele. Homozygotes for both floxed genes were generated and crossed to animals harboring a cre recombinase gene under the control of the rhodopsin promoter to create animals with conditional deletion of both Hk2 and Pkm2 from rods specifically. OCT was performed monthly and ERG was performed at specific time points. Whole eyes were fixed, and sectioned for H&E staining. The total number of PRs at each time point were counted using a custom macro in ImageJ and normalized to inner retinal area. Immunofluorescence was used on sections to verify deletion of HK2 and PKM2 from rods. Whole retinas were extracted for protein, RNA, or metabolite purification for Western blotting, qRT-PCR, or metabolomics analysis, respectively. Experimental retinal detachment was induced and whole eyes were collected at 3 days for TUNEL analysis and at 1 month for PR viability assessment.

Results: OCT analysis showed shortening of outer segments by 4 months of age and thinning of the outer nuclear layer (ONL) by 5 months of age. Western blotting and immunofluorescence confirmed successful deletion of both HK2 and PKM2 from rods and a compensatory upregulation of HK1 and PKM1. Total cell counts of H&E stained retina showed a significant loss of photoreceptors at 10 months of age compared to control animals.

Conclusions: Our data demonstrate that loss of both HK2 and PKM2 in double cKO retinas leads to outer segment shortening followed by PR degeneration, a phenotype different from the conditional deletion of HK2 or PKM2 alone. Early shortening of outer segments suggests metabolic, structural, and functional deficits prior to loss of PRs.

TITLE: The cost, components and affordability of eye examinations in optometry practices in Western Nova Scotia, Canada.

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.F. Smith, Department of Ophthalmology, King's College London, London, London, UNITED KINGDOM|A.F. Smith, Medmetrics Inc., Wolfville, Nova Scotia, CANADA|

Commercial Relationships Disclosure (Abstract): Andrew Smith: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore variations in the cost, components and affordability of eye examinations conducted in optometry practices in Western Nova Scotia, Canada.

Methods: A telephone survey was undertaken to assess the cost of obtaining an eye examination provided by a licensed optometrists in a sample of optometry practices in Western Nova Scotia, Canada. Descriptive summary statistics were tabulated for the key variables of interest.

Results: Complete responses were obtained from a total of fourteen (14) unique optometric practices. The mean cost for an eye examination was CDN \$ 121 (SD: \$17.92; Range: \$95 to \$140). The mean waiting time to the first available appointment was 4.14 weeks (SD: 2.4 weeks; Range: 1 to 9 weeks). All eye examinations included an overall assessment of the health of the eye, an intra-ocular pressure (IOP) test and the provision of a prescription if required. 85% (n=12) of the eye examinations also included some sort of retinal imaging, most commonly via Optical Coherence Tomography (OCT), while only 14% (n=2) included visual field perimetry as part of the eye examination. 50% (n=6/12) of optometry practices who did not include visual fields as part of the eye exam, however, responded that they could arrange for visual field testing at an additional mean cost of CDN \$ 45.50 (SD: \$ 11.69; Range: \$ 25 to \$ 56) if required. The mean number of hours worked at a minimum wage of CDN \$12.55 to afford an eye examination was 9.68 hours (SD: 1.48 hours; Range: 7.57 to 11.16 hours).

Conclusions: The cost of accessing an eye examination was found to be high, particularly among lower wage earners in Nova Scotia. Either increasing the supply of optometrists across Nova Scotia or reducing the cost of obtaining an eye examinations may assist in increasing the affordability of eye exams, thus potentially preventing avoidable vision loss and blindness.

ABSTRACT BODY:

Purpose: To develop calibrated measures of hand-eye coordination for ULV individuals in virtual reality (VR), allowing objective quantification of visual ability in realistic activities of daily living (ADLs).

Methods: Based on an inventory of ADLs valued by ULV individuals (Adeyemo et al., TVST 2017) and prior data from visual information gathering ADLs in VR (Kartha et al., ARVO 2019/2020), we created 20 scenes with hand-eye coordination ADLs; examples include locating and flipping a light switch, giving a high five to an avatar, picking up common objects, building a block tower, sorting pills, putting on a mitt, and baking cookies and a pancake. Most scenes were implemented at 3 visibility levels by varying contrast or size, for a total of 55 activities. Scenes were presented in a Vive Pro Eye VR headset using a Leap Motion hand tracker to visualize the subject's hand. Subjects were allowed to practice manipulating objects in normal vision (NV). Simulated ULV (sULV) was achieved in these normally sighted subjects through Bangerter foils, reducing visual acuity to 2.0 LogMAR. Performance was compared across observers and across vision status (NV vs. sULV).

Results: All four subjects were able to complete 98% of activities in NV and 81% in sULV. Completion times in NV were 4.0 s [2.0,9.7] (median[IQR]), in sULV 6.4 s [3.7,17.8]; 67% of completed activities required (on average 33%) more time in sULV than in NV, with 20 of 55 requiring significantly more time (by ANOVA);. Rank correlations of completion times between NV and sULV within observers ranged from 0.62 to 0.71, suggesting that task difficulties were unequally affected by vision degradation. Rank correlations between observers ranged from 0.81 to 0.89 for NV, and from 0.65 to 0.89 for sULV, suggesting subjects were unequally affected, despite equal vision degradation levels.

Conclusions: Most of these activities, representative of ADLs valued by individuals with ULV, could be completed by individuals with sULV equivalent to 20/2000. The wide range of completion times in sULV suggests that these activities cover a broad difficulty range, required to cover the full spectrum of ULV. They will be validated in our population with ULV due to a wide variety of conditions.

ABSTRACT BODY:

Purpose: Limbal stem cells (LSC) residing in the limbus continually repopulate the corneal epithelium. Limbal stem cell deficiency (LSCD) occurs when these LSC are damaged (due to trauma such as burns) or missing (due to genetic conditions). Patients with LSCD are unable to regenerate the corneal epithelium, resulting in blindness due to invasion of the conjunctiva and neovascularization. For patients with unilateral LSCD, transplantation of autologous limbal tissue or ex vivo expanded limbal cells from the unaffected eye can be used to treat LSCD. However, patients with inflammation as well as those with severe pathologies resulting in total, bilateral LSCD have no source of autologous LSC and must rely on allogeneic transplants, associated with poor outcomes and requiring lifelong immunosuppression. Such patients would greatly benefit from an alternative autologous source of stem cells and reconstructed LSC niche to sustain donor stem cells. We previously demonstrated that human ABCB5+ LSC were capable of restoration of the corneal epithelium in an NSG mouse model of LSCD. We found that ABCB5 is also expressed by skin stem cells and hypothesized that these dermal cells could provide an alternative source of stem cells for corneal epithelial regeneration.

Methods: Human ABCB5+ dermal stem cells (DSC) expanded in vitro and purified by cell sorting were cultured in corneal differentiation media to determine their ability to transform into corneal epithelial cells. ABCB5+ DSC were also transplanted onto NSG mice with mechanically induced LSCD. In vitro, a 3D bioprinter was used to layer collagen and precisely deliver ABCB5+ DSC to the peripheral rim of human central corneas, their normal anatomical location, which we predict will enhance reconstruction of the LSC niche.

Results: Human ABCB5+ DSC were induced in vitro to express significant levels of PAX6 and KRT12 and mice transplanted with human purified ABCB5+ DSC had clearer corneas compared to mice transplanted with carrier only or ABCB5- cells (Fig 1). Bioprinted ABCB5+ DSC surrounding a human central cornea (Fig 2).

Conclusions: Our results support the use of 3D-printed ABCB5+ DSC as an alternative autologous source of stem cells to regenerate the corneal epithelium and reconstruct the LSC niche in patients with bilateral LSCD.

ABSTRACT BODY:

Purpose: This study aims to investigate the influence of blue LED light on the visual cortex layer-5 pyramidal neurons (L5PN) and the protective efficacy of 2 commercially available blue blocking lenses (BBL) namely Crizal Previsiona (CP) and Duravision Blue (DB).

Methods: This study was approved by animal ethics committee of The Manipal Academy of Higher Education, Kasturba Medical College (IAEC/02/2017). 24 male Wistar rats divided into 4 groups: 1 light exposure (LE), 2 BBL group (CP and DB) and 1 control group (NC). In LE group, rats were exposed to blue LED (400-490nm), in CP and DB group, BBL was fitted on top of LED, in NC group, rats were in normal lab illumination. In all groups, rats were exposed for 28 days, 12:12 hours of light:dark cycles and a uniform (450-500 lux) light intensity. Rats were sacrificed at the end of 28 days; brain was embedded in Golgi-cox stain. Brain tissues of 150 microns sections were obtained using sledge microtome. Golgi stained L5PN were identified using the 20X objective of a wide-field microscope and images were captured using a Moticam 580-5.0 mp. Totally 30 photomicrographs were obtained from each neuron and they were separated by 5 μ m in the z-plane. All photomicrographs were projected to a calibrated Sholl's grid. Dendrites were manually traced in a masked fashion. For apical and basal dendrites, the number of branching and intersections with 20 μ m concentric circles up to 140 μ m from the soma were quantified using Sholl analysis.

Results: The L5PN of NC had significantly more intersections compared to LE, CP and DB. LE group had significant ($p < 0.001$) loss of dendritic branches (13.72 ± 3.2) compared to NC (21.3 ± 0.3). Similarly, the CP (10.69 ± 1.93) and DB (15.58 ± 3.88) group had significantly less ($p < 0.05$) dendritic branches compared to NC group (21.3 ± 0.3) (Figure:1). Although, not statistically significant the number of dendritic branches and intersections were higher in CP and DB compared to LE group.

Conclusions: Exposure to blue LED damages the L5PN of visual cortex. BBL may offer moderate protection from blue LED.

ABSTRACT BODY:

Purpose: Pathogenic variants in ABCA4 are associated with Stargardt disease. One particular variant, c.5603A>T, p.Asn1868Ile, has previously been shown to be significantly enriched in Stargardt patients and is regarded as supportive of the diagnoses; however this variant is relatively common (6.3% allele frequency in Europeans). The purpose of this study was to determine whether this variant is associated with effects on macular thickness among the general population.

Methods: Quantitative OCT data using the Topcon 3D OCT-1000 Mk2 machine and genetic data from whole exome sequencing for the c.5603A>T variant was available for 20180 participants of European ancestry in the UK Biobank, following quality control. Of these, 101 were homozygous and 2610 were heterozygous for c.5603A>T. Linear regression analyses, adjusted for age and sex, were performed to test for association between this variant and total retinal thickness as well as three available segmented layer thicknesses (retinal nerve fibre layer, RNFL; ganglion cell-inner plexiform layer, GC-IPL; retinal pigment epithelium, RPE). Further linear regression analyses were performed with eight automated QC measures as the outcome variable to determine whether c.5603A>T is associated with abnormal or scans of low quality.

Results: No association was identified between c.5603A>T and retinal thickness ($p=0.76$) or with any of the three segmented layer thicknesses (RNFL $p=0.16$; GC-IPL $p=0.82$; RPE $p=0.52$). No association was identified between c.5603A>T and any of the eight quality control measures (all $p>0.25$). Participants with the c.5603A>T variant were also no more likely to be excluded during quality control, indicating an absence of pathogenic effects affecting scan quality. Finally, out of 144 homozygotes (pre-QC), only two (1.4%) have been diagnosed with degeneration of macula and posterior pole.

Conclusions: The c.5603A>T variant alone does not appear to affect total retinal thickness in the general population. The variant is likely therefore to require a distinct pathogenic trans-allele to cause retinopathy. Moreover, other cis- or trans-acting modifiers might contribute to pathogenicity of such a c.5603A>T genotype and in part might cause the enrichment seen in Stargardt patients.

TITLE: Impact of COVID-19 Shelter-In-Place orders on pediatric device use, outdoor activity and eye symptoms

SESSION TITLE: Impacts of Covid on patients and practice

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Carvajal, J. Cunningham, A. Tang, W.P. Shibley, A.G. de Alba Campomanes, E.N. Harb, School of Medicine, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nicole Carvajal: Commercial Relationship: Code N (No Commercial Relationship) | Jake Cunningham: Commercial Relationship: Code N (No Commercial Relationship) | Alice Tang: Commercial Relationship: Code N (No Commercial Relationship) | William Shibley: Commercial Relationship: Code N (No Commercial Relationship) | Alejandra de Alba Campomanes: Commercial Relationship: Code N (No Commercial Relationship) | Elise Harb: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic caused the implementation of public health measures globally, including a call to Shelter-In-Place (SIP). In most cases, traditional classroom teaching became remote, pediatric outdoor programs such as organized sports were halted and parks closed. This study primarily aimed to understand the impact of COVID-19 SIP orders on pediatric habitual device use, outdoor activity, and reported eye symptoms.

Methods: Eligible participants included English and Spanish speaking UCSF pediatric ophthalmology patients aged 5-10 years with no history of ocular disease, surgery or trauma. A parental survey was administered electronically or over the phone by a trained examiner. The survey included questions regarding their child's average daily device use, outdoor activity and how often their child typically reported eye symptoms before and during SIP. Statistical analysis was performed using paired t-tests to examine changes in behaviors before and during SIP.

Results: 42 participants (n=17 female, mean age 6.6 ± 1.3 years) were enrolled in the study. 98% (n = 41) of those surveyed reported that their child was in remote online learning during SIP, with the majority (56%) using a laptop as their main device for remote learning. On average, laptop and hand-held device (smartphone or tablet) use increased significantly during SIP for both weekdays and weekends (Laptops: ~3 hour increase weekdays and 1 hour increase weekends, $p < 0.001$; Hand-held devices: ~1 hour increase weekdays and weekends $p < 0.002$). Outdoor activity decreased on average by approximately 1 hour on both weekdays and weekends ($p < 0.008$). Despite the increase in device use, there was only a slight increase in 'eyes feeling uncomfortable or tired' (from never to occasionally, on average). None of the other eye symptoms surveyed (seeing words moving, jumping, swimming, or floating; headache; dry eyes; blurry vision) were reported to change during SIP.

Conclusions: This study provides insights into how COVID-19 SIP orders impact habitual pediatric device use and outdoor activity. Despite children spending significantly increased time on devices during SIP, there was a low prevalence of reported eye symptoms in our cohort. Further work is warranted to determine the potential longer term impacts of these behavior modifications on pediatric eye health.

TITLE: Association of carotenoid status between mothers and infants in the Lutein and Zeaxanthin in Pregnancy (L-ZIP) clinical trial

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Addo, A. Gorusupudi, P.S. Bernstein, Department of Ophthalmology, Moran Eye Centre, University of Utah Health, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Emmanuel Kofi Addo: Commercial Relationship: Code N (No Commercial Relationship) | Aruna Gorusupudi: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bernstein: Commercial Relationship(s);Kemin Health:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Macular pigment (MP), comprised of the dietary carotenoids lutein (L), zeaxanthin (Z), and meso-zeaxanthin (MZ), protects the macula from photo-oxidative damage and enhances visual acuity. MP selective accumulation in the human retina begins before birth, implying a possible physiological and protective role in early visual development. Given the paucity of data on maternal and infants' carotenoid status during pregnancy, we sought to determine associations between postpartum maternal carotenoid status and newborn infants' skin and umbilical cord blood carotenoids.

Methods: We used masked study data from participants who had completed the ongoing L-ZIP study (ClinicalTrials.gov identifier: NCT 03750968; still recruiting). Participants were randomized (1:1 allocation) to consume daily a standard prenatal multivitamins (Spring Valley™ Prenatal Multi + DHA capsule) with an added capsule containing 10 mg L and 2 mg Z in safflower oil (Carotenoid group) or with a capsule containing only safflower oil with no added carotenoids (Control group) for a period of 6 to 8 months. Skin, MP, and serum carotenoids were measured at every study visit (i.e., baseline, before 14 weeks gestational age [GA]; 22-26 weeks GA; 37-39 weeks GA and 0-2 weeks of giving birth). Skin, MP, and serum carotenoid status assessments were by resonance Raman spectroscopy (RRS), dual-wavelength autofluorescence, and high-performance liquid chromatography (HPLC), respectively.

Results: The present sample comprises 12 mother-infant pairs who had completed the ongoing L-ZIP study. Maternal serum L+Z levels significantly correlated with infant cord blood L+Z levels ($r = 0.82$, $p = 0.002$) and skin carotenoid levels ($r = 0.59$, $p = 0.042$). Maternal skin carotenoids significantly associated with infant cord blood L+Z levels ($r = 0.60$, $p = 0.040$). Infant skin carotenoids significantly correlated with cord blood L+Z levels ($r = 0.61$, $p = 0.037$). Maternal skin carotenoid levels correlated with serum L+Z levels ($r = 0.63$, $p = 0.027$).

Conclusions: Our findings indicate that maternal serum carotenoid status associates with carotenoid levels in infants. Hence, increasing maternal carotenoid status during pregnancy may improve infants' carotenoid status and could consequently enhance infant visual development.

TITLE: Telemedicine in Pediatric Ophthalmology

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Borkhetaria, M. Chiam, M. Langue, A. Ely, Ophthalmology, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rucha Borkhetaria: Commercial Relationship: Code N (No Commercial Relationship) | Mckenzee Chiam: Commercial Relationship: Code N (No Commercial Relationship) | Michael Langue: Commercial Relationship: Code N (No Commercial Relationship) | Amanda Ely: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Telemedicine use has risen in light of the COVID-19 pandemic as many ophthalmologists face barriers to providing in-person eye care. This study aims to describe caregiver experience using telemedicine for managing pediatric eye care at a rural academic medical center.

Methods: An anonymous online survey was distributed to 35 caregivers of pediatric patients who had been contacted to participate in a telehealth eye appointment during the COVID-19 pandemic. Average scores were calculated for statements posed in the form of a five-point Likert scale (1 = strongly disagree, 2 = disagree, 3 = neutral/not applicable, 4 = agree, 5 = strongly agree).

Results: A total of 17 responses were collected, of whom all had participated in telehealth. This was the first telehealth experience for 64.7% (11/15) of participants. The mean child and caregiver ages were 4 and 37 years old, respectively. The preferred telehealth platform was Zoom (15/17, 88.2%). Caregivers reported ease with obtaining at-home exam information including visual acuity and 9gaze motility photos (14/16, 87.5%). Additionally, 64.7% (11/17) of caregivers stated a telehealth appointment was more convenient than an in-person appointment. Overall, caregiver satisfaction with their child's telehealth appointment was high with an average satisfaction score of 4.18/5.00.

Conclusions: The telemedicine model for managing pediatric eye health was met with high levels of patient satisfaction at one rural academic medical center. This care approach should be considered for clinical management of pediatric eye health in the presence of barriers to in-person care, such as COVID-19.

TITLE: Comparison of Gortex Sutured and Fibrin-Glued Secondary Intraocular Lenses, including Visual Acuity, Lens Tilt, and Adverse Events

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Jeang, L. Vander Woude, A. weaver, S.S. Iyer, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lauren Jeang: Commercial Relationship: Code N (No Commercial Relationship) | Logan Vander Woude: Commercial Relationship: Code N (No Commercial Relationship) | alex weaver: Commercial Relationship: Code N (No Commercial Relationship) | Siva Iyer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Surgical techniques vary significantly for Gortex sutured intraocular lenses (IOL) and fibrin-glued IOLs and the type of lens is often chosen based on surgeon preference. However, the sutured vs glued IOLs have 4 points vs 2 points of fixation, respectively, which may result in different positioning and stability of the IOL. The purpose of this retrospective chart review is to analyze the long-term stability of these IOL implantation techniques and their impact on best corrected visual acuity (BCVA), IOL tilt, and adverse events.

Methods: This study examines 63 patients over a 2-year follow up period at the University of Florida from 1/1/2011 to 5/1/2020. Patients were included if they were implanted with a Gortex sutured B&L Akreos A060 or Alcon CZ70BD (with cow-hitch technique) or Alcon MA60AC fibrin-glued IOL. Patients were excluded if they had concurrent macular pathology, required a second surgery for any reason, or had less than one month follow up. The primary outcomes measured were BCVA, IOL tilt, as measured by change in cylinder on refraction over time, and adverse events, as listed in Table 1.

Generalized estimating equations and Wald Chi-squared test were used to compare logMAR VA between sutured and glued IOLs. An independent t-test was used to analyze lens tilt. A Chi-squared test was used to analyze the difference in adverse events measured as categorical variables.

Results: There was no significant difference in BCVA between the Gortex sutured ($M=0.73$, 95% CI 0.59 – 0.87) and fibrin glued IOLs ($M=0.74$, 95% CI 0.55 – 0.93) with the Wald $\chi^2 = 0.01$ and $p=0.94$. With “M” being marginal means of logMAR where 0.73 and 0.74 are equivalent to the Snellen values of 20/107.4 and 20/109.9, respectively. There was also no significant difference in IOL tilt between the Gortex 4-point and glued 2-point fixated IOLs (mean=0.409, 95% CI -1.08 – 2.63, $p=0.225$), nor significant differences in adverse events (Table 1).

Conclusions: There was no significant difference in BCVA, IOL tilt, or adverse events between our studied IOLs. With a 2 year-follow up period, this study has the longest observational study to the authors’ knowledge. Clinically, this provides evidence that a surgeon may implant their preferred choice of studied IOL.

TITLE: COMSOL Multiphysics 3D modeling of drug diffusion to the vitreous following subconjunctival injection

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Dosmar, X. Su, Biology and Biomedical Engineering, Rose-Hulman Institute of Technology, Terre Haute, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Emily Dosmar: Commercial Relationship: Code N (No Commercial Relationship) | Xingqi Su: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Build a 3D model of the eye to simulate the diffusion of Vancomycin (VAN) delivered via subconjunctival injection and predict VAN profile and concentration buildup in the vitreous.

Methods: COMSOL Multiphysics was used to simulate VAN diffusion through the vitreous, where a “Time Dependent” and “Transport of Diluted Species” study was constructed.

The model was created by establishing three 2D work planes for each tissue layer in the eye. In each work plane, a curve with a diameter and thickness of the tissue layer was created and revolved around the central axis. In addition, the bottom of the sclera layer was made flat to represent a site where VAN diffusion begins. After the three layers were constructed, a solid sphere with the diameter of the vitreous was created to represent the vitreous humor. COMSOL's “Form Union” method was employed to create a single geometry object composed of many different domains.

Material properties and transport properties were applied to each layer. The initial concentration for the compartments were assume zero. The initial concentration of the flattened bottom of the eye was assumed to be 1 mg/ml in the subconjunctival space. After all parameters were set, the element size in Mesh was set to “Normal” to discretize the geometry. The simulation was executed over 1440 minutes (24 hours) and data were collected at 144 minute increments.

Results: Final results from the simulation were displayed as a diffusion profile over a period of time (24 hours). The concentration of the eye was illustrated as both Streamline (with slices) and Surface (Figure 1).

The simulation suggests the steady build-up of VAN in the center of the vitreous over time where 12% of the initial VAN concentration is present in the vitreous after 24 hours and diffuses at a rate of ~0.005mg/ml per hour. Based on these findings, a therapeutic concentration (0.007 mg/ml) of VAN in the vitreous is achieved after 2 hours following injection. This preliminary model suggests potential to predict minimum drug loading requirements for sustained release drug delivery systems meant to be placed in the subconjunctival space.

Conclusions: This model predicts drug build-up in the vitreous following a subconjunctival injection and can be expanded to predict sustained release drug delivery system drug loading requirements.

TITLE: Ultrasound-directed, microbubble-assisted Crispr/Cas9 delivery in RPE cells

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Lo, M.S. Humayun, L. Yue, Ophthalmology, University of Southern California, Los Angeles, California, UNITED STATES|P. Lo, J. Castillo, M.S. Humayun, L. Yue, Ginsburg Institute for Biomedical Therapeutics, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Pei-An Lo: Commercial Relationship: Code N (No Commercial Relationship) | Johnny Castillo: Commercial Relationship: Code N (No Commercial Relationship) | Mark Humayun: Commercial Relationship: Code N (No Commercial Relationship) | Lan Yue: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Crispr/Cas9 is a popular gene editing tool whose therapeutic potential in ophthalmology is being actively explored. Our goal is to develop a microbubble (MB)-assisted sonoporation method to deliver the Crispr/Cas9 constructs into the eye for the treatment of hereditary retinal diseases with minimal invasiveness and high spatial precision. This study investigates the feasibility of sonoporating Crispr/Cas9 plasmids into cultured human retinal pigment epithelial (RPE) cells, a cell type that is heavily involved in the pathology of the outer retinal degeneration.

Methods: Sonoporation was tested in ARPE-19 cells and HEK cells. The GFP plasmid and the RPE65 Crispr/Cas9 knockout plasmid with a GFP tag were employed to fluorescently label the transfected cells. The GTS Sonoporation System equipped with a plane wave transducer (center frequency of 1 MHz) was used as the ultrasound (US) source. The cell monolayer cultured on a cover slip was placed in a customized polydimethylsiloxane (PDMS) well supplied with the MBs and the DNA plasmids. US was delivered from the transducer placed ~35 mm below and the entire system was submerged in heated distilled water. Transfection under variations of sonoporation parameters was examined by fluorescence microscopy. The trypan blue assay was employed to test cell viability.

Results: Our in vitro experimental setup successfully introduced the GFP plasmid and the commercial Crispr/Cas9 plasmid into the HEK and the ARPE-19 cells. Among the sonoporation parameters examined, increase of the acoustic intensity from 2 to 4 W/cm² enhanced the GFP delivery by 1.6 fold and increase of the MB concentration from 0.4 to 4% (V/V) resulted in a 6.8 fold enhancement. However, the transfection efficiency of the Crispr/Cas9 plasmid was substantially lower than that of the GFP under similar sonoporation conditions, either at 100 Hz or 1000 Hz pulse repetition frequency (PRF). All sonoporation experiments did not lead to increased cell death.

Conclusions: This study shows the possibility of sonoporating an all-in-one Crispr/Cas9 plasmid into cultured human HEK cells and RPE cells at 1 MHz acoustic frequency. The lower delivery efficiency of Crispr than GFP may stem from the bulky size of the all-in-one Crispr plasmid that encodes both the Cas9 nuclease and the guide RNA (gRNA). Further studies are underway to investigate the microbubble-assisted sonoporation of more versatile Cas9 and gRNA constructs.

ABSTRACT BODY:

Purpose: Induced pluripotent stem cell-retinal pigment epithelium (iPSC-RPE) in vitro models of maculopathies such as Sorsby's fundus dystrophy (SFD) and Doyme honeycomb retinal dystrophy (DHRD) display drusen-like basal deposits that appear consistent with the human diseases. The purpose of this study was to evaluate the proteomic relatedness of the basal deposits in the SFD and DHRD iPSC-RPE cultures with the human drusen proteome.

Methods: Extracellular matrix (ECM) and/or basal deposits were isolated from parallel patient-derived SFD and DHRD iPSC-RPE cultures and control (unaffected family member and/or gene-corrected line) iPSC-RPE cultures that were grown in culture for 40-100 days. ECM/basal deposit proteins were extracted in SDS, and digested with trypsin. Peptides were fractionated by reversed-phase high performance liquid chromatography (RPHPLC) at pH 10 then analyzed by Liquid chromatography-mass spectrometry (LC MS/MS) and proteins identified using the human UniProt database. Bioinformatic analyses was performed using PANTHER and Ingenuity Pathway analysis software.

Results: Proteome analyses identified 1689 and 2237 number of total proteins with 2 or more unique peptides in the ECM of SFD and DHRD cultures respectively. Of note, 61 proteins present in ECM/basal deposit underlying SFD iPSC-RPE cultures and 56 proteins present in ECM/basal deposit underlying in DHRD iPSC-RPE cultures were common with the 123 proteins previously reported in human AMD drusen (2002 PNAS, (23) 14682-14687). Furthermore, 49 of the previously identified drusen proteins in the AMD eyes were seen in both SFD and DHRD iPSC-RPE cultures. Notably, cytoskeletal, calcium-binding, and inflammation associated proteins constituted the majority of proteins detected in the ECM/basal deposits from SFD and DHRD cultures.

Conclusions: LC MS/MS analyses demonstrate overlap between the proteome of drusen from AMD donor eyes and basal deposits in SFD and DHRD iPSC-RPE cultures. The results further support the utility of these in vitro models for mechanistic studies of macular degeneration.

ABSTRACT BODY:

Purpose: Fibulin-3 (F3), a secreted ECM glycoprotein, has been linked to retinal pathologies, namely Malattia Leventinese (ML) and age-related macular degeneration (AMD), with evidence supporting association of F3 with drusen deposits in both of these diseases. Mouse models of ML form basal laminar deposits after extensive aging, but do not appear to form other pathological characteristics of AMD (drusen, RPE atrophy, etc). This may simply be due to physiological differences in expression levels, timing of expression, or localization of key contributing factors (like F3) between mice and humans within the eye. To address this, we examined and compared the expression levels and localization of F3 and another fibulin family member, fibulin-5 (F5), in the posterior eye cups of mice, pigs, non-human primates (NHP), and humans. Finally, we assessed the potential for age-related changes in fibulin expression in mice.

Methods: qPCR was performed to determine levels of F3 and F5 in neural retina (NR) and RPE of mice, pigs, NHPs, and humans. Immunohistochemistry (IHC) was performed to determine the localization of fibulins in the different retinal layers of mice and compared to NHPs and human tissues. qPCR studies to assess age-related changes in F3 and F5 were also performed in mice at 2, 6, 15, and 18 months of age.

Results: qPCR revealed a surprisingly low level of F3 in the RPE compared to the NR in mice (~1.25 fold). In contrast, F3 expression was found to be much higher in RPE for pigs (~15 fold), NHPs, and human donors (~70 fold) compared to their respective NR. IHC showed localization and higher expression of F3 in the ganglion cell layer and inner retina of mice, while F3 labeling of NHP and human tissues revealed higher expression in the RPE, corroborating the gene expression data. Gene expression studies also showed that F3 expression in the RPE increases with age (albeit slightly, N=4, p=0.02 (2 vs 18 mo)) while F5 levels are similar across ages.

Conclusions: These studies suggest that there are differences in expression of F3 in mice compared to other higher-order mammals, specifically in the RPE, where the primary disease pathology of ML and AMD occurs. These observations may partially explain the need for aging ML mice to obtain a phenotype. More closely matching the expression of F3 in mouse RPE to that of humans may result in a model with an earlier onset and better fidelity to human disease.

ABSTRACT BODY:

Purpose: Atomic force microscopy (AFM) cantilevers have been used to measure the biomechanical properties of the full-thickness cornea ex vivo. In this study we examine the effect of repetitive cantilever indentations on corneal epithelial integrity to assess the utility of cantilevers for in vivo applications.

Methods: Human cadaveric corneas prepared for research purposes were obtained from the Miracles in Sight Eye Bank (Winston-Salem, NC) without apparent epithelial or stromal defect and mounted in a custom-designed holder, which enabled complete submersion of the corneas in Optisol GS (Bausch + Lomb, Rochester, NY) at room temperature. The corneal bath was placed in the Puima nanoindenter (Optics 11 Life, Amsterdam, Netherlands). Standard AFM cantilevers (4.59 N/m, 45.5 μ m diameter, Optics 11 Life) were used to complete 1000 indentations in the same location with a 5 μ m indentation depth over 4 hours. The cornea was sectioned for histology and expression of apoptotic/stress markers. Hematoxylin and eosin staining was used to compare epithelial integrity in indented and adjacent non-indented areas of the cornea. Expression of apoptotic/stress markers, including cleaved Caspase-3 (Asp175), phospho-HSP27 (Ser82), phospho-c-Jun (Ser73), and phospho-SAPK/JNK (Thr183/Tyr185), were compared between indented and adjacent non-indented areas.

Results: Young's modulus of elasticity was 14.6kPa with drift towards lower values over the duration of the trial. Hematoxylin and eosin staining of the indented cornea demonstrated epithelial deformation and partial stromal edema without epithelial denuding. There was no expression of the four apoptotic/stress markers observed in the indented area, which was comparable to the adjacent non-indented area from the same cornea.

Conclusions: AFM cantilevers can accurately assess Young's modulus of elasticity without significant damage to the corneal epithelium. This suggests that cantilevers can be used in in vivo applications to assess biomechanical properties.

ABSTRACT BODY:

Purpose: Muller glia (MG) respond to retinal injury through a process referred to as reactive gliosis, driven by changes in gene expression that promote both neuroprotective and neurotoxic functions. Differences in the MG reactivity induced by inner and outer retinal injury suggest MG locally respond to insults via differential gene expression and local translation. Here, we describe a novel molecular approach to label newly synthesized mRNA in vivo to characterize transcriptional changes in MG associated with glaucomatous injury and photoreceptor degeneration. Further, we show inner and outer MG processes can be isolated by laser ablation to assess local transcriptional and translational changes.

Methods: Thiol uracil (TU) tagging of nascent mRNA is facilitated by introduction of the uracil salvage enzyme uracil phosphoribosyltransferase (UPRT) that converts 4-thio-uracil (4sU) to 4-thio-uridine-5'-monophosphate (4TU). A transgenic mouse line, UPRT/GFAPcre25/TdTom, was used to express the UPRT enzyme in MG cells specifically. UPRT-expressing mice were injected with 4-sU every 3 hours over a 6-hour period and assessed TU-tagged RNA (TU-RNA) levels by HPLC. TU-RNA was treated with iodoacetamide to alkylate, enabling identification of labeled transcripts by RNA seq. To assess translational changes, a transgenic line, Ribo/GFAPcre25/TdTom, was used to obtain Ribo-Tag expression in MG and an excimer laser was used to ablate the inner or outer retina to isolate MG processes.

Results: Comparison of 4sU/RNA sequencing and MG single cell sequencing reveals that 85% of identified genes overlap in both RNA sequencing results. Inner and outer retinal injury were induced by optic nerve crush and photocoagulation, respectively. Both optic nerve injury and photocoagulation resulted in MG reactivity and peak GFAP expression was detected 4 days after insult. The inner and outer retina were successfully ablated using an excimer laser with a desirable precision. Tissue sections confirmed the ablation of the inner nuclear layer. Eight excimer treated retinas were required to obtain the minimum amount of RNA for sequencing

Conclusions: Identifying transcriptional and translational changes in MG after various types of retinal insult provides insights into the molecular mechanisms that underlie MG reactivity and may ultimately lead to new approaches to prevent vision loss associated with retinal injury or disease.

ABSTRACT BODY:

Purpose: To measure refractions and eye lengths in the periphery of eyes with a range of refractive errors and to devise numerical models of these eyes consistent with both sets of measurements.

Methods: Central and peripheral cycloplegic refractions were obtained (Grand Seiko Open-field Autorefractor) in 22 healthy subjects (12–39 years old) at eccentricities from 40° nasal (N) to 40° temporal (T), by directing their gaze using a fixation target at 1 m. Then, eye lengths and corneal curvatures were measured (LenStar Optical Biometer) at N/T horizontal eccentricities 0°, 10°, 20°, and 30°; optical path lengths of the cornea, anterior chamber, lens, vitreous, and retina were exported and transformed into geometrical lengths using custom software. A complete optical model was developed (Zemax optical design code) that incorporated all of these parameters.

Results: Relative to central refractive errors, eccentric peripheral refractive errors were hyperopic in myopes (0.49 ± 1.10 D at 30° T), but myopic in emmetropes (-0.93 ± 0.47 D at 30° T) and hyperopes (-1.96 ± 1.62 D at 30° T). These refractions corresponded to central and peripheral axial length measures (myopes at 0°: 25.24 ± 1.73 mm, 30° T: 24.65 ± 1.68 mm; emmetropes 0°: 23.46 ± 1.06 mm, 30° T: 23.02 ± 1.14 mm; hyperopes 0°: 23.81 ± 0.23 mm, 30° T: 23.10 ± 0.01 mm). For one hyperope, one emmetrope, and one myope, optimized Zemax eye models, supplied with the measured corneal curvatures, path lengths, and individual refractions, captured most of the optical behavior of the eye with only (1) a small tilt ($\sim 2^\circ$) on the lens and (2) a fitted posterior lens curvature. With a finite diameter (2 mm) refractor beam, coma was the dominant remaining aberration. In the examined cases, significant differences were found in the "shape-factor" (ratio of anterior to posterior curvature at given optical power) of the lens.

Conclusions: In the modeling, a single fitted parameter, representing the posterior curvature of the lens, produced substantial agreement among off-axis refractive profiles and eye lengths. Thus, the resultant, self-consistent model eyes can derive previously unmeasurable lenticular parameters that may be helpful in clinical studies. The shape factor for the lens appears to depend upon the refractive state of the eye which, in turn, may be implicated in refractive development; longitudinal study of refractive development will be needed to determine the predictive validity of such an indicator.

Commercial Relationships Disclosure (Abstract): Peter Koulen: Commercial Relationship: Code N (No Commercial Relationship) | Genea Edwards: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Johnston: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The study was designed to quantify retina function in a genetic mouse model of diabetes, in which sustained dyslipidemia was induced chemically. The goal of the study was to identify if dyslipidemia in the presence of hyperglycemia resulted in either a synergistic, or merely additive, exacerbation of retinopathy in the context of the two most clinically-relevant components or features of the metabolic syndrome.

Methods: Two cohorts of mice, C57BL/6 and C57BL/KsJ-db/db mice were divided into two groups each. One group of each strain received the triblock copolymer, poloxamer 407 (P-407), administered by intraperitoneal injection ("P-407" and "P-407 db/db" groups) with saline as a control in the remaining two groups ("saline" and "db/db" groups). Blood glucose, total cholesterol (TC) and total triglyceride (TG) levels were quantified using enzyme-based colorimetric assays. Retina function was measured using electroretinography (ERG) and visual acuity was determined behaviorally.

Results: TC and TG levels were normal in both saline controls and db/db mice, but were significantly elevated in the P-407 group ($P < 0.05$), while levels of the same lipids were further elevated in the P-407 db/db group when compared to the P-407 group levels ($P < 0.0001$). ERG measurements of scotopic retina function showed a significant decline in the b/a wave ratio of the P-407 and db/db groups and a further reduction for the P-407 db/db group when compared to controls ($P < 0.01$). Similarly, behavioral assessment of the optomotor reflex indicated reduced visual acuity for both the P-407 and db/db groups and was further reduced in the P-407 db/db group when compared to either the P-407 or the db/db groups ($P < 0.001$).

Conclusions: Dyslipidemia in the presence of hyperglycemia synergistically exacerbated disease severity of diabetic retinopathy. P-407 administration significantly elevated plasma TC and TG levels in wild-type and diabetic mice (db/db), but the resulting hyperlipidemia was more significantly pronounced in the diabetic mice. While elevated plasma lipid and blood glucose levels were individually correlated with a decline in retinal function, the combination of both exacerbated retina dysfunction. This model of combined hyperglycemia and dyslipidemia can be used to dissect individual contributions of features of the metabolic syndrome to the pathogenesis of diabetic retinopathy.

TITLE: Stride length in different luminance in non-advanced age-related macular degeneration

SESSION TITLE: AMD: Clinical and translational research II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Quealy, E. Bensinger, K. Theberge, M.B. Abelson, Ora, Andover, Massachusetts, UNITED STATES|M.B. Abelson, Ophthalmology, Harvard University, Cambridge, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kara Quealy: Commercial Relationship(s);Ora:Code E (Employment) | Ethan Bensinger: Commercial Relationship(s);Ora:Code E (Employment) | Kelly Theberge: Commercial Relationship(s);Ora:Code E (Employment) | Mark Abelson: Commercial Relationship(s);Ora:Code E (Employment)

ABSTRACT BODY:

Purpose: Detecting early stage age-related macular degeneration (AMD) needs clinical tests that correspond to impacts on activities of daily living. The purpose of this study is to determine if stride length is affected in early AMD subjects under different luminance levels.

Methods: Six participants with non-advanced AMD (grade 1 to 4 on AREDS simplified scale) and 9 age-matched normal controls (AREDS grade 0) with best visual acuity (VA) 20/25 or better during their baseline visit were included. Stride length was measured using the 16 feet long GAITRite electronic walkway system. The testing room was set up to test under 3 luminance levels, high (about 300 Lux), moderate (about 20 Lux) and low (mesopic, about 5 Lux). A practice session was done prior to recording the test conditions. For each luminance condition, foot falls were automatically detected, stride length was measured and averaged across 4 trials. Best corrected visual acuity (BCVA) was recorded.

Results: For all light levels, stride length trended shorter in the non-advanced AMD group compared to the normal control group, although statistical significance was not reached. Stride length did not considerably alter with change in luminance for either normal or non-advanced AMD groups. For all subjects combined, the mean stride length was 105.5 ± 14.6 cm at high luminance, 104.8 ± 15.6 cm at moderate luminance and 104.3 ± 14.7 cm at low luminance (mesopic). Stride length at moderate and low luminance mesopic testing did not significantly differ from high luminance photopic testing ($p=0.32$ for moderate vs high, $p=0.16$ for low luminance vs high comparisons). LogMAR BCVA was also not significantly different between AMD (mean 0.05 ± 0.10) and normal group (mean 0.02 ± 0.12) ($p=0.65$).

Conclusions: Subjects with non-advanced AMD trend towards smaller stride length than age-matched normal controls. An effect of change in stride length in response to luminance was not observed in this small cohort, possibly due to a combination of small sample size and less challenging test conditions. An additional study with larger sample size and alterations in test conditions is currently in progress.

ABSTRACT BODY:

Purpose: By combining next generation whole exome sequencing and induced pluripotent stem cell (iPSC) technology we found that an Alu repeat inserted in exon 9 of the MAK gene results in a loss of normal MAK transcript and development of human autosomal recessive retinitis pigmentosa (RP). The purpose of this study was to determine if a viral gene augmentation strategy could be used to safely restore functional MAK protein as a step toward a treatment for early stage MAK-associated RP.

Methods: Patient-specific iPSC-derived photoreceptor precursor cells were transduced with the MAK gene transfer vector, and immunocytochemistry, rt-PCR and western blot analysis were performed to evaluate the effect on MAK expression. To demonstrate transgene function, cilia length assays were performed using patient-derived fibroblast cells in vitro and mak knockdown zebrafish in vivo. In addition, visual function testing was also performed in the zebrafish. Local and systemic toxicity studies of cGMP clinical grade MAK vector were performed via subretinal injection into wildtype rats.

Results: MAK mutant iPSC-derived photoreceptor cells harboring the previously identified Alu insertion (Tucker et. al., 2011) were generated and transduced with viral vectors containing the retinal MAK transcript. One week after transduction, normal retinal MAK transcript and protein could be detected via rt-PCR and western blotting respectively. Using patient-derived fibroblast cells and mak knockdown zebra fish we demonstrate that over-expression of the retinal MAK transgene restored primary cilia length in both MAK RP patient-derived fibroblasts and mak knockdown zebrafish. In addition, the visual defect in mak knockdown zebrafish was mitigated via treatment with the retinal MAK transgene. There was no evidence of local or systemic toxicity at 1-month or 3-months following subretinal delivery of clinical grade vector into wild type rats.

Conclusions: We developed a MAK gene replacement strategy and validated it in human iPSC-derived photoreceptor precursor cells in vitro as well as mak knockdown zebra fish and wildtype rats in vivo. The findings reported here provide the efficacy and safety data required for initiation of a phase 1 clinical trial for the treatment of patients with MAK-associated RP.

ABSTRACT BODY:

Purpose: An aberrant fibrotic repair process after a chemical corneal burn may lead to corneal opacity, inflammation and neovascularization and, therefore, vision impairment. Pirfenidone is clinically approved antifibrotic and anti-inflammatory drug for the treatment of idiopathic pulmonary fibrosis. We evaluated the effect of pirfenidone on human corneal fibroblast (HCF) treated with TGF β . We also tested the effect of pirfenidone and pirfenidone-loaded liposomes against alkali burn-induced corneal damage in mice.

Methods: HCF primary cultures were established from human donor corneas. HCFs were treated with TGF β 1 (5ng/ml) to induce myofibroblastic transformation and fibrosis for 7 days under serum-free conditions. Cultures were treated with pirfenidone at two concentrations (100 and 300 μ M) α -SMA mRNA expression levels were measured using Real-time quantitative PCR.

C57BL/6 mice were treated with 0.5 N NaOH to the cornea for 30 seconds. Pirfenidone (100 μ M) and pirfenidone-loaded liposomes (100 μ M) were administered topically to damaged corneas four times a day during 14 days. Corneal opacity and neovascularization were clinically evaluated at 24, 48 hours, and 2 weeks after chemical burn injury. Histology of corneas was performed after day 14 and corneal thickness, neovascularization, inflammatory infiltrate, edema and goblet cell differentiation of corneal epithelium was evaluated with hematoxylin and eosin and Masson stains.

Results: Pirfenidone at 100 μ M significantly reduced α -SMA mRNA levels ($p < 0.5$) in HCF cultures. Both pirfenidone and pirfenidone-loaded liposomes reduced corneal opacity and neovascularization, as well as histologic corneal thickness, neovascularization, inflammatory infiltrate, edema and goblet cell differentiation of corneal epithelium in mice models, however, liposome-free pirfenidone showed a more pronounced improvement.

Conclusions: Pirfenidone and pirfenidone-loaded liposomes have the potential to treat chemical corneal injury, however, further evaluations of liposome effectiveness are warranted.

ABSTRACT BODY:

Purpose: The death of retinal ganglion cells (RGCs) is a primary cause of irreversible blindness in glaucoma. In this study, we determined the neuroprotective effect of chaperone peptides (peptain-1 and peptain-3a) against RGC death in two models of ocular hypertension in mice.

Methods: The chaperone activity of peptain-1 and peptain-3a was tested in protein aggregation assays. Two mouse models were employed to simulate ocular hypertension. In the first, microbeads were injected into the anterior chamber. After 3 weeks, peptains were injected intravitreally at 1 µg each in PBS and subsequently once a week for 3 weeks. In the second model, silicone oil (2 µl, 1,000 mPa.s) was injected into the anterior chamber; after 2 weeks the oil was removed and peptains were injected intravitreally at 1µg each in PBS. In both models, the control group received PBS alone.

Results: The in vitro assays showed both peptain-1 and peptain-3a possess robust chaperone activities. The injection of microbeads into the anterior chamber elevated the IOP to 30 mmHg (from 12 mmHg in control) within a week. IOP progressively declined over the following 6-week period, but the levels were still significantly higher than controls ($p<0.05$). The number of Brn3a-positive RGCs decreased by 31% following microbead injection as compared to contralateral eyes. Injection of peptain-1 and peptain-3a significantly decreased RGC death by 4 and 12%, respectively, when compared to PBS-treated eyes. Flat-mounted retinas immunostained for β III-tubulin showed that peptains were able to inhibit axonal degeneration. In eyes injected with silicone oil, the number of Brn3a-positive RGCs decreased by 39% at 2 weeks post-injection compared to contralateral eyes. Two weeks after silicone oil removal, the number of RGCs further decreased even though IOP returned to normal levels (48.3% reduced at 2 weeks post-oil removal). However, the injection of peptain-1 and peptain-3a significantly reduced RGC loss by 26.6% and 25.3%, respectively ($p<0.05$).

Conclusions: Peptain-1 and peptain-3a both protect RGC somas and axons against ocular hypertension and suggest that they could be developed as neuroprotective agents for the treatment of glaucoma.

ABSTRACT BODY:

Purpose: A potential consequence of outer retinal degeneration is an accumulation of glucose in the retinal pigment epithelium (RPE). iGlucoSnFR-TS (GS), a fluorescence lifetime-based sensor for cellular glucose, presents a powerful new tool to study disease mechanisms in the living eye. We developed adaptive optics fluorescence lifetime imaging ophthalmoscopy (AOFLIO) to image GS in healthy mice and those with outer retinal degeneration.

Methods: A custom adaptive optics scanning light ophthalmoscope (4-6° square field of view, 25 Hz frame rate, 180 s exposure) was used for two-photon excitation of fluorescence (790 nm, ~55 fs pulse width, 80 MHz repetition rate, 7 mW mean power). We performed AOFLIO of RPE at multiple locations in one healthy C57BL/6J (B6/J) mouse and 3 GS-labeled mice (2 B6/J, 1 $\rho^{-/-}$) injected subretinally at birth with an adeno-associated viral vector encoding GS driven by the Best1 promoter. The fluorescence lifetime decay histograms were measured using time-correlated single-photon counting (SPC-160, Becker & Hickl GmbH) across emission bandwidth 380-550 nm. A two-component exponential function was fit to each decay curve from which the mean fluorescence lifetime (τ_m) was calculated.

Results: AOFLIO can measure the lifetimes of both intrinsic fluorophores and extrinsic GS at cellular resolution. In GS-injected mice, we observed patches of RPE cells with high and low fluorescence intensity, which we interpret as high (GS+) and low expression. Additionally, some RPE appeared to have no expression (GS-). In GS-injected B6/J mice, there was a significant ($p < .0001$) difference in τ_m between GS+ (162 ± 16 ps) and GS- (96 ± 16 ps) RPE. τ_m of GS- B6/J RPE was not significantly ($p = 0.11$) different from the uninjected mouse (79 ± 3 ps). Similar trends were observed for τ_m in $\rho^{-/-}$ mice (GS+ 331 ± 61 ps; GS- 194 ± 105 ps). The τ_m of GS+ RPE in $\rho^{-/-}$ mice was significantly longer than in B6/J mice ($p < .0001$).

Conclusions: The longer lifetimes observed in labeled cells of $\rho^{-/-}$ mice suggest an increase in cellular glucose of RPE compared to the labeled B6/J. However, we have not determined the optical impact on fluorescence lifetime due to blur or disease-related photoreceptor loss. Two-photon AOFLIO will allow longitudinal assessment of fluorescence lifetime markers, such as GS, in vivo to track metabolism at cellular-scale in RPE of healthy and diseased mice.

ABSTRACT BODY:

Purpose: An association between corneal nerves and resident leukocytes during steady state and their dissociation following injury has previously been shown. We hypothesize that corneal nerves may directly modulate leukocyte migration via chemotactic mediators. Thus, our aim was to assess the migration of leukocytes and characterize alterations in chemotactic neuropeptide and chemokine expression within the trigeminal ganglion (TG), following corneal nociceptor stimulation.

Methods: Expression of select chemotactic neuropeptides/chemokines in the TG was assessed by RT-qPCR. TG neurons were co-cultured with plasmacytoid dendritic cells (pDCs) in a modified Boyden chamber, using transwell inserts with 3-mm pore size for the cell migration assay. To investigate the effect of nociceptor stimulation in the absence of injury, CO₂ was applied to the central cornea of adult C57BL/6 mice in a series of 3 pulses every hour over 4 hours, using a modified Belmonte CO₂ esthesiometer. TGs were excised at 30 minutes or 24 hours following final CO₂ application and RNA isolated for RT-qPCR analysis for candidate molecules.

Results: RT-qPCR results indicated that TG neurons directly express various chemotactic neuropeptides and chemokines, including CGRP, Substance P, ADM, and CXCL12. Higher density of TG neurons co-cultured in the modified Boyden chamber (10⁴ and 10⁵ cells) had higher percentage of pDCs migrating through the transwell membrane after 24 hours (1.67±0.72% vs. 6.67±1.44%) and 48 hours incubation period (2.08±0.72% vs 9.58±2.60%) (p<0.05) compared to no migration in the absence of neurons. Following corneal nociceptor stimulation with CO₂, the cornea had elevated inflammatory cytokine IL-1β expression (4-fold; p<0.05). In the TG, there was significant 12.83-fold increase in CGRP (p<0.05), 4.35-fold increase in Substance P (p<0.05), 0.11-fold decrease in NGF (p<0.05), 0.02-fold decrease in Urocortin (p<0.05) and no significant change in ADM and CXCL12 expression compared to naïve controls.

Conclusions: Our study demonstrates that TG neurons express chemotactic molecules and have a direct chemotactic effect on leukocytes, and that changes in expression levels of pro-inflammatory and anti-inflammatory neuropeptides in the TG following CO₂-induced pain may further mediate leukocyte chemotaxis.

ABSTRACT BODY:

Purpose: A high-speed full-field (FF) swept-source (SS) optical coherence tomography (OCT) was implemented incorporating an adaptive optics (AO) subsystem to image the human retina in vivo. It has been previously reported that digital aberration correction (DAC) permits visualization of cones with FF-SS-OCT, but only in the perifovea and periphery. By combining hardware AO with FF-SS-OCT this system is able to resolve foveal cones and measure their functional responses. With the reference arm blocked, the system is a high speed (kHz) AO flood illumination (FI) fundus camera.

Methods: The FF-SS-OCT imaging system is arranged as a Mach-Zehnder interferometer with tunable source (Superlum BS-840-2-HP). In the sample arm the light that is backscattered from the retina is imaged at a CMOS sensor (Photron NOVA S12 Fastcam). The reference arm hits the camera with an angle of $\approx 1^\circ$ with respect to the sample arm to suppress common path artifacts. In parallel, a deformable mirror (ALPAO DM-97-15) is operated by custom software in closed-loop with a Hartmann-Shack wavefront sensor for real-time aberration correction. The system also incorporates a stimulus channel based on a green (555 nm) LED, used to elicit optoretinographic (ORG) responses. Two subjects were imaged at eccentricities between 1° and 2° TR.

Results: With closed-loop AO correction, diffraction-limited FI and OCT images of the retina were successfully collected at rates of 1 kHz and 200-1000 Hz, respectively. Cones were laterally resolved in the FI images and resolved in 3D in the OCT images. ORGs were collected at 2° TR and 200-400 vol/s, showing a characteristic, stimulus-evoked pattern of initial rapid contraction followed by slower elongation of the outer segment, similar to what was previously reported by others using FF-OCT in the periphery or confocal scanning AO-OCT in the fovea.

Conclusions: The system was demonstrated to be capable of producing multimodal images and measuring ORG responses in the foveal cone mosaic. Future plans include incorporation of a DMD-based visible stimulus channel and modification of the AO system to permit higher correction speed and dynamic range. Comparison of images acquired with AO with images acquired with DAC is also of interest.

ABSTRACT BODY:

Purpose: Blebs from bleb-forming glaucoma surgeries utilize sub-conjunctival lymphatics for aqueous outflow and intraocular pressure (IOP) reduction. Here, we test the ability to pharmacologically manipulate sub-conjunctival lymphatics as a way to modulate bleb biology

Methods: Lymphatics are natively visible in reporter mice that express GFP under a Prox-1 promoter. Superior sub-conjunctival injections were performed (vascular endothelial growth factor-C [VEGFC; n=11 at 0.36 mg/ml], mitomycin-C [MMC, n=10 at 0.25 mg/ml and n=9 at 0.5 mg/ml], 5-fluorouracil [5FU; n=10 at; 50 mg/ml]), control (BSS; n=10), and non-injected controls (n=10). Three sub-conjunctival injections were given (every other day), and eye were harvested and fixed in 4% PFA on the 7th day. Anterior segment flat mounts were visualized by fluorescent microscopy. Sub-conjunctival lymphatic length and branch number were quantified. Comparisons were made by Mann-Whitney U test.

Results: Sub-conjunctival lymphatics were readily visible. Many comparisons were made and main results included increased lymphatic branch number ($p=0.007$) with trending increase in length ($p=0.06$) after BSS injection, demonstrating the impact of trauma. VEGFC increase lymphatic length and branch number compared to all conditions ($p<0.001$ - $p=0.004$). 5FU demonstrated decrease in lymphatic branch number and length (both $p=0.015$) to BSS control. MMC also demonstrated a significant or trending decrease in lymphatic branch and length ($p<0.001$ - 0.075) to BSS control. A mild dose-dependent effect was seen for MMC with trending lesser lymphatic length at the higher dose ($p=0.079$). These overall changes were further less significant on the temporal/nasal to inferior portions of the eye as the injections were superior.

Conclusions: Sub-conjunctival lymphatic presence can be pharmacologically manipulated. Enhanced presence may be useful for improving aqueous outflow and IOP reduction after performing bleb-forming glaucoma surgeries. Limiting sub-conjunctival lymphatic presence may improve the sub-conjunctival space as a drug delivery depot by diminishing lymphatic drainage from that space.

ABSTRACT BODY:

Purpose: Understanding trends and patterns in the use of minimally invasive glaucoma surgery (MIGS) as well as patient profiles undergoing each procedure is important given their relative expense and unknown long-term safety and effectiveness.

Methods: We used the American Academy of Ophthalmology (AAO) Intelligent Research in Sight (IRIS®) Registry between 2013-2018 (inclusive) to measure adjusted annual number of MIGS and standard surgical techniques (trabeculectomy or glaucoma drainage device (GDD)) performed in the US, stratified by demographic characteristics. Secondary analyses of concurrent surgeries and of subsequent surgeries for MIGS and standard surgical technique were also conducted.

Results: 202,574 eyes and 232,537 unique procedures had associated, documented ICD 9/10 codes for glaucoma and were included in final analyses. Those receiving either iStent or endoscopic cyclophotocoagulation (ECP) were more likely to be female, while those receiving GDDs were more likely to be younger and male ($p < 0.05$). Those receiving either iStent or Xen Gel stent were more likely to be White, while those receiving GDD, goniotomy or trabeculectomy were more likely to be Black ($p < 0.001$). There was an increase in annual MIGS procedures over the study period (from 7,586 in 2013 to 39,677 in 2018), and a reciprocal decrease in standard glaucoma procedures (from 16,215 to 13,701). The proportion of iStent procedures tripled during the study period (from 14% to 40%), and by 2017 accounted for 43.7% of all glaucoma surgeries in the US. 21,524 (10.6%) of all eyes received multiple procedures; 7,381 (34.3%) on the same day and 14,143 (65.7%) on subsequent days. ECP and iStent were the most common concurrent procedures (58.9% of all concurrent procedures). Trabeculectomy and GDD were most commonly followed by another standard glaucoma surgery.

Conclusions: There was a significant increase in MIGS use over the recent six-year period despite limited evidence of their long-term safety or effectiveness, highlighting the need for studies comparing safety and outcomes of novel MIGS vs traditional surgical treatments for glaucoma.

ABSTRACT BODY:

Purpose: The benefit of cataract and cataract plus iStent[®] (Glaukos Corp. Laguna Hills, CA) surgeries in reducing intraocular pressure (IOP) has been noted in open-angle glaucoma (OAG), yet the impact of race has not been studied. The purpose of our study is to compare intraocular pressure (IOP) and number of glaucoma medications (meds) in cataract extraction alone (CE) vs. cataract extraction plus iStent (CE+iStent) in Caucasians (CA) vs. African Americans (AA) at 1 year.

Methods: 88 OAG patients (58 CA, 30 AA) who underwent CE and 147 (99 CA, 48 AA) who underwent CE+iStent at Edward Hines, Jr. VA and Loyola University Medical Center from 2015 to 2019 were retrospectively reviewed. IOP and meds were recorded at baseline and postoperative months 1, 3, 6, and 12. IOP spikes (>21 mmHg) on postoperative day 1 were recorded. Independent samples t-test analyses were performed.

Results: In the total patient sample, baseline IOP was significantly higher in CE+iStent group vs. CE ($p=0.0001$). IOP at 1 year was significantly higher after CE+iStent vs. CE ($p=0.013$). Meds at 1 year were significantly less after CE+iStent vs. CE ($p=0.019$).

Regarding race, baseline IOP was significantly higher in CE+iStent group vs. CE ($p=0.039$ CA; $p=0.0005$ AA). CE resulted in a significant decrease in IOP at 1 year in CA ($p=0.001$). CE+iStent resulted in a significant decrease in IOP at 1 year in both CA ($p<0.0001$) and AA ($p=0.012$). Comparing CE+iStent to CE at 1 year, IOP was higher after CE+iStent for both races ($p=0.178$ CA; $p=0.011$ AA).

CE+iStent resulted in a significant decrease in meds at 1 year in CA ($p=0.002$) but not AA ($p=0.082$). Comparing CE+iStent to CE at 1 year, meds were significantly reduced with CE+iStent in CA ($p=0.004$) but not AA ($p=0.841$).

29.2% of AA and 14.4% of CA had severe OAG in CE+iStent group vs. only 16.7% of AA and 13.8% of CA in CE group.

39.7% of CA and 36.7% of AA had an IOP spike on postop day 1 in CE group compared to 20.2% of CA and 33.3% of AA in CE+iStent group.

Conclusions: This study shows significant benefit in lowering pressure and medication burden after cataract extraction alone and with iStent. Racial differences are seen in postoperative outcomes, and further research is needed to understand how race impacts these surgical outcomes. A limitation of the study is smaller sample size.

ABSTRACT BODY:

Purpose: Endophthalmitis after cataract surgery is a vision-threatening but rare event with an incidence of ~0.5 to 3 per 1,000, thus necessitating a large sample size to conduct meaningful studies. As of Sep. '20, the IRIS® Registry (Intelligent Research in Sight) includes data from >60 M (million) unique patients, making it an ideal data source to assess rare events. Hydrogel Sealant (ReSure Sealant) creates an in situ temporary soft surface barrier to prevent wound leakage of any clear corneal incision after cataract surgery. Here, we evaluate the incidence of endophthalmitis following any cataract surgery (routine or complex) between sites with and without access to ReSure Sealant.

Methods: This retrospective study analyzed patient data from the IRIS Registry from Jan 1, 2016 to Dec 1, 2019 on the incidence of endophthalmitis following cataract surgery in practices with & without access to hydrogel sealant. Inclusion criteria for patients included having cataract removal via phacoemulsification with intraocular lens insertion, ≥1 visits within 30 days after surgery, & being at least 22 years. Practices must have provided data for at least 30 days after each surgery.

Results: Approximately 6 M eyes of 4 M patients were eligible for inclusion. Mean age was 70.91 (SD: 8.95). Overall endophthalmitis incidence was 0.644 (all incidence rates calculated per 1,000 cataract surgeries; 95% Confidence Interval: 0.625, 0.663). Endophthalmitis rate at practices with ReSure Sealant access was 0.619 (0.59, 0.64) vs. without 0.671 (0.64, 0.7) (P=0.01). Endophthalmitis rate (87% cases) after routine cataract procedures was 0.582 (0.56, 0.61) at practices with Sealant access vs. without 0.625 (0.60, 0.65) (P=0.03). Endophthalmitis rate (13% cases) after complex cataract procedures at practices with Sealant access was 1.097 (0.97, 1.22) vs. without 1.227 (1.09, 1.37) (P=0.18).

Conclusions: To our knowledge, this is the largest reported recent review of endophthalmitis cases after cataract surgery. Overall endophthalmitis rate was low (0.644 per 1,000 cataract surgeries). Patients undergoing complex cataract surgery had a higher incidence of endophthalmitis. Sites with access to ReSure Sealant had a statistically significant lower rate of endophthalmitis than sites without access. This difference was not clinically meaningful.

SUBMITTER (NAME ONLY): Maryam Rezaei

TITLE: A new functional test sensitive to a reduction in light absorption by photoreceptors

SESSION TITLE: Assessing human vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Rezaei, G.N. Chamaa, C. Rodrigue, J. Renaud, R. Allard, School of optometry, Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Maryam Rezaei: Commercial Relationship: Code N (No Commercial Relationship) | Gerry Chamaa: Commercial Relationship: Code N (No Commercial Relationship) | Clement Rodrigue: Commercial Relationship: Code N (No Commercial Relationship) | Judith Renaud: Commercial Relationship: Code N (No Commercial Relationship) | Remy Allard: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The amount of light absorbed by photoreceptors likely drops at early stages of retinal diseases (e.g., age-related macular degeneration) although basic visual functions like visual acuity (VA) and contrast sensitivity (CS) remain normal. The current study adapted a psychophysical paradigm to create a novel psychophysical test (photon noise test) presumably sensitive to the amount of light absorbed by photoreceptors. This experimental study tested the hypothesis that the photon noise test is better at detecting a reduction in the amount of light absorbed by photoreceptors compared to current standard functional tests: ETDRS (VA), Pelli-Robson (CS) and MARS (CS).

Methods: Twenty-one young healthy adults participated in this study comparing the capability of the photon noise test and three standard clinical tests (ETDRS, Pelli-Robson, MARS) to discriminate the baseline viewing condition from a reduction of light absorbed by photoreceptors. To simulate a reduction of light absorbed by photoreceptors, neutral density (ND) filters of 0.5, 1.0 and 1.5 reducing the amount of light by a factor of 3.1, 10 and 31, respectively were used. The capability of each test to detect a reduced absorption of light was quantified by measuring the area under the ROC curve (AUC). Then, the capability of the photon noise test was compared to the capability of each clinical test using a chi-square test.

Results: The figure shows the AUC for the four tests and three levels of light reduction. Even for the smallest amount of simulated reduction in absorption rate tested (ND filter=0.5), the capability of the photon noise test was outstanding (AUC=.95) and significantly higher ($p<.015$) than the three clinical tests, which were poor or acceptable (AUC of .66, .75 and .73 for ETDRS, Pelli-Robson and MARS tests, respectively).

Conclusions: The photon noise test is better at detecting a small decline in light absorption than standard functional tests. The photon noise test may be useful to detect early signs of retinal diseases affecting the photoreceptors.

ABSTRACT BODY:

Purpose: To describe visual outcomes and characteristics of thyroid eye disease patients undergoing therapeutic contact lens use at a tertiary care center.

Methods: Records were identified and reviewed of consecutive patients with a diagnosis of thyroid eye disease utilizing billing records with ICD 9 code 242.0, 376.21 or ICD 10 code E05.00. Eligible patients were those evaluated in the contact lens service of the Illinois Eye and Ear Infirmary at the University of Illinois at Chicago between July 1st 2015 and July 1st 2020. Demographics, history of orbital decompression, eyelid/orbital surgery, orbital radiation, clinical findings, visual acuity and contact lens parameters were recorded. Snellen visual acuities were converted to LogMAR for analysis. Descriptive statistics are presented as well as paired T tests.

Results: Fourteen patients met inclusion criteria with a mean age of 59.6 years [15.3, 30-80]. The majority were female (78.6%). About one third of the patients had undergone orbital decompression surgery (n=5/14) and 3 had non-healing corneal epithelial defects. Clinical findings in these patients included punctate keratitis 78.6%, eyelid retraction 50.0%, bulbar conjunctival injection 42.9%, corneal scarring 35.7% and corneal thinning and steepening consistent with keratoconus 14.3%. There were 7 patients fit with soft lenses, 1 with corneal gas permeable lenses, 1 with hybrid and 5 with scleral lenses.

Vision in the right eye improved from baseline mean LogMAR 0.41 [0.47, 0.0-1.46; n=13] to 0.07 [0.11, 0.0- 0.30) with contact lenses (difference in means 0.34, 95%CI[0.076 to 0.598], t(12)=2.81, P=0.016).

One left eye was limited to light perception; however the other eyes improved from mean baseline LogMAR 0.55 [0.58, 0.0-1.83; n=13] to 0.065 [0.12, 0.0- 0.40) with contact lenses (difference in means 0.49, 95%CI[0.188 to 0.789], t(12)=3.55, P=0.004).

Conclusions: This series of patients demonstrates the characteristics of patients with thyroid eye disease. Moreover, therapeutic lenses, including soft and scleral lenses, were utilized most often and associated with visual improvement.

ABSTRACT BODY:

Purpose: Bacterial keratitis (BK) is a major cause of blindness worldwide. *Staphylococcus aureus* is the predominant organism implicated in BK and causes considerable ocular tissue damage largely due to the ability to significantly modulate the host immune response via secreted virulence factors. In *S. aureus*, Agr and Sae are two important virulence regulators, yet their role in BK is yet unknown. This study investigated the role of Agr and Sae in host cytokine production in a murine model of BK.

Methods: *S. aureus* isolates USA300 (WT), USA300 Δ saePQRS, and USA300 Δ agr, were used to inoculate the corneas of BLALB/c mice. At 24 and 48 hours, eyes were harvested, homogenized and evaluated for the abundance of a panel of cytokines including interleukin 6 (IL6), interleukin 12 (IL12), and tumor necrosis factor alpha (TNF α) using standard sandwich ELISA assays. Three biological replicates were assayed for each strain and time point.

Results: IL-6 was significantly elevated in mice infected with *S. aureus* USA300 Δ saePQRS at 24 h post infection compared to USA300 (WT) or USA300 Δ agr (ANOVA, $P = 0.005$; Tukey-Kramer post hoc test, $P = 0.021$ and $P = 0.005$, respectively). Production of IL6 at 48 h post infection was not significantly different between the three strains (ANOVA, $P = 0.34$). No significant differences were detected between strains at 24 or 48 hours for IL12 (ANOVA, $P = 0.1753$ and $P = 0.1951$, respectively) or TNF α (ANOVA, $P = 0.5440$ and $P = 0.3663$, respectively).

Conclusions: Agr and Sae are well-known virulence factor regulators in *S. aureus* yet their downstream effectors and resulting host response is not well characterized in BK. Here we demonstrate that Sae significantly impacts IL-6 production in a murine model of BK in the early stages of infection. Targeting bacterial factors that modulate the host immune response may provide a therapeutic approach to treating this blinding disease.

ABSTRACT BODY:

Purpose: To study the effects of ALK-001 on the progression of Stargardt disease (STGD1). STGD1 is the most prevalent inherited macular dystrophy and results from defects in the ABCA4 gene that cause accelerated formation of vitamin A dimers in the retina. No treatment exists.

Methods: The TEASE study is a multicenter two-year Phase 2 double-masked, randomized, placebo-controlled clinical trial that randomized 50 subjects with STGD1 and a well-delineated area of RPE atrophy. The investigational drug ALK-001 is a selectively deuterated vitamin A used as vitamin A replacement and taken orally once-a-day. Deuterium slows vitamin A dimer formation 4-5 fold without inhibiting the visual cycle. Subjects were randomized 2:1 ALK-001:placebo during the first year, with 50% of placebo subjects randomly crossed over to ALK-001 for the second year of treatment. The prespecified primary efficacy outcome measure is the rate of growth of the square root of atrophic lesions, as measured on short wavelength fundus autofluorescence imaging, and evaluated using a linear mixed model. The study was performed at 7 centers in the USA. 50 subjects (38 white; 28 female) were randomized. Median age was 46 years (range, 18-60) and disease duration 9 years (0-36). Atrophic lesions at baseline were bilateral in 74% of cases with a $\sim 5 \text{ mm}^2$ median area.

Results: The growth rate of the square root of atrophic lesions in the ALK-001 treated group was 21% slower than in the untreated group ($p < 0.001$). When using areas, the growth rate was 28% slower in the ALK-001 arm than the placebo arm. There were no significant changes in BCVA in either treated and untreated arms after 2 years as expected in this patient population. On average, $\sim 90\%$ of vitamin A was replaced with deuterated vitamin A, which was maintained over time. ALK-001 was well-tolerated with no unexpected adverse reactions, no report of night blindness or impaired dark adaptation, and no clinically-significant increases in liver enzymes.

Conclusions: These data represent the first time that a therapeutic intervention slows the progression of STGD1 in a clinically and statistically meaningful way. In addition, the data provides clinical evidence that vitamin A dimers contribute to the pathophysiology of STGD1, and that slowing vitamin A dimerization is beneficial even in advanced stages of STGD1.

TITLE: A non-invasive imaging method to detect retinal hypoxia in a rat model of 50/10 oxygen-induced retinopathy using HYPOX4

SESSION TITLE: Animal imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Jamal, J. Penn, M.I. Uddin, ophthalmology, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sara Jamal: Commercial Relationship: Code N (No Commercial Relationship) | John Penn: Commercial Relationship: Code N (No Commercial Relationship) | MD Uddin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Neovascularization a condition that might arise due to retinal hypoxia is a leading cause of vision loss in a variety of retinopathies. The development of hypoxia detecting probes will provide a platform for early disease diagnosis and therapy monitoring. This study demonstrates the utility of HYPOX4 which is a hypoxia sensitive fluorescein-based imaging probe for early detection of retinal hypoxia in a 50/10 rat model of oxygen-induced retinopathy (OIR) in real-time.

Methods: OIR rat model was induced by exposing newborn Brown Norway rats (BN) to a 24 hrs alternate cycle of 50% and 10% oxygen for 14 days. The pups were returned to normoxia for 2 hrs and HYPOX4 was injected intraperitoneally for in vivo imaging of retinal hypoxia in 50/10 OIR model compared to age-matched control (exposed to normoxia throughout the duration of the experiment). A Separate group of OIR pups were injected with pimonidazole and sacrificed 90 min post-injection. Retinas were harvested and immune-stained for pimonidazole-adducts as an established method for ex vivo detection of retinal hypoxia. Post in vivo imaging, HYPOX4 injected pups were euthanized after 24 hrs for ex vivo imaging of retinal hypoxia. Vascular structures were counterstained using Isolectin B4 (IB4).

Results: Retinal hypoxia was observed within the avascular area in the peripheral retina that was detected with HYPOX4. The observation was validated using pimonidazole immune-staining. Confocal imaging allowed us to detect this retinal hypoxia in the inner retina hypoxic region.

Conclusions: Retinal hypoxia plays a major role in the onset and progression of neovascularization. HYPOX-4 was successfully used as a highly sensitive molecular imaging probe to detect retinal hypoxia in BN 50/10 OIR. Thus, HYPOX-4 could be utilized as a promising and noninvasive imaging tool for early-stage diagnosis and tracing of hypoxia in OIR and potentially in other vascular diseases.

TITLE: The ILUVIEN implant in DME – are we leaving it too late?

SESSION TITLE: AI in the retina/ AMD imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.N. Sadiq, M. Habib, Sunderland Eye Infirmary, Sunderland, Tyne and Wear, UNITED KINGDOM|S.N. Sadiq, Royal Victoria Infirmary, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Salman Sadiq: Commercial Relationship: Code N (No Commercial Relationship) | Maged Habib: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optimising medicines usage remains a focus as healthcare resources continue to shrink. We performed a retrospective, observational study in diabetic macular edema (DME) patients treated with the ILUVIEN (0.2µg/day fluocinolone acetonide; FAc) implant to understand the impact of disease duration on outcomes.

Methods: We analysed DME patient records treated with the FAc implant between 02/2014 and 11/2017. Baseline parameters included the duration of DME, prior intravitreal therapies, history of vitrectomy and tractional pathologies, and retinopathy status. We analysed changes in visual acuity (VA, Early Treatment Diabetic Retinopathy Study [ETDRS] letters), central macular thickness (CMT, µm), maximum macular thickness (MMT, µm), intraocular pressure (IOP, mmHg), and recorded any further treatment for DME or ocular hypertension (OHT). Two sub-groups were compared: those with baseline DME duration below the mean of 25 months (shorter DME duration), or ≥25 months (longer DME duration). Groups were compared using unpaired tests: Student's t-test, Wilcoxon (Mann-Whitney U test) and Fischer's exact test.

Results: Of the 84 eyes treated, 59.5% had shorter DME duration and 40.5% had longer DME duration; the duration of follow-up for each group was 28.7 months ±10.9 (mean ±standard deviation) and 26.1 months ±10.3, respectively. At last observation, shorter DME duration was associated with larger VA gains (+5.4 vs -1.5 letters, P=0.0566, see image 1), a greater reduction in central (-151.7 vs. -88.1 microns, P=0.0141) and maximum macular thickness (-157.6 vs. -91.9 microns, P=0.008) from baseline, and higher rates of anatomical response (defined as a reduction of ≥20% from baseline) for CMT (P=0.0132) and MMT (P=0.0110). Supplementary treatments were given in a lower percentage of patients with shorter compared with longer DMO duration (34.0% vs 50.0%). Furthermore, there were lower rates of surgical intervention for OHT observed in the shorter DMO duration sub-group (n=1 and 3, respectively). See Table 1.

Conclusions: Our results demonstrate the anatomical and functional benefits of considering earlier treatment with FAc implant in the course of DME disease, or earlier conversion of treatment to the use of slow release steroid implants. These results could help optimise future management plans for DME. Limitations of the study include being retrospective and the differences in baseline characteristics that may have impacted on results.

TITLE: Induced Peripheral Blur and its Effect on Visual functions

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.A. Alzghoul, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Eman Alzghoul: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Peripheral hyperopic defocus has been considered to be a contributing factor to myopic progression. Thus, it has been suggested that reducing peripheral blur may slow down myopia progression. However, how the eye recognizes optical blur in different meridians and responds to change in peripheral visual functions is not fully understood. This prospective study hypothesized that inducing myopic peripheral blur using utilized multifocal contact lenses will improve detection visual function and may be involved in reducing myopia progression. In this study, we quantified the impact of peripheral blur on visual function which may provide further insights on myopia development

Methods: 20 myopic subjects (Mean age 21 ± 2 years) were fitted with Proclear multifocal lenses of distance center design in one eye. All subjects were with a central spherical equivalent myopic refraction of -1.00D or more, $\leq 0.75\text{DC}$ cylindrical power, and 1.00D or more peripheral blur at the horizontal visual field. Peripheral refraction and detection acuity were measured with the contact lens on the eye. All measurements were taken along the horizontal meridian at $\pm 10^\circ$, $\pm 20^\circ$, $\pm 30^\circ$, and $\pm 35^\circ$, and under three conditions; no blur, $+0.50\text{D}$, and $+1.00\text{D}$. Linear mixed model and Post-hoc t-tests were used for statistical analysis; to assess changes in visual functions under different peripheral defocus conditions

Results: Compared to the baseline, peripheral refraction was significantly more hyperopic at all points along the horizontal meridian when compared to the center except at nasal and temporal 10° ($p < 0.05$). No significant difference was found in detection ability with varying amounts of peripheral blur at different locations ($p=0.764$). However, detection acuity was highest centrally (± 10 degrees) and gradually started to decrease peripherally with the lowest acuity at location ± 35 degrees

Conclusions: The results of this study showed that inducing optical blur changed peripheral refraction across horizontal meridian when compared to spherical contact lenses. Further, the results showed that inducing optical defocus does not change peripheral detection ability along the horizontal visual field which contradicts our hypothesis that improvement in peripheral visual function may be involved in reducing myopia progression. However, more studies need to be conducted to comprehensively establish the impact of hyperopic blur on peripheral detection abilities

ABSTRACT BODY:

Purpose: The Cancer Genome Atlas (TCGA) is a genetic based classification of 33 types of cancer including uveal melanoma and is highly predictive of uveal melanoma-related metastasis and death. We performed a retrospective, cohort study to evaluate TCGA classification and outcomes for uveal melanoma based on patient age at presentation.

Methods: Retrospective analysis of patients with uveal melanoma at a single ocular oncology center treated with plaque radiotherapy or enucleation from 1998 to 2020 and who completed genetic testing of chromosome 3 and 8 after fine needle aspiration biopsy. Patients were classified by age group (<21 years vs. 21-40 years vs. 41-60 years vs. >60 years) at presentation. Categorical variables were compared using χ^2 tests or Fisher's exact tests. Kaplan-Meier analysis was performed for metastasis (liver metastasis, any metastasis) and death from uveal melanoma.

Results: Of 1001 eyes with uveal melanoma, 9 (1%) were <21 years, 104 (10%) were 21-40 years, 420 (42%) were 41-60 years and 468 (47%) were >60 years of age at presentation. By comparison, the older age group had higher frequency of class D tumor (0% vs. 4% vs. 10% vs. 14%, $p<0.001$) and greater tumor basal diameter (11.6 vs. 12.0 vs. 11.7 vs. 12.6, $p=0.02$) and the younger age group had higher frequency of 20/400-no light perception (NLP) vision (56% vs. 8% vs. 8% vs. 11%, $p<0.001$). By Kaplan-Meier analysis (10 years), the older age group had higher rate of liver metastasis (0% vs. 14% vs. 11% vs. 14%, $p=0.017$), any metastasis (0% vs. 14% vs. 12% vs. 14%, $p=0.033$), and uveal melanoma-related death (0% vs. 2% vs. 1% vs. 3%, $p=0.049$).

Conclusions: Uveal melanoma diagnosis at an older age is associated with more advanced TCGA classification, larger tumor size, and higher metastasis and death rate.

ABSTRACT BODY:

Purpose: Non-infectious uveitis (NIU) is an intractable and painful disease that is a significant cause of vision loss in humans and horses. Current treatments of NIU are non-specific and have serious side effects which limits them to short-term use. As NIU necessitates long-term immunosuppression to prevent vision loss, a single dose treatment that mediates long-term immunosuppression without side effects is desired. The purpose of this work was to develop an effective long-term therapy for NIU in horses. We investigated the use of adeno-associated virus (AAV) gene therapy as a vehicle for delivering anti-inflammatories to the uveal tract. The ciliary body was the targeted ocular tissue for gene therapy as it is the location of the blood ocular barrier break down. We exploited the use of an endogenous anti-inflammatory protein, Equine-IL10.

Methods: To simulate the prevention of NIU, naïve Lewis rats received a single intravitreal injection of a low dose or high dose AAV particles harboring codon-optimized cDNAs encoding Equine-IL10 one week prior to experimental autoimmune uveitis (EAU) induction. Daily blinded biomicroscopy examination and optical coherence tomography (OCT) examinations were performed. Genome biodistribution and transduction efficiency were characterized using Q-PCR for ocular tissues. Blinded histological examinations were performed and the level of inflammation was scored. To determine if intravitreal injection of AAV vectors resulted in an antibody response to the injected capsid, neutralizing antibody assays were performed.

Results: Intravitreal injection of AAV-EqIL-10 successfully mediated expression of Equine-IL-10 in the ciliary body of both treatment groups. There was a dose dependent influence of viral expression in other ocular tissues. There was a significant decrease in clinical and histological inflammatory scores in both treatment groups compared to control EAU eyes ($p < 0.5$). Mean cellular infiltrative scores were significantly less in treated eyes compared to control eyes on days 10, 12 and 14 post EAU induction ($p < 0.5$).

Conclusions: Localized gene delivery of Equine-IL10 establishes a long-term anti-inflammatory effect, that would be a novel therapeutic strategy for refractory and recurrent uveitis as well as other ocular autoimmune inflammatory diseases in both human and veterinary patients.

ABSTRACT BODY:

Purpose: To evaluate the relationship between optical coherence tomography (OCT) features and demographic characteristics on the development of incomplete retinal pigment epithelial and outer retinal atrophy (iRORA) in eyes with nonneovascular intermediate age-related macular degeneration.

Methods: Fifty eyes from fifty subjects with nonneovascular intermediate age-related macular degeneration and no history of atrophy or macular neovascularization (MNV) in the study eye, were enrolled in this retrospective cohort study. OCT B-scans data and electronic medical records were reviewed for all subjects. The visit with first evidence of intermediate age-related macular degeneration on OCT was labeled as “baseline”. Baseline OCT B-scans from the study eye were annotated for previously described high-risk biomarkers including intraretinal hyperreflective foci (IHRF), subretinal drusenoid deposits (SDD), hyporeflective foci within core drusen (hDC), while the fellow eye was assessed for presence of atrophy and/or MNV. Electronic medical records were reviewed for socio-demographic characteristics including age, gender, ancestry, use of AREDS supplements and treatment with statins. OCT B-scans from the study eye obtained at month 6, 12, 18, 24, 30 and 36 were reviewed by masked graders for evidence of incident iRORA. The appearance of iRORA was plotted as a survival curve over a period of 36 months. Cox proportional hazards regression analysis was used to assess the factors associated with the development of iRORA.

Results: By month 36, 70% of eyes (35/50) demonstrated evidence of iRORA. The overall mean time to development of iRORA was 23.2 (1.4) months. Baseline socio-demographic factors showed no significant association with the development of iRORA. Among baseline OCT features, only IHRF showed a statistically significant association with the development of iRORA (HR 3.06; 95% confidence interval [CI] 1.69 – 7.94; p = 0.001).

Conclusions: A substantial proportion of intermediate eyes, particularly those with IHRF, can progress to demonstrate evidence of iRORA over a three year period. These findings may be of value in risk stratification and study design in early intervention trials of dry AMD.

ABSTRACT BODY:

Purpose: To describe microsaccade magnitude, microsaccade peak velocity, and number of microcrossades when using distance center multifocal contact lenses in emmetropic and myopic subjects.

Methods: Binocular microsaccades were measured on 22 subjects using a custom developed binocular optical system with a field of view of 1.25 degrees coupled to an Eye Link 1000 eye tracker. The main components of the optical system were two Badal systems, two high luminance pico-projectors, and two diaphragms placed in conjugated planes to the subject's pupils. Badal systems allowed for the correction of refractive error between the powers of +5.00D and -10.00D without inducing magnification. External pupil diaphragms were used to maintain constant retinal illumination on all subjects by setting the artificial pupil size to 4mm. Each participant was measured under three different conditions: Naked Eye (NE), Biofinity Multifocal "D" +1.50D (BM1), and Biofinity Multifocal "D" +2.50D (BM2). Within each condition nine levels of defocus were presented, +4.00D to -4.00D in one diopter steps, using the Badal system. Each participant performed a total of 27 trials (total 3 hours). A single trial consisted of a subject fixating on the center of a Maltesse Cross for two minutes with breaks allowed as necessary. The NIMO instrument from Lambda-X was used to perform the analysis of BM1 and BM2 and coupled with custom developed software (Matlab) in order to evaluate the VSOTF for a 4 mm pupil.

Results: In the graph below, each row represents a viewing condition (71,012 binocular microsaccades, Engbert and Kliegl method). The upper row shows Naked Eye trials, the middle row shows Biofinity +1.50 D trials, and the bottom row shows Biofinity +2.50 D trials. The data for myopes (n=18) is in blue and data for emmetropes/hyperopes (n=4) is in orange. Lines represent moving averages (period 2). The optical profile and the VSOTF of the Biofinity +1.50 "D" and the +2.50 "D" for a 4 mm pupil can also be found on the left panels.

Conclusions: Emmetropic patients modify their average microsaccade size to a larger extent in comparison to myopic patients in the presence of induced blur. The use of BM1 significantly decreases the average size and the peak velocity of the microsaccades produced by myopic subjects when exposed to myopic blur. The number of microcrossades of myopic subjects is higher than in emmetropic.

ABSTRACT BODY:

Purpose: We have previously reported that the intravenous injection of bone marrow-derived cells (BMDC) programmed with the RPE65 gene promoted visual recovery in a mouse model of AMD. Because of that, the aim of this study was to characterize the spatial and temporal recruitment of those programmed cells to the RPE layer.

Methods: 2-month old C57BL/6J female mice received a subretinal injection of AAV1-SOD2 ribozyme to induce the AMD mouse model. One month after the injection, systemic intravenous injection of 50,000 GFP⁺ RPE65-programmed mouse bone marrow-derived cells (BMDC)/animal was performed. Animals were terminated at different time-points from one to 60 minutes after cell injection and the localization of GFP⁺ cells was determined by fluorescence microscopy in RPE/retinal flat mounts and sections.

Results: The analysis of RPE/retina flat mounts showed that the majority of the GFP⁺ cells were found exclusively in the RPE layer. In the first two time-points, the cells were found especially in the proximity of ora serrata (peripheral) region of the RPE flat mount while few cells were observed in the center, near the optic nerve. In the following time-points, up to one hour after cell injection, the number of cells in the peripheral area was reduced while in the central area the number was increased. The neural retina showed cells scattered in the center of the tissue that presented a higher density in the first 2 minutes which decreased in the following time-points after cell injection. These findings were confirmed by immunofluorescence analysis of retinal sections, where we observed individual cells expressing both GFP and RPE65 markers.

Conclusions: In this study our group shows that the reprogrammed BMDC, administrated systemically, are capable of migrating to the eye, enter the retina via both the central retina and posterior ciliary arteries and migrate to the injured RPE layer.

ABSTRACT BODY:

Purpose: Pseudoexfoliation glaucoma (PEXG) is a form of open angle glaucoma that is characterized by outflow resistance dysregulation and elevated intraocular pressure (IOP). The LOXL1-AS1 gene codes for a long non-coding RNA, whereby polymorphisms decrease its expression and are associated with risk of PEXG. Since LOXL1-AS1 influences the transcription of many genes, we hypothesize that LOXL1-AS1 in outflow cells regulates the expression of gene-products known to participate in outflow resistance regulation, including extracellular matrix (ECM), cell adhesion and mechanotransduction signaling proteins.

Methods: Knockdown of LOXL1-AS1 expression was achieved in primary cultures of human trabecular meshwork (TM) and Schlemm's canal (SC) cells using a targeted Ad-shRNA, or by introducing targeted siRNA into HLE-B3 cells. Knockdown efficiency of LOXL1-AS1 and ECM gene expression was assessed using qPCR. Western blots were used to monitor ECM and mechanotransduction protein expression after LOXL1-AS1 knockdown, comparing to scrambled controls. Lastly, morphological changes due to LOXL1-AS1 knockdown in HLE-B3, SC, and TM cells were evaluated by calculating semi-axis ratios using FIJI.

Results: Knockdown of LOXL1-AS1 in HLE-B3 cells significantly altered the expression of seven ECM proteins ($p < 0.05$, $n = 3$), but did not change phosphorylation status of candidate mechanotransduction proteins AKT, MAPK, FAK ($p > 0.05$, $n = 3$). Experiments in one TM cell strain show that knockdown of LOXL1-AS1 results in dysregulation of ECM target genes including, but not limited to, MMP2, MMP14, MMP28, and MYC. In SC cells, knockdown of LOXL1-AS1 led to significant expression changes in ECM target genes including neuronal adhesion protein, vascular adhesion protein, integrin alpha 2, and laminin gamma 1 ($p < 0.05$, $n = 4$). With LOXL1-AS1 knockdown, SC cells significantly increased the proportion of phosphorylated AKT ($p = 0.008$, $n = 4$), but no changes were observed with phosphorylation status of FAK or MAPK. Knockdown of LOXL1-AS1 resulted in a shortening of the major axis of SC cells ($p = 0.006$, $n = 3$).

Conclusions: LOXL1-AS1 regulates genes involved in ECM remodeling and mechanotransduction signaling in human ocular cells. These data indicate that LOXL1-AS1 has a regulatory role in outflow resistance homeostasis, and represents a potential target for PEXG therapies.

ABSTRACT BODY:

Purpose: Our main goal was to identify intrinsic host factors responsible for defending against viral infections of the eye. We used herpes simplex virus-1 (HSV-1) as a model virus to characterize a mammalian protein, optineurin. Optineurin is a glaucoma-associated gene, and mutations in this gene are also commonly reported in many other neurodegenerative diseases.

Methods: Cell types including human corneal epithelial, HeLa, Vero cells as well as primary cultures of neurons were used for infection with various HSV-1 strains. Viral plaque assays, viral genome counts by real-time PCR, and virus growth was estimated over time using time lapse fluorescence microscopy. TIRF/Super-resolution microscopy was used to demonstrate degradation of HSV-1 proteins and HSV-1 xenophagy. Immunohistochemistry was performed to detect optineurin localization in postmortem human nervous system tissues from patients with HSV encephalitis and ALS disease. Flow cytometry was performed to estimate cell death. Novel object recognition test was used to determine cognitive decline in mice.

Results: We provide the very first evidence that lack of optineurin results in measurably enhanced HSV-1 infection of the cells of ocular and non-ocular origins. We demonstrate that optineurin selectively binds to and degrades HSV-1 viral proteins via autophagy. In addition to selective degradation of HSV-1 proteins, optineurin may potentially participate in xenophagy of HSV-1 virions, which significantly restricts viral spread in wild-type compared to optineurin knockout cells. Loss of optineurin in intact animals demonstrates a more robust effect on nerve damage and potential loss of optimal vision in HSV-1 infected eyes. These animals show significantly reduced corneal sensitivity and succumb to HSV-1 infection due to rapid onset of encephalitis. Most interestingly, HSV-1 infected animals lacking optineurin show significantly lower scores in object recognition tests, suggesting a rapid loss of cognitive functions compared to wild-type animals

Conclusions: Optineurin is an important host defense factor that prevents severe damage to corneal cells and innervating nerves as well as the brain upon HSV-1 infection. Ours may be the first demonstration to explain an important protective role for this protein in infection as well as neurodegeneration.

ABSTRACT BODY:

Purpose: Primary Open Angle Glaucoma (POAG), the most common form of glaucoma, is characterized by progressive loss of retinal ganglion cells (RGCs) and their axons. Elevated intraocular pressure (IOP) is the major risk factor for POAG. The neurodegeneration in POAG extends beyond the eye into the visual centers of the brain (VCB). Unfortunately, the underlying pathological mechanisms responsible for IOP-induced glaucomatous neurodegeneration still remain unclear. To this end, we have developed a novel glucocorticoid (GC)-induced mouse model of glaucoma, and determined the role of GC-induced ocular hypertension (OHT) on synaptic dysfunction, and how alterations in synaptic plasticity contribute to glaucomatous neurodegeneration in the VCB.

Methods: C57BL/6J mice were injected with either Dexamethasone (Dex) or Vehicle (Veh) via periocular-route, once a week for 10-weeks. IOP was measured every week and glaucomatous neurodegeneration was examined using pattern ERG (pERG), whole mount retina staining with RBPMS antibody and PPD staining for optic nerve (ON) degeneration. The electrical response of the brain's primary visual cortex was measured using visually evoked potential (VEP). Expression of synaptic markers in the VC of the brain were assessed by immunostaining.

Results: Dex-induced sustained OHT led to glaucomatous neurodegeneration in 10-weeks Dex treated mice compared to Veh treated mice. Glaucomatous neurodegeneration was associated with significant functional and structural loss of RGCs as evident from reduced pERG amplitudes (10 μ V v/s 25 μ V), with ~33% RGC loss and ~62% axonal loss. We observed RGC hyper excitability during the early stages of axonal damage with significantly increased VEP amplitudes with decreased latencies in 5-weeks Dex treated mice (32 μ V; 73ms) compared to Veh mice (26 μ V; 79ms). Interestingly, we observed complete collapse of neuronal excitability, with decreased VEP amplitudes and increased latencies in 10-weeks Dex treated mice (12 μ V; 132ms) due to chronic IOP elevation. Also, we observed an altered synaptic plasticity with decreased expression of both pre and post synaptic markers (VGLUT-2 and PSD-95 respectively) in the VC of the 10-weeks Dex treated mouse brain.

Conclusions: These data highlights that OHT alters neurotransmission and axonal synaptic plasticity in the VC of the brain during the progression of glaucomatous neurodegeneration.

ABSTRACT BODY:

Purpose: This study evaluates the longitudinal retinal and sub-retinal pigment epithelium (RPE) dynamics on spectral domain optical coherence tomography (SD-OCT) and their associations with the long-term development of subfoveal geographic atrophy (sfGA) in non-neovascular age-related macular degeneration (AMD).

Methods: This retrospective cohort study compared eyes with non-neovascular AMD without sfGA using macular cube SD-OCT scans available at baseline, year 1, and year 5. Based on disease status at year 5, eyes were classified into one of two subgroups: non-conversion or sfGA converter. Macular cube scans at baseline and year one were evaluated using a machine learning-enhanced multi-layer segmentation software followed by manual verification by expert readers. Outer retinal integrity (e.g., ellipsoid zone (EZ)) and the sub-RPE compartment metrics were exported for comparative assessment. T-tests and Wilcoxon signed-rank test were used to compare sfGA converters and non-converters.

Results: One hundred and seventeen eyes were included in this analysis. Baseline mean EZ-RPE volume (i.e., surrogate for photoreceptor outer segment volume) was significantly smaller in the sfGA converter group compared to the non-converter group ($0.017 \pm 0.008 \text{ mm}^3$ vs $0.027 \pm 0.006 \text{ mm}^3$, $p=0.003$). In the first year, mean EZ-RPE volume decreased significantly in the sfGA converter group ($-0.0067 \pm 0.008 \text{ mm}^3$, $p<0.001$) but unchanged in the non-converter group ($-0.0007 \pm 0.003 \text{ mm}^3$). Baseline total EZ attenuation was significantly higher in the sfGA converter group compared to the non-converter group (4.14% vs 0.64%, $p<0.001$). The baseline RPE-BM volume (i.e., drusen burden) was significantly higher in the sfGA converter group (compared to the non-converter group ($0.045 \pm 0.024 \text{ mm}^3$ vs. $0.021 \pm 0.013 \text{ mm}^3$, $p=0.001$).

Conclusions: Higher order assessment of targeted retinal layer compartments identified significant differences in eyes that developed sfGA compared to eyes that did not over a 5-year period. Specific anatomic features, such as photoreceptor integrity are associated with development of sfGA and should be further explored as potential predictive biomarkers.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) is the leading cause of blindness in 20-74 year-old U.S. adults. Genetic factors, including single nucleotide polymorphisms (SNPs), have been correlated with DR susceptibility and progression. Our goal is to develop a platform to explore novel associations between DR phenotypes and genetic variants.

Methods: We queried the Synthetic Derivative (SD), a de-identified database from VUMC's electronic health record linked to DNA samples. A combination of ICD and CPT codes was used to classify all SD records by presence of diabetes mellitus (DM), DR, non-proliferative and proliferative DR (NPDR, PDR), and diabetic macular edema (DME). We used Quanto software to calculate the expected statistical power of this platform to detect associations between vision threatening DR (VTDR) and SNPs of varying allele frequencies (AF). To confirm the accuracy of our code-based search criteria, presence of DM, DR, NPDR, PDR and DME was confirmed by manual review for a random sub-sample. Data regarding additional characteristics (risk factors, comorbidities, diagnostics, therapeutics) were also manually collected. We used Pearson's analysis to correlate the prevalence of these characteristics with DR susceptibility and progression (control vs DR, NPDR vs PDR, and no DME vs DME) in our sub-sample.

Results: A total of 5447 controls, 1168 NPDR, 734 PDR, and 441 DME cases met ICD/CPT code-based search criteria. This platform has >80% power to detect odds ratios >1.4 for SNPs with AF >35% using pre-existing genetic data, and for SNPs with AF >10% among all records. DR status and clinical characteristics were confirmed by manual review of 155 controls, 134 NPDR, 178 PDR, and 188 DME cases. Among these, Type 1 DM, nephropathy, and neuropathy were more prevalent in DR cases than controls ($p<0.00001$) and in PDR than NPDR cohorts ($p<0.05$). Type 2 DM, obesity, and hypertension were more prevalent in cohorts with DME than without ($p<0.05$) but had no evidence of association with progression to PDR. There was no evidence of association between gender, smoking, mortality, and hyperlipidemia with DR susceptibility or progression.

Conclusions: Our platform is clinically relevant and adequately powered to detect associations between SNPs and VTDR. We will use this resource to explore novel associations that may provide insights into DR pathophysiology, diagnosis, and management.

ABSTRACT BODY:

Purpose: While it is known that altitude affects intraocular pressure (IOP), the underlying mechanisms remain unclear. Mean arterial pressure (MAP) and osmotic pressure difference (OPD) are considered important factors governing the IOP change with altitude. Herein we use a novel physiology-enhanced approach to analyze data from the Mont Blanc Study (MBS) (Bruttini et al. 2020), with the goal of assessing the relative roles of MAP and OPD on IOP.

Methods: In MBS, IOP and MAP were measured in 33 healthy volunteers at 77 m above sea level (a.s.l.) (Pavia, PV, Italy), at 1,300 m a.s.l. (Courmayeur, CM, Italy) and 3,466 m a.s.l. (Pointe Helbronner, PH, Mont Blanc Mountain, Italy), in addition to other systemic factors. A validated mathematical model for aqueous humor (AH) circulation (Szopos et al 2016) was used to analyze the MBS data. In the model, IOP is predicted as the result of the balance between AH production and drainage, with MAP and OPD included as parameters regulating AH production.

Results: A first analysis is conducted using measured MAP as an individualized model input to predict the corresponding IOP and compare it with IOP measured at different altitudes (PV, CM, PH). Fig.1 shows that changes in MAP are not sufficient to explain the measured IOP differences, since the measured IOP decreases with altitude while the model-predicted IOP increases. A second analysis is conducted by using the measured MAP and IOP as an individualized model inputs and estimates the OPD that would be necessary to have AH flow balance at different altitudes (PV, CM, PH). Fig. 2 shows that changes in OPD, in conjunction with MAP, capture the decreasing trend of IOP with altitude as observed in MBS.

Conclusions: Physiology-enhanced data analytics based on mathematical modeling suggests OPD plays an important role in regulating IOP with changes in altitude. Modeling factors that are conjectured to be relevant such as OPD may provide insights into parameters that cannot be measured directly. Future model analytics will include the effect of temperature and central corneal thickness for enhanced specificity.

TITLE: The Development of Retinal Function and Refractive Error in Retinopathy of Prematurity

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. De Bruyn, N. Mergia, V. Selian, R. Hansen, J.D. Akula, A.B. Fulton, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|R. Hansen, J.D. Akula, A.B. Fulton, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hanna De Bruyn: Commercial Relationship: Code N (No Commercial Relationship) | Nebyou Mergia: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Selian: Commercial Relationship: Code N (No Commercial Relationship) | Ronald Hansen: Commercial Relationship: Code N (No Commercial Relationship) | James Akula: Commercial Relationship: Code N (No Commercial Relationship) | Anne Fulton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the association of development of retinal function with refractive error in those with a history of retinopathy of prematurity (ROP).

Methods: Rod-mediated thresholds for detecting blue, 2°-diameter, 50-ms duration spots at both 10° and 30° were estimated in dark-adapted subjects (N=140) aged 10 weeks post-term through adulthood using a two-alternative, forced-choice, transformed up-down staircase method. Preterm-born subjects were stratified according to maximum severity of acute phase ROP: (1) Never developed ROP, None (n=32); (2) Mild ROP, resolved without treatment (n=67); and (3) Severe ROP that required ablative treatment (n=13). Healthy Term-born subjects (n=28) served as controls. Additionally, maturation of visual acuity [VA, expressed as log₂(cycles/degree)] and spherical equivalent (SE, diopters) were summarized; a single value for VA and SE at age 10 years was predicted using linear mixed-effects modeling. Each subject's course of threshold maturation was expressed relative to normal threshold development (De Bruyn et al., ARVO 2020) at both 10° and 30°. These parameters were evaluated as significant predictors of SE at age 10 years using stepwise linear regression, by: (1) Group (None, Mild, Severe), (2) threshold at 30°, (3) threshold at 10°, (4) difference (Δ 10–30), and (5) VA.

Results: In accord with previous reports, threshold development at 10° was significantly delayed in those with ROP. Developmental increase in VA proceeded most rapidly in None and most slowly in Severe. Likewise, all preterm groups showed progression of SE from hyperopia to myopia, slowest in None and most rapid in Severe. Preterm group (None, Mild, Severe) was a predictor of SE. Of the threshold parameters, only threshold development at 10° was a significant predictor of SE at age 10 years. Threshold development at 30° was not.

Conclusions: Given that the retina is a controller of refractive development, that VA is a measure of central retinal function, and that threshold development at 10° and 30° are respective measures of retinal function at nearer and farther peripheral retina, these data suggest that the nearer periphery (i.e., 10°) mediates refractive development. These results dovetail with the demonstration that retinal control of simian eye growth and refractive development is greatest at near-peripheral retinal eccentricities (Smith III et al., IOVS 2020).

TITLE: Ocular Injuries Caused by Intimate Partner Violence Using an Emergency Room Database – a Gender-Based Analysis

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Malhotra, Y. Shah, N. Bhagat, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Radhika Malhotra: Commercial Relationship: Code N (No Commercial Relationship) | Yash Shah: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intimate partner violence (IPV) is a leading cause of visits to the emergency department (ED), estimated in up to 35% cases. Literature suggests that orbital fractures are highly suggestive of domestic violence injuries and can often go underreported. It is important for emergency room physicians and ophthalmologists to be able to recognize ocular injuries caused by IPV. The aim of our study is to determine the epidemiologic trends of IPV related-ocular injuries presenting to the emergency department.

Methods: The National Electronic Injury Surveillance System-All Injury Program (AIP) (NEISS–AIP) was queried for injuries specifically involving the eyeball for the years 2006 to 2016. IPV was defined by sexual or other assault conducted by a spouse or a partner. Cases were weighted per the SUDAAN protocol, and statistical analysis was conducted with weighted data for frequency of injury by gender. Frequencies of race, incident locale, disposition from ED, reason for assault, precipitating injury, diagnosis, hospital size, and treatment month were conducted.

Results: Females were more likely to experience ocular injury as a result of IPV than males (n=18748 vs n=6667) at a younger average age (32.8 vs 36.7). By race, Black males and females were more likely than their white counterparts to have ocular injury as a result of IPV (black men 47.5% vs white men 18.1%, black females 35.5% vs white females 27.2%). The most common ocular injury in both genders involved ocular contusion/abrasions (males 43.4% vs females 53.4%), and subjects were most likely to be treated and released home. In males, the precipitating cause of injury was either being struck by an object or injury by fire (struck 66.1% vs fire 30.6%), whereas females were overwhelming injured by a striking injury (90.4%). Both males and females were most likely to be diagnosed with a contusion or abrasion injury.

Conclusions: Females are more likely to present with ocular injuries as a result of IPV, especially younger females. However, our study shows that men can also be victim to IPV, and are more likely to present with ocular injuries due to fire or burns as a result of intimate partner violence. The Black population is at higher risk of intimate partner violence. Consideration of IPV when a patient presents with a contusion or abrasion injury is important as IPV patients are likely to present to the ER again due to abuse.

TITLE: The SF properties of European, Middle-Eastern and Asian text and the potential implications for myopia development.

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.I. Flitcroft, B. Fitzpatrick, J. Loughman, Centre for Eye Research, Technological University Dublin, Dublin, Dublin, IRELAND|D.I. Flitcroft, Ophthalmology, Children's Health Ireland at Temple Street, Dublin, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Daniel Flitcroft: Commercial Relationship: Code N (No Commercial Relationship) | Brian Fitzpatrick: Commercial Relationship: Code N (No Commercial Relationship) | James Loughman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Reading and education are a well-recognised risk factors for myopia development, furthermore there are marked geographical differences in myopia prevalence in school age children. This study analyses the spatial frequency (SF) attributes of the printed text in a range of different alphabets/languages to determine the potential implications for myopia development.

Methods: Texts in 12pt font in English (Roman alphabet), Russian (Cyrillic script), Greek, Hebrew, Arabic, Chinese (simplified and traditional characters), Korean and Japanese were analysed at a 30cm viewing distance. The page layout was identical for each language. A photopic luminance image was generated and analysed to generate rotationally averaged SF spectra. The slope of the log amplitude vs log SF relationship (SF slope) was the calculated for each text sample at low (0.5-2 c/deg), intermediate (2-8 c/deg) and high (8-32 c/deg) spatial frequencies.

Results: Printed text has SF properties that differ markedly from natural or man-made images, yet the very different alphabets shared similar spatial characteristics. The log amplitude vs log SF relationship was highly non-linear with three distinct quasi-linear segments in low, intermediate and high SF ranges. This was most marked in Chinese text. There were also narrow spectral peaks corresponding to line spacing and/or character spacing. The slope of the low and intermediate SF segment was much flatter than natural images (low: mean -0.39, sd 0.30; intermediate: mean -0.27, sd 0.19) but the high frequency segment was much steeper, comparable to those reported for indoor environments (mean -1.76, sd 0.16) (See Table 1). There was a significant difference between low/intermediate and high SF slopes ($P < 0.0001$). All Asian languages showed a significantly steeper high SF slope than European/Middle Eastern languages ($P < 0.0005$). No significant differences were observed between serif and sans-serif fonts in English text.

Conclusions: The printed word has very different spatial properties to natural scenes with increased contrast at low/intermediate SF, but reduced high SF content which resembles man-made environments. At high spatial frequencies Asian languages show a significantly steeper log amplitude vs log SF relationship than European/Middle Eastern languages. Spatial properties of the written word may potentially contribute to regional variations in myopia.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRDs) are a group of rare genetic conditions that lead to degenerative vision loss. Current literature gaps exist around the lived experience of Canadian individuals with IRDs and the associated impacts on health usage, policy, and care. This study aims to understand the physical, psychosocial, and practical challenges faced by those with lived experience, and to identify areas of need and reform from a medical, health policy, and social care perspective.

Methods: This sequential mixed method study comprised an online survey of Canadians living with or caring for someone with an IRD. Survey data fields included demographics, self-reported vision, genetic testing, information needs and preferences, healthcare management and experiences, treatment goals, and disease impact on productivity and social functioning. Recruitment occurred through Fighting Blindness Canada's patient database, filtering by disease-type. Survey dissemination also occurred via social media, newsletters, and not-for-profit stakeholder organizations to their constituents. A subset of respondents also participated in telephone interviews to more deeply explore the burden of their condition.

Results: Between March and June 2020, 408 individuals (mean age = 51.4 yrs \pm 16.7; male = 45.7%) participated in our survey. Respondents identified having one of over 14 IRDs, with 72% specifying retinitis pigmentosa. 68% reported being legally blind. Having an IRD had significant impacts on daily functioning, with 53% of participants indicating affected employment or education and 43% specifying a severe or very severe impact on mobility. Psychological burdens were evident: >70% worried about coping with daily life and 68% indicated frequent feelings of depression and hopelessness. Interviewees described their most significant disease impacts being loss of independence and challenges with social interaction. Despite this, the majority of respondents had not accessed support services, including counseling, mobility training or career support, due to a lack of awareness and/or access.

Conclusions: Our study describes the Canadian IRD community, including support network and impact of vision loss on daily activities and wellbeing. This data highlights the pronounced psychosocial burden that IRDs have on Canadian patients and families while elucidating unmet need for treatments, awareness, and support.

TITLE: Handheld chromatic pupillometry detects functional retinal loss in patients with retinal dystrophies

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.W. Lam, National University of Singapore, Singapore, SINGAPORE|R. Mathur, C. Chan, D. Milea, R. Najjar, Singapore National Eye Centre, Singapore, Singapore, SINGAPORE|R. Mathur, P. Chougule, D. Milea, R. Najjar, Singapore Eye Research Institute, Singapore, SINGAPORE|

Commercial Relationships Disclosure (Abstract): Walter Sze Tung Lam: Commercial Relationship: Code N (No Commercial Relationship) | Ranjana Mathur: Commercial Relationship: Code N (No Commercial Relationship) | Choi Mun Chan: Commercial Relationship: Code N (No Commercial Relationship) | Pratik Chougule: Commercial Relationship: Code N (No Commercial Relationship) | Dan Milea: Commercial Relationship: Code N (No Commercial Relationship) | Raymond Najjar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the ability of handheld chromatic pupillometry (HCP) to characterise and evaluate functional loss in patients with inherited retinal dystrophies (IRD).

Methods: In a cross-sectional study, we included 47 patients with IRD and 26 age-matched controls (44.5 ± 14.2 years, 53.8% males). The IRD population included 27 patients with rod-cone dystrophies (RCD, 50.7 ± 16.9 years, 55.6% males) and 20 patients with cone or cone-rod dystrophies (CRD, 53.8 ± 15.8 years, 50% males). Prior to an extensive ophthalmic examination that included electroretinography, participants underwent monocular evaluation of the pupillary response to 9 seconds of ramping-up blue (469nm) and red (640nm) light stimuli (45° field, 12.5-14 log photons/cm²/s). Pupillary light responses (PLRs) were assessed using a custom-built handheld pupillometer. Baseline-adjusted pupillary constriction traces were calculated for each participant and pupillometric features were extracted and compared between groups using a one-way ANOVA followed by a Holm-Sidak pairwise comparison.

Results: PLRs were altered in IRD patients (Fig. 1) who displayed a reduction in phasic constriction to blue and red lights compared to controls ($P < 0.05$). RCD patients showed a greater reduction in the phasic constriction to blue light compared to CRD patients ($P = 0.03$). Maximum constrictions to both lights were also reduced in IRD groups compared to controls. The early pupil redilation slope, calculated within 1.7s from blue light offset, an indicator of outer retinal contribution to the predominantly melanopsin-driven post-illumination pupillary response (PIPR), was decreased in IRD patients compared to controls ($P < 0.001$). Consequently, the Net PIPR (blue PIPR - red PIPR) was increased in IRD patients, yet, this increase was not statistically significant ($P = 0.09$) (Fig. 2).

Conclusions: Pupillometric features mainly driven by rods and cones (e.g., phasic constriction, early redilation slope) are altered in IRD patients. HCP can identify outer-retinal dysfunction and may provide a rapid method for detecting eyes with IRD.

TITLE: Effects of cigarette smoke extract on the zebrafish visual system

SESSION TITLE: Retinal physiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Gómez Sánchez, B. Colligris, Ocupharm Diagnostics Group Research, Madrid, SPAIN|A. Gómez Sánchez, Y. Álvarez Teruel, B.N. Kennedy, University College Dublin School of Biomolecular and Biomedical Science, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Alicia Gómez Sánchez: Commercial Relationship: Code N (No Commercial Relationship) | Basilio Colligris: Commercial Relationship: Code N (No Commercial Relationship) | Yolanda Álvarez Teruel: Commercial Relationship: Code N (No Commercial Relationship) | Breandan Kennedy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cigarette smoke is composed of hundreds of chemical products. Chronic smoking can damage human vision and is linked to development of age-related macular degeneration, cataract, glaucoma, diabetic retinopathy and dry eye syndrome. Here, we investigate the acute effect of cigarette smoke extract on the visual system of zebrafish larvae (*Danio rerio*).

Methods: Cigarette smoke extract (CSE) was tested at 10 and 20 µg/ml by adding directly to zebrafish embryo medium at 3 days post fertilisation (dpf). At 5 dpf, visual behavioural assays were conducted using a rotating striped drum which evokes saccadic eye movements known as the optokinetic response. Heartbeats were manually counted in one minute by direct observation. Startle response to touch was measured by touching larval caudal fins and manual observation. Retinal sections were imaged by light microscopy.

Results: There were no differences in gross morphology between vehicle control and the CSE treated larvae. However, CSE treatment resulted in a significantly ($p=0.0001$) lower number of saccades (10/minute) than 0.05% DMSO controls (19/minute) at standard frequency of 0.02 cycles per degree (cpd). Visual acuity data indicates CSE treated larvae exhibit a significant ($p=0.047$) deficit (0 saccades/minute) compared to control larvae (5 saccades/minute) at the highest frequency of 0.2 (cpd). Images of retina sections revealed no obvious effects of CSE on retina histology. The heartbeat rate of CSE treated larvae was within standard range and locomotor activity evoked by touch response was indistinguishable from 0.05% DMSO larvae.

Conclusions: Acute CSE treatment affects zebrafish visual function but retina histology remains intact. CSE has no adverse effects on zebrafish heart rate or startle response. Zebrafish offer an *in vivo* model to investigate the effects of CSE on vision.

Commercial Relationships Disclosure (Abstract): Soobin Song: Commercial Relationship: Code N (No Commercial Relationship) | Colin Lemire: Commercial Relationship: Code N (No Commercial Relationship) | Purva Atreay: Commercial Relationship: Code N (No Commercial Relationship) | Brendan Seto: Commercial Relationship: Code N (No Commercial Relationship) | Keiko Yamada: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Arroyo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetes Mellitus can lead to ocular complications that include retinal ischemia and macular edema. Current common practices to treat patients with such conditions often include anti-vascular endothelial growth factor (VEGF) injections or focal lasers, which target the production of angiogenic factors such as VEGF and vascular leakage, respectively. This retrospective study explored the supplemental effects of Nocturnal Normobaric Hyperoxia (NNBH) treatment in patients with Diabetic Macular Edema (DME).

Methods: Of 9 patients diagnosed with diabetic retinopathy and presenting macular edema, 7 adhered to self-administering 3 to 5 LPM normobaric hyperoxia (40% FiO₂) overnight for at least 180 days. Macular Optical Coherence Tomography (OCT) imaging and ETDRS Visual Acuity measurements were taken for each eye (n=14) periodically for 180 days before NNBH and a following 180 days while on NNBH. Subjects' measurements during the control time period were compared with those from the time period on NNBH using Wilcoxon Rank Sum Test. The number of anti-VEGF injections administered to each eye during each time period was also analyzed.

Results: On average, patients saw decreases in the number of anti-VEGF injections needed while on NNBH ($p<0.05$). Additionally, the length of time between injections increased on average. Variability in macular thickness and volume while on NNBH was also shown to be decreased when compared to measurements collected while off NNBH.

Conclusions: The data suggests that oxygen therapy may be beneficial in minimizing the progression of edema and its detrimental effects to visual acuity as evidenced by the more stable values of macular thickness and volume in patients with DME. NNBH is a low-cost therapy that may reduce the burden of treatment for diabetic retinopathy by lessening the need for anti-VEGF injections. These results also suggest further long-term studies may be necessary to delineate the comprehensive effects and elucidate the mechanism of supplemental oxygen in patients with DME.

ABSTRACT BODY:

Purpose: Corneal transplantation over the last decade has increasingly shifted towards selectively addressing pathologic layers as opposed to full-thickness tissue replacement. Such procedures include DMEK (Descemet's membrane endothelial keratoplasty), DSAEK (Descemet Stripping Automated Endothelial Keratoplasty), and DSO (Descemet's Stripping Only). In many cases, these newer procedures have led to improved final visual acuity, faster recovery times, and decreased incidence of graft rejection. Proper descemetorhexis is a critical step in these surgeries to avoid potential complications such as graft detachment, and stromal scarring.

Methods: Several variants of a handheld surgical device apparatus were designed to allow insertion into the anterior chamber through a standard 2.4 mm corneal incision. Parametric device designs were created using computer-aided design (CAD) software. An SLA 3D printer (Form 2, Formlabs ©) was used for prototyping using a commercially available, biocompatible resin. Prototypes were evaluated for their potential descemetorhexis application using ex vivo porcine eyes. The quality of descemetorhexis creation and relative ease of use were assessed. Results from empirical testing were then used to iterate and refine the design.

Results: Several prototypes were created, each evaluated based on intraocular manipulation stability, ease of use, and ability to create a circular descemetorhexis at the appropriate depth. Current device iterations— which include magnetically controlled, mechanically controlled, and a combined magnetic and mechanically controlled scoring of Descemet's membrane— resulted in successful descemetorhexis creation with minimal damage to neighboring anatomic structures.

Conclusions: A novel surgical device for descemetorhexis creation was created with a 3D printer for rapid prototyping, using an iterative design process. Prototypes were successfully used to create a circular descemetorhexis in ex vivo porcine eyes. Future work will be directed toward necessary design improvements and testing in vivo.

ABSTRACT BODY:

Purpose: Telemedicine utilization has risen dramatically during the COVID-19 pandemic, particularly during the state-wide shut down, but multiple factors contribute to its potential inaccessibility to different populations. To explore these factors, we conducted a prospective mixed-methods study to assess the relationship between telemedicine utilization and socio-demographic factors among patients seeking eye care. We also assessed patient satisfaction with eye care using a health disparities lens.

Methods: We conducted phone interviews with a stratified random sample of 1,720 patients who had a visit scheduled at the University of Michigan Kellogg Eye Center in Ann Arbor, Michigan from 4/30/20-5/25/20 to ascertain patient perception of care received during the COVID-19 pandemic. The participant data was stratified by visit type and then analyzed by demographic variables. A Chi-square test was used to assess for association between categorical variables. Associations between visit type were determined using a multinomial logistic regression model. Open ended questions were stratified by race and analyzed using grounded theory to identify whether themes varied through a disparities lens.

Results: Non-white patients had lower odds of having an in-person visit ($p < 0.02$). Older patients had lower odds of having a video visit ($p = 0.007$) and higher odds of having an in-person visit ($p = 0.023$) compared to younger patients. The mean neighborhood median household income varied significantly ($p < 0.0001$) by race with Blacks having the lowest estimated mean. Access to broadband signal with faster download speeds compared to slower was associated with lower odds of an in-person visit ($p = 0.022$). No differences between races were identified in patient satisfaction or perception of care.

Conclusions: Disparities existed in how patients accessed eye care during the COVID-19 pandemic with non-white patients less likely to access care. Coupled with other barriers such as lower income, which, on a population level, may limit access to broadband internet, reimbursing telemedicine solely through broadband internet connection may further exacerbate disparities in access to eye care. Insurers should consider continued reimbursement of telemedicine delivered via phone to prevent further marginalization of underserved communities.

ABSTRACT BODY:

Purpose: Impaired development and maintenance of the Schlemm's Canal (SC) vasculature, characterized by both venous and lymphatic identity, is associated with impaired aqueous humor outflow regulation and the progression of glaucoma and loss of vision. Several key molecular regulators, such as Angpt/TEK, VEGFC/VEGFR3, and PROX1, were demonstrated to regulate SC development and maintenance, but mechanisms of paracrine signaling from neighboring tissues and cells contributing to SC development are poorly understood. Human forkhead box (FOX) FOXC2 variants were identified as modifier factors in congenital glaucoma (Medina-Trillo et al. PLoS One 2019) and our laboratory demonstrated that neural crest (NC)-derived periocular mesenchymal cells require expression of Foxc2 for development of the anterior segment (Seo et al. IOVS 2017). However, the role of Foxc2 in contribution to the development of the SC has yet to be investigated.

Methods: Using Foxc2-Cre^{ERT2}; mTmG reporter mice, we identified positive FOXC2 expression in both NC-derived trabecular meshwork and SC endothelium. Foxc2 was deleted from NC-derived cells by crossing Foxc2^F mice with Wnt1-Cre mice. Eyes of NC-Foxc2-KO and control mice were imaged in vivo using a visible light optical coherence tomography (Vis-OCT) system as previously described (Zhang et al., IOVS 2020). Inducible deletion of Foxc2 from endothelial cells (EC) was achieved by administering tamoxifen postnatally to Cdh5-Cre^{ERT2}; Foxc2^F mice. Immunohistochemistry for characterization of SC morphology was performed on flatmounted eyes where the lens and retina were removed.

Results: Vis-OCT image volumes showed different levels of narrowed and discontinuous SC morphology in NC-Foxc2-KO mice while OCT angiography showed various levels of corneal neovascularization. Immunostaining of CD31 identified abnormal SC morphology, or the absence of SC, in NC-Foxc2-KO compared to Cre-negative mice, which was accompanied by reduced PROX1, VEGFR-3, and TEK expression. Additionally, deletion of Foxc2 in the endothelium resulted in impaired SC morphogenesis at postnatal day 7, which was accompanied by reduced TEK expression compared to littermate controls.

Conclusions: Both Foxc2 expression in the NC lineage and ECs is required for morphogenesis of the SC vasculature. NC-derived Foxc2 expression is key for maintenance of SC identity and EC-derived Foxc2 expression regulates SC TEK expression.

ABSTRACT BODY:

Purpose: Glaucoma is an insidious, asymptomatic and progressive eye disease that damages the optic nerve, and is one of the leading causes of blindness worldwide. People over the age of 60 are at highest risk, but it can occur in younger adults as well. Our research aims to identify novel loci influencing the age-at-onset (AAO) of glaucoma. Previous studies have identified susceptibility genes for glaucoma, i.e. those associated with glaucoma as a binary trait. Here, we examine a large dataset to identify specific genes that might influence the variation of AAO of glaucoma.

Methods: With large amounts of data available from the UK Biobank, a cohort of half a million individuals, we selected participants of European ancestry that presented with AAO for glaucoma as a case-only design study (n = 13,000). Over 800,000 genotyped and 92 million imputed single nucleotide polymorphisms were available in the dataset. We used Bayesian mixed-model association analysis (BOLT-LMM) to test for associations between the AAO and genotypes. Genetic variants with $P < 5 \times 10^{-8}$ were declared genome-wide significant.

Results: We identified two novel associations to AAO on chromosomes 9 and 18. SNPs rs7866318 at GLIS3 and rs72899117 at LINC01477 both show significant association with AAO of glaucoma, $P = 2.4 \times 10^{-8}$ and $P = 1.4 \times 10^{-8}$ respectively. Mutations in GLIS3 (GLI-similar zinc finger protein family, chr9), which encodes a protein involved in the development of the eye, have been previously associated with many diseases, such as neonatal diabetes, congenital hypothyroidism, Alzheimer's, and congenital glaucoma. LINC01477 (Long Intergenic Non-Protein Coding RNA 1477, chr18) has no known associated eye disorders, but it has been associated with mathematical ability and intelligence.

Conclusions: These discoveries further our understanding of the genetic loci influencing AAO of glaucoma, and shed new light on the biological processes underlying glaucoma.

TITLE: Inhibition of TNF- α and NF- κ B decreases epithelial-mesenchymal transition in cigarette smoke-induced proliferative vitreoretinopathy

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Wang, University of Rochester Medical Center, Rochester, New York, UNITED STATES|A. Heffer, E. Roztocil, S.E. Feldon, C. Woeller, A.E. Kuriyan, University of Rochester David and Ilene Flaum Eye Institute, Rochester, New York, UNITED STATES|A.E. Kuriyan, Retina Service, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Victor Wang: Commercial Relationship: Code N (No Commercial Relationship) | Alison Heffer: Commercial Relationship: Code N (No Commercial Relationship) | Elisa Roztocil: Commercial Relationship: Code N (No Commercial Relationship) | Steven Feldon: Commercial Relationship: Code N (No Commercial Relationship) | Collynn Woeller: Commercial Relationship: Code N (No Commercial Relationship) | Ajay Kuriyan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is the growth and contraction of cellular membranes within the vitreous cavity and on both surfaces of the retina and is the most common cause for recurrent retinal detachments. Cigarette smoke is associated with higher rates of PVR and our lab previously demonstrated elevations in proinflammatory cytokines TNF- α , IL-6, and IL-8 when RPE cells were exposed to cigarette smoke. Prior studies have shown that TNF- α induces RPE cells to upregulate epithelial-mesenchymal transition (EMT). The purpose of this study was to assess the effect of anti-inflammatory drugs on EMT pathogenesis in vitro and of cigarette smoke exposure on EMT markers in vivo.

Methods: Human ARPE-19 cells were pre-treated with a direct TNF- α inhibitor (Cas 1049741) or Bay-11, an NF- κ B inhibitor, before culture with concentrations of cigarette smoke extract (CSE) ranging from 0% to 1%. Cells were harvested after 24 hours and analyzed by quantitative PCR (qPCR) for known markers of inflammation and EMT, with at least 3 replications. In vivo mouse eyes were injected with ARPE-19 cells alone or ARPE-19 cells treated and resuspended in 0.5% CSE and sacrificed at 4 weeks for histologic analysis and immunohistochemistry staining (n=25). T-test and qualitative analysis were performed for in vitro and in vivo assays, respectively.

Results: ARPE-19 cells pre-treated with direct TNF- α inhibitor showed no significant differences in TNF- α expression but significantly decreased expressions of Snail (by 53%), IL-6 (by 50%), and IL-8 (by 82%) mRNA ($p < 0.05$). Bay-11 pre-treatment resulted in 78% decreased TNF- α as well as decreased expressions in Snail (by 77%), IL-6 (by 74%), and IL-8 (by 93%) ($p < 0.05$). Our in vivo studies showed a significantly higher mean PVR grade in mice injected with CSE-treated RPE cells (4.82 \pm 1.08) compared to mice injected with RPE cells alone (3.43 \pm 1.45, $p < 0.05$). Immunohistochemistry data showed that intravitreal injection of CSE-treated RPE resulted in significantly elevated vimentin and α -SMA protein expression in mouse retinal tissue, compared to RPE cells alone.

Conclusions: We demonstrate that inhibiting TNF- α or the NF- κ B pathway in RPE cells exposed to CSE also inhibits downstream proinflammatory and EMT pathways, suggesting that the TNF- α /NF- κ B/Snail pathway may be a viable target for inhibiting EMT pathogenesis and PVR progression.

ABSTRACT BODY:

Purpose: To determine if intravitreal administration of the core peptide of α -B crystallin, peptain-1 (P1) conjugated to a cell permeable peptide CPP (P1-CPP) could inhibit retinal ganglion cell (RGC) loss and functional decline in a rodent model of glaucoma.

Methods: Primary RGCs were isolated from post-natal day 4-6 rat pups. The cultured RGCs were deprived of neurotrophic factors for 48 h in the presence of either P1-CPP (12.5 μ g/ml) or vehicle, following which RGC survival was assessed by CytoCalcein™ Violet 450. In a different set of experiments, intraocular pressure (IOP) was elevated in one eye of Brown Norway (BN) rats and intravitreally injected with 2 μ l of either P1-CPP (2 μ g per eye) or vehicle, once in a week for a period of 6 weeks. RGC function was assessed by the pattern electroretinogram (PERG) amplitude and compared between all the treatment groups. Following the treatments, the rats were euthanized by approved methods, retinal flat mounts obtained were stained with an antibody to the RGC marker, Brn3a, to assess RGC counts. Retinal flat mounts were imaged and surviving RGCs were counted.

Results: In primary RGCs neurotrophic factor deprivation treatment for 48h led to 83% of RGC loss compared to cells grown in complete medium ($p < 0.0001$). P1-CPP treatment significantly lowered the neurotrophic factor-mediated RGC loss by 64% ($p < 0.0001$). IOP elevated and vehicle injected animals had 1192 ± 279 per mm^2 surviving RGCs in eccentricity 2 and 700 ± 246 per mm^2 in eccentricity 3, while P1-CPP treated rats had significantly higher RGC counts (1482 ± 388 and 1054 ± 343 respectively; $**p < 0.01$). P1-CPP treatment also promoted axonal protection during IOP elevation. IOP elevation caused 63% decline in the PERG amplitude ($*p < 0.03$) in comparison with naïve rats, which was sustained by P1-CPP treatment.

Conclusions: Intravitreal administration of P1-CPP provides cellular as well as functional protection of RGCs, and has the potential to facilitate neuroprotection in glaucoma.

ABSTRACT BODY:

Purpose: Advanced glycation end products (AGEs) promote retinal endothelial cell (EC) activation, a hallmark of early diabetic retinopathy (DR). We recently reported that lysyl oxidase (LOX)-dependent subendothelial matrix stiffening mediates the inflammatory effect of AGEs on retinal ECs. Yet, precisely how matrix stiffening promotes AGE-mediated retinal EC activation remains unknown. Addressing this question is the main objective of this study.

Methods: Human retinal endothelial cells (HRECs) were treated with methylglyoxal (MGO, 10 μ M) for 10 days. AGE (MG-H1) and RAGE levels were measured by ELISA and western blotting (WB), respectively while EC activation was determined by ICAM-1 expression (WB) and monocyte-EC adhesion. LOX expression and collagen IV (Col IV) deposition were assessed by WB and immunofluorescence, respectively, while the stiffness of decellularized matrix was measured using atomic force microscope. The direct effect of matrix stiffness on RAGE and ICAM1 mRNA was assessed by plating the fresh ECs on decellularized matrices. Finally, the role of LOX and RAGE in AGE-mediated effects was confirmed by adding LOX inhibitor BAPN and RAGE-antagonist in these studies.

Results: Our findings revealed that MGO-treated HRECs exhibit significant increase in AGE formation (MG-H1, $p < 0.001$), RAGE ($p < 0.01$), and ICAM-1 ($p < 0.01$) expression while simultaneously increasing LOX, Col IV deposition, and matrix stiffness. Importantly, inhibition of LOX-dependent matrix stiffening suppressed the AGE-induced ICAM-1 expression/clustering ($p < 0.0001$) and monocyte-EC adhesion ($p < 0.0001$). Crucially, we found that inhibiting LOX-dependent matrix stiffness blocks the inflammatory effects of AGEs by decreasing RAGE expression. Finally, pharmacological inhibition of RAGE prevented AGE-induced LOX expression ($p < 0.001$). Collectively, these studies indicate that although RAGE signaling is upstream of LOX-dependent matrix stiffness, the latter feeds back to regulate RAGE expression. Ongoing in vivo studies aim to confirm the role of LOX-dependent vascular stiffening in controlling RAGE-mediated retinal vascular inflammation in diabetes.

Conclusions: These findings reveal a previously unknown and potentially crucial role of LOX-dependent vascular stiffening in AGE/RAGE signaling and associated retinal EC activation and provide the basis to examine this pathway as a novel anti-inflammatory strategy for effective DR management.

ABSTRACT BODY:

Purpose: Photoreceptor death induces remodeling of bipolar cell (BC) dendrites. This remodeling is accompanied by changes in gene expression, but the gene networks that are involved in this rewiring are poorly understood. Furthermore, gene therapies are being developed to halt and rescue photoreceptors from degeneration. The halting of photoreceptor death at different timepoints in the degeneration process is likely to have distinct consequences on the morphologies and gene expression patterns of postsynaptic BCs. The purpose of this study was to examine how progressive photoreceptor degeneration impacts the transcriptomes of BCs and how these transcriptomes are altered by the genetic rescue of rods from degeneration.

Methods: Mice with a floxed neomycin cassette inserted into the Cngb1 locus (Cngb1^{neo/neo}) were crossed with UBC-cre and Grm6-GFP mice to create a triple transgenic line. These mice express green fluorescent protein (GFP) in BCs and exhibit a slow form of rod degeneration (all rods are lost ~6 months). Also, this line allows for genetic rescue of rods by tamoxifen-induced cre-recombination that triggers the expression of Cngb1 from the endogenous locus. Littermates heterozygous for the neomycin cassette were used as controls. At designated ages, mice were sacrificed, retinas dissociated using papain, and FACS sorted into GFP+ and GFP- cell populations, which yielded relatively pure populations of sorted BCs for RNA extraction and transcriptomic analysis.

Results: We found significant BC gene expression differences between groups that depended on the amount of rod degeneration and the time-point of rod rescue: WT vs degenerating (P30, P90, P210), untreated vs treated, and early treatment (Tx at P30) vs late treatment (Tx at P90). There were fewer differentially expressed genes between late-stage degenerating bipolar cells (P90 untreated) and late treated bipolar cells (Tx at P90, sac at P150), indicating that late therapy is not fully reversing pathology.

Conclusions: These results identify gene networks in postsynaptic BCs that respond to rod degeneration and death. These results also point toward the development of novel therapies to ameliorate blinding conditions and increase the effectiveness of vision restoration.

TITLE: Elevated Expression of ADAM 12 and 19 in Human Glaucoma Lamina Cribrosa Cells

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Smyth, C.J. O'Brien, Dept of Ophthalmology, Mater Misericordiae University Hospital, Dublin, IRELAND|A. Smyth, M. Irnaten, S.K. Powell, C.J. O'Brien, Clinical Research Centre, University College Dublin, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Aoife Smyth: Commercial Relationship: Code N (No Commercial Relationship) | Mustapha Irnaten: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Powell: Commercial Relationship: Code N (No Commercial Relationship) | Colm O'Brien: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The lamina cribrosa (LC) of the optic nerve head is a key site of damage in glaucoma. A disintegrin and metalloproteinase (ADAM) 12 & 19 are members of a family of transmembrane, multidomain proteins implicated in a variety of cellular activities including proteolysis, cell adhesion, signalling and the regulation of growth factors through ectodomain shedding. Both ADAM 12 & 19 have been shown to be upregulated in numerous cancers and fibrotic processes. Stimulation of renal cells with TGF β , a key mediator of fibrosis, upregulates ADAM 12/19 expression via Smad2/3 phosphorylation. MiR29b, a microRNA which is believed to play an antifibrotic role, blocks the TGF β -induced overexpression of ADAM12. Our lab has previously shown that glaucoma LC cells have elevated pro-fibrotic gene expression. Here, we investigate the expression of ADAM12 & 19 in normal and glaucoma lamina cribrosa cells and examine their role in extracellular matrix gene production.

Methods: LC cells were obtained from 2 normal and 2 glaucoma age matched human eye donors. Cells were cultured under physiological conditions. Quantitative real time reverse transcriptase Polymerase Chain Reaction (qRT-PCR) was performed to measure the expression level of ADAM 12 and 19 mRNA in normal LC cells compared to glaucoma LC cells. The relative expression of both genes of interest ADAM 12 & 19 was calculated using $\Delta\Delta C_t$ method. The ribosomal gene 18S was used as housekeeping gene.

Results: ADAM 12 and ADAM 19 transcription levels are significantly ($p < 0.05$) enhanced in glaucoma LC cells compared to normal LC cells. The relative transcription level of ADAM 12 increased from 0.48 ± 0.049 in NLC to 0.76 ± 0.067 in GLC, and the relative expression level of ADAM 19 increased from 0.61 ± 0.058 in NLC to 0.82 ± 0.077 in GLC. The relative expression level of genes was determined using the $\Delta\Delta C_t$ method, with data normalized to the internal reference gene 18S.

Conclusions: Here we have shown ADAM 12 and 19 to be significantly upregulated at the lamina cribrosa in glaucoma. We are currently investigating whether mir29b may play a role in suppressing the upregulation of ADAM 12/19 in glaucoma LC cells and therefore, may represent a potential future therapeutic target for the prevention of fibrotic transformation at the lamina cribrosa in glaucoma.

TITLE: Differential bile acids biosynthetic pathways in the developing retina and in the oxygen-induced model of retinopathy of prematurity

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Thounaojam, S. Rajpurohit, H. Abouhish, M. Bartoli, Ophthalmology, Augusta University, Augusta, Georgia, UNITED STATES|J. Zou, Chemistry, Augusta University, Augusta, Georgia, UNITED STATES|R. Jadeja, P.M. Martin, Biochemistry and Molecular Biology, Augusta University, Augusta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Menaka Thounaojam: Commercial Relationship: Code N (No Commercial Relationship) | Shubhra Rajpurohit: Commercial Relationship: Code N (No Commercial Relationship) | Hossameldin Abouhish: Commercial Relationship: Code N (No Commercial Relationship) | Juan Zou: Commercial Relationship: Code N (No Commercial Relationship) | Ravirajsinh Jadeja: Commercial Relationship: Code N (No Commercial Relationship) | Pamela Martin: Commercial Relationship: Code N (No Commercial Relationship) | Manuela Bartoli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently reported the differential ability of various secondary conjugated bile acids (BAs) in ameliorating pathological neovascularization in a mouse model of oxygen-induced retinopathy (OIR). Several studies have also shown the existence of primary BAs synthetic pathways in extrahepatic tissues, such as brain and retina, however no information is available on this metabolic pathway in the postnatal developing retina. Here, we have investigated retinal BAs synthesis in mice during normal postnatal development and in response to the OIR model of retinopathy of prematurity (ROP).

Methods: OIR was induced in mouse pups by subjecting them to different oxygen tensions, according to the protocol of Smith et al. Changes in sterol and BAs metabolic pathways in control and OIR mice were evaluated by RNA sequencing(RNAseq) using an Illumina HiSeq 2500 sequencer. Retinal expression of key enzymes of the classical (CYP7A1) and alternate (CYP46A1 and CYP27A1) BAs synthetic pathways were analyzed at different postnatal days (7, 12, 14, 17, and 23) in control mice and age-matched mice subjected to OIR by immunostaining (cell-specific localization), qPCR and immunoblotting. Retinal BAs content was evaluated using LC-MS/MS assay.

Results: RNAseq data, followed by validation with QPCR and immunoblotting analyses, showed a significant increase in mRNA and protein levels of CYP46A1 (at P12, 14, 17 & 23) and CYP27A1 (at P14, 17 and 23) in normal postnatal retina. On the contrary, CYP7A1 was progressively down-regulated (at P14, 17 and 23). Dual immunofluorescence staining of these enzymes with neuronal (NeuN) and endothelial (CD31) cell markers revealed that while CYP27A1 is immunolocalized in endothelial cells, CYP46A1 is co-localizing with neuronal and endothelial cell markers. A significant dysregulation in retinal sterol and BAs synthetic pathways was found in OIR mice retinas in comparison to control. This was characterized by a significant loss of CYP46A1 and CYP27A1. LC-MS/MS assay further confirmed a significant dysregulation of BAs profiles content in OIR mice compared to control.

Conclusions: In summary, we have found that the developing retina relies primarily in the alternate BAs synthetic pathway. However, in the OIR condition BAs synthesis is significantly down-regulated, thus potentially implicating these signaling molecules also in ROP pathogenesis.

TITLE: In Vitro Potency of Tobramycin Against Common Bacterial Pathogens Implicated in Blepharitis

SESSION TITLE: Antimicrobials and Immunomodulators

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.E. Deom, Hazleton Eye Specialists, Hazle Township, Pennsylvania, UNITED STATES|M.E. Cavet, C.M. Sanfilippo, H.H. DeCory, Medical Affairs, Bausch + Lomb, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): James Deom: Commercial Relationship(s);Bausch Health US, LLC:Code C (Consultant) | Megan Cavet: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment) | Christine Sanfilippo: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment) | Heleen DeCory: Commercial Relationship(s);Bausch Health US, LLC:Code E (Employment)

ABSTRACT BODY:

Purpose: Although the etiology of blepharitis is not fully understood, bacteria are commonly implicated. Combination topical antibiotic/corticosteroid medications are often used as a short-term therapy with or without lid hygiene. We evaluated the in vitro potency of the anti-infective in the combination product loteprednol etabonate 0.5%/tobramycin 0.3% (Zylet[®], Bausch + Lomb) against common bacterial pathogens implicated in blepharitis.

Methods: The antibacterial activity of tobramycin was tested against 487 isolates from 14 genera (67 species) known to be associated with blepharitis. Minimum inhibitory concentrations (MICs) were determined by broth microdilution or agar dilution as appropriate per CLSI M07 and M11 guidelines. ATCC strains were included for quality control (QC) testing.

Results: The MIC range, MIC₅₀ (MICs for 50% of isolates) and MIC₉₀ (MIC for 90% of isolates) for tobramycin are shown in the table. The MIC₅₀/MIC₉₀ against the subset of methicillin-sensitive and methicillin-resistant staphylococci were, respectively, 0.25/0.5 and 0.5/>64 for *Staphylococcus aureus* and 0.12/0.25 and 0.12/16 for *Staphylococcus epidermidis*. All QC data were within CLSI approved ranges.

Conclusions: Tobramycin demonstrated low MICs against most bacterial species associated with blepharitis, including staphylococci and most methicillin-resistant strains thereof. Together with previous published clinical studies, these data support the use of combination loteprednol etabonate 0.5%/tobramycin 0.3% in the treatment of blepharitis, including in staphylococcal blepharitis.

TITLE: Development of a gaze-contingent electroretinogram system

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Aghajari, F.A. Vera-Diaz, T. Panorgias, New England College of Optometry, Boston, Massachusetts, UNITED STATES|P. Bex, Northeastern University College of Science, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sara Aghajari: Commercial Relationship: Code N (No Commercial Relationship) | Peter Bex: Commercial Relationship: Code N (No Commercial Relationship) | Fuensanta Vera-Diaz: Commercial Relationship: Code N (No Commercial Relationship) | Thanasis Panorgias: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The presence of eye movements during multifocal electroretinograms hinders the spatial resolution and location specificity that can be achieved. A solution to this problem could be a gaze-contingent display coupled with an ERG system. Here, we present the early development of such a system that could potentially improve the diagnostic value of ERG recordings.

Methods: Eye movements were recorded using an Eyelink 1000 plus eye tracker with a 2KHz sampling rate (SR Research CA). Simultaneously, single channel ERG signals were recorded from one eye using a 1902 amplifier and a 1401 data acquisition system (CED UK) with 100K gain and frequency bandwidth 0.2 - 100Hz. Stimuli were generated using Psychtoolbox and MATLAB, and were presented onto a monitor with a refresh rate of 120Hz through the Bits# stimulus generator (CRS UK). We recorded electroretinograms (ERG) with and without gaze-contingency. The stimulus, a white 10 degree disk (330 cd/m^2) on a neutral background (165 cd/m^2), was on for one monitor frame, and for the gaze-contingent mode its location was updated based on an average gaze location sampled over 30 ms before the stimulus onset. The ERG acquisition system was time-locked with the stimulus presentation via a TTL trigger generated by the Bits#. The gaze-contingent system's latency was measured with a modified method described before (Saunders & Woods 2013). Briefly, an Arduino Duo board that controlled an infrared LED generated artificial blinks and disrupted the eye tracking causing a luminance change on the monitor. With a high-speed camera (1000 fps) the frame difference between the onset of a blink and the onset of the monitor luminance change, i.e. the system latency, was estimated.

Results: The latency of the gaze-contingent system based on 34 measurements was calculated to be $10.79 \pm 2.9 \text{ ms}$. Qualitative comparison of the ERG responses recorded with a gaze-contingent and a fixed stimulus suggests that the recordings are similar, in terms of the ERG components, but also latency and amplitude.

Conclusions: Using a video-based eye tracker and a data acquisition system we created a gaze-contingent ERG system. The use of our system in future studies using a multifocal stimulus could potentially improve the spatial resolution and location specificity that can be achieved without the need of spatial averaging.

ABSTRACT BODY:

Purpose: To describe a patient-reported visual functioning outcome (PRO) at baseline in RUSH2A participants and explore relationships between PRO, visual acuity (VA) and hill of vision (V_{TOT}).

Methods: The Rate of Progression of USH2A-related Retinal Degeneration (RUSH2A) is a multicenter, international, longitudinal natural history study of individuals with biallelic disease-causing variants in USH2A. History of hearing loss and baseline audiology exams were used to assign a clinical diagnosis of Usher syndrome type 2 (USH2) or autosomal recessive non-syndromic retinitis pigmentosa (ARRP). The VALVVFQ-48 was administered verbally in the local language of participants ≥ 18 years. ETDRS VA was measured in both eyes. V_{TOT} was determined from full-field static perimetry in the study eye (better VA). Baseline PRO measure was calculated using the method of successive dichotomizations, a type of Rasch analysis.

Results: Median age of the 120 participants at enrollment was 41 years (range: 19 to 80); 65 (54%) were female. Clinical diagnosis was USH2 in 75 participants and ARRP in 45. Median age of onset was 16 years [IQR: 13-22] in USH2 and 32 [IQR: 20-41] in ARRP, and median duration of disease was 17 [IQR: 10-27] and 13 years [IQR: 6.8-18], respectively. Median VA was 80 letters (interquartile range (IQR): 75, 85) in the study eye and 75 letters (IQR: 69, 82) in the fellow eye, and median V_{TOT} in the study eye was 20 dB-sr (IQR: 5.4 – 45). A wide range of PROs was seen with person measures ranging from -2.0 to 7.4 logits (median (IQR): 2.9 (1.5-3.8)). ARRP participants had similar PRO to USH2, both before (mean (95% CI): 2.8 (2.3-3.4) and 2.7 (2.3-3.2), respectively), and after adjusting for baseline differences in age, VA, duration of VA loss, and V_{TOT} [mean (95% CI): 2.5 (2.1-3.0) and 2.9 (2.6-3.3), respectively; $p=0.25$]. VA and V_{TOT} , separately, accounted for 29% and 26% of variation in PRO, respectively; ($p<0.001$ for each). Together, they accounted for 36% of variation in PRO.

Conclusions: Bi-allelic USH2A variants are associated with a large range of PRO using VALVVFQ-48. PRO in ARRP and in USH2 were similar, despite concomitant hearing loss in USH2. VA and V_{TOT} appear to be significant and approximately equal contributors to PRO in this population. However, these 2 measures account for less than $\frac{1}{2}$ of variation in PRO.

ABSTRACT BODY:

Purpose: Subretinal fibrosis can develop in the course of neovascular age-related macular degeneration (AMD) and can lead to further vision loss of AMD patients. Intravitreal anti-VEGF treatment can reduce the choroidal neovascularization (CNV), but not the subretinal fibrosis. Until now, there is no successful treatment nor established animal model for subretinal fibrosis. We aim to introduce a novel animal model of subretinal fibrosis that might facilitate the development of novel therapeutic strategies for the reduction or inhibition of subretinal fibrosis.

Methods: C57BL/6J mice underwent laser photocoagulation to induce CNV-related fibrosis. Mice were anesthetized, and pupils were dilated with 5% phenylephrine and 0.8% tropicamide. Using a 532-nm laser, a slit-lamp delivery system, and a cover glass as a contact lens, six spots (100 mW, 50 mm, 100 ms) were placed in each eye. Volume of CNV and fibrosis was quantified with optical coherence tomography (OCT) measurements and confocal microscopy of choroidal flat mounts stained with isolectin B (CNV) and type 1 collagen (fibrosis) every week after laser injury (d7, d14, d21, d28, d35, d42, d49, n=6 per timepoint). Additionally, we performed autofluorescence and fluorescence angiography at every timepoint to document CNV and fibrosis changes over time.

Results: From day 21 to day 49 after laser injury of mice eyes the CNV and leakage decreased and the subretinal fibrosis increased in OCT and fluorescence angiography. The expression of collagen 1 in lesions of choroidal flat mounts increased, whereas isolectin B decreased.

Conclusions: The current results indicate that the CNV-related fibrosis model can be used for screening of anti-fibrotic treatment of subretinal fibrosis in neovascular age-related macular degeneration.

TITLE: Sensory nerve retraction and sympathetic nerve innervation are involved in the immunopathology of murine recurrent Herpes Stromal Keratitis (HSK)

SESSION TITLE: Corneal Immunology and T cell Responses

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Yun, A. St. Leger, Department of Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|A. St. Leger, Department of Immunology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|X. Yin, P. Stuart, Department of Ophthalmology, Saint Louis University, Saint Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hongmin Yun: Commercial Relationship: Code N (No Commercial Relationship) | Xiao-Tang Yin: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Stuart: Commercial Relationship: Code N (No Commercial Relationship) | Anthony St. Leger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: HSK is a potentially blinding corneal disease caused by herpes simplex virus type 1 (HSV-1) infection, which manifests in both humans and mice as corneal edema, opacity, neovascularization, and hypoesthesia. After primary corneal infection, the virus gains access to the trigeminal ganglion through the ophthalmic branch of the trigeminal nerve and establishes lifelong latency. The virus can reactivate under certain circumstances and travel to the cornea to cause recurrent HSK (rHSK). We have found that the replacement of corneal sensory nerves with sympathetic nerves in murine primary HSK led to severe and diffuse inflammation, and CD4⁺ T cells and myeloid cells, through the production of vascular endothelial growth factor A, maintained the disrupted corneal nerve landscape. Here, we aimed to identify whether this mechanism governs rHSK.

Methods: Male and Female C57BL/6 and NIH mice were infected with HSV-1 McKrae strain and were protected from primary infection by intraperitoneal injections of pooled human serum. The eyes were then exposed to 170 (NIH mice) or 250 (C57BL/6 mice) mJ/cm² of UV-B light. Groups of mice received anti-CD4 antibody (150ug, once a week) to deplete CD4⁺ T cells or appropriate control. Mice were monitored for corneal opacity, neovascularization, and blink reflex. Virus reactivation was determined by eye swabbing for live virus and IHC staining for HSV-1 antigens. Corneal whole mounts were stained for β III tubulin, tyrosine hydroxylase, and substance P to define sympathetic and sensory nerves, respectively.

Results: No virus was detected in mice that did not receive U.V. irradiation. Live virus was detected in 30% of both strains of mice after U.V. irradiation. IHC study detected HSV-1 antigens in 100% of the corneas. Mice developed progressive HSK and eventually lost blink reflex with a significant reduction in corneal sensory nerve density. Different from the primary HSK, the invasion of sympathetic nerves in the rHSK cornea was sectorial. Finally, depletion of CD4⁺ T cells correlated with less severe disease, more sensory nerve retention, and less dense sympathetic innervation of the cornea.

Conclusions: U.V. light-mediated viral reactivation from latency is more consistent than previously realized. CD4⁺ T cell-dependent induction of sympathetic innervation of the cornea acts both in the primary HSK and rHSK.

ABSTRACT BODY:

Purpose: Recently, our lab discovered that the eye harbors a resident ocular microbiome that includes *Corynebacterium mastitidis* (C. mast), which can stimulate local immunity to protect the eye from infection. We know that C. mast remains associated with the ocular surface indefinitely and can stimulate protective immunity. Our studies are now focused on better understanding the microbial factors that govern colonization of the ocular mucosa and stimulation of the host immune response. To achieve the study goals, we performed transposon mutagenesis on C. mast to generate a library of mutants for the purpose of identifying microbial genes critical for colonization and immunogenicity of C. mast.

Methods: We created a transposon mutant library containing ~1,500 candidates with distinct insertion sites and varying phenotypes. To do this, we used the EZ-Tn5 kit (Lucigen) to generate transposomes that contained genes encoding the fluorescent protein, mCherry, and a kanamycin-resistance cassette. Tn mutants were initially selected on kanamycin-treated plates. Functional mutants were then screened for desired phenotypes.

Results: We found several mutant candidates of interest. First, a mutant constitutively expressed mCherry in vitro and in vivo when associated with the ocular mucosa. This candidate colonized the eye and induced immunity similar to that observed with the parental C. mast strain. A separate candidate lost the ability to colonize the ocular mucosa and failed to elicit an immune response in vivo; however, it still induced the production of cytokines in vitro. A final candidate corresponded with a reduced immune response both in vitro and in vivo compared to the parental strain.

Conclusions: We have demonstrated that an ocular commensal, C. mast, can be mutated. Using in vivo imaging and Tn-C. mast mutants, we can conclude that C. mast only colonizes the conjunctiva and does not associate with the cornea. Furthermore, we can conclude from our library of transposon mutants that simple exposure to C. mast does not induce a measurable immune response, but colonization of the ocular surface is required for in vivo immunity. These studies are the first steps towards understanding what makes an ocular commensal bacterium what it is, and from this, we can begin to engineer ocular bacteria to promote ocular health to limit disease and pathogenesis.

ABSTRACT BODY:

Purpose: The aging human lens accumulates protein modifications that are dramatically elevated in cataracts. Among chemical processes involved ascorbylation protein adducts carboxymethyl-lysine (CML), carboxyethyl-lysine (CEL) and methylglyoxal hydroimidazole (MG-H1) (Fan et al Aging Cell 2020) are thought to destabilize the proteins based on Ortwerth(1968) who showed that crystallins incubated with ascorbate precipitate under both aerobic and anaerobic conditions. Here we determined ascorbylation sites present solely in insoluble protein exposed to ascorbate.

Methods: Calf lens crystallin homogenate was fractionated by Sephadex G200 gel filtration into Pool 1-4 (P1-P4) corresponding to alpha-, beta-H, beta-L and gamma crystallin, respectively. Pool 3 and 4 were incubated sterile in 50 mM K+/PO4 buffer for 7days with 10 mM ascorbate or dehydroascorbate and centrifuged. Precipitates and supernatants were processed for proteomics analysis. Electrospray MS/MS spectra were obtained and tryptic peptides were analyzed for modified lysine (CML (m/z: +58), CEL (m/z: +72)) and arginine residues by MG-H1 (m/z: +54).

Results: 30-40% of P3 proteins precipitated upon incubation with ASA or DHA. Presence of chelator DTPA suppressed precipitation from DHA, but not ASA. Precipitation of P4 proteins was suppressed by DTPA suggesting ASA/DHA fragmentation are necessary for precipitation. Robust CML modifications sites were K88 (CRYAA), K23 (CRYBB1), K168 (CRYBB2) and K163 (CRYGD). For CEL K168 (CRYBB2). For MG-H1: R188 (CRYBB2), R147 (CRYGC) and R10 (CRYGD). Multiple other sites were also modified, but deemed less important for insolubilization. The significance of the ascorbylation sites for cataract remains to be established. However, K88 is in the minichaperone domain of CRYAA, K23 in the highly conserved sequence GPDGKGK(23)G of CRYBB1, K168 in the conserved QYLLEKGD domain of CRYBB2. R188 in CRYBB2 is in the last strand of β B2-crystallin Greek-key motif 4 and its mutation to R188H promotes β B2-crystallin aggregation via perturbation of the dynamic equilibrium by dissociating the dimer and stabilizing the tetramer (Zhang et al. BBA 1842, 2014). R10 in CRYGD is highly conserved and so is the positive charge at K/R163.

Conclusions: The uncovered robust ascorbylation sites in various bovine crystallins are hypothesized to play a destabilizing role in age-related human cataract.

TITLE: Automating the Detection of Retinal Tears from Vascular Deformation using Machine Learning

SESSION TITLE: Machine learning I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H.H. Wang, A. Peitzsch, L. Martinez, S. Tewolde, S. Cardin, Combat Casualty Care & Operational Medicine, Naval Medical Research Unit San Antonio, Fort Sam Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Heuy-Ching Wang: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Peitzsch: Commercial Relationship: Code N (No Commercial Relationship) | Laura Martinez: Commercial Relationship: Code N (No Commercial Relationship) | Senay Tewolde: Commercial Relationship: Code N (No Commercial Relationship) | Sylvain Cardin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the modern combat environment, ocular trauma is becoming more common while the detection of retinal tears still requires a limited number of trained professionals to detect. In this study, we investigated whether automated image processing systems using machine learning could detect subtle changes in the retinal vasculature that are indicative of retinal tearing.

Methods: Full color fundus images were taken from nine rabbits with penetrating eye injury (Figure 1). MATLAB® programming toolbox was used to analyze a total of 704 images taken before and after retinal tearing. The images were segmented using a combination of color filtering, difference of Gaussian functions, and k-means clustering to isolate the retinal vessels. These images were used to train convolutional neural network and support vector machine (SVM) models to classify individual images based on the presence or absence of a tear. Models were compared using sensitivity, specificity, and the area under the receiver operating characteristic curve.

Results: A SVM Gaussian kernel performed better than the other machine learning models used in this study. This model had a true positive classification rate of 85.53% and a true negative classification rate of 91.11%.

Conclusions: Our study shows that machine learning models are able to detect retinal tear features at a rate comparable to and even exceeding human diagnosis.

ABSTRACT BODY:

Purpose: Blepharitis affects approximately 20 million Americans, of whom about 45% have an associated Demodex mite infestation. We analyzed a large data set of patients with confirmed Demodex blepharitis to characterize the population affected by this condition and to better understand their symptoms and motivations for seeking care.

Methods: Adult patients (age ≥ 18) with Demodex blepharitis were examined clinically and asked questions about their ocular symptoms, diagnoses, and history. These 311 patients had objective signs of Demodex blepharitis, including the presence of Demodex mites, presence of collarettes (cylindrical dandruff) on the lashes, and lid margin erythema. Questionnaire responses from these 311 patients with confirmed Demodex blepharitis were analyzed.

Results: Among these Demodex blepharitis patients, 38% were male; 62% female. The mean age was 67 (range: 23 to 92). Over half of them (51%) had been experiencing signs and symptoms of blepharitis for at least 4 years, but most (58%) had never been diagnosed with blepharitis. There was a high degree of overlap with other ocular surface conditions, including those having been previously diagnosed with dry eye (81%), rosacea (3%), or both (16%). The most bothersome symptoms for patients were itchy eyes, dry eyes, foreign body sensation, and eyes tearing (Fig 1). The majority experienced symptoms of dryness, itching, and ocular irritation frequently or all of the time in the past month. 28% had first seen an optometrist about their symptoms, while 61% had seen an ophthalmologist and 11% had gone to a primary care physician. Although most had seen a doctor only once, 33% had made at least 2, and sometimes more than 6, visits to a doctor for this condition. 81% of patients seek some type of treatment for the condition. Of those who discontinued treatment, 43% discontinued due to ineffectiveness, tolerability issues, or other reasons. Women were more likely than men to have tried medication to treat their symptoms (90% vs. 66%).

Conclusions: The symptom burden of blepharitis is considerable and leads patients to seek treatment and medical care, mostly unsuccessfully. Proven safe and effective treatments for Demodex blepharitis are needed.

ABSTRACT BODY:

Purpose: Natural killer (NK) cells are a subset of lymphocytes that participate in the innate immune defense via their cytotoxic effector functions and cytokine secretion. NK cells play a role in the development of uveitis such as Behçet's uveitis. Additionally, several cytokines have been associated with promoting inflammation and contributing to the development of uveitis in both animals and humans. The purpose of this study is to understand the effect of cytokines relevant to human uveitis on NK cells.

Methods: Peripheral serum cytokines for 126 uveitis patients and 34 healthy controls were investigated using SOMAScan, an aptamer-based proteomics platform that measures over 1300 analytes. Human NK-92 cells were incubated with recombinant human cytokines that were relevant from the SOMAScan studies at previously titrated concentrations for 24 and 48 hours. At each timepoint, expression levels of several activation and inhibitory markers were characterized using a Cytoflex flow cytometer.

Results: SOMAScan proteomic analysis of serum showed elevated levels of certain cytokines, including interleukin (IL)-8, IL-9, IL-18Bpa, and IL-23 in the sera of uveitis subgroups. Flow cytometry from the peripheral blood of the same subgroup of patients also showed NK cell expansion. NK-92 cells demonstrated increased activation upon exposure to IL-12, IL-23 and IL-18, as indicated by elevated CD69 and CD314 expression after 24 hours. Additionally, there was a change in inhibitory receptor expression between the control and ED₅₀ MFI, but to a lesser extent, illustrated by the level of CD94 expression.

Conclusions: The subset of cytokines previously identified to be associated with uveitis may play a role in immunomodulation of effector cells. We plan to further characterize the effect of these cytokines on human PBMCs and NK cells from uveitis patients and healthy controls.

ABSTRACT BODY:

Purpose: The application of artificial intelligence (AI) in diagnosing and treating disease has gained popularity in all areas of medicine including eye care. There has been considerable amount of work dedicated to utilizing AI to improve the practice of eye care and patient outcomes. The objective of this study was to survey optometrists on their perspectives of AI in eye care.

Methods: Members of the American Academy of Optometry were sent an electronic invitation to complete a 17-question survey administered via Qualtrics between September 30, 2020 and November 30, 2020. Participants were included if they indicated they were an optometrist. Survey items assessed perceived advantages and concerns regarding AI using a 5-point Likert scale ranging from "strongly agree" to "strongly disagree." Descriptive statistics were used to analyze perceptions surrounding AI.

Results: There were a total of 400 optometrists that completed the survey. The participant's mean years from graduating optometry school was 25 ± 15.08 , and over half were male (54.5%). The majority of participants (55.8%) self-reported completing a residency, most commonly focused on ocular disease (34.6%) or primary care (17.6%). The most common practice setting was private (33.0%) or optometry school (20.0%). The majority of participants reported they were familiar with AI (66.8%) and felt AI should be incorporated into the optometry school or residency curriculum (80.3%). Some participants felt that there was concern for AI to replace providers (25.1%). When selecting what role participants believed AI should play in the future of eye care, optometrists indicated: disease screening (86.8%), monitoring disease progression (69.0%), triage (61.8%), diagnosis (35.3%), and management of decisions (27.0%) or determining refractive error (27.0%). Though half of participants had concerns about the diagnostic accuracy of AI (53.0%), most believed it would improve the practice of optometry (72.0%). Interestingly, participants reported willingness to incorporate AI into practice increased from 53.3% before the pandemic to 65.5% after the onset of the pandemic ($p < 0.001$).

Conclusions: The findings from this study suggest that optometrists are optimistic about the use of AI in eye care. Future studies will be aimed at better understanding optometrist's knowledge of AI and best practices when integrating AI into clinical practice.

TITLE: Comparing threshold estimation methods for the psychometric function of electrically induced perception

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sadeghi, M.P. Barry, Biomedical Engineering, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|C. Bradley, A. Kartha, S. Lee, G. Dagnelie, Ophthalmology, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|P. Troyk, Armour College of Engineering, Illinois Institute of Technology, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Roksana Sadeghi: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Michael Barry: Commercial Relationship: Code N (No Commercial Relationship) | Arathy Kartha: Commercial Relationship: Code N (No Commercial Relationship) | Soo Hyun Lee: Commercial Relationship: Code N (No Commercial Relationship) | Philip Troyk: Commercial Relationship: Code N (No Commercial Relationship) | Gislin Dagnelie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Controlling the dynamics of electrically induced perception in neural prostheses requires threshold estimation for each electrode, which becomes burdensome for high electrode counts. In this study, we compared four common threshold estimation methods in terms of speed of convergence and accuracy for epiretinal Argus II visual implants.

Methods: Threshold testing methods that are compared here are 1) the standard hybrid (H) method for Argus II epiretinal implants — a combination of the method of constant stimuli (non-adaptive) and maximum likelihood estimation (MLE; adaptive); 2) stochastic approximation staircase (SC; adaptive); 3) minimizing the variance (MV; adaptive); and 4) maximizing the information (MI; adaptive). Data were collected concurrently across all electrodes for adaptive methods, but by groups of 6 electrodes for the H method.

Weibull psychometric function thresholds were estimated in a yes/no experiment for two Argus II users for 24 and 56 electrodes respectively using the four methods. For each subject, data were collected in one session per adaptive method, and two sessions for the hybrid method. Subject responses across all sessions were used offline to estimate the thresholds and confidence intervals (CI) with MLE. To test method accuracies, we computed the average normalized root mean square error (RMSE) between estimated thresholds and MLE thresholds.

Results: Fig.1 shows that hybrid threshold testing requires more trials compared to adaptive methods and only 25% of the thresholds estimated by H were within MLE estimated CI, compared to SC 35%, MV 58%, and MI 61%. The adaptive methods were also more accurate compared to H (RMSE for H: 11%, SC: 10%, MV: 6%, and MI: 6%).

Conclusions: Our results show that the adaptive methods provide more accurate threshold estimates within fewer trials. Adaptive methods enable threshold estimation for a greater number of electrodes concurrently in a session, which is important for neural prostheses with a high number of electrodes.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is a leading form of inherited blindness impacting more than 1 million individuals across the globe. RP is characterized as a progressive loss of photoreceptor cells. However, RP is a heterogeneous disease involving over 100 mutations and genes with various disease mechanisms. While microglia activation in RP patient retinas has been reported, the role that microglia play in the progression of disease is not well understood. Microglia, the myeloid cells of the central nervous system (CNS) typically have a tolerogenic function that is lost in neurodegenerative diseases like RP. This study aims to understand the role of microglia in RP disease. Due to the differing mechanisms that underlie RP, each of these mouse models will provide an opportunity to identify how retinal microglia change phenotypically through the varied progressions of disease.

Methods: We evaluated 11 mouse models recapitulating disease phenotypes for RP, including $rd1^{-/-}$, $rd7^{-/-}$, $Rho^{-/-}$, $RhoP347S^{-/-}$, $RhoP23H$, $Nrv1$, $Nrv2$, $Cep290$, $BBS1^{-/-}$, $Abca4^{-/-}$, and $ApoE^{-/-}$ through immunohistochemistry to determine the distribution of retinal microglia at early, mid, and late stage of disease progression compared to C57BL/6J (B6) wild-type control. IPA analysis was also performed looking at the genes involved in microglia activation as well as their function in both inflammatory and neurodegenerative pathways.

Results: Microglia, including those that indicated disease phenotype, were observed in varying amounts across multiple models of retinal degeneration. Immunohistochemistry also indicated increased microglia activity in degenerative retinas. These changes, likely mediated by activation of inflammatory pathways and possibly the presence of chronic inflammation, create microglia with cytotoxic neurodegenerative function rather than neuroprotective.

Conclusions: Microglia activation has implications for many diseases involving neurodegeneration, including RP. This study enhances current understanding of how microglial altered morphology impacts disease pathology in various degenerative models. Additionally, these results add to the current knowledge of the therapeutic potential for patients with retinal degeneration to protect photoreceptors through the inhibition of neurotoxic microglia and reversion to the wild-type homeostatic microglia state.

ABSTRACT BODY:

Purpose: Dry eye disease (DED) is a common ocular condition known to impact everyday activities. Examining the relationship between subject and disease characteristics like age, disease duration, ocular symptoms etc., without the confounding effects of therapies, are critical for better understanding the disease process.

Methods: Data from 1154 subjects who came for study screening prior to initiation of any therapeutic intervention were included for this analysis. The mean age (\pm SD) was 57.4 ± 15.5 years; 70% of the subjects were females and 30% were males. Subject symptoms were captured using the Ocular Surface Disease Index (OSDI) questionnaire which comprises of 12 questions and overall OSDI score, ranging from 0 to 100, was calculated. Relationship between subject symptom based on OSDI overall score and subject age was assessed by correlation of the continuous variables. In addition, subjects were divided into 4 groups based on overall OSDI score; Normal:0 to 12 (N=123), Mild:13 to 22 (N=200), Moderate:23 to 32 (N=201), or Severe: 33 to 100 (N=630). ANOVA was used to compare outcomes between the groups. For each subject, data from only the right eye was included for analysis.

Results: For all subjects, the overall OSDI score showed significant, mild to moderate negative correlation with age ($R = -0.20$, $p < 0.0001$), indicating that the OSDI scores were showing improvement with increasing age. Consistently, subjects in mild, moderate and severe OSDI group were younger when compared to those in the normal OSDI group. Mean age in normal OSDI group was 63.3 ± 14.8 years compared to mild group (mean 60.8 ± 14.3 years, $p = 0.30$); Mean age in moderate OSDI group was 57.3 ± 15.8 years ($p = 0.0018$ vs normal group) and in the severe group was 55.2 ± 15.7 years ($p < 0.0001$ vs normal group). More severe groups, based on OSDI scores, also showed longer DED duration when compared to normal group. Mean DED duration was 7.9 years in normal, 9.5 years in mild, 10.9 years in moderate and 11.3 years in severe ($p = 0.01$ for moderate vs normal and $p = 0.0006$ for severe vs normal comparisons).

Conclusions: Subjects with dry eye show reduced symptoms with increased aging and increased duration of the disease. This could be attributed to reduced sensitivity that occurs as a consequence of increased aging and long-standing disease.

ABSTRACT BODY:

Purpose: Vision loss is a prominent feature of neuronal ceroid lipofuscinosis Type 2 (CLN2) Batten disease, developing after cognitive, motor and language impairments are already present. While progressive, symmetrical loss of central retinal thickness (CRT) has been well characterized in CLN2 disease, measurement of visual acuity (VA) using standard methods is difficult and unreliable in this population, resulting in lack of natural history data on the range, severity and impact of visual impairment. We conducted a pilot study of a novel VA test using optokinetic nystagmus (OKN) detection technology (Threshold Visual Acuity Test, Objective Acuity, Ltd., Auckland, NZ) to determine its usefulness in children with CLN2 disease.

Methods: 23 children ages 3 to 9 with classic CLN2 disease followed at University Medical Center Hamburg-Eppendorf (UKE) were included. Binocular and monocular VA testing using Threshold Visual Acuity Test and binocular VA testing using preferential looking (PL) were performed at two consecutive visits two weeks apart. CRT was measured under anesthesia using SD-OCT. VA testing results were correlated with CRT.

Results: Seventeen children (74%) tested with the Threshold Visual Acuity Test had measurable binocular VA, while 6 (26%) had no detectable OKN, indicating VA>1.3 logMAR. Binocular VA ranged from 0.3 to >1.3 logMAR and was strongly correlated with CRT ($R = -0.93$; Figure 1). Eighteen children (78%) had measurable VA with PL and 5 (22%) were unresponsive. VA measured by PL was poorly correlated with CRT ($R = -0.44$). Monocular VA measured by OKN was obtained in 12 right eyes and 11 left eyes; 9 children cooperated with monocular testing in both eyes. Monocular VA was highly symmetric between right and left eyes ($R = 0.95$) and correlated with CRT ($R = -0.84$ OD; $R = -0.88$ OS).

Conclusions: The novel, OKN detection-based Threshold Visual Acuity Test appears to be useful in children with CLN2 disease. Results demonstrate the high correlation between CRT and VA as well as symmetrical VA between eyes in this population. More longitudinal data are needed to characterize the pattern and progression of VA loss in CLN2 disease. Additional validation studies with an expanded range of VA are underway.

ABSTRACT BODY:

Purpose: The lamina cribrosa (LC) is considered to play an important role in the pathogenesis of glaucoma. In this study, we investigate the shape variation (SV) of the LC pores as a potential biomarker for quantifying the morphological irregularity in vivo.

Methods: 36 healthy and 14 glaucomatous (GL) eyes (total: 39 subjects) underwent a comprehensive ophthalmic examination and scanning of the optic nerve head with swept-source OCT (Table 1). Images were converted to isotropic and pores were segmented using ImageJ. SV was defined as the mean-squared error of the pore pattern with respect to a solid circle (Figure 1(a)) with SV of a circle marked as zero, and higher SV value with increasing shape irregularity. SV of each pore was automatically calculated by a MATLAB code. The overall SV value was generated as the average of SV in the stack of individual slices. Age effect on SV was examined in all healthy eyes and a subset of 14 eyes was selected for age-matched comparison with the glaucomatous eyes (Table 1).

Results: No significant correlation was detected between SV and age ($p=0.145$; Spearman correlation) in all healthy subjects. Examining the effect of depth on the difference between SV of glaucomatous and healthy eyes, the posterior third of the LC had significantly lower than other sections ($p=0.007$; Figure 1(b)). SV in glaucoma eyes was significantly higher than in the healthy group ($p=0.008$; Figure 1(c)).

Conclusions: We demonstrated morphological differences in pore shape variation between healthy and glaucoma eyes that is mostly affecting the anterior 2/3 of the LC. Further studies are warranted to assess the use of SV as a structural biomarker in glaucoma.

ABSTRACT BODY:

Purpose: Meibomian gland (MG) dysfunction is considered the leading cause of dry eye disease, a common, multifactorial disease with a global prevalence ranging from 5 to 50%. MG are modified sebaceous glands (SG) that secrete lipids at the ocular surface which increase the stability of the tear film. MG are composed of several acini organized around a central duct similar to a hair follicle (HF) without a hair shaft. It is well known that the hedgehog (Hh) pathway is required for the growth of HF and implicated in SG differentiation. However, its role in MG development remains unknown. In this study, we investigate how components of the Hh pathway interplay during MG development.

Methods: To assess the role of Hh signaling in MG development we ablated Smoothed (Smo), required to activate Gli transcription factors, and Ift88, a component of the intraflagellar transport required for trafficking Hh pathway components within the primary cilium. Smo and Ift88 were selectively deleted in keratin 14 (K14)-expressing epithelial cells to generate K14cre;Smo^{fx/fx} and K14cre;Ift88^{fx/fx} mice. To monitor the Hh activity, we utilized the Gli1-LacZ reporter mouse line. MG morphology was evaluated by lipid staining, histology, immunostaining, and two-photon microscopy.

Results: First, we showed that meibocytes are ciliated, mainly in the developing part of the MG central duct and in the ductules at the junction between the central duct and the acini. Using the Gli1-LacZ reporter mouse, we found that in wild-type (WT) mice, Gli1 is highly expressed so the Hh pathway is highly activated in developing MG between E18.5 and P3, but dramatically decreased at P5 and in older mice. Surprisingly, the conditional ablation of the primary cilium in the K14-positive cells (K14cre;Ift88^{fx/fx} mice) leads to an increase of MG size when compared to WT mice, mostly due to the development of supernumerary acini. In contrast, MG size was significantly reduced when Smo is conditionally deleted in K14-positive cells (K14cre;Smo^{fx/fx} mice).

Conclusions: Our data suggest that the Hh pathway is required for MG development and could have implications in the regenerative process of MG. Moreover, ablation of primary cilia or Smo leads to opposite phenotypes during MG development suggesting a possible novel role of primary cilia in Hh regulation in MG tissue.

ABSTRACT BODY:

Purpose: Vessels distal to Schlemm's canal (SC) play a significant role in outflow resistance generation, contributing up to 50% of total resistance. Regulatory regions within distal vessels and their contribution to IOP are not well understood. We hypothesize that vasomotion of distal vessels are control points for outflow resistance generation.

Methods: We used two models to test our hypothesis. The first was OCT imaging of human anterior segments (hAS) in organ culture under constant flow conditions (2.5µl/min). Distal vessel behavior was monitored post treatment with the vasoconstrictor ET-1, or the vasodilator DETA-NO. The treatment protocol was repeated post-trabeculotomy in the same eyes to visualize collector channels (CCs). In the second model, enucleated eyes from C57BL/6 mice were perfused ex vivo with fluorescein tagged soy bean agglutinin lectin, immediately or 24 hrs post enucleation. One eye was treated with 10nM ET-1, while the paired eye received perfusion media. The outflow pathway was visualized in PECAM1-labeled limbal flat mounts by confocal microscopy. Masked analysis of images was conducted using ImageJ. Data are presented as Mean±SD (hAS) or Mean±CI (mice).

Results: The cross-sectional area (CSA) of intrascleral vessels decreased by 60.3±20.2% in hAS treated with ET-1 compared to baseline (p=0.003), while CSA increased by 79.5±121.4% (p=0.02) with DETA-NO treatment compared to ET-1. The SC lumen CSA increased with ET-1 by 68.7±29.1%, p=0.003 and decreased with DETA-NO by 21.8±11.8%, p=0.01. Post-trabeculotomy, neither ET-1 (3.4±16.3% decrease p=0.98) nor DETA-NO (16.1±22.7% increase p=0.17) had a significant effect on CC CSA. In C57BL/6 mice, ET-1 decreased outflow facility (C) (4.6±1.6 to 2.7±1.5 nl/min/mmHg, p=0.04) in freshly enucleated eyes, and decreased C (4.1±1.8 to 3.0±2.0 nl/min/mmHg, p=0.12) 24 hrs post enucleation. Interestingly, lectin staining was largely located in the SC lumen with less lectin distal to CCs in ET-1 treated eyes compared to control.

Conclusions: Vasomodulator (NO and ET-1)-mediated changes in intrascleral vessel diameter was easily visualized by OCT in perfused human eyes, while ET-1 effects on behavior of CC ostia was better visualized indirectly using lectin as a flow tracer in perfused mouse eyes. Taken together, there are at least two vasoactive control points that regulate distal outflow resistance.

ABSTRACT BODY:

Purpose: Glaucoma is a chronic, degenerative optic neuropathy, and the leading cause of irreversible blindness. It affects about 70-90 million people worldwide. Primary open-angle glaucoma is the most common form of glaucoma. At present, there is no cure for glaucoma. Early detection and treatment are crucial for preventing vision loss from this blinding disease. Polygenic risk scores (PRSs) enable disease early prediction based on an individual's genetic makeup. We constructed PRSs and utilized advanced machine learning for glaucoma prediction.

Methods: We conducted this study using participants from the UK Biobank cohort, a population-based prospective study of 500,000 individuals. All study subjects were 40 years of age and older. The participants were genotyped and further imputed to 92 million genetic markers. About 118,000 study subjects participated in the eye and vision component of the study, where numerous ocular measurements were obtained, including intraocular pressure (IOP). Glaucoma information was extracted from electronic medical records and self-reported medical history (cases n = 13,712). We constructed PRSs for multiple diseases/traits, such as glaucoma and IOP, and evaluated their predictive power using XGBoost (an efficient machine learning algorithm) and cross-validation. To avoid overfitting in predictive models, we used independent datasets for model training and testing.

Results: The glaucoma PRS was significantly associated with glaucoma disease risk ($P = 4.69 \times 10^{-24}$) in our testing dataset, after adjusting for covariates, such as age and sex. Subjects in the top 10% of PRSs were 10.28 times more likely to have glaucoma, compared to those in the bottom 10% category ($P = 7.5 \times 10^{-27}$). The area under the receiver operating characteristic curve (AUC) for glaucoma risk prediction was 0.82. Furthermore, the XGBoost method gave better prediction accuracy than traditional logistic regression.

Conclusions: We determined that an ensemble of PRSs and advanced machine learning improve the prediction of glaucoma.

ABSTRACT BODY:

Purpose: Bright ambient light has protective effects on the development of myopia. Recently, we have shown that in addition to bright light, dim ambient light is also protective in a mouse model of myopia, while intermediate, indoor ambient light was not (Landis et al., IOVS 2021). Since rod photoreceptor pathways can still be active in bright light conditions (Tikidji-Humburyan et al., Nature Comm 2017), we investigated the role of the rod pathway signaling in the protective effects of dim and bright light against lens-induced myopia (LIM) using transgenic mice that only have functional rods.

Methods: We developed an in-house breeding colony that produced mice with a “rod only” genotype: rod transducin α Gnat1^{+/+}, cone transducin α Gnat2^{-/-}, and melanopsin Opn4^{-/-}. Myopia was induced by affixing a -10D lens over the right eye starting at postnatal day 28; naïve left eyes were used as contralateral controls. Mice were housed in dim (1 lux), indoor (50 lux), or bright (10,000 lux) lighting for the entirety of lens wear. In each light group, we compared LIM mice (n=3) to naïve littermate controls (n=4). Refractive error, corneal curvature, and ocular axial parameters were measured weekly until 3 weeks post-LIM.

Results: Under all light levels, “rod only” mice with LIM developed significant refractive shifts (difference in refractive error between right and left eye) compared to naïve controls (p<0.02). However, the ambient light level significantly influenced the magnitude of LIM development (two-way RM ANOVA, p<0.001). Similar myopic shifts developed in the indoor (-6.95±0.05D) and bright light (-6.69±0.61D) groups (p=0.99). However, mice housed in dim light had a reduced myopic shift (-4.22±0.32) that was significantly different from mice housed in indoor lighting (p=0.04). No differences were found between groups for corneal curvature or ocular axial parameters.

Conclusions: “Rod only” mice were able to respond to lens defocus under all ambient light conditions, suggesting that rod pathways are sufficient to detect the myopigenic signal. In the absence of cone and melanopsin function, bright light was not found to be protective on myopia development. However, rod pathways appear to underlie the protective effects of dim light on myopia. Future research will determine the selective contribution of cone and melanopsin pathway signaling in the protective effects of bright light on myopia.

ABSTRACT BODY:

Purpose: Anemia may contribute to increased local hypoxia, leading to optic nerve head cupping seen in glaucoma. The purpose of this study was to examine possible associations between erythrocyte parameters and glaucoma in a nationally representative sample of non-institutionalized civilian adults in the United States.

Methods: This was a cross-sectional study of participants in the 2005-2008 National Health and Nutrition Examination Survey (NHANES) dataset who had optic disc photos and erythrocyte parameter laboratory tests performed, including hemoglobin concentration (Hgb), Hematocrit concentration (Hct), and red blood cell count (RBC). A binary variable for anemia was also created based on sex specific Hgb cutoffs defined by the World Health Organization (WHO). The outcome of interest was diagnosis of glaucoma based on ophthalmologist grading of optic disc photos for characteristic features of glaucoma. Logistic regression modeling was performed to assess for associations between each of the individual erythrocyte parameters and glaucoma, controlling for demographic information, including age and race/ethnicity. All analyses were weighted according to the NHANES multistage sampling design.

Results: A total of 4,396 sampled participants were included, of whom 41 had prevalent glaucoma (0.9%). The sample represented a weighted estimate of 90,577,744 participants with a weighted glaucoma prevalence of 0.5%. After adjusting for covariates, a 1 gram/deciliter increase in Hgb resulted in a 26% reduction in odds of glaucoma (odds ratio [OR]: 0.74, 95% confidence interval [CI]: 0.63-0.88), a 1% increase in Hct resulted in a 10% reduction in odds of glaucoma (OR: 0.90, 95% CI: 0.84-0.97), and a 1 million cell increase in RBC resulted in a 68% reduction in odds of glaucoma (OR: 0.32, 95% CI: 0.17-0.60). The presence of anemia was associated with a non-significant 2.26 increased odds of glaucoma (OR: 2.26, 95% CI: 0.76-6.71) after adjusting for covariates.

Conclusions: In the 2005-2008 NHANES adult population, increases in erythrocyte parameters (Hgb, Hct, RBC) are associated with decreased odds of glaucoma; however, the presence of anemia is not statistically significantly associated with glaucoma. It may be that the WHO cutoff value for anemia does not have direct impact on the pathogenesis of glaucoma. Further population-based studies are needed to examine associations between additional erythrocyte parameters and glaucoma.

ABSTRACT BODY:

Purpose: To determine modifiable and genetic factors associated with progression to advanced age-related macular degeneration (AMD) for eyes with different baseline severity scales, and to assess population attributable fraction of these factors.

Methods: An eye that progressed was defined as a transition from no AMD or non-advanced AMD (AREDS severity scales 1-8) to any advanced AMD (scales ≥ 9) at 2 consecutive visits during 12 years of follow up. Eight genetic variants were associated with progression, adjusting for age, sex, education, smoking history, BMI, baseline severity scale, and AREDS treatment. A Genetic Risk Score (GRS) was calculated. Kaplan-Meier survival curves were constructed for the impact of GRS and smoking on rate of progression within categories of the baseline AMD scales, and population attributable fractions were calculated for specific factors.

Results: Among 5421 eyes, 948 progressed to advanced AMD. Genetic variants associated with progression included genes in the complement, immune, inflammatory, lipid, extracellular matrix, DNA repair and protein binding pathways. Eyes from subjects with GRS in the upper tertile had three times higher risk of progression than the lowest tertile (HR=3.03, 95% CI: 2.31-3.97) (Fig. 1). For overall advanced AMD, as well as the neovascular and atrophic subtypes, there was a strong effect for GRS among eyes with baseline intermediate level severity scales 6-8, while the differences were smaller among eyes starting with severity scales 1-5. As shown in Fig. 2, for eyes among past smokers with baseline severity scale 8, the 12 year probability of progression was 55% for GRS 1 vs. 90% for GRS 3, while among current smokers, the corresponding progression rates were 80% vs. > 95%. Calculation of population attributable fraction showed that the percent of disease prevented if smoking and body weight behaviors changed to past or never smoking and BMI < 25, was about 15%. In a similar calculation, if GRS tertiles changed from higher levels to the lowest risk, the percent prevented would be 37%, holding severity scale constant.

Conclusions: Carriers with higher GRS have higher risk of progression for eyes with the same level of baseline severity scale, and smoking further increases risk. Changing to healthier behaviors could reduce risk of progression from non-advanced to advanced stages of AMD.

ABSTRACT BODY:

Purpose: The cone mosaic sets the primary limit on the fidelity of luminance and color vision. Here we describe the spectral composition of the cone mosaic in the parafovea using an adaptive optics (AO) line-scan OCT-based optoretinogram (ORG) and compare the modality against AO retinal densitometry and flicker-photometric electroretinogram (ERG).

Methods: Two subjects were imaged in an AO line-scan OCT from at 1.5 to 10 deg temporal eccentricity (ecc.) after 3-4 min. of dark adaptation. OCT volumes were recorded after a 10-20 ms 660±10 nm LED flash. The B-scan rate was 6 to 12 kHz and field of view was 1 to 1.6 deg. The stimulus-induced optical phase change was computed between individual cone inner/outer segment junctions and outer segment tips in registered and segmented volumes and converted to optical path length (OPL). The change in OPL was subjected to Gaussian mixture model clustering to distinguish the three cone types. In one subject, cone spectral identities so obtained with ORG were compared against AO retinal densitometry at 1.5 deg ecc. and the nature of disagreements explored. ERG was conducted on both subjects with a 35 deg stimulus for comparison against ORG.

Results: Depending on cone type, bleach strength and ecc., OPL amplitudes vary from 10 - 700 nm, thus offering up to ~2 log units of sensitivity for separating cone types in ORG. Thus, high probability and low uncertainty in LMS assignments were obtained for both subjects across a large population of cones at each ecc. The cone types obtained from ORG and densitometry had ~90.5 % agreement, tested over 813 cones at 1.5 deg ecc. Disagreement of spectral-type assignments included incidence of cones with normal reflectivity in one system but not the other, typed as "dysflective". Of the disagreements, ~44% of mismatches were between L vs. M, ~5% were between LM vs. S, and ~51% involve instances of dysflectivity. For subject 1, the L:M ratio was 2.2, 3.0, 3.0 and 2.4 at 1.5, 3.5, 4.75, and 10 deg ecc., respectively. For subject 2, the L:M ratio was 2.2, 2.0, 2.1 at 1.5, 4.75 and 10 deg ecc. For both subjects, % S-cones increased with ecc., from 4 - 7.6%. The L:M ratios derived from ERG were 2.2 and 2.7 respectively.

Conclusions: Cone spectral composition based on ORG aligned well with densitometry and ERG. The L:M cone ratio remained relatively uniform in the parafovea.

ABSTRACT BODY:

Purpose: There have been no randomised controlled trials comparing off-label bevacizumab to aflibercept for treating neovascular Age-related Macular Degeneration (nAMD). Recent advances in the emulation of target trials suggests that the standard-of-care arms can be approximated with real-world cohorts. Given that the treatment of retinal disorders with inhibitors of Vascular Endothelial Growth Factor accounts for 12% of Medicare expenditure, evidence for the non-inferiority of bevacizumab relative to licensed therapies could have implications for on the cost of treating nAMD.

Our hypothesis was that the visual acuity at 54 weeks of nAMD eyes treated with bevacizumab (q6w pro re nata) would not be inferior relative to aflibercept (q8w fixed-interval).

Methods: We emulated a target trial using the bevacizumab arm (n 65) of the ABC trial — a prospective, double-masked, randomised controlled trial — with external synthetic control arms derived from real-world cohorts receiving aflibercept as part of routine healthcare in the United Kingdom. Analyses were pre-specified and undertaken in accordance with the Target Trial Framework. External real-world cohorts were restricted to eyes that would have been eligible for the ABC trial and, to overcome the non-random treatment assignment in the real-world, we undertook conditional randomisation via 1:1 exact matching (EM), 1:1 propensity score matching (PSM), and inverse probability of treatment weighting (IPTW) on hypothesised confounding (age, sex, baseline read). Ordinary least squares regression was modelled on the change in visual acuity from baseline to week 54, stratified by treatment in eyes that received three loading doses within 70 days. Non-inferiority was declared if the lower confidence interval bound was \geq than a non-inferiority margin of -4 ETDRS letters.

Results: Of 31,151 eyes that started aflibercept treatment for nAMD, 4,471 (14%) fulfilled the ABC and target trial eligibility criteria. Eyes included in the bevacizumab trial & aflibercept synthetic arms were, respectively: 131 & 8,506 for IPTW (pseudo-population); 43 & 43 for EM; and 65 & 65 for PSM. The results show, with exception of PSM, that bevacizumab is not inferior to aflibercept, on a noninferiority margin of 4 ETDRS letters.

Conclusions: We found off-label bevacizumab to be non-inferior to licensed aflibercept. We show the potential of real-world cohorts as external control arms.

ABSTRACT BODY:

Purpose: Quantifying optic nerve (ON) axons is the gold standard method of disease progression in glaucoma animal models; however, this can only be done after enucleation. Optical coherence tomography (OCT) and scanning laser ophthalmoscopy (SLO) have been used to monitor pathological changes of the optic nerve head (ONH) and retinal nerve fiber layers in patients with glaucoma. In this study, we report the relationship between the number of ON axons and OCT parameters of the ONH at different disease stages in a clinically relevant canine open-angle glaucoma model (OAG).

Methods: Dogs with moderate- and advanced- stage OAG due to an ADAMTS10 mutation (6 eyes, 6 dogs) and one normal control (2 eyes, 1 dog) were included. Ages of the dogs with OAG ranged from 3 to 7 years (median of 4 years old); the control dog was 6 years old. An equal number of mutant males (n=3) and females (n=3) were included while the control dog was male. High-resolution spectral-domain OCT and SLO (Spectralis®, Heidelberg Engineering) imaging of the ONH and the peripapillary retina were performed. ONs were collected and embedded in epoxy resin. Semi-thin cross-sections were stained with 1% p phenylenediamine and digitally scanned (Aperio digital pathology slide scanner, Leica). The number of axons in the entire ON was counted manually. An image analysis software (Image J, National Institute of Health) was used to measure the OCT parameters and count ON axons.

Results: A strong positive correlation was found between ON axon numbers and neuroretinal rim ($r=0.91$, $p<0.01$) and ONH area[KA1] s ($r=0.73$, $p=0.04$). There was a moderate positive correlation between ON axon number and ONH diameter ($r=0.52$, $p=0.19$). A strong negative correlation was found between ON axon numbers and optic cup area ($r=-0.75$, $p=0.03$) and a moderate negative correlation between ON axon numbers and the age of dogs[KA2] with OAG ($r=-0.70$, $p=0.12$).

Conclusions: OCT and SLO parameters of the ONH area showed a moderate to a strong correlation with ON axon numbers in the canine ADAMTS10-OAG model.

ABSTRACT BODY:

Purpose: Acrolein, a volatile organic compound, was used as a warfare agent in World War I and has the potential viable public threat worldwide. Recently, we studied the impact of acrolein exposure to the cornea and other ocular surface tissues in vivo using a rabbit model. The study sought to uncover the mechanisms of acrolein's toxicity to the cornea using an in vitro model.

<!--[if !supportLineBreakNewLine]-->

<!--[endif]-->

<!--[if !supportLineBreakNewLine]-->

<!--[endif]-->

Methods: Primary human corneal stromal fibroblasts cultures (h-CSFs) from donor human corneas were used. Presto blue and MTT assays were used to determine the dose of acrolein, N-acetyl cysteine (NAC), and Buthionine sulfoximine (BSO) for h-CSFs. Different biochemical assays using standard commercial kits and qRT-PCR analysis were performed to understand the mode of acrolein toxicity.

Results: The MTT and PrestoBlue assays defined that 100 μ M dose of acrolein represents IC_{50} , for h-CSFs an acute level at 4h ($p < 0.001$). The biochemical assays revealed that acrolein exposure to h-CSFs led to oxidative stress and a compromised level of glutathione. These biochemical variations led to mitochondrial dysfunction via changes in the mitochondrial membrane potential ($\Delta\Psi_m$). The mRNA data, TUNEL, and caspase-3/7 assays showed that acrolein induces apoptosis in h-CSFs. Treatment with NAC; a precursor of glutathione, in h-CSFs decreased the oxidative stress, elevated the GSH level, regulated the mitochondrial membrane potential ($\Delta\Psi_m$), and rescued h-CSFs from apoptosis under acrolein-exposed conditions.

<!--[if !supportLineBreakNewLine]-->

<!--[endif]-->

Conclusions: Acrolein's exposure to human corneal fibroblasts induced alterations in phenotype, and cell death through oxidative damage at least in part of toxicity, in vitro.

ABSTRACT BODY:

Purpose: To evaluate the changes in the retinal structure and retinal vasculature in type-1 diabetic mice (C57BL/6-Ins2^{Akita}/J) over time.

Methods: Fluorescein angiography (FA), Indocyanine green angiography (ICGA) and OCT imaging was performed on Akita mice at 3 months and 6 months of age. The confocal scanning laser ophthalmoscopy (cSLO) images were analyzed for FA and ICGA. OCT images were evaluated for thickness measurement of distinct layers of the retina. A total of 25 (male) animals were used in the study. FA was performed after IP injection of Na- fluorescein, and images were collected at ~three mins and ~six mins for early and late phase of dye circulation. ICG was administered via tail vein. Statistical comparison were made using non-parametric two tailed t-test with significance at P<0.05.

Results: Using ImageJ, a simple thresholding protocol was developed, which uses IsoData algorithm, and fixed lower and upper threshold values for all the FA and ICG images. Both FA and ICGA showed significantly increased retinal vasculature leakage (92% increase in FA and 101.9 % increase in ICGA) in 6-month old Akita mice compared with age matched WT (Fig. 1). OCT based total retinal thickness was significantly reduced in Akita mice at both three (2.8%) and six (2.5%) months of age. The middle retinal layer thicknesses, OPL and ONL were significantly different in mice in the 6-month age group (Fig.2). However, at three months, only the OPL layer had thinning in the outer and middle retinal region (Fig. 2). No observable changes were observed in the outer retinal layers (IS/OS and RPE).

Conclusions: Aging diabetic mice exhibit clear imaging biomarkers such as retinal fluid leakage and inner retinal layer degeneration.

ABSTRACT BODY:

Purpose: Rhesus macaques are a common animal model in ophthalmology because of the high similarity of their eyes and visual pathway to human. The characterization of optic nerve head (ONH) and peripapillary region in monkeys reported so far mostly involved a manual process which is laborious and subjected to operator errors. It is also usually generated from a cohort of similar age group. In this cross-sectional observational study, we deploy automated and manual segmentations to evaluate the OCT retinal nerve fiber layer (RNFL) thickness, ONH and lamina cribrosa (LC) microstructure parameters in a cohort of free roaming macaques.

Methods: In-vivo ONH spectral-domain OCT scans (Leica, Chicago, IL) were obtained by a single experienced operator after excluding eyes with any retinal pathologies. The margins of the optic disc were drawn manually and the resultant scans were analyzed using an automated segmentation software of our own design. The LC microstructure parameters were obtained through a previously described segmentation algorithm. The other parameters of ONH, namely the cup-to-disc (C/D) ratio and minimum rim width (MRW) were assessed manually. Wilcoxon rank sum test was used to test the association of LC parameters, C/D ratio and MRW with age, while the rest of the parameters were analyzed using mixed effects model accounting for age, sex and intra-subject correlation.

Results: 29 eyes from 19 monkeys (11 females, 8 males) with age ranging from 4.2 to 23.8 years were analyzed. Males were overall bigger and significantly heavier than females in our cohort (Table 1). Superior RNFL was thicker in male and is the only RNFL parameter that was associated with age or sex in this healthy cohort. No significant association was detected for any of the ONH parameters with age or sex. LC was more visible and thicker in male with higher beam to pore ratio and connective tissue fraction than in female.

Conclusions: The characterization of normal macaque eyes from a cohort of free roaming animals is useful as a standard reference to assess pathological changes in future experimental studies.

ABSTRACT BODY:

Purpose: Chemically burned cornea requires appropriate measures for preventing inflammation and tissue damage, as well as for being repaired. Here we investigated an artificial corneal graft (ACG) based on lower lip mucosa stem cells (LMSC). The aim of this study was to characterize cells derived from lower lip mucosa in two species, including human and rabbit, as well as to understand if ACG can promote corneal restoration.

Methods: Both human and rabbit LMSCs were characterized by several criteria, especially in terms of their proliferation capacity, differentiation ability, genomic stability, and immunophenotypic characterization. The proliferation rate of LMSCs was evaluated by producing their growth curves. Osteogenic, chondrogenic, and adipogenic differentiation potential was examined by culturing LMSCs in differentiation media for several weeks and after that von Kossa, safranin-O, and Oil Red O staining, respectively. Genomic stability was evaluated by producing their karyotypes, and the percentage of chromosomal rearrangements was assessed. The abundance of ABCB5, ABCG2, ALDH3A1, CK3, CK14, and CK15 was examined by immunocytochemistry. Finally, a decellularized human amniotic membrane (HAM) was used as a scaffold, and rabbit LMSCs were seeded on it in a density of 100000 cells/cm². In vivo, the ability of ACG to repair damaged cornea was evaluated in a limbal stem cell deficiency (LSCD) rabbit model. Inflammation and corneal wound healing were examined by histological analysis. Untreated cornea and cornea with total LSCD acted as a control.

Results: LMSCs were characterized at 6 passages. Among both human and rabbit LMSCs grew at the highest speed. The population doubling time of human and rabbit LMSCs was 36.22±0.57 and 54.78±1.3 hours (p<0.05), respectively. It was found that LMSCs were able to differentiate toward osteogenic, chondrogenic, and adipogenic lineages. However, rabbit LMSCs differentiation potential was slightly lower. The genome of both human and rabbit LMSCs was stable with the chromosomal rearrangements number of 6.67% and 10%, respectively. Immunocytochemistry showed that both human and rabbit LMSCs expressed epithelial and stem cell markers. In vivo, it was found that the transplantation of ACG promoted corneal reepithelization via 1 month.

Conclusions: Thus, our results suggest that ACG based on HAM and LMSCs are able to repair the corneal structure and decrease inflammation after being wounded.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) is a ubiquitous ophthalmic imaging technology. However, currently patients are required to position themselves in chin/forehead rests for stabilization with the system operator in close proximity. Introducing a robot to the clinic enabled distanced, no-contact imaging of a retina clinic population.

Methods: We developed a custom robotically (UR3e) aligning swept source OCT (RAOCT; 1040nm) system with a low mass (2.4kg) sample arm utilizing 70mm diameter achromatic lenses with 3D printed optomechanics providing a clinically relevant 32° view on the retina (Fig. 1A&B). During acquisition, face and pupil tracking cameras triangulated 3D eye and pupil motion which were compensated in real-time by the robot and OCT system (Fig. 1C&D). We acquired B-scans and volumes in triplicate from the right eyes of 20 subjects from the Duke Eye Center clinics (10 normal, 10 diseased; 25 - 91 years old) with RAOCT and Heidelberg Spectralis under an IRB approved protocol. Differences between device foveal thickness maps were tested using two-tailed t-tests.

Results: Subjects were seated and free of any head restraints (no forehead strap or chin rest, Fig. 1A). The system automatically aligned on the subject's eye allowing for motion compensated OCT B-scans and volumes of the retina (Fig. 2). There was a mean paired inter-device $1.2 \pm 5.9\mu\text{m}$ difference ($p = 0.53$) in healthy retinal thickness and $3.7 \pm 7.5\mu\text{m}$ ($p = 0.13$) difference in diseased retinal thickness (Fig. 2E).

Conclusions: In a clinic population, we demonstrated a robotically aligned OCT system that provides retinal views and measurements comparable to current clinical OCT.

ABSTRACT BODY:

Purpose: Purpose: Fuchs endothelial corneal dystrophy (FECD) is a genetic, female predominant, and late-stage oxidative disorder characterized by progressive loss of corneal endothelial cells (CEnCs). Previously, we have reported a decrease in [NAD(P)H: quinone oxidoreductase 1 (NQO1)], an estrogen metabolite detoxifying enzyme, and altered estrogen metabolism in FECD. In this study, we have investigated the role of reactive estrogen metabolites in the estrogen genotoxic pathway for FECD.

Methods: Methods: NQO1^{+/+} and NQO1^{-/-} male and female mice were irradiated with UVA (500 J/cm²). CEnCs were imaged using a Heidelberg Retinal Imaging Rostock Corneal module (HRT-RCT) and quantified manually at weeks 1, 2 and 4 post-UVA. At week 4 post-UVA, toxic estrogen metabolites (4-OHE_{1/2}, 2-OHE_{1/2}), depurinating DNA adducts, and neutralized protective estrogen conjugates (4-OCH₃E_{1/2} and 2-OCH₃E_{1/2}) were analyzed by Ultraperformance Liquid Chromatography/Tandem Mass Spectrometry (UPLC/MS) in the cornea and reactive oxygen species (ROS) was analyzed in the aqueous humor.

Results: Results: At week 2 post-UVA, when compared to the baseline, UVA irradiation led to the greatest decrease in HCEncs in NQO1^{-/-} female mice (45.7%), followed by NQO1^{-/-} males (25%), NQO1^{+/+} females (24.8%) and then NQO^{+/+} males (6.8%). UPLC/MS-based metabolites analysis demonstrated that NQO1^{-/-} females had a 4.2-fold increase (p<0.05) in the ratio (OD/OS) of 4-OHE_{1/2}, a 7.4-fold increase (p<0.05) in 2-OHE_{1/2}, a 10.1-fold increase (p<0.05) in 4-OHE_{1/2} DNA adducts compared to NQO1^{-/-} males, a 10-fold increase (p<0.05) in 2-OHE_{1/2} for NQO1^{+/+} female compared to NQO1^{+/+} male. Thus, increased reactive estrogen adducts may lead to increased susceptibility to CEnC loss in NQO1^{-/-} females. For 4-OCH₃E_{1/2} and 2-OCH₃E_{1/2}, NQO1^{-/-} females had a 5-fold and 2.7-fold decrease (p<0.05, respectively) compared to NQO^{-/-} males, explaining the conversion of most estrogen metabolites to toxic byproducts in females. NQO1^{-/-} females had a 3-fold increase in ROS compared to NQO1^{-/-} males and unaltered in NQO1^{+/+} females and males.

Conclusions: Conclusions: Our study indicates that NQO1 deficiency accelerates UVA-induced CEnC loss in females due to increased reactive toxic estrogen DNA adducts. This novel study highlights the potential role of NQO1-mediated estrogen metabolite genotoxicity in explaining the higher incidence of FECD in females.

ABSTRACT BODY:

Purpose: To evaluate intraocular pressure (IOP) following phacoemulsification in eyes with prior tube shunts.

Methods: Retrospective chart review of consecutive open angle glaucoma patients with a prior tube shunt and IOP \leq 21 mmHg, who underwent phacoemulsification and had \geq 24 months of follow-up following cataract surgery. The main outcome measure was cumulative surgical failure at post-operative month 24, which was defined as IOP $>$ 21 mmHg, progression to no light perception (NLP) vision, glaucoma reoperation, or removal of the implant. Additional analysis of surgical failure defined as IOP $>$ 18 and $>$ 15 mmHg (for eyes with baseline IOP below these cutoff points) was performed. Changes in visual acuity (VA), IOP, and medications number were also assessed.

Results: 27 eyes of 27 patients with mean age of 64.2 ± 10.8 years and 2-year follow-up duration were included. The average interval between the tube shunt and cataract surgeries was 28.8 ± 25.0 months. All patients had moderate to severe glaucoma. At month 24, 4 (14.8%) eyes met the failure criteria, and mean time to failure was 19.3 ± 3.8 months. Reasons for failure were high IOP in 2 (50.0%) and glaucoma reoperation in 2 (50.0%) eyes. No eyes progressed to NLP vision. Additional analyses of surgical failure defined as IOP $>$ 18 and $>$ 15 mmHg showed increasing failure rate (18.5% and 48.5%, respectively). Kaplan-Meier survival analysis showing the cumulative rate of surgical failure at 24 months using the main and alternate failure criteria is displayed in Figure 1. The mean IOP and number of glaucoma medications remained stable at month 24 compared to baseline ($P=0.131$ and $P=0.302$, respectively). VA showed initial improvement at month 6 ($P=0.001$), but at month 24 this improvement was not significant ($P=0.430$).

Conclusions: IOP remained controlled in most eyes with prior tube shunt surgery 2 years following phacoemulsification.

ABSTRACT BODY:

Purpose: Advanced driver assistance systems (ADAS), including blind spot warning and forward collision warning, are becoming widely available in many new cars. It has been reported that these systems improve the driving safety of elderly and normally sighted drivers. The purpose of this study was to assess exposure to, perceived safety with and interest in using ADAS among older drivers with age-related macular degeneration (AMD).

Methods: Current drivers aged 60+ years were recruited at four sites (the Ohio State University, University of California, Los Angeles, New England College of Optometry, and Envision Research Institute) to complete a cross-sectional survey about driving habits and use of: forward collision warning, forward collision avoidance, blind spot warning, lane departure warning, rearview camera, cruise control, adaptive cruise control, and GPS. If subjects had a particular ADAS in their vehicle, they completed survey items about frequency of use and improvements in safety associated with the system. If participants did not have a particular ADAS, they completed survey items about knowledge and anticipated benefits.

Results: One hundred twelve participants completed the survey (69 with AMD vs. 43 without, 54% female). Subjects with AMD were older (77 ± 8 years vs. 71 ± 7 years, $p < .001$), had poorer self-rated vision (64% good to excellent rating vs. 98%), and drove significantly fewer miles per week (55 ± 74 miles vs. 85 ± 64 miles, $p = .032$) than those without. A majority of participants used cruise control (AMD 54%, non-AMD 72%), rearview camera (AMD 54%, non-AMD 63%), and GPS (AMD 70%, non-AMD 77%). Subjects with AMD believed their safety was improved with use of rearview camera (89%), GPS (72%), and cruise control (54%). Of the less common systems, most drivers with AMD who did not have them believed their safety would be improved by: blind spot warning (83%), forward collision warning (72%), lane departure warning (64%), adaptive cruise control (59%), and forward collision avoidance (57%).

Conclusions: Many drivers with AMD utilize common ADAS, which subjectively improve their road safety. They are inclined to believe a variety of less common ADAS would further improve their driving safety, particularly the use of forward collision warning and blind spot warning. Further work is needed to objectively assess whether road safety actually improves as a result of these systems.

TITLE: IL-17 is involved in a CNS demyelination model of optic neuritis

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Hirose, S. Wang, H. Ghiasi, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Satoshi Hirose: Commercial Relationship: Code N (No Commercial Relationship) | Shaohui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Homayon Ghiasi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously reported that ocular infection of different strains of mice with a recombinant HSV-1 constitutively expressing murine IL-2 (HSV-IL-2) but not wild-type HSV-1 causes CNS demyelination and optic neuropathy. Interleukin-17 (IL-17) pathway plays an important role in host defense and various inflammatory diseases. However, the relationship between IL-17 pathway and CNS demyelination is not well established. Thus, we investigated the role of IL-17 pathway in HSV-IL-2 model of optic neuritis and multiple sclerosis.

Methods: We studied the role of IL-17 on CNS demyelination in IL-17A^{-/-} and IL-17 receptor -deficient (IL-17RA^{-/-}, IL-17RC^{-/-}, IL-17RD^{-/-}, and IL-17RA^{-/-}RC^{-/-}) mice. These female mutant mice were ocularly infected with HSV-IL-2 or parental virus and demyelination in brain, spinal cord and optic nerves of infected mice were determined on day 14 post infection using Luxol Fast Blue staining.

Results: Regions of demyelination were not found in the brain, spinal cord or optic nerves of HSV-IL-2-infected IL-17A^{-/-} mice, while demyelination was observed in mice lacking IL-17RA, RC, RD or both RA and RC. However, mice lacking both RA and RC had lower level of demyelination than mice lacking RA, RC, or RD. Both focal and diffuse regions of demyelination were detected in WT mice infected with HSV-IL-2 but not with WT virus. Transfer of T cells from IL-17A^{-/-} mice to Rag^{-/-} recipient mice induced CNS demyelination. Similarly, transfer of T cells from WT mice to IL-17A^{-/-} recipient mice induced CNS demyelination.

Conclusions: Our results suggest that the absence of IL-17A blocks CNS demyelination in ocularly infected mice. Presence to at least one receptor is sufficient to cause demyelination, suggesting a level of redundancy between the three receptors. In addition, T cell transfer experiments suggested that both T cell and non-T cell producing IL-17 are contributing to CNS pathogenesis. Thus, this study shows that IL-17 plays an important role in induction of CNS demyelination, and provides insight towards the mechanism of IL-17 pathway in induction of demyelination.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of blindness in the United States with vascular endothelial growth factor (VEGF) being one of the main hallmarks that exacerbates this condition. In this study, we will determine the effects of acrolein and hypoxia on VEGF secretion under different glucose concentrations in mouse cone photoreceptors (661W) to study the molecular mechanisms of DR.

Methods: 661W cells were cultured in P100 dishes and then seeded in 6 wells plates at 300k cells/per well. Upon confluency of 80%, cells were subjected to the appropriate treatments consisting of complete culture media with normal (NG; 5.5mM) or high glucose (HG; 30 mM). Hypoxia was induced chemically by using cobalt (II) chloride hexahydrate solution of 300ug/ml. Acrolein concentrations consisted of low (25uM and 50uM) and high (100uM and 200uM). Elisa was used to measure the VEGF protein in conditioned media.

Results: Hypoxia had a significant impact by increasing the amount of VEGF secretion (NG=234 pg./ml, NG + hypoxia=658, HG=246, HG+ hypoxia =630; p=0.002 and 0.0275 respectively) and decrease number of viable cells (NG=2,200,000, NG + hypoxia=762,333, HG=2,230,000, HG+ hypoxia =1,040,000; p=0.003 and 0.037 respectively). Additionally, acrolein played a significant role in decreasing cell viability (p=0.035 in HG with 25uM acrolein=1,470,000, 50uM =760,200, 100uM =95,833, 200uM =76,233 and p=0.0064 in NG with 25uM acrolein=1,500,000, 50uM =1,290,000, 100uM =228,500, 200uM =58,600) and decreased VEGF secretion (p=0.05 in HG with 25uM acrolein=204 pg./ml, 50uM =112, 100uM =27.4, 200uM =18 and p=<0.0001 in NG with 25uM acrolein =272, 50uM =283, 100uM =56.6, 200uM =19.4) in 661W photoreceptor cells.

Conclusions: Hypoxia exerted significant effects to reduce 661W cell viability and increase VEGF secretion. However acrolein induced a reduction in cell viability, along with a decrease VEGF secretion. Since hypoxia (low oxygen) and acrolein (a highly reactive aldehyde) are known to affect significantly oxidative pathways, it is possible that their effects may be mediated by the TGFb pathway. Further experiments will be conducted to determine the underlying molecular mechanism.

ABSTRACT BODY:

Purpose: Dry Eye Disease (DED) is a symptomatic, chronic inflammatory disease. Most DED patients are thought to suffer from episodic exacerbations of their signs and symptoms (DED flares). However, very limited clinical data and patient insights exist on DED flares in the literature. We collected and analysed real-world patient insights into DED flares from unsolicited, self-reported and publicly available online data sources using internet technology driven data collection approaches from a 15-year period.

Methods: Real-world data patient- and HCP-reported information (English language) were collected from 2005 to 2020. Collected and analyzed patient experiences included DED flares symptoms, comorbid conditions, treatment usage, lifestyle behaviors and quality of life impact using an array of keywords associated with DED flares and a combination of technology driven approaches like natural language processing, machine learning, artificial intelligence (AI) and manual curation techniques used to standardize patient reports from real world data. SPEC-R (Social, Physical, Emotional, Cognitive and Role activity), an analytical framework was used to categorize functional impairments and symptoms from unstructured patient, caregiver and provider narratives.

Results: A total of 116,450 internet posts about DED flares and a population of 12,743 patient profiles were identified, collected and analysed from 75 data sources during the 15-year period. The identified DED flare patient population was predominately female (88%) and fell between the ages of 35 and 70 (86%). The most reported symptoms associated with reported DED flares were eye discomfort, pain and redness. Majority (78%) of the patients suffered DED flare resurgence within 2 months suggesting an annual occurrence of ~6 flares. Allergy and depression were most mentioned comorbidities and laser in-situ keratomileusis (LASIK) was the most common trigger for DED flares. SPEC-R analysis revealed that social and family life, work and the ability to concentrate were impacted the most by DED flares

Conclusions: This novel approach to collect a multitude of patient-reported, real-world insights revealed a wealth of data, which may help improving diagnosis, treatment and patient education on DED flares and quality of life.

ABSTRACT BODY:

Purpose: Examination of the ocular vasculature plays an important role in diagnosing eye diseases including age-related macular degeneration, diabetic retinopathy, and glaucoma. We developed a new imaging platform to visualize the vasculature without additional contrast agents and over large areas. The purpose of the current study was to identify vascular differences between rats with retinal degeneration and healthy rats.

Methods: A choroidal and retinal hemodynamic imager (CHARMER) has been developed enabling measurements of retina/choroid structure and ocular blood flow based on optical coherence tomography (OCT) and line-scanning Doppler flowmetry (LSDF). Ten rats with retinal degeneration (RD - eight Royal College of Surgeons rats and two heterozygous transgenic P23H rats) and ten age-matched Sprague-Dawley healthy controls (CD) have been imaged following an IACUC approved protocol.

Results: Large area Velocity maps have been obtained with the LSDF channel in CHARMER as shown in Fig. 1. The retinal blood vessels originating at the ONH are more visible and distinguishable in CD rats (left column in Fig. 1) than in RD rats (right column) indicating a reduced retinal flow in RD rats. On the other hand, the choroid vasculature is more visible in RD rats than in CD rats and with much better contrast than the retinal vasculature. As confirmed with OCT, the retina is thinner in RD rats as compared to CD rats and the LSDF light can penetrate deeper into the tissue and interrogate the choroid, less affected by scattering in the inner retina. The same trend is noticed between younger and older normal rats, the older ones (bottom left) have slightly thinner retina than the younger ones (top left) and therefore, a more visible choroidal vasculature. The choroidal vasculature is similarly visible in younger and older RD rats indicating that thinning of retina has already occurred in the younger ones, as confirmed with OCT.

Conclusions: Large area mapping of retinal and choroidal blood flow using LSDF can be used to investigate retinal and choroidal vascular changes due to disease. Such an advanced diagnostic imaging system will help understanding hemodynamic processes in the eye as a response to disease or treatment.

ABSTRACT BODY:

Purpose: Blood flow is important to multiple ocular diseases and has been shown to be impaired in patients with glaucoma. Nailfold capillaroscopy visualizes peripheral capillaries and their blood flow while erythrocyte mediated angiography (EMA) precisely and accurately quantifies retinal blood flow. The purpose of this study is to compare the velocities of erythrocytes in the retina and nailfold.

Methods: We conducted a cross-sectional study using EMA in twenty-six patients to determine retinal venular, arteriolar, and capillary velocities, and a subset of seven patients underwent nailfold capillaroscopy. EMA uses ICG loaded erythrocytes to directly visualize blood flow in the retina and find erythrocyte velocities via a scanning laser ophthalmoscope (Tracey et al., Scientific Reports, 2019). Nailfold video capillaroscopy is a non-invasive approach to visualize capillaries at the fingernail base (Cousins et al., British Journal of Ophthalmology, 2019). By tracking blood gap displacement in the capillaries through the image frames, erythrocyte velocities were obtained.

Results: Average retinal arteriolar velocities for control (7.60 ± 2.16 mm/s), glaucoma suspect (6.82 ± 1.67 mm/s), and glaucoma subjects (7.84 ± 2.62 mm/s) were not significantly different from each other ($p = 0.30$). However, average retinal venular velocities for control (5.00 ± 1.57 mm/s), glaucoma suspect (6.78 ± 1.63 mm/s), and glaucoma subjects (6.41 ± 1.46 mm/s) significantly differed ($p = 0.0016$). Average nailfold capillary velocity was not significantly different ($p = 0.11$) among control (0.301 ± 0.119 mm/s), glaucoma suspect (0.242 ± 0.103 mm/s), or glaucoma subjects (0.394 ± 0.153 mm/s). Retinal capillary velocities were obtained in seven subjects with a mean of 1.54 ± 0.35 mm/s.

Conclusions: Retinal capillary velocities are markedly higher than nailfold capillary velocities, consistent with the high metabolic rate of the retina. While nailfold capillary velocities are more accessible, a higher degree of precision may be necessary to detect differences given the lower velocities. Our nailfold capillary velocities were within range of what is reported in literature. Future work will compare nailfold capillary velocities to retinal capillary velocities in controls, glaucoma, and glaucoma suspects.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is an inherited blinding disease that causes degeneration of rod photoreceptors. Rod death causes many second-order changes in retinal circuits including the remodeling of bipolar cell dendrites and cone death. For treating vision loss from RP, a critical issue is determining how the fidelity of cone-mediated visual signaling depends on the amount of rod death.

Methods: We measured responses of retinal ganglion cells (RGCs) to artificial and natural visual stimuli under mesopic and photopic conditions using a mouse model of Cngb1-RP. In this model, rod death is a relatively slow process: rods progressively die until all are lost at 6-7 months. We measured RGC responses in animals at 1 month intervals from 1-7 months and compared responses to RGCs from WT mice. Ex vivo retinal recordings were performed using a 512 electrode array. Retina were placed RGC side down on the array, spikes were identified and sorted while presenting visual stimuli to the photoreceptors. The fidelity of signaling was examined in two ways. First, checkerboard noise was used to estimate the spatial and temporal receptive fields (RFs) of the RGCs. Second, repeated sequences of checkerboard noise or a natural movie were presented. These two approaches allowed an examination of the visual features encoded by the RGCs and the fidelity of this encoding process.

Results: Under both mesopic and photopic conditions, RF structure was relatively robust to the loss of rods out to 6 months of age (<10% rods surviving). Despite this relative stability in RF structure, the fidelity of visual signaling, measured by the mutual information (MI) between stimulus and response, was strongly impacted by rod loss. MI rates under mesopic conditions rapidly deteriorated when 50-80% of the rods remained. Under photopic conditions, MI rates were higher and less impacted by rod loss. Surprisingly, MI rates to natural movies were minimally impacted by rod loss and did not deteriorate significantly until after nearly all rods were lost and cones began to die.

Conclusions: Our results indicate that cone-mediated signaling of natural stimuli are minimally impacted by rod loss. This indicates that therapies for RP are likely to result in useful cone-mediated vision so long as rod photoreceptor death is halted.

TITLE: Vimentin as Regulator of Spreading and Migration of Corneal Fibroblasts in 3D Collagen Matrices

SESSION TITLE: Corneal stromal wound repair and healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Miron Mendoza, K. Poole, H. Hassaniardekani, M. Petroll, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Miguel Miron Mendoza: Commercial Relationship: Code N (No Commercial Relationship) | Kara Poole: Commercial Relationship: Code N (No Commercial Relationship) | Hajar Hassaniardekani: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Petroll: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The intermediate filament (IF) vimentin has been associated with myofibroblast transformation of corneal keratocytes and the development of fibrosis in vivo. Studies in other systems suggest it can play a central role in regulating key aspects of cell mechanical behavior, including mechanosensing, polarization, and migration. In this study, we investigate the role of vimentin in mediating spreading and migration of corneal fibroblasts in 3D collagen matrices.

Methods: To assess 3D cell spreading, human corneal fibroblasts were embedded in fibrillar collagen matrices. To assess 3D cell migration, compacted cell-populated collagen matrices were embedded in cell-free collagen matrices. Once polymerized, samples were cultured for 24h in serum-free media (S-), S- plus PDGF (50 ng/ml), or S- plus TGF β (5 ng/ml). Withaferin A (WFA), a vimentin polymerization inhibitor, was added at a concentration of 2 μ M based on initial dose response experiments. 3D and 4D imaging were used to assess cell-matrix mechanical interactions, global matrix contraction, and live cell spreading and migration. F-actin labeling was used to assess cell morphological changes.

Results: During initial cell spreading in PDGF, corneal fibroblasts randomly extended and retracted dendritic processes; these protrusions disappeared over time as cells elongated. When WFA was present, cells maintained their protrusive activity but did not elongate. As shown in Figure 1, cells treated with WFA had a significant decrease in both length and area, and a less elongated morphology (as indicated by a higher shape factor). In contrast, during culture in S- or TGF β (which do not induce cell elongation or migrational polarity), WFA induced an increase in cell length and area. Global matrix contraction in response to PDGF was reduced by 39% when WFA was present ($P < 0.035$), and cell migration assays showed a reduction of 40%.

Conclusions: Our results suggest that cells cultured with WFA are unable to polarize and elongate in response to PDGF, which results in a reduction in migration through 3D collagen matrices. In addition, inhibition of cell-induced matrix reorganization by WFA suggests that polymerization of IFs is important for development of cell tractional forces. Overall, vimentin may mediate key aspects of cell mechanical activity during corneal wound healing.

ABSTRACT BODY:

Purpose: Detailed knowledge regarding genetic and clinical characteristics of X-linked retinoschisis (XLRs) is necessary to provide patients with a more accurate prognosis, but also to identify clinical endpoints and optimal patient selection for (gene) therapy. This study aims to improve clinical counseling and acquire crucial information for the development process of treatment by evaluating the largest cohort of XLRs patients to this date.

Methods: This multicenter retrospective study reviewed medical records for medical history, symptoms, best-corrected visual acuity (BCVA), ophthalmoscopy, full-field electroretinography and retinal imaging (fundus photography, spectral-domain optical coherence tomography (SD-OCT), fundus autofluorescence).

Results: In total, 340 patients from presumably 178 different families were included with a mean age of 28.6 ± 19.3 years at last visit. The median BCVA of the better-seeing eye at last examination was 0.52 logarithm of the minimum angle of resolution (logMAR) (Interquartile range, Q1: 0.30, Q3: 0.70 logMAR). Severe visual impairment below 1.0 logMAR was predominantly present in patients above 40 years old, with a prevalence of 13.5% in that age group. Linear mixed models revealed a slow annual decline of 0.39% in BCVA ($P < 0.001$), with a relatively stable visual acuity until the age of 20 years. The integrity of the ellipsoid zone (EZ) as well as the photoreceptor outer segment (PROS) length on SD-OCT were significantly correlated with visual acuity (Spearman's $r = -0.604$, $P < 0.001$; $r = -0.759$, $P < 0.001$; respectively). Fifty-three different RS1 gene mutations were found. The most common variants were two founder mutations: c.214G>A (p.Glu72Lys; 102 subjects, 38.2%) and a deletion of exon 3 (38 subjects, 14.6%). There was no significant difference in decline of BCVA between mutations that were predicted to be severe and mild ($p=0.852$).

Conclusions: In general, XLRs showed a slow progression starting around the age of 20, suggesting an optimal window of opportunity for treatment within the first two decades of life. The integrity of EZ as well as the PROS length on SD-OCT may be important potential clinical endpoints in future therapeutic studies. No clear genotype-phenotype

correlations were found.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) cells present geographical differences across human eyes. In the macula, RPE cells are smaller in size and present distinct shapes of apical processes, in comparison to peripheral RPE. In addition, there are functional and molecular differences in these two RPE populations, such as RPE metabolism and expression of specific transporters. Moreover, selective death of macular RPE cells occurs during retinal degenerative diseases, such as age-related macular degeneration (AMD). Currently, there is no thorough description of human regional RPE diversity and vulnerability, thus limiting the understanding of regional degenerative diseases. This study aims to provide a detailed and comprehensive morphometric map of the entire human RPE.

Methods: RPE/choroid flatmounts were generated from more than 20 human non-AMD and AMD eyes. The entire flatmounts were stained for RPE cell borders and imaged. An open-source software for image analysis, based on machine learning, was developed to quantify RPE morphometry. Spreadsheets with raw data and color-coded images were generated to compare regional RPE differences.

Results: Human RPE cell shape analysis of non-AMD eyes revealed the presence of 5 morphometrically different RPE subpopulations, which we named as P1 to P5, going from the macula toward the periphery. RPE cell area increases with eccentricity; in the mid-periphery (P3), RPE cells are almost double the size of macular RPE (P1) (median: $238.7 \mu\text{m}^2$ ($\pm 18.9 \mu\text{m}^2$ sd) vs $149.6 \mu\text{m}^2$ ($\pm 16.7 \mu\text{m}^2$ sd)). In addition, a peripheral ring of smaller RPE cells (P4) was discovered (median: $181.8 \mu\text{m}^2$ ($\pm 19.8 \mu\text{m}^2$ sd)). So far, the nature of P4 population remains elusive. RPE lesions were detected in the periphery of non-AMD eyes, revealing selective vulnerability of peripheral RPE populations (P4 and P5). Quantification of RPE lesions from AMD eyes and ultra-widefield retinal images of patients with monogenic disorders shows differential susceptibility of RPE subpopulations to degeneration.

Conclusions: Overall, the study provides the first comprehensive morphometric map of the human RPE and it provides a geographic reference of RPE subpopulations for other researchers in the field. Finally, studying the nature of each RPE subpopulation might help to understand regional retinal degeneration.

ABSTRACT BODY:

Purpose: To determine the role of GDF-15, a divergent member of the transforming growth factor beta superfamily in trabecular meshwork physiology and homeostasis of intraocular pressure (IOP).

Methods: Telomerase inhibitor, lipopolysaccharide (LPS), and tunicamycin were used to determine whether cellular senescence, inflammation, and ER (endoplasmic reticulum) stress, respectively, influence the expression of GDF-15 in human trabecular meshwork (TM) cells, utilizing ELISA and immunoblot analyses. To determine the role of GDF-15 in regulation of IOP, mildly anesthetized human GDF-15 overexpressing transgenic mice (C57BL/6J) and GDF-15 null mice (C57BL/6J) were monitored for changes in IOP using a rebound tonometer.

Results: Treatment with telomerase inhibitor (20 μ m BIBR1532, 24 hrs) and Tunicamycin (one μ g/ml for 48 hrs) but not LPS (1-5 μ g/ml for 24 hrs) significantly increased GDF-15 levels in human TM cells. Transgenic mice expressing human GDF-15 exhibited significantly elevated human GDF-15 levels in both serum and aqueous humor compared to age-matched control mice. GDF-15 transgenic mice also exhibited a significant increase in IOP (~24 % $P < 0.01$; $n = 16$) compared to control mice. On the other hand, the GDF-15 null mice ($n = 15$) maintained normal IOP.

Conclusions: The increase in GDF-15 levels under senescence and ER stress and elevated IOP in GDF-15 overexpressing transgenic mice, when considered together with the known effects of GDF-15 on TM contractile/cell adhesive characteristics and elevated levels of GDF-15 in the aqueous humor of glaucoma patients, suggests that dysregulation of GDF-15 levels may be linked to ocular hypertension and glaucoma.

ABSTRACT BODY:

Purpose: To examine the association between visual impairment and driving performance at left turns at four-way intersections with traffic control among drivers aged ≥ 70 .

Methods: A 6-month prospective cohort study focused on drivers aged ≥ 70 years with eye conditions which could cause impairment using naturalistic driving methods was completed. After enrollment, participants completed a battery of visual and visual-cognitive function assessments including visual acuity, contrast sensitivity, visual field sensitivity, visual processing speed, and motion perception. To objectively collect driving information, a data acquisition system (DAS) was installed in participant vehicles. The DAS recorded continuous data streams from accelerometers, vehicle network, GPS, and 5-channel video camera system. Left turns were identified using accelerometer and GPS data and mapped to identify the location. To obtain 500 turns for data reduction, turns were randomized by participant and the location assessed to choose the first 3 or 4 turns for each participant occurring at a four-way intersection with traffic control. Trained analysts coded two outcomes: safe versus unsafe traversal and normal versus improper turn behavior. Generalized estimating equations, which account for repeated measures, were used to calculate age-adjusted odds ratios (ORs) and 95% confidence intervals (95% CIs) for the outcomes and association with visual impairment.

Results: A total of 473 left turns were assessed among 151 participants. Impaired visual processing speed (Trails B) was associated with 46% reduced odds of unsafe traversal (OR: 0.54, 95% CI: 0.34-0.85). Visual field sensitivities (overall, peripheral, lower, left) were significantly associated with 42-44% reduced odds of unsafe traversal. Similar significant protective associations were seen for those with impaired contrast sensitivity, visual processing speed (Trails B), and visual field sensitivities (peripheral, upper, lower, left) and improper turn behavior.

Conclusions: Older adults with vision impairment had reduced odds of unsafe traversal and improper behavior. While this finding could seem counterintuitive, it is consistent with self-report literature indicating that older drivers are aware of challenging driving situations and therefore could be more cautious. As this is the first examination of these associations, future work should further explore these findings continuing to use objective means.

ABSTRACT BODY:

Purpose: To explore the potentiality of quinoline based small molecules for matrix metalloproteinase 14 (MMP14) inhibitors.

Methods: We optimized and established to identify specific and unique MMP14 inhibitors through two-stage assays. Primary high-throughput (HTS) by fluorescence-based enzymatic assay was performed to determine IC_{50} value. We determined dissociation equilibrium constant (K_D) between cat-MMP14 with candidate compounds using surface plasmon resonance (SPR) to validate selected hit compounds. cat-MMP14 was immobilized on a CM5 sensor chip using the standard amine-coupling method using a Biacore 8K instrument. Compound solutions with a series of increasing concentrations (0 to 50 μ M at 1.5-fold dilution) were applied to all channels at a 30 mL/min flow rate at 25 °C. The K_D values were determined by fitting the data with either steady-state affinity or 1:1 Langmuir kinetic fitting. To investigate the potentiality to develop MMP14 inhibitors, we determined a structure-activity relationship (SAR) with twelve quinoline analogs using a fluorescence-based enzymatic assay.

Results: Three compounds (clioquinol, chloroxine, and folic acid) containing quinoline as a base structure showed inhibitory effects of MMP14. We found that two compounds (clioquinol and chloroxine) directly bound to act-MMP14 using SPR analysis. Clioquinol, chloroxine, and folic acid did not show cytotoxicity on corneal epithelial and fibroblast cells.

Conclusions: Our results show that quinoline containing small molecules inhibited MMP14 enzymatic activity. Based on these findings, we propose that the unique MMP14 inhibitors can specifically inactivate the MMP14 enzyme activity, leading to inhibition of corneal neovascularization via MMP14.

ABSTRACT BODY:

Purpose: Multiple studies have investigated the mechanisms of infant adaptation to visual stimulus as well as the residuals of developmental misadaptation in adults. Considerably less is known about the respective dissemination of factors and dynamics in juvenile populations. The purpose of this study was to assess the occurrence of stereo deficiency and its determinants in adolescents and young adults.

Methods: Routine eye examination data of 224,604 military recruits aged 17 to 21 yrs were retrospectively assessed and analyzed using standard statistical software. Data were assigned to either stereonormal or stereo-deficient individuals and substratified by grade of stereopsis. Presumed determinants were addressed on three levels (low, moderate, high) and included myopia (≤ -0.5 ; < -2.0 ; < -5.0 D), hyperopia ($\geq +0.5$; $> +2.0$; $> +5.0$ D), astigmatism (≥ 0.5 ; ≥ 2.0 ; > 3.0 D), anisometropia (≤ 1 ; ≤ 2 ; > 3 D), amblyopia (BCVA < 1.0 ; < 0.6 ; ≤ 0.2), and residual strabism. For each subset, logistic regression was performed using iterative log-likelihood approximation for calculation of odds ratios (OR) and confidence intervals (0.95 CI).

Results: A total of 20,762 cases of stereo deficiency was identified relating to 9.2% of the population analyzed in this study. Of these, 26.8% displayed myopia, 13.8% hyperopia, and 23.8% astigmatism. Correctable refraction error was present in 46.6% of cases, as compared to 29.7% in stereonormal individuals. Rates of uncorrectable refractive error increased dependent on the extent of stereo deficiency, with the left eye persistently displaying amblyopia at rates 1-2% higher than the right eye. Risk factor analysis identified strabism (OR 26.8 [0.95 CI: 25.2; 28.5]) and high hyperopia (OR 10.3 [0.95 CI: 8.9; 11.9]) being the predominant determinants, while interaction with anisometropia (OR 3.75 [3.57; 3.94]), astigmatism (OR 2.45 [2.38; 2.53]), and myopia (OR 1.21 [1.18; 1.24]) was much less pronounced ($p < 0.0001$).

Conclusions: Our results might be useful in bridging the gap between pediatric and adult-related research in developmental ophthalmology. Given the hyperdominance of motor deficiency and the over-representation of left eye visual deficiency found in this study, we hypothesize that the adaptive expression of higher binocular functions such as depth perception and ocular rivalry may not be fully understood.

TITLE: Alternative Promoter Use in Photoreceptors: Implications for Cell Signaling?

SESSION TITLE: Regulating Photoreceptor Development and Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Campello, H. Mast, L. Dong, A. Swaroop, National Eye Institute, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Laura Campello: Commercial Relationship: Code N (No Commercial Relationship) | Hannah Mast: Commercial Relationship: Code N (No Commercial Relationship) | Lijin Dong: Commercial Relationship: Code N (No Commercial Relationship) | Anand Swaroop: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Transcriptome analyses of photoreceptors have identified numerous genes with alternative promoter usage. Importantly, many of these alternate promoters are regulated by NRL and CRX, suggesting a crucial role in photoreceptors. However, how alternative promoter usage confers photoreceptor-specific regulation and function to widely expressed genes is not well-characterized. In the present work, we have explored the regulation and function of Hcls1 (hematopoietic cell-specific Lyn substrate 1), implicated in actin remodeling and receptor tyrosine kinase (RTK) signaling in immune cells but with unknown function in the retina.

Methods: RNA-seq analyses of mouse retina and flow-sorted photoreceptors identified genes with putative alternative promoter usage in photoreceptors. ATAC-seq, epigenetic marks (H3K4me3, H3K27ac) as well as NRL and CRX ChIP-seq data analyses predicted new transcription start sites. 5'-RACE was used to identify novel Hcls1 photoreceptor-specific transcripts. Expression of these transcripts was examined by in situ hybridization. Electrophoretic mobility shift assays (EMSA) were used to validate the NRL and CRX binding sites.

Results: We identified by 5'-RACE analysis a novel photoreceptor specific isoform of Hcls1 (Hcls1r), generated by alternative promoter usage. The expression of Hcls1r is concordant with photoreceptor morphogenesis and maturation trajectory. The protein encoded by this new transcript does not include the N-terminal domain involved in actin remodeling but retains signaling elements associated with receptor tyrosine kinase (RTK) signaling, which drives essential cellular processes in response to extracellular cues. In situ hybridization analysis confirmed the enrichment of this novel Hcls1 transcript in the photoreceptor layer. EMSA demonstrated the binding of Nrl and Crx to conserved Hcls1 intronic sequences, close to the transcription start site of the alternate Hcls1r transcript and contained open chromatin regions.

Conclusions: We propose that Hcls1r is a part of the regulatory network associated with photoreceptor function. Specifically, we predict an important function of Hcls1r in RTK signaling to modulate responses to the retinal microenvironment in photoreceptors and maintenance of homeostasis. We hypothesize that alternative promoter usage contributes to highly specialized structural and functional complexity of retinal photoreceptors.

ABSTRACT BODY:

Purpose: Numerous diseases detrimentally affect corneal nerves. Corneal nerve dysfunction has been linked to dry eye syndrome onset, neurotrophic keratopathy, and other diseases. The morphology and histology of corneal nerves in health and disease has been extensively studied. However, studies of corneal nerve function have been limited (e.g., electrical recordings of ciliary nerves or calcium reporter dyes in ex vivo corneas). Here, we present a non-contact method for functional imaging of corneal nerves. This tool has great potential to improve understanding of diseases of corneal nerves and the development of therapies for diminished neural function.

Methods: We made a cre-lox murine line expressing a genetically encoded calcium indicator, GCaMP6f, against the Nestin promoter for expression in the cornea nerves. We built a custom confocal imaging system with an air objective to image the corneal nerves while excluding autofluorescence from the lens. We designed various stereotactic and imaging apparatus to minimize motion of the mouse cornea relative to our imaging system (see Figure 1).

Results: Figure 1 shows our cornea imaging setup and Figure 2 shows a demonstration of in vivo corneal functional neuro-imaging. Using this technique, we were able to stably image the murine corneal nerves over long periods (e.g., 10 minutes). We have also demonstrated longitudinal imaging of the same field of nerves through multiple successive experiments.

Conclusions: Our developed tools and methods can enable study of the relationship between corneal nerve function and diseases of the ocular surface. The use of an in vivo system potentially allows for the study of factors that could slow the development of neuropathies and help develop new clinical interventions and therapies, which is a major goal of this work.

ABSTRACT BODY:

Purpose: Age is a major risk factor for cataract. However, the influence of aging on the lens transcriptome is under studied. While age related cataract affects both sexes, it is more prevalent in women than men. While estrogen withdrawal at menopause is implicated in this observation, how sex influences lens gene expression is unknown. Here, we elucidate the effect of sex and age on the lens transcriptome of inbred mice.

Methods: Lens epithelial (LEC) and fiber cells (LFC) were isolated from young (3 month) and aged (24 month) old C57Bl/6J mice of both sexes, RNA prepared, and subjected to RNAseq. EdgeR was used to estimate differential gene expression in pairwise contrasts, with Advaita's lpathway guide and custom R scripts to evaluate the biological significance of differentially expressed genes (DEGs).

Results: RNAseq revealed age dependent decreases in lens differentiation marker expression in both LECs and LFCs, with gamma crystallin transcripts downregulating nearly 50 fold in LFCs. Aged LECs upregulate genes controlling the immune response, complement pathways, and cellular stress responses, including glutathione peroxidase 3 (GPX3). Aged LFCs exhibit broad changes in the expression of genes regulating cell communication, and upregulate genes involved in antigen processing/presentation, cholesterol metabolism, and calcium signaling, while changes in the expression of mitochondrial respiratory chain genes are consistent with mitochondrial stress. While young LECs only differentially express genes known to be associated with sex determination (i.e Xist in females, and Ddx3y in males), female LECs do not reduce crystallin transcription with age to the same extent as males nor do they upregulate GPX3 expression as dramatically as males. In contrast, young LFCs from males and females differentially express nearly fifty genes, many of which remain differentially expressed in aged LFCs. Notably, female LFCs retain substantially greater gammaD crystallin expression with age compared to males while also exhibiting enhanced upregulation of NDufa4l2, which encodes an alternate electron transport chain protein and is a marker of mitochondrial stress.

Conclusions: Lens cells downregulate the expression of lens markers with age while upregulating markers of inflammation, complement pathways, and cellular stress. Sex does not have a large impact on the young LEC transcriptome, but it does have a modest influence on gene expression in the aging lens.

ABSTRACT BODY:

Purpose: Macular telangiectasia type 2 (MacTel) is a vision-altering retinal disease with a high prevalence of diabetes. Fluorescence lifetime imaging ophthalmoscopy (FLIO) was used to further investigate differences between MacTel patients with and without diabetes.

Methods: 89 eyes from 89 patients with MacTel (mean age 59 ± 12 years) were investigated at the Moran Eye Center, with the diagnosis of MacTel confirmed by the Moorfields reading center. 40 patients (45%) did not have diabetes, 16 eyes (18%) were prediabetic, and 33 patients (37%) were diabetic. Of these, 5 patients had diabetic retinopathy. A prototype Heidelberg Engineering FLIO was used to obtain autofluorescence lifetimes in short (SSC, 498-560 nm) and long (LSC, 560-720 nm) spectral channels from different areas of interest within the MacTel zone and in the periphery.

Results: FLIO lifetimes did not show significant differences in any area when comparing diabetic to nondiabetic eyes (MacTel zone SSC diabetic: 265 ± 57 ps, nondiabetic: 259 ± 49 ps, $p=0.59$; LSC diabetic: 333 ± 64 ps, nondiabetic: 317 ± 52 ps, $p=0.23$). When comparing nondiabetic eyes to eyes with diabetic retinopathy, significant differences were only found in the periphery ($P<0.01$) but not within the MacTel zone ($P=0.22$). Longitudinal changes in FLIO within the MacTel zone were similarly unrelated to the diabetes status.

Conclusions: Although MacTel has a high prevalence of diabetes, FLIO lifetimes from the MacTel zone seem to be unrelated to diabetes. This indicates that FLIO retains diagnostic abilities in patients with MacTel even in the presence of prediabetes, diabetes, and advanced diabetic retinopathy.

ABSTRACT BODY:

Purpose: Dry eye disease (DED) can be a debilitating disease of the eye. With several clinical tools available to evaluate severity and impact of the disease, it is often unclear how outcomes assessed using one test relates to others, specifically outside the context of therapeutic interventions. In this study, several different clinical tests were compared to examine their relationships.

Methods: Subjects (N=1149), who were brought in for screening prior to any therapeutic intervention were included for this analysis. The mean age (\pm SD) was 57.4 ± 15.5 years; 70% of the subjects were females and 30% were males. Subjects were divided into three groups based on results from unanesthetized Schirmer's Test; Normal group: Schirmer's >10 mm, Borderline: Schirmer's = 6 to 10mm, Severe DED: Schirmer's ≤ 5 mm. Several outcomes including corneal fluorescein staining (CFS) total and regional (NEI grading), Ocular Surface Disease Index (OSDI) overall score, disease duration and age were compared between the groups. For CFS, each region was graded on a scale of 0 to 3, with a total possible maximum score of 15. Correlation coefficient (R) was calculated for continuous variables. ANOVA was used for group comparisons. Only data from the right eye was included for analysis.

Results: Schirmer's scores showed significant moderate correlation with total CFS ($R = -0.29$, $p < 0.0001$). CFS was progressively worse in groups with reduced Schirmer's score. Total CFS was 9.2 ± 2.4 in severe Schirmer's group and 8.9 ± 2.4 in the borderline group compared to 7.4 ± 2.7 in normal group ($p < 0.0001$ for both comparisons vs normal). These results were also consistent for all 5 sub-regional staining analysis. Inferior CFS was 2.1 ± 0.6 in severe group, 2.0 ± 0.6 in borderline group and 1.8 ± 0.7 in the normal group ($p < 0.0001$ for both comparisons vs normal). Schirmer's score showed significant mild correlation with age ($R = -0.11$, $p = 0.0001$) with severe subjects being significantly older (mean 61.1 ± 13.4 years) than those with normal Schirmer's (mean 54.7 ± 16.6 years) ($p < 0.0001$). Severe subjects also had significantly longer DED duration (mean 11.5 ± 9.2 years) than those with normal Schirmer's (mean 9.8 ± 8.8 years) ($p = 0.02$).

Conclusions: Schirmer's score captures DED intensity that aligns with total and regional corneal staining measures as well as age and duration.

ABSTRACT BODY:

Purpose: Oxidative stress in corneal endothelial cells (CECs) preserved under hypothermic conditions is thought to be a major driver of cell death prior to surgery as well as decreased graft survival after keratoplasty. To mitigate oxidative damage and reactive oxygen species (ROS) in CECs, we aimed to develop a highly dispersible and stable formulation comprising a complex of ubiquinol and gamma-cyclodextrin (γ -CD) for use in aqueous-phase ophthalmic products including corneal storage media, intraocular irrigation solution, and topical eye drops.

Methods: Molecular docking study in AutoDock Vina indicated that γ -CD has the strongest binding affinity with ubiquinol. Ubiquinol/ γ -CD complex (UBCD) was prepared using the kneading method and its physiochemical properties were characterized. Stability of UBCD in Optisol-GS®, balanced salt solution, and Refresh® artificial tear eye drops for up to 1 week was determined by HPLC. High ROS-generating cells (A549) and B4G12 human corneal endothelial cells (HCEC-B4G12) were exposed to antimycin A, and UBCD ROS scavenging activity was measured using DHE fluorescence. Cytotoxic effect was determined up to 72 hours using MTS reagent. A NaviCyte vertical diffusion chamber was used to assess transcorneal penetrance of topically applied UBCD in human donor corneas. Lastly, UBCD penetrance of stored CECs was assayed using human corneas preserved for 7 days in Optisol-GS®.

Results: UBCD showed significantly higher stability compared to free ubiquinol by HPLC analysis. UBCD was more effective at lowering ROS at far lower concentrations compared to free ubiquinol. No evidence of cellular toxicity was detected in B4G12 cells. Topically applied UBCD penetrated the entire thickness of human donor corneas with significantly greater ubiquinol retention in the endothelium compared to free ubiquinol ($p=0.059$). UBCD demonstrated higher amounts of ubiquinol retained in the corneal endothelium of preserved donor corneas compared to free ubiquinol ($p<0.05$).

Conclusions: Findings indicate that UBCD can better preserve human CEC function during cold storage, and may be useful in preventing post-keratoplasty cell loss, increasing donor cornea preservation time, and reducing graft failure by scavenging ROS. UBCD's higher bioavailability and stability in the aqueous phase will allow its incorporation into a variety of products for ophthalmic use to protect CECs against oxidative damage.

TITLE: Synaptic transmission in rod bipolar dendrites is desensitized and does not support significant TRPM1 responses in the degenerating retina

SESSION TITLE: Inner retinal function

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E. Ellis, A.P. Sampath, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|H. Xu, J. Chen, Physiology and Neuroscience, University of Southern California, Los Angeles, California, UNITED STATES|G. Field, Neurobiology, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Erika Ellis: Commercial Relationship: Code N (No Commercial Relationship) | Hui Xu: Commercial Relationship: Code N (No Commercial Relationship) | Greg Field: Commercial Relationship: Code N (No Commercial Relationship) | Jeannie Chen: Commercial Relationship: Code N (No Commercial Relationship) | Alapakkam Sampath: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During the early stages of retinal degeneration rod photoreceptors begin to functionally uncouple from downstream rod bipolar cells, retracting their synaptic terminals. Previous studies have shown that rod bipolar cells lack a light-evoked response under these conditions even though some synaptic puncta remain at their dendritic tips. We tested whether the lack of rod bipolar response is due to impaired glutamate release from rods, or deficient mGluR6 transduction in bipolar dendrites.

Methods: Voltage clamp recordings from rod bipolar cells were made with patch electrodes in dark-adapted retinal slices from 1- and 2-month-old CNGB1^{neo/neo} mice, which display gradual retinal degeneration over 6 months. Light responses were evoked by an LED ($\lambda_{\text{max}} \sim 405\text{nm}$). Responses in the absence of light were evoked with puffs of the weak mGluR6 antagonist, CPPG, onto their dendrites while the retina was bathed in Ames' media with and without the strong mGluR6 agonist, DL-AP4.

Results: Light-evoked responses in 1- and 2-month-old CNGB1^{neo/neo} rod bipolar cells were largely absent, consistent with previous studies. In these same bipolar cells, puffs of the glutamate receptor antagonist CPPG (1 mM) also evoked either a minimal or no inward current. The size of the inward current increased in some rod bipolar cells when the solution bathing the retina also contained 5 mM DL-AP4. Puffs of CPPG in control retinas produced an inward current, which was also increased in the presence of DL-AP4.

Conclusions: Rod bipolar cells largely lack light-evoked responses in the degenerating retina, and under these conditions support minimal responses to puffs of CPPG. The increased response size to CPPG in the presence of DL-AP4 suggests that the molecular machinery remains in place to support responses, but that reduced rod glutamate release causes this mGluR6 machinery to be strongly desensitized. The retained ability of mGluR6 transduction to open TRPM1 channel during degeneration may explain why rod-to-rod bipolar cell synapses can be strengthened following the rescue of rod function.

TITLE: Knockout of the mechanotransducer, Integrin- α 7, in trabecular meshwork cells affects signaling through Akt and mTOR

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Staverosky, J.A. Vranka, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|V. Raghunathan, Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Julia Staverosky: Commercial Relationship: Code N (No Commercial Relationship) | VijayKrishna Raghunathan: Commercial Relationship: Code N (No Commercial Relationship) | Janice Vranka: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is a primary risk factor in the development and progression of glaucoma. The trabecular meshwork (TM) is responsible for maintaining homeostatic IOP. However, specific molecular regulators of IOP remain elusive. Integrin- α 7 (ITGA7) binds laminin and acts as a mechanotransducer in muscle tissue. We previously demonstrated that ITGA7 is upregulated in TM in response to elevated pressure, that the integrin α 7- β 1 heterodimer is expressed in the TM, and that signaling in response to plating on laminin is primarily through Akt. Here we investigate the expression of the three isoforms of Akt in hTM. We further elucidate the impact of ITGA7 on hTM cell signaling by knocking out ITGA7 and measuring its effect on downstream molecules in response to stretch.

Methods: Knockout of ITGA7 in hTERT-GFP immortalized (CL-27) and primary (2020-1183) hTM cells was achieved via lentiviral CRISPR. Percent knockout was determined using Western blotting post puromycin selection. hTM cells were plated on laminin coated Flexcell plates and stretched for 5, 15 or 30 minutes (n = 3 replicates). Protein expression levels and phosphorylation activity was determined by Western blot with protein and phospho-specific antibodies to the following downstream molecules: Akt, p38, JNK, Erk, mTOR, p70S6K, GSK3b, BAD, and 4EBP1.

Results: Knockout in the immortalized CL-27 hTM cell line was complete whereas it was approximately 50% in the primary cell strain. In immortalized hTM cells Akt activation in response to stretch on laminin was more pronounced in the absence of ITGA7. This correlated with increased mTOR phosphorylation. The results in primary cells were similar but less pronounced. There was no notable effect of stretch on the phosphorylation of JNK or Erk. We also demonstrate that all three isoforms of Akt are robustly expressed in hTM cells.

Conclusions: In the absence of ITGA7 Akt activity is increased in hTM cells in response to stretch on laminin. We previously showed that Akt is activated in response to laminin binding, the primary ligand of the integrin α 7- β 1 heterodimer. Thus an increase in Akt phosphorylation in the absence of ITGA7 is unexpected and suggests a key role in modulating signaling pathways in the TM. Further studies in primary hTM cells will provide insight into whether this effect is shared or specific to immortalized hTM cell lines.

TITLE: Defining clinically meaningful improvement in ocular itching following treatment with reproxalap in an allergic conjunctivitis field trial

SESSION TITLE: Antimicrobials and Immunomodulators

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Raval, P.J. Gomes, Allergy, Ora, Inc., Andover, Massachusetts, UNITED STATES|B. Cavanagh, T.C. Brady, Aldeyra Therapeutics, Inc., Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yesha Raval: Commercial Relationship(s);Ora, Inc.:Code E (Employment) | Paul Gomes: Commercial Relationship(s);Ora, Inc.:Code E (Employment) | Bill Cavanagh: Commercial Relationship(s);Aldeyra Therapeutics, Inc.:Code E (Employment) | Todd Brady: Commercial Relationship(s);Aldeyra Therapeutics, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: The clinically minimally important difference (MID) has not been defined for the commonly used 9-point ocular itching scale (0 – 4 with half-unit increments). Based on results from an allergic conjunctivitis (AC) field trial evaluating topical reproxalap compared to vehicle, the ocular itch score MID was calculated using a quality of life anchor-based approach and distributional statistics.

Methods: In a double-masked, multi-center field trial, 60 patients with AC were randomized 1:1:1 to receive topical ocular solutions of either 0.25% reproxalap, 0.5% reproxalap, or vehicle four-times daily for one month during allergy season. Ocular itching scores (Ora Calibra™, 0-4 scale) were compared to the Allergic Conjunctivitis Quality of Life Questionnaire (ACQLQ), comprised of 15 sub-scales (0-6) to quantify how bothersome symptoms and signs are across a variety of parameters. Assessments were obtained at baseline (Day 2) and at the end of the trial (Day 28). Average MID across all sub-scales was calculated by subtracting improvement in itching score for subjects that did not improve on the bother scale from improvement in itch score for subjects that improved on the bother scale by one point (mean difference method). Baseline standard deviation (SD) and standard error of measurement (SEM) were used to confirm the anchor-based findings.

Results: The MID was calculated to be 0.42 (95% CI 0.21, 0.64). Half of the baseline SD was 0.43, and the SEM was 0.48. The correlation of itch bother to ocular itch score was statistically significant ($p < 0.0001$), with an r value of 0.8.

Conclusions: Clinically meaningful change in the ocular itching scale was determined to be between 0.42 and 0.48 units, approximately the smallest unit of the itch score scale. The results provide clinically relevant context for the interpretation of AC clinical trials using the 9-point itching scale.

ABSTRACT BODY:

Purpose: The role of bacterial proteases in upon microbial pathogenesis of the cornea has been well studied; however, little work has gone into the effect these proteases have on corneal wound healing and cell migration. *Serratia marcescens* secretomes (proteins, lipids and other molecules) efficiently inhibit corneal cell migration, but no secreted proteins have been identified as being responsible for the phenotype. In this study we investigated the bacterial factors required to inhibit wound healing using an in vitro corneal epithelial model, specifically by analyzing the impact of bacterial metalloproteases.

Methods: Stratified layers of human corneal limbal epithelial cells were exposed to normalized and filter sterilized culture supernatants of *Serratia marcescens*, *Pseudomonas aeruginosa*, and *Klebsiella aerogenes*. Purified metalloproteases and the *P. aeruginosa* metalloprotease inhibitor AprI were also used to test wound healing.

Results: Mutation of individual *S. marcescens* metalloprotease genes prtS, slpB, and slpE did not affect this phenotype; however, mutation of all three genes eliminated the inhibitory phenotype. This suggested that the three metalloproteases had redundant function. Consistently, plasmid-based expression of each of the individual protease genes restored inhibition ability. Furthermore, exogenous addition of purified PrtS, SlpB, and SlpE metalloproteases was sufficient to inhibit cell migration, and the metalloprotease inhibitor protein, AprI, from *Pseudomonas aeruginosa* restored migration. The role of similar metalloproteases from other important pathogens was addressed.

Conclusions: Bacterial metalloproteases can inhibit cellular migration and our results suggest that protease inhibitors may be useful in experimental therapeutic approaches for chronic wounds or to promote wound healing.

ABSTRACT BODY:

Purpose: To describe a novel physical exam finding in thyroid eye disease (TED) – the “Rainbow Brow (RB)” – and quantify the finding mathematically

Methods: Eyebrows of subjects with TED and controls were analyzed, and the presence of RB appearance was determined by unanimous agreement of 3 oculoplastic surgeons. Eyebrow curvature was assessed by plotting 15 points along the eyebrow (figure 1A). The quadrinomial was fitted to each eyebrow in Excel.¹ Mann-Whitney U analysis was performed on the five coefficients (a, b, c, d, & e) of the quadrinomial in the form $ax^4 + bx^3 + cx^2 + dx + e$ to evaluate for a difference in brow curvature. TED eyes with RB appearance were compared to age-sex-matched normal controls and other TED eyes without RB appearance. Univariable and multivariable logistic regression were performed to evaluate anatomical features that predicted RB appearance in TED eyes.

Results: A total of 271 eyes were analyzed (200 TED and 71 control). The majority of TED patients were female (82.5%) with a mean age of 53 ± 16 years. A Rainbow Brow was identified in 42% of TED patients, with 13% of TED patients having only unilateral RB appearance. Mann-Whitney U analysis of the quadrinomial coefficients yielded significant differences between RB eyes and controls for the coefficients a ($p = 0.034$), b ($p = 0.003$), c ($p = 0.001$), and d ($p = 0.000$). Similar analysis between TED eyes with and without RB appearance showed differences in coefficients a ($p = 0.034$) and b ($p = 0.041$). Features that were found to increase the odds of RB appearance included age greater than 50 (OR 2.307, $p = 0.009$, 95% CI 1.229 – 4.328) and the presence of brow fat expansion (OR 3.555, $p = 0.000$, 95% CI 1.935 – 6.529). When considering the contribution of these features in a multivariable analysis, only the brow fat expansion was a statistically significant contributing factor for RB appearance ($p = 0.009$).

Conclusions: The Rainbow Brow is a distinct entity in TED and is likely a consequence of the expansion of the brow fat pad. Eyes with RB have a statistically significant difference in eyebrow curvature compared to those of TED without RB and controls.

ABSTRACT BODY:

Purpose: Fibroblast growth factor-10 (FGF10) is a member of the fibroblast growth factor family-7 (FGF7), which controls epithelial morphogenesis and proliferation. This suggests that FGF10 signaling is necessary for the development of functional lacrimal glands. Several recent studies have implicated the in vitro biological functions of FGFs for the regeneration of different organs. However, little is known about the proliferative effects of FGF10 on human corneal and lacrimal glands. We aimed to study the proliferative effects of fibroblast growth factor-10 (FGF10) on human primary corneal and lacrimal gland epithelial cells.

Methods: Epithelial cells were derived from donor transplant tissue by incubating the corneoscleral rims in dispase for 1 hour and then gently scraping the cells from the epithelia. Cultures were expanded in growth-factor-containing medium for two passages and plated on 96-well plates. When the cells reached 50-70% confluency, the medium was replaced with a growth-factor-free base medium with FGF10 (30 ng/mL), with two different added supplements, or with combinations of FGF10 and each individual supplement. Cell viability/proliferation was examined by ATP quantification 72 hours after application. Similarly, human lacrimal gland cells cultured in defined medium were treated with FGF10 (20ng/ml), and cell proliferation was estimated 48-72 hours later.

Results: We found that FGF10, as well as the supplements, increased corneal cell proliferation by $23 \pm 20\%$, $32 \pm 16\%$, and $43 \pm 13\%$, respectively (\pm SD), compared to defined medium alone (N=8). However, combinations of FGF10 and each of the two supplements increased proliferation by $64 \pm 20\%$ and $66 \pm 27\%$, respectively (N = 8). Similarly, FGF10 resulted in increased lacrimal gland cell proliferation ($71 \pm 18\%$) cultured in defined medium with the second supplement compared to the defined medium with the second supplement on its own.

Conclusions: FGF10 is an effective proliferative factor for human corneal and lacrimal epithelial cells. Moreover, the synergistic effects of FGF10 in combination with specific growth supplements suggest the role of FGF10 in cell survival and as a potential use for expansion of human corneal and lacrimal gland epithelial cells.

Commercial Relationships Disclosure (Abstract): Santiago Delgado-Tirado: Commercial Relationship: Code N (No Commercial Relationship) | Lucia Gonzalez-Buendia: Commercial Relationship: Code N (No Commercial Relationship) | Miranda An: Commercial Relationship: Code N (No Commercial Relationship) | Jose M. Ruiz-Moreno: Commercial Relationship: Code N (No Commercial Relationship) | Leo Kim: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Arboleda-Velasquez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Runt-related transcription factor 1 (RUNX1) inhibition is a novel therapeutic strategy in ocular neovascularization and has previously been shown to be safe and effective for the treatment of retinal and choroidal neovascularization in animal models. Furthermore, topical application of RUNX1 inhibitor, Ro5-3335, as a nanoemulsion (eNano-Ro5) has demonstrated efficacy in experimental proliferative vitreoretinopathy. This study assessed the preclinical efficacy of topical RUNX1 inhibition in alkali burn-induced corneal neovascularization

Methods: 6-8-week-old C57BL/6J male and female mice were used for this study. eNano-Ro5 was administered topically four times a day after alkali burn-induced corneal neovascularization. To induce the corneal injury, a 2-mm paper disc soaked in 1M NaOH was placed on the surface of the central cornea for 30 seconds followed by a thorough washing with saline solution for 60 seconds. Animals were evaluated with slit lamp examination at days 1, 3, 7 and 14. Corneal defect, corneal opacity and corneal neovascularization were analyzed after treatment with either eNano-Ro5 (n=22) or vehicle (n=23) for 14 days after alkali burn. We also included another group treated with Dexamethasone 0.1% (n=9)

Results: RUNX1 positive cells were observed after injury by immunofluorescence within the corneal tissue. We found a significant reduction in corneal defect in the eNano-Ro5 treated group compared to control at day 14 ($P<0.05$). In addition, corneal opacity was significantly improved at day 1, 7 and 14 in the eNano-Ro5 treated animals ($P<0.05$, $P<0.05$ and $P<0.01$, respectively). Corneal neovascularization was also significantly reduced at day 14 compared to control ($P<0.01$). In the dexamethasone group, we found persistent corneal defect ($P<0.001$), improved corneal transparency at day 3, 7 and 14 ($P<0.001$, $P<0.01$ and $P<0.001$) and reduced neovascularization at day 7 and 14 ($P<0.05$ and $P<0.001$)

Conclusions: The severe reduction in corneal thickness observed in the dexamethasone-treated group may explain the reduced corneal opacity and neovascularization. Taken together, these findings suggest a beneficial effect of RUNX1 inhibition with topical eNano-Ro5 in preventing the blinding effects of alkali burn injury. This could be a potential therapy to treat this sight-threatening condition

TITLE: Caspase-8 plays an apoptosis-independent role in retinal angiogenesis.

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Johnson, M. Choi, C. Troy, Pathology and Cell Biology, Columbia University Irving Medical Center, New York, New York, UNITED STATES|C. Troy, Neurology, Columbia University Irving Medical Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kendra Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Monica Choi: Commercial Relationship: Code N (No Commercial Relationship) | Carol Troy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have shown certain caspases to be activated in the course of vascular development, but the specific roles of these proteases remain unclear. In this study, we investigate previously unexplored mechanisms and signaling pathways involved in the outgrowth and subsequent remodeling of the retinal vasculature. We hypothesize that caspase-8 (Casp8) modulates signaling pathways involved in retinal angiogenesis.

Methods: Retina flatmounts from C57BL/6 pups aged P2-P21 were stained for Casp8 and TUNEL. Vascular development was assessed in retinas isolated from inducible endothelial cell specific Casp8 knock mice (EC Casp8 KO) and inducible microglia-specific casp8 knock out mice (mG Casp8 KO) at P7, P10 and P14. At P7 cytokine array was performed and at P10 biocytin-TMR was used to assess barrier establishment in EC Casp8 KO mice. Student's T-test was used for statistical analysis.

Results: Casp8 was expressed in endothelial cells and microglia during early retinal angiogenesis, with expression peaking between P7-P10. Casp8 was selectively activated in microglia. TUNEL assay revealed few apoptotic cells during angiogenesis. At P7, EC Casp8 KO resulted in a significant decrease in vascular outgrowth ($66.90 \pm 2.52\%$ in EC Casp8 KO vs. $83.92 \pm 1.76\%$ controls; $p < 0.0001$), vessel area ($59.96 \pm 2.75\%$ in EC Casp8 KO vs. $78.45 \pm 2.09\%$ controls; $p < 0.0001$) and vascular density ($49.23 \pm 1.90\%$ in EC Casp8 KO vs. $49.23 \pm 1.33\%$ in controls; $p < 0.0001$). The delay in vascular outgrowth persisted up to P14, however barrier establishment was not affected. EC Casp8 KO also resulted in premature vessel regression and increased microglia localization at the vasculature, likely associated with an increase in proinflammatory cytokines. mG Casp8 KO did not affect vascular outgrowth or remodeling, however this did result in a significant decrease in microglia associated with the vasculature and a change in microglia morphology.

Conclusions: Casp8 function during early retinal angiogenesis is independent of apoptosis. EC Casp8 KO resulted in delayed vascular outgrowth and premature vascular remodeling, however mG Casp8 KO had no effect on vascular development indicating cell specific roles of the protease. Microglia localization and activation was also perturbed with EC Casp8 KO indicating a role of caspase-8 in the cell-to-cell communication between endothelial cells and microglia.

ABSTRACT BODY:

Purpose: Uveitis is a group of ocular inflammatory diseases that can derive from both infectious and noninfectious causes. This study investigates patients diagnosed with a variety of uveitic diseases utilizing Fluorescence Lifetime Imaging Ophthalmoscopy (FLIO).

Methods: 49 eyes of 49 subjects with varying uveitic diseases (mean age 48 ± 19 years) and 49 age-matched healthy subjects ($p=0.899$) were investigated in this study. Clinical grading of uveitic disease subtypes were confirmed by uveitis specialists (ATV, AS, MBL). FLIO images of a 30° retinal field centered at the fovea were acquired using a prototype Heidelberg Engineering Spectralis-based FLIO. FLIO lifetimes were recorded in short (498-560 nm, SSC) and long (560-720 nm, LSC) spectral wavelength channels, with mean autofluorescence lifetimes (t_m) calculated and analyzed.

Results: FLIO is able to categorize uveitic diseases based on phenotype, and lifetimes of patients with uveitic diseases showed significant prolongation in central, inner and outer ring regions of the ETDRS grid compared to age-matched controls ($p=0.03$, $p=0.006$, $p=0.003$, respectively). FLIO lifetimes were variable depending on the type of disease with shortened lifetimes correlating to regions of active inflammation or in areas adjacent to lesions.

Conclusions: FLIO can effectively discriminate between various uveitic diseases with high specificity. While prolonged FLIO lifetimes were found in regions of atrophy or scarring, shortened FLIO lifetimes were observed in regions adjacent to lesions and in patients with clinically active ocular inflammation. FLIO may provide insight into understanding these complex diseases, as well as monitoring disease activity, progression, and remission.

Paul Chan: Commercial Relationship: Code N (No Commercial Relationship) | De-Ann Pillers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although the two major risk factors for the development of retinopathy of prematurity (ROP) are premature birth and low birth weight, there is a question as to whether intrauterine growth restriction (IUGR) may be an important risk factor for ROP. A previous study that investigated this relationship found no correlation, however the study population consisted of only non-Black subjects. This retrospective cohort study aims to further explore whether IUGR impacts the development of ROP and its severity in a subset of Black infants to see how the inclusion of these demographics impact any correlation that may exist.

Methods: This is a single center retrospective chart review of all infants admitted to the UI Hospital and Health System NICU between 1/1/2010 and 1/1/2020 with a birth weight less than or equal to 1500g who had a pupillary dilation event. Infants were excluded if they died or were transferred before an ROP exam or had missing data in the chart. IUGR was defined as less than the 10th percentile for gestational age using the Fenton growth chart. Statistical analyses included single variable analysis, Spearman correlation and cumulative logistic regression analysis for predicting ROP stage from IUGR, Black ancestral background, and the interaction of these two parameters.

Results: The study population consisted of 518 infants, with 341 (66%) Black infants. In this subset of Black infants, 47 (14%) had IUGR and 149 (44%) were diagnosed with ROP. Within the Black population, IUGR vs. non-IUGR did not significantly impact the risk of an ROP diagnosis (0.56 OR, 95% CI 0.029 – 1.08, P=0.08) or the stage of ROP should it exist (Spearman Rho= 0.16, P=0.05). In contrast, within the subset of all infants with IUGR, we found a significant association between IUGR and ROP stage between Black and non-Black patients (P=0.01). Black infants with IUGR and ROP are more likely to have a more severe stage of ROP than their non-Black counterparts.

Conclusions: Our results illustrate that although IUGR is not a significant risk factor for ROP in Black infants, those that do develop ROP are at a higher risk for more severe disease compared to non-Black infants. Further analysis into the differences between these two populations is warranted.

TITLE: Genetic Ablation of Cx43 in Astrocytes is Neuroprotective in Experimental Glaucoma and Optic Nerve Injury

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Batsuuri, A. Toychiev, M. Srinivas, SUNY College of Optometry, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Khulan Batsuuri: Commercial Relationship: Code N (No Commercial Relationship) | Abduqodir Toychiev: Commercial Relationship: Code N (No Commercial Relationship) | Miduturu Srinivas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Reactivity of astrocytes in the retina and optic nerve head (ONH) is observed in glaucoma and other optic nerve injuries. Astrocytes are densely interconnected by gap junction (GJs) formed by connexin 43 (Cx43). The role of astrocytic connectivity on glial reactivity and RGC survival in optic nerve degeneration is not fully understood. Here, we assessed expression of Cx43 with sustained intraocular pressure (IOP) elevation and after optic nerve crush injury. We also examined whether deletion of Cx43 in astrocytes impacted RGC loss and ONH astrocyte reactivity in the two injury models.

Methods: The astrocyte-specific Cx43 knockout (KO) mouse was established using the Cre-loxP recombination system. Experimental glaucoma was induced in C57BL/6 (WT) and Cx43KO mice by intracameral injection of polystyrene microbeads. Optic nerve of one eye was crushed for 10 seconds using fine curved forceps ~ 1 mm behind the eyeball. Immunohistochemistry was used to assess Cx43 expression, RGC survival (using Brn3a labeling), and astrocyte reactivity in the ONH (using GFAP labeling), after 4 and 8 weeks of IOP elevation and 7 days post nerve crush. Student's t-test was used for statistical analyses.

Results: IOP elevation for 8 weeks produced a 35% increase in astrocytic Cx43 expression in the retina (n=5, p=0.001) and ONH (n=3, p=00001). Similarly, Cx43 expression was increased by 30% after optic nerve crush injury (n=5, p=0.0001). Deletion of Cx43 in astrocytes was neuroprotective in glaucomatous injury, with RGC survival increasing by 57% at 4 weeks (n=5-8, p=0.03) and 63% by 8 weeks (n=7-8, p=0.0003) compared to control eyes. The absence of Cx43 also increased viable RGCs after optic nerve crush by twofold compared to control eyes (n=8, p=0.003). Finally, Cx43 deletion caused a decrease in astrocytic reactivity in the ONH of bead injected eyes compared to WT (n=3, p<0.05). However, astrocyte reactivity in the retina was unaffected by Cx43 deletion (n=5-6, p=0.55).

Conclusions: Results in two different models of optic nerve injury indicate that astrocytic Cx43 channels contribute significantly to RGC death. There is an upregulation of Cx43 in astrocytes in both models, and a reduction in astrocyte reactivity in the ONH upon Cx43 deletion, suggesting that GJ coupling might lead to the spread of signals associated with astrocyte reactivity.

TITLE: The Role of NQO1 in the Increased DNA Damage Response in Fuchs Endothelial Corneal Dystrophy

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Gauthier, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|A. Gauthier, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alex Gauthier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Fuchs Endothelial Corneal Dystrophy (FECD) is an oxidative stress disorder characterized by accelerated loss of corneal endothelial cells (CEnCs) and high amounts of DNA damage, mediated partly by loss of NAD(P)H:quinone oxidoreductase 1 (NQO1). Ataxia Telangiectasia Mutated (ATM) is a major DNA damage response (DDR) kinase in post-mitotically arrested cells, which orchestrates the modulation of cell cycle checkpoints, DNA repair, and/or apoptosis. In this study, we investigate the role of NQO1 on ATM -mediated DDR in FECD pathogenesis.

Methods: Immortalized normal CEnC line HCEnC-SV-67F-16 and FECD patient-derived cell line FECD-SV-73F-74 (with TCF4 CTG repeat expansion) were treated with or without 25 μ M menadione (MN). Additionally, wild-type and NQO1 null CEnCs were irradiated with UVA (10 or 25 J/cm²) and then lysed at 1, 3, and 24 h post UVA. The phosphorylation status and levels of pATM (Ser1981) and its downstream effectors pCHK2 (Thr68), γ H2AX (Ser139), and binding partner, pNBS1 (Ser343), were evaluated by Western blotting.

Results: In HCEnC-SV-67F-16 cells, MN induced a time-dependent increase in DNA damage markers γ H2AX and pATM. FECD-SV-73F-74 cells exhibited increased activation of pATM (6.9-fold), which was significantly greater compared to HCEnC-SV-67F-16 (4.3-fold) after 1 hr of MN treatment. There were no significant differences observed in downstream effectors pCHK2 and γ H2AX between FECD-SV-73F-74 and normal CEnCs. Similarly, 10 J/cm² UVA-irradiation-induced a significant increase in the phosphorylation of pATM (3.03-fold), γ H2AX (4.23-fold), pCHK2 (1.77-fold) in NQO1 null cells compared to WT CEnCs. UVA-irradiated NQO1 null cells maintained the phosphorylation of pATM after 3 h (2.44-fold), whereas WT cells returned to baseline (0.98-fold).

Conclusions: These results indicate there is increased activation of ATM-mediated DDR upon ROS induction in FECD. NQO1 null CEnCs exhibit enhanced and prolonged activation of ATM-mediated DDR compared to WT cells after irradiation with UVA. Thus, NQO1 deficiency in CEnCs may play an important role in pathogenesis of FECD.

TITLE: Evaluating the accuracy and utility of a cataract simulation video for relieving patient anxiety

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.A. Abbas, R. Sella, R. Lian, S.D. Fuller, S.S. Bentley, H. Fukuoka, N.A. Afshari, Shiley Eye Institute and Viterbi Family Department of Ophthalmology, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Anser Abbas: Commercial Relationship: Code N (No Commercial Relationship) | Ruti Sella: Commercial Relationship: Code N (No Commercial Relationship) | Rebecca Lian: Commercial Relationship: Code N (No Commercial Relationship) | Spencer Fuller: Commercial Relationship: Code N (No Commercial Relationship) | Sean Bentley: Commercial Relationship: Code N (No Commercial Relationship) | Hideki Fukuoka: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Afshari: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patient anxiety about cataract surgery can lead to undesired outcomes before and during surgery. We performed a cross-sectional survey-based study to test whether a point-of-view cataract simulation video could (1) accurately represent what patients see during surgery and (2) help relieve patient anxiety.

Methods: In follow-up clinical visits, 100 cataract surgery patients were shown a video depicting cataract surgery from a patient's point of view. The patients were then given a multiple-choice questionnaire about their recollections of visual experiences from surgery. They were asked to evaluate how well the video matched their experience, whether they would have wanted to see the video before their operations, and whether they would recommend the video to other patients.

Patients received surgery with monitored anesthesia care (MAC). Patients younger than 18 years or with a post-operative best-correct visual acuity worse than 20/50 in both eyes were excluded. The simulation video was created in by performing cataract surgery on a porcine eye.

Results: Of patients surveyed (n=100), 78% (n=78) recalled visual experiences during surgery, (65%, n=65) saw bright lights and flashes, 18% (n=18) saw instruments or other objects.

Of patients who recalled visual experiences (n=78), 47.4% (n=37) said that the video was the same or similar to what they experienced overall. Of patients who saw bright lights and flashes (n=65), 46.1% (n=30) said that the video was the same or similar. Of patients who saw objects (n=18), 72.2% (n=13) said that the video was the same or similar.

Thirty-six percent of patients surveyed (n=36) said that seeing the video before their procedures would have helped them relax, and 48% of patients (n=48) would recommend the video to future patients.

Conclusions: Reported visual experiences during surgery differ widely and a simulation video may be helpful in reducing anxiety in patients undergoing cataract surgery.

Daniel Stamer: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Saban: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Macrophages reside in tissues throughout the eye and their phenotypes and functions are shaped by both their sub-anatomic location in tissue as well as their respective developmental origins (ontogeny). Developmentally, macrophages are mostly either (a) derived prenatally and are long-lived; or, (b) from circulating monocytes and are short-lived. The purpose of this study was to characterize the presence and distribution of long-lived versus short-lived macrophages in the conventional outflow tract.

Methods: We took advantage of Cx3cr1-YFP^{CreER/+} transgenic mice with various Cre reporters to tamoxifen-induce conditional labeling of tissue resident macrophages in anterior segment tissues. Mice were tamoxifen pulsed (60 mg/kg) and rested. Fixed anterior segment whole mounts were prepared. Tissues were labelled with antibodies against cluster of differentiation 31 (CD31), alpha-smooth muscle actin (Sma-1) and DAPI, along with their isotype controls in separate cohorts. We categorized long-lived macrophages as YFP⁺ cells that retained the Cre reporter labeling (>2 weeks post tamoxifen pulse), whereas short-lived macrophages did not (O’Koren, 2019). Immunolabelled tissue samples were imaged by confocal microscopy.

Results: Macrophages were found throughout the conventional outflow tract, including the trabecular meshwork (TM), Schlemm’s canal (SC), collector channels and surrounding distal vessels (DVs). Macrophage density was measured in the DVs (84 ±42 cells per high-powered field (HPF), 40X magnification) and in the SC and TM (103 ± 32 cells per HPF). Macrophages were counted and averaged over 6-7 randomly selected HPFs imaged from anterior segment whole mounts from 3 mice. Long-lived macrophages comprised a subpopulation of macrophages in the TM, SC, and around the DVs. In the SC and TM, macrophages generally retained a dendritic morphology, whereas DV-associated macrophages were largely elongated or rounded in appearance and in close apposition to the vessels.

Conclusions: Macrophages are present throughout the conventional outflow tract of TM, SC and DVs. The presence of short-lived and long-lived or tissue resident macrophages suggests two distinct populations of macrophages reside in the outflow tract.

ABSTRACT BODY:

Purpose: Non-invasive quantification of retinal axonal and neuronal loss have been proposed as surrogate markers of axonal loss in multiple sclerosis (MS). We assessed their longitudinal relationship with measures of brain atrophy and disability.

Methods: Retinal nerve fiber layer (RNFL) thickness and total macular volume (TMV) were estimated in patients with MS (n=60) and age-matched, healthy controls (n=52) by optical coherence tomography (OCT) at baseline and 24-month follow-up. Brain volumes were quantified from cranial magnetic resonance imaging using NeuroQuant®. Neurological disability was assessed by means of the expanded disability status scale.

Results: In patients with MS compared to controls there was a significant reduction in RNFL ($p<0.0001$) and TMV ($p=0.0004$) at baseline. Specifically, RNFL was significantly reduced in the temporal-superior ($p<0.0001$), temporal ($p<0.0001$), temporal-inferior ($p<0.0001$), nasal-inferior ($p=0.0005$) and nasal-superior ($p=0.001$) aspects of the optic nerve. Patients with secondary progressive MS (SPMS) showed a greater reduction in RNFL ($p=0.003$) and TMV ($P<0.0001$) compared to patients with relapsing-remitting MS (RRMS). RNFL / TMV were significantly correlated (Pearson's r) with grey matter (GM) ($p=0.0003/p=0.0287$), temporal lobe (TL) ($p=0.0007/p=0.0287$), thalamus (TH) ($p=0.0001/p=0.0012$), putamen (PU) ($p<0.0001/p=0.0006$) and whole brain (WB) ($p=0.0028/p=0.0206$) volumes at baseline. At follow-up, there was a further significant reduction in temporal-inferior RNFL ($p=0.009$) and TMV ($p=0.009$). Patients with SPMS had significantly more advanced loss of RNFL ($p=0.01$) and TMV ($p=0.02$) compared to patients with RRMS. RNFL / TMV were significantly correlated with GM ($p=0.0143/p=0.0449$), TL ($p=0.0141/p=0.0381$), TH ($p=0.0004/p=0.0019$) PU ($p<0.0001/p=0.0012$) and WB ($p=0.0015/p=0.0211$) volume at follow-up. Patients with baseline TMV $< 25^{\text{th}}$ percentile ($n=12$) showed a further significant reduction at follow-up in GM ($p=0.02$), TL ($p=0.03$), caudate ($p=0.009$), TH ($p=0.0003$), PU ($p=0.009$) and WB ($p=0.001$) volume. There was no significant relationship between retinal measures and clinical disability at baseline or follow-up.

Conclusions: There is a strong longitudinal relationship between retinal and brain atrophy in MS which further underpins the viability of OCT as a surrogate measure of axonal loss.

ABSTRACT BODY:

Purpose: Working with African-born Blacks living in America, the aims were to: (1) determine the prevalence and risk factors associated with diabetic retinopathy (DR) (2) evaluate for other ocular abnormalities

Methods: This was a cross-section evaluation of 265 African-born blacks living in the United States (male 62%, age 39.7 ± 10.2 y (mean \pm SD), BMI 27.8 ± 4.5 kg/m²) who self-identified as healthy. Participants had oral glucose tolerance test (OGTT) to determine glucose tolerance status, comprehensive eye exams, spectral domain optical coherence tomography (OCT) and fundus photos. In addition, A1C, glycated albumin (GA) and fructosamine levels were determined, allostatic load score (ALS) as a measure of physiologic stress was calculated and visceral adiposity was assessed with abdominal CT scan.

Results: Newly diagnosed diabetes mellitus (DM) occurred in 10.2% (27/265), preDM in 40.0% (106/265), normal glucose tolerance (NGT) in 49.1% (130/265). Retinopathy was present in 1.5% (4/265) overall, 18.5% (3/27) in those with DM, 1.0% (1/104) with preDM, and 2.3% (3/130) with NGT. The 3 NGT cases with retinopathy had hypertension and were excluded from analysis. Among diagnostic testing modalities, on univariate analyses, statistical significant associations with DR were found in fasting plasma glucose ($P < 0.002$), 2h glucose from the OGTT ($P = 0.010$), and fructosamine ($P = 0.025$) but no associations were found with A1C or GA ($P = 0.089$, $P = 0.142$, respectively); and higher visceral adipose tissue and allostatic load score were associated with DR ($P = 0.049$ and $P = 0.025$, respectively). The number of participants affected with DR is too low for meaningful analyses with multivariate regression. Additional ocular features evaluated showed 34.7% of all participants had 0.5 or greater cup/disc ratio while the mean intraocular pressure was 15 ± 3 mmHg. The mean visual acuity was 20/25 for those without retinopathy and 20/36 for those with retinopathy ($P = 0.037$). The retinal thickness measured by OCT demonstrated no differences in the inner retinal thickness when comparing glycemic status.

Conclusions: In conclusion, the overall combined prevalence of DM and preDM was high (50.2%) in this population, DR was present in 18.5% with DM. There is relatively high proportion of the participants with large cup/disc ratios. Multivariate regression was not performed. These findings warrant further exploration in this population.

ABSTRACT BODY:

Purpose: This is a proof-of-concept study to determine the accuracy of non-mydriatic ultra-widefield (UWF) fundus photography taken by clinic personnel in screening for sickle cell retinopathy (SCR) in a non-ophthalmology clinic setting.

Methods: This prospective study compared SCR findings on UWF fundus photography to the gold standard dilated fundus exam (DFE). Adults 18 years or older with sickle cell disease and a DFE within two years of acquisition of fundus photos were included. An UWF fundus camera was used to obtain bilateral non-mydriatic fundus photos by clinic personnel during the participants' routine hematology appointment. These photos were graded by two separate masked retina specialists to assess image quality, visualization of peripheral retina, presence of non-proliferative SCR, and presence of proliferative sickle retinopathy (PSR). A third retina specialist reviewer assessed photos in instances of disagreement.

Results: Forty-five participants (88 eyes) met inclusion criteria. The average age was 37.2 ± 10.8 years. Hemoglobin SS disease was the most common genotype ($n = 30$), followed by hemoglobin SC ($n = 9$) and sickle cell beta thalassemia ($n = 6$). Non-proliferative SCR and PSR were documented in 31.8% and 21.6% of eyes, respectively, on DFE. When comparing UWF grading to DFE for the presence of non-proliferative SCR, 54.4% of eyes were graded accurately and 20.5% were graded inaccurately ($p = 0.014$). For the 18 eyes graded inaccurately by UWF imaging, most were false positives ($n = 16$). UWF image quality was insufficient for grading in 18 eyes. No consensus was reached for 4 eyes. When assessing for PSR, 65.9% of eyes were graded accurately and 4.5% were graded inaccurately by UWF imaging, all as false negatives. UWF image quality was insufficient for grading for 23 eyes and there was no consensus for 3 eyes. When UWF image quality was sufficient, UWF grading was accurate for non-proliferative SCR and PSR in 72.7% and 93.5% of eyes, respectively ($p < 0.001$ for both). Of note, one participant had active sea-fan neovascularization detected on UWF imaging and DFE, and was treated with laser photocoagulation.

Conclusions: UWF imaging provides a useful screening modality for SCR, particularly for proliferative PSR. Tele-ophthalmology-based SCR screening in a hematology clinic may improve adherence to SCR screening recommendations and identify patients with PSR who may require treatment.

TITLE: Extracellular vesicles from R345W-Fibulin-3 retinal pigment epithelial cells induce epithelial-mesenchymal transition in recipient cells.

SESSION TITLE: Retinal diseases: molecular and biochemical disease mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Zhou, Y. Zhao, S. Weber, A. Barber, S.L. Grillo, J. Sundstrom, Ophthalmology, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|H. Chen, TEM core facility, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mi Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Yuanjun Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Weber: Commercial Relationship: Code N (No Commercial Relationship) | Han Chen: Commercial Relationship: Code N (No Commercial Relationship) | Alistair Barber: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Grillo: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Sundstrom: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our previous studies found that expression of R345W-Fibulin-3 induces retinal pigment epithelial (RPE) cells to undergo epithelial-mesenchymal transition (EMT). In the current study we investigated the effect of the R345W-Fibulin-3 mutation on the size, cargo and function of extracellular vesicles (EVs) derived from RPE cells, as well as the role of these EVs in regulating RPE cell dysfunction.

Methods: EVs were isolated from the media of ARPE-19 cells by conventional ultracentrifugation or density gradient ultracentrifugation. The amount and size distribution of EVs were determined by Nanoparticle Tracking Analysis (NTA). EV protein concentrations were quantified using the DCTM Protein Assay (Bio-Rad). EV cargo were analyzed by unbiased proteomics using LC-MS/MS with subsequent pathway analysis (Advaita). The EV-associated TGF- β 1 protein was measured by ELISA. The effect of EV transplantation on ARPE-19 migration was evaluated using a scratch-injury assay.

Results: TEM imaging revealed concave-appearing vesicles, while cryo-EM imaging showed spherical vesicles with two subpopulations of EVs: a small group with diameters around 30nm and a large group with diameters around 100nm. Imaging also indicated a greater number of small EVs (~30 nm) in the mutant group compared to the WT group. This result was further confirmed by NTA showing that, in the mutant group, the particle size distributions were smaller than those of the WT EVs. The protein concentration per EV in the mutant group was not significantly different from that of the WT group. Proteomics identified critical members of sonic hedgehog (SHH) signaling and ciliary tip components in the EVs derived from WT ARPE-19 cells, whereas EVs derived from mutant ARPE19 cells contained EMT mediators. ELISA confirmed the elevated TGF- β 1 associated with mutant EVs compared to WT EVs. Critically, EV transplant studies showed that treatment of recipient cells with EVs derived from mutant cells was sufficient to increase migration and elevate EMT markers in RPE cells after scratch-injury.

Conclusions: The protein cargo of EVs is determined by the phenotype of their parental cells. Expression of R345W-Fibulin-3 mutation also alters the size and autocrine function of EVs. Notably, EVs derived from RPE cells expressing R345W-Fibulin-3 are sufficient to induce EMT in wild-type RPE cells.

ABSTRACT BODY:

Purpose: Vascular insufficiency has been suggested to be of pathogenic role in normal tension glaucoma (NTG). This study evaluated the associations between baseline retinal-vessel caliber measured by an automated deep-learning system to the risk of NTG progression.

Methods: In this longitudinal cohort study, 390 eyes from 253 NTG patients with a follow-up period of ≥ 24 months were included. Central retinal arteriolar equivalent (CRAE) and central retinal venular equivalent (CRVE) were measured from retinal photographs by a validated deep-learning system (SIVA-DLS). We assessed the agreement of retinal vessel caliber measurements between SIVA-DLS and humans, and used the Cox proportional-hazards model to examine the relationships between baseline retinal vessel caliber and subsequent NTG progression. We further assessed the incremental value of adding the retinal vessel caliber for prediction of NTG progression beyond previously reported risk factors. NTG progression was defined as progressive retinal nerve fiber layer (RNFL) thinning over time on Cirrus HD-OCT detected by its built-in guided progression analysis.

Results: Agreement of retinal vessel caliber measurement between SIVA-DLS and human was good to excellent, with intraclass correlation coefficients of retinal vessel caliber between SIVA-DLS and human ranging from 0.87 to 0.90. Sixty-nine eyes (17.7%) developed NTG progression over the follow-up period. Narrower CRAE (hazard ratio [HR] 1.36 [95%CI 1.05, 1.76]) and CRVE (HR 1.38 [95%CI 1.03, 1.84]) at baseline were independently associated with NTG progression in the multivariable model. Addition of baseline CRAE and CRVE improved the discrimination (C-statistic 0.703 vs 0.695, $p=0.038$ and 0.704 vs 0.695, $p=0.038$, respectively) of NTG progression risk beyond previously reported risk factors.

Conclusions: This study demonstrated significant associations between baseline retinal vessel caliber and risk of NTG progression. These findings provided evidence to support the hypothesis of vascular insufficiency in NTG pathogenesis and the utility of a high-throughput deep-learning system for risk assessment in NTG.

ABSTRACT BODY:

Purpose: To characterize contrast sensitivity function (CSF) in cataract and pseudophakia compared to healthy control eyes using a novel quick CSF test with active learning algorithms.

Methods: CSF was prospectively measured in eyes with visually significant cataract, at least 2+ nuclear sclerosis (NS) and visual acuity (VA) more than 20/50 (cataract group), as well as in pseudophakic eyes (pseudophakic group) and in healthy control eyes with no more than 1+ NS and no visual complaints (control group), using the novel Manifold Contrast Vision Meter (Adaptive Sensory Technology, San Diego, CA). Outcomes included Area under the Log CSF (AULCSF), contrast acuity (CA), and CS thresholds at 1, 1.5, 3, 12, and 18 cycles per degree (cpd). A subgroup analysis as performed on cataract eyes with good acuity ($VA \geq 20/25$)

Results: A total of 167 eyes were included, 58 eyes in the cataract group, 77 controls, and 32 pseudophakic eyes with respective AULCSF of 1.053 (0.352) vs 1.228 (0.318) vs 1.256 (0.360). When controlling for VA and age in our multivariate regression model, the presence of cataract was associated with significantly reduced AULCSF ($P=0.04$, $\beta=-0.11$) and contrast threshold at 6 cpd ($P=0.01$, $\beta=-0.16$) compared to controls. Of note, contrast threshold at 6 cpd was significantly reduced even in the subgroup of cataract eyes with $VA \geq 20/25$ ($P=0.02$, $\beta=-0.16$). The presence of cataract was not associated with significantly reduced CSF threshold at lower (1, 1.5, 3 cpd) or higher (12, 18 cpd) spatial frequencies. Pseudophakia was not associated with significantly different contrast outcome measures compared to control eyes.

Conclusions: The novel qCSF test was able to detect disproportionate significant contrast deficits at 6 cpd in cataract eyes, that remained significant even in the cataract eyes with $VA \geq 20/25$.

CSF testing may be a valuable addition to standard cataract evaluation to enhance surgical decision-making, particularly in patients with subjective visual complaints despite good VA.

ABSTRACT BODY:

Purpose: Peripheral prisms have been used for field expansion in homonymous hemianopia (HH). We recently developed multi-periscopic prism (MPP) using half-penta prisms, which provided higher prism power (45°) with wider eye scanning (15°) and better image quality. For a useful field expansion through a car windshield, we further develop oblique peripheral MPP that provides a vertical shift as well as a horizontal shift.

Methods: Five half-penta prisms that provide 45° angular shift through a double internal reflection were arranged in a cascade to enable 45° wide field expansion into the blind side. Since the peripheral prisms are located 20° above and below the horizontal midline, we designed the oblique MPP to achieve 18° vertical shift toward the horizontal midline by rotating the half-penta prisms (20° relative to the vertical meridian). This reduces the lateral shift to 42°. To minimize the obscuration scotoma, the half-penta prisms were also tilted (pitch) 20° to match the line of sight. A 3D printed module was developed to mount the prisms at the required position and orientation in front of the carrier lens (Fig. 1). Field expansion through the oblique MPP was verified using optical simulations (LightTools and KeyShot) and also measured (Goldmann perimetry) for a patient with right HH.

Results: Monocular perimetry demonstrated about 36° field expansion with almost 17° vertical shift. The oblique MPP provided the desired field expansion to the blind side through the car windshield (Fig 2). The slight deviation from the optical simulation results may be attributed to the prototyping process and perimetry measurement errors.

Conclusions: The oblique peripheral MPP provides vertically shifted field expansion toward the horizontal midline. The expanded field covers the view through the car windshield, necessary for HH driving. The current configuration of the oblique peripheral MPP may be improved to reach even wider field expansion.

ABSTRACT BODY:

Purpose: Human tyrosinase (Tyr) is a glycoenzyme that catalyzes the first and rate-limiting steps in melanin production and its gene (TYR) is mutated in many cases of oculocutaneous albinism type 1 (OCA1). The mechanisms by which individual mutations contribute to the diverse pigmentation phenotype in patients with OCA1 has only begun to be examined and remains to be delineated. Here, we analyze the temperature-dependent kinetics of wild type Tyr (WT) and R422Q mutant using Michaelis-Menten and van't Hoff analysis.

Methods: Recombinant truncated human WT and R422Q mutant proteins (residues 19-469) were expressed in baculovirus and produced in whole insect *Trichoplusia*. Ni larvae. Proteins were purified by immobilized metal affinity chromatography followed by size-exclusion chromatography. Diphenol oxidase activities of WT and R422Q were measured using 0.05 mg/ml protein and L-DOPA as substrate at 28, 31, 37, and 43 degrees Celsius at physiological pH 7.4. Absorbance measurements of dopachrome formation were measured at 475 nm and converted to concentration. For Michaelis-Menten kinetics, absorbance measurements were performed at 0.09, 0.19, 0.38, 0.75, 1.5, 3, and 6 mM L-DOPA. Kinetic parameters of WT and R422Q catalyzed reactions were determined using nonlinear polynomial fit on OriginPro 7.5. The thermodynamic signature of dopachrome production was determined by measurement of Michaelis-Menten constant (K_m) followed by an analysis using the van't Hoff equation.

Results: The Michaelis-Menten kinetics showed an increasing K_m (WT: $R^2 = 0.87$; R422Q: $R^2 = 0.88$) and V_{max} (WT: $R^2 = 1.00$; R422Q $R^2 = 1.00$) as the temperature increased. It also revealed that the V_{max} , k_{cat} , and k_{cat}/K_m are significantly higher for the WT compared to R422Q. The van't Hoff analysis displayed a negative trendline for both the WT and R422Q. Subsequently, the ΔH (kJ/mol) and ΔS (kJ/mol*K) values were calculated (WT: $\Delta H = 21.25 \pm 6.37$, $\Delta S = 0.11 \pm 0.02$; R422Q: $\Delta H = 21.14 \pm 6.09$, $\Delta S = 0.11 \pm 0.02$), which resulted in a $\Delta G < 0$ for both WT and R422Q.

Conclusions: Overall, the analysis of the temperature-dependent kinetics showed that R422Q is less active than WT at all temperatures examined here. Elucidating the thermodynamics and kinetics of both the WT and mutant Tyr is indispensable for understanding the molecular mechanism of OCA1 to discover drugs that may treat OCA1.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the most common cause of irreversible blindness in the United States among those older than 50. Dysfunction and death of retinal pigment epithelial (RPE) cells are key to the pathogenesis. Previous work has shown that iron accumulates in the RPE of AMD eyes, and iron overload is sufficient to trigger RPE cell death in vitro and in vivo. However, the mechanism of RPE iron accumulation in AMD is unknown.

Methods: Herein, we use in vitro primary human RPE and in vivo mouse RPE studies, in addition to human single-cell RNAseq data from AMD cases and controls, to study an inflammatory mechanism of iron accumulation.

Results: Herein we show that high fat diet, an AMD risk factor, drives systemic and local inflammatory circuits upregulating interleukin 1 β (IL-1 β). IL-1 β upregulates RPE iron importers and downregulates iron exporters. This, in turn, triggers RPE iron accumulation, oxidative stress, and dysfunction. We term this maladaptive, chronic activation of a nutritional immunity pathway the cellular iron sequestration response, or CISR. Single cell RNAseq analysis of choroid and neurosensory retina from human donors revealed that hallmarks of this pathway are present in AMD microglia and macrophages.

Conclusions: Together, these data suggest that obesity, through CISR, can lead to RPE iron accumulation in AMD.

ABSTRACT BODY:

Purpose: To identify the molecular basis of disease in 4 pedigrees with IRD that remained unresolved after the initial analysis of WGS data.

Methods: Two pedigrees of Indian origin and one each of Hispanic and European American (EA) origin were analyzed. WGS was done on one affected individual and two unaffected siblings from each pedigree using Illumina HiSeq X Ten. Initial analysis by mapping reads to hg19 and variant calling using GATK did not identify disease causing variants. The data was further analyzed using two methods: (1) the reads were re-aligned to hg38 and variants were called using GATK; (2) read alignment and variant calling was done using the Illumina DRAGEN Bio-IT platform. Validation of a large inversion identified was performed by isolating high molecular weight DNA from the patient and unaffected family members using the Bionano DLS kit and analyzed on Bionano Saphyr. Segregation analysis was done by PCR followed by Sanger sequencing.

Results: Re-analysis using the hg38 reference genome identified 2 novel compound heterozygous variants p.[Pro3Ser;Thr1749Ala] in ALMS1 in one Indian pedigree. Analysis of remaining pedigrees using Illumina DRAGEN Bio-IT identified unique pathogenic variants in known IRD genes. In the second Indian pedigree, uniparental isodisomy (UPiD) involving a 39Mb homozygous region on chromosome-15 that included a novel pathogenic homozygous NR2E3 variant, p.Trp257Ser, was observed. In the EA pedigree, a heterozygous nonsense mutation p.Gln874* and a large inversion in the EYS gene were detected. This inversion (Chr6: g.65986120_67623958inv) was further characterized by analyzing the samples of the patient and unaffected family members using Bionano Saphyr. This analysis confirmed the presence of a 1.6Mb inversion on chromosome-6, which includes exons 1 to 12 of EYS. In the third Hispanic family with 1 affected female and 2 unaffected female siblings, a previously reported p.Glu746ArgfsTer23 mutation in RPGR was identified. All detected mutations segregated with IRD in all 4 families.

Conclusions: Analysis using the hg38 reference genome identified causative variants in one pedigree among four. Additional analysis using Illumina DRAGEN identified a 39Mb segmental UPiD, a mutation in RPGR and mutations in the EYS gene including a large inversion.

ABSTRACT BODY:

Purpose: Traumatic brain injury (TBI) causes neuroinflammation and neurodegeneration leading to various pathological complications such as motor, and sensory (visual) deficits, cognitive deficit, and depression. N-3 polyunsaturated fatty acid (n-3 PUFA) containing lipids are known to be anti-inflammatory, whereas sphingolipid, ceramide (Cer) is an inducer of neuroinflammation and degeneration. The purpose of this study was to understand whether the presence of an elevated systemic level of n-3 PUFA in the Fat1-transgenic mice is associated with the prevention of TBI-mediated sensory-motor deficits by preventing Cer generation.

Methods: We used Fat1-transgenic mice and their WT littermates and subjected them to mild TBI using left side focal cranial air blast (50-psi) or sham blast (0-psi, control). We conducted visual functional tests, histological, and molecular assays in the brain tissue at 30-days post-blast.

Results: Among different heterogeneous complications, visual function is one of the major sensory parameters affected by TBI. By Optokinetic Nystagmus (OKN) recording, we found that visual acuity decreased, whereas contrast sensitivity increased significantly in WT-blast animals compared to their pre-blast values but not in Fat1-blast animals. By rotarod and open-field studies, we also found Fat1-blast mice were resistant to the declining of motor functions from blast injury. Immunohistochemical labeling of oculomotor nucleus motoneurons for choline acetyltransferase (CHAT) showed a significant reduction in the area of the oculomotor nucleus in WT-blast mice, and immunostaining for IBA1 in the optic tract showed significantly higher numbers of activated microglia of WT-blast mice. Further LC-MS/MS analysis confirmed an elevated level of n-3 PUFA, eicosapentaenoic acid (EPA) in the plasma and brain of the Fat1-transgenic animals. TBI increased Cer level in the brain of the WT mice, which was decreased significantly in the brain of Fat1-blast mice. We further demonstrated that expression of Cer biosynthetic and inflammatory genes was significantly lower in the brain of Fat1-blast mice compared to their WT littermates.

Conclusions: Our result demonstrates that suppression of ceramide biosynthesis and inflammatory factors in Fat1-transgenic animals is associated with significant protection of visual and motor deficits caused by mild TBI.

Commercial Relationships Disclosure (Abstract): Nancy Aychoua: Commercial Relationship: Code N (No Commercial Relationship) | Xiaofan Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Taha Bhatti: Commercial Relationship: Code N (No Commercial Relationship) | Ambreen Tariq: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Webster: Commercial Relationship: Code N (No Commercial Relationship) | Pirro Hysi: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Hammond: Commercial Relationship: Code N (No Commercial Relationship) | Omar Mahroo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The dark-adapted electroretinogram (ERG) response to a standard bright flash contains rod and cone components. Negative waveforms usually indicate loss of post-receptoral signals. However, when rod responses are lost completely, the waveform reflects the dark-adapted cone system response (usually not seen due to a larger superimposed rod system response). In order to explore the possible form of the dark-adapted cone system response, we recorded ERGs to flashes delivered on a dim rod-saturating background.

Methods: ERGs to white xenon flashes ($13 \text{ photopic cd m}^{-2} \text{ s}$, similar to the standard DA 10 stimulus), delivered on a dim blue background (1.0 photopic and $30 \text{ scotopic cd m}^{-2}$), were recorded in 211 healthy adults from the TwinsUK cohort, as part of a wider study. Recordings were made with conductive fibre electrodes in the lower fornix following mydriasis. The background was designed to achieve rod saturation, but minimal cone desensitisation, so that the cone system might resemble the dark-adapted state. The standard ISCEV background is much brighter ($30 \text{ photopic cd m}^{-2}$) and significantly light-adapts the cones. A-wave and b-waves were extracted, and the b:a amplitude ratio calculated. Ratios <1 indicated a negative waveform.

Results: Mean (SD) age was 62.5 (11.3) years. 93% were female. Following exclusion of traces with noise artefact, ERGs from 199 right eyes and 208 left eyes were included. Mean (SD) b:a ratio was 1.22 (0.27) and 1.20 (0.30) for right and left eyes respectively; medians were 1.19 and 1.18. Coefficient of inter-ocular correlation was 0.70. ($p < 0.0001$). No significant correlation with age was found. Proportions of eyes with negative waveforms were 22% and 26% for right and left eyes respectively.

Conclusions: Over 20% showed negative waveforms, consistent with this being a feature of the dark-adapted cone system response to standard bright flashes in many people. The majority did not show negative waveforms. In patients with complete loss of rod function, a negative ERG (with reduced a-wave) could reflect the normal dark-adapted cone system response. Our study suggests that it might also be possible for complete loss of rod function to occur without a negative ERG. A limitation is that the blue background might elicit some cone system adaptation, and this will affect our estimate of the true dark-adapted cone-driven ERG.

ABSTRACT BODY:

Purpose: Glaucoma is the primary cause of irreversible blindness worldwide. There are various subtypes of glaucoma – primary open angle (POAG), primary angle closure (PACG), and normal tension glaucoma – that share the common clinical pathologies of retinal ganglion cell (RGC) degeneration, optic nerve damage (ON), and subsequent loss of vision. Although intraocular pressure (IOP) is a major risk factor for the development and progression of glaucoma, the relationship is complex and not fully understood. Our goal was to identify genomic regions that modulate the number of healthy axons in the ON and to probe its relationship with IOP using the BXD family of mice.

Methods: IOP data was collected on a large cohort of BXD family aged > 13 months. ONs from 74 strains and the DBA/2J (D2) parent were harvested, sectioned, and stained with p-phenylenediamine. The number of healthy axons per ON cross-section were counted and strain means and standard errors were uploaded to GeneNetwork, a set of systems genetics tools for multi-layered data analysis. Using our previous methods (Stiemke et al, 2020), we mapped the trait using the GEMMA mapping tool and applied stringent criteria to narrow the list of positional candidates. The relationship between the number of healthy axons and IOP was assessed using regression analysis.

Results: The number of healthy axons per nerve varied 2.3-fold in older (> 13-month) BXD strains, and ranged from a low of 28,000 healthy axons/nerve in BXD98 to a high of 64,900 healthy axons/nerve in BXD6.

Identical to our findings on the regulation of the number of necrotic axons in the optic nerve, *Tyrp1* and *Gpnmb*, the two genes that are responsible for pigmentary dispersion glaucoma of the D2 parent, do not influence the endophenotype of the number of healthy axons in the ON. We identified two QTLs with genome-wide significance, one each on chromosomes 3 and 9. Using our inclusion criteria, we narrowed the list of 140 positional candidates to eight genes that could modulate the number of healthy axons in ONs of the BXD family. Lastly, IOP and the phenotype of healthy axons in the ON have no significant correlation.

Conclusions: We identified two genomic regions that modulate the number of healthy axons in the ON. Additional studies are underway to narrow the list of plausible candidate genes. We also demonstrated IOP is not indicative of ON health, thus adding to the complexity of glaucoma-associated endophenotypes.

ABSTRACT BODY:

Purpose: Eyes with moderate to severe non-proliferative diabetic retinopathy (NPDR) are at high risk for disease progression and development of vision-threatening complications. The DRCR Retina Network Protocol W aimed to determine if aflibercept can prevent the development of proliferative diabetic retinopathy (PDR) and center-involved diabetic macular edema (CI-DME) over 2 years and if so, whether there is an associated visual benefit at 4 years.

Methods: In this multi-center randomized clinical trial, eligible eyes had moderate to severe NPDR (ETDRS severity levels 43-53), without center-involved diabetic macular edema. Eyes were randomly assigned to intravitreal 2.0-mg aflibercept or sham injections performed at baseline, 1, 2, and 4 months and every 4 months through 2 years. Thereafter, through 4 years, treatment was deferred if the eye had no worse than mild NPDR. Aflibercept was provided in both groups if CI-DME with vision loss or high-risk PDR developed. Time to development of PDR or CI-DME with vision loss (primary outcome) were analyzed with marginal Cox regression models, and 2-year change in visual acuity was analyzed with a linear mixed model.

Results: We enrolled 328 participants (mean age 56 years; mean HbA1c 8.8%; 42% female; 47% White, 30% Hispanic and 15% Black) with 399[KJ1] study eyes across 64 clinics in the U.S. and Canada[KJ2]. There were 200 eyes assigned to aflibercept and 199 eyes assigned to sham. At enrollment, 17% of study eyes had moderate NPDR (level 43), 32% had moderately severe NPDR (47A), 27% had moderately severe NPDR (level 47B-D), and 24% had severe NPDR (level 53). Mean baseline visual acuity was 87.6 [KJ3] letters and mean baseline central subfield thickness was 281 μ m [KJ4] (Heidelberg Spectralis equivalent). All available data by the time the last participant completed the 2-year visit will be presented. Results have been analyzed and reviewed by the Data and Safety Monitoring Committee, but per National Eye Institute requirements for NIH-funded clinical trials, primary results cannot be made publicly available before publication. Publication is anticipated shortly before or at the time of presentation.

Conclusions: Conclusions will follow from the results presented.

ABSTRACT BODY:

Purpose: To establish a well-defined 3D corneal organoid model that will be useful in studying ocular surface diseases, their genetic modeling and screening of pharmaceutical drugs. We performed single-cell RNA sequencing (scRNA-seq) of a human donor cornea and a cornea organoid developed in culture from induced pluripotent stem cells (iPSC) to elucidate corneal cell populations represented in the organoid.

Methods: One cornea organoid (7 month old), and a healthy donor (41 year old) cornea (Lions Eye Institute for Transplant and Research, FL) were digested for 5 h with Collagenase type I (2 mg/ml) in complete DMEM-F12 containing 5% FBS followed by Accutase treatment for 20 min, washed and re-suspended in PBS with 0.04% BSA. Live cells were counted by trypan-blue exclusion in a Countess® II automated cell counter. For scRNA-seq, the cells were captured and libraries generated using Chromium Single Cell 3' Library & Gel Bead Kit v2 (10x Genomics). Libraries were run on an Illumina HiSeq 4000 as 150-bp paired-end reads. The Cell Ranger Single-Cell Software Suite v3.01 was used to perform sample demultiplexing, barcode processing and single-cell 3' gene counting. Quality control filtering was applied to remove any cells with fewer than 1000 reads or greater than 15% mitochondrial reads. The 10x Chromium Single Cell 3' Library & Gel Bead Kit v2 was used to capture cells from the donor cornea (10,000 cells) and the organoid (2792 cells). The Loupe Browser 4.2.0 was used to analyze and visualize the data.

Results: We detected 11 and 18 cell clusters in the cornea organoid and donor cornea, respectively. Among these, the cornea organoid revealed clusters of epithelial cells expressing MUC1 and MUC16, a small set of TP63⁺ cells and a stromal cell cluster expressing COL1A1, COL5A, and a small subset of these expressing LUM and KERA. Unlike the cornea, the organoid also contained cells expressing KRT13 and MUC4, indicative of cornea atypical epithelial differentiation. We also found the expression of SARS-CoV2 receptors (ACE2 and TMPRSS2) in the organoid and the donor cornea.

Conclusions: The cornea organoid displayed considerable overlap with the cornea with respect to stromal cell and some epithelial cell markers. However, the organoid also harbored a cluster indicative of dermal and conjunctival differentiation.

ABSTRACT BODY:

Purpose: To test UC Davis 2nd generation multimodal retinal imaging system equipped with tracking scanning laser ophthalmoscope (TSLO) to stabilize the optical coherence tomography angiography (OCTA) acquisition in real-time. In parallel, ocular aberrations are recorded with a custom Shack–Hartmann wavefront sensor (SHWS). The system has two key applications: production of stabilized OCT angiograms of retina and choroidal microvasculature and screening of patients for adaptive optics (AO) imaging, based on OCT image quality, fixation stability, and aberration severity.

Methods: The system schematic is shown in Fig. 1. All three subsystems (OCTA, TSLO and SHWS) are optically coupled with a use of dichroic mirrors before entering the eye. The wavefront detection path is then separated using a beams splitter as the ophthalmic lens is translated to correct for the patient's refractive error and thus would move the pupil plane. The TSLO uses 840 nm light to image the retina at 30 Hz frame rate with a 5° field-of-view with 960 Hz bandwidth for motion detection. The OCTA uses a 1060 nm swept laser operating at 100 kHz sweep frequency to image the retina and the wavefront sensing is done with a 755 nm superluminescent diode. The real-time motion correction from TSLO to the OCTA is done by combining voltage signals controlling the scanning mirrors and the TSLO-generated correction (motion) signal using an analog summing amplifier.

Results: The proposed system has been tested on several subjects without known retinal disease. OCT images and angiograms have been collected with and without active tracking, and the performance of tracking system has been validated using galvanometer-based moving model eye. Data from all three subsystems have been collected from subjects who were later imaged using AO-OCT and data from the wavefront sensor has been used to exclude some patients from AO-OCT imaging.

Conclusions: Real-time eye tracking provides two-fold benefit for the combined system. First, as OCT angiograms are generated from the volumes, eye motion produces OCT artifacts due to spurious decorrelation, which are suppressed by real-time tracking. Second, OCTA with motion tracking further improves visualization by permitting averaging of images without computational motion correction. In addition, subjects' wavefront error can be quantified to determine whether it is suitable for the dynamic range of the sensors and correctors in the AO systems.

ABSTRACT BODY:

Purpose: To quantitatively assess, in-vivo, the choriocapillaris (CC) vessels of patients with age-related macular degeneration (AMD) in regions under and near pathological features such as drusen.

Methods: Imaging was performed with a custom swept-source OCTA prototype, operating at 1.65MHz A-scan rate. Between 2 and 7 volumes were acquired, centered at the fovea or a nearby region of interest, with a field of view of 2x2mm across. Each volume required a 1 second capture time. En face projections of the choriocapillaris (CC) and retinal vessels were generated for each volume, and the images were averaged to create a high-contrast angiogram. Images were then registered to angiograms from a commercial OCT system () to account for motion distortions. The lateral scale was adjusted using a separate eye length measurement. CC images were binarized and skeletonized using a previously published algorithm (PMID: 31646049). Image portions affected by projection artifacts from retinal vessels were removed from analysis and the vessel density (VD), the number of vessel branches per area, was calculated. These metrics were computed for areas outside and directly below manually segmented pathological features such as drusen and CNV.

Results: Five dry AMD subjects, one suspected wet AMD subject, and 4 age-matched normal subjects were imaged and the CC vessel images skeletonized for quantitative analysis. Fig. 1 shows an example of an AMD subject with the commercial images (a-b), the equivalent images shown with our custom system (c-d), the skeleton segmentation of the CC vessels (e), and the CC vessel map with an overlaid vessel density color map (f). Drusen areas are outlined in magenta. Another example of an AMD subject with drusen and pseudodrusen is shown in Fig. 2, in which more obscuration of the underlying vessels is possible due to eye dryness or blurring caused by the drusen. The scalebars are 1mm.

Conclusions: The ultrahigh-speed OCTA system demonstrated clear visibility of most CC vessels in the CC layer, allowing for effective vessel quantification. Images with this system may provide more insight into the manifestation and progression of AMD pathology.

ABSTRACT BODY:

Purpose: Visual acuity (VA) requirements for drivers in the US vary, with most states requiring a minimum Snellen VA of 20/40 in the better-seeing eye. We compared treatment (tx) patterns and VA outcomes in patients (pts) with nAMD or DME receiving anti-vascular endothelial growth factor (VEGF) IVT, and characterized the likelihood of pts to maintain vision following yr 1, specifically VA needed to drive over 4yrs.

Methods: Electronic health record data (Vestrum Health; 01-01-2014 to 06-30-2020) for tx naïve pts at index (i.e. first tx) were analyzed. Number of IVT and VA yr over yr (YoY) were evaluated for pts with nAMD and DME, and by baseline VA. A Kaplan Meier curve was used to assess likelihood of losing “driving vision”, defined as first VA <20/40 sustained for ≥6 months in the treated, better-seeing eye (≥20/40). Pts were censored at end of follow up or date of event and grouped into high frequency IVT (HFI; ≥8) and low frequency IVT (LFI; 1–7) groups.

Results: On average, nAMD pts received ~1.5 more injections vs DME pts in any given yr. In yr 1, pts with nAMD and DME gained 8.5 and 9.5 Early Treatment Diabetic Retinopathy Study letters, respectively. In yrs 2-4, nAMD pts experienced YoY losses of 1.9, 2.2 and 2.5 letters, respectively, while DME pts lost 1.1, 0.7 and 0.9 letters. Overall, from yr 1 to yr 4, pts with nAMD and DME lost 6.6 and 2.7 letters, respectively. nAMD and DME pts with ≥20/40 VA at index gained 1.4 and 2.3 letters, respectively, while those with <20/200 gained >20 and >30 letters. However, pts with ≥20/40 VA maintained better overall vision throughout the study. After 4 yrs, 69% and 72% of pts with nAMD and DME were able to maintain driving vision. When stratified by number of IVTs received in yr 1, the HFI group was more likely to maintain driving vision vs the LFI group in pts with nAMD (Fig 1) and DME (Fig 2).

Conclusions: Pts with nAMD and DME experience similar VA gains, which peak at yr 1, but consistently lose vision beyond yr 1. While nAMD pts had roughly their baseline VA at 4 yrs, pts with DME were able to maintain most vision gained. In pts with nAMD and DME, receiving ≥8 anti-VEGF IVTs reduced the risk of losing driving vision by 5-10% in following yrs.

ABSTRACT BODY:

Purpose: Through the use of fluorescently-labeled erythrocytes, Erythrocyte Mediated Angiography (EMA) allows for direct observation of retinal blood flow in vivo (Tracey et al., Scientific Reports, 2019). We present a novel technique for quantifying capillary blood flow velocity (BFV) in the superficial vascular plexus (SVP), the intermediate capillary plexus (ICP), and the deep capillary plexus (DCP) in humans and non-human primates (NHPs) using EMA.

Methods: Human red blood cells (RBCs) loaded with 1 mM indocyanine green and rhesus macaque RBCs loaded with up to 10 mM carboxyfluorescein succinimidyl ester (CFSE) were prepared for autologous injection. RBCs were injected intravenously, and a Heidelberg Spectralis was used to acquire angiograms and perform optical coherence tomography angiography (OCTA) at the macula. High intraocular pressure (IOP) was induced in the NHPs by using a tight lid speculum. RBCs in capillaries were tracked using a custom MATLAB script. To identify the corresponding vascular plexus, overlays were made using a time-lapse stack of EMA frames and en-face OCTA images of the SVP, ICP, and DCP (Figure 1). Two-tailed, unpaired t-tests were used to compare velocities in different plexuses or conditions.

Results: Mean retinal capillary BFV in each plexus was quantified in 6 eyes of 4 humans and 4 eyes of 2 NHPs (Table 1). Mean BFV in the NHPs was significantly lower when IOP was increased as compared to the baseline velocities for the SVP, ICP, and DCP ($p < 0.01$, $p < 0.01$, and $p < 0.01$, respectively).

Conclusions: Adequate capillary blood flow is essential to supporting the metabolic functions of retinal tissue. However, our understanding of flow dynamics in the various retinal capillary networks is limited. To our knowledge, we are the first to measure absolute retinal capillary BFV in the SVP, ICP, and DCP in humans and NHPs. Additionally, we found a significant decrease in BFV across the three vascular plexuses when IOP was increased in the NHPs. Retinal capillary velocities are highly dependent on ocular perfusion, both IOP and blood pressure. The ability to quantify blood flow in retinal capillaries may further the understanding of disease progression as a result of impaired ocular flow.

ABSTRACT BODY:

Purpose: Retinal macrophages play key roles in vascular inflammatory regulation and angiogenesis. A novel automated density mapping technique and clinical OCT was used to examine the relationship between surface macrophages density and perfused capillary density in the maculae of healthy and diabetic eyes.

Methods: 49 patients with diabetic retinopathy (DR) and 14 controls were imaged using clinical SD-OCT(Avanti RTVue-XR; Optovue). Ten 3x3mm scans centered at the fovea were acquired and averaged (PMID: 28068370). Ocular magnification of each image was corrected for axial length . Foveal avascular zone (FAZ) border was outlined manually on the OCT-A scan. Automated surface macrophage cell density measurements within the FAZ were performed on the 3µm OCT-Reflectance (OCT-R) slab above the ILM surface using MATLAB (Fig. A1 & B1) (PMID: 32574351). Surface macrophage cell density maps were also generated for each subject. OCT-Angiography (OCT-A) full vascular slab, from the ILM to 9µm below the posterior boundary of the outer plexiform layer OPL, was used to measure capillary density (Fig. A2 & B2) (PMID: 31106029).

Results: Maculae of control eyes revealed a few slender, ramified surface macrophage cells . Diabetic maculae showed more cells which were rounder with fewer protrusions, irregularly distributed. Surface macrophage cells within the FAZ were found in 14% of controls and 80% of diabetic eyes (Fig. A3 & B3). Statistically significant differences were observed between control and DR groups in surface macrophage cell density (Kruskal-Wallis tests, $P=0.0005$) with mean±SDs of 1 ± 4 , 12 ± 16 , 15 ± 12 , and 17 ± 16 cells/mm² in the controls, diabetes without DR, NPDR, and PDR, respectively. Linear regression showed significant correlation between surface macrophage cell densities within the FAZ and surrounding perifoveal perfused capillary densities ($R=-0.36$, $P=0.005$).

Conclusions: Clinical OCT is capable of detecting and mapping the density of macular surface macrophage cells in control and diabetic eyes. Our findings suggest that these cells migrate towards the center of the FAZ in diabetic eyes as compared to control eyes. Higher surface macrophage cell density within the FAZ appears to correlate with progressive reduction of perfused capillary density as DR worsens. Density mapping of surface macrophage cells may provide a useful clinical biomarker of progressive retinal vascular disease or response to therapy.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) plays an important role in maintaining outer blood-retinal barrier integrity. RPE function declines with age due to endoplasmic reticulum (ER) stress, which results in age-related macular degeneration (AMD). Tanilast, a specific NLRP3 inflammasome inhibitor, has been shown to possess anti-inflammatory potential that so far untested in RPE dysfunction under ER stress. Therefore, the objective of this study is to test the efficacy of tranilast on ER stress-induced RPE dysfunction and cell death.

Methods: ER stress was induced in a RPE cell line ARPE-19 in culture by adding tunicamycin (TM, 1µg/mL) in the presence or absence of 10 µM tranilast for 48 h. Mitochondrial function and membrane potential ($\Delta\psi_m$) were measured by cellular ATP level and JC1 assay, respectively. Cell death was determined by measuring the release of lactate dehydrogenase (LDH) into media and by MTT assay. RPE barrier integrity was evaluated by transepithelial electrical resistance (TER) using an electric cell-substrate impedance sensing (ECIS) system and immunostaining of ZO-1, a tight junction protein. 2D gel protein electrophoresis was performed, then stained with SyproRubyTM dye to determine differential protein profiles. Statistical analysis was performed using One-way ANOVA followed by Bonferroni post-hoc test. $p < 0.05$ was considered statistically significant.

Results: TM treatment of ARPE-19 causes mitochondrial dysfunction ($\Delta\psi_m \downarrow$ and ATP \downarrow) and cell death (LDH leakage and reduced MTT activity). These deleterious effects of TM on ARPE-19 are alleviated by treatment with tranilast. Furthermore, we show that TM-induced mitochondrial dysfunction and cell death are associated with a significant reduction in TER suggesting ARPE-19 barrier breakdown, which is prevented by tranilast. In addition, TM-treatment reduces ZO-1 immunostaining accompanied by changes in proteomic profile compared to controls without TM.

Conclusions: Our results show that ER-stress causes mitochondrial damage and RPE barrier dysregulation. The beneficial effects of tranilast on RPE function and cell viability under stress may represent a new interventional therapy to ameliorate early pathological pathways that occur in age-related retinal diseases and vision loss.

ABSTRACT BODY:

Purpose: Apart from its function in perception of stimuli, the sensory innervation of the cornea is important for the maintenance of hydration and homeostasis of the ocular surface. Corneal nerve degeneration is progressive during normal aging. Aging reduces the ability of mitochondria to get rid of free radicals and oxidative stress. The aim of this work is to study the effect of induced oxidative stress on the corneal sensitive innervation.

Methods: Oxidative stress was induced by intense light exposure to trigeminal ganglion cell cultures from adult Wistar rats (blue light: 470 nm and 500 lux, 4 hours a day for 10 days). Also, rats were exposed to a source of blue light under the same conditions and corneas and trigeminal ganglia were collected. An equivalent group of animals and cultures were maintained in the dark during light exposure cycles and were used as controls. A group of rats and cultures were treated with antioxidants before light exposure.

Immunofluorescence analysis and qPCR for β tubulin III, tau-p, CaMKII, Hemoxigenase-1, Tomm 20 and Cytochrome C Oxidase, were performed to evaluate oxidative stress and axonal cytoskeleton degeneration. Alexa Fluor 594 and 488 secondary antibodies were used to visualize the results. WST-1 assay was performed to evaluate cell viability. Whole mounted cornea preparations were immunolabeled with β tubulin III and imaged under a Leica SP8 confocal microscopy. FIJI software (ImageJ 1.49d, NIH) was used to analyze nerve loss on the subbasal plexus.

Rats were handled and cared following ARVO statements for the use of animals.

Results: Exposure to intense light caused expression of HE-1 (oxidative stress inducible) and cleavage of Cit C from the mitochondrion membrane. Activated α CaMKII participated in tau phosphorylation and axonal microtubule disassembly. This cascade of events caused the rupture of neurites in cultured trigeminal neurons without affecting severely to neuronal survival. Distal degeneration was also observed as a reduction of corneal subbasal nerve plexus density.

Conclusions: Axonal distal degeneration of sensory nerve terminals in the cornea may be initiated by oxidative insults, such as intense light exposure or normal aging. Reduction of corneal nerve density is associated with ocular diseases such as age-related dry eye. Reducing oxidative stress may prevent axonal loss and functionality.

ABSTRACT BODY:

Purpose: Optic neuropathies are a major cause of irreversible blindness worldwide. While we know many risk factors, the molecular progression towards synaptic instability, neurite retraction, and, ultimately, neuronal loss has yet to be fully elucidated. The first step in halting or reversing this progression is to identify potential molecular targets for intervention. Studies show that ephrin signaling is one of the most dysregulated signaling pathways in the pathophysiology of optic neuropathies. We hypothesize that synaptic instability, neurite retraction, and subsequent neuronal apoptosis are initiated by the anachronic reactivation of the Eph-receptor forward signaling.

Methods: To investigate the correlation between Eph-receptor reactivation and RGC loss we will use the DBA/2J (D2J) mouse model along with its genetically matched control, the DBA/2J-Gpnmb+/SjJ mouse. A semi-quantitative immunoblot-based assay to profile the phosphorylation in Eph-receptors will characterize receptor activation temporally. Immunofluorescence confocal microscopy (IF) will identify Eph-receptors localization within the inner retina, and the interplay between retina neuronal and glial compartments.

Results: Our results show an age-dependent increase in the activation of several Eph receptors in the retina of D2J mice, with the majority of Eph receptors present in a hyperphosphorylated state at age 23mo. Interestingly, results show that EphA1, EphA3, EphA6, EphA7, EphB1, EphB2, and EphB6, are significantly phosphorylated as early as 2mo of age ($p < 0.05$). IF of 2mo and 10mo D2J retinas shows an overall increase in phosphorylation temporally in both EphA and EphB classes. Both EphA and EphB class receptors are observed to be localized within the GCL with suspected localization within the OPL and the IPL for both Eph classes.

Conclusions: These preliminary results indicate that Eph receptor activation may play a role in the neuropathic progression of hereditary optic neuropathy. These results demonstrate that Eph activation can be observed as early as 2mo of age and is localized within the inner retina, indicating their potential interactions with glial components within the retina. Together these results underscore the need to explore this pathway in early optic neuropathies and it provides a glimpse of the number of receptors that are present in the retina of mice and which are engaged in neuropathic states.

ABSTRACT BODY:

Purpose: Basal cell carcinoma (BCC) is the most common peri-ocular skin cancer. It is a slow growing tumour and early clinical diagnosis is often challenging. Admittedly, patients presenting with BCC report having the lesion for several years, having seen many health professionals before they are referred to oculoplastics.

In an era where telemedicine is the new norm, and in addition to stay-at-home orders in effect, patients are reluctant to seek medical attention in large specialized care centers. In attempt to facilitate referral of patients with suspicious lesions, primary eye care providers may benefit from an additional diagnostic tool.

Our team has previously shown how optical coherence tomography (OCT), a well-established and broadly available imaging modality, may facilitate the diagnostic of peri-ocular skin cancers. The aim of this project is to highlight common OCT features observed in BCC.

Methods: This is part of an ongoing prospective study assessing patients with peri-ocular cancers; OCT images and clinical photos are obtained prior to surgical excision of the lesion. For this specific study, 51 patients with histopathologically confirmed BCC were selected. For each, OCT images were compared to their respective histopathological tissue sections.

Results: A total 994 OCT images were obtained. The dermal-epidermal junction nearing the lesion is disrupted in 100% of malignancies. Hypo-reflective tumour nests underneath the epithelium are observed in 82% of BCC, while they are seldom observed in other malignancies. When present, hyperkeratosis and telangiectasia can also be viewed on OCT, however they are not pathognomonic of BCC.

The presence of sub-epithelial hypo-reflective nests on OCT appears to be a hallmark feature of nodular BCC, allowing to rule-in the diagnostic. This hypothesis is supported by a tight correlation between the OCT image and the microscopic histopathological findings for each lesion.

Conclusions: Basal cell carcinoma on OCT shows a distinctive signature consisting of sub-epithelial hypo-reflective tumour nests with a neighboring disrupted epidermal-dermal junction.

Facilitating the early recognition of this slow-growing, often asymptomatic cancer provides eye care professionals with an additional tool to increase their confidence in the diagnosis of BCC and to encourage and expedite referral to a surgical specialist.

ABSTRACT BODY:

Purpose: Acyclovir is most commonly used for treating ocular Herpes Keratitis, a leading cause of infectious blindness. However, increasing resistance to Acyclovir in treating ocular Herpes Keratitis has prompted the need for new therapeutics directed against a different viral protein. One novel target is the HSV-1 Processivity Factor which is essential for tethering HSV-1 Polymerase to the viral genome to enable long-chain DNA synthesis.

Methods: A series of peptides, based on the crystal structure of the C-terminus of HSV-1 Polymerase, were constructed with hydrocarbon staples to retain their alpha-helical conformation. The stapled peptides were tested for blocking both HSV-1 DNA synthesis and infection. The most effective peptide was further optimized by replacing its negative N-terminus with two hydrophobic valine residues. This di-valine stapled peptide was tested for inhibiting HSV-1 infection of human primary corneal epithelial cells.

Results:

The stapled peptides blocked HSV-1 DNA synthesis and HSV-1 infection. The unstapled control peptide had no inhibitory effects. Specificity of the stapled peptides was confirmed by their inability to block infection by an unrelated virus. Significantly, the optimized di-valine stapled peptide effectively blocked HSV-1 infection in human primary corneal epithelial cells.

Conclusions: Hydrocarbon stapled peptides that simulate the α -helix from the C-terminus of HSV-1 DNA polymerase specifically block DNA synthesis and infection of HSV-1 in human primary corneal epithelial cells. These stapled peptides provide a foundation for developing a topical therapeutic for treating human ocular Herpes Keratitis.

ABSTRACT BODY:

Purpose: Refractive error is one of the most common eye diseases in the world. While genome-wide association studies (GWAS) have identified many potential risk loci for refractive error, these variants have been common with moderate to small effect on the disease trait. The aggregated Cauchy association test (ACAT) allows for the combination of single variant p-values into an overall gene p-value, providing increased power on rare variants (RV) compared to single marker tests.

Methods: We jointly analyzed exome-based genotype data and quantitative mean spherical equivalent (SER) measurements in diopters (D) on 13 population-based cohorts. These cohorts were combined and then split into two ancestry groups, Indo-Europeans (13,037 subjects) and East Asians (4,867 subjects), for analysis. Three additional European cohorts: the Raine Eye Health Study, the Beaver Dam Eye Study, and the EPIC-Norfolk study were used as replication sets, giving a total of five cohorts analyzed.

We performed single variant association analysis (one RV at a time with the SER phenotype) using EMMAX, which accounts for cryptic relatedness and ancestry differences. Variants were filtered to $MAF \leq 0.01$; only exonic variants were included. We used ACAT to combine the single variant p-values in a given gene into a single p-value for that gene. This is distinct from burden style tests, such as the variable threshold test, which combines RVs into a single, new marker on which association analysis is performed. Different approaches have different strengths and weaknesses, which is beneficial when searching for candidate genes. Fisher's method was further used to combine the gene p-values.

Results: The meta-analysis across the five cohorts identified 28 genome-wide significant genes using a significance threshold of 1×10^{-5} . The most significant gene was MUC16 ($p=9.61 \times 10^{-10}$). 11 of the 28 genes were found to be significant in one cohort and replicated in another. Good candidate genes for causality include GDF15 ($p=1.95 \times 10^{-9}$), which is known to be overexpressed in myopic eyes, ST6GALNAC5 ($p=9.03 \times 10^{-10}$), which may stimulate new rod development in zebrafish, and PER3 ($p=1.08 \times 10^{-6}$) located near the known myopia locus MYP14 on 1p36.

Conclusions: We have identified 28 novel genes that are associated with refractive error using gene-based RV tests. Further validation studies are planned to confirm these results.

ABSTRACT BODY:

Purpose: To describe patient characteristics and Emergency Department (ED) disposition between patients presenting with transient vision loss (TVL) and transient ischemic attack (TIA).

Methods: Data was sourced from the Nationwide Emergency Department Sample (NEDS) dataset (2006-2015). ICD-9-CM codes were used with a diagnosis of TVL, Amaurosis Fugax (AF), and TIA to identify cases, aged 18 years and older. These were compared for patient characteristics and management differences in the ED. Statistical analyses included descriptive statistics, trends analyzed using national incidences using US population.

Results: Patient characteristics and demographics were similar amongst type of diagnosis and disposition. Majority of patients were elderly (44.1% TVL, 66.5% TIA) with female preponderance (>50% both). There was a trend toward routine discharge in the TVL group (51.9%) versus TIA group (34.1%) with length of stay, if admitted, being longer in TVL group (4.2 days (Standard deviation (SD)= 4.8) versus 3.2 days (SD=3.9) in the TIA group), resulting in higher inpatient costs (\$181 million vs \$68 billion). CCI differed between groups, which was normal/mild (86.8%) in TVL group and mild/moderate (94.4%) in TIA group. 12.1% of TVL encounters and 16.5% of TIA encounters resulted in ED procedures.

Conclusions: This study highlights the difference in patient characteristics, procedural care, cost, and discharge practices from the ED with diagnosis of TVL compared to TIA. It shows discrepancies in management between patients with primary diagnosis of TVL compared to TIA, which highlights the current clinical dilemma amongst neurologists, ophthalmologists, and emergency medicine physicians in how to best manage patients with transient neurologic deficits without acute infarction. This needs to be addressed better with need for coherent guidelines to be established.

ABSTRACT BODY:

Purpose: Glaucoma is an optic neuropathy which includes retinal ganglion cell (RGC) death and cupping of the optic nerve head. The underlying mechanisms of RGC degeneration is not well understood. Studying differentially expressed retina genes from glaucoma donor samples offers the opportunity to understand the disease biology and identify key drivers of disease. The lack of detailed clinical records from sample donors complicates the data analysis. Here we describe the use of histological methods to qualitatively rank corresponding optic nerves for the loss of myelination then stratify samples for differential gene expression analysis from retinal transcriptional profiling studies.

Methods: Frozen optic nerves corresponding to RNAseq profiled human glaucomatous (per medical record) and non-glaucomatous donor retinæ (n = 15 each; age: 65-97) were prepared for cryosections and sectioned at 7µm thickness on a cryotome. For myelin detection, sections were fixed with 2% Osmium Tetroxide, and stained with p-phenylenediamine (PPD). For other markers sections were fixed with isopropanol and probed with neurofilament or GFAP antibodies. Severity of axon degeneration was ranked in a masked manner and divided into 4 bins – no apparent change, mild, moderate, and severe myelin loss. The differential gene analysis of RNAseq data was analyzed using these groups for comparison.

Results: Demyelination of the optic nerve assessed by PPD, mirrored the loss and disorganization of neurofilament. GFAP signaling in general was more condensed and intense in damaged samples but did not specifically correlate with myelin loss. Samples designated by medical record as glaucomatous were enriched in groups 3 and 4. RNAseq expression data were analyzed either by combined groups 1/2 compared with groups 3/4 or glaucomatous vs non-glaucomatous groups per medical records. More differentially expressed genes were identified in the comparison between groups 1/2 vs the groups 3/4, particularly known RGC markers.

Conclusions: We have a protocol for analyzing glaucomatous optic nerve tissue from human donor samples for myelin loss offering an alternative method for donor sample stratification to potentially overcome limited donor medical records. We have observed an increased sensitivity in detection of differentially expressed genes in a transcriptional profiling study based on binning optic nerves at different stages of glaucoma.

ABSTRACT BODY:

Purpose: FTY720 (Fingolimod) is an FDA approved drug for Multiple Sclerosis. It is a structural analog of the bioactive sphingolipid sphingosine, but also inhibit the enzyme Ceramide Synthase (CS) thereby inhibiting ceramide biosynthesis. Increase in ceramide levels had been associated with photoreceptor apoptosis and reducing ceramide levels by FTY720 have been shown to prevent their degeneration in multiple animal models. This study was aimed to develop a novel topical formulation of FTY720 and test its efficacy in preventing photoreceptor degeneration in animal models.

Methods: Sprague-Dawley rats (8-10 weeks) raised in dim (~50 lux) cyclic light (12 hours ON/OFF) from birth receive eye drops of a novel nano-particle based formulation with or without 0.3% FTY720 (w/w) twice a day. After three days, they were subjected to light induced retinal degeneration (LIRD) by exposure to white fluorescent light (~3000 lux) for 12 hours, and the treatment were continued for another seven days. Same age littermates either treated with placebo formulation or without LIRD served as control. At the conclusion of the treatment, retinal functions were measured by Electroretinography (ERG) and the retinas were used for histochemical and lipidomic analysis.

Results: We were able to identify formulation #1003-92, as a stable proprietary formulation that does not cause any ocular inflammation, irritation to the eye or visible distress, in the treated animals. FTY720 can be detected in picomole levels in the retina of the treated animals after ten days of treatment. Histochemical analysis showed preservation of photoreceptors in FTY720 treated animals compared to the placebo treated animals after LIRD. Eye drops with FTY720 protects the retinal functions after LIRD as observed by scotopic and photopic ERG.

Conclusions: Our study identified a novel proprietary ocular eye-drop formulation that can deliver the drug of interest to the retina without causing any distress to the eye. Our results also confirmed that reducing ceramide level by FTY720 prevents photoreceptor apoptosis and preserve retinal function. Our data established FTY720 as a potentially promising drug candidate for ocular diseases that causes photoreceptor apoptosis. It also emphasizes the fact that reducing ceramide levels could be a potential therapeutic approach for preventing photoreceptor degeneration in multiple human retinal diseases.

ABSTRACT BODY:

Purpose: The seven neuronal cell types of the retina arise in a well defined sequence of temporal windows from retinal progenitor cells (RPCs). Over the course of neurogenesis, RPCs express different transcription factors predicted to control gene regulatory networks guiding cell fate decisions and pluripotency capacity. The Kruppel-like factor (KLF) family is enriched within the late stage RPC population. We hypothesize that the KLF family members dictate cell cycle exit and cell lineage within the developing retina, and maintain this capacity outside their developmental expression window.

Methods: All procedures with animals were conducted in accordance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research. CD-1 wildtype E14 and P0 (representing early and late stages of neurogenesis) retinas were harvested and electroporated with pCAGIG overexpression plasmids encoding just the IRES-GFP cassette (control) and KLF3/6/9/13. Retinal explants were cultured for two days and subsequently dissociated into a single cell suspension. GFP positive cells were obtained by flow sorting and prepared for single cell RNA sequencing (scRNA-Seq). Cell suspensions for control and KLF3/6/9/13 electroporated E14 and P0 retinas were process on the 10x Genomics Chromium Single Cell System to assess the KLF family's impact on the transcriptional profile at a single cell level after two days of overexpression. Downstream analysis was performed using the Seurat package in R.

Results: Clusters of retinal neurogenic cells and retinal neurons were identified by the expression of marker genes for each timepoint for the control and KLF3/6/9/13 scRNA-seq profiled cells. In addition, when comparing the gene expression patterns within the RPC and neurogenic precursors between the control and KLF samples, changes were observed in genes dictating cell cycle and neurogenesis.

Conclusions: Determining which transcription factors control the transition from early and late-stage RPCs as well as the temporal patterning dictating cell fate and divisions is paramount to understanding how certain cell types arise within the mammalian retina. By establishing the KLF family as a group of transcription factors regulating retinal neurogenesis, this work can potentially inform the design of stem cell-based therapies for retinal dystrophies.

ABSTRACT BODY:

Purpose: A decade after the Affordable Care Act (ACA) became law, the ACA and its marketplace exchanges remain highly politicized. Lack of aggregated exchange claims data has made it difficult to assess the marketplaces' success in achieving their central aims (promotion of high-value care, protection against catastrophic out-of-pocket cost, etc.). We performed a cross-sectional study to understand how beneficiaries on ACA marketplace plans are utilizing ophthalmic care and experiencing out-of-pocket cost for ophthalmic services.

Methods: We analyzed claims data from Wakely Consulting Group's proprietary WACA 2018 data set, containing detailed claims, eligibility, and premium data from national EDGE Servers. Among 3.9 million 2018 beneficiaries, we used the data set to identify all claims and beneficiaries with an ophthalmology-specific ICD-10 diagnosis or CPT procedure code. Medication analysis was performed with National Drug Codes (NDCs) in claims for ophthalmology beneficiaries identified in the above manner. We then analyzed cost by service to calculate total allowed cost and member out-of-pocket cost.

Results: Among all beneficiaries in the WACA 2018 data set (median age of 40), roughly 12% (459,000 beneficiaries, median age 50) had claims related to Ophthalmology services and/or diagnoses. Most commonly, refractive error was seen in 45 per 1000 beneficiaries, cataract in 25 per 1000, and glaucoma in 16 per 1000. Ophthalmology claims generated \$242 million (M) in total cost, with \$24M in medications, \$69M in diagnostics and imaging, and \$150M due to procedures and surgery. The highest total procedural costs were due to cataract surgery (\$50M), glaucoma procedures (\$45M), and retina surgery/procedures (\$42M). \$70M (29%) were paid out-of-pocket on ophthalmic services after premiums, amounting to a mean of \$153 among such beneficiaries.

Conclusions: Despite a much younger population than that covered by Medicare, ophthalmic care for beneficiaries on ACA marketplace exchange plans nonetheless generated substantial cost (nearly \$250M) in 2018. Nearly 30% of total ophthalmic cost was paid out-of-pocket by the beneficiary. In order to identify potential disparities or gaps in affordable ophthalmic care, further analysis is needed to understand how ophthalmic care is being utilized and translating to out-of-pocket cost for various ophthalmic conditions, metal plan tiers, and income levels.

ABSTRACT BODY:

Purpose: Hydrogels may be an advantageous alternative to the clinically used fibrin gel in the treatment of corneal wounds. In this study, we created an acellular porcine corneal stroma hydrogel (APCS-gel) and evaluated its physical and regenerative properties.

Methods: The optimized APCS-gel was prepared by adjusting the concentration of acellular porcine corneal stroma (APCS). We evaluated its turbidimetric gelation kinetics, light transmittance and protein content using spectrophotometry, SDS-gel electrophoresis and mass spectrometry. Surface ultrastructure, biomaterial permeability and cellular infiltration of the APCS-gel were evaluated by scanning electron microscopy, permeability, H&E staining and tissue culture, respectively. Additionally, the cellular biocompatibility was evaluated by MTT, live/dead assays, and corneal epithelium reconstruction in vitro, using rabbit corneal epithelial (RCEC) and stromal keratocyte (RCSC) cells seeded on the APCS-gel. In vivo, the APCS-gel was transplanted onto the mouse cornea subjected to epithelium debridement and the injury recovery was evaluated by slit-lamp imaging and fluorescence immunostaining.

Results: The APCS-gel was successfully prepared by using APCS concentrations ranging from 10-30 mg/ml. The APCS-gel prepared from 20 mg/ml APCS demonstrated the highest light transmittance and fastest gelation kinetic properties. It retained most collagens, proteoglycans, glycoproteins and growth factors of native cornea. Compared with fibrin gel, the APCS-gel demonstrated a higher porosity ratio, increased permeability, and deeper RCSC cellular infiltration. Additionally, the APCS-gel showed better biocompatibility as evidenced by higher cellular survival and proliferation. After 7 days of culture, 3-4 layers of RCEC were formed on APCS-gel versus 1-2 layers on fibrin gel. We also found higher RCEC stem/progenitor cell phenotypes (K3-, p63+, ABCG2+) and proliferation phenotypes (Ki67+) on the APCS-gel. In vivo, the APCS-gel demonstrated faster corneal reepithelization after corneal epithelium debridement than both untreated mice and mice treated with fibrin gel.

Conclusions: APCS-gel demonstrated similar properties of native cornea, maintained corneal epithelial stemness, enhanced corneal epithelial proliferation in vitro and in vivo. It may be a promising therapeutic intervention for the treatment of corneal wounds in the future.

ABSTRACT BODY:

Purpose: To determine the effect of integrating point-of-care macular spectral domain optical coherence tomography (SDOCT) within a diabetic retinopathy (DR) ultrawide field (UWF) retinal imaging telemedicine program using Monaco device (Optos, plc).

Methods: This retrospective, comparative cohort study evaluated consecutively imaged patients from 1/8/2020 to 3/16/2020 at an UWF image-based DR teleophthalmology program. Both UWF photos and SD-OCT images were acquired using the same instrument at the same session. UWF photos were assessed for DR and DME by a centralized reading center grader masked to SDOCT findings. OCT images were evaluated using standardized templates by a grader masked to UWF photos and findings. Normative OCT measures are currently not available for the Monaco, thus SDOCT scans were evaluated qualitatively for macular pathology (DME, epiretinal membrane [ERM], pigment epithelial detachment, neovascular macular degeneration, tractional retinal detachment). Reliability indices were calculated with SDOCT as gold standard.

Results: 422 eyes from 211 diabetic patients were evaluated. Severity by UWF grading: No DR 57.8%, mild NPDR 30.3%, moderate 7.1%, severe 1.7%, proliferative 2.4%, ungradable 0.7%; no DME 93.4%, non-ciDME 5.2%, ciDME 0.7%, ungradable 0.7%. SDOCT was ungradable in 0.5%. The distribution of macular pathology observed on UWF and SDOCT is shown in Table 1. SDOCT identified 5 (25%) non-ciDME, 9 ciDME (75%) and 28 (97%) ERM eyes that were undetected on UWF. SDOCT did not confirm 14 (56%) non-ciDME, 2 ciDME (67%) and 9 (90%) ERM eyes identified on UWF. Reliability indices are presented in table 2.

Conclusions: Addition of SDOCT increased the identification of macular pathology by 62%. DME and ERM represented 36% and 53% of SD-OCT identified referable macular pathology, respectively. Only 27.3% of eyes with ciDME and only 3.4% with ERM present on SDOCT were identified on UWF imaging. The integration of SDOCT with UWF imaging markedly increased detection and reduced false positive assessments of DME and ERM in a large-scale DR screening program. Given the reduced effort, compact footprint and reduced overall cost of integrated SDOCT/UWF devices, their use in large DR screening programs could substantially improve disease identification and improve visual outcomes.

ABSTRACT BODY:

Purpose:

The basement membrane is a specialized extracellular matrix sheet mainly composed of collagen IV and laminins. Laminins are heterotrimeric proteins forming a network which is directly linked to the cell surface via cell adhesion molecules. The secreted extracellular matrix protein netrin-4 is able to intercalate into the network via binding to the laminin $\gamma 1$ chain. The resulting complex of netrin-4 and laminin $\gamma 1$ disrupts the laminin network and the entire basement membrane. The functional role of the laminin network during angiogenesis and vessel maintenance in inflammatory eye diseases has not been addressed so far. We hypothesis that laminin networks are necessary for blood vessel maintenance in the inflamed cornea.

Methods: Three interrupted 11-0 nylon sutures were placed into the corneal stroma of Balb/C mice (6 weeks old) and left in place for 14 days to induce neovascularization. Two weeks after suture placement sutures were either removed (supportive regression) or left in place for another 7 days (active regression). At that time, to disrupt laminin networks, the treatment group (n=10) received eye drops (3 μ l/3x/day; 7 days) of either Netrin-4 (1mg/ml), a laminin-binding mutant of Netrin-4 (Net4^{E195A,R199A}, 1mg/ml) or PBS as negative control. For immunohistochemistry, corneal flat mounts were stained with CD31 as pan endothelial marker and laminin $\gamma 1$. Image analysis was performed by fluorescence and confocal microscopy.

Results: Netrin-4 eye drops significantly supported the regression of preexisting corneal blood vessels compared to the control group (p= 0.0010; Net4: 13.03 \pm 1.7%; control: 21.7 \pm 5.9%) where as Net4^{E195A,R199A}, which is unable to disrupt preexisting laminin networks, could not support vessel regression (p= n.s.; Net4^{E195A,R199A}: 17.45 \pm 3.1%; control: 21.7 \pm 5.9%). Furthermore, destabilization of the laminin network by Netrin-4 actively induced blood vessel regression (p= 0.0156; Net4: 14.29 \pm 2.3%; control: 19.2 \pm 5.4%) whereas Net4^{E195A,R199A} could not induce blood vessel regression (p=n.s.; Net4: 16.07 \pm 2.8%; control: 19.2 \pm 5.4%). Immunohistochemistry revealed that the target structure Laminin $\gamma 1$ is co-localized with corneal CD31+ blood vessels.

Conclusions: We show that the basement membrane is pivotal to guarantee blood vessel maintenance in the inflamed cornea. Moreover, our data identify the laminin network as a promising therapeutic target for angiogenesis associated diseases.

ABSTRACT BODY:

Purpose: To validate a novel artificial intelligence (AI) machine learning algorithm for the automated quantification of lesion size in the mouse choroidal neovascularization (CNV) model.

Methods: CNV was induced in male C57Bl/6JRj mice using a diode laser. The progression of CNV was monitored using live in vivo imaging: fluorescent angiography and spectral-domain optical coherence tomography (SD-OCT). SD-OCT scans covering the whole retina were analyzed by a proprietary algorithm, which uses a combination of convolutional neural network (CNN) and traditional computer vision algorithms. The neural network was trained to recognize and quantify CNV lesions using a transfer learning approach.

Results: We used the Dice coefficient to evaluate AI algorithm-derived results. Dice coefficient comparing predicted lesion volume with volume from the manually annotated data was 0.87 and 0.89 for follow-up day 3 and day 7, correspondingly.

Conclusions: Our data provide evidence that our novel AI algorithm can successfully detect and quantify CNV lesions in the mouse CNV model. Notably, the algorithm accurately recognized temporal changes in retinal structure and pathology over a one-week experimental period. Automated vs. manual analysis resulted in approx. 90% congruence. The novel AI algorithm will provide automated computational analysis of phenotypes in the commonly-used CNV model for age-related macular degeneration, and offer complementary quantitative and bias-free data to accelerate and support drug discovery efforts.

ABSTRACT BODY:

Purpose: The formation of retinal ganglion cells (RGCs) is a stepwise process subject to tight genetic control. Our purpose in this study is to use single cell ATAC-seq (scATAC-seq) to investigate how the epigenetic landscape changes along the RGC developmental trajectory.

Methods: We used two knock-in mouse lines, Atoh7-zaGreen and Pou4f2-tdTomato, to enrich different cell populations by FACS. scATAC-seq and scRNA-seq libraries were then generated using the 10X Chromium platform and sequenced on an Illumina sequencer. The sequence data were then analyzed using Cell Ranger, Seurat, and archR. We also used CRISPR and RNAscope in situ hybridization to investigate the function of one candidate enhancer of Pou4f2, a key gene for the RGC lineage.

Results: We first performed UMAP clustering and gene score calculation of the scATAC-seq data and were able to cluster the cells into the same groups as achieved by scRNA-seq. We next identified enriched accessible peaks in individual clusters, which represented potential enhancers for each developmental stage/cell types. We further performed DNA motif enrichment and footprinting analysis which revealed stage/cell type-specific motif binding by key transcription factors. Further, we performed peak-to-gene linkage analysis by integrating scATAC-seq data with the scRNA-seq data and assigned the stage/cell type-specific enhancers to the genes they likely regulate, thus generating a global enhancer-gene linkage map for the developing retina at E14.5 and E17.5. We also compared the wild-type and Atoh7-null scATAC-seq data and identified peaks (enhancers) that were dependent on Atoh7. Finally, as a pilot validation, we used CRISPR to delete one of the candidate enhancers of Pou4f2, a key gene involved in RGC genesis, and confirmed by RNAscope in situ hybridization that the enhancer indeed played a critical role in the expression of Pou4f2.

Conclusions: Using scATAC-seq, we identified stage/cell-specific enhancers in the developing retina, assigned them to genes they likely regulate, and identified DNA-motifs in them likely bound by key transcription factors. Our results shed significant new light on the shifting epigenetic landscape along the developmental trajectory of the RGC lineage.

ABSTRACT BODY:

Purpose: Chronic hypoxia accompanied by decreased glycolysis in the retina and ON has been observed in retinal cells following long-term ocular hypertension. Declines in glycolysis despite its hypoxia-associated promotion suggest the retina may transition into a pseudohypoxic state, with HIF-1 α stabilization despite sufficient oxygen. This project investigates the role of chronic HIF-1 α stabilization in metabolic dysfunction in mouse eyes.

Methods: To induce chronic HIF-1 α stabilization, the prolyl hydroxylase inhibitor Roxadustat (Roxa) was injected into CAG-creERT2-ODD HIF-1 α reporter mice for 2 or 4 weeks. These mice express tdTomato protein when HIF-1 α is stabilized. Protein and mRNA isolated from retina and optic nerve was used to analyze glucose transporters, metabolic enzymes, and mitochondrial proteins. We also used the Seahorse XFe24 Analyzer to measure dependency and flexibility of Roxa retina on glycolysis.

Results: Roxa injection resulted in tdTomato expression in the retina, confirming the stabilization of HIF-1 α . Chronic HIF-1 α stabilization was associated with significant changes in the levels of key metabolic proteins. There was a progressive decrease in the mitochondrial protein TOM20 and metabolic enzymes pyruvate dehydrogenase and succinate dehydrogenase. The antioxidant protein SOD2 levels also decreased over time. Glucose transporter 1 (GLUT-1), specific for glial cells, significantly decreased after 4 weeks; however, the levels of glucose transporter 3 (GLUT-3), specific for neurons, did not change. Seahorse results indicated Roxa-injected mouse retinas were less dependent on glycolysis than control retinas. More relevant for function and perhaps indicative of pseudohypoxia, chronic HIF-1 α stabilization reduced the flexibility of retinas to use other metabolic substrates.

Conclusions: Our results show that chronic hypoxia leads to significant decline in mitochondrial function in mice retinas. This is expected because hypoxia promotes glycolysis. However, the limit on glycolysis dependence along with limited metabolic flexibility indicates HIF-1 α stabilization may contribute to metabolic dysfunction in glaucoma. These indicate that chronic hypoxia, as we observe in glaucoma, possibly impairs the primary metabolic pathways in mice retina and cellular response to metabolic stress.

ABSTRACT BODY:

Purpose: This study examines the anatomic and visual outcomes of pars plana vitrectomy with membrane peeling for degenerative lamellar macular holes.

Methods: A retrospective chart review was conducted on 5 years of vitreoretinal surgeries performed at a large hybrid retina practice in the Chicagoland area. All pre- and post-operative OCTs over the study period were examined for all patients who had vitrectomy with a concomitant diagnosis of a lamellar hole. These OCTs were used to codify lamellar holes as degenerative as opposed to tractional or pseudoholes. Pre-operative best corrected visual acuity (BCVA) and post-operative BCVA (6 to 12 months after membrane peel), as well as hole closure, were documented. Student's two-tailed T-test was used to compare pre- and post-operative visual and anatomic outcomes with an alpha of 0.01.

Results: 23 degenerative lamellar holes in 22 patients, 59 tractional lamellar holes in 55 patients, and 9 pseudoholes in 9 patients were operated on over the study period. The degenerative holes were found to have an statistically significant improvement of 2.5 lines in BCVA ($p < 0.01$). Only 2 patients had a one line loss in BCVA in the post-operative period, and 100% of the degenerative lamellar holes closed post-operatively.

Conclusions: Degenerative lamellar holes have been postulated to have a unique pathophysiology in contrast to tractional lamellar holes and pseudoholes. Previous, smaller-sample case series have shown mixed visual outcomes after vitrectomy with membrane peel for degenerative lamellar holes. To our knowledge, this is the largest series of surgical cases of degenerative lamellar holes published to date, and our results suggest a significant visual benefit to peeling. Further study of our dataset will include comparison to outcomes of surgeries done on tractional holes and pseudoholes.

ABSTRACT BODY:

Purpose:

Manual fluid segmentation in SD-OCT is tedious and subject to variability. This study compared machine learning (ML) model architecture performance in fluid segmentation and classification to understand the optimal model architecture for use in automated segmentation.

Methods:

A deep convolutional neural network was tested modifying parameters such as batch normalization, kernel size (10x10 compared to a 5x5), and dilation (rate = 2 compared to rate = 0). The training set was composed of 1369 SD-OCT slices for classification, and 1593 slices for segmentation and included retinal disorders, such as diabetic macular edema and age-related macular degeneration. The segmentation model detected “all fluid” whereas the classification model categorized the type of fluid [e.g., intraretinal fluid (IRF), subretinal fluid (SRF)] present in ground truth segmented “generic” fluid. Performance was evaluated using F-scores.

Results:

Segmentation F-scores ranged from 0.00 (when batch normalization not performed) to 0.72. The optimal model architecture for segmentation was the 5x5-kernel, with batch normalization, and no dilation. This may be caused by reduced training data dilution when using smaller kernels. Classification F-scores varied from 0.78 to 0.87. The optimal classification architecture used 5-kernel with batch normalization and a dilation rate of 2. This 5x5-kernel model took the same amount of spatial context as a 10x10-kernel model, using fewer nodes. This efficiently incorporates contextual information from relative location and retinal features.

Conclusions:

Model architecture impacts fluid segmentation and classification performance. Optimizing architecture to incorporate contextual information efficiently is key to high performance in spatial problems with limited datasets.

ABSTRACT BODY:

Purpose: Mutations in the LCA5 gene disrupt its cognate ciliary protein lebercilin, causing Leber congenital amaurosis (LCA), one of the most severe forms of inherited blindness. Previous proteomics studies performed in non-retinal cells (HEK293T) identified a lebercilin interactome that contained several submodules, including the ciliary intraflagellar transport (IFT) complex. This suggested that defective ciliary trafficking underlies the congenital blindness in LCA5 patients. In this study, we set out to identify the retina-specific interactome of lebercilin by applying two complementary retinal affinity proteomics approaches.

Methods: To optimize an ex vivo affinity purification of lebercilin interactors from bovine retinal extracts, we first purified correctly processed recombinant N-TAP tagged lebercilin bait-proteins, both wild-type (WT) and mutant (LCA5 p.P493TfsX1), from HEK293T cells employing an SDS 'bait-purification' procedure. These purified lebercilin baits were then used to pull-down specific interactors from bovine retinal lysates, followed by mass spectrometry (MS) analysis. For an in vivo approach, we used the AAV serotype AAV7m8 to intravitreally deliver a 3xFLAG-tagged human LCA5 cDNA in the eyes of Lca5^{+/gt} mouse pups (P2). After four weeks, retinas were isolated and subjected to affinity purification of lebercilin followed by MS analysis.

Results: Ex vivo, we found that all IFT-B proteins, two members of the multi subunit C-terminal to LisH (CTLH) complex, and the dynein light chain 1 complex are significantly enriched in purifications of lebercilin WT versus control. However, only the IFT-B and CTLH proteins were lost from the interactome due to the mutation. In vivo, we found that two specific IFT-B proteins and four CTLH complex proteins were significantly enriched in AAV/3xFLAG-lebercilin purifications from mouse retinas compared to controls. Analysis of additional potential interactors is currently ongoing.

Conclusions: Our results indicate that the IFT complex and the CTLH complex, previously identified in HEK293T cells, are conserved in the retinal context. Furthermore, we identified that the interaction of all IFT-B proteins and several CTLH complex proteins is lost when lebercilin is mutated. Overall, these findings highlight the potential contribution of these protein complexes to the disease mechanism.

ABSTRACT BODY:

Purpose: Diabetes mellitus appears to be an epigenetic disease with DNA methylation and histone acetylation changes. It causes persistent corneal epithelial alterations including impaired wound healing, which may occur due to the dysfunction of limbal epithelial stem cells (LESC). Previously, DNA methylation analysis showed WNT5A gene to be hypermethylated in diabetic primary cultured human limbal epithelial cells (LEC) enriched in LESC. Our purpose was to examine the effect of Wnt5a on diabetic corneal epithelial wound healing and limbal stem cell expression.

Methods: LEC were isolated from age-matched autopsy non-diabetic and diabetic limbal rims and eyes with IRB approval. Scratch wound healing was carried out in LEC treated with recombinant Wnt5a (200 ng/mL) or DNA methylation inhibitor, zebularine (1, 5, 10 μ M), or transfected with siRNA to WNT5A or with miR-203a mimic or inhibitor. Healing of epithelial wounds created with 1-heptanol was monitored in organ-cultured diabetic corneas with or without the addition of exogenous Wnt5a. Protein expression was determined in these LEC and corneas using Western blot and immunostaining.

Results: Diabetic LEC and corneal epithelium showed significantly decreased expression of Wnt5a protein apparently due to hypermethylation of WNT5A gene. Wnt5a treatment significantly stimulated wound healing in cultured cells and organ-cultured corneas and increased the expression of putative stem cell markers, K15 and K17. In contrast, siRNA knockdown of WNT5A in non-diabetic LEC decreased wound healing vs. control. Zebularine significantly decreased the expression of DNA methyltransferase DNMT1 and 5-methylcytosine and increased Wnt5a expression with an acceleration of wound healing in diabetic LEC. siRNA experiments suggested that demethylating effect was directly related to Wnt5a level changes. Transfection of LEC with Wnt5a-suppressing miR-203a significantly retarded wound healing in non-diabetic LEC, whereas miR-203a inhibitor increased Wnt5a expression and promoted wound healing in diabetic LEC.

Conclusions: In summary, this study confirms the epigenetic changes in diabetic limbal epithelium with reproducible differential methylation in non-diabetic and diabetic primary LEC. Wnt5a is a new diabetic marker in the cornea that appears to be under dual inhibition in diabetic corneas by DNA hypermethylation and miRNA action.

TITLE: Electroretinographic Responses to Full Field Stimuli in Children with a History of Retinopathy of Prematurity (ROP) Treated with Anti-VEGF

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Curran, L. Ambrosio, D. Vanderveen, I. Mantagos, C. Wu, J.D. Akula, A.B. Fulton, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|L. Ambrosio, D. Vanderveen, I. Mantagos, C. Wu, J.D. Akula, A.B. Fulton, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amber-Lee Curran: Commercial Relationship: Code N (No Commercial Relationship) | Lucia Ambrosio: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Vanderveen: Commercial Relationship: Code N (No Commercial Relationship) | Iason Mantagos: Commercial Relationship: Code N (No Commercial Relationship) | Carolyn Wu: Commercial Relationship: Code N (No Commercial Relationship) | James Akula: Commercial Relationship: Code N (No Commercial Relationship) | Anne Fulton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate dark adapted, full field electroretinographic (ffERG) response parameters in children with a history of retinopathy of prematurity (ROP) treated only with an anti-vascular endothelial growth factor (anti-VEGF) therapy and those in which anti-VEGF treatment was subsequently supplemented with laser photocoagulation.

Methods: Full field electroretinography (ffERG) was performed in patients (N=18) who had ROP treated with anti-VEGF therapy. The subjects were born at median gestational age of 24 weeks (range 23 - 29 weeks) and median birth weight at 645 g (range 410 - 960g). The median corrected age at ffERG test was 41.9 weeks (range 8 to 83 weeks). None had a retinal detachment. In every patient, the ffERG was performed following anti-VEGF treatment. In one group (n=9), the anti-VEGF treatment was deemed adequate (i.e., the ROP required no further treatment); in the other group, subsequent retreatment with laser photocoagulation was administered following inadequate anti-VEGF treatment (n=9). Sensitivity and saturating response amplitude parameters were calculated from the a-wave, b-wave, and oscillatory potentials (OPs), respectively, to provide information about rod mediated photoreceptor, post-receptor, and inner retinal function. Linear mixed modeling was used to evaluate response parameters for differences between those in the anti-VEGF adequate versus inadequate groups.

Results: Neither gestational age at birth nor birthweight differed significantly between the group wherein anti-VEGF treatment was adequate and the group requiring additional laser treatment. Furthermore, there were no significant differences in any amplitude or sensitivity parameter between these groups.

Conclusions: These ffERG results indicate no evidence that dark adapted ffERG photoreceptor and post-receptor activity parameters differ between children with ROP for whom anti-VEGF is adequate and those who will require additional laser treatment. This is despite the strong evidence that photo receptor activity instigates the vascular abnormalities that are the clinical hallmark of ROP (Akula et al., ExER 2010).

ABSTRACT BODY:

Purpose: To develop a fully-automated, learning-based system to identify referable retinal pathology in different imaging modalities obtained remotely at the primary care clinic.

Methods: We used a dataset of 1148 Optical Coherence Tomography (OCT) and color fundus (CFP) retinal images obtained from 647 diabetic patients using Topcon's Maestro care imaging unit. A Convolutional-Neural Network (CNN) with dual-modal inputs (OCT and CFP images) was developed to identify retinal pathology. We developed a novel alternate gradient descent algorithm to train the CNN that allowed for the use of uninterpretable images (i.e., images that do not contain sufficient image biomarkers to conclude a definitive diagnosis). Specifically, a 9:1 ratio to split the training and testing dataset was used for training and validating the CNN. The CFP/OCT inputs obtained from a patient's single eye were grouped as retinal pathology negative (RPN, 924 images) in the absence of retinal pathology in both imaging modalities, or if only one of the imaging modalities was uninterpretable and the other without retinal pathology. If any imaging modality exhibited referable retinal pathology, the corresponding inputs were deemed retinal pathology positive (RPP, 224 images). Additionally, if both imaging modalities were uninterpretable, the inputs were labeled retina pathology potentially present (RPPP).

Results: We achieved $88.60 \pm 5.84\%$ (95% CI) accuracy in identifying referable retinal pathology, along with the false-negative rate of $12.28 \pm 6.02\%$, the sensitivity of $87.72 \pm 6.03\%$, the specificity of $89.47 \pm 6.13\%$, and area under the curve of the receiver operating characteristic (AUC-ROC) of $92.74 \pm 4.76\%$.

Conclusions: Our newly developed learning-based approach can be successfully used in clinical practice to facilitate the presence of referable retinal pathology.

TITLE: Effects of Spectrum of Wavelengths of Blue-Light on Retinal Pigment Epithelial Cells

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Abdouh, A.A. Goyeneche, E. Youhnovska, R. Denis, P. Garcia de Alba Graue, J.V. Burnier, M.N. Burnier, McGill University Ocular Pathology and Translational Research Laboratory, McGill University Health Centre, Montreal, Quebec, CANADA]

Commercial Relationships Disclosure (Abstract): Mohamed Abdouh: Commercial Relationship: Code N (No Commercial Relationship) | Alicia Goyeneche: Commercial Relationship: Code N (No Commercial Relationship) | Emma Youhnovska: Commercial Relationship: Code N (No Commercial Relationship) | Raphaelle Denis: Commercial Relationship: Code N (No Commercial Relationship) | Paulina Garcia de Alba Graue: Commercial Relationship: Code N (No Commercial Relationship) | Julia Burnier: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a major cause of blindness in the elderly population. It is characterized by loss of central vision due to damaged retinal pigment epithelium (RPE) cells and photoreceptors. Blue Light (BL) is recognized as a risk factor for AMD as it triggers RPE cell death. As BL covers a large light spectrum, we undertook this study to determine the exact range of BL wavelengths that affect the behaviour of RPE cells.

Methods: RPE cells (ARPE-19 and h-TERT-RPE1 cells) were exposed or not to BL (400 – 500 nm) under a Solar Simulator (TSS-156R, OAI) set at 50 mW/cm². RPE cells were analyzed for (i) their growth (using the Incucyte live imaging system to assess cell confluence, and the CCK8 assay to assess cell metabolic activity), and (ii) their oxidative stress by measuring mitochondrial reactive oxygen species (mROS) (using the MitoSox probe). All experiments were performed at least 3 times, and data were compared using an ANOVA followed by the Dunnett post-hoc test for multiple comparisons with one control group. A p value < 0.05 was considered statistically significant.

Results: We observed that BL exposure significantly decreased the proliferation of RPE cells (58 +/- 4% decrease in cell confluence), and their metabolic activity (51 +/- 5% reduction). To get an insight on the mechanisms underlying the observed effects, we analysed the effects of BL on oxidative stress. We noted that although non-exposed RPE cells displayed a baseline level of mROS, BL significantly increased the amount of mROS production (3 times increase). Using a set of filter cut-offs, we noticed that BL at wavelengths above 460 nm did not affect RPE cell behavior. In contrast, BL at wavelengths ranging from 400 to 460 nm was responsible for the deleterious effects observed on exposed RPE cells.

Conclusions: Our data show that BL at wavelengths below 460 nm are deleterious to RPE cells due to increased oxidative stress. The use of lenses with a filtering potential below 460 nm may reduce the harmful effects of these radiations on RPE cells and delay the onset of AMD.

Commercial Relationships Disclosure (Abstract): Christina Mastromonaco: Commercial Relationship: Code N (No Commercial Relationship) | Sabrina Bergeron: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Coblenz: Commercial Relationship: Code N (No Commercial Relationship) | Mohamed Abdouh: Commercial Relationship: Code N (No Commercial Relationship) | Julia Burnier: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration(AMD) is a disease that affects central vision and is the leading cause of blindness in the developed world. Despite the lack of a clear understanding of AMD pathogenesis, growing evidence suggests a link between photooxidative stress caused by short-wavelength(blue) light and subretinal drusen accumulation. This study examines the relationship between blue-light filtering intraocular lens(IOL) implants and drusen development through the histopathology of post-mortem eyes.

Methods: A total of eighty donor eyes with IOL implants(Forty with clear IOL and 40 with yellow IOL) were obtained from the Minnesota Lions Eye Bank and examined at the MUHC-McGill University Ocular Pathology Lab. The age, sex, ocular history, clinical history, time from IOL implantation(cataract surgery) to enucleation, and lens model type were obtained for each eye. Eyes were sectioned in their sagittal axis, and formalin-fixed paraffin embedded macular cross sections were obtained H&E stained sections were digitalized using the Zeiss Axio Scan.Z1 scanner.Drusen were identified and classified according to the following criteria: type (soft, cuticular, hard), size (small, medium, large, flat ovoid), and quantity (none, few, multiple, zonal, multiple zonal or extensive).

Results: The presence of soft drusen is observed in 51.32% (n=39) of our samples, while cuticular is observed in 10.53% (n=8) of cases and hard drusen in 14.47% (n=11). The remaining 23.68% does not show macular drusen (n=18). The presence of soft drusen is greater in the group implanted with a clear IOL implant (61.5%, n=24) when compared to the yellow IOL implant. In addition, the number of eyes without apparent drusen is greater in the yellow IOL implant group.The ratio of soft drusen for clear vs yellow IOL is 16:9 for the initial five years after implantation and 22:15 for a ten-year period. Soft drusen accounts for 80% of the aggregate in the 90-99 years old group, while only 42.31% of the drusen in the 70-79 years old group are categorized as soft drusen.

Conclusions: We observe a lesser presence of drusen of all groups of patients with a yellow IOL implant. The presence of soft drusen, which is known for its relationship with macular disease, is also markedly less in patients with yellow blue-light filtering IOL implant when compared to the clear one. This effect is observed across all age groups.

TITLE: Endocannabinoids reduce NF- κ B signaling in Müller glia and promote the formation of Müller glia-derived progenitor cells in damaged retinas

SESSION TITLE: Glial Cells

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W.A. Campbell IV, S. Blum, A. Reske, A. Fischer, Neuroscience, The Ohio State University, Columbus, Ohio, UNITED STATES]

Commercial Relationships Disclosure (Abstract): Warren Campbell IV: Commercial Relationship: Code N (No Commercial Relationship) | Sydney Blum: Commercial Relationship: Code N (No Commercial Relationship) | Alana Reske: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Fischer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Endocannabinoids (eCB) are lipid-based neurotransmitters that are known to influence visual function and perception. Additionally, eCBs are known to reduce inflammatory signaling in pathological states. However, little is known about the role of the eCB system in modulating inflammation after damage and during reprogramming Müller glia (MG) into progenitor cells (MGPCs).

Methods: Chick retinas after excitotoxic damage were implemented as a model of partial retinal regeneration. The expression of eCB signaling genes were analyzed using single cell RNA sequencing (10X Genomics) in postnatal chicks (P7-P21) with intravitreal injection of NMDA (2 μ mol/dose). Small molecule drugs targeted the CNR1 receptor and eCB synthesis and degradation. MGPCs were identified via 5-ethynyl-2'-deoxyuridine incorporation. Microglia morphology was characterized via Sholl Analysis (ImageJ). Retinal NF- κ B activation was determined using cis-NF- κ B EGFP reporter mice. Statistical Significance was assessed via a Student's T test, Wilcoxon Rank Sum test with Bonferroni correction, one-way ANOVA, and Tukey's test.

Results: MG express eCB signaling and synthesis genes (CNR1, PLCB, NAPELPD, DAGLB, MGLL). Intravitreal injections of eCB increased numbers of MGPCs after damage ($n = 8$, $p < 0.05$). The CNR1 agonist win55, 212-2 ($n = 8$, $p < 0.05$) and inhibition of eCB-degradation with JJKK048 ($n = 8$, $p < 0.05$) resulted in comparable increases in numbers of MGPCs. The CNR1 antagonist rimonabant ($n = 8$, $p < 0.05$) and lipase inhibitor Orlistat ($n = 8$, $p < 0.05$) reduced MGPC formation. However, chick microglia reactivity (proliferation, accumulation, area, CD45 intensity, morphology) after damage was unaffected by all treatment conditions ($n = 8$, $p > 0.05$). In damaged mouse retinas, numbers of NF- κ B-GFP⁺ MG increased after rimonabant treatment ($n = 4$, $p < 0.05$) and decreased with win55, 212-2 ($n = 4$, $p < 0.05$) and eCBs ($n = 4$, $p < 0.05$).

Conclusions: MG respond to inflammatory signaling factors, which influence the capacity of MG to transition into a proliferative state. eCBs result in fewer MG with NF- κ B activation in mouse, and promote MGPC formation in the chick, without significant changes to microglia reactivity. These findings suggest that eCB inhibits NF- κ B signaling in MG which promotes MPGC formation.

TITLE: Lipid Layer Thickness, Blink Parameters, and Meiboscore in Patients with Dry Eye Disease: A Retrospective Cohort Study

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Brahmabhatt, S. Khanna, W. Adams, B.I. Gaynes, C.S. Bouchard, Loyola University Health System, Maywood, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Puja Brahmabhatt: Commercial Relationship: Code N (No Commercial Relationship) | Sheena Khanna: Commercial Relationship: Code N (No Commercial Relationship) | William Adams: Commercial Relationship: Code N (No Commercial Relationship) | Bruce Gaynes: Commercial Relationship: Code N (No Commercial Relationship) | Charles Bouchard: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although meibomian gland structure and function can be assessed through meibography and measurement of lipid layer thickness (LLT), the role of blink parameters on the tear film has not yet been fully elucidated. Blink frequency and completeness may impact the lipid layer thickness measurement. In this retrospective cohort study, the relationship between LLT, meiboscore, blink rate, partial blink rate, and inter-blink interval were investigated.

Methods: This is a single-center, retrospective cohort study at the Loyola University Medical Center. We analyzed 2 years of data (2018-2020) generated from the LipiView Interferometer device for 456 eyes. The meiboscore of each eye was graded using the (4 point) Heiko Pult meiboscore. Inter-blink interval was determined from the Lipiview report using the measuring tool application on Adobe Acrobat DC. Linear mixed-effects models were used to analyze the relationship between LLT, meiboscore, blink rate, partial blink rate, and inter-blink interval.

Results: For every 1-point increase in the Pult meiboscore, the average LLT declined by -1.31 units (95% CI: -3.57 to 0.95; $p = .26$) and the total blink rate decreased by 4% (RR = 0.96; 95% CI: 0.91 – 1.03; $p = .26$). Both measures were not statistically significant. LLT and inter-blink interval did not differ significantly between disease states (floppy eyelid syndrome, obstructive sleep apnea, meibomian gland dysfunction, ocular graft vs host disease, Stevens-Johnson Syndrome). There was no statistically significant difference in LLT in patients with a partial blink rate >50% as compared to a partial blink rate <50%. However, there was an association between inter-blink interval (in seconds) and partial blink rate (%). That is, a partial blink rate between >0% to 50% had an inter-blink interval that was -0.73 (95% CI: -1.33 to -0.13) seconds shorter on average than with a 0% partial blink rate ($p = .01$).

Conclusions: A decrease in LLT is associated with increased meibomian gland dropout (meiboscore). Patients who blink more completely (have an incomplete blink rate less than 50% of the time) have a shorter inter-blink interval (time between blinks). We speculate that in patients with an increase in partial blinks, the longer inter-blink interval results from impaired corneal sensation related to the chronic exposure.

TITLE: Crispr/Cas9 correction of the TIMP3 S204C mutation in Sorsby fundus dystrophy iPSC-derived RPE

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Engel, R. Lim, K. Gonzalez, J.R. Chao, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Abbi Engel: Commercial Relationship: Code N (No Commercial Relationship) | Rayne Lim: Commercial Relationship: Code N (No Commercial Relationship) | Keli Gonzalez: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Chao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sorsby fundus dystrophy (SFD) is an early onset macular degenerative disease that is defined by a mutation in the TIMP3 gene. Retinal pigment epithelial (RPE) cells are important in the pathogenesis of age-related macular degeneration and SFD. Cell culture models show promise in reproducing some prominent disease features. By correcting the TIMP3 mutation, we propose to determine the role of TIMP3 in disease phenotype and identify factors that might be independent of the mutation.

Methods: Induced pluripotent stem cells (iPSCs) derived from SFD patients with the Ser204Cys TIMP3 mutation were electroporated with a ribonucleoprotein (RNP) complex of Cas9 and gRNA with donor ssDNA using Amaxa nucleofactor in the presence of ROCK inhibitor and HDR enhancer. Individual colonies were selected and plated into 96-well plates. DNA was extracted and nested PCR was performed. The purified PCR product was sent for Sanger sequencing analysis and karyotype. Clones were differentiated into RPE, which were then cultured on filter membranes to determine structural and functional characteristics using TEM or IHC analysis. RPE cultured on chambered slides were stained with Alizarin Red S. Western blot was performed to determine changes in protein expression.

Results: The Crispr/Cas9-corrected SFD iPSC-derived RPE have typical RPE cobblestone morphology and form tight junctions as observed by ZO-1 staining. Cell polarization and maturation is demonstrated by the presence of apical microvilli, basal infoldings, and tight junction formation visualized by TEM. We previously reported a significant increase in TIMP3 accumulation in the extracellular matrix (ECM) of SFD RPE. CRISPR/Cas9-corrected iPSC RPE were noted to have decreased basal TIMP3 accumulation. SFD iPSC-derived RPE form basal calcium deposits that stain for Alizarin Red S, while Crispr/Cas9-corrected SFD RPE demonstrate decreased calcium deposition ($p < 0.0001$), similar to control levels.

Conclusions: CRISPR/Cas9 correction of the TIMP3 mutation in SFD RPE results in reduced accumulation of extracellular TIMP3 and reversal of the formation of calcium-staining sub-RPE deposits.

ABSTRACT BODY:

Purpose: To test the hypothesis that newly developed topographic and volumetric foveal outcome measures can discriminate patients with early perimetric glaucoma from normal subjects.

Methods: We used new measures defining inner foveal shape and central macular volume that were recently developed based on parametric modeling of central macula with cubic Bézier (Figure). Global, hemiretinal, and quadrant parameters were calculated for a group of 50 glaucoma eyes (50 patients) with MD of -6 dB or better and 181 eyes of 96 normal subjects. 8×8 arrays of ganglion cell layer (GCL) and inner plexiform layer (IPL) measurements within 3°×3° superpixels were exported and GC IPL thickness parameters were estimated for 5 macular sectors in the superior and inferior hemiretinas. Multivariate logistic regression and area under ROC curves were used to compare the performance of foveal topographic and volumetric measures to that of thickness measurements.

Results: The average (±SD) visual field mean deviation was -3.6 (±1.5) in the glaucoma group. The main global parameters discriminating glaucoma from normal eyes were the macular rim volume and the area of the maximum foveal slope (AUC:0.786). Among the regional topographic/volumetric parameters, a combination of four temporal hemiretinal parameters (rim height, inner rim volume, foveal pit depth, and pit volume) performed best for discrimination of glaucoma from normal eyes (AUC:0.903; 95% CI=0.858-0.948). A combination of 13 regional parameters selected with elastic net regression resulted in AUC of 0.931 (95% CI:0.899-0.966). In comparison, the AUC for the best GC IPL thickness parameter (inferior sector 2) was 0.895 (95% CI:0.844-0.946).

Conclusions: The newly defined topographic and volumetric foveal biomarkers are able to detect early perimetric glaucoma with clinically relevant performance. Such biomarkers do not depend on segmentation of intraretinal layers and may be helpful where adequate segmentation of macular layer cannot be achieved; they may be used to define macular phenotypes in glaucoma and could assist for detection of disease progression in the later stages of glaucoma.

ABSTRACT BODY:

Purpose: Adeno-associated virus (AAV) mediated gene delivery is showing great potential for treating genetic diseases that disrupt retinal structure and function. The human disease, complete congenital stationary night blindness (cCSNB) is a genetically heterogeneous disorder of the retina characterized by impairment of low light vision and loss of the b-wave of the electroretinogram (ERG). In mouse models of cCSNB the normal ON retinal ganglion cell responses are absent. Synaptic function requires proper alignment of pre- and postsynaptic elements, including alignment of signaling molecules that govern neurotransmitter release and reception. LRIT3 is a presynaptic, leucine rich repeat protein that when absent causes loss of the postsynaptic TRPM1 and Nyctalopin expression from the dendritic tips of rod bipolar cells, and in addition mGluR6, GPR179 and the RGS complex of proteins from dendritic tips of cone ON bipolar cells. Here we investigate whether LRIT3 expression in cone photoreceptors regulates the cone ON bipolar cells signalplex expression and localization.

Methods: To express LRIT3 in cone photoreceptors we used a human GNAT2 promoter to selectively express LRIT3 in cones. The construct GNAT2::Lrit3, was packaged in rAAVs, which were injected subretinally into adult mice. We characterized overall retinal function of GNAT2::Lrit3 rAAVs in Lrit3^{-/-} mice using ERG, and retinal ganglion cell (RGC) responses by patch-clamp recording. Expression and localization of synaptic proteins were examined by immunohistochemistry.

Results: We show that expression of LRIT3 in cones restores cone mediated retinal function. Light adapted ERGs from 12 GNAT2::Lrit3 mice showed restoration of the b-wave to between 32% and 72% of WT values. Recordings from ON alpha RGCs showed recovery of light responses and synaptic current oscillations characteristic of Lrit3^{-/-} retina were absent or negligible. Immunohistochemistry showed that LRIT3 expression was restored to cone terminals, as were the post-synaptic signalplex proteins, TRPM1, Nyctalopin, mGluR6, and GPR179.

Conclusions: Our data show that LRIT3 functions in a trans-synaptic manner and controls the expression and localization of the cone ON bipolar cell signalplex proteins. These data also show the potential for gene therapy of cCSNB patients with mutations in LRIT3 by AAV mediated gene delivery.

ABSTRACT BODY:

Purpose: Temporal macular thinning has been shown in patients with Alport syndrome (AS), particularly in X-linked males (XLM). We investigated macular retinal thickness measurements in a cohort of AS patients (including females with X-linked disease (XLF) and patients with autosomal recessive (AR) disease), making comparisons with matched control subjects and exploring association with visual acuity (VA).

Methods: Patients underwent macular optical coherence (OCT) imaging (3D OCT-1000, Topcon Corporation, Japan). One eye was included per subject. Data collected included age, genotype, VA, average retinal thickness (AvRT) and ETDRS 9-subfield thickness (outer (O), inner (I); superior (S), inferior (I), nasal (N) temporal (T) and central (C)). Temporal thinning index (TTI) was calculated using the formula $((ON+IN)-(OT+IT))/(IN+ON) \times 100$. Data were compared using Mann-Whitney-U tests and associations measured with robust logistic or linear regression models. OCT measurements were compared with similar data from 30 age and sex-matched control participants.

Results: 30 patients (15 XLM, 10 XLF, 5 AR genotypes) were included. Comparison with controls revealed a significant difference for TTI, AvRT and all EDTRS subfields (all $p \leq 0.01$), except for the IN region ($p = 0.162$). On subgroup analysis, only OT and OS subfield thickness remained significantly different from controls in each AS subgroup (all $p < 0.05$), while TTI only remained significantly different in XLM ($p \leq 0.001$). XLM subjects had significantly greater TTI than XLF subjects ($p < 0.001$). Age-adjusted logistic regression demonstrated significant association between AvRT, OT and OS with each AS subgroup (all $p < 0.05$), and TTI with XLM phenotype (OR: 3.85 [95%CI: 1.68-8.84], pseudo- R^2 0.79, $p = 0.001$). OT thickness was most strongly predictive of XLF or AR genotypes (AUC 0.89), while TTI was most strongly predictive of XLM genotype (AUC 0.99). In the XLM group, age-adjusted VA was significantly associated with all retinal thickness measurements (all $p \leq 0.02$), except the ON subfield ($p = 0.078$).

Conclusions: Alport syndrome is associated with generalized macular thinning, which is detectable in all EDTRS subfields, with the exception of the IN region. We found that retinal thickness metrics varied by subgroup, but numbers were small. In addition, most OCT thickness metrics demonstrated correlation with VA in the XLM subgroup.

ABSTRACT BODY:

Purpose: ABCA4-retinopathy (including Stargardt disease, STGD1) is by far the most common single-gene inherited retinal disease (IRD). Entire ABCA4 sequencing in a large cohort of over 1,000 STGD1 cases demonstrated the importance of non-coding, mainly deep intronic splicing variants in ABCA4-associated disease pathogenesis. This raises the hypothesis that variants in other non-coding regions, such as cis-regulatory elements (CREs), may be implicated in missing heritability of ABCA4-associated disease. Previous studies have shown that CRISPR/Cas9 editing can be used to disrupt CREs in model organisms. *Xenopus (X.) tropicalis* is an interesting model organism for IRD, having the major cell types of the human eye, thousands of eggs that are easy to manipulate for CRISPR/Cas9 injections, and a true diploid genome. Here, we aimed to map and functionally study CREs of the abca4 region in *X. tropicalis*. Moreover, we aimed to generate and characterize a stable knock-out of a CRE of abca4 in *X. tropicalis* using CRISPR/Cas9 editing.

Methods: Putative CREs of abca4 were determined according to epigenetic markers H3K4me1 and Pol II in *X. tropicalis* whole embryo. Regulatory activity of putative CREs was tested using in vitro luciferase assays. Paired guide RNAs (gRNA) and Cas9 in *X. tropicalis* embryos was used to create a deletion of a selected CRE.

Results: A putative CRE of abca4, showing around 2-fold increase in luciferase activity compared to empty vector was selected as a target for disruption. Two gRNAs were designed as flanking the target CRE of abca4. The genomic region flanking the CRISPR target site was amplified and sequenced. Genome editing using a paired gRNA CRISPR/Cas9 system showed the deletion of the target CRE compared to using one gRNA and/or non-injected embryos. Further assessments including histology, immunohistochemistry, TUNEL assays and electroretinography to characterize the disease phenotype are ongoing.

Conclusions: In conclusion, regulatory elements can be disrupted in model organisms using paired gRNAs. Regulatory animal models may contribute to the annotation of the non-coding genome and provide insights into the regulation of IRD genes such as abca4.

ABSTRACT BODY:

Purpose: Most studies have focused on abnormalities in large vessels and capillaries that supply the optic nerve head (ONH) in glaucoma but there is little evidence on macular microvascular abnormalities in pre-perimetric glaucoma (PPG) and their effects on retinal ganglion cells (RGC) function. The purpose of this cross-sectional prospective study was to determine the relationship between foveolar avascular zone (FAZ) area, a biomarker for macular vascular integrity and RGC function assessed by pattern electroretinogram (PERG)

Methods: Twenty consecutive PPG participants (31 eyes) with normal visual fields tests and suspicious glaucomatous ONH appearance were enrolled in this study conducted at Manhattan Eye Ear & Throat hospital and underwent a complete ophthalmologic examination, standard automated perimetry, optical coherence tomography-angiography (OCTA) and PERG. FAZ area was measured using ImageJ software, with ICC of 0.99 between 2 raters. Mediation analysis Process by Andrew Hayes was tested using the Sobel test, and the bias corrected nonparametric bootstrapping procedure with 5000 bootstrapped samples, at 95% CI. The indirect effect (IE) was significant if the CI did not contain zero. $p < 0.05$ was used

Results: After controlling for risk factors for glaucoma [age, sex, intraocular pressure (IOP), central corneal thickness (CCT) and refractive error (RE)], PERG parameters Magnitude (Mag), and MagnitudeD (MagD) were significantly correlated with FAZ ($r > -0.503$, $p < 0.028$), all PERG parameters correlated with superior quadrant RNFL ($r > 0.498$, $p < 0.030$), with superior (S), superior temporal GCL-ILP thickness ($r > 0.545$, $p < 0.016$); MagD and MagD/Mag ratio with average and minimum GCL-IPL thicknesses ($r > 0.495$, $p < 0.031$). Mediation analysis revealed that FAZ area was a significant mediator in the relationship between MagD and S GCL-ILP thickness, independent of CCT and RE (effect = 4.92, $p = 0.0033$, 95% CI [0.41-9.44]). While the direct effect of MagD remained significant (effect = 4.92, $p = 0.033$, 95% CI [0.41-9.44]), the indirect effect was also significant, indicating that FAZ area partially mediated the effect of MagD on S sector GCL+IPL (effect = 2.71, 95% CI [0.22-6.06]).

Conclusions: RGC dysfunction is associated with structural thinning of the GCL-IPL layer, and this effect is partially mediated by the disruption of the macular vascular integrity and FAZ enlargement

TITLE: Short-Term Effects on Corneal Endothelial Cell Density and Morphology After Deep Small Incision Lenticule Extraction (SMILE)

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Mangwani Mordani, E.O. Graue-Hernandez, A. Navas Perez, A. Ramirez Miranda, Cornea and Refractive Surgery, Instituto de Oftalmologia Fundacion Conde de Valenciana IAP, Mexico City, Mexico City, MEXICO|

Commercial Relationships Disclosure (Abstract): Simran Mangwani Mordani: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Graue-Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Navas Perez: Commercial Relationship: Code N (No Commercial Relationship) | Arturo Ramirez Miranda: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify the effect of deep SMILE (160µm Cap depth) on corneal endothelium cell density (ECD) and morphology.

Methods: Retrospective, single arm pre-post study that included 30 eyes. During September-December 2020, 15 patients were identified as candidates for refractive surgery. Before surgery, measurements of endothelial cell density (ECD), coefficient of variation (CV) and hexagonality (HEX) were performed with specular microscopy. Follow up measurements of ECD, CV and HEX were repeated a week and month after SMILE surgery.

Results: All patients were within the age range of 22-42 years. Paired T-Student tests were performed to compare preoperative and postoperative measurements for ECD, CV and HEX individually, at one week and month follow up. Mean values for HEX showed no change, while ECD (2971.2 vs. 2952.1, $p=0.59$) and CV (31.9 vs. 30.5, $p=0.11$) presented a slight non-significant decrease after a week when compared to preoperative values. Compared to basal measurements, follow up mean values after a month of surgery showed a small increase in ECD (2986.9 vs. 3008.8, $p=0.49$), CV (31.9 vs. 32.3, $p=0.66$) and HEX (64.1 vs. 64.4 $p=0.79$). The same pattern was identified comparing week one and month results for ECD (2952.1 vs. 3008.8, $p=0.18$), CV (30.53 vs. 32.2 $p=0.003$) and HEX (64.2 vs. 64.4 $p=0.90$). No complications were observed.

Conclusions: Deep SMILE has no statistically significant effect on ECD and morphology. The 160µm Cap depth has no adverse effects on corneal endothelial cells and no correlation with the amount of myopia or astigmatism treated.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is an inherited retinal degenerative disease characterized by rod cell death followed by cone loss. Recently, non-apoptotic cell death mechanisms have been implicated in RP. In a comprehensive biochemical analysis of ten mammalian RP models, evidence of non-apoptotic cell death, such as activation of Poly (ADP-ribose) Polymerase (PARP), was common across all models while apoptosis was implicated in only one. Previously, our lab generated a nitroreductase (NTR)/metronidazole (Mtz) based transgenic zebrafish model enabling inducible rod cell death to study rod cell regeneration. However, relevance of NTR/Mtz-induced cell death to retinal degeneration was unclear. The purpose of this study was to investigate the cell death mechanism of NTR/Mtz-induced rod photoreceptor degeneration.

Methods: Five day old zebrafish larvae expressing yellow fluorescent protein (YFP) and NTR in rod photoreceptors were pre-treated with cell death pathway inhibitors for four hours followed by Mtz addition to induce rod cell death. After two days, rod cell survival was assessed using an established plate reader assay. Genes encoding key factors for three cell death pathways were knocked down using CRISPR/Cas9 and rod cell survival assessed following NTR/Mtz-induced cell death. Targeted genes included parp1 (parthanatos pathway), receptor (TNFRSF)-interacting serine-threonine kinase 1 like (ripk1l; necroptosis) and caspase 3a/3b (casp3a/3b; apoptosis). qPCR was performed to confirm reduced expression of targeted genes and western blots used to assess PARP activation, i.e., accumulation of poly (ADP-ribose) (PAR) polymers.

Results: Increased rod cell survival was observed in larvae treated with PARP/parthanatos inhibitors and a necroptosis inhibitor, but not an apoptosis inhibitor. Similarly, knock down of parp1 and ripk1l, but not casp3a/3b, improved rod cell survival. Moreover, PAR polymers accumulated in Mtz-treated fish compared to controls, indicating PARP activation, a signature of parthanatos.

Conclusions: Mtz/NTR induced rod cell death involves both the PARP1/parthanatos and ripk1l/necroptosis. As both of these pathways have been implicated in neurodegeneration, including RP, we conclude that the NTR/Mtz system serves as an inducible model of RP providing a useful tool for exploring neuroprotective therapeutics.

ABSTRACT BODY:

Purpose: Limbal stem cells (LSCs) lack specific markers. This study is to identify putative LSC markers by analyzing label-retaining cells (LRCs) from limbus of H2B-GFP mice at single-cell level.

Methods: H2B-GFP mice express H2B-GFP under doxycycline (dox). Mice were fed with dox for 4 weeks, followed by 2 rounds of wound healing on corneal epithelium. Limbal epithelium and anterior stroma from wounded and unwounded eyes was collected and GFP⁺ cells (LRCs) were obtained by FACS followed by single-cell RNA sequencing. Data were analyzed by Seurat to partition cells into clusters based on expression similarity. The characteristic markers for each cluster were calculated by Seurat and used to identify the nature of cluster. To find correlation among clusters from wounded and unwounded eyes, the clusters from both samples were ranked in a dendrogram by hierarchical clustering.

Results: All limbal epithelial cells were GFP⁺ with dox, and no limbal epithelial cell was GFP⁺ without dox, indicating no false-negative or false-positive expression. Wounded corneas showed GFP⁺ migration from limbus to cornea, suggesting healing property of LRCs and inclusion of LSCs within LRCs. In total 11 clusters from 3136 cells were obtained from unwounded eyes and 12 clusters from 4967 cells obtained from wounded eyes. Epithelial clusters were identified by expressing epithelial-specific cytokeratins and non-epithelial clusters fell into the categories of stromal cells (Dcn, Col1a2, Col3a1) and 2 types of immune cells (Lyz2, C1qa, Trdc). Epithelial clusters were divided into stem, progenitor, and differentiated groups based on low, medium, and high expression of maturation markers (Krt12, Krt13). From dendrogram, 2 clusters in stem group were closely related to 2 clusters in progenitor group in unwounded eyes and gave rise to a new cluster in progenitor group in wounded eyes, indicating the possibility of putative LSCs. The 2 putative LSC clusters expressed a comparable high levels of progenitor markers (e.g. Krt14, Trp63). Their characteristic markers showed a specific labeling on discrete basal limbal epithelial cells.

Conclusions: Two putative LSC clusters were identified from the LRCs based on their low expression of maturation markers, close correlation to progenitor clusters, ability to produce progenitor cluster upon wounding, and discrete location on basal limbal epithelium.

ABSTRACT BODY:

Purpose: Genome-wide association studies (GWAS) have identified numerous common genetic variants associated with intraocular pressure (IOP), the only modifiable risk factor for glaucoma treatment. However, these common variants typically show small effect sizes. Rare variants may provide important information in furthering our understanding the IOP genetic regulation and suggest potential therapeutic targets for glaucoma. We carried out a genome-wide rare-variant analysis for IOP.

Methods: We conducted this study using data from the UK Biobank, a cohort of half a million individuals. We used 62,810 individuals of European ancestry who had both whole-exome sequencing and IOP data for this study. We performed single-variant and gene-based analyses to identify rare variants with minor allele frequency (MAF) < 1% and their corresponding genes associated with IOP using the variant-Set Test for Association using Annotation information (STAAR) method.

Results: We confirmed the known association of rs28991009 (MAF = 0.007), a nonsynonymous variant located on chromosome 1p36.22 in ANGPTL7, with IOP ($P = 2.98 \times 10^{-8}$). The gene-based analysis also showed a significant association for ANGPTL7 ($P = 1.6 \times 10^{-10}$). We identified a candidate novel nonsynonymous variant, rs372786669 (MAF = 0.0001, GRCh38/hg38 position 13613559) located on chromosome 4p15.33 in BOD1L1, that is significantly associated with IOP ($P = 3.76 \times 10^{-8}$). The gene-based association p-value for BOD1L1 was 1.6×10^{-4} . BOD1L1 was previously reported to have an association with ovarian carcinoma.

Conclusions: We confirmed known and identified candidate novel rare variants and genes associated with IOP. Our findings provide insights into the genetics of rare variants affecting IOP.

ABSTRACT BODY:

Purpose: In-vitro evaluation of increased hydroxyl radical scavenging activity of a new dispersive ophthalmic viscosurgical device (ClearVisc OVD, Bausch and Lomb, Inc.).

Methods: Using the 2-deoxy-D-ribose oxidation method, hydroxyl radicals (OH) are formed for detection via high-performance liquid chromatography (HPLC) with UV detection. Various OVD components such as buffer and additives as well as other OVD formulations have been utilized to measure their ability to scavenge free radicals that are typically formed during phacoemulsification.

Results: The results of testing provide a comparison of water as control as well as standard sodium hyaluronate formulations to the ClearVisc OVD. The results show the effectiveness of the new buffer and sorbitol additive capabilities to scavenge free radicals.

Conclusions: Hydroxyl free radicals generated during phacoemulsification in cataract surgery can contribute to corneal endothelial damage. The overall results in this study show the effectiveness of the combination of buffer and additives in this new dispersive OVD in hydroxyl free radical inhibition.

ABSTRACT BODY:

Purpose: Accurate measurement of anterior chamber (AC) flare requires a lot of experience and skill. There is a need for widely accessible tool to objectively detect and measure AC flare. The purpose of this study is to assess the use of novel imaging technique employing slit-lamp camera to reliably measure anterior chamber (AC) flare by utilizing artificial intelligence.

Methods: Subjects from a tertiary care uveitis clinic were enrolled in the study. Each subject underwent ophthalmic examination including measurement of AC flare using SUN scale, followed by imaging using a slit-lamp camera. The images were processed to extract regions of interest (ROI) between the cornea and lens indicative of presence or absence of flare (Fig. 1B-D). Next, the image was converted to the HSV (hue, saturation, value) color space; a 50×50 sample of color values resulting in 2,500 features from the ROI were organized as the feature set for that image for training and validation using a 10-fold cross validation (1E-1H). We evaluated the use of HSV color space and machine learning techniques such as support vector machines (SVM) and decision trees. Principal component analysis (PCA) was utilized to reduce the number of features without information loss and to improve model performance by addressing multi-collinearity and removing redundant features. Classification models were built using decision trees, and SVMs to classify images as with and without flare on 60 principal components (PCs) and ground truth labels with a 10-fold cross validation in R.

Results: Twenty-three (23) subjects (57% female) were enrolled in the study. Mean age was 50 years. Ninety-three (93) images (30 eyes/15 subjects) were analyzed. Slit-lamp images from eight patients were excluded due to poor image quality or ambiguous image captures (1A). PCA demonstrated that 60 components result in variance close to ~98% (1I). Table 1 outlines the results of classification models using 60-PCs as features. The model built using the HSV color space and SVM classifier showed the highest accuracy, specificity of 0.936 and 0.905 respectively, while the C5.0 classifier showed the highest sensitivity of 0.965.

Conclusions: Artificial intelligence-based image analysis of slit-lamp photographs of anterior chamber can reliably assess anterior chamber flare with high accuracy in uveitic eyes.

ABSTRACT BODY:

Purpose: Basal cell carcinoma and squamous cell carcinoma, the two most common non-melanoma skin cancers, are epidemiologically and molecularly linked to ultraviolet radiation (UVR) exposure. Keratinocytes and fibroblasts are the major targets of UVR within the epidermis and dermis respectively. In this study, we assessed the impact of solar radiation exposure on keratinocytes and fibroblasts in respect to genotoxic, metabolic, and oxidative stress effects.

Methods: Cells of human origin were used: primary epidermal keratinocytes (normal adult; HEKa) and normal diploid fibroblasts (Malme-3). Cells were exposed to 1-SUN by a Tri-Sol Solar Simulator (300-1800 nm), or under long path filters that gradually reduced exposure to the UVR wavelengths. Acute direct DNA damage was assessed through the accumulation of cyclobutane pyrimidines dimers (CPDs). Photo-oxidative stress was evaluated by the capacity of UVR to induce mitochondrial superoxide production. Metabolic activity was assessed by the CCK8 assay and on cell viability and toxicity by the Live/Dead assay.

Results: Solar exposure induced CPD formation in both keratinocytes and fibroblasts. Notably, a proportion of non-exposed normal adult keratinocytes were positive for CPDs, while fibroblasts were CPD negative. 1-SUN exposure caused a decrease in metabolic activity in both cell types when compared to non-exposed cells, but more markedly in fibroblasts. Viability and cell death were not affected by light exposure. Blockage of artificial sunlight spectrum by a 355 nm filter prevented the formation of CPDs, but not a decrease in metabolic activity—this was only prevented by a 380 nm filter. The production of mitochondrial superoxide was higher in solar-exposed compared to non-exposed keratinocytes and fibroblasts. Keratinocytes under the long path filters of 355, 380, 395, and 400 nm maintained a non-exposed basal level of superoxide production.

Conclusions: Exposure to wavelengths from 300 to 355 nm is enough to cause DNA damage via CPD formation in both keratinocytes and fibroblasts. Moreover, light exposure at 355-380 nm causes a reduction in metabolic activity without CPD induction. Decreased UVR stimuli resulted in increased oxidative stress in fibroblasts. Our data suggests that there is a degree of stimuli within the UVR spectrum that causes genotoxic, metabolic, and oxidative stress effects on keratinocytes and fibroblasts.

ABSTRACT BODY:

Purpose: The role of anemia on retinopathy of prematurity (ROP) is unclear; however, gene expression studies of phlebotomy induced anemia (PIA), its treatment with recombinant human erythropoietin (EPO) and oxygen induced retinopathy (OIR) may shed new light on the underlying molecular mechanism of ROP. Quantitative polymerase chain reaction (qPCR) is a sensitive technique for estimating the gene expression changes at the transcript level; however, there is no current consensus on reference genes for qPCR analysis of neonatal rat retinal tissue with PIA and OIR. We hypothesize that s18 is an unstable reference gene across these experimental conditions. In this interest, we carried out an evaluation of 8 commonly used reference genes, Ppia, Mapk1, Rplp0, S18, Hprt, Tbp, Rpp30 and Gapdh, and identified the most stable genes.

Methods: 4 groups of Sprague Dawley newborn rat pups with the following experimental conditions were generated: normoxia (control), normoxia with PIA, OIR, and OIR with PIA and EPO. The Penn et al. rat 50/10 model of OIR was used. PIA groups reached their hematocrit target of 15-20% (a 50% reduction from baseline) by P14-15. EPO groups received IP injections from P10-P20. At target timepoint, P14.5 or P20, pups were euthanized, followed by immediate whole retinal dissection. Retinas from 4-6 pups/group underwent RNA extraction, cDNA synthesis, and qPCR with 8 candidate reference genes selected from the literature. qPCR was run in duplicate. Cycles threshold (Ct) values were analyzed by RefFinder which combines ΔCt , geNorm, Normfinder, and BestKeeper algorithms to determine and rank stability of each reference gene.

Results: The three most stable reference genes were Rpp30 (stabilization index (S.I.) 1.316), Tbp (S.I. 1.732) and Ppia (S.I. 2.828). S18 and Gapdh showed the lowest stability (Figure 1). Variation of reference gene Ct values is shown in Figure 2.

Conclusions: Rpp30, Tbp and Ppia expression is least affected by experimental conditions of OIR, PIA and EPO administration, therefore suitable to use for qPCR data normalization across any of these experimental conditions.

ABSTRACT BODY:

Purpose: Glaucoma drainage device (GDD) implantation has a 5-year failure rate of ~50% because of post-operative fibrosis. Our group has developed two drug delivery devices that reduced fibrosis after GDD implantation in an animal model (TVST 2015;4(3)4). This study advances these devices toward clinical trials by characterizing the effects of FDA-approved sterilization methods on drug release.

Methods: We compared drug release in unsterilized (US), gamma sterilized (GS), and e-beam sterilized (EBS) PHEMA and PLGA devices (n=8). Devices were manufactured and lyophilized in a GMP facility, then sterilized using gamma or e-beam irradiation. The PHEMA-device contained mitomycin C (MMC) and the PLGA device contained 5-fluorouracil (5-FU). We used UV/Vis spectroscopy to quantify drug release into saline over a 30-day period.

Results: Plots of 5-FU released vs time in the PLGA device had sigmoidal character and were fitted to a variant of the Hill equation, where " K_A " was redefined as " $T_{1/2}$ ", the time of 50% drug release, and the "Hill coefficient" was redefined as the "sigmoidicity coefficient" (SC). A lower SC indicates that similar quantities of drug are released over equal time intervals. Mean values of the $T_{1/2}$ for GS, US, EBS sterilized PLGA were 23.04, 27.67, 29.55 days. The $T_{1/2}$ of the GS product was significantly lower ($p<0.0001$) than the US or EBS material. We hypothesize that GS (at 15 kGy) introduced free radicals that enhanced PLGA degradation. Lower energy (10.5 kGy) EBS provided a product with an SC significantly lower ($p<0.013$) than that of the GS or the US product (4.57, 6.32 and 7.92, respectively). The slower, more gradual drug release provided by the EBS product may be advantageous, since optimal drug release from this product would extend over 20-30 days in order to attenuate the post-op wound-healing response. MMC release from PHEMA followed a one-phase exponential decay. GS and EGS increased polymer crosslinking, which significantly slowed drug release ($p<0.0001$). $T_{1/2}$ was 2.12, 4.17, and 5.79 days for the US, EBS and GS PHEMA, respectively

Conclusions: PHEMA and PLGA devices respond differently to sterilization. EBS led to a more gradual drug release from PLGA. Both GS and EBS slowed drug release from PHEMA. Both devices can be manufactured in a GMP facility, which provides a path for these devices to enter clinical trials.

TITLE: In Vivo Neural Imaging: The Impact of Retinal Neuropathy on Axonal Transport

SESSION TITLE: Animal imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Le Roux, Cancer Systems Imaging, The University of Texas MD Anderson Cancer Center, Houston, Texas, UNITED STATES|L. Le Roux, Neuroradiology, The University of Texas MD Anderson Cancer Center, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lucia Le Roux: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The goal of this study was to illustrate retinal axonal transport with a fluorescent nerve imaging tracer based on fast axonal transport in control and neuropathic eyes. Our hypothesis was that loss of axonal transport could be an early event in the development of neuropathy.

Methods: Neuropathy was induced in Norway brown rats eyes by injecting N-methyl-D-aspartic acid (NMDA) into the vitreous of one eye and PBS into the contralateral eye as a control. 48 Hours after the NMDA injection, a fluorescently labeled neural imaging probe based on the non-toxic, C-fragment of Tetanus Toxin (TTc) was injected into the vitreous of both the treated and control eyes. In vivo imaging of the distribution of TTc was performed using retinal ophthalmoscopy. Retinas were harvested at 3 hours after TTc injections, followed by whole retinal flat mount microscopy and immuno-histology.

Results: Axonal TTc co-localizes with the retinal axonal (RA) neurofilament marker (SMI32) while a selective cytoplasmic marker (RBPMS) for retinal ganglion cells (RGC), confirmed the presence TTc endovesicles in the RGC neural somas. In contrast, neuropathic eyes showed a marked reduction in the RA TTc uptake. Plotting circular transects around the optic nerve head at a radius of 500 μ m demonstrated that axonal strand crossings were markedly reduced in retinopathic eyes at 365 ± 41.46 vs control eyes 479 ± 48.41 ($P=0.003$). There is co-localization (Pearson's $r = 0.7 \pm 0.05$) between TTc and the neurofilament marker in the control eye RAs. A relative loss of RA fluorescence in retinopathic eyes showed a reduction in co-localization (Pearson's $r = 0.4 \pm \text{SD}$) between neurofilament marker and the neural probe.

Conclusions: The retinal uptake and transport of the neural tracer, TTc, could be observed using ophthalmoscopy, and was markedly different between the normal and neuropathic state. These findings were confirmed to be specific with specific histologic markers for RAs and RGCs. NMDA induced retinopathy decreases neuronal uptake and transport of TTc, indicating that abnormalities of neuronal uptake and transport are early events in the development of retinal neuropathy.

TITLE: Role of circadian clock-controlled increase in GABA inhibitory feedback to cones at night.

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.C. Mangel, H. Choi, Neuroscience, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Stuart Mangel: Commercial Relationship: Code N (No Commercial Relationship) | Heejoo Choi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Following maintained (30 min) darkness, repetitive mid-mesopic stimulation for 5-20 min increases the cone ERG by ~50%, while the rod ERG is rapidly suppressed in seconds (Bui, Fortune, 2006). This phenomenon, which has been called a “suppressive rod-cone interaction” (SRCI) (Eysteinnsson, Frumkes, 1989) (aka a “dark-light switch” (Morgan, Boelen, 1996)), has been observed in many vertebrate species including humans. Because 1) GABA inhibitory feedback from horizontal cells to cones is strongest at night in the dark, reduces the size of cone light responses, and is suppressed by light (Mangel, 2019, ARVO), and 2) closing of rod-cone electrical synapses by repetitive mid-mesopic stimulation contributes to SRCI (Heikkinen et al., 2011), we studied whether GABA inhibitory feedback to cones also mediates SRCI.

Methods: Following maintained darkness, the effects of 10 min of repetitive (0.1 Hz) mid-mesopic stimulation on goldfish cone light responses were studied in day and night using whole-cell patch-clamp recording. Because inhibitory feedback to cones is dependent on cone dopamine D_4 Rs and GABA_ARs (Mangel, 2019), we studied the effects of spiperone (SPI; D_4 R antagonist), gabazine (GBZ; GABA_AR antagonist) and/or meclofenamic acid (MFA; gap junction blocker) on SRCI.

Results: We found that after maintained darkness repetitive mid-mesopic stimulation increased cone light responses and input resistance at night but not in the day. Prior application of SPI for 30 min blocked the nighttime effect. Also, following 30 min of SPI, application of MFA or GBZ increased cone response size, and following 30 min of both SPI and MFA, GBZ increased cone response size.

Conclusions: These results indicate that the retinal circadian clock, by modulating cone D_4 Rs, enhances the GABA_AR-gated chloride conductance of cones at night so that SRCI is stronger at night than in the day. The findings suggest that as mid-mesopic illumination and/or the retinal clock gradually increase dopamine release and D_4 R activation at dawn, the resultant decrease in GABA_AR-mediated inhibition of cone terminals enhances the size of cone light responses. Conversely, the slow increase in GABA_AR inhibition of cones at dusk gradually reduces cone light response size. Because rods do not express GABA_ARs in day or night, circadian clock control of GABA inhibitory feedback to cones speeds up the transitions between rod and cone vision at dawn and dusk.

TITLE: CRISPR/Cas9-based genome editing approaches for RP1 associated autosomal dominant Retinitis Pigmentosa

SESSION TITLE: Gene therapy in ocular diseases

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Collin, Q. Liu, Massachusetts Eye and Ear Infirmary Department of Ophthalmology, Boston, Massachusetts, UNITED STATES]

Commercial Relationships Disclosure (Abstract): Caitlin Collin: Commercial Relationship: Code N (No Commercial Relationship) | Qin Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Developing a gene therapy for autosomal dominant Retinitis Pigmentosa (adRP) is extremely challenging, since suppression of the mutant protein may be required, in addition to delivery of a healthy gene. Furthermore, overexpression of many IRD genes can also lead to retinal degeneration, therefore it is necessary to maintain wild-type protein expression at endogenous levels. Around 35% of RP is caused by autosomal dominant mutations, with mutations in RP1 accounting for around 5-10% of cases. The CRISPR/Cas9 system can distinguish target sequences differing by a single base pair, thus we propose to develop a haplotype based approach to specifically ablate mutant RP1 alleles which bear any dominant frameshift or nonsense mutation in exon 4

Methods: Three common RP1 haplotypes carrying distinct SNPs were identified from the 1000 Genome Project. sgRNAs for SNPs on each of the three haplotypes were synthesized and cotransfected with Cas9 expressing plasmids into human cell lines that are heterozygous or homozygous for the RP1 haplotypes. Editing efficiency and allele-specificity was determined by PCR and amplicon sequencing. The most efficient sgRNAs were then tested in combination with a non-allele specific sgRNA targeting intron 3. Dual DSBs and deletion of a fragment of RP1 genome were analysed and quantified by qPCR. The expression level of the targeted RP1 allele was quantified by qPCR in modified RP1-expressing Hap1 cells.

Results: A non-allele specific sgRNA with high editing efficiency was tested in pair-wise combinations with allele specific sgRNAs targeting intron 1, or exon 4. These dual Cas9/sgRNAs were able to delete 3.5-6 kb of genomic DNA, encompassing either exons 2 and 3, or a large portion of exon 4 of RP1 in an allele specific manner. Deletion of the large fragment of RP1 genome led to reduction of RP1 expression in edited Hap1-EF1a-RP1 cells

Conclusions: This proof-of-concept study is an important step towards the application of CRISPR/Cas9 gene editing technology in the treatment of patients with RP1 associated dominant IRDs. Our haplotype-based approach greatly enhances the feasibility of using the CRISPR-Cas9 system because a small number of sgRNAs are necessary to specifically target relatively large sets of mutant alleles. Furthermore, it paves the avenue of its application in human RP1 patients

ABSTRACT BODY:

Purpose: Patients with uveal melanoma (UM) may also develop other tumors before or after being diagnosed with UM, but there is little characterizing data in the literature. We assessed the survival of UM patients with second malignancies in Israel.

Methods: A retrospective review and analysis of a cohort of 927 uveal melanoma patients at the Ocular Oncology Service of the Hadassah University Hospital from 1982 to 2017.

Results: Seventy-four (7.9%) patients (42 (57.5%) women) had second tumors. In 37 (50.7%) patients UM was diagnosed 69.5 months before a second malignancy, while in the rest it appeared 128.3 months after another malignancy. The most common malignancies in descending order were: breast (32%), colon (16%), renal cell carcinoma (9%), cutaneous melanoma (8%), basal or squamous cell carcinoma (8%), and other tumors (27%). The mean (\pm SE) survival for UM patients without and with second malignancies was similar (230.4 (\pm 7.5) vs. 200.9 (\pm 16.9) months, respectively, Log-Rank $p=0.48$). Survival was also similar whether UM was diagnosed first or after another malignancy (205.5 (\pm 19.6) vs. 159.1 (\pm 16.8) months, respectively, Log-Rank $p=0.52$). There is a trend for a higher chance to develop UM metastases if patients did not have a second malignancy (16.7% vs. 9.5%, respectively, Likelihood ratio $p=0.083$). Whether UM was diagnosed first did not impact that chance (Likelihood ratio $p=0.50$).

Conclusions: Second malignancies in UM patients are uncommon and do not affect the overall survival.

ABSTRACT BODY:

Purpose: To evaluate the utility of Swept-Source Optical Coherence Tomography Angiography (SS-OCTA) in non-invasively assessing change in perfusion and density after anti-VEGF therapy in diabetic retinopathy (DR) when compared to ultra-widefield Fluorescein Angiography (UWFA) leakage metrics.

Methods: This is a retrospective review of consecutive DR patients who had received repeated SS-OCTAs (Zeiss Plex Elite) and UWFAs (Optos California). 6mm x 6mm and 3mm x 3mm images of non-proliferative and proliferative DR eyes were analyzed. Both perfusion density (total area of perfused vasculature per unit area ranging from 0-1) as well as vessel density (total perfused vasculature per unit area) were obtained. UWFA metrics were quantified using a customized feature analysis platform that detected leakage indices automatically (3-disc diameter and 6-disc diameter areas of leakage centered on the macula). Statistical analysis was performed using MS-Excel.

Results: 20 eyes were included in the 6x6 SS-OCTA non-treatment group while 8 eyes were in the treatment group. Of these, 16 also had 3x3 SS-OCTA for the non-treatment group and 4 had treatment. UWFA analysis was available for 15 of the eyes without treatment and 6 of those with treatment. Average follow up was 12.1 months.

In the 3x3 non-treatment group there was significant reduction in superficial and deep perfusions and densities over time within the average field of view ($p<.05$). Superficial perfusion density averaged at 0.314 at baseline and decreased 12.1%. Deep perfusion density averaged 0.184 at baseline and reduced by 23.5%. No significant difference was seen in the treatment group ($p>0.1$). Similar associations were seen in the 6x6 SS-OCTA non-treatment ($p<0.1$) vs treatment groups ($p>0.1$).

Findings of UWFA showed similar trends, with leakage indices worsening in those not treated vs treated. 6-disc diameter macula centered leakage area showed an average baseline leakage of 1.8% that increased 50.7% in the non-treatment group ($p=0.056$) and had insignificant change in the treatment group $p>0.1$.

Conclusions: SS-OCTA and UWFA can quantify the impact of anti-vegf therapy in DR patients over time. Using both modalities, trends towards better perfusion metrics in those treated vs non treated were seen. Further larger investigations will verify whether SS-OCTA can quantify a difference from anti-VEGF treatment over time in DR patients.

TITLE: Arginase Isoforms and Diabetic Retinopathy in the db/db Mouse

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.L. Bunch, R.W. Caldwell, Pharmacology and Toxicology, Augusta University, Augusta, Georgia, UNITED STATES|R.B. Caldwell, Research, Charlie Norwood VA Medical Center, Augusta, Georgia, UNITED STATES|R.B. Caldwell, Vascular Biology Center, Augusta University, Augusta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Katharine Bunch: Commercial Relationship: Code N (No Commercial Relationship) | Ruth Caldwell: Commercial Relationship: Code N (No Commercial Relationship) | Robert Caldwell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The obese, type 2 diabetic db/db mouse has been established as suitable model for the pathogenesis of human diabetic retinopathy (DR), but the role of arginase in this model is unknown. Given the association of arginase isoforms, A1 and A2, in several models of retinopathy, we hypothesize that A1 and A2 are associated with the pathophysiology of DR in the db/db mouse. A1/A2 compete with nitric oxide synthase (NOS) for L-arginine and increased A1/A2 decreases nitric oxide (NO) levels. NO is imperative for tissue perfusion in many pathologic disease states, including stroke, DR, and cardiovascular disease (CVD). Increased NO has been shown to be protective in murine models of stroke, CVD, and DR, while A2^{-/-} mice were protected against western diet-induced DR.

Methods: Whole eyes, retinas, and plasma were collected from 16 (n=8) and 23 week-old (n=6) female db/db mice and their DB/db (control) littermates (#000642). Globes were sectioned and immunofluorescence (IF) was performed for A1, A2, markers of inflammation, and neuroglial activation, including GFAP and IL-6. Retinas were used to western blot for proteins in the NLRP3 inflammasome cascade, products of reactive oxygen species, and hypoxia, including A1, A2, GFAP, HIF-1 α , and IL-1 β . Western blot signals were quantified by densitometry using ImageJ software and normalized to loading controls. Plasma was used for A1 ELISA analysis, reported in ng/mL. GraphPad Prism 9 was used to implement unpaired t-test analyses. Values of p<0.05 were considered significant.

Results: A1 levels were markedly increased in both the plasma (16 weeks p=0.011, 23 weeks p<0.0001) and retina lysates (p=0.005) of the db/db mice compared to controls. Retinal A2 was also significantly increased (p=0.0332). Markers of inflammasome activation were significantly increased in db/db retinas (Eg: IL-1 β p=0.008). Hypoxia marker HIF-1 α , a VEGF transcription factor, was also markedly elevated in db/db retinas (p=0.027). IF of GFAP, an indicator of neurodegeneration, showed increased expression in db/db retinas compared to controls.

Conclusions: These results are consistent with our hypothesis that A1 and A2 are linked to the pathophysiology of DR in the db/db mouse, as elevated A1 and A2 correlate with increased markers of hypoxia, inflammation, neurodegeneration in db/db mouse retina compare to controls. Further investigation is needed to elucidate the mechanistic effects of A1/A2 on the pathogenesis of db/db DR.

ABSTRACT BODY:

Purpose: Oligodendrocytes in the central nervous system (CNS) produce myelin, which is essential for ensuring fast signal transmission in neurons, providing synchronization of neuronal impulses, and maintaining axonal health. Unlike previously believed, increasing evidence show that myelin changes throughout life. Oligodendrocyte precursor cells differentiate into myelinating oligodendrocytes until old age. Several studies demonstrate that de novo myelination onto previously unmyelinated axons and myelin remodeling of existing sheaths' length, thickness, and number occurs in many CNS regions. Both human and murine studies suggest that neuronal activity plays a role in de novo myelination and myelin remodeling, the two components of myelin plasticity. In light of this, we asked how neuronal activity regulates myelin plasticity, and whether bidirectional changes could occur.

Methods: Using designer receptor exclusively activated by designer drugs (DREADDs), we increased and decreased neuronal activity of retinal ganglion cells via the Gq (hM3Dq) and Gi (hM3Di) pathways to observe myelin plasticity in the optic nerve. Recent studies showed that the inert DREADD ligand clozapine N-oxide does not cross the blood brain barrier, and that its metabolite clozapine is responsible for DREADD activation in vivo. Since clozapine is an antipsychotic drug that affects multiple endogenous receptors at high concentration, we performed a dose-response curve to determine the optimal concentration for long-term neuronal activity change without affecting endogenous receptors. Using the PDGFR α -CreER^{T2}:Tau-mGFP and OPALIN-iCreER^{T2}:Tau-mGFP mouse lines, which label newly myelinating and currently existing OLs, we quantified how neuronal activity regulates de novo myelination and myelin remodeling during adulthood.

Results: We demonstrated that clozapine has greater affinity to DREADDs in vivo than CNO and at low concentrations, clozapine does not cause off-target effects. Moreover, we showed that neuronal activity bidirectionally affects the rate of differentiation of OPCs as well as the morphology of existing and newly myelinating oligodendrocytes.

Conclusions: Our data suggest that myelinating glia can detect functional activity in axons and respond with adaptive change. Additionally, these findings indicate that activity-dependent communication may stretch beyond synaptic transmission.

TITLE: Metabolic changes in optic nerve head astrocytes following glaucoma-associated deformation

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Pappenhagen, K. Zaman, L. Prokai, D.M. Inman, University of North Texas Health Science Center, Fort Worth, Texas, UNITED STATES|N. Pappenhagen, Biomedical Sciences, Kent State University, Kent, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nate Pappenhagen: Commercial Relationship: Code N (No Commercial Relationship) | Khadiza Zaman: Commercial Relationship: Code N (No Commercial Relationship) | Laszlo Prokai: Commercial Relationship: Code N (No Commercial Relationship) | Denise Inman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The astrocytes of the optic nerve head are in a unique position in glaucoma as the predominant glial cell in the unmyelinated portion of the optic nerve. We tested the metabolic changes these cells face in glaucoma by exposing them in vitro to degrees of deformation/stretch that these cells would similarly experience from increased intraocular pressure in order to better understand the role of metabolism in glaucomic degeneration.

Methods: Primary astrocytes were cultured from the cortices of P1 mouse pups or P7 optic nerve head explants then seeded on collagen-coated FlexCell plates. The astrocytes were then biaxially stretched by 12% for 24 hours using the FX-6000T FlexCell system. Conditions were chosen to mimic the forces applied to optic nerve head astrocytes (ONHAs) during glaucoma. ONHA glycolytic rates and mitochondrial fuel preferences were measured using the Seahorse XFe24 Analyzer, while changes in the proteome were measured using mass spectroscopy.

Results: Stretched cortical astrocytes showed at least twofold increases in metabolic proteins such as glutamate dehydrogenase 1, isocitrate dehydrogenase 1, and aldolase fructose-bisphosphate c (n=3, p=0.00024, p=0.022, and p=0.00065). There was also a twofold decrease in citrate synthase, a 10-fold decrease in isocitrate dehydrogenase 2, and 2.5-fold decreases in glycogen phosphorylase B and adenylate kinase 1. In the Seahorse Analyzer, stretched ONHAs showed an increased glycolytic extracellular acidification rate (ECAR), maximal ECAR, and baseline oxygen consumption rate (n=18, p=0.0032, p=0.0070, and p=0.0203). Stretched astrocytes showed no difference in their dependence on pyruvate compared to controls, but a significant decrease in their capacity for mitochondrial respiration from pyruvate (n=18, p=0.0828 and p=0.0001).

Conclusions: Exposing astrocytes, both cortical and ONHAs, to glaucoma-associated deformation altered their metabolism in ways that indicated increased glycolytic activity compared to control astrocytes. The increase in glutamate dehydrogenase 1 combined with a decrease in isocitrate dehydrogenase 1 and citrate synthase suggest a shift away from mitochondrial energy production. The decrease in pyruvate-based mitochondrial respiration capacity is consistent with these findings.

ABSTRACT BODY:

Purpose: Formation of advanced glycation endproducts (AGEs) in tissues with negligible protein turnover, such as the lens capsule, leads to their accumulation with aging. We have previously shown that AGEs in the lens capsule exacerbate TGF β 2-mediated mesenchymal transition of lens epithelial cells and proposed that capsule AGEs could play a role in posterior capsule opacification (PCO) after cataract surgery (Raghavan et al., Aging Cell, 15, 465, 2016). To determine the effects of diabetes on capsule AGEs, in this study we measured the levels of AGEs in capsulorhexis specimens collected from non-diabetic and diabetic [with or without retinopathy (DR)] cataract patients.

Methods: Capsulorhexis specimens were obtained at the time of cataract surgery from consented patients at the Sue Anschutz-Rodgers Eye Center. Following removal of adherent epithelial cells and fiber cell mass, capsulorhexis specimens were hydrolyzed with enzymes or 6N HCl to measure AGEs. We measured 14 AGEs using an LC-MS/MS multimethod and reference compounds. Means and 95% confidence intervals of each AGE were compared across the three patient groups.

Results: Patients included 48 non-diabetic, 42 diabetic without DR and 30 diabetic with DR. Among the AGEs measured, the levels of CMA were highest for all patient groups but did not significantly differ; 205.9 ± 21.4 , 246.7 ± 22.8 and 217.1 ± 27.8 pmoles/ μ mol OH-proline equivalent in nondiabetics, diabetics and diabetics with DR, respectively. The levels of other AGEs were < 50 pmoles/ μ mol OH-proline equivalent. When adjusted for age and gender, the levels of most AGEs were similar between diabetics (with or without DR) and nondiabetics, although glucosepane was significantly lower for non-diabetics.

Conclusions: Our data show that the AGE levels are similar in non-diabetic and diabetic (with or without DR) capsules and provide a biochemical basis for the similar incidence of PCO in nondiabetic and diabetic cataract patients, observed in some studies.

ABSTRACT BODY:

Purpose: iPSC derived RPE transplants potentially offer a treatment for macular degeneration. The clinical use of iPSC-derived RPE cells requires testing of the final product for the presence of contaminating iPSCs. While LIN28A has been suggested as a marker of iPSC contamination in RPE, it is likely that regulatory bodies will require redundant testing with additional markers. To accomplish this we sought to identify and validate a new marker of pluripotency that could be used to identify contaminating iPSCs in a preparation of iPSC-derived RPE cells.

Methods: We performed RNASeq on iPSC's and iPSC-derived RPE from the same donor and screened for mRNAs that were in the iPSC dataset and not the RPE dataset. To confirm the RNASeq data we performed SybrGreen reverse transcription PCR on ZSCAN10 a candidate gene identified from the RNASeq dataset. qPCR was used to determine relative levels of expression of ZSCAN10 across iPSC clones from different donors and from clones isolated from the same donor. Publicly available databases were screened to determine expression of ZSCAN10 in tissue.

Results: Of the top 10 genes identified by our RNASeq screen, ZSCAN10 was the only gene identified that is a known marker of pluripotency. Using RT-PCR we observed ZSCAN10 expression in 15 of 15 iPSC cell clones from 6 different donors, but not in RPE cultures derived from those donors. Using qPCR the ZSCAN10 signal was observed in similar amounts in all iPSC tested regardless of donor. ZSCAN10 was only observed in the iPSC cells and was absent from all iPSC-RPE preparations tested. Screening of publicly available databases identified very low levels of expression in human tissue, predominantly in brain and kidney.

Conclusions: ZSCAN10 is a strong marker of undifferentiated iPSC impurities in a population of iPSC-derived RPE.

ABSTRACT BODY:

Purpose: Purpose: The vision-threatening vascular pathology that can develop in diabetic retinopathy (DR) is highly influenced by angiogenic factors such as vascular endothelial growth factor (VEGF). There is evidence that retinal inflammation also promotes vascular injury in DR, but the mechanisms involved are not fully understood. We previously reported that increasing the number of anti-inflammatory Foxp3 regulatory T cells (Tregs) reduced inflammation and vasculopathy in mice with proliferative retinopathy. Tregs exist in balance with pro-inflammatory Th17 cells via the retinoic acid receptor-related orphan receptor (ROR) γ . Here, we hypothesised that ROR γ inhibition would attenuate retinal inflammation and vasculopathy in DR by reducing the abundance of Th17 cells and increasing Treg functionality.

Methods: Methods: Female Sprague Dawley rats were made diabetic with streptozotocin (STZ) and then studied for 8 weeks. To evaluate Tregs, male Foxp3^{rfp} mice (C57Bl6/J background) expressing Foxp3 as a red fluorescent protein (rfp) were administered STZ and studied for 26 weeks. Comparisons were made to non-diabetic controls, and animals administered the ROR γ inhibitor, SR2211 (3mg/kg) intraperitoneally one week after STZ and once every three days until the end of the studies. Twenty-four to 36 animals were studied per group, and data were analysed by unpaired t-tests or one-way ANOVAs. Statistical significance was defined as $p < 0.05$.

Results: Results: SR2211 had no effect on body weight and blood glucose and Hba1c levels. In rats with DR, the number of Th17 cells was increased compared to non-diabetic rats and reduced with SR2211. In mice with DR, SR2211 did not alter the number of Tregs in blood, lymph nodes and spleen, but did increase the number of effector Tregs (CD44⁺CD62L⁻) in lymph nodes. Importantly, in both rats and mice with DR, SR2211 reduced retinal vascular leakage and VEGF protein levels compared to diabetic controls. In diabetic rats, the mRNA levels of the inflammatory factors, tumour necrosis factor (TNF) and intracellular adhesion molecule (ICAM)-1 in retina were reduced by SR2211.

Conclusions: Conclusion: ROR γ inhibition attenuates DR by reducing pro-inflammatory Th17 cells and boosting the functionality of Tregs.

ABSTRACT BODY:

Purpose: Dominant cone-rod homeobox (CRX)-associated Leber congenital amaurosis (LCA7) is a severe retinal degenerative disease for which no treatments are currently available. Disease-causing variants in CRX typically result in the production of a dominant negative form of the protein, which disrupts normal photoreceptor maturation. To gain further insight into LCA7, we aimed to establish an in vitro model system to investigate CRX variant-specific disease mechanisms.

Methods: Human iPSC lines were generated from LCA7 patient whole blood samples, which harbor dominant mutations in CRX (CRX^{T155ins4/+} and CRX^{K88Q/+}). The patient-derived hiPSC lines were differentiated to generate retinal organoids, and immunohistochemistry, TEM, qPCR, and single-cell RNA sequencing were utilized to characterize photoreceptor cell development and maturation up to day 240 (D240) of differentiation.

Results: Retinal organoids were successfully generated from patient iPSCs, and both lines exhibit retinal tissue thickness and photoreceptor cell numbers comparable to those of CRX^{WT} organoids throughout differentiation. Morphologically, both CRX^{T155ins4/+} and CRX^{K88Q/+} organoids remain identical to CRX^{WT} until D240, when they fail to develop outer segments, similar to what has been reported in LCA7 patients and mouse models. Although both CRX^{T155ins4/+} and CRX^{K88Q/+} organoids exhibit similar levels of OTX2 protein and mRNA compared to control, CRX^{T155ins4/+} organoids show an increase in total CRX, while CRX^{K88Q/+} organoids show a decrease. CRX^{T155ins4/+} and CRX^{K88Q/+} organoids both reveal a reduction in RCVRN, AIPL1, ARR3, RHO, OPN1SW, OPN1MW, and OPN1LW compared to CRX^{WT} organoids (p<0.05), suggesting a decrease in expression of key photoreceptor genes. Variant-specific differences in levels of NRL, NR2E3, SAG, and cone opsins were also observed through D240 of differentiation, highlighting intriguing differences in disease mechanisms between variants.

Conclusions: Here, we have established an early photoreceptor cell-specific LCA phenotype in our patient organoids, and these data provide promise for a reliable in vitro model system which can be used to study variant-specific disease mechanisms. Future work will focus on studying disease mechanisms and therapeutic approaches in our organoid model system.

ABSTRACT BODY:

Purpose: To provide complementary imaging contrast of optical absorption and optical scattering through a completely non-contact imaging system. For the first time, photoacoustic remote sensing (PARS) microscopy is combined with a swept-source optical coherence tomography (SS-OCT) system and applied for non-contact, in-vivo functional and structural imaging of the murine ocular tissue.

Methods: Multi-wavelength, photoacoustic remote sensing microscopy is combined with swept-source optical coherence tomography. The PARS subsystem has a 532-nm nanosecond-pulsed fiber laser which is co-focused with an 830-nm interrogation beam within the tissue. Stimulated Raman Scattering (SRS) happening inside the excitation fiber was used to implement multiwavelength imaging. The difference in optical absorption of oxy and de-oxy hemoglobin at different wavelengths is utilized to evaluate oxygen saturation inside ocular tissue and reconstruct the oxygen saturation (SO₂) map. The OCT subsystem consists of a swept-source laser centered at 1060 nm with 100 nm spectral bandwidth and frequency swept at 60 kHz.

Results: Figure A represents a cross-sectional OCT image acquired from the anterior segment in the mouse eye which provides depth-resolved scattering contrast over the anterior part of the eye. Figure B is acquired from iris vasculature in the mouse eye using PARS microscopy covering an area of 2 mm × 2mm. Figure C represents the SO₂ map in the iris vasculature acquired using PARS microscopy using 532 nm and 545nm wavelengths.

Conclusions: The presented dual-modal system can provide complementary imaging contrast of optical absorption and optical scattering. The non-contact imaging ability of the system makes it a favorable technology for clinical ophthalmic imaging applications. The system is a major step toward non-invasive, simultaneous, and accurate measurement of the metabolic rate of oxygen (MRO₂) in the ophthalmic tissue and can assist ophthalmologists with the diagnostics and treatment of major eye diseases.

ABSTRACT BODY:

Purpose: To develop a novel therapy to suppress acute and long-term ocular complications after injury by using an injectable thermosensitive drug delivery system (DDS) for sustained subconjunctival delivery of anti-TNF- α and anti-VEGF reagents.

Methods: A thermosensitive, biodegradable hydrogel DDS (PLGA-PEG-PLGA triblock) loaded with 2mg of infliximab and aflibercept (1:2; Infli/Afli) was injected subconjunctivally in 3 Dutch-belted rabbits after corneal alkali injury. Control rabbits received human IgG loaded DDS (n=4) or only aflibercept DDS (n=3). Animals were followed for 3 months and assessed in vivo for tolerability, corneal neovascularization (CoNV), re-epithelialization, and ex vivo for retinal ganglion cell (RGC) loss, optic nerve axon loss, and expression of inflammatory markers. Drug release kinetics was assessed in-vitro by using fluorescein-dextran as a model drug, and in-vivo by aqueous humor analysis.

Results: Infli/Afli DDS treatment led to complete suppression of CoNV for over 3 months without adverse effects or reactions by the eye, while aflibercept DDS showed mild CoNV (~10% of cornea) and IgG DDS significantly more CoNV (~30% of cornea). Eyes treated with Infli/Afli DDS showed minimal corneal epithelial defect (0-2% of cornea) over 3 months, while IgG DDS treated eyes exhibited epithelial defect up to 11% of the cornea area albeit wound closure at 3 months. Aflibercept DDS group exhibited persistent corneal epithelial defects (~7% at 3 months). Histologically, Infli/Afli DDS reduced CD45⁺ immune cell accumulation (92%, P<0.05) and ameliorated TNF- α expression (70%, P<0.05) in the cornea, as compared to IgG DDS. Subconjunctival administration of infli/afl DDS achieved sustained retinal drug diffusion, and prevented RGC loss as compared to the other two groups at 3 months which exhibited 33-63% RGC loss. Quantification of IgG content in the aqueous humor using ELISA assay demonstrated that the DDS provided sustained, first-order drug release for over 3 months.

Conclusions: Sustained subconjunctival administration of infliximab and aflibercept using a thermosensitive biodegradable DDS that targets TNF- α and VEGF signaling pathways is an extremely effective therapy for preventing post-injury corneal inflammation and neovascularization, while providing the much needed retinal protection against RGC loss. Further studies are warranted.

ABSTRACT BODY:

Purpose: To investigate the prevalence, visual significance, and genotype-phenotype associations of foveal hypoplasia (FH) in inherited retinal degenerations (IRDs).

Methods: In this retrospective case-control study, the case group of 285 patients (492 eyes) consisted of genetically-confirmed IRDs while the control group contained 256 IRD-free patients (444 eyes). Exclusion criteria were age less than four, poor-quality/absent optical coherence tomography (OCT), or loss of retinal OCT lamination. LogMAR Best corrected visual acuity (BCVA), OCT, and demographic data were obtained. Published FH grading was used.

Results: Foveal hypoplasia was significantly prevalent in retinitis pigmentosa (RP; 110/351, 31.33%, $p < 0.001$), as well as IRDs overall (135/492, 27.44%, $p < 0.001$), compared to controls (20/444, 4.50%). In RP, LogMAR BCVA in FH grade 1 (0.18) was not different from age and gender matched patients with fully-developed fovea (0.18) ($p = 0.06$). Similarly, in controls BCVA of FH grade 1 (-0.01) was not different from age/gender-matched eyes with fully-developed fovea (0.02) ($p = 0.06$). RPGR (21/50, 42%) and USH2A (16/75, 21.33%) were significantly associated with FH compared to controls ($p < 0.001$, $p < 0.001$).

Conclusions: FH is associated with IRDs, and RP in particular. Genotypes RPGR and USH2A are each individually associated with FH. Although grade 1 FH is associated with IRDs that may reduce visual function, grade 1 FH is not associated with reduced visual acuity within the IRD cohort, indicating visual insignificance of persistent inner retinal layers. The presence of grade 1 or atypical grade FH in a patient with reduced vision should prompt consideration of an IRD diagnosis.

ABSTRACT BODY:

Purpose: Survey research has defined primary indications for scleral lens wear as corneal irregularity (74%), ocular surface disease (16%), and uncomplicated refractive error (10%). Data on secondary indications or specific conditions for lens wear have not been systematically reported. This multicenter study reports primary and secondary indications and specific conditions for which scleral lenses were prescribed within a single health care system from 2006 through 2019.

Methods: A retrospective chart review collected demographic information, primary and secondary indications for scleral lens wear, and specific conditions treated of patients who completed scleral lens fitting from 2006 through 2019. Descriptive statistics are reported.

Results: Scleral lenses were prescribed for 850 patients. The mean age at the time of scleral lens fitting was 53.5 [16.4] years of age (range 6-93 years). Male/female distribution was 372/478. Primary indications were corneal irregularity (434 patients, 51%), ocular surface disease (407 patients, 48%) and refractive error (9 patients, 1%). The numbers of patients with specific conditions causing corneal irregularity were: keratoconus (138), S/P keratoplasty (87), S/P RK (56), S/P LASIK (42), S/P trauma (30), S/P keratitis (29), pellucid marginal degeneration (22), S/P PRK (7), Terrien's marginal degeneration (2), unspecified corneal scarring (9), and unspecified irregular astigmatism (12). The numbers of patients with specific ocular surface conditions were: exposure keratopathy (103), unspecified dry eye syndrome (89), neurotrophic keratopathy (58), chronic GvHD (53), Sjogren syndrome (34), Salzmann degeneration (18), cicatrizing conjunctivitis (16), anterior basement membrane dystrophy (11), dry eye syndrome related to refractive surgery (11), limbal stem cell deficiency (11), congenital disorder (2), and superior limbic keratoconjunctivitis (1). A secondary indication was noted for 129 (30%) patients with corneal irregularity. A secondary indication was noted for 87 (21%) patients with ocular surface disease. A secondary indication was noted in only 1 patient with refractive error.

Conclusions: Ocular surface disease was the primary indication for lens wear in almost 50% of patients within this cohort, compared to less than 20% in previous studies. A secondary indication for scleral lens wear was noted in 20-30% of these patients, which may suggest that complex disease can be managed with scleral lenses.

ABSTRACT BODY:

Purpose: Purpose: To characterize retinal hemodynamics and identify sensitive biomarkers for quantifying age-related changes in retinal microcirculation, we investigate high-order dynamic characteristics relating to the time derivatives of the velocity of erythrocyte flow in human retinal capillaries, using high speed adaptive optics ophthalmoscopy.

Methods: Erythrocyte flows in retinal capillaries were imaged in human subjects with normal healthy retinae using an adaptive optics near-confocal ophthalmoscope (AONCO) at a frame rate of 800 Hz. Continuous pulsatile velocity of the erythrocytes flowing in the capillary was measured from the consecutive frames. In addition to conventional measures of the velocity (Figure 1), such as the maximum (V_{max}), the minimum (V_{min}), the mean velocity (V_m), the amplitude (V_d), and the pulsatility index (PI), we proposed new metrics, including the maximum acceleration (A_{max}), the acceleration time index (T_p), the rising rate (Rr). We further introduced the acceleration change index (AI) of the second order derivative of the velocity for estimating the acceleration change. This metric has been used to assess age-related vascular stiffness in photoplethysmography. Hemodynamic characteristics were measured in human subjects in normal physical health in 2 age groups: 24-25 years old ($n = 8$) and 50-60 years old ($n = 4$).

Results: Conventional measures pertaining to the velocity (V_{max} , V_{min} , V_m , V_d , and PI) showed no difference between the 2 age groups. In contrast, high-order characteristics disclosed significant differences (Figure 2). The prolonged T_p for cells to reach peak velocity in one cardiac cycle may indicate that the capillary or the erythrocytes have higher rigidness that increases the friction between the cell and the capillary, thereby delaying the time to reach the maximum velocity. Likewise, increased stiffness may increase the Rr and reduced A_{max} as well as AI.

Conclusions: High-order hemodynamic characteristics of the erythrocyte flow in the retinal capillary provide new and sensitive biomarkers for assessing age-related changes in the retinal microcirculation that cannot be differentiated by conventional metrics. These metrics may reflect the mechanical properties of the erythrocyte-capillary system.

ABSTRACT BODY:

Purpose: RPE is one of the most phagocytic cells in the body, both autophagy and phagocytosis are highly active in the RPE. The terminal events of both autophagy and phagocytosis involve degradation in the lysosome. Lysosome plays a crucial role in the proper functioning of both autophagy and phagocytosis in the RPE. Imbalances in lysosomal function can lead to the accumulation of undegraded autophagy and phagocytic substrates in the RPE. Transcription factor EB (TFEB) is identified as a master of the regulator of autophagy and lysosomal function. Decrease expression and activity of TFEB is known to increase the pathological accumulation of cellular substrates in different cell types. In this study, we investigated the expression and regulation of TFEB in the ABCA4 knockout (KO) RPE.

Methods: ABCA4 KO RPE cells were isolated and the expression of TFEB was monitored using immunoblotting analysis and quantitative real-time PCR (qRT-PCR) analysis. The expression of TFEB regulated coordinated lysosomal expression and regulation (CLEAR) network genes was studied by qRT-PCR analysis. The cells were also transfected with a constitutively active TFEB S142AS211A and the expression of TFEB and CLEAR network gene, Cathepsin D (CTSD), Lysosomal-associated membrane protein 1 (LAMP1), Beclin-1(BECN1), UV radiation resistance-associated gene (UVRAG), Sequestosome 1(SQSTM1), Microtubule Associated Protein 1 Light Chain 3 Beta (MAP1LC3B) by qRT-PCR. Cathepsin D activity was also measured using the Cathepsin D activity assay kit.

Results: Our result shows that both mRNA and protein levels of TFEB were downregulated in the ABCA4 KO RPE compared to age-matched WT RPE. The expression of TFEB regulated CLEAR network genes were rescued upon overexpression of constitutively active TFEB in the ABCA4 KO RPE. Our results also show rescue of Cathepsin D activity in ABCA4 KO RPE upon overexpression of constitutively active TFEB in the ABCA4 KO RPE.

Conclusions: Our study shows that decreased expression of TFEB in the ABCA4 KO RPE is accompanied by downregulation of TFEB-regulated CLEAR network genes. TFEB-regulated transcriptional program is rescued by overexpression of constitutively active TFEB in the ABCA4 KO RPE. These results suggest that TFEB plays a crucial role in the regulation of cellular clearance in the ABCA4 KO RPE.

TITLE: L-DOPA Stimulates Neurite Outgrowth during Early Retinal Organoid Development

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.D. Bennett, B. Radojevic, Ophthalmology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|L.D. Bennett, Dean McGee Eye Institute, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lea Bennett: Commercial Relationship: Code N (No Commercial Relationship) | Bojana Radojevic: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human retinal organoids made from inducible pluripotent stem (iPS) cells mimic retinogenesis and have been crucial for uncovering diseases mechanisms that cannot be recapitulated in animal models. However, mature retinal organoids are disorganized and unlike fetal retina, do not express important cellular pathways (circadian entrainment and axon guidance). Therefore, the goal of this study was to evaluate a key regulator of circadian entrainment, dopamine (DA) in developing retinal organoids.

Methods: At day 30 (D30) and D60, human retinal organoids were dissociated and grown on laminin-coated coverslips for neurite outgrowth assay. At D30, L-DOPA with ascorbic acid was added to the media for 2-3 hours to stimulate DA synthesis. Cells were stained with neuron-specific marker TUJ1 (β III tubulin) and MAP2 to visualize axon outgrowth. Axon-guiding signals (e.g. *Irx4*, *Foxg1*, *Nfil3*) and cell type-specific markers were quantified with RT-qPCR.

Results: Exogenous L-DOPA with ascorbic acid induced expression of the penultimate enzyme, tyrosine hydroxylase (TH) and DA synthesis prior to the appearance of dopaminergic amacrine cells (DACs). Cells treated with L-DOPA and ascorbic acid at D30 modified neurite outgrowth in early retinogenesis and showed increased axon lengths as well as expression of axon guiding genes (RT-qPCR). Expression of TH was 3 fold higher in the cells treated with L-DOPA and ascorbic acid at D30 compared to cells that were not treated with L-DOPA.

Conclusions: This work aimed to determine how developing retinal neurons respond to DA to ultimately create functional retinal organoids that mimic the structure and physiology of human retina which will have broader potential for ophthalmic research.

TITLE: Effect of anti-inflammatory eye drops on cultured porcine corneal endothelial cell viability

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.F. Hakim, T. Noguchi, A.A. Abbas, E.N. Finburgh, N.A. Afshari, University of California at San Diego Department of Ophthalmology at the Shiley Eye Institute, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Dominic Hakim: Commercial Relationship: Code N (No Commercial Relationship) | Takako Noguchi: Commercial Relationship: Code N (No Commercial Relationship) | Anser Abbas: Commercial Relationship: Code N (No Commercial Relationship) | Emma Finburgh: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Afshari: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the effect of three commonly used anti-inflammatory eye drops: cyclosporin (0.05%), lifitegrast (5%), and tacrolimus (0.1%) on porcine corneal endothelial cell viability.

Methods: We harvested porcine eyes and separated their corneascleral rims. Corneal endothelial cells were scraped from Descemet membrane after 0.5% trypsin treatment for 15 min. Cells derived from pig eyes were first plated into one well of a 12 well plate, proliferated to confluency in a low growth factor medium, passaged to a well of 6-well plate, and then passaged to a 96 well plate for drug treatment. Wells were separated into the following three treatment groups: cyclosporine 0.05%; lifitegrast 5%; tacrolimus 0.1%, as well as two control groups: a balanced salt solution (BSS) group and no treatment group. The cells were exposed to medium containing 20% cyclosporin (original 0.05% diluted to 0.01%), 20% lifitegrast (original 5% diluted to 1%), and 10% tacrolimus (original 0.1% diluted to 0.01%) and washed out after 1h, 2h, 4h, and 24h (N = 6 wells for each condition derived from 3 pig eyes). The survival rates of corneal endothelial cells were assessed by ATP quantification 48 h after the beginning of eye drop application.

Results: Measurements of porcine endothelial cell viability after application of cyclosporine, lifitegrast, and tacrolimus revealed a statistically significant decrease down from 100±10% survival in the untreated group to 75±6%, 42±21%, and 0±0% (mean ± SD, N = 6), respectively. Compared to non-treated control group, decreases in viability after application of cyclosporine became statistically significant at 24h [75±6% (mean ± SD, N = 6)]. After application of lifitegrast, decreases became statistically significant at 1h and 24 hours [67±22% at 1h, 42±21% at 24h (mean ± SD, N = 6)]. After application of tacrolimus, decreases became statistically significant at 1h, 2h, 4h and 24h [58±21% at 1h, 61±10% at 2h, 16±13% at 4h, 0±0% at 24h (mean ± SD, N = 6)].

Conclusions: Porcine endothelial cell viability decreased progressively across application of cyclosporin, lifitegrast, and tacrolimus containing anti-inflammatory eye drops. These findings may serve as a resource for appropriate selection of anti-inflammatory eyedrops in the clinical setting and provide further insight into the study of inflammatory signaling and cell death pathways.

ABSTRACT BODY:

Purpose: To compare the reliability of visualizing scattering defects as seen on the Digital Light Ophthalmoscope (DLO) vs on OCT images.

Methods: Twenty subjects (53.1 +/- 13.7 yrs, range 27-73 yrs) were imaged using both the DLO (Aeon Imaging, Bloomington, IN, USA) and OCT (Spectralis, Heidelberg, Germany). The DLO uses 860 nm light in a line scan to collect retinal images over a 37 deg field of view at 20 Hz. Multiply scattered light imaging suppresses superficial light scatter and reveals scattering disruptions in the deeper retina. Thus, we used a mode that offsets the scanning beam from the camera aperture by 51µm, leading and lagging, for collecting multiply-scattered light in equal but opposite directions. These pairs of images were automatically aligned and then processed to obtain images of differences to emphasize scattering defects. Three graders independently marked the center of each region with scattering defects. The DLO has a digital resolution of 10.8 µm/pixel.

One reviewer marked the center of the defects found in vertical OCT B-scans, which were taken with 870nm light. OCT scans were spaced 11 µm apart, and only the center of drusen or other sufficiently large scattering defects in the outer retina was marked. The en face scan provided by the Spectralis was aligned to the DLO image. The OCT scan boundary rectangle provided on the en face scan was used to compare the defect coordinates between the OCT scans and DLO images.

Results: Ten subjects were fully analyzed with both OCT and DLO, and 26 light-scattering defects were found on both instruments, with agreement in locations of at least two of the DLO image graders. Regions where OCTs were taken comprised of a smaller area than the total area imaged with the DLO, thus, a larger number of defects were found on the DLO, because of the larger field of view.

Conclusions: There was good agreement between the marked defects on the DLO and OCT B-scan images. The DLO images covered a larger region of the retina than the dense OCT scans, and numerous small defects were immediately and simultaneously observable from a single composite image, making it a promising device for detecting early signs of AMD.

ABSTRACT BODY:

Purpose: Purpose: Intraretinal macular neovascularization (MNV) is often preceded by hyperreflective foci (HRF) attributed to ectopic retinal pigment epithelium (RPE) and non-RPE. RPE migration may reflect a response to choroidal ischemia. We investigated with histology clinically documented HRF in fellow eyes, each with 3 MNV.

Methods: Methods: A white woman receiving anti-VEGF was monitored by optical coherence tomography (OCT) and angiography (OCT, dye-based) (OD, n=37; OS, n=6; last visits 3 and 2 months, respectively, before death). Eyes were recovered 4:05 hours after patient death at age 97 years. Eye-tracking (Heidelberg Engineering) aligned clinical and ex vivo imaging of the preserved eye prior to epoxy embedding for high-resolution light microscopic and transmission electron microscopic (TEM) investigation. Horizontally oriented 12 mm wide sections, 30 µm apart, were interleaved with 30 µm-thick slabs re-embedded for TEM.

Results:

Results: In OD, 2 MNV were investigated via TEM. In the first MNV, a hyperreflective triangle, with base-down and apex disrupting outer retinal and RPE layers correlated to an intraretinal vascular complex with numerous pericytes, ensheathed by collagenous material. Fully pigmented RPE distributed upward along this complex, entering but not contacting vessels. The complex rested on persistent basal laminar deposit overlying a completely calcified druse. Bruch's membrane was intact. In the second MNV, a hyperreflective column atop a soft druse correlated to a column of RPE emerging from the top of intact RPE covering a lipid-rich druse. Cells at the column tip encircled a vessel dipping into the Henle fiber layer from the deep capillary plexus. Pericytes were not seen.

Conclusions:

Conclusion: The components and morphology of the first MNV resembled our recent description of treated type 3 MNV and added new observations of pericytes, and lack of penetration into the sub-RPE-BL space, which contained calcified drusen. The second MNV did not resemble the first MNV or others in either eye. It may represent another entity such as perifoveal exudative vascular anomalous complex (PEVAC; PMID 29079450), which is non-responsive

to anti-VEGF. Recognition of different intraretinal MNV morphologies through clinicopathologic correlation may assist management decisions for neovascular AMD.

ABSTRACT BODY:

Purpose: To investigate pedigrees, clinical phenotype and TGFB1 mutational status in patients with corneal epithelial basement membrane dystrophy (EBMD) patterns.

Methods: Patients displaying sub epithelial bleb-like micro cysts, geographic map-like lines, dots or fingerprint lines at slit lamp examination were prospectively included between April 2018 and September 2019. We gathered both medical history and pedigree. We confirmed phenotypic patterns from biomicroscopic examination by anterior segment optical coherence tomography (OCT). We collected blood samples from patients and submitted to molecular genetics to investigate TGFB1 mutations.

Results: We included 22 eyes with typical patterns of EBMD from 13 patients. Anamnesis failed to report any case or symptom in relatives. All patients reported clinical symptoms. The main complaint associated a foreign body sensation, pain linked to recurrent epithelial erosions and/or visual symptoms. Over the 22 eyes, 9 eyes (7 patients) displayed the typical map-dot-fingerprint triad. Other patterns were "map-dot" (3 eyes, 2 patients), "dot-fingerprints" (3 eyes, 2 patients), "maps" (3 eyes, 2 patients), "dot" (2 eyes, 2 patients), "map-fingerprint" (one eye) and "fingerprint" (one eye). Split EBM was observed with OCT in all eyes. All patients failed to respond to medical lubricant and underwent excimer laser phototherapeutic keratectomy (PTK). We did not identify any TGFB1 mutation in our patients.

Conclusions: EBMD phenotype is heterogeneous in the absence of familial history. In our patients, EBMD was not related to an anomaly of TGFB1 gene, and compatible with an ill-understood degenerative process. Some work is still mandatory to discriminate hereditary and degenerative EBMD.

TITLE: Small molecule Wnt signaling activators inhibit TGF β signaling in the trabecular meshwork

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Mao, C.K. Sugali, N.P. Rayana, J. dai, M. Peng, Ophthalmology, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Weiming Mao: Commercial Relationship: Code N (No Commercial Relationship) | Chenna Sugali: Commercial Relationship: Code N (No Commercial Relationship) | Naga Rayana: Commercial Relationship: Code N (No Commercial Relationship) | jiannong dai: Commercial Relationship: Code N (No Commercial Relationship) | Michael Peng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Elevated TGF β 2 is found in the aqueous humor and trabecular meshwork (TM) of glaucoma patients. TGF β 2 induces excessive accumulation of extracellular matrix, alters cytoskeleton, and increases intraocular pressure in various experimental models. We previously reported that the Wnt signaling is able to inhibit TGF β signaling in the TM at transcriptional level. Here, we determined if small molecule Wnt signaling activators are able to inhibit TGF β 2 signaling.

Methods: GTM3 cells were transfected with Wnt signaling reporter luciferase vectors. The cells were treated with different GSK3 β inhibitors (Wnt activators) at different concentrations, and luciferase levels were measured using a plate reader. After determination of the optimal concentration, TM cells were transfected or transduced with TGF β signaling reporter luciferase vectors. These cells were treated with 5ng/ml TGF β 2 with or without GSK3 β inhibitors, and luciferase levels were measured. Primary human TM (pHTM) cells were also treated with or without TGF β 2 and/or GSK3 β inhibitors to study fibronectin and collagen I using Western immunoblotting and immunofluorescent microscopy.

Results: We found that the optimal concentration of the GSK3 β inhibitors in TM cells was 1uM for 6-bromoindirubin-3'-oxime (BIO), 10uM for SB216763 (SB), and 5uM for CHIR-99021 (CHIR). Also, these compounds were more potent compared to Wnt3a recombinant proteins in Wnt signaling activation. At these concentrations, they inhibited TGF β 2-induced TGF β signaling activation in the TM. They also inhibited TGF β 2-induced expression of fibronectin and collagen I in pHTM cells.

Conclusions: Small molecule Wnt signaling activators inhibit TGF β signaling in the TM and may have potentials for therapeutic use in treating glaucoma.

ABSTRACT BODY:

Purpose: Rose Bengal Photodynamic Antimicrobial Therapy (RB-PDAT) has been shown to effectively treat antimicrobial resistant and atypical infectious keratitis. RB-PDAT works by generating antimicrobial singlet oxygen ($^1\text{O}_2$) by exciting Rose Bengal (RB) photosensitizer with 525 nm light. While the cumulative $^1\text{O}_2$ dose distribution generated during RB-PDAT is currently unknown, this project aims to create a predictive model to calculate this distribution under clinical conditions. This model will eventually enable optimization of $^1\text{O}_2$ dose by optimizing RB-PDAT treatment parameters.

Methods: A chemical kinetics model was previously developed (Wang et al., 2010) for modeling $^1\text{O}_2$ dose distributions in tumors treated with photodynamic therapy. To describe ground-state oxygen (O_2) supply specific to the cornea, the oxygen supply term was adapted to include the model described by Larrea & Büchler (2009) and Castillo et al. (2014). RB distribution was modeled using Fick's second law, and 525 nm excitation light distribution by a time-dependent application of Beer's law. Rate constants for RB diffusion were then derived from experimental data describing RB corneal penetrance (Naranjo, Pelaez, et al., 2019; Peterson et al., 2018; Wertheimer et al., 2019). Lateral variation of all species was assumed to be minimal to allow for one-dimensional modeling. The resulting system of partial differential equations was solved numerically in MATLAB. Cumulative $^1\text{O}_2$ dose was calculated for RB-PDAT during typical conditions (6 mW/cm², 5.4 J/cm², 0.1% RB), as well as for conditions of pulsed and increased light dose, and addition of 90% supplemental O_2 .

Results: Under typical RB-PDAT conditions, calculated O_2 decreases to approximately 0 beyond 10 μm depth in the first 1 min of treatment. In this scenario, $^1\text{O}_2$ dose distribution was calculated to be limited to the first 10 μm of the cornea. Adding supplemental O_2 increases $^1\text{O}_2$ dose depth by approximately 5–10 μm . Increasing the light dose from 5.4 J/cm² to 10 J/cm² while adding 1s on, 1s off pulsing increases calculated $^1\text{O}_2$ surface dose 1.85x. Adding supplemental O_2 to the 10 J/cm² scenario, $^1\text{O}_2$ surface dose is 1.7x the dose seen in the 5.4 J/cm² condition.

Conclusions: We demonstrate a proof-of-concept predictive model for $^1\text{O}_2$ dose generated during RB-PDAT, capable of testing a range of experimental parameters. This model can be used for optimizing RB-PDAT clinical efficacy.

TITLE: Unbiased omics analyses of the sigma-2 antagonist CT1812 in age-related diseases and models

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Waybright, C. Rehak, E. Watto, A. Caggiano, M.E. Hamby, Cognition Therapeutics Inc, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lora Waybright: Commercial Relationship: Code N (No Commercial Relationship) | Courtney Rehak: Commercial Relationship: Code N (No Commercial Relationship) | Emily Watto: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Caggiano: Commercial Relationship: Code N (No Commercial Relationship) | Mary Hamby: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: CT1812, now in Ph2 clinical trials for Alzheimer's disease (AD), is an orally bioavailable, brain penetrant small molecule antagonist of the sigma-2 receptor, which contributes to key pathways involved in age-related diseases including autophagy, lipid trafficking, and amyloid- β (A β) toxicity. Human genetics points to a role of the sigma-2 receptor in dry age-related macular degeneration (dAMD); namely, a SNP in the chief sigma-2 receptor constituent TMEM97 locus confers an increased risk for dAMD (Fritsche et al., 2016). In support, CRISPR knockdown of TMEM97 in retinal pigment epithelial (RPE) cells significantly ameliorates oxidative stress-triggered cell death (Wang et al., 2020). We hypothesized that CT1812 will alter dAMD-relevant biologies in patients and in human iPSC-RPE cells treated with disease-relevant stressors.

Methods: Proteomics analysis was performed with plasma and cerebrospinal fluid (CSF) from AD patients treated with CT1812 or placebo for 28 day (N=14) or 6 mo (N=18). Unbiased pathway analyses were performed using Metacore to identify the pathways significantly altered in AD patients treated with CT1812 compared to placebo, and data were compared to publicly available dAMD proteomic datasets to identify significantly altered proteins linked to dAMD. Human iPSC-RPE cells were exposed to hydrogen peroxide, TNF- α and IFN- γ , A β oligomers, or vehicle to assess the effect of CT1812 under physiological and pathophysiological conditions. RNAseq analysis, including differential expression and pathway analysis, was performed to evaluate the transcriptomic changes elicited by CT1812 in vehicle- or stressor-treated cultures.

Results: Unbiased pathway analysis of AD clinical trial CSF proteomics indicated that geographic atrophy was the most significantly altered functional disease ontology by CT1812 compared to placebo ($p < 0.05$), and comparative analyses to publicly available AMD datasets illuminated a subset of dAMD-relevant proteins altered by CT1812 ($p < 0.05$). In iPSC-RPEs (n=3-4), transcriptomic analyses revealed highly regulated genes and pathways ($p < 0.05$) altered by oxidative stress, inflammation, and A β oligomers and by CT1812 vs vehicle data, illuminating the role of sigma-2 signaling in RPE cells under physiological and pathophysiological conditions.

Conclusions: In sum, data indicate a key role of sigma-2 in AMD and suggest CT1812 may be a promising therapeutic approach for dAMD.

ABSTRACT BODY:

Purpose: Analysis of 10 pedigrees with a diagnosis of IRD to identify the underlying cause of pathology

Methods: DNA isolation was performed on 24 affected and 29 unaffected individuals from 10 pedigrees with IRD. WGS was performed on 21 individuals using Illumina HiSeq X Ten. The sequence alignment and variant calling was done with the Illumina DRAGEN Bio-IT Platform, BWA-MEM+GATK-HC software with high accuracy for both SNPs and INDELs. Annotation of variants included SpliceAI and PrimateAI. Segregation analysis of all identified candidate variants was performed by PCR followed by Sanger sequencing.

Results: The pedigrees analyzed belonged to four different ethnic groups: one each of Ashkenazi Jewish, Hispanic and Pakistani origin, while the remaining 7 are of European American (EA) origin. Our analysis detected 12 pathogenic variants in 9 genes associated with IRD. Two novel compound heterozygous nonsense variants (p.[Glu526*;p.Gln1629*]) segregated with disease in one EA pedigree. A set of known compound heterozygous mutations c.5012+5G>A and p.Arg1752Trp in CEP290 were observed in another EA pedigree. Interestingly, two large structural variants were identified in the PRPF31 gene in two unrelated EA pedigrees. A known heterozygous mutation p.Ser212Gly in the PRPH2 gene segregated with IRD in an EA family with dominant IRD. A novel homozygous variant in DRAM2 (p.Ser234Tyr) and a reported nonsense mutation in RLBP1 (p.Tyr111*) were detected in the remaining two EA pedigrees. A known homozygous CRB1 mutation, p.Arg764Cys was detected in the Pakistani pedigree, while a previously reported nonsense mutation p.Gly723* in RP1 was found in the Ashkenazi Jewish pedigree. In the Hispanic pedigree, a novel intronic homozygous variant c.1107+3A>G in PDE6B was identified as a disease-causing variant.

Conclusions: Our analysis detected 4 novel and 8 previously reported mutations segregating with IRD in 10 pedigrees. These mutations include 4 nonsense, 2 intronic, 4 missense and two large structural changes in ALMS1, PDE6B, CEP290, DRAM2, RLBP1, PRPF31, RP1, PRPH2 and CRB1.

TITLE: Elastic anisotropy of the cornea: comparison of non-contact A μ T-OCE with mechanical tests

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Kirby, I. Pelivanov, H. Liou, R. Wang, M. O'Donnell, Bioengineering, University of Washington, Seattle, Washington, UNITED STATES|R. Wang, T.T. Shen, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mitchell Kirby: Commercial Relationship: Code N (No Commercial Relationship) | Ivan Pelivanov: Commercial Relationship: Code N (No Commercial Relationship) | Hon-Cin Liou: Commercial Relationship: Code N (No Commercial Relationship) | Ruikang Wang: Commercial Relationship: Code N (No Commercial Relationship) | Matthew O'Donnell: Commercial Relationship: Code N (No Commercial Relationship) | Tueng Shen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal stiffness, along with intraocular pressure (IOP), determines corneal shape, providing a majority of the refractive power to the human visual system. We demonstrate non-contact acoustic micro-tapping (A μ T) optical coherence elastography (OCE) of porcine cornea to quantify the shear moduli which contribute to corneal refraction using a nearly-incompressible transversely isotropic (NITI) model based on corneal microstructure.

Methods: The cornea contains layered collagen sheets (lamellae) arranged mostly parallel to the surface, which suggests a transversal isotropy of its mechanical properties. Consequently, corneal shear and tensile behavior (Fig.1) are described by different moduli. We introduce a shear modulus, G , to quantify out-of-plane shear modulus and tensile elastic modulus, E , responsible for corneal deformation.

We perform non-contact A μ T-OCE measurements in ex vivo porcine cornea to reconstruct both shear moduli using a nearly incompressible transversally isotropic (NITI) model and compare OCE results with parallel-plate rheometry and strip extensimetry.

Results: Figure 2a shows modulus estimates from A μ T-OCE under varying IOP. The OCE test in an exemplary sample yielded a mean Young's modulus of 16.8 – 33 MPa and shear storage modulus of 50.4 - 120.5 kPa (IOP 5mmHg- 20mmHg). Tensile tests yielded a Young's modulus (E) of ~2 -25 MPa (1-9% strain) (Fig. 2c). Shear rheometry yielded a storage modulus (G') of 100- 148 kPa and loss modulus (G'') of 15.7- 31.5 kPa over the low-frequency (1-10Hz) regime (Fig. 2b).

Conclusions: Both A μ T- OCE and destructive mechanical tests performed on ex vivo cornea reveal anisotropic elastic behavior with the tensile modulus E differing by orders of magnitude from the shear modulus G . However, mechanical tests are destructive, and each test type measures either G or E , but not both moduli together. On the other hand, A μ T-driven OCE is non-contact and non-destructive and is capable of in vivo measurement of both moduli simultaneously.

ABSTRACT BODY:

Purpose: Purpose: G91-deletion (Δ G91), a mutational hotspot in β A3-crystallin (CRYBA3/A1), causes pediatric congenital cataract in several families worldwide. However, the molecular mechanism of β A3 Δ G91-induced cataract is presently unknown. The purpose of the study to understand the molecular mechanism through comparative analysis of gene expression profiles in lenses of β A3 Δ G91- and wild-type mice.

Methods: Methods: We have generated β A3 Δ G91 mouse model by the CRISPR-Cas9 methodology using the UAB Transgenic & Genetically Engineered Models Core (TGEMs) facility. Lenses from 1-month-old β A3 Δ G91- and wild-type mice were examined for cataract development using Micron IV slit-lamp analysis. The relative protein profile by SDS-PAGE and the differential gene expression (transcriptome) followed by Ingenuity pathway analyses were performed in the 1-month old lenses of β A3 Δ G91- and wild-type mice.

Results: Results: β A3 Δ G91 mice showed congenital cataract relative to wild-type mice. SDS-PAGE analysis showed that β A3-crystallin level was relatively reduced in lenses of β A3 Δ G91 mice compared to the wild-type mice, which seems to be due to its insolubilization. The transcriptome analysis identified 93 dysregulated genes (q-value<0.05), out of which 11 genes were upregulated and 82 genes were downregulated. Biological function analysis revealed that the major affected genes were associated with protein synthesis, RNA damage and repair and cellular compromise. EIF2 signaling was identified as the top canonical pathway affected, showing that during congenital cataract development, ribosomal proteins (RPL, RPS) and genes involved in cellular stress (GADD34) were downregulated.

Conclusions: Conclusions: Our study provides informative data about the potentially affected candidate genes and biological mechanisms during β A3 Δ G91-induced congenital cataract development. Taken together, targeting EIF2 signaling might be a stepping-stone in developing therapeutic strategies to mitigate the congenital cataract.

TITLE: Improvement in mask utilization with 3D-printed ear protectors

SESSION TITLE: Healthcare Delivery during Covid Pandemic

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Choi, E. Meer, B.J. Nguyen, J.M. O'Brien, V.M. Addis, P.J. Tapino, Ophthalmology, Scheie Eye Institute, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Daniel Choi: Commercial Relationship: Code N (No Commercial Relationship) | Elana Meer: Commercial Relationship: Code N (No Commercial Relationship) | Brian Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Joan O'Brien: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Addis: Commercial Relationship: Code N (No Commercial Relationship) | Paul Tapino: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Face masks have been associated with significant discomfort for health care workers. Face mask ear protectors (EP) may reduce discomfort by allowing ear loop masks to be worn without tension. In Ophthalmology, given the close proximity required for the exam, appropriate mask usage and fit is essential. There is evidence of higher COVID-19 disease burden in ophthalmology compared to other specialties. This study aims to assess how a simple, attachment may decrease discomfort and increase compliance in an academic institution's Ophthalmology department.

Methods: EPs were distributed to the Ophthalmology department. A validated questionnaire was administered before and 2 weeks after EP usage, which surveyed demographics, likelihood of wearing a mask during select activities, and degree of mask usage (measured as number of times mask was removed/hour) during these activities. Descriptive statistics were performed with Fischer's t test to assess for a change in face mask utilization pre- and post-EP distribution.

Results: Although changes in mask usage post-EP were not statistically significant, post-EP responses demonstrated increased likelihood of mask usage across all activities. The greatest change was seen during outdoor activities with a 14.3% increase in those responding as "very likely" to wear a mask after using the EP. There was a 7.3% increase in responders who were likely to wear a mask in the workplace. EP decreased noncompliance while visiting friends. Nearly no subjects reported mask removal of >15 times/hr post-EP. 91.9% reported improved comfort, 91.9% improved fit, and 81.6% increased mask usage.

Conclusions: Our results suggest that simple 3D-printed EPs may improve fit, comfort, and overall mask compliance. This has potential implications not only for healthcare workers, but for the larger population as well. The statistical significance of this study may be limited due to the small subset of healthcare workers who were already high mask utilizers pre-EP, and thus may not truly appreciate the effect of EPs on the general population. The results of this study should drive broader public health efforts to further investigate whether mask attachments can improve overall mask compliance through better comfort and fit.

ABSTRACT BODY:

Purpose: Cognitive impairment and age-related macular degeneration (AMD) are progressive, often irreversible causes of disability. Using 10-year longitudinal data from the Age-Related Eye Disease Study 2 (AREDS2), a multi-center randomized trial of nutritional supplements in older people, we investigated bidirectional associations between cognitive impairment and late AMD.

Methods: AREDS2 participants received annual eye exams and regular testing of cognitive function, which included the Modified Telephone Interview for Cognitive Status (TICS-M). A centralized reading center reviewed fundus photographs to assign severity ratings using the AREDS AMD severity scale (i.e., a score ≥ 7 indicated worse AMD severity) and determine progression to late AMD (i.e., development of geographic atrophy or choroidal neovascularization). Proportional hazards regression was used to examine associations between cognitive impairment (i.e., a TICS-M score < 30) and progression to late AMD by the end of the trial (5-years) and extended follow-up (10-years). Associations between having worse AMD severity at baseline and development of cognitive impairment was also examined. Models were adjusted for baseline age, gender, and risk factors (e.g., smoking status).

Results: The analysis included 5189 eyes (3157 participants from 82 US clinics). Most participants were female (57%) older adults (mean 73 years), who never smoked (43%) or were former (50%) smokers at baseline. Eyes of cognitively impaired participants were more likely to progress to late AMD at 5 years (HR, 1.24; 95%CI, 1.08-1.43) and 10 years (HR, 1.20; 95%CI, 1.05-1.37), compared with eyes of those who were not cognitively impaired (Figure). No associations were observed between worse AMD severity at baseline and development of cognitive impairment at 5 years (HR, 1.13; 95%CI, 0.89-1.44) or 10 years (HR, 1.10; 95%CI, 0.92-1.32).

Conclusions: Our finding that people with cognitive impairment were more likely to progress to late AMD calls for greater awareness of the importance of eye care for people with cognitive impairment. Cognitive impairment may impede on a person's ability to identify changes in their vision, or that individual may not have adequate access to eyecare services because of more obvious issues linked to impaired cognition.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is considered one of the most well genetically defined complex disorders; however, the mechanisms underlying disease pathophysiology are poorly understood. Current therapies address advanced AMD when vision loss is largely irreversible. Interventions directed towards earlier disease stages are desperately needed to prevent AMD blindness. Our analysis of allele-specific expression (ASE) profiles in AMD diseased tissues offers a robust approach toward identification of candidate gene and gene variants relevant to local pathophysiology and environmental risk.

Methods: Well characterized donor eye tissue (postmortem time of less than 6 hours) of 14 patients over the age of 70 years (6 with intermediate stage AMD and 8 healthy age-matched controls) were surveyed using whole exome sequencing, RNA sequencing and whole genome genotyping using illumina chips. To generate ASE profiles, Exome Seq Fastq data was processed and merged with SNP chips and RNA sequencing data to build "personal" alignment indexes using Lofreq and STAR. Using these alignments, differential gene analysis was performed on high quality SNPs to calculate an ensemble prioritization score for each gene using the data from the imprinted gene, eQTL and GTEx databases. ASE candidates were then selected given a specific prioritization score cutoff which was compared to the prioritization score distribution of known AMD genes and genes not associated with AMD using a Kolmogorov-Smirnov test. Validation of identified candidate genes was performed using drop-seq PCR of macular neural retina and RPE/choroid from AMD patients versus normal patient tissues.

Results: After initial identification using our novel pipeline and subsequent validation as described, our analysis identified three novel genes, EOC1, FMN1 and TF, to be statistically associated with intermediate AMD within the local diseased tissues. Statistical analysis using a Kolmogorov-Smirnov test further showed a significant difference between the distributions, $p < 0.05$.

Conclusions: Using our ASE pipeline to identify disease mechanisms could pinpoint novel therapeutic targets for intermediate AMD with relevance to local disease mechanisms and therefore, potential to slow or stop disease progression.

ABSTRACT BODY:

Purpose: Familial dysautonomia (FD) is an autosomal recessive neurodegenerative disorder caused by a splice mutation in the gene encoding Elongator complex protein 1 (ELP1). A T-to-C base change in the 5' splice site of ELP1 gene results in exon 20 skipping with tissue specific reduction of ELP1 protein predominantly in the nervous system. In addition to a complex neurological phenotype, FD patients also exhibit progressive retinal degeneration severely affecting their quality of life. To test novel splicing-targeted therapeutic approaches, we have developed a phenotypic mouse model, TgFD9; Ikbk^{Δ20/flox} which exhibits most of clinical features of the disease while displaying the same tissue specific mis-splicing observed in patients.

Methods: Spectral domain optical coherence tomography (SD-OCT) was used to evaluate thickness of the retinal layers. Retinal whole mounts were performed to count the number of retinal ganglion cells (RGCs). Immunohistochemical staining was performed to detect degeneration of the optic nerve in FD mice. Adeno Associated Viral (AAV) vectors expressing ExspeU1s were generated to correct ELP1 splicing.

Results: We have comprehensively characterized the retinas of our FD mouse using SD-OCT and immunohistochemical assays during disease progression. Our findings showed a significant decrease in the thickness of the retinal nerve fiber layer (RNFL) and the ganglion cell layer (GCL) starting from 3 months of age ($p < 0.009$ and 0.005). Retinal whole-mount analysis showed reduction of RGC cell counts from 6 months of age ($p < 0.002$). Neurofilament (NF) staining analysis of the optic nerve from FD mice indicated diffuse degeneration of axonic bundles, demonstrating that our mouse model correctly recapitulates the retinal degeneration observed in patients. To correct ELP1 splicing defect, we have designed a novel splice targeted therapy using modified version of the spliceosomal U1 snRNAs (ExSpeU1s) that permit targeted binding to intronic sequences downstream of the mutant 5' splice site enabling efficient recruitment of spliceosomal machinery. In vivo delivery of FD ExSpeU1 using AAV led to successful correction of ELP1 splicing.

Conclusions: Our findings demonstrate that our novel FD mouse model exhibits most of retinal degeneration pathology observed in FD patients and highlight the valuable therapeutic potential of ExSpeU1 delivery to treat retinal degeneration in FD.

ABSTRACT BODY:

Purpose: The efficient diurnal RPE-mediated phagocytosis of photoreceptor outer segment (OS) relies on a tightly coordinated cascade of extra- and intracellular events that includes OS binding and internalization, followed by phagosome maturation and degradation. However, many aspects of phagocytic machinery, including mechanisms linking cytoskeleton-dependent temporal events with maturation of newly formed phagosomes remain elusive. We used previously established model systems of defective phagocytosis (cBEST1 and MREG/LC3B) to uncover molecular factors contributing to RPE phagocytic clearance in health and disease.

Methods: A combination of LC-MS/MS, Western blot, and co-IP analyses were used to explore the molecular signature of RPE and validate protein-protein interactions. In vivo (UHR-OCT) and ex vivo (H&E/IHC) assessments were performed to characterize retinal phenotype of Ahnak^{-/-} mouse. Subcellular localization, spatial and temporal association of AHNAK with OS were determined in vitro in primary human and mouse RPE cells using phagosome uptake and maturation assays.

Results: Expression of a giant protein AHNAK (~630kDa) was confirmed across mammalian retina, co-localizing with actin filaments at the RPE apical aspect, suggesting AHNAK's involvement in regulating RPE cell membrane cytoarchitecture. In vivo imaging revealed a spectrum of abnormalities in Ahnak^{-/-} eyes, predominantly associated with RPE-photoreceptor and RPE/choroid complexes, which was further confirmed by H&E, IHC, and ex vivo study in Ahnak^{-/-} retinal flat-mounts. The involvement of AHNAK in OS processing was examined using in vitro OS uptake model, which showed AHNAK-OS phagosome co-localization at the apical surface of hRPE and accumulation of phagosomes in the RPE of Ahnak^{-/-} model. Notably, proteomic study exposed association of AHNAK with MREG and its binding partner LC3B, linking temporal regulation of OS to MREG/LC3B-dependent machinery mediating OS phagosome maturation.

Conclusions: We report a new molecular regulator of RPE phagocytic machinery, AHNAK, and show an essential role of this scaffold protein in temporal regulation of OS phagocytosis and MREG/LC3B-mediated phagosome maturation. Further study is required to better understand the extensive signaling network of the AHNAK-MREG nexus, which ultimately will lead to identification of new therapeutic targets for inherited as well as age-related retinopathies.

ABSTRACT BODY:

Purpose: The role of microRNA in age-related macular degeneration (AMD) is of great interest for understanding disease progression, and the development of possible treatment(s). This study investigates microRNA modulation in our in vitro AMD model. The “personalized” transmitochondrial cybrids are cell lines that have identical nuclei, but mitochondria from different individuals. Previously we showed that AMD cybrids express higher mir135b-5p and mir148a-3p compared to age-matched normal cybrids, and that inhibition of these microRNA can alter gene expression in our cybrids. We hypothesize that in addition to gene expression changes, modulation of these microRNAs can potentially altar cellular health.

Methods: Cybrids were generated from AMD (n=5) and aged-matched normal (n=5) subjects by fusing platelets from clinically well-characterized patients with human retinal pigmented epithelial cells (ARPE-19) lacking mitochondria (Rho0). Since all cell lines have identical nuclei, differing responses between AMD and age-matched normal cybrids can be attributed to mitochondrial influence. MicroRNA inhibition was achieved through transfection of antisense miRNA inhibitors. Caspase 3/7 assays used the IncuCyte live cell imager. Statistical analyses were by paired t-test.

Results: Inhibition of mir135b-5p in AMD cybrids decreased expression of pro-apoptotic genes, BAX, BCL2L13 and CASP3 (0.85*, 0.7*, 0.82* fold) and decreased Casp3/7 staining by 40%*. In contrast, inhibition of mir148a-3p increased expression of pro-apoptotic CASP9 gene (1.3* fold) ER Stress gene DDIT3 (4.6* fold), autophagy genes ATG5 and ATG12 (1.75*, 1.73* fold) and inflammatory genes IL6 and IL1B. (12.3*, 4.4* fold). Inhibition of mir148a-3p also increased expression of mitochondrial biogenesis genes TFAM, POLG, TFB2M. (1.5*, 1.98*, 2.0* fold), and decreased ROS levels by 15%*. (*=p<0.05)

Conclusions: This study shows that inhibition of mir135b-5p decreases expression of apoptotic genes, and decreased Caspase 3/7 staining in AMD cybrids, supporting our hypothesis that modulation of this microRNA may improve ARPE cybrid cell health. In contrast, inhibition of mir148a-3p was associated with increased expression of cell death, inflammation, ER stress, and interestingly an increase in mitochondrial biogenesis genes as well as decreased cellular ROS levels. This data demonstrates that manipulation of specific microRNA can have dramatic effects on many pathways relevant to AMD.

ABSTRACT BODY:

Purpose: Functional retinal pigment epithelium (RPE) cultures can be derived from human induced pluripotent stem cells (iPSCs) to investigate the molecular mechanisms underlying human disease via an in vitro model. The RPE secretes various molecules and growth factors which can play a critical role in eye development. Retrospective analysis from RNA-sequencing and gene expression data (<https://eyeintegration.nei.nih.gov/>) showed that insulin-like growth factor 2 (IGF2) is expressed in RPE at the transcript level. IGF2 is a peptide hormone known to regulate cell proliferation, growth, migration, differentiation, and survival (Bergman et al., 2013). We aimed to validate the data via protein studies and investigate whether IGF2 could be a growth factor secreted by the RPE.

Methods: Human iPSC lines were derived from unaffected individuals and differentiated toward RPE cells. The RPE cells were cultured on a 2-D trans-well system for 6-8 weeks to mature and form an epithelial monolayer. All experiments were performed after 6-8 weeks of post-selection maturation. Western blot was performed to study IGF2 protein levels in RPE. Immuno-fluorescence followed by confocal microscopy (Zeiss 880) was performed to study cellular localization of IGF2. ELISA was performed using cell-culture supernatant media to quantify secreted levels of IGF2 from the apical and basal sides of RPE monolayers.

Results: A 20 kDa band was consistently observed in RPE monolayer lysates from three different RPE sources when incubated with anti-IGF2 antibody (ab9574). Immuno-fluorescence staining of RPE monolayers was performed using the same anti-IGF2 antibody and counter stained with ZO1 and nuclear stain (Hoechst333142). ZO1 staining was observed on the apical cell borders, and IGF2 staining localized in the apical portion of the cells just basal to the ZO1 staining.

To confirm IGF2 protein is secreted from the RPE monolayer, we performed ELISA using the apical and basal media sides of the RPE monolayer 24 hours after media change. We consistently observed IGF2 in the range of 200-400 pg/mL in the supernatant media.

Conclusions: IGF2 is expressed at the transcript and protein levels and secreted from the human RPE monolayer in vitro. This novel finding is important as IGF2 could play a crucial role in the development of the neural retina. Ongoing work is testing this hypothesis through an in vivo mouse model.

ABSTRACT BODY:

Purpose: Retinal ganglion cells (RGCs) connect the eye and the brain, allowing for visual perception, and these cells are known to be damaged in various blinding disorders such as glaucoma. The degeneration of RGCs is known to occur in a compartmentalized fashion, with the axonal compartment degenerating via different mechanisms than the somatodendritic compartment. While previous studies have demonstrated the ability to study certain aspects of RGC neurodegeneration with human pluripotent stem cells (hPSCs), they have lacked a focus upon the compartmentalized nature of RGC neurodegeneration. Thus, the goal of this study was to examine how RGC neurodegeneration occurs within different cellular compartments.

Methods: RGCs were differentiated from isogenic control and CRISPR/Cas9 edited OPTN(E50K) hPSCs. RGCs were enriched via Magnetic Activated Cell Sorting (MACS). Initially, RGCs were plated upon laminin-coated coverslips, and studies explored neurodegenerative features within RGCs over the first 4 weeks of maturation including neurite retraction and changes in excitability. Subsequently, RGCs were also plated onto microfluidics slides to allow for the recruitment of RGC axons away from the somatodendritic compartments, which allowed for an analysis of cellular changes within discrete compartments of RGCs.

Results: Glaucomatous OPTN(E50K) RGCs showed reduction in soma size and neurite outgrowth compared to isogenic controls, correlated with an enhanced excitability. Upon growth in microfluidic platforms, RGC axons and dendrites could be readily distinguished, and changes in the complexity of these processes were analyzed and compared for significant changes. Overall, OPTN(E50K) RGCs demonstrated morphological and functional deficits, mimicking some aspects of the phenotypes observed during the progression of glaucomatous neurodegeneration.

Conclusions: The results of this study demonstrate the ability to study neurodegenerative phenotypes in RGCs differentiated from human stem cells, including those with a glaucoma-associated OPTN(E50K) mutation along with the further application of microfluidic platforms that allows for the analysis of neurodegenerative changes in separate neuronal compartments. The results of this study will expand our understanding of the cellular changes that occur in human RGCs, and will support future studies including disease modeling and drug screening.

ABSTRACT BODY:

Purpose:

We have previously shown that stress-induced premature senescence (SIPS) is a key pathogenic component of diabetic retinal vascular dysfunction. Here we have investigated the reciprocal role of histone deacetylase 6 (HDAC6) and sirtuin 1 (SIRT-1) in diabetes-induced SIPS. These two HDACs have been shown to play opposing roles in regulating SIPS, however their reciprocal interaction in this process was not investigated before.

Methods: We used streptozotocin-induced diabetic rats at 8 weeks of hyperglycemia (STZ-rats) and age-matched normoglycemic rats. Human retinal endothelial cells (HREC) were cultured for 48 hours in different glucose conditions (HG=25mM D-glucose). Senescence was determined by senescence-associated-beta-galactosidase activity assay. Extracellular vesicles (EVs), were isolated from HREC supernatants using ultracentrifugation. Inhibition of HDAC6 was achieved in STZ-rats by treatment with the specific inhibitor Tubastatin (TS;10mg/Kg/day) and in HREC by 5µM TS. HDAC6 expression in HuREC was also halted using human specific gRNA and compared to negative controls. MicroRNA arrays were conducted on HREC extracts and in EVs in response to the different treatments.

Results: Hyperglycemia stimulated HDAC6 while downregulating SIRT1 retinal expression and activity. TS prevented diabetes-induced loss of SIRT-1 in rats and significantly reduced senescence markers. In HuREC, HG treatment inhibited and TS treatment restored SIRT-1 while decreasing the number of senescent cells. MiRNA arrays of HREC extracts and EVs collected from the cells supernatants showed the up-regulation of miR-34a and down-regulation of miR-146a. Treatments of the cells with TS or transfection with HDAC6-specific gRNA, halted HG-induced cells senescence while restoring SIRT-1 expression and activity. Loss of HDAC6 (TS and gRNA) also down-regulated miR-34a expression while restoring miR-146a. Finally, transfection of HREC with miR-34a mimic overrode the effects of TS in blocking HG-induced loss of SIRT-1 and miR-146a.

Conclusions: We have identified in the HDCA6-miR-34a axis a key molecular event leading to diabetes-induced retinal vascular senescence and diabetic microangioapthy through loss of SIRT1 and of miR-146a. Overall, our results suggest the potential therapeutic use of HDAC6 inhibitors for diabetic retinopathy

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has placed unprecedented challenges on the provision of eye care. This study assessed patient attitudes about eye care with relation to visit type at the outset of the coronavirus pandemic when eye care offices were limiting patient visits to urgent and emergent care based on recommendations from the American Academy of Ophthalmology.

Methods: This is a cross-sectional survey of patients who completed either an in-person or telemedicine visit or who deferred their previously scheduled visit at the Callahan Eye Hospital & Clinics at the University of Alabama at Birmingham during April 2020. Quantitative self-reported responses about eyesight quality, worry about eyesight, and satisfaction were collected. Responses to qualitative questions were categorized positively or negatively by themes of quality, risk, precaution, convenience, trust, and communication. Responses were assessed by visit type and compared using Fisher's exact or the Pearson chi-square test.

Results: 450 patients completed the survey with a mean age 55.1 ± 22.7 years. The majority were female (63.7%) and white (54.7%). A greater number of patients reporting fair to very poor eyesight were seen in-person (25.6%) or by telemedicine (40.0%) compared to those who deferred (19.1%) ($p=0.0005$). Worrying about eyesight some, most or all of the time was significantly greater in patients seen in-person (18.8%) or by telemedicine (14.9%) compared to deferral (9.7%) ($p=0.0002$). When asked about feelings regarding their visit, those who had a telemedicine visit more frequently responded with a positive comment about quality ($p<0.0001$) while those completing in-person visits were more positive regarding precaution ($p<0.0001$). There were no significant differences by visit type with regard to positive or negative comments on risk, trust, and communication. Patients completing a telemedicine visit less frequently reported complete satisfaction (67.8%) compared to deferred (86.3%) and in-person visits (74.4%) ($p=0.0001$).

Conclusions: Patient responses demonstrate that telemedicine may be an acceptable modality for eye health management, especially among patients with fair to poor eyesight. During the COVID-19 pandemic, telemedicine may provide a way for patients worried about their eyesight to feel supported by their eye care provider. Further analysis regarding patient satisfaction with telemedicine is needed.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is an important cause of visual impairment, characterized by degeneration of retinal photoreceptors (PR). Mutations in pre-mRNA processing factor 31 (PRPF31) are the second most common cause of autosomal dominant RP. Gene therapy holds promise to treat retinal inherited diseases, and AAV-mediated PRPF31 augmentation has been shown to restore critical functions in iPSC-derived PRPF31[±] cells. Currently, there are no satisfying animal models with similar phenotypes to human PRPF31 patients. Our study aims at establishing animal models of this disease by AAV-CRISPR/Cas9 gene editing and testing gene therapy efficiency in vivo in these models.

Methods: Cas9 and/or guide RNA with/without GFP reporter gene targeting early coding exons of PRPF31 were delivered to the retina of WT and SpCas9-expressing transgenic mice using AAV. Different delivery routes including systemic injection, intravitreal injection (IVT), and sub-retinal injection (SRI) were evaluated. AAV-PRPF31 gene augmentation was achieved using SRI. Retinal conditions were evaluated by fundus imaging, OCT, ERG, and histology.

Results: Systemic delivery of knockout (KO) vectors to P0 neonatal mice caused low body weights and high early mortality rates. IVT delivery to the retina resulted in reduced thickness of the inner plexiform layer and reduced amplitude of the ERG b-wave. SRI, which led to higher expression levels of KO vectors in PR, induced retinal pallor and formation of black-brown pigmentation, which spread away from the injection site over time. OCT revealed the disappearance of the inner and outer segment layers, followed by loss of the outer nuclear layer, indicating PR degeneration. ERGs showed notable reductions in a-, b- and c-wave amplitudes, with prolonged c-wave implicit time. Co-injection of PRPF31 therapeutic vectors with KO vectors decreased retinal pallor and pigmentation, improved retinal thickness, as well as a-, b- and c-wave responses compared to PBS and KO vectors co-injected eyes.

Conclusions: PRPF31 RP mouse models with early on-set morphological and functional impairments like those in patients were established, providing new platforms to investigate the pathogenetic mechanisms of PRPF31 and to evaluate treatment efficacy. AAV-mediated gene therapy rescued the function of PRPF31-mutant retinas, further demonstrating proof-of-concept for gene therapy to treat PRPF31 RP.

TITLE: Prevalence of hyper-response to CAE challenge in dry eye disease

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G.W. Ousler, M. Watson, D. Narayanan, Ora, Inc., Andover, Massachusetts, UNITED STATES|G. Wallstrom, SDC Clinical, Phoenix, Arizona, UNITED STATES|

Commercial Relationships Disclosure (Abstract): George Ousler: Commercial Relationship(s);Ora:Code E (Employment) | Michael Watson: Commercial Relationship(s);Ora:Code E (Employment) | Divya Narayanan: Commercial Relationship(s);Ora:Code E (Employment) | Garrick Wallstrom: Commercial Relationship(s);SDC Clinical:Code E (Employment)

ABSTRACT BODY:

Purpose: It has been previously reported that patients with dry eye disease (DED) who exhibit a rapid symptomatic response to the Ora CAE® challenge demonstrate enhanced investigational treatment differences as well as a reduction of placebo effects in clinical studies. The purpose of this study is to report the prevalence of this CAE hyper-response across treatment naïve dry eye patients.

Methods: Data from 1209 DED patients were analyzed. The CAE is a controlled chamber which allows for highly standardized atmosphere of low relative humidity, increased airflow, and constant visual tasking. This controlled environment overcomes a dry eye subject's ability to maintain a stable tear film and allows for reproducible evaluation of signs and symptoms of dry eye. Each subject's ocular discomfort is documented using the Ora Calibra® Ocular Discomfort scale (0 = none to 4 = worst) before and periodically during the 90 minutes CAE challenge. A subject is defined as a CAE hyper-responder if their ocular discomfort worsens to 3 or greater (or to 4 if 3 at time 0) in less than 20 min in CAE (considered a more symptomatic patient or hyper-responder) versus \geq 20 minutes in CAE (i.e. not hyper-responder). For each study, number of subjects identified as hyper-responders were documented and percentage was calculated.

Results: Among the 1209 subjects, 496 (41%) were identified as CAE hyper-responders and 713 (59%) were not hyper-responders to the CAE. Overall reproducibility of subjects meeting these criteria at more than one CAE challenge was 787/1209 (65%). When considering a 10 min. window of the 90 min. challenge for re-qualification, CAE hyper-responders reproduced 79% of the time.

Conclusions: Hyper-response to CAE is a phenomenon well-documented across a large number of patients. An individual DED patient's inherent sensitivity to respond to a challenge might be a contributing factor and indicator of their ability to report symptoms and better distinguish treatment differences. Additional study is ongoing to identify specific individual characteristics that might be related to exhibiting hyper-response on CAE. A hyper-response to the CAE as an inclusion criterion or pre-defined subpopulation may result in patient enrichment in dry eye clinical trials.

ABSTRACT BODY:

Purpose: Intravitreal injection (IVI) is the only feasible method of drug delivery to the retina. However, IVIs are only suitable for drugs with large therapeutic indices and long half-lives, as rapid diffusion mediates clearance and loss of therapeutic effects. There is a need to improve IVI systems to reduce injection frequency and allow for delivery of drugs with unfavorable properties. Nanoparticle encapsulation of a drug can improve drug solubility, stability, and half-life. Exosomes are cell-derived vesicles that can be used as drug delivery nanoparticles. Hyaluronan is an aminoglycan found in high concentrations in the vitreous of the eye. Conjugation of hyaluronan-binding moieties is one strategy that can be used to restricting diffusion and improve the intravitreal half-life of therapeutics. The objectives are to design and evaluate hyaluronan-binding peptides using in silico modeling and in-vitro modeling. Then, peptides are evaluated for their ability to restrict exosomes drugs using an in vitro diffusion model. We hypothesize that presence of hyaluronan solution will decrease the diffusion rate of peptide conjugated exosomes, and thus may be useful for increasing the half-life of therapeutics for retinal drug delivery.

Methods: Exosomes will be isolated from retinal cell culture using differential ultracentrifugation. Exosome cell uptake into retinal cells will be evaluated qualitatively by fluorescence microscopy. Drug loading and release will be evaluated following loading of exosomes with model small molecule drugs. Hyaluronan-binding peptides will be designed using molecular docking techniques. Candidate peptides will be conjugated to the surface of exosomes using click chemistry. Exosome diffusion rates will be evaluated using a diffusion cell model.

Results: Exosomes were positive for CD63, had a mean diameter of 85.0 nm, and had round morphology as imaged by STEM. Molecular docking identified several peptides with strong interaction to hyaluronan. Exosomes displayed time depending uptake into ARPE19 cells in culture.

Conclusions: Exosomes derived from retinal cell culture are a promising nanoparticles system for IVI as they have favorable properties for drug delivery. Molecular docking is a useful tool to design peptide ligands. Future work should evaluate the extent of drug loading and release and evaluate the effect of peptides on diffusion through hyaluronan solution.

ABSTRACT BODY:

Purpose: Worldwide lockdown reduced global air pollution during the SARS-CoV-2 pandemic. In this study, we evaluate whether the UK lockdown impacted upon dry eye symptoms in severe ocular surface disease (OSD) patients and whether there is a relationship with changes in air pollution levels.

Methods: 35 OSD patients (median age 70 (range 42-85) years; 17(48.5%) females; 22(63%) ocular mucous membrane pemphigoid; 3(9%) high-risk corneal transplant recipients; 4(12%) ulcerative keratitis; 2(6%) Stevens-Johnson syndrome; 3(9%) other (granulomatous polyangiitis, Sjögren's syndrome, pemphigus vulgaris) maintained on systemic immunosuppression including mycophenolate mofetil, azathioprine, tacrolimus, methotrexate and cyclophosphamide achieved a risk stratification score of >3, defined as coronavirus high-risk and fulfilled the government criteria for shielding for a minimum of 12 weeks. Symptoms and air pollutions data were considered from three different time periods categorised as pre, during and post-lockdown. Pre-lockdown symptoms were curated from hospital electronic databases using the OSDI[®] symptom questionnaire (Allergan plc, Irvine, CA) whilst during and post-lockdown data were obtained via postal hardcopy. Air pollution data for patient postcodes were derived from Department for Environment, Food, & Rural Affairs (DEFRA) and from the Automatic Urban and Rural Network (AURN) monitoring network for nitrogen dioxides (NO₂), nitrogen oxides (NOx) particulate matter 10µm (PM₁₀) and 2.5µm (PM_{2.5}).

Results: A 12% increase in symptom scores were observed during versus pre periods (36.11±16.09 vs 32.24±29.17, p=0.381). Similarly, a 19% reduction was observed between the during and post periods (36.11±16.09 vs 29.46 ± 26.29, p=0.144). However, significant reduction of NO₂ (35%, from 17.11±6.87 to 11.17±4.79, p<0.001) and NOx (44%, from 26.06±11.64 to 14.53±7.18, p<0.001) respectively, were observed between pre and during periods. Symptoms and air pollutants were not correlated across all the considered periods.

Conclusions: Despite the reduction of air pollutants due to lockdown measures, dry eye symptoms experienced by immunosuppressed OSD patients were increased. This might be due to a range of environmental factors such as increase use of electronic blue screen electronic devices as well as the psychological impact of lockdown on patient wellbeing.

ABSTRACT BODY:

Purpose: 1-To evaluate the comparability of visual field (VF) measurements obtained using Heru VF that uses a cloud based artificial intelligence (AI)-powered software application downloadable on commercial augmented reality headset to those of standard automated perimetry in normal, glaucoma and neuro-ophthalmology patients.

2-To evaluate the reproducibility of Heru VF measurements in normal and pathological eyes.

Methods: This prospective clinical study included 47 eyes (21 healthy and 26 of patients with glaucoma and neuro-ophthalmic diseases). VF results were obtained using Heru VF application that uses a cloud based AI testing algorithm (Heru Visual Field, Miami) downloaded on Magic Leap 1 augmented reality device (Magic Leap, Plantation, FL) and a Humphrey Field Analyzer (HFA) 800 series (Carl Zeiss Meditec, Inc, Dublin, CA, USA) using SITA Standard. Patients underwent 24-2 test point pattern in both devices. Comparing test times and correlations of threshold values (TV) and mean deviations (MD) obtained using both were calculated to determine agreement. Test time (TT) was compared between the two devices. In Heru device, testing is paused when patient is not fixating, thus testing time excludes idle time when patient was not interacting with the test. Pathological VF defects seen were typical glaucomatous VF defects and ring scotomas.

Results: There were strong correlations between Heru VF MD and TV and those of HFA in normal, glaucoma and neuro-ophthalmology patients ($R=0.91$, $P<0.001$ and $R=0.81$, $P<0.001$, respectively). MD and TV of Heru VF in normal and pathologic eyes showed excellent reproducibility with ICC of 0.95 (95%CI 0.86-0.98) and 0.80 (95%CI 0.78-0.82), respectively. Heru VF was statistically significantly faster than the HFA SITA Standard (4.3 vs 5 minutes respectively; $P<0.001$). Mean TT in Heru VF was 15.4% faster than HFA in pathologic eyes (4.7 vs 5.5 minutes, $P<0.001$) and 7.8% faster than HFA in healthy eyes (3.9 vs 4.24 minutes, $P<0.001$).

Conclusions: Central VF measurements from Heru VF that uses a cloud-based AI-powered software application downloadable on commercial augmented reality headset were comparable to HFA in normal, glaucoma and neuro-ophthalmology patients. Heru VF measurements are reproducible in normal and pathologic patients. Heru VF is faster than HFA SITA Standard.

Commercial Relationships Disclosure (Abstract): Danielle ClarksonTownsend: Commercial Relationship: Code N (No Commercial Relationship) | Kelleigh Hogan: Commercial Relationship: Code N (No Commercial Relationship) | Dillon Brown: Commercial Relationship: Code N (No Commercial Relationship) | Machelie Pardue: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Circadian rhythms in ocular tissues play important roles in homeostasis, photoreceptor disc shedding, and visual function and are also thought to influence ocular growth and emmetropization. To test whether circadian disruption caused by environmental light affects refractive development, we utilized an experimental model of environmental circadian disruption and longitudinally measured refractive error in mice.

Methods: Wild-type C57Bl/6J male and female mice were developmentally exposed throughout gestation and after weaning to either a control light (CL, 12:12 light:dark, n=17-20) or environmental circadian disruption (CD, weekly light:dark inversions, n=16-22) light cycle. Refractive error (photorefractometry), corneal curvature (keratometry), and eye biometry (spectral domain optical coherence tomography) were measured at 4, 5, and 6 weeks of age. A mixed-effects analysis with Sidak's method to control for multiple comparisons (significance threshold $p < 0.05$) was performed to test for differences in refractive error and corneal curvature by treatment group and time. Student's unpaired t-tests (significance threshold $p < 0.05$) were used to evaluate differences in eye biometry measures in a subset of mice (n=14 CL, n=12 CD) at 4 weeks of age.

Results: Mice in the CD group had greater refraction values compared to CL at 4, 5, and 6 weeks of age (Figure 1, main effect of group, $F(1, 41) = 174.7$, $p < 0.001$). Corneal curvature does not appear to significantly differ between groups, but eye biometry measures from a subset of mice suggest trends towards decreased corneal thickness ($p = 0.122$), decreased lens thickness ($p = 0.117$), and shorter axial length ($p = 0.283$), in the CD mice.

Conclusions: These results suggest that the developmental light environment can influence refractive error. We plan to further evaluate eye biometry measures in the remaining mice at all time points. Because mice were kept in the light conditions for the duration of the experiment, it is possible that circadian changes in choroidal dynamics may also play a role in these results.

TITLE: Role of Notch Signaling Pathway in Steroid Induced Glaucoma

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Ghag, P.P. Pattabiraman, Department of Ophthalmology, Indiana University Purdue University at Indianapolis, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sachin Anil Ghag: Commercial Relationship: Code N (No Commercial Relationship) | Padmanabhan Pattabiraman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Treatment with corticosteroid hormone Dexamethasone (DEX) results in increased fibrogenic stimulus, extracellular matrix (ECM) accumulation in the trabecular meshwork (TM) and elevated intraocular pressure (IOP) leading to steroid induced glaucoma (SIG). Notch signaling pathway is an evolutionarily conserved signaling mechanism contributing to the pathophysiological processes like tissue fibrosis. Here, we investigated the effects of DEX on Notch signaling and ECM remodeling in the TM.

Methods: Primary Human TM (HTM) cells were treated with 100nM DEX in serum free media alone or in combination with- a) N-(N-[3, 5-difluorophenacetyl])-L-alanyl)-S-phenylglycine t-butyl ester - DAPT (Notch signaling inhibitor), b) Phenethyl isothiocyanate - PEITC (Notch signaling activator), and c) RU486 (Glucocorticoid receptor inhibitor) - and investigated for changes in protein expression by immunoblotting for- canonical notch signaling including Notch receptor - Notch1, Notch ligand - Jagged-1, Notch effector - Hes1, ECM proteins - Fibronectin (FN) and Collagen1A (COL1A), pro-fibrogenic marker - α -Smooth Muscle Actin (α -SMA), and pro-fibrotic growth factor - Transforming growth factor β 2 (TGF β 2). Student's t-test and/or one-way ANOVA was used for statistical analysis and results were significant if $p \leq 0.05$ with a sample size of $n \geq 3$ in each experiment.

Results: DEX treatment significantly - downregulated - Notch1 ($p=0.008$), Jagged1 ($p=0.050$), Hes1 ($p=0.001$) and upregulated - a) α -SMA ($p=0.001$), b) TGF β 2 ($p=0.048$), and c) ECM- COL1A ($p=0.018$) and FN ($p=0.024$) proteins. Inhibition of Notch signaling using DAPT mimicked the effect of DEX in upregulating COL1A and FN. Conversely, activation of Notch signaling using PEITC downregulated ECM proteins. Finally, inhibition of DEX signaling by RU486 restored the Notch1 ($p=0.016$) and Hes1 ($p=0.001$) and decreased FN ($p=0.024$) levels similar to PEITC treatment in presence of DEX.

Conclusions: Our preliminary data in TM demonstrates that - 1) canonical Notch signaling pathway is downstream of DEX mediated events, 2) DEX induces ECM production by downregulating the Notch pathway, and 3) activation of Notch signaling mimics inhibition of DEX receptor-mediated signaling. From this study, we speculate that notch signaling plays an important role in ECM remodeling in TM outflow pathway and help maintain the IOP homeostasis. The activation of notch signaling pathway can be a potential therapeutic target for SIG.

ABSTRACT BODY:

Purpose: A 6-year clinical trial randomized subjects to MiSight 1 day (Omafilcon A, dual focus design, CooperVision, Inc.; M1d) or Proclear 1 day (Omafilcon A, single vision, CooperVision, Inc.;P1D) contact lenses for the first three years during which M1d significantly slowed axial elongation Chamberlain et al. (2019). This analysis reports annual axial elongation and overall treatment effects over 6 years using a virtual control group.

Methods: Part 1: 144 myopic children (8-12 years of age) were randomized to wear either M1d or P1d. Part 2: After 3 years, the P1d wearers (n=56) were switched to M1d lenses (M1d-3) while the original treatment group (M1d-6; n=52) continued with M1d. All subjects were followed, unmasked, for an additional 3 years. In the absence of a concurrent control group, a virtual control group was created, based on the axial elongation model of Brennan et al. (AAO 2018). Estimated annual elongation (EAE) was calculated using the age and ethnicity of the P1d control cohort and used to quantify the myopia treatment effect of MiSight over the full 6 years.

Results: EAE for the virtual control group agrees well with the experimental control group during years 1-3. The EAE was 0.619 mm and 0.624 mm respectively, validating the virtual control group and its use for estimating EAE for an untreated control group for the final 3 years. The EAE for the virtual control group growth in years 4 to 6 was 0.395 mm. The year 4-6 total elongation in the M1d-3 and M1d-6 groups were 0.190 mm and 0.184 mm indicating 0.205 mm and 0.211 mm treatment effects. The treatment effect for the M1d-6 group when compared to the virtual control group over the full 6 years revealed a 0.529 mm reduction in axial eye growth (six year cumulative growth of 1.014 (control) – 0.485 mm (treatment)).

Conclusions: Using a virtual control group, M1d substantially retards myopia by slowing axial elongation throughout six years of wear. This approach also shows effectiveness in newly treated older subjects in years 4-6.

TITLE: Relationship between Time spent using Video Display Terminals and Dry Eye Disease

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.S. Steinkerchner, R.R. Sayegh, Ophthalmology, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|R.R. Sayegh, Ophthalmology, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Megan Steinkerchner: Commercial Relationship: Code N (No Commercial Relationship) | Rony Sayegh: Commercial Relationship(s);Allergan:Code R (Recipient);Novartis:Code R (Recipient)

ABSTRACT BODY:

Purpose: To evaluate how time spent viewing video display terminals (VDT) influences ocular surface disease index (OSDI) scores and ocular pain rating scales, and to report VDT users' treatment responses to available dry eye disease (DED) therapies.

Methods: A cross-sectional study evaluated patients presenting for dry eye management in an academic setting. Demographics, ocular and medical history, time spent on VDTs (computers, tablets, and cellphones), OSDI scores, ocular numeric rating scale (NRS) and descriptors, and subjective response to previously tried eye drop, systemic, and non-pharmacologic treatments were collected from the patient population. Statistical analysis was performed to assess the correlation between time utilizing VDTs with OSDI and NRS scores and to examine the treatment response in VDT users.

Results: 144 patients were included in the study, with a mean age of 58.1 years. The average reported daily time spent on all VDT was 5.6±4.5 hours, with an average of 3.2±3.5 hours on computers, 0.8±1.5 hours on tablets, and 1.7±1.6 hours on cellphones. There was a very weak correlation between OSDI score and time spent on computers ($R^2=0.002$), tablets ($R^2<0.001$), cellphones ($R^2=0.01$), and all VDT combined ($R^2<0.001$). The lack of correlation persisted when controlling for age. There was a similarly very weak correlation between NRS score and time spent on computers ($R^2=0.01$), tablets ($R^2=0.001$), cellphones ($R^2<0.001$), and all VDT combined ($R^2=0.006$). Patients with more than four hours of daily VDT use and ocular pain had a response rate of 90.6% with artificial tears, 82.7% with hot compresses, 79.1% with steroid eyedrops, 74.5% with tinted lenses, 63.6% with lifitegrast, and 60.0% with cyclosporine A 0.005%.

Conclusions: Time spent engaging VDT was not related with OSDI or NRS scores, highlighting the need for further investigation of dry eye diagnostic tools in VDT users. There was a trend towards decreased computer usage with increased ocular pain, possibly reflecting the loss of productivity in this group. Available DED therapy has a high rate of efficacy in patients with ocular pain associated with VDT use.

TITLE: Post-Operative Outcomes After Pediatric Cataract Surgery in an Urban Hospital Setting

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Skula, Z. Mendelson, S. Guo, Rutgers New Jersey Medical School Department of Ophthalmology & Visual Science, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Steven Skula: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Mendelson: Commercial Relationship: Code N (No Commercial Relationship) | Suqin Guo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pediatric cataracts remain a challenge throughout all ages. The post-operative management after pediatric cataract surgery continues to be challenging. Advancement in surgical techniques and better long-term post-operative care have improved these outcomes, but there is still more to learn. We performed a retrospective chart review of pediatric cataract surgery outcomes over an 11-year period in an urban inner-city hospital. The goal of our study was to further understand the post-operative outcomes and compare our results to the current literature.

Methods: Data was initially collected from 21 patient charts which accounted for 35 eyes. Inclusion criteria required eyes to have a congenital cataract that was not associated with either trauma or previous ocular disorders or surgery and had postoperative follow up for a minimum of 6 months. Of those 35 eyes identified during the chart review, 32 met our inclusion criteria. Subgroups were stratified based on age at time of surgery (infantile ≤ 18 months, Juvenile > 18 months), unilateral or bilateral cataracts, and aphakic or pseudophakic. Average follow up was for 30 months (2.5 years) with a range of follow up from 6 months to 11 years. Statistical analysis for each group was performed using fisher exact test with an α of 0.05.

Results: Incidence of glaucoma was significantly higher in the group with infantile cataract (50% (6/12)) compared to the juvenile group (0% (0/20), $p=0.001$) and in the aphakic group (35% (6/17)) compared to the pseudophakic group (0% (0/15) $p=0.0192$). Posterior capsular opacity (PCO) was significantly greater in the juvenile group (50% (10/20)) than in the infantile cataract group (8.3% (1/12), $p=0.0232$). In the latter group 11 were left aphakic due to the young age and underwent both primary posterior capsulotomy and anterior vitrectomy at the time of the cataract surgery.

Conclusions: We found that children with infantile cataract were associated with a higher incidence of glaucoma. While aphakia was associated with a greater incidence of glaucoma, we believe that children with infantile cataract often have other associated congenital anterior segment anomaly, which may be more influential in the development of glaucoma. PCO was found to occur more frequently in the juvenile group because all of these eyes had their posterior capsule left intact to support intraocular lens implant. Our findings were consistent with the literature.

ABSTRACT BODY:

Purpose: Although obesity, tobacco and alcohol use have been linked to the development and progression of numerous chronic and degenerative diseases, objective evidence of the association of such aspects of a patient's social history with glaucoma progression is yet to be determined. The purpose of this study was to investigate the effect of the body mass index (BMI) and history of use of tobacco and alcohol on the rates of retinal nerve fiber loss (RNFL) loss over time in patients with and suspected of glaucoma.

Methods: This study included 8,424 eyes of 4,480 patients from the Duke Glaucoma Registry. All patients had at least 2 good-quality optical coherence tomography (OCT) tests over a minimum follow-up of 6 months. Self-reported history of alcohol and tobacco consumption was extracted from electronic health records and the mean BMI was calculated for each individual. Linear mixed models were used to determine the effect of each parameter on the rates of change in RNFL over time, with adjustments for sex, race, age at baseline, mean intraocular pressure, central corneal thickness, baseline RNFL, and follow-up time.

Results: Mean follow-up time was 3.9 ± 2.0 years, with an average of 4.0 ± 1.8 (range: 2 to 13) OCT tests per eye. 41% and 58% of the eyes were from subjects with a history of tobacco or alcohol consumption, respectively, and 71% were classified as overweight or obese ($\text{BMI} \geq 25 \text{ kg/m}^2$). Eyes from subjects with history of tobacco consumption had, on average, $0.072 \mu\text{m/year}$ faster rates of RNFL loss over time than subjects that never used tobacco ($P=0.021$). Higher BMI, however, had a protective effect on the rates of glaucomatous progression over time ($0.005 \mu\text{m/year}$ slower per each 1 kg/m^2 higher; $P=0.047$). Alcohol consumption was not significantly associated with rates of RNFL change over time ($P=0.130$). No significant association was observed between smoking intensity (pack-years) and rates of progression ($P=0.757$). After adjustment for confounding factors, only BMI remained significantly associated with rates of RNFL loss ($\beta=0.012$; $P<0.001$).

Conclusions: Habits of tobacco and alcohol consumption showed no significant effect on the rates of RNFL change in glaucoma. Higher BMI was significantly associated with slower rates of RNFL loss. Future studies should investigate the mechanisms by which BMI may affect structural progression in glaucoma.

TITLE: Contrast sensitivity assessment in children with brain injury.

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.M. Alam, S.W. Mooney, L. Tesfaye, G.T. Prusky, Burke Neurological Institute, White Plains, New York, UNITED STATES|G.T. Prusky, Weill Cornell Medicine, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nazia Alam: Commercial Relationship: Code N (No Commercial Relationship) | Scott Mooney: Commercial Relationship(s);16/661,596:Code P (Patent) | Leul Tesfaye: Commercial Relationship: Code N (No Commercial Relationship) | Glen Prusky: Commercial Relationship(s);16/661,596:Code P (Patent)

ABSTRACT BODY:

Purpose: The contrast sensitivity function (CSF) is a highly valuable measure of visual health, but has generally been difficult or impossible to assess in individuals with cognitive impairment. We show that a rapid gaze-based task can assess contrast sensitivity in children with a range of neurological disorders such as cortical visual impairment (CVI), including non-verbal children.

Methods: We measured CSFs in fifteen child in-patients (age 4 to 18) with varying levels of neurological deficit using the eye-tracking-based task Gradiate. This task displays drifting band-filtered noise targets and determines when the participant is smoothly tracking a target with their eyes, then advances the target's spatial frequency and contrast in real time until it is no longer visible. Five distinct thresholds were measured multiple times over multiple sessions in order to form a CSF. We also measured six-threshold CSFs in the most impaired children with a variant of Gradiate that uses scrolling full-screen noise. In this variant, the tester can manually toggle an attractive cartoon overlay to recapture the participant's attention (a "bait-and-switch").

Results: Well-formed CSFs were obtained from ten out of fifteen children, though different patients required different numbers of testing sessions to overcome their varying cognitive and attentional deficits. The low rate of false positives in the Gradiate task allows us to infer thresholds from the best results across multiple sessions with high confidence. Figures 1 and 2 depict example CSFs from children with severe (non-verbal) and mild traumatic brain injury, respectively. Five children exhibited no tracking behavior in any session and could not be assessed.

Conclusions: Our findings indicate that a non-verbal, gaze-based tracking task makes it possible to measure contrast sensitivity in young and/or impaired participants. Due to the task's inherent low false positive rate, transiently poor performance that is due to cognitive rather than visual impairment is readily detectable. Quantitative contrast sensitivity measurements in these clinical populations would aid in diagnosing specific visual disorders in greater detail than broad-spectrum categories such as CVI. These assessments may also be developed further into potential behavioral therapies, which we are currently exploring.

ABSTRACT BODY:

Purpose: Despite our growing understanding of dry AMD, effective treatments remain elusive. In the early stages of AMD, drusen accumulate between the RPE and the Bruch's membrane, leading to RPE atrophy and ultimately, central vision loss. Exosomes, cell-derived extracellular vesicles containing proteins and RNAs have been found in drusen of AMD patients. Exosomes play a role in spreading toxic-aggregated proteins in other diseases. Our goal is to recapitulate key features of AMD in human RPE, including drusen-like deposits and, to characterize the cargo of secreted exosomes under cellular stress.

Methods: We established an efficient protocol to produce functionally RPE cells from hiPSC. We induced oxidative stress in the hRPE by exposure to cigarette smoke extract. To characterize exosomes secreted by hRPE cells, we analyzed the concentration, morphology, and proteomic content of released exosomes. We validated the proteins found in exosomes by western blot. For exosome uptake assays, exosomes released by GFP-hRPE were co-cultured with wt hRPE, followed by PCR and immunofluorescence analysis to evaluate internalized exosomes in the recipient cells.

Results: We have established an efficient strategy to derive functionally RPE monolayers from hiPSC. We introduced a model that combines several key aspects of AMD and then, characterize the directional exosomal protein cargo of hRPE. Proteomic profiling of hRPE exosomal cargo revealed that exosomes were selectively enriched in proteins involved in oxidative stress, immune response, inflammation, and drusen-associated proteins pathways. Interestingly, exosomes secreted by hRPE cells within an AMD environment significantly enhanced the release of AMD-associated proteins. Finally, we confirmed the uptake of exosomal proteins and mRNAs released from hRPE cells by recipient cells.

Conclusions: This work represents the first proteomic profile from exosomes released by hiPSC-derived RPE and the first demonstration that proteins linked to drusen are released in association with exosomes. The exosomal cargo suggests a role for exosomes in both, normal physiology of the retina and the progression of retinal disorders. The

identification of well-known drusen proteins secreted in exosomes also suggests a potential involvement of exosomes during drusen development. The confirmation that exosomes released from hRPE are taken up by target cells opens new avenues for possible therapeutic interventions.

TITLE: Defective DNA Repair in Fuchs endothelial corneal dystrophy

SESSION TITLE: Corneal endothelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Deshpande, G. Melangath, S. Vasanth, U.V. Jurkunas, Ophthalmology, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|M. Price, F. Price, Cornea Research Foundation, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Neha Deshpande: Commercial Relationship: Code N (No Commercial Relationship) | Geetha Melangath: Commercial Relationship: Code N (No Commercial Relationship) | Shivakumar Vasanth: Commercial Relationship: Code N (No Commercial Relationship) | Marianne Price: Commercial Relationship: Code N (No Commercial Relationship) | Francis Price: Commercial Relationship: Code N (No Commercial Relationship) | Ula Jurkunas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Fuchs endothelial corneal dystrophy (FECD) is a genetic, age-related corneal endothelial (CE) degeneration from lifelong exposure to oxidative stress. We previously reported heightened nuclear (nDNA) and mitochondrial (mtDNA) damage to be a hallmark of FECD. This was recapitulated in the ultraviolet-A (UVA) light-induced FECD mouse model which showed early stage mtDNA and late stage nDNA damage to contribute to degenerative CE phenotype. In this study, we investigated whether impaired DNA repair pathways can cause the build-up of deleterious DNA lesions in FECD

Methods: Differential expression profiles of 84 DNA repair and 5 housekeeping genes were analyzed by real-time (RT)PCR arrays. Total RNA was extracted from Descemet's membrane-CE stripped from age-matched normal donors (n=4) and FECD specimens (n=8). cDNA was subjected to RTPCR on Human DNA Repair RT Profiler plates. A change of <0.5 or >2.0-fold mRNA expression in FECD relative to normal was set as the cutoff for down- and upregulation. Total protein was extracted from CE of 7-9 weeks C57BL/6 mice irradiated with 1000 J/cm² UVA at 1 day and western blotting was carried out to assess LIG3 and XPC levels

Results: FECD specimens differentially expressed (p<0.05) 8 nucleotide excision repair (NER), 5 base excision repair (BER), 4 double strand break (DSB) repair and 4 mismatch repair (MMR) pathway genes compared to normal donors. While the total 11 upregulated (>2-fold; p<0.05) genes were equally distributed between the 4 pathways, the set of 10 downregulated (<0.5-fold; p<0.05) genes predominantly (8 out of 10 genes) belonged to NER or BER pathways. NER gene XPC and BER gene LIG3 were downregulated (0.2-fold; p<0.005 and 0.36-fold; p<0.005) in FECD specimens and were also reduced (0.3-fold; p<0.05 and 0.4-fold; p<0.05) in mouse CE cells after UVA irradiation; correlating to the early time-point of mtDNA damage seen in UVA mouse model of FECD. Differentially expressed DSB and MMR pathways were primarily upregulated (3 out of 4 genes each) in FECD compared to normal donors

Conclusions: Our findings indicate that deficient NER and BER pathways may trigger the accumulation of unrepaired DNA lesions in FECD. Downregulation of XPC and lig3 may contribute to the mtDNA damage and mitochondrial dysfunction seen in FECD. This is the first study to provide evidence that DNA repair pathways are deficient in FECD and may be important when designing therapeutics for degenerative cell loss

TITLE: Detection of Corneal Ectasia Using OCT Maps of Pachymetry and Posterior Surface Mean Curvature

SESSION TITLE: Keratoconus and biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Pavlatos, D. Huang, Y. Li, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elias Pavlatos: Commercial Relationship(s);Optovue, Inc.:Code F (Financial Support) | David Huang: Commercial Relationship(s);Optovue, Inc.:Code F (Financial Support);Optovue, Inc.:Code I (Personal Financial Interest);Optovue, Inc.:Code P (Patent);Optovue, Inc.:Code R (Recipient) | Yan Li: Commercial Relationship(s);Optovue, Inc.:Code F (Financial Support);Optovue, Inc.:Code P (Patent)

ABSTRACT BODY:

Purpose: To formulate an Ectasia index to quantify the abnormal corneal thinning and posterior surface steepening that is associated with ectatic pathologies such as keratoconus.

Methods: 32 eyes from normal subjects and 131 eyes with varying degrees of keratoconus severity were imaged using a Fourier-domain OCT system (Avanti, Optovue, Fremont, CA). Maps of corneal pachymetry and mean curvature of the posterior corneal surface were generated. All pachymetry and mean curvature maps were converted to pattern deviation (PD) maps to show differences in normalized thickness and curvature relative to the healthy population (Li et al, JCRS, 2016). The minimum value on the pachymetry PD map was located, and a 2D symmetric Gaussian function was fit to a sub-region of the map centered at this location. The average vector between the pachymetry PD map minimum and the mean curvature PD map maximum was calculated using all of the keratoconus eyes. Gaussian fitting of the mean curvature PD map was performed with the center of the fit shifted by this average vector with respect to the location of the pachymetry PD minimum. The Ectasia index was calculated from the product of the two Gaussian fits. K-fold cross-validation was used to compare the diagnostic performance of the Ectasia index compared to minimum pachymetry and maximum mean curvature.

Results: The ectatic pattern of coincident corneal thinning and posterior surface steepening was evident for the keratoconus eyes, but not for the normal eyes (Figure 1). The average Ectasia index value for the normal eyes was $-0.1 \pm 1.0\%$. The Ectasia index was larger for the manifest, subclinical, and forme fruste keratoconus groups, with average values of $-19.4 \pm 6.9\%$, $-13.7 \pm 4.6\%$, and $-3.7 \pm 3.9\%$ respectively (all $p < 0.0002$). The Ectasia index was statistically more sensitive than minimum pachymetry in detecting manifest keratoconus and more sensitive than maximum mean curvature in detecting forme fruste keratoconus. The specificity of the Ectasia index did not differ statistically from the specificity of the two other metrics.

Conclusions: The Ectasia index was effective in differentiating between normal and keratoconic eyes and could therefore be a useful additional metric for clinicians to consider when screening for ectasia.

TITLE: Resident Performed MIGS Outcomes at a Veterans Hospital

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Lehman, E. Meer, T. Liu, E. Miller, Ophthalmology, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amanda Lehman: Commercial Relationship: Code N (No Commercial Relationship) | Elana Meer: Commercial Relationship: Code N (No Commercial Relationship) | Tianyu Liu: Commercial Relationship: Code N (No Commercial Relationship) | Eydie Miller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore the comparative safety and efficacy of evolving MIGS procedures/devices, the Hydrus, Kahook, and iStent in the Philadelphia VA population to guide future decision-making about the most suitable glaucoma treatment in a resident-training population with diverse demographics.

Methods: A retrospective chart review was conducted for patients who underwent a Minimally Invasive Glaucoma Surgery (MIGS) operation in conjunction with cataract surgery at the Philadelphia Veterans Administration Medical center from approximately 01/01/2015 – 11/1/2020. Descriptive analyses, ANOVA and chi-squared analyses were performed to compare across MIGS types.

Results: 126 patients undergoing MIGS procedure were included. 96% were male, 69.84% African-American, and 29.36% Caucasian. 46.03% patients received a Hydrus, 31.75% an iStent, and 22.22% a Kahook. The average preoperative maximum intraocular pressure was 23.78 mmHg, with an average preoperative IOP of 15.78 mmHg and an average preoperative drop number (total number of glaucoma medications used per day) of 1.45, not significantly different across MIGS types. When separated out by MIGS used, Hydrus demonstrated the greatest reduction in IOP, on average a reduction of 6.14 mmHg at initial post-operative visit and 4.08 mmHg at final post-operative visit, a statistically significant decrease in intraocular pressure when compared to both the iStent and the Kahook ($p < .05$) at postoperative day 1 and postoperative week 1. However, at the 9-12 months postoperative visit the Hydrus was only statistically significantly better at reducing IOP compared to the iStent, and performed similarly to the Kahook. The Hydrus demonstrated a statistically significant decrease in medication reduction (either frequency or number) when compared to both the Kahook and iStent ($p < .05$). There were no significant differences in complication rates across MIGS types.

Conclusions: Overall, this study suggests that Hydrus may be more efficacious than the iStent and the Kahook initially in decreasing glaucoma medication use and IOP postoperatively, however, this difference may not be statistically significant in longer term follow up. More studies are needed to evaluate outcomes in glaucoma populations of different severities.

ABSTRACT BODY:

Purpose: A single target in the conventional outflow pathway has been approved for glaucoma treatment but the ubiquitous ocular distribution of Rho kinases (ROCKs) is not ideal in terms of specificity and potential side effects. To obviate this, we sought to determine the upstream driver of ROCK in the trabecular meshwork (TM) and Schlemm's canal and tested the efficacy of its modulation as an IOP lowering strategy in acute and chronic models of ocular hypertension.

Methods: Novel anti-TRPV4 compounds were tested by calcium imaging and electrophysiology in vitro in overexpressing HEK293 (HEK-V4OE) cells and primary trabecular meshwork (pTM) cells. IOP was elevated in mice acutely via cannulation or chronically with the microbead occlusion method. IOP lowering was also tested in beagles that express the ADAMTS10 mutation. IOP was measured tonometrically for roughly 24 hrs (mice) or a week (dogs) following topical antagonist administration.

Results: The calcium-permeable stretch-activated channel TRPV4 was identified as the upstream driver of mechanically induced ROCK activation in the TM. SMC-0151 and SMC-0155 inhibited TRPV4 activity at picomolar concentrations, with dose-dependent suppression of agonist-evoked responses. SMCs, but not the commercial antagonist HC067047, lowered IOP in the acute mouse model. Intraocular injection and topical administration significantly lowered IOP in the chronic model. The IOP-lowering effect in dogs was facilitated by increasing the drug concentration.

Conclusions: We demonstrate that TRPV4 and calcium drive mechanically-induced Rho pathway signaling in the TM. Novel, cornea-permeant TRPV4 antagonists were developed as effective reducers of intraocular pressure in two animal models of glaucoma. These results shed light onto the basic mechanisms of IOP-induced TM injury and expand the roster of potential anti-glaucoma strategies and targets.

ABSTRACT BODY:

Purpose: For patients requiring regular ocular drug therapy, frequent intravitreal injection is painful, undesirable, and unnecessarily risky, and therefore, sustained delivery is a viable alternative. One type of sustained-release systems includes micro-pellets loaded with the drug, encapsulated in a porous shell that can be injected into the vitreous humor where the released drug diffuses while the physiological flow of water provides the convective transport. The purpose of this work is to quantify the drug release rate from a spherical microcapsule for given drug diffusion and capsule permeability properties in the vitreous. The goal is to provide useful parameters such as capsule half-life for various transport parameters for the system.

Methods: The model consists of a porous microsphere shell encapsulating a specific drug. The fluid flow within the vitreous is described by Darcy's equations for the analytical model and Brinkman flow for the computational analysis, while the drug transport is given by the classical convection-diffusion equation. With the timescale for the drug depletion being quite large, we consider the exterior surrounding the capsule to be quasi-steady and the interior is time dependent. In the vitreous, the fluid-flow process is relatively slow, and meaningful results can be obtained for small Peclet number (Pe) whereby a perturbation analysis is possible. For an isolated capsule, with approximately uniform flow in the far-field around it, the mass-transfer problem requires singular perturbation with inner and outer matching. The computational model, however, allows for fully time-dependent solution and also admits large Peclet numbers.

Results: The analytical/computational modeling provides the drug distribution within and around the microsphere. Additionally, the effective lifetime of the drug capsule is obtained in terms of the shell permeability and the biophysical transport parameters. The perturbation analysis has been carried out to order Pe^2 and agrees very well with the computational model. The results are sufficiently general and may be applied to a range of drugs and capsule permeability.

Conclusions: The release rate diminishes with time as expected since the drug source depletes and lowers the driving potential. The predictive results are applicable to the design of the sustained-release microspheres, especially in terms of selecting the capsule permeability.

Commercial Relationships Disclosure (Abstract): Aleksandra Mihailovic: Commercial Relationship: Code N (No Commercial Relationship) | Catalina Garzon: Commercial Relationship: Code N (No Commercial Relationship) | Jian-Yu E: Commercial Relationship: Code N (No Commercial Relationship) | Sheila West: Commercial Relationship: Code N (No Commercial Relationship) | Laura Gitlin: Commercial Relationship: Code N (No Commercial Relationship) | David Friedman: Commercial Relationship: Code N (No Commercial Relationship) | Pradeep Ramulu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the associations between fall status and subsequent away-from-home excursions in older adults with glaucoma.

Methods: Prospective observational cohort of individuals with glaucoma or suspected glaucoma who reported falls prospectively via monthly calendars for 1 year and wore a GPS for 1-week at study baseline and again at follow-up 1 year later. GPS data were utilized to quantify average daily excursions, average daily time away from home, average time per excursion, and percentages of days without excursions. Fall status was defined as fallers (≥ 1 fall), recurrent fallers (≥ 2 falls), injurious fallers (≥ 1 injurious fall), and recurrent injurious fallers (≥ 2 injurious falls) using falls data collected over the first study year. Separate negative binomial regression models were used to evaluate the association between fall status and each excursion parameter at follow-up. Integrated visual field (IVF) sensitivity was evaluated as a potential confounder and effect modifier, and models were adjusted for covariates (Table 1). Generalized estimating equations models accounting for clustering by individual were utilized to evaluate change in excursion parameters comparing follow-up assessment to baseline.

Results: One-hundred and eighty-five individuals participated in the study, and roughly half were males (50.8%) with a mean age of 70.3 years; just over one fourth were Black (28.1%) (Table 2). There were no statistically significant associations between fall status and excursion parameters at the follow-up assessment ($p > 0.52$ for all) and IVF sensitivity did not appear to modify these relationships, at baseline or follow-up ($p > 0.14$ for all). Excursion patterns at the follow-up assessment were not significantly different from those at baseline and did not differ by fall status ($p > 0.131$ for all).

Conclusions: Individuals with poor vision from glaucoma who fell did not modify their away-from-home excursions and did not display any restrictions in their excursion patterns compared to their counterparts who did not fall. Even if participants sustained recurrent or injurious falls, daily excursions patterns were not altered.

TITLE: Novel Metrics of Contrast Sensitivity for Glaucoma and Suspects

SESSION TITLE: Visual Fields and Psychophysics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Tunstill, R. Trevino, J.C. Rabin, University of the Incarnate Word Rosenberg School of Optometry, San Antonio, Texas, UNITED STATES|G. Slagle, W.E. Sponsel, Clinical Research, Sponsel Foundation, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Talia Tunstill: Commercial Relationship: Code N (No Commercial Relationship) | Grant Slagle: Commercial Relationship: Code N (No Commercial Relationship) | Rick Trevino: Commercial Relationship: Code N (No Commercial Relationship) | William Sponsel: Commercial Relationship(s);Guardion Health Sciences:Code C (Consultant) | Jeff Rabin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma can cause dramatic reduction in visual field prior to any loss of high contrast visual acuity (VA). However, spatial and temporal contrast sensitivity (CS) and color vision can be impaired early in glaucoma. Our purpose was to quantify novel measures of CS and VA with and without glare in a heterogenous cohort of glaucoma patients to develop new metrics for detection and monitoring.

Methods: 30 subjects (mean age 54 ± 12 , 23 females) with diagnosed or suspected open or narrow angle glaucoma, scheduled to undergo laser peripheral iridotomy, participated in our IRB approved protocol after written informed consent. Measures included high contrast VA with and without glare (BAT; Brightness Acuity Tester, Marco Ophthalmic), CS across four spatial frequencies (3, 6, 12, 18 CPD) with and without glare (Vector Vision/Guardion: VVG CS), and Pelli-Robson CS. Repeated measures ANOVA, t-tests and sensitivity analyses were used to evaluate CS metrics.

Results: Mean VA (n=60 eyes) without glare was 0.053 log MAR and slightly decreased (.084) with glare ($P < .03$). However, two-way ANOVA of VVG CS across spatial frequency and glare showed a significant effect of spatial frequency ($F=71.4$, $P < .0001$) but no significant effect of glare ($F = 2.53$, $P = 0.1$). The VVG CS test did reveal decreased CS in 54% to 79% of eyes across four spatial frequencies with the greatest decrease at 12 CPD (20/50 equivalent). Moreover, the sum of VVG log CS values computed to approximate area under the CS curve showed that 74% of eyes were below age comparable norms, with Pelli-Robson log CS (mean 1.47) below age norms in 68% of eyes (Elliot et al., 1990).

Conclusions: Glare disability did not prove to be a strong index of glaucomatous dysfunction, but CS is often decreased in various types and degrees of glaucoma including suspects. Pelli-Robson large letter (20/700) CS proved sensitive, as did VVG higher spatial frequency CS (20/50) also measurable with small letter CS testing, a potential new metric for glaucoma. Finally, the VVG test can be used to sum log CS across spatial frequencies as a sensitive, expedient metric of overall CS which may prove useful to monitor vision in advanced disease.

ABSTRACT BODY:

Purpose: To identify marker genes, differential gene expression and retinal ganglion cell (RGC) subtypes in human induced pluripotent stem cell (iPSC) derived retinal ganglion cells.

Methods: Human pluripotent stem cells were differentiated into RGCs using a novel step-wise differentiation protocol developed in our laboratory (PMID:32678240). Single cell sequencing was performed on mature and functional iPSC-RGCs at day 40 using 10X Genomics Single Cell RNA Sequencing following the Chromium Single Cell 3' V3 protocols. Sequencing libraries were run on Illumina Novaseq to generate 150 PE reads. The demultiplex FASTQ files were mapped to the hg38 ref genome using STAR package, and cluster analysis were performed using the cell ranger single cell software. The qc analysis was performed by removing the reads corresponding to ribosomal and mitochondrial genes, as well as cells that had a mean absolute deviation (MAD) lower than 1X. Sub-populations of single cell clusters were identified using unsupervised clustering. Differential expression gene (DEG) analysis of the identified clusters was performed to characterize subsets of RGCs and RGC markers in the iPSC-RGCs. Results from day 40 were compared and analyzed with single sequencing data obtained from iPSC-RGCs matured till day 35 and day 74.

Results: After filtering for mitochondrial reads (>20%), ribosomal reads (>50%) and 1X MAD, 4705 cells that passed quality control were analyzed. Cells were separated into 11 clusters based on the gene expression normalization via PCA and TSNE analysis in the Seurat tool. Several previously known RGC marker genes like MAP2, RPBMS, TUJ1, BRN3A, SOX4, TUBB3, SNCG, PAX6 and NRN1 were found to be expressed in iPSC-RGC clusters. Differential expression analysis between the separate clusters identified (average log fold change > -0.25 and < 0.25) significant DEG transcripts associated with cell cycle, transcription factor neuron regulatory networks, protein kinases, calcium signaling, growth factor hormones and homeobox transcription factors. Further cluster refinement identified RGC diversity and subtype specification within iPSC-RGCs.

Conclusions: We have identified both known and novel marker genes to distinguish subsets of RGCs. The DEGs can be used as biomarkers for RGC subtype classification that will allow screening model systems that represent a spectrum of RGC damaging disease.

Amer Riazuddin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal endothelial dystrophies are responsible for a large percentage of corneal transplants performed around the world. A number of corneal transplant techniques, full and partial thickness keratoplasties, have been developed that are highly effective in restoring vision. However, in many areas of the world, there is a shortage of transplantable-grade donor corneal tissue. Here, we evaluate the efficacy of cryopreserved human embryonic stem cell (hESC)-derived corneal endothelial cells (CECs) to form a functional monolayer of corneal endothelium (CE) in pre-clinical animal models.

Methods: H9 hESCs were differentiated to generate CECs under xeno-free conditions. A silicone needle was used to remove the resident CECs in an 8 mm diameter area of the central cornea of rabbits and monkeys, and cryopreserved hESC-derived CECs were injected in the anterior chamber. The animals were placed in an eye-down position for three hours to allow the injected cells to settle on denuded Descemets Membrane (DM). The clinical examination of post-operative eyes was performed by evaluating intraocular pressure, corneal thickness, and CEC density at different time points. Immunohistochemical (IHC) analysis was performed to confirm the expression of ZO-1, Na⁺/K⁺ ATPase α 1, and N-cadherin. A detailed necropsy and CBC/blood chemistry examination was completed 9- and 12-months post-injection in rabbits and monkeys, respectively.

Results: The injected corneas became clear within 3-4 weeks post-injection in both rabbits and monkeys accompanied by a negligible difference in the corneal thickness between the injected (right) eye and the untreated (left) eye. Confocal scanning microscopy confirmed an intact layer of hexagonal/polygonal cells in the CE formed from the cryopreserved hESC-derived CECs. IHC analysis illustrated intact tight junctions, pump function, and structural integrity of the injected cryopreserved hESC-derived CECs. Finally, all parameters examined during the CBC/blood chemistry analysis were within the normal physiological range while necropsy examination confirmed no remarkable change in multiple tissues examined for teratoma formation.

Conclusions: We present an alternative to eye bank donor corneal tissue of cryopreserved hESC-derived CECs for restoring vision in corneal endothelial dystrophies.

ABSTRACT BODY:

Purpose: To investigate cholesterol efflux capacity (CEC) of serum samples from patients with age-related macular degeneration (AMD), and to analyse the serum lipid subfractions of the lipidomics data obtained by using nuclear magnetic resonance (NMR).

Methods: CEC of the serum and their routine lipoprotein profiles were analysed in control, early AMD, typical neovascular AMD (tAMD), and PCV groups and lipid subfractions were measured using NMR analysis in control, early AMD, and PCV samples (Nightingale Ltd, Helsinki, Finland). Analysis of covariance (ANOVA) was conducted to compare the baseline characteristics and routine lipoprotein profiles of the serum samples among the four groups. Multiple regression analysis was used to investigate the difference in CEC between the four groups. Associations between CEC and the lipid subfractions were examined by Pearson correlation coefficient. $P < 0.05$ was considered to be significant.

Results: Mean (SD) ages were similar across four groups (controls, 66.7 (8.5); eAMD, 67.1 (9.3); tAMD, 69.4 (7.9); PCV, 68.3 (9.2) years old: $P = 0.1515$). Early AMD and PCV had a significantly higher CEC than controls, while that of tAMD was comparable with controls after adjusting for age, gender, and use of lipid lowering drug ($P < .0001$). CEC in PCV was higher than early AMD ($P < .0001$). Using conventional lipid biochemistry, tAMD and PCV had higher levels of HDL and LDL cholesterol compared with controls ($P < .02$), although there was no significant difference of those between tAMD and PCV ($P > .05$). NMR lipidomics demonstrated that mean diameter of HDL and LDL was larger and that of VLDL was smaller in PCV compared to control. In early AMD, the diameter of HDL was higher, whereas the diameter of LDL and VLDL was not different from controls. Lipid subfraction analysis showed that the concentrations of large and medium HDLs and large and medium VLDLs as well as the ratio of ApoB to ApoA1, were significantly associated with PCV ($P < .00022$). However, extra-large HDL and small VLDL were not associated with PCV ($P \geq .00022$).

Conclusions: CEC of the serum samples was higher in PCV and early AMD than controls, while that of typical AMD was comparable to controls. Additionally, the lipid subfractions (especially HDL subfractions) were altered in PCV, suggesting that especially HDL among all lipids has a role in the pathogenesis of PCV.

ABSTRACT BODY:

Purpose: Hydrogen sulfide (H_2S) is a common environmental pollutant and a chemical warfare agent. H_2S exposure to the eye leads to ocular irritation, pain, and vision loss, however, underlying molecular mechanisms driving its toxicity to the cornea is still unclear. We sought to study changes in cellular and molecular parameters in primary human corneal stromal fibroblasts following H_2S exposure in vitro.

Methods: A total of 30 healthy human donor corneas obtained from the eye bank were used in this study. Primary human corneal stromal fibroblasts (hCSFs) were generated from healthy donor corneas following our standard protocol and passages two to five were used for in vitro experiments. Sodium hydrosulfide (NaSH) was used as a source of H_2S and hCSF cells were exposed to H_2S for up to 72h and the changes in mitochondrial function were assessed using Complex IV (cytochrome c oxidase) Human Specific Activity Microplate Assay Kit (Abcam, Cambridge, MA, USA) according to the manufacturer's guidelines. The mRNA expression of cell death genes - Receptor-interacting serine/threonine-protein kinase 1 (RIP1), Tumor necrosis factor receptor type 1-associated DEATH domain protein (TRADD), Caspase 8, and Mixed lineage kinase domain-like protein (MLKL) was studied using QuantStudio 6 Flex Real-Time PCR System (Applied Biosystems, CA, USA).

Results: H_2S exposure showed dose and duration dependent cytotoxicity to hCSFs in cytotoxicity assays and IC_{50} of H_2S was determined to be 5.35 mM. H_2S IC_{50} exposed hCSFs showed significantly decreased levels of cytochrome c oxidase enzyme activity ($p < 0.01$) and quantity ($p < 0.0001$) compared to healthy cells. The mRNA expression of RIP1, TRADD, Caspase 8, and MLKL genes were significantly altered in H_2S IC_{50} exposed hCSFs compared to control ($p \leq 0.05$).

Conclusions: H_2S exposure to human corneal fibroblasts activates cell death pathways and damages mitochondrial function in vitro.

ABSTRACT BODY:

Purpose: Patients with rapidly progressing glaucoma must be identified quickly to receive aggressive treatment to save their vision. Progression is diagnosed with visual field tests, but current tests lack precision, with a test-retest variability of ~1.0 dB in mean sensitivity (MS) for moderate to severe glaucoma. New at-home tests with redesigned psychophysical procedures have recently made it practical to test 10 times in 5-10 days (Deiner, Damato & Ou, 2020. Implementing and Monitoring At-Home VR Oculo-kinetic Perimetry During COVID-19. Ophthal 127:1258). The additional data reduces test-retest variability by a factor of $\sqrt{10}$, to 0.3 dB. We asked how many months are needed to detect rapid progression (-2 dB/year) for a patient taking quarterly clusters of 10 tests, as compared to a conventional test quarterly or twice-yearly.

Methods: Simulations in Matlab modeled progression in 10,000 cases each at rates of 0 dB or -2 dB/year, respectively. Test-retest variability for single tests was 1.0 dB. Specificity was set to 0.95 and sensitivity to 0.8. The testing procedure continued until the fitted rate parameter for progression (the slopes of the regression lines) could be segregated by a boundary, with 95% of non-progressors below, and 80% of progressors above, the boundary.

Results: Detecting progression took 24 months for tests administered twice yearly, 18 mos for quarterly, but only 9 mos for 10-test clusters quarterly. Alternatively, specificity and sensitivity could be 99% and 98% respectively, for time-to-detect of 36, 27, and 12 months, respectively. Many glaucoma patients have test-retest variability < 1.0 dB. In a patient whose test-retest variability is 0.5, time-to-detect is 6 months for quarterly clusters. It is similarly reduced if the new at-home test has better test-retest variability than conventional tests.

Conclusions: Even by itself, at-home testing of visual fields using conventional psychophysical methods would greatly improve treatment of glaucoma. Additionally, new testing procedures that are less fatiguing for the patient mean that 10 tests can be collected at a time, shortening the time to detect progression to as little as 6 months.

ABSTRACT BODY:

Purpose: NAC Attack is a Phase III multicenter, randomized, and placebo-controlled study to evaluate the efficacy and safety of oral N-acetylcysteine (NAC) in patients with RP and is in the planning phase. It aims to enroll 438 eligible patients who will be randomized to either 1800mg/bid NAC or placebo. This study aimed to learn patients attitudes of participating a clinical trial to facilitate the trial design and assess recruitment potential.

Methods: Crowdsourcing is a method that utilizes social media to quickly involve a group of people for ideas. It was used to survey RP patients attitudes toward a study of over 4 years to test an oral medication to slow or stop vision loss caused by RP. The survey questionnaire was developed by the NAC Attack Study Chair and Coordinating Center in collaboration with the USHER 2020 foundation. The survey required no protected health information. It was administered using Google Form by USHER 2020 from Aug to Nov of 2020. The survey link was sent to various email lists of retinal patient advocacy groups, social media, emails through My Retina Tracker of Foundation Fighting Blindness, and was picked up by other RP patients listserve. The study was approved by the JHU IRB.

Results: There were 1473 responses: 24% were of age 18-40, 60% were 40-69, and 15% were >70 years; female was 56%; 20% patients had genetic testing done before but the genetic cause was not found; 96% used a mobile phone and among them 96% received text messages; 61% were very and 18% somewhat enthusiastic about participating in a trial; 70% were very and 28% somewhat willing to have a clinical visit every 4-5 months for 45 months; 83% were very and 15% somewhat willing to have a tele-visit with a doctor between clinical visits.

Acceptability of a daily text reminder of medication was 60% Yes, 24% No, and 13% don't know; 70% were willing to report any missing dosages or problems related to medication using a text message based system daily or weekly.

Conclusions: Enthusiasm was high for participating a clinical trial that may find an effective treatment for RP. Rates of possession of mobile phones and usage of text messages were high. Using SMS messages to keep patients engaged and to encourage and survey their medication adherence is feasible. NAC Attack will have in-clinic follow-up visits every 9 months and in-between every 4.5 months a televisit with site investigator.

ABSTRACT BODY:

Purpose: Cataract is the most prevalent cause of avoidable blindness worldwide. Poverty and blindness are inextricably linked. We developed a protocol to evaluate the potential economic benefits of cataract surgery for the household in resource-limited settings. This report describes baseline characteristics of the current cohort and lessons learned from following-up patients during the pandemic.

Methods: In this prospective cohort study, patients 40 years or older with symptomatic age-related cataract seeking care at "Instituto Mexicano de Oftalmología" (Queretaro, Mexico) and residing within 30 km of the facility were eligible. Patients with complicated cataracts and coexisting eye conditions were ineligible. Patients received a comprehensive eye exam, assessment of economic status at baseline, and standard clinical care for cataract. Follow-up is planned at 6, 12, and 36 months using surveys on surgical and economic outcomes, including monthly household income and total household budget (USD).

Results: The present cohort includes 42 patients. 61.90% were women and 38.09% were men. The mean age was 71 (standard deviation; SD 10.30). 19.04% were uninsured, 45.23% were covered by the Institute of Health for the Wellbeing and 35.71% were covered by employment-based government insurance entities. 42.85% and 57.14% of patients lived in a rural and urban area, respectively. At baseline, average monthly household income was \$438 (SD = \$377 USD); it was \$330. USD (SD = \$320) for patients in rural areas and \$508 (SD = \$400) for patients in urban areas. The average monthly household budget before cataract surgery (including food basket, health, educational, housing, personal and housing expenses) was \$240 (SD = \$294) and \$144 (SD = \$114) for patients in urban and rural areas, respectively. Of 5 patients followed up at 6 months, the average monthly household income was \$239 (SD = \$46), with a difference of \$199 from baseline. Recruitment was challenging because we restricted eligibility by how far patients lived from the hospital. Follow-up in the context of the Covid-19 pandemic continues to be a challenge, although administering surveys by phone may facilitate it.

Conclusions: Our findings show feasibility of conducting this study. To ensure a representative patient sample, effort is underway to implement the study protocol at multiple centers in Mexico, India and Brazil.

ABSTRACT BODY:

Purpose: Genetic mutations in the RHO gene lead to structural disability of the photopigment rhodopsin, resulting in rod cell death and vision loss accounting for 25-30% of autosomal dominant retinitis pigmentosa cases. The goal of this study is to seek pharmacological strategies for preventing rod cell death by restoring rhodopsin homeostasis.

Methods: A total of 23 single mutations have been generated on the extracellular side of human rhodopsin, and these cDNA constructs were transfected to NIH3T3 cells in 384 wells. Cells were treated with compounds at 24 h after transfection and DMSO was used as vehicle control. Cell-surface immunostaining of rhodopsin was performed after 24 h of treatment, and immunofluorescence images were taken by a high-content imaging system.

Immunofluorescence of rhodopsin per cell was quantified based on the analyses of 400-600 cells per well, averaged by three replicates. Cell viability was quantified by the number of cells per well. A docking calculation was performed by the AutodockVina software using the bovine rhodopsin structure (PDB ID: 1f88) as the structure template. 11-cis-retinal was deleted from the density to leave the chromophore pocket for the docking of small molecules. ΔG s were obtained indicating the stability of the complex of rod opsin with each compound. To test the effect of small molecule chaperone on retinal morphology and function in vivo, we injected YC-001 suspension in PBS intravitreally to the eyes of Rho^{P23H/+} mice at PND15, OCT and ERGs were taken at PND28.

Results: We showed that three rhodopsin chaperones we identified previously improved the transport of multiple, but not all mutants of rhodopsin to the plasma membrane. Scriptaid showed non-selective rescue to all the mutants of rhodopsin, with high cytotoxicity. YC-001 was docked within the chromophore pocket at the ionone side. One intravitreal injection of YC-001 showed improved scotopic ERG responses in the Rho^{P23H/+} mice at PND28.

Conclusions: Our results provide a pharmacological profile of two small molecule chaperones towards misfolding rhodopsin mutants, suggesting the efficacy of pharmacological chaperones are highly dependent on the mutation site and residue of rhodopsin. The short-term efficacy of YC-001 in Rho^{P23H/+} knock-in mice strongly supports that restoring rhodopsin folding can prevent rod cell death caused by RHO mutants that carry mild folding defects.

ABSTRACT BODY:

Purpose: Lens epithelial cells undergo epithelial to mesenchymal transition (EMT) after injury, resulting in the generation of myofibroblasts and tissue fibrosis in the lens. This process is comparable to the maturation process of a cataract and also to the postoperative features on the anterior capsule after cataract surgery.

In some cases, literature suggests the possibility of an anterior subcapsular cataract after Implantable Collamer Lens (ICL) implantation. This effect is associated with the contact of the ICL with the crystalline lens, especially in older patients and patients with a narrow anterior chamber. The aim of this work is to study the generation of anterior subcapsular opacity in the lens after mechanical stimuli.

Methods: Anterior lens capsules were obtained from cataract surgeries and from healthy donors from the Community Center for Blood and Tissues - CCST.

An explant culture model was performed using the total tissue collected in surgery, usually a 6 mm in diameter disc of the anterior capsule of the lens, containing the anterior subcapsular epithelium.

One group of cultures was exposed to mechanical contact with an sterile ICL with cycles of 2 hours for one week. Control cultures were maintained in normal conditions. Selected cultures from each group were treated with SIS3 inhibitor or with Rapamycin.

The molecular phenotype of the cells in culture was evaluated by means of immunocytochemical techniques in the different phases. Epithelial markers, such as E-Cadherin or β -Catenin, was used, as well as mesenchymal and fibroblast cell markers such as vimentin or smooth muscle actin (α -SMA).

Results: Capsular epithelial cells maintain epithelial morphology and biochemistry in culture. These cells presented the ability to spontaneously express markers of contractile cells, such as α -SMA or vimentin. Expression of α -SMA was increased after mechanical contact with ICL in vitro.

Cultures in which EMT was inhibited showed a lower proportion of SMA cells. Cultures in which ICL contact was interrupted, also exhibited a partial reversion of the fibrotic phenotype.

Conclusions: Contact with implanted collamer lenses in vitro triggered the signaling of contractile fibers production in anterior subcapsular epithelium. This process was partially reversible by removing contact stress.

ABSTRACT BODY:

Purpose: Too many people in the world are visually impaired by glaucoma, largely because the disease is detected too late. Aim: to build a labeled dataset for training an AI algorithm for automated glaucoma screening by fundus photography.

Methods: Color fundus photographs of over 110,000 eyes were obtained from EyePACS, California, USA, from a population screening programme for diabetic retinopathy. A tool was developed specifically for efficient grading. Thirty carefully selected graders (ophthalmologists and optometrists) graded the images. To qualify, they had to pass the EODAT¹ stereoscopic optic disc assessment with at least 85% accuracy and 92% specificity. Of 87 candidates, 30 passed. Each image of the EyePACS set was then scored by varying pairs of two randomly matched graders as 'Referable glaucoma', 'No referable glaucoma' or 'Ungradable'. In case of disagreement, a glaucoma specialist ('third grader') made the final grading. 'Referable glaucoma' was scored only if visual field damage was expected.

¹ Reus NJ, Lemij HG et al. Clinical Assessment of Stereoscopic Optic Disc Photographs for Glaucoma: The European Optic Disc Assessment Trial. Ophthalmology. 2009 Dec 31. [Epub ahead of print] Ophthalmology. 2010 Apr;117(4):717-23.

Results: Approximately 14,000 eyes were graded per week. For the first two weeks, the average time per grading was 21.6 sec, but the grading of "Referable glaucoma" took longer, on average 50.3 sec. Approximately 20 % was scored by a third grader. The overall sensitivity and specificity were, initially, 84% and 90%, respectively. The reference standard for these was the final label, i.e., the consensus between the first two graders, or, in case of any disagreement between the two, the label of the third grader. Measures were then taken to improve these scores for the consecutive gradings. Six graders were disqualified for further participation. Both individualized and general feedback was provided to each of the remaining 24 graders. In addition, online meetings were scheduled to discuss difficult cases. Graders with high sensitivity scores were matched with those who showed high specificities. With these measures, the individual scores improved and the overall quality of the labels as well.

Conclusions: Building a labeled dataset is a huge, but quite feasible task, which calls for careful planning, execution, monitoring and refinement.

ABSTRACT BODY:

Purpose: To characterize the development of non-human primate (NHP) derived retinal organoids in comparison to those derived from human embryonic stem cells (hESCs).

Methods: Human embryonic stem cells (hESCs) and induced-pluripotent stem cells (hiPSCs) derived from non-human primates (*Macaca mulatta*) were differentiated into retinal organoids by using a well-established differentiation protocol. Briefly, embryoid bodies were formed from pluripotent stem cells and induced into neural lineage with neural induction media with the addition of BMP4. Thereafter, self-formation of optic vesicles was allowed to form in a 2D culture in retinal differentiation media (RDM). Optic vesicles were then picked off and suspended in 3D-RDM until analysis. Differences in the timing of differentiation and efficiency of retinal organoid development were assessed by light microscopy, electron microscopy, immunocytochemistry, and next-generation sequencing.

Results: Generation of retinal organoids was achieved from both human and several NHP pluripotent stem cells lines. All hiPSC lines resulted in retinal differentiation with the formation of optic vesicle like structures similar to what has been observed in hESC retinal organoids. NHP retinal organoids had defined structure and were composed of mature retinal cells types including cone and rod photoreceptors. Characterization of cell populations in NHP retinal organoids were assessed by single cell RNA sequencing which allowed comparison of expression profiles of retinal neurons to hESC derived retinal organoids and to samples of retinal tissue. Important differences between rhesus and human cells were measured regarding the timing and efficiency of retinal organoid differentiation. While culture of NHP-derived iPSCs is relatively difficult compared to human stem cells, generation of retinal organoids is feasible and may be more time effective due to an intrinsically faster timing of retinal differentiation.

Conclusions: Retinal organoids can be produced from iPSCs derived from rhesus macaque using established protocols. Important species-specific differences exist that warrant further investigation. The production of NHP retinal organoids may be advantageous to reduce experimental time and cost for basic biology in retinogenesis as well as for preclinical trials in NHPs.

ABSTRACT BODY:

Purpose: Cell technology is one of the most promising approaches to reconstruct the ocular surface and restore the integrity and transparency of the damaged cornea. In the present study, we investigated rabbit limbal stem cells (LSCs) in vitro during several passages in different conditions and used them as a component of the cornea substitute in an animal model of limbal stem cell deficiency (LSCD). The goal was to find a highly proliferative population that can be used for cornea recovery.

Methods: Rabbit LSCs were isolated from rabbit corneoscleral rims using the Dispase II, Collagenase I, and trypsin. Cells were cultured under standard conditions in different media: epithelium growth medium and in DMEM/F12 with serum. LSCs cultured in different media were compared by the main stem markers and markers of differentiation (PAX6, ALDH3A1, ABCB5, p63, cytokeratins 3/12, 14, 15, 19). LSCs at the 6th passage were subjected to air-lifting, cells were cultured in cell culture inserts for 14 days in the epithelial medium. Then cytokeratin 14 and actin were observed. For in vivo study rabbits with previously formed limbal stem cell deficiency were used. LSCs were transplanted inside collagen hydrogel. As a control collagen hydrogel without cells was used. The process of corneal restoration was examined by histological analysis.

Results: It was shown that in DMEM/F12 LSCs have high proliferative potential and after several passages change their morphology and mainly mesenchymal-like cells are observed. In mesenchymal-like LSCs some markers such as $\Delta Np63\alpha$ and PAX6 are present, but change their localization from nucleus to cytoplasm. Even though the population has a mesenchymal-like phenotype, the presence of various cytokeratins was observed in the cytoplasm. Also, it was shown that in LSCs that were subjected to air-lifting, the expression of cytokeratin 14 increased. On the 90th day after transplantation mesenchymal-like LSCs to rabbits with previously formed LSCD, normal corneal epithelium was restored, vascularization, and goblet cells were absent. In the control group opacity and neovascularization of the stroma was observed.

Conclusions: During in vitro cultivation, LSCs may undergo an epithelial-mesenchymal transition. It was shown that mesenchymal-like LSCs are a highly proliferative population and are able to restore corneal epithelium in rabbits.

ABSTRACT BODY:

Purpose: Prior studies demonstrate the impact of specific cis-regulatory variants in retinal disease. However, genetic variants are common within cis-regulatory elements and determining which variants have a functional impact remains a major challenge. In this study, we develop a machine learning approach, trained on retinal epigenomic data, to systematically quantify the predicted functional impact of cis-regulatory variants.

Methods: We generated 35 human retinal epigenomic datasets to determine a core set of 47k cis-regulatory elements and train a machine learning model utilizing a gapped k-mer support vector machine. In silico saturation mutagenesis was applied in tandem with the model to predict the functional impact of all potential single nucleotide variants within cis-regulatory elements. Impact scores were validated against known TF binding motifs, previously characterized variants, phylogenetic conservation, and population frequencies.

Results: Five-fold cross-validation demonstrates that the model distinguishes between active human retinal regulatory elements and negative test sequences within 95% accuracy. Positively-scoring sequences are enriched for motifs corresponding to transcription factors necessary for retinal function. Additionally, this model quantified the predicted impact of all possible single nucleotide variants (SNVs) within 20k human retinal CREs, yielding a wide range of impact scores. Variant scoring correlates with observed changes in population frequency.

Conclusions: In this study, we demonstrated the use of human retinal epigenomic data to train an effective machine learning model, which can be used to predict the impact of sequence variations. Our model demonstrated the ability to accurately score sequences and identify relevant motifs, which can be used to identify sequence variants of interest. This modeling has potential to expedite the search for and characterization of natural sequence variants in the context of retinal disease.

ABSTRACT BODY:

Purpose: Trabecular meshwork (TM) stiffening in primary open-angle glaucoma (POAG) arises from elevated ROCK-mediated TM cell contraction and extracellular matrix (ECM) deposition/crosslinking. YAP/TAZ play central roles in TM mechanoregulation and increased YAP/TAZ activity has been linked to glaucomatous TM stiffening. Common cholesterol-lowering statins competitively inhibit HMG-CoA reductase (HMGCR), which potently decreases YAP/TAZ activity. Statins also inhibit ROCK activity upstream of YAP/TAZ. Here, we investigate whether statins can reverse glaucomatous TM cell dysfunction using a tissue-engineered TM hydrogel model.

Methods: Normal TM/glaucomatous GTM cells were isolated from surgical discard corneal rims/POAG globes. Cells were plated on glass coverslips or encapsulated in photocrosslinked hydrogels (collagen type I, elastin-like polypeptide and hyaluronic acid). Glaucomatous conditions were induced with DEX/TGF- β 2, then treated with cerivastatin or simvastatin; GTM cells were used for validation and proven ROCK inhibitor Y27632 served as treatment control. Cell morphology and cytoskeletal organization were assessed by phalloidin staining for f-actin. Immunoblot and immunostaining were used to evaluate YAP/TAZ expression/activity and changes in cell contractile force regulation. TM hydrogel contraction and stiffness were determined by longitudinal imaging and oscillatory rheology.

Results: Induced TM and GTM cells exhibited decreased cytoplasmic (inactive) pYAP and increased nuclear (active) YAP/TAZ with increased downstream TGM2 (an ECM crosslinking enzyme) vs. controls ($p < 0.01$); this was significantly reduced with either statin in a dose- and time-dependent manner. These effects were reversed by supplementation of mevalonate, thus bypassing statin-mediated HMGCR inhibition. Statin treatment restored glaucomatous actin stress fibers, and pMLC/ α -SMA levels to baseline. Immunostaining revealed significant statin-mediated reduction of glaucomatous fibronectin deposition. Pathologic TM hydrogel contraction and stiffening were potently rescued with statin treatment; constructs were significantly relaxed and softened ($p < 0.01$), comparable to direct ROCK inhibition.

Conclusions: Our data suggest that indirectly targeting the YAP/TAZ mechanoregulatory axis with statins presents an intriguing avenue for treating glaucomatous TM dysfunction with high translational potential.

ABSTRACT BODY:

Purpose: Adaptive-optics scanning laser ophthalmoscopy (AOSLO) uses a wavefront detection and a deformable mirror for wavefront correction. These instruments are very expensive and cumbersome to maintain and operate. We have used the high-magnification module objective for a commercial scanning laser ophthalmoscope to image the photoreceptor cone mosaic. We wanted to compare the photoreceptor images captured with both devices.

Methods:

The Heidelberg Engineering High Magnification Module for the Spectralis SLO is a special lens that images an area of 8° x 8° degrees. The normal imaging modes of high-speed and high-resolution are supported. Blue and green imaging are not supported. We imaged 10 subjects with and without glasses. We used proper refraction to allow imaging with proper spherical and cylindrical correction. We used room light to limit the pupil to about 3 mm to achieve diffraction-limited imaging. We compared the photoreceptor images obtained with the HMM lens with images obtained with a custom-built adaptive optics scanning laser ophthalmoscope (AOSLO).

Results: We found that in more than half the subjects we were able to image the photoreceptor mosaic in the patients using 3 mm pupil and proper spherical and cylindrical correction.

We used image steering to confirm that our imaging areas were similar for the AOSLO and HMM imaging.

The photoreceptor density using the High Magnification Module was within 10% of the density as measured in the same region using the AOSLO.

Conclusions: The High Magnification Module was able to image the photoreceptor cone mosaic in more than half the cases. The use of the HMM lens has some limitations. Since the module is a fixed optical element, the module cannot correct for aberrations. Instead, the HMM uses the diffraction-limited 3 mm pupil to achieve optical imaging conditions. The human eye can be considered diffraction-limited up to a pupil diameter of 3 mm. This was confirmed by our experiments. Increase the pupil diameter beyond 3 mm decreased image quality.

We found that we could use the High Magnification Module for pre-screening of patients for imaging with the AOSLO. It is well known that AOSLO imaging is not possible in all subjects due to other optical limitations. If we were able to image the mosaic with the HMM lens, it was also possible to image with the AOSLO.

ABSTRACT BODY:

Purpose: Subconjunctival blebs are utilized in glaucoma surgeries and in drug delivery with lymphatics hypothesized to drain them. Limited direct evidence for lymphatic outflow is available in live human subjects. The purpose of this study is to perform simultaneous subconjunctival outflow imaging and structural assessment to uncover pathway identity in live human subjects.

Methods: Patients were identified who required intravitreal injections to treat retinal disorders. For anesthesia, they receive subconjunctival lidocaine. Subjects were consented for subconjunctival lidocaine injections (1.98%) that also contained indocyanine green (ICG; 0.005%) (UCLA IRB 20-001064) to perform ocular surface lymphangiography. Subjects were angiographically imaged on their ocular surface (Spectralis; Heidelberg Engineering) to visualize the bleb and ICG-labeled outflow pathways. Simultaneous anterior segment optical coherence tomography (OCT) was performed in cross-section or longitudinal to these pathways.

Results: Fourteen subjects were imaged (M/F=6/8; 77.4±2.6 years [mean±SEM]). Subjects (n=4) who were immediately imaged after tracer injection demonstrated fluorescent blebs but no outflow pathways. All subjects who were imaged after completion of the clinical visit (n=10 subjects; 16±1.6 min after subconjunctival tracer injection) showed visible blebs with 7/10 subjects also demonstrating visible outflow pathways. The pathways appeared sausage-shaped (thicker alternating with thinner regions). OCT in cross-section to these pathways clearly demonstrated superficial subconjunctival lumens. OCT longitudinal to these pathways demonstrated the presence of semi-lunar valves or flaps.

Conclusions: Angiographic imaging of subconjunctival outflow demonstrated sausage-shaped outflow pathways that have been described and that are hypothesized to represent lymphatics. Simultaneous OCT imaging demonstrated valves, a lymphatic hallmark. This study provides multimodal outflow/structural imaging evidence confirming the hypothesis that lymphatics drain blebs in live humans.

ABSTRACT BODY:

Purpose: Swabs are the most widely used sampling devices for ocular surface infections, including infectious corneal ulceration. However, no current standards of care exist to inform optimal swab compositions that maximize pathogen yield from the cornea. We evaluated the performance characteristics of a range of commercially available swabs, with a view to improve the sensitivity of culture-based microbiology and emerging molecular diagnostics for corneal infections.

Methods: Candidate swabs were chosen according to the American Academy of Ophthalmology Preferred Practice Pattern for Bacterial Keratitis, including mini-tipped flocked (Puritan® PurFlock and HydraFlock, and Copan FLOQSwab®), and traditional spun-fiber swabs (Puritan® polyester, rayon, calcium alginate and cotton). Swab absorption was determined with serial weights before and after immersion in phosphate buffered saline (PBS), and distribution volumes obtained by applying saturated swabs to tryptic soy agar (TSA) using the roll-plate technique per the Clinical Laboratory Standards Institute (CLSI). Recovery efficiencies were determined using a modified CLSI swab-elution protocol. Swabs were contaminated with a standardized inoculum of log-phase *Staphylococcus aureus* (ATCC 29213), eluted in PBS, and serial dilutions plated in tracks on 0.3% TSA. Viable counts were observed at 18 hours, and recovery efficiency calculated as the ratio of colony forming units (CFU/mL) in swab solutions compared to that of the original liquid culture, corrected for swab absorption.

Results: Flocked swabs had higher mean absorption values than spun-fiber swabs, both in absolute volume (Fig.1A) and per unit mass (1359–1543% vs. 200–578%, respectively). Agar distribution volumes were also greater among flocked swabs (Fig.1B and C). Mean recovery efficiencies (%) for PurFlock, HydraFlock and FLOQSwab were 78.9±10.1, 84.4±9.0, 84.5±13.9, respectively, compared to 52.7±14.4 for polyester, 91.0±17.7 for rayon, 54.0±15.8 for calcium alginate and 8.1±2.6 for cotton (Fig.2, $p<0.001$). Bonferroni-adjusted pairwise comparisons revealed significantly lower recovery efficiencies for calcium alginate compared to each flocked swab (all $p<0.001$).

Conclusions: New-generation flocked swabs outperformed spun-fiber swabs in terms of absorption, distribution, and recovery efficiency. Their use may translate to greater microbial yield, which could aid in diagnosing low-biomass corneal infections.

ABSTRACT BODY:

Purpose: VEGF Receptor dimer activation is critical for regulating downstream signaling cascades in angiogenesis. However, not much is known about these processes in corneal nerve repair. Previous studies have shown that the non-angiogenic ligand VEGF-B has potent roles in the peripheral nervous system (PNS). The molecular mechanism of VEGF-B-mediated corneal nerve growth is unclear and may be due to differences in VEGFR1 homo- and heterodimer presence. The purpose of this study was to investigate the presence of VEGFR1 and R2 homo- and heterodimers and characterize similarities and differences in their distribution compared to endothelial cells.

Methods: Rat neuronal (PC12), mouse aortic endothelial (MAE), mouse venous endothelial (MVE) and human umbilical venous endothelial (HUVEC) cell lines were used. Cells were acutely stimulated either with VEGF-A (50 ng/μL; VEGFR1 and VEGFR2 binding) or VEGF-B (50 ng/μL; VEGFR1 binding) or “vehicle” (PBS; control group). We also isolated mouse trigeminal ganglion cells from thy1-YFP neurofluorescent mice. After treatment, cells were used as follows: (i) One group was fixed in 4% paraformaldehyde and processed for VEGFR1 and VEGFR2 immunostaining and visualized using confocal fluorescence microscopy and Total Internal Reflection (TIRF) microscopy; (ii) the second group was harvested in cell lysis buffer (containing anti-protease / anti-phosphatase cocktail), lysed and processed for immunoprecipitation (IP; Thermo Fisher IP kit) and immunoblotting (IB; LI-COR® Systems). Immunoprecipitated proteins were probed either with anti-VEGFR1 or anti-VEGFR2 IgG antibodies to evaluate VEGFR1-R2-heterodimerization; (iii) a third group of cells were also processed for Proximity Ligation Assay (PLA; Sigma) to assess the presence and distribution of VEGF Receptor homo- and heterodimers.

Results: TIRF and fluorescence confocal microscopy showed presence of VEGFR1 co-localized with VEGFR2 in endothelial and neuronal cells. Cell lysates immunoprecipitated with anti-VEGFR1 further validated the existence of VEGFR1-R2 heterodimers in neuronal cells. Neuronal cells showed higher levels of VEGFR1-R2 heterodimers compared to endothelial cells whereas endothelial cells showed higher levels of VEGFR2-R2 homodimers as shown by PLA studies.

Conclusions: Differences in VEGF Receptor homo- and heterodimer distribution may explain the differential role of VEGF ligands in neuronal vs endothelial cell types.

ABSTRACT BODY:

Purpose: Lebers Congenital Amaurosis (LCA16) is a monogenic pediatric blindness caused by point mutations in the KCNJ13 gene. This gene encodes an inwardly rectifying potassium channel (Kir7.1) required for retinal pigment epithelial (RPE) function. Gene augmentation, through lentiviral delivery of healthy KCNJ13 ORF, has been shown to rescue Kir7.1 channel function in patient iPSC-RPE cells and a conditional knockout (cKO) mouse. The rescue of RPE cell function in the cKO mouse also resulted in ERG c-wave recovery and preserved retinal integrity. The present study tested in vitro transgene expression from HUB-101, a gene therapy product in development for Kir7.1 replacement in LCA16.

Methods: Eyes from 4-6-week old wildtype C57BL6 mice were used to culture mature primary RPE cells. After culturing cells in 96-well plates for 0, 7, 14, and 28 days, RNA was isolated and converted to cDNA to assess maturation markers. Maturity of cells was confirmed using qPCR to measure Gapdh, Rpe65, Best1, and Rbp1 gene expressions. HUB-101 is an adeno-associated virus (AAV5) containing KCNJ13 under the control of the VMD2 promoter. Mature RPE cells were transduced with 1×10^8 , 1×10^9 , or 1×10^{10} particles of HUB-101 per well. HUB-101 vehicle served as a negative control. Seven days after transduction of HUB-101, RNA was isolated and converted to cDNA for qPCR assay. Specific molecular expression of HUB-101 in mouse RPE was assessed by measuring hGAPDH, hKCNJ13, and AAV ITR transcripts, along with mGapdh, mKcnj13 serving as experimental controls.

Results: Expression profiles of Rpe65, Best1, and Rbp1 indicated that RPE cells matured as early as 14 days in culture, with characteristic pigmented appearance. The matured primary RPE cells in culture, when transduced with HUB-101, showed dose-dependent expression of both hKCNJ13 and AAV ITR transcripts compared to vehicle-treated controls. In comparison, no changes in expression of mGapdh or mKcnj13 transcripts were detected, as expected.

Conclusions: We established a species-specific detection of candidate gene therapy product as a preclinical validation. Our results further confirm that HUB-101 can transduce mature RPE cells in vitro, with the KCNJ13 gene's dose-dependent expression. These data support the further evaluation of HUB-101 in nonclinical safety and toxicity studies, with the ultimate aims of clinical testing and restoration of sight in patients with LCA16.

TITLE: Topical Application of Hydralazine Induces Resistance Against Oxidative Stress In Eye Lenses By Activating Nrf2-mediated Antioxidant Response Genes

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.P. Singh, B. Chhunchha, Ophthalmology and Visual Sciences, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|H. Sasaki, E. Kubo, Ophthalmology, Kanazawa Medical University, Kanazawa, Ishikawa, JAPAN|

Commercial Relationships Disclosure (Abstract): Dharendra Singh: Commercial Relationship: Code N (No Commercial Relationship) | Bhavana Chhunchha: Commercial Relationship: Code N (No Commercial Relationship) | Hiroshi Sasaki: Commercial Relationship: Code N (No Commercial Relationship) | Eri Kubo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Deterioration of antioxidant response with advancing age is a leading cause of age-related pathologies. Therapeutic activation of antioxidant pathway has been suggested as an effective strategy to combat aging pathobiologies. Hydralazine (Hyd), an antihypertensive, has been shown to be a potent activator of Nrf2 (NFE2-related factor 2) pathway. Using C57BL/6 mice as a model system, we showed that topical instillation of Hyd in the eye activates Nrf2/ARE (antioxidant response element) pathway, and these lenses gained resistance against oxidative stress-induced insult.

Methods: 16-month old mice (n=12) were used for study, and anaesthetized with an oxygen-isoflurane before Hyd instillation. Buffered saline (n=6) or 25µM/5µl (n=6) of Hyd in buffered saline (pH7.4) was instilled once daily in the eyes for 5 days and lenses were collected. Total RNA and protein were isolated and processed for qPCR and Western analyses to assess levels of Nrf2 and its target genes like Prdx6 and other phase II enzymes expression using probes specific to the molecules. In another set of ex-vivo experiments, Hyd-treated or untreated lenses were exposed to 100µM of H₂O₂ to assess lens opacity. 72h later lenses were photographed (Nikon SMZ 745T) and intensity of lens opacity was determined using densitometry. H2DCF-DA dye measured reactive oxygen species (ROS) levels. Two-tailed Student's t-test and one-way ANOVA were used for statistical analysis.

Results: Hyd instilled lenses displayed significantly increased expression of Nrf2 and its target antioxidant genes mRNA and protein, such as Prdx6, Catalase, SOD1, HO1, Gpx1 and GSTπ (p<0.001) compared to untreated lenses. ROS quantitation showed that Hyd instilled lenses had significantly reduced ROS levels compared to untreated lenses. Untreated lenses developed H₂O₂-induced lens opacity ex-vivo, while Hyd treated lenses showed significantly less opacity; 82% at 48h and 70% at 72h of H₂O₂ exposure in comparison to untreated lenses as analyzed by densitometry.

Conclusions: Our findings, for the first time, reveal that topical instillation of Hyd can activate Nrf2/ARE-pathway in lenses in vivo and these lenses engender resistance against oxidative stress. Our study also provide a foundation for further study of Hyd as a viable therapeutic candidate for the treatment or prevention of age-related diseases, including cataract.

ABSTRACT BODY:

Purpose: Axon regenerative failure in the mature CNS contributes to functional deficits following traumatic injuries, ischemic injuries and neurodegenerative diseases. Although neuro-immune interactions modulate critical CNS functions, potential contributions of the classical complement cascade and myeloid cells to CNS axon regeneration or its failure are largely unknown. Building on our recent finding that classical complement proteins C1q and C3 and CR3⁺ (CD11b⁺) myeloid cells each increase locally following experimental mouse optic nerve injury and are each required for retinal ganglion cell (RGC) axon regeneration, we tested the hypothesis that complement and phagocytic myeloid cells support RGC axon regeneration by altering the local environment of the injured optic nerve.

Methods: We quantified RGC axon regeneration (GAP43 immunolabeled axons 0.5mm past the injury site) in adult mice 14 days after optic nerve crush plus intravitreal injection of pro-regenerative treatment (zymosan + CPT-cAMP) and localized (either intravitreal, intra-nerve, or intraperitoneal) injection of C1q function-blocking antibody or IgG control (N = 8-16/group). We characterized the local environment of the injured optic nerve with regard to inflammatory response and myelin debris in optic nerve sections collected 1, 5, 7 and 14 days after injury and immunolabeled for CR3, CD68, and myelin basic protein (MBP). We assessed MBP⁺ myelin debris levels 5 and 14 days after optic nerve injury in CR3^{-/-} mice and CR3^{+/+} controls, both with and without pro-regenerative treatment (zinc chelation; N = 6-8/group).

Results: Whereas intravitreal anti-C1q injection did not alter RGC axon regeneration, intra-nerve and intra-peritoneal injections of anti-C1q each decreased axon regeneration by ~50%. We observed an MBP-negative area that expanded from the injury site over time and that closely corresponded to a dense CR3⁺ and CD68⁺ myeloid cell area, as well as MBP localized inside these myeloid cells. CR3^{-/-} mice exhibited a 3.3-fold increase in myelin debris remaining in the vicinity of the injury site compared to CR3^{+/+} controls.

Conclusions: Our data demonstrate that classical complement proteins and myeloid cells act within the optic nerve to support RGC axon regeneration, primarily through phagocytic removal of growth-inhibitory myelin debris. These results point to the importance of the innate immune response for CNS repair.

ABSTRACT BODY:

Purpose: Image curation is one of the fundamental aspects of AI algorithm training, and application of deep learning (DL) and application of DL methods for retinal diseases depends on well-organized, representative images. In this project, we have developed a DL workflow to more efficiently curate retinal photographs, relieving the need for manual evaluation by graders.

Methods: Stereoscopic four-field wide-capture images of the retina are commonly used for evaluating diabetic retinopathy in clinical trials. This entails acquiring red reflex images followed by stereo pair of the disc, macula, a superior, nasal, and inferior field (figure) using 50 – 60-degree camera. Graders review these images in a systematic fashion, one eye at a time, to arrive at a diabetic retinopathy severity level. Submission from clinical sites is not always organized in a manner conducive for grading or for DL training. We designed and trained a neural network to label individual image files in 3 aspects: (1) differentiating red reflex image from a retinal photograph (2) differentiating right eye images from left eye, and (3) identifying the field of the retina. Based on these three parameters, labels were generated by the model and affixed to the image file name. 1631 annotated images from 88 participants were used to train the model, and 404 images from 22 participants were used for validation during training. An independent dataset of 180 images (12 participants) with variable image quality was used for testing the performance of the trained DL model. A human grader independently reviewed the quality of field definition and assigned the field number. This was compared with the DL-generated label. All images were clinical trial submissions for various DR trials across multiple international sites.

Results: Field definition was considered adequate quality in 141 images (78.3%). The labeling model was accurate in 152 / 180 (84.4 %) images in the testing dataset. Of the 28 inaccurately labeled images 18 (64.3%) had poor field definition.

Conclusions: The deep learning model is an accurate automated method that can assist with workflows for organization of images for grader evaluation. This also helps develop well curated training images for future DL development towards disease identification.

ABSTRACT BODY:

Purpose: To evaluate the effect of intraocular pressure (IOP) on the rates of macular thickness (ganglion cell layer [GCL] and ganglion cell and inner plexiform layer [GCIPL]) change over time, measured by spectral-domain optical coherence tomography (SDOCT).

Methods: The study involved 469 eyes of 268 patients from the Duke Glaucoma Registry, a database of electronic medical records of patients with glaucoma and suspected disease followed under routine clinical care at the Duke Eye Center and satellite clinics. All records from patients with a minimum of 6 months of follow-up, at least 2 good-quality Spectralis SDOCT scans, and 2 clinical visits with Goldmann applanation tonometry were included. Rates of change for GCIPL and GCL thickness were obtained using linear mixed models.

Results: Eyes had a mean follow-up of 2.0 ± 1.6 years. Average rate of change in GCL thickness was -0.17 ± 0.22 $\mu\text{m}/\text{year}$ (median -0.17 ; IQR -0.27 to -0.06 $\mu\text{m}/\text{year}$) and -0.15 ± 0.36 $\mu\text{m}/\text{year}$ (median -0.13 ; IQR -0.28 to 0.01 $\mu\text{m}/\text{year}$) in the combined GCIPL thickness. Each 1-mmHg higher mean IOP during follow-up was associated with an additional loss of -0.027 $\mu\text{m}/\text{year}$ of GCL thickness ($P = 0.007$) and -0.048 $\mu\text{m}/\text{year}$ of GCIPL thickness ($P = 0.001$), after adjusting for confounding factors such as baseline age, baseline thickness, sex, race, central corneal thickness and follow-up time.

Conclusions: We quantified the effect of IOP on the rates of macular thickness thinning over time using a clinical population. Higher levels of IOP during follow-up were significantly associated with faster rates of GCL and GCIPL loss over time measured by SDOCT. These findings support the use of SDOCT GCL and GCIPL thickness measurements as biomarkers for the evaluation of the efficacy of IOP-lowering therapies.

TITLE: Ocular surface kinetics of topical fluorescein in Systane Gel

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.P. Srinivas, P.S. Kollbaum, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|H. Farhath Pattan, N. Ravi, P. Padmanabhan, R. Reddi Sudhir, Sankara Nethralaya, Chennai, Tamil Nadu, INDIA|

Commercial Relationships Disclosure (Abstract): Sangly Srinivas: Commercial Relationship: Code N (No Commercial Relationship) | Hadiya Farhath Pattan: Commercial Relationship: Code N (No Commercial Relationship) | Nandini Ravi: Commercial Relationship: Code N (No Commercial Relationship) | Prema Padmanabhan: Commercial Relationship: Code N (No Commercial Relationship) | Pete Kollbaum: Commercial Relationship: Code N (No Commercial Relationship) | Rachapalle Reddi Sudhir: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the Systane gel (SG) effect on the ocular surface kinetics of fluorescein using a custom-made spot fluorometer.

Methods: Experiments were performed with a cohort of healthy subjects with no ocular disease. Informed consent was obtained from all subjects before measurements. Fluorescein (0.5%), formulated in normal saline or SG, was administered as a 30 μ L drop into the lower cul-de-sac. The patients were asked to blink after the drop, and corneal surface fluorescence measurements were begun immediately using a custom-made spot fluorometer. The fluorometer, built to measure fluorescence from any spot in the anterior segment, can record fluorescence at > 1 kHz. The fluorescence measurements, which could be started typically in < 10 seconds after the drop, were continued until baseline levels were observed. The measurements were performed frequently after the drop's administration but at 1-2 samples/min at the later stages. The dynamics of tear fluorescence was fitted to monoexponential decay to determine the elimination rate constant (expressed as half-life) and fluorescence at $t = 0$ (expressed in mV; i.e., initial concentration of fluorescein in tears). The tear meniscus height (TMH) and tear breakup time (TBUT) were also assessed after administration of the drops with a keratograph (Oculus 5M) every 20 mins for 1 hour.

Results: After administration of fluorescein in NS or SG, the tear fluorescence decayed with a single exponential profile. The half-life of tear fluorescence and the fluorescence at zero time after an SG drop were much higher than those with NS ($n = 8$; $p < 0.05$). Fig. 1 shows tear fluorescence vs. time in one subject following SG and NS drops. Although fluorescence vanished from the ocular surface by ~ 20 min (with SG), the mucoadhesive property of SG lasted longer. This was apparent by the keratograph measurements, which showed an increase in TBUT for more than 40 min after an SG drop ($p < 0.05$). NS did increase TBUT significantly, even at 20 min.

Conclusions: The increase in half-life with SG is consistent with increased tear film stability noted with the agent [1-2]. Thus, the half-life of fluorescein on the ocular surface is a measure of the potential efficacy of SG in the artificial tear substitutes employed in the palliative treatment of DED. In conclusion, we have demonstrated a paradigm to assess formulations of artificial tear substitutes for DED with our new custom-made fluorometer.

ABSTRACT BODY:

Purpose: Purpose: Neurons in the central nervous system have a limited ability to survive and regenerate their axons following injury. As a tractable system to study nerve injury, many researchers have turned to the optic nerve crush (ONC) model. In mice, ONC results in the loss of ~85% of retinal ganglion cells (RGCs) within 2 weeks. While many treatments that improve RGC survival and promote axon regeneration have been identified, only a fraction is protected in each case and fewer regenerate. Why do some RGCs respond to interventions while others do not? In this project, we investigated the transcriptional programs mediating survival and axon regeneration in injured RGCs.

Methods: Methods: Targeting the mTor pathway (via Pten deletion) in injured RGCs promotes the survival and regeneration of a subset of RGCs. This effect is broadened when the Jak/STAT pathway is co-targeted (via Socs3 deletion or Cntf overexpression (OE)). Gene expression was characterized by single-cell RNA-seq (scRNA-seq) in >125,000 RGCs following 3 treatments: RGC-specific Pten deletion, Pten deletion with Cntf-OE, or Pten+Socs3 deletion with Cntf-OE at multiple timepoints after ONC. Computational analysis was developed to map cell types, cluster cells, and evaluate expression patterns. Results were validated by immunohistochemistry and in situ hybridization. Candidate genes were tested in vivo using AAV-mediated overexpression or knockdown.

Results: Results: Key results from scRNA-seq expression screens included the following. First, all interventions preserved the expression of cell type markers and suppressed injury-related changes following ONC; much of the effects were observed with Pten deletion alone. Second, each intervention resulted in neuroprotection and axon regeneration with distinct type-specificity. Third, we identified multiple population-specific transcriptional modules correlating with degeneration, survival, and axon regeneration, highlighting the differences among RGCs in their responses to treatment.

Conclusions: Conclusions: Our results gene expression programs that correlate with, and presumably help explain, the enhancement of survival and axon regeneration following targeting of Pten, Socs3, and Cntf in injured RGCs. These findings provide potential therapeutic targets and enhance understanding of why neuronal cell types respond differently to neuroprotective and regenerative treatments.

ABSTRACT BODY:

Purpose: Current glaucoma surgeries utilize stents placed in the subconjunctival or subtenon space to create blebs for eye pressure lowering. However, choice of placement has long been debated in terms of clinical benefit and biological principles. The purpose of this ex-vivo experimental study is to evaluate the subconjunctival vs. subtenon space accessibility for lymphatic outflow pathways after creation of tracer-filled blebs at each location.

Methods: Post-mortem porcine eyes received a subconjunctival (n =10) or subtenon injection (n=10) of 500kD fixable fluorescent dextran tracers. Angiographic bleb and bleb-related outflow pathway images were obtained (Spectralis HRA+OCT; Heidelberg Engineering). Bleb-related outflow pathways were counted as lymphatics only if the lumens showed valve-like structures using near simultaneous anterior segment OCT. We also compared the number of outflow pathways arising from subconjunctival and subtenon blebs in different locations (superior/inferior/temporal/nasal). As the tracers could be fixed in place, histologic analysis of the exact pathways seen on angiographic imaging was performed to confirm imaging results.

Results: Subconjunctival blebs showed a greater number of lymphatic outflow pathways compared to subtenon blebs in every quadrant. (superior, 6.10 ± 1.18 vs. 0.50 ± 0.27 [mean \pm SEM], temporal, 2.30 ± 0.40 vs. 0.10 ± 0.10 , nasal 5.30 ± 0.60 vs. 0.30 ± 0.21 , inferior, 6.00 ± 1.29 vs. 0.1 ± 0.1 ; $p < 0.001$, $p < 0.001$, $p < 0.001$, $p = 0.001$, respectively). For subconjunctival blebs, the temporal location gave rise to fewer pathways compared to nasal ($p = 0.005$). Histological sectioning confirmed these pathways. For subtenon blebs, no quantitative difference in the number of pathways was found comparing locations. Further, histological sectioning around subtenon blebs did not demonstrate the presence of deep pathways that could have been missed on angiographic imaging owing to the increased depth.

Conclusions: Subconjunctival blebs accessed greater lymphatic outflow compared to subtenon blebs

ABSTRACT BODY:

Purpose: Suprachoroidal injection (SCI) via SCS Microinjector[®] is an investigational ocular injection providing high, compartmentalized drug concentrations to chorioretinal layers via the suprachoroidal space (SCS). This post hoc study evaluated safety of SCIs across multiple clinical trials involving an investigational proprietary suspension of triamcinolone acetonide (CLS-TA), focusing on events occurring peri-procedurally.

Methods: Datasets from 8 clinical trials involving three disease states: noninfectious uveitis (NIU), diabetic macular edema (DME) and retinal vein occlusion (RVO) and included patients who received one or more SCI, either as monotherapy or with intravitreal (IVT) anti-VEGF. Procedure-related ocular serious adverse events (SAEs) assessed, occurring rarely with intraocular injections, included lens injury, suprachoroidal hemorrhage, retinal tear, retinal detachment, endophthalmitis, and reduced visual acuity. Treatment emergent adverse events (TEAEs) assessed included eye pain on the day of the procedure. Outcomes were compared to control eyes randomized to receive IVT anti-VEGF monotherapy and sham SCI.

Results: 621 patients received one or more SCI, either as monotherapy (N=161) or with IVT aflibercept (N=460). 3 of 621 patients experienced 3 SAEs of interest, all occurring in patients receiving multiple injections. One NIU monotherapy patient had a retinal detachment, and 2 RVO patients receiving combination therapy had reduced vision; each were deemed not related to treatment by a masked Investigator. There were no SAEs involving lens injury, suprachoroidal hemorrhage, endophthalmitis, or retinal tear in patients receiving SCIs, either alone or in conjunction with anti-VEGF. 449 control patients received IVT anti-VEGF in conjunction with a sham SCI. Three RVO patients experienced 3 SAEs of interest, including retinal detachment, vitreous hemorrhage and endophthalmitis. Each were deemed not related to treatment by a masked Investigator. Of 621 patients undergoing SCIs (161 as monotherapy, and 460 in conjunction with IVT injection), 37 (6%) experienced a TEAE related to eye pain, compared to control, 7 of 449 (1.6%) undergoing IVT injection.

Conclusions: Across 8 clinical trials involving NIU, DME and RVO, the safety profile of SCI, either as monotherapy or in conjunction with IVT injection, is comparable to IVT injections alone for events occurring at or after the procedure.

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of blindness worldwide with elevated intraocular pressure (IOP) being the major risk factor and its reduction being the only approved treatment. In many patients, impaired ocular hemodynamics has also been shown to be involved in its pathogenesis. While it is known that IOP is affected by altitude, the relationship between elevation and ocular hemodynamics is unclear. Here we use mathematical modeling for a physiology-enhanced analysis of the Mont Blanc Study (MBS) (Bruttini et al 2020) to estimate the effects of altitude on retinal hemodynamics.

Methods: IOP, mean arterial pressure (MAP) and heart rate (HR) were measured in 33 healthy volunteers at 77m (Pavia, PV, Italy) and at 3,466m (Pointe Helbronner, PH, Mont Blanc Mountain, Italy) above sea level. A validated mathematical model for retinal hemodynamics (Guidoboni et al 2014) is utilized to analyze the MBS data. Pressures, flow rates and resistances in the central retinal artery and vein (CRA and CRV) and in the retinal microvasculature are predicted by the model, based on individually measured values of IOP, MAP and HR. The model accounts for IOP and MAP induced variables resistances in the retrobulbar segments of the CRA, CRV and in retinal venules (RV). Results between PV and PH are analyzed using t-test with $p < 0.05$ statistically significant.

Results: With altitude, the results predict a statistically significant increase in all retinal pressures ($p < 0.001$, which follows the increasing MAP with altitude observed in the MBS) and in the retinal blood flow across the full retinal circulation ($p < 0.001$, from the CRA inflow to the CRV outflow via the retinal microvasculature), Figure 1. With altitude, the results predict a significant decrease in CRA ($p < 0.001$) and RV (and $p = 0.003$) resistances, and a non-significant increase in the CRV resistance ($p = 0.253$), Figure 2. The resistance in the RV is markedly higher than in the CRA and CRV, suggesting that the venules are withstanding most of the IOP load on the vasculature.

Conclusions: Mathematical modeling can be used to enhance measured datasets with hemodynamic variables that cannot be measured directly, such as the venous resistance. This analysis suggests that venules bear the significant portion of IOP pressure load within the ocular vasculature. Advancement of this approach may include the study of the effect of altitude on oxygen saturation via autoregulation.

ABSTRACT BODY:

Purpose: Pentosan Polysulfate Sodium (PPS) is prescribed to treat bladder pain or discomfort. Pearce et al. [2018] reported a maculopathy in adults taking this medication. We then showed that systemic treatment with PPS causes retinal function diminution in a common laboratory mouse [Girardot et al. 2019]. Here we report further ex-vivo features of this toxicity.

Methods: 10 male and 10 female 129S2/SvPasCrl mice were given intraperitoneal injections of 0.1X Hanks' Balanced Salt Solution (vehicle) or PPS (12 PPS, 8 vehicle mice). Injections were given several days weekly for 31 weeks. Concentration of drug was 10 mg/kg. Mice regularly had retinal function assessed by electroretinography (ERG). After sacrifice, one eye was fixed using freeze substitution for sagittal paraffin sectioning and histology. The contralateral globe was fixed in z-fix for RPE-flatmounts. Flatmounts were dissected within 1 week of sacrifice and stained for ZO-1 and α -catenin.

Results: At 2.5 months we reproduced findings of decreased ERG a- and b-wave amplitudes in the PPS-treated animals, ($p=0.0195$ for b-waves, 0.0084 for a-waves beginning at 3.5 months, two-way ANOVA). We observed several discrepancies in post-mortem immunostaining. In transverse sections, arrestin and rhodopsin staining was increased. Staining was also increased for synaptic markers PSD95 and synaptophysin, and PKC α , a marker of bipolar and retinal ganglion cells. En-face RPE flatmounts showed trends of decreased cytosolic and nuclear α -catenin, which has been associated with DNA damage responses [Serebryanny et al. 2017]. Gender differences were observed and are the subject of ongoing experiments.

Conclusions: PPS treatment has nuanced effects on the retina. Functional decline is accompanied by increases in a variety of cell markers, as well as a trend of differential α -catenin protein translocation. Maybe this is all indicative of damage-induced remodeling (Marc et al. 2003). We are still optimizing our model to simulate a phenomenon that is the result of years, and sometimes decades, of drug treatment. Perhaps cell death and more apparent morphological disruption comes with longer durations of treatment. The link between our work and the clinical observations may become clearer as we continue to improve our model and investigate the underlying biochemical mechanisms.

ABSTRACT BODY:

Purpose: Stargardt disease is inherited as an autosomal recessive trait caused by mutations in the ABCA4 gene, which lead to accelerated accumulation of lipofuscin in the retinal pigment epithelium (RPE) leading to RPE atrophy and photoreceptor cell death. There is currently inadequate information on the complexity of changes in lipid composition, homeostasis, metabolism, and lipid-mediated signaling of the RPE, leading to ABCA4 retinopathy. ABCA4^{-/-} mouse model has shown similar phenotypes of human ABCA4 retinopathy, particularly lipofuscin deposits in the RPE. To understand the role of ABCA4 in RPE lipid profile and its contribution to Stargardt disease pathogenesis, we used the ABCA4^{-/-} mouse model and developed Stargardt iPSC-derived RPE with complete loss of ABCA4 function as an in vitro disease model.

Methods: Lipid extraction was performed from collected RPE/choroid samples of 12-month-old wild type and ABCA4^{-/-} (C57BL/6J) mice. To validate the observed alterations in RPE/choroid's lipid profile obtained from ABCA4^{-/-} mice, fully characterized Stargardt iPSC (patient and two ABCA4^{-/-} iPSC lines) were differentiated into functionally validated RPE using a developmentally guided protocol. Stargardt- iRPE was cultured on semi-permeable membranes for six weeks to obtain a functionally mature and polarized monolayer tissue. For lipid extraction, cell medium and lysate from Stargardt- iRPE cells were collected after exposure to photoreceptor outer segment regimen (8 days). Lipid extracts were subjected to liquid chromatography–mass spectrometry (LC-MS/MS) for lipidomic analysis.

Results: LC-MS/MS analysis revealed altered RPE/choroid and Stargardt- iRPE lipid profile, including changes in phosphatidylcholine (PC), phosphatidylethanolamine (PE), and phosphatidylserine (PS) molecular species and fatty acids and their derivatives with complete loss of ABCA4 function. RPE/choroid samples collected from ABCA4^{-/-} mice showed general trends of having less amounts of stable metabolites leading to elovanoic pathways and less abundance of VLC-PUFAs (FA32:6 n3 and FA34:6 n3) compared with the wild type.

Conclusions: Our results indicate that ABCA4 plays an essential role in RPE lipid profile, and mutations in the ABCA4 result in the changed RPE lipidomic contributing to Stargardt disease pathogenesis. This work provides an improved understanding of Stargardt disease mechanism.

ABSTRACT BODY:

Purpose: We aimed to characterize a rodent model of gradual chronic ocular hypertension, without an initial intraocular pressure (IOP) spike common to many current inducible models.

Methods: Adult Long Evans rats were anesthetized and a Nylon 8-0 suture was passed around subconjunctivally 5-6 times 1.5 mm posterior to the limbus, and tied off using a slipknot anchored with 3-5 simple throws. Care was taken to make sutures snug, but not tight, without inducing an IOP spike. This generated gradual ocular hypertension (gOHT) as the sutures tightened over time. Control eyes (CON) were loosely sutured. Follow-up included weekly IOP measurements, monthly OCT scans of the angle and circumpapillary retinal nerve fiber layer (cpRNFL), and vision assessment using OptoMotry. Eyes were collected after 12 weeks of elevated IOP for cryosectioning and confocal microscopy. Anti-RBPMS was used to stain retinal ganglion cells for quantification of cell survival on 250 μ m from both sides of the optic nerve insertion.

Results: Baseline IOP (mean \pm SE) for CON and gOHT were 10.2 \pm 0.2 and 10.5 \pm 0.3 mmHg, respectively ($p=0.33$). IOP immediately after suturing were 9.2 \pm 0.2 and 9.6 \pm 0.2, respectively ($p=0.12$). IOP in gOHT increased above 20 mmHg 3-5 weeks post-suturing. After 12 weeks, the measurements were 15.2 \pm 0.8 and 27.8 \pm 0.8 mmHg in CON and gOHT groups, respectively ($p<0.001$). The number of RBPMS positive cells per 100 μ m was 4.22 \pm 0.06 for CON and 3.43 \pm 0.06 for gOHT ($p<0.001$). Optokinetic vision at baseline was 0.708 \pm 0.009 and 0.683 \pm 0.009 cycles/deg ($p=0.09$), respectively, and after 12 weeks of elevated IOP, 0.647 \pm 0.010 and 0.489 \pm 0.008 cycles/deg ($p<0.001$), respectively, representing a 28.4% decrease in gOHT. The average cpRNFL thickness was 42.7 \pm 0.4 and 43.6 \pm 0.8 at baseline ($p=0.31$), 41.7 \pm 0.2 and 39.3 \pm 1.1 at 8 weeks of elevated IOP ($p=0.05$) and 41.2 \pm 0.5 and 35.0 \pm 1.1 at 12 weeks of elevated IOP ($p<0.001$). Angles remained open throughout, and all sections were negative for CD68 (microglia), F4/80 (macrophages) and SOD2 (oxidative stress marker).

Conclusions: The gOHT model produces chronic mildly elevated IOP in rats, accompanied by loss of retinal ganglion cells and visual function, and no evidence of inflammatory cell infiltration. The advantages with this model include the absence of a pathological initial spike in IOP, no intraocular entry or inflammation, and induction of a gradual increase in IOP, similar to clinical glaucoma.

ABSTRACT BODY:

Purpose: To characterize the contrast sensitivity function (CSF) in patients with central serous chorioretinopathy (CSCR) compared to healthy controls using novel computerized contrast sensitivity (CS) testing with active learning algorithms.

Methods: CSF was prospectively measured in CSCR eyes and healthy controls between December 2016 and November 2017 at W. K. Kellogg Eye Center and Massachusetts Eye and Ear Infirmary using the novel active learning Sentio Platform (Adaptive Sensory Technology, San Diego, CA). A mixed effects multivariate regression model was employed and outcomes included Area under the Log CSF (AULCSF), CS thresholds at 1, 1.5, 3, 12, and 18 cycles per degree (cpd) and best corrected visual acuity (BCVA). Associations of contrast outcomes with structural findings and subjective symptomatology were investigated.

Results: A total of 40 eyes of 36 CSCR patients and 84 healthy control eyes were included. Median BCVA in CSCR eyes was logMAR 0.10 (0.23) versus 0.00 (0.04) in controls ($P = 0.01$). The median AULCSF in CSCR eyes was 1.11(0.70) versus 1.24 (0.31) in controls. When accounting for age, the presence of CSR was associated with significantly reduced median AULCSF ($P = .02$, $\beta = -0.14$) and reduced mean CS thresholds at spatial frequencies of 6cpd ($P = .009$, $\beta = -0.18$), 12cpd ($P < .001$, $\beta = -0.23$) and 18cpd ($P = .04$, $\beta = -0.09$), compared to controls. Within the CSCR group, subjectively perceived visual impairment ($N=22$) was associated with decreased contrast thresholds at all spatial frequencies and in AULCSF, when compared to asymptomatic CSCR eyes ($N=18$). Ellipsoid zone attenuation was associated with decreased AULCSF ($P = 0.002$, $\beta = -0.473$) and decreased contrast thresholds specifically at 3,6 and 12 cpd, whereas presence of extrafoveal fluid was associated with decreased thresholds at 1, 1.5, 3 and 6 cpd.

Conclusions: Contrast sensitivity is significantly reduced in CSCR, and seems to strongly correlate with subjective visual impairment. Different structural biomarkers correlate with contrast thresholds reductions at different spatial frequencies. The novel qCSF method may serve as a valuable adjunct visual function metric for CSCR patients in the routine clinical practice.

ABSTRACT BODY:

Purpose: Proper transmission of visual information relies on neurons forming appropriate synaptic connections to their respective targets during development. In the outer retina, photoreceptors are the main detectors of lights that synapse selectively to distinct partners. Cone photoreceptors synapse to the dendrites of horizontal cells and to the dendrites of cone bipolars, whereas rod photoreceptors synapse to the axon of horizontal cells and to the dendrites of rod bipolars. The molecular mechanisms that guide selective wiring of photoreceptors to their distinct targets remains poorly understood.

Methods: Our initial data identified the L1 cell adhesion molecule Neurofascin (Nfasc) to be localized in the developing synaptic layer and exclusively expressed in rods, horizontal cells, and rod bipolars. Moreover, other cell adhesion molecules (i.e. Cntn1, Caspr, Nrcam) that are known to work alongside Nfasc are expressed in the complementary cone pathway. Based on these data, we hypothesize that restricted expression of cell adhesion molecules mediates selective wiring of photoreceptors to their respective targets. To test our hypothesis, we perform loss- and gain-of-function experiments using mouse transgenics, in vivo genetic manipulations, and single neuron labeling approaches.

Results: We found that disruption of Nfasc leads to synaptic defects affecting rod connectivity but not cone connectivity. These include loss of pre- and post-synaptic protein expression among rods and rod bipolars as well as a decrease in rod-driven visual responses. However, synaptic connections among cones and cone bipolars do not appear to be affected. Moreover, ectopic expression of the cone-restricted cell adhesion molecule, Nrcam in rods results in rod terminals projecting deeper and making aberrant contacts to cone bipolars. These data suggest that Nfasc may be required for rod connectivity and Nrcam for cone connectivity.

Conclusions: Our findings support a novel role for Nfasc and Nrcam in photoreceptor connectivity. Future work will further disseminate these molecular interactions to reveal new molecular pathways that guide selective wiring of photoreceptors. Through these experiments, we will uncover the molecular mechanisms involved in complex wiring of neural circuits during development.

TITLE: Retinylation of Opsins by Retinyl Formate

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Hong, Ophthalmology, University of California Irvine School of Medicine, Irvine, California, UNITED STATES|Á. Placeres, G.P. Tochtrop, Chemistry, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): John Hong: Commercial Relationship: Code N (No Commercial Relationship) | Ángel Placeres: Commercial Relationship: Code N (No Commercial Relationship) | Gregory Tochtrop: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Defects in visual cycle enzymes or retinoid carrier proteins may deplete 11-cis retinal (11cRAL) and are implicated in multiple blinding diseases. Therefore, retinal analogues that aid in vision independent of chromophore recycling have invaluable translational implications in addressing visual cycle impairments and controlling visual cycle kinetics. Conversely, intense light exposure causing overstimulation of photoreceptors can overwhelm the outer segment with atRAL that form toxic bisretinoid lipofuscin species that contribute to Age-Related Macular Degeneration. Therefore, retinal analogues also have an important role in either attenuating opsin activity or serving as transient molecular brakes of the visual cycle.

Methods: The chemistry of retinyl formate (RF) in forming a covalent interaction with primary amines of lysine was tested in solution with different solvent, and the resultant reaction mixture was analyzed by high performane liquid chromatography. The covalent binding efficiency of RF was assessed by UV-Vis spectrophotometry. The site of retinyl modification by RF was determined by protein digest of RF treated opsin, followed by peptide liquid chromatography mass spectrometry (LC-MS).

Results: RF interacts with primary amines to form a covalent interaction, producing a retinyl secondary amine. The UV-Vis spectrum of the RF treated opsin that was thoroughly washed shows a spectrum resembling opsin modified by a retinyl group. Over time, the spectrum gradually shifted to that of the Schiff base, demonstrating that the modification is transient and reverts to normal opsin physiology. Protein digest of our positive control in borohydride reduced native bovine rhodopsin and subsequent peptide LC-MS showed presence of retinyl peptides. The same will be done on RF treated rhodopsin.

Conclusions: RF can serve as retinylating agent of amines and therefore likely retinylates the amine side chain of lysine within the chromophore binding pocket of opsin. RF treated opsin shows spectrum indicative of such a reaction occuring within opsin. Retinylated opsin gradually oxidized to the Schiff base, suggesting that the modification can be a way to restore visual pigment. Protein digest and peptide LC-MS on borohydride reduce native bovine rhodopsin demonstrated efficacy in detecting retinyl peptides; therefore, the same can be done on retinylated opsin to confirm the retinylation modification and the preference site of modification within opsin.

ABSTRACT BODY:

Purpose: Glaucoma is a multifactorial disease leading to irreversible blindness. Glaucoma is associated with elevation of intraocular pressure (IOP) due to damage to the trabecular meshwork (TM). Transforming growth factor (TGF)β2 is known to cause TM damage and elevate IOP. Mouse models of TGFβ2-induced IOP elevation help understand the underlying molecular mechanism of the disease progression. The goal of this study was to develop a mouse model of IOP elevation using lentiviral gene transfer of active TGFβ2.

Methods: Lentiviral vector constructs encoding active hTGFβ2(C226,228S) with CMV or CBh promoter were purchased from VectorBuilder. Empty lentivirus vector (LV-CMV-Null-Puro) obtained from SignaGen Labs was used as control. C57BL/6J and BALB/cJ mouse strains, age group of >4 months old, were used for the study. The ultra-pure lentiviral particles expressing TGFβ2 or null were intravitreally injected (2×10^6 TU/eyes) into contralateral eyes of each anesthetized mice. IOP was weekly monitored followed by assessment of aqueous outflow facility. TGFβ2 expression was assessed in aqueous humor (AH) and anterior segments of injected eyes. Hematoxylin and eosin staining was performed to examine the morphology of mouse eyes. Effect on RGC function and cell count was determined via pattern ERG (pERG) and RBPMS staining, respectively.

Results: Eyes injected with lenti-CMV-TGFβ2 viral particles significantly increased IOP post 3-weeks of injection compared to the control eyes. The average IOP elevation observed was 3.3 mmHg and stayed consistent up to 7-week post injection. Individual mice assessment revealed 50% response rate to lenti-TGFβ2-induced IOP elevation with average delta change of 6.19 mmHg among the responders. Likewise, the responder mice showed 64.05% drop in AH outflow facility. Nevertheless, no cellular or functional loss of RGC was observed even among the responders. Increased expression of active TGFβ2 was observed in both AH and anterior segment samples of injected mice compared to null injected mice. Mild development of lenticular opacity was detected in some TGFβ2-injected eyes, however, there were no visible signs of inflammation noticed in any of the injected eyes.

Conclusions: Sustained increase in IOP with consequent decrease in outflow facility was effectively demonstrated via lentiviral gene delivery of active TGFβ2 under control of CMV promoter.

ABSTRACT BODY:

Purpose: Knowledge of the average refractive index of the human crystalline lens along its optical axis is useful to obtain accurate estimates of the lens thickness and posterior lens shape with OCT (Borja et al, Biomed Opt Express 2010). We present a method for measuring the average group refractive index of the lens by acquiring OCT images in patients before and after cataract surgery.

Methods: Eighteen eyes from 13 patients (age 73.5 ± 5.3 years) who underwent cataract surgery and IOL implantation at Bascom Palmer Eye Institute were imaged with an extended depth SD-OCT system at 840 nm (Ruggeri et al, Biomed Opt Express 2012) before and one to six months after surgery. All surgeries were performed by one of two surgeons using standard monofocal IOLs (Acrysof, Alcon). Optical path lengths of the anterior chamber, crystalline lens, IOL and vitreous were measured in the pre- and post-operative images of all eyes using custom-made software (MATLAB). Except for the crystalline lens, all intraocular optical lengths were converted to geometrical distances using the group refractive indices at 840 nm of the aqueous and vitreous ($n_{AQ} = n_V = 1.341$; Ruggeri et al Biomed Opt Express 2012) and of the IOL ($n_{IOL} = 1.601$), which was measured on a non-sterile IOL sample using the method of Uhlhorn et al (Vis. Res. 2008). For each eye, the geometrical thickness of the lens was calculated from the pre- and post-operative geometrical distances assuming that axial eye length does not change after surgery. The average group refractive index of the lens was then calculated as the ratio between the optical and geometrical lens thickness.

Results: The average group refractive indices of all crystalline lenses are summarized in the table, giving an overall average of 1.425 ± 0.009 mm (range: 1.413 – 1.439), which is comparable to the group refractive index measured with OCT in vitro (1.416 ± 0.004 ; Uhlhorn et al Vis. Res. 2008).

Conclusions: The study demonstrates the feasibility of measuring the average axial group refractive index of the crystalline lens in vivo by quantifying ocular distances before and after IOL implantation.

TITLE: Relationship of Retinal Vessel Diameters with Age-Related Macular Degeneration

SESSION TITLE: AMD: clinical research - biomarkers and outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Toulouie, California Northstate University College of Medicine, Elk Grove, California, UNITED STATES|G. Yiu, J. Pan, S. Chang, K. Snyder, University of California Davis, Davis, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sara Toulouie: Commercial Relationship: Code N (No Commercial Relationship) | Glenn Yiu: Commercial Relationship: Code N (No Commercial Relationship) | Julia Pan: Commercial Relationship: Code N (No Commercial Relationship) | Sean Chang: Commercial Relationship: Code N (No Commercial Relationship) | Kiersten Snyder: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A hemodynamic role in the pathogenesis of age-related macular degeneration (AMD) has been proposed, but the relationship of retinal vascular parameters and AMD severity has not been evaluated. Here, we explored if retinal arterial or venous diameters, or arteriole-to-venule ratio (AVR) may be associated with AMD severity by analyzing fundus photographs from the Age-Related Eye Disease Study (AREDS).

Methods: We evaluated field 1 color fundus photographs from 1172 eyes to measure retinal vascular parameters including central retinal artery equivalent (CRAE), central retinal vein equivalent (CRVE), and AVR. Images were graded by two masked graders using a semi-automated software to determine the diameters of the 6 largest venules and arterioles surrounding the optic disc and using the Parr-Hubbard formula to standardize vessel calibers. Univariate and multivariate regressions were used to determine the association of CRAE, CRVE, and AVR with age, sex, smoking status, and AMD severity based on the 9-step AMD severity score.

Results: Both CRAE and CRVE were higher in men than women ($P=0.001$), and in current smokers vs. former or never-smokers ($P<0.001$), consistent with prior studies. In eyes without late AMD, the AMD severity score was associated with older age ($P = 0.001$), current smokers ($P = 0.011$), and higher AVR ($P = 0.001$), but not with CRAE or CRVE. The prevalence of choroidal neovascularization (CNV) was associated with older age ($P = 0.003$), but not with retinal vascular parameters ($P=0.258-0.681$). The prevalence of central geographic atrophy (CGA) showed a significant association with lower CRAE ($P = 0.002$) and possible association with lower CRVE ($P = 0.045$) or AVR ($P = 0.080$). None of these retinal vascular measurements were predictive of change in AMD severity score, CNV, or CGA at 5 years.

Conclusions: Retinal vascular caliber parameters such as AVR may be associated with AMD severity, supporting a retinal hemodynamic contribution to the pathogenesis of this condition.

ABSTRACT BODY:

Purpose: Congenital nasolacrimal duct obstruction (CNLDO) in children can be treated surgically with probing and irrigation, canalicular stenting, or balloon dacryoplasty. Success rates for both stenting and dacryoplasty have ranged from 73-90%. This study aims to determine the success rate of balloon dacryoplasty with concurrent monocanalicular stenting (BD+S) as a primary or secondary procedure in congenital nasolacrimal duct obstruction (CNLDO).

Methods: Single-center retrospective cohort study of all children with CNLDO who underwent BD+S from 2009-2019. Patients who had previous probing and stent placement or probing alone were also included. All BD+S procedures were performed at the Children's Hospital of Philadelphia by one of three surgeons (JK, WK, KR). Primary outcome was failure rate, defined as recurrence of tearing symptoms after stent removal.

Results: 98 children (143 NLD) were included in the study; 16 patients (16%) with 22 nasolacrimal ducts (15%) were under the age of 2 years. Mean follow up was 3.3 months (range 3 days – 9.3 months). On follow up, 46/143 (32%) eyes were still symptomatic. Recurrent tearing was seen in 5/22 (23%) NLD below age 2 years and 41/121 (34%) above age 2 years. Chi square analysis did not show any significant difference between the two groups ($p=0.36$). Failure rates were similar for primary (25/79, 32%) vs secondary (18/55, 33%) BD+S. Stenosis of the NLD was seen in 47% of the failures.

Conclusions: Balloon dacryoplasty with concurrent monocanalicular stenting either as a primary or secondary procedure had a success rate of 68% for reducing tearing in CNLDO, lower than previously reported rates of 73-87% for BD. Failures were frequently associated with NLD stenosis.

ABSTRACT BODY:

Purpose: Retinal organoids are three-dimensional aggregates of cells that self-organize into retinal-like tissues. Current protocols utilize human pluripotent stem cells (hPSCs) to generate retinal organoids in vitro, however few protocols have explored the factors that regulate the earliest stages of retinal organoid specification. As such, a more reproducible and efficient method for differentiating early-stage retinal organoids would provide a reliable and reproducible platform for studying human retinogenesis and disease.

Methods: In the current study, 3D aggregates of hPSCs were generated using quick reaggregation methods in 96-well U-bottom plates to ensure reproducibility among culture conditions. Various cell densities were tested for the most efficient generation of retinal organoids. Additionally, a role for BMP signaling in retinal organoid differentiation was tested by treatment with either BMP4 or Noggin, and efficiency was assessed at different time points based on morphological analysis and expression of retinal progenitor markers. Ongoing experiments are assessing transcriptional changes that are associated with the specification of a retinal organoid fate.

Results: Results indicate that cell aggregates generated using the quick reaggregation differentiation method are highly reproducible in both their size and shape at early time points compared to traditional methods. Early-stage retinal organoid differentiation using the quick reaggregation method was also significantly improved after BMP4 activation. Ongoing experiments will continue to focus on optimizing current retinal organoid differentiation protocols, as well as identifying the transcriptional alterations that are associated with the development of retinal organoids.

Conclusions: The precise regulation of multiple parameters within this study provides a novel highly reproducible retinal organoid model that can improve our understanding of human retinogenesis as well as retinal degenerative diseases. The efficient generation of reproducible retinal organoids will also accelerate the development of translational approaches for debilitating blinding disorders.

TITLE: The Chemokine CXCL1 Contributes to Vascular Inflammation and Disruption of Tight-Junctions Associated with Diabetic Retinopathy

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Monickaraj, G. Acosta, A. Cabrera, A. Das, University of New Mexico School of Medicine, Albuquerque, New Mexico, UNITED STATES|F. Monickaraj, A. Das, NMVA Health Care System, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Finny Monickaraj: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Acosta: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Cabrera: Commercial Relationship: Code N (No Commercial Relationship) | Arup Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Inflammation plays an important role in the pathogenesis of diabetic retinopathy. By examining the transcriptome profile and molecular signaling pathway analysis of human retinal endothelial cells (HREC) treated with advanced glycation end products, we have previously shown that the chemokine CXCL1 gene was significantly up-regulated. The purpose of the present study is to determine the effect of CXCL1 and its contribution to the increased vascular permeability and disruption of tight-junctions in retinal vessels in DR.

Methods: Recombinant CXCL1 (100 ng/eye) or sterile water (vehicle) was injected intravitreally into the eyes of C57bl/6 mice (n=5) followed by FACS analysis of immune cell infiltration in the retinas. Next, qPCR analysis was used to determine mRNA expression of key proteases and chemokines. Western Blot analysis was used to evaluate the expression of albumin and VE-cadherin. CXCL1 levels in retinas of streptozotocin induced diabetic mice b(two months duration) was measured by qPCR. ELISA was used to measure CXCL1 levels in serum samples of human diabetic retinopathy patients.

Results: Recombinant CXCL1 injected intravitreally caused significant increase in the infiltration of immune cells: two fold increase of neutrophils and 3-fold increase in monocytes. Importantly, qPCR analysis of retinas revealed increased mRNA expression of CCL2 (4-fold), MMP12 (3-fold) and Cathepsin L (2-fold). Western Blot analysis confirmed that CXCL1 caused a significant increase in retinal vessel permeability, which correlates with increased albumin and decreased VE-cadherin expression. CXCL1 expression was significantly increased in the retinas from diabetic mice. Also, CXCL1 level was significantly increased in the serum samples of diabetic retinopathy patients compared to non-diabetic subjects (p=0.001).

Conclusions: In this study we have shown the role of the chemokine CXCL1 in alteration of blood retinal barrier in diabetic retinopathy, and thus as a potential novel therapeutic target.

TITLE: Combined Dual Blade Goniotomy and Direct Viscodilation of the Collector Channels with Cataract Surgery: 4 Year Results

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Gilmore, L. Burk, UT Southwestern, The University of Texas Southwestern Medical Center, Dallas, TX, US, academic/hospital, Dallas, Texas, UNITED STATES|L.L. Gilmore, Dallas Eye and Ear, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): JANE Gilmore: Commercial Relationship: Code N (No Commercial Relationship) | Linda Burk: Commercial Relationship: Code N (No Commercial Relationship) | Linda Gilmore: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose is to evaluate a hybrid MIGS procedure using Goniotomy and Direct Viscodilation of the collector channels with cataract surgery in all levels of glaucoma. This unique technique called "clean the gutter and power wash the downspouts", not only removes the trabecular meshwork but also directly viscodilates the collector channels.

Methods: After cataract surgery, the Dual Blade removed 180° of trabecular meshwork. Viscoelastic was injected into the exposed ostium of the Collector Channels as the perpendicular viscoelastic cannula was held firmly against the outer wall and dragged through the gutted canal. Moderate to severe glaucoma comprised 64% of the 177 eyes followed at least 2 years. 32% had previous glaucoma surgery. 71% were African American. 44% were diabetics. 50% were on an anticoagulant.

Results: Initial IOP was 18.5mmHg(SD+/-7.2)on 1.6 medications. At 3 months the IOP was 15.6mmHg(SD+/-5.1). Throughout the first year the IOP hovered around 16.5mmHg. IOP then settled to 15.5mmHg (SD+/-4.4) in 74 of the 177 eyes that were seen for 3 years. Although the IOP was reduced by 15%, 85-90% of the eyes had all drops stopped. All eyes had ≤ 15 mmHg AND no meds in 71% (1yr), 59% (2 and 3yr), and 78% (4yr). The moderate to severe group had ≤ 15 mmHg AND no meds 70% (1yr), 50% (2yr), 55% (3yr), and 75% (4yr). Medications were reduced by 1.5 to 1.0 drops per eye over the course of 4 years.

Conclusions: The synergy of Goniotomy and Viscodilation markedly reduces drops even in advanced glaucoma with at least 50% of eyes achieving IOP ≤ 15 mmHg,thus improving compliance and reducing the associated financial burden. The Goniotomy-Viscodilation-Cataract technique addresses both trabecular outflow resistance and salvages the collapsed collector channels.

TITLE: Pulsed Low Frequency Ultrasound for Corneal Phonophoresis

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Lamy, M. Sahasrabudhe, J.M. Stewart, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|P.D. Jones, C.J. Diederich, Radiation Oncology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ricardo Lamy: Commercial Relationship: Code N (No Commercial Relationship) | Peter Jones: Commercial Relationship: Code N (No Commercial Relationship) | Manjiri Sahasrabudhe: Commercial Relationship: Code N (No Commercial Relationship) | Chris Diederich: Commercial Relationship: Code N (No Commercial Relationship) | Jay Stewart: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose : To determine the effect of pulsed low frequency ultrasound (PLFU) at 250 kHz and 500 kHz on the delivery of topical compounds into the corneal stroma.

Methods: Fresh cadaveric rabbit eyes with intact corneal epithelium were placed in a solution of 0.1% riboflavin. Treated eyes received PLFU (60% duty cycle) with a Spatial Average Temporal Average Intensity (I_{sata}) of 1.0 W/cm² for 6 minutes at either 250 kHz or 500 kHz, and the eyes were then left in riboflavin solution for a total immersion time of 20 minutes. Control eyes without ultrasound treatment received the same exposure to riboflavin solution. Corneas were then excised, and confocal microscopy was performed to measure the penetration and distribution of riboflavin in the corneal stroma.

Results: At a corneal depth of 300 microns, the average fluorescence intensity of riboflavin in the groups treated with PLFU 250 kHz and 500 kHz was respectively 9232 ± 2595 A.U. (n = 6) and 7454 ± 2184 A.U. (n=6). When compared to controls (1449 ± 690 A.U.; n=6) the difference was statistically significant for both treated groups (p-value < 0.05), demonstrating 5 - 6 fold therapeutic gain. The difference between corneas treated at 250 KHz and 500 KHz was not statistically significant.

Conclusions: PLFU was very effective in delivering riboflavin into the corneal stroma despite the presence of a previously intact epithelial barrier. This approach may offer a means of achieving clinically useful concentrations and penetration of topically applied drugs in the corneal stroma without removing the corneal epithelium.

ABSTRACT BODY:

Purpose: We have established vis-OCT fibergraphy (vis-OCTF) for visualizing and quantifying retinal ganglion cell (RGC) axon bundles in vivo. Here we further investigate whether we could track and quantify changes in the retinal nerve fiber layer (RNFL) in mice with optic nerve crush (ONC) injury.

Methods: Optic nerve crush procedure was performed on C57BL/6 mice. Mice were imaged using vis-OCT before and 12-days after ONC. For each mouse, we acquired four vis-OCT volumes (512 A-lines × 512 B-scans) from the same eye with the optic nerve head (ONH) aligned in the four corners of the field of view. After fibergram processing, the images from each mouse were montaged to generate the final vis-OCT fibergram. The four rectangular OCT image volumes were resampled from each retina to generate a 400 µm radius circumpapillary scan centered on the ONH. After acquiring vis-OCT data at 12-days post ONC, the same retinas were immunostained for RGC axons and imaged by confocal microscopy.

Results: We quantified the thickness of the retina and RGC axon bundle layer before and after ONC using the resampled circumpapillary B-scans. We found a significant reduction in overall retinal thickness as well as in RGC axon bundle layer thickness after ONC. We compared the vis-OCT fibergrams with their corresponding confocal images of flat-mounted retinas at 12-days post ONC. The Sholl regression coefficient (k) value, a measure for RGC axon bundle density, was consistent in vis-OCTF compared with confocal microscopy. Following ONC injury, the vis-OCTF k values increased for three mice that we have monitored, which corresponded to a higher slope in the Sholl regression plot. Our results indicate a faster change in RGC axon bundle density moving away from the ONH. We further quantified the axon bundle width for all five mice, and a 25% reduction in RGC axon bundle width was observed at 12 days after ONC.

Conclusions: Our results show that vis-OCTF can be used to evaluate RNFL damage in vivo in mice with optic neuropathy. The quantifications of lateral RGC axon bundle thickness and density could provide more detailed information for better diagnosis at the earlier stages of optic neuropathies.

TITLE: Retrospective study of ellipsoid zone integrity following treatment with intravitreal ocriplasmin (OZONE study)

SESSION TITLE: Metabolism and protein processing: retina, photoreceptors and RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.A. Drenser, Associated Retinal Consultants, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kimberly Drenser: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess generalized- (GD) and focal-disruption (FD) of the ellipsoid zone (EZ) in patients with symptomatic vitreomacular adhesion (sVMA) using spectral domain optical coherence tomography (SD-OCT) following a single intravitreal injection of ocriplasmin (0.125 mg).

Methods: OZONE was a Phase 4, retrospective study of patients with sVMA treated with intravitreal ocriplasmin. Data from patients 18 years or older with a diagnosis of sVMA with at least 6 months of follow-up after ocriplasmin were included. A baseline visit within 30 days prior to ocriplasmin was required. SD-OCT was performed at baseline, and before Day 21 post-injection. Early observation (EO) data were obtained from the last SD-OCT scan available prior to Day 21. Last observation (LO) data were obtained from the last SD-OCT scan performed up to a maximum of 6 months post-injection or prior to vitrectomy. The main outcome measure was the development of new and the evolution of existing or new FD/GD by EO and LO. Fisher exact tests were used to assess if baseline characteristics were associated with persistent FD/GD at LO.

Results: The study enrolled 134 eyes of 134 patients from 22 retina centers across the USA. At baseline, 87 eyes (64.9%) had FD, 21 eyes (15.7%) had GD and 26 eyes (19.4%) were without EZ disruption. Among eyes without FD or GD at baseline, 13 (50%) developed FD and 8 (30.8%) developed GD following ocriplasmin. By LO, improvement or resolution of FD/GD was seen in over 80% of these eyes. Presence of FD/GD at baseline was associated with persistent FD/GD at LO ($P < 0.001$) and less than 40% of these eyes had improving or resolving EZ integrity at LO. Presence of MH at baseline was associated with persistent FD ($P = 0.027$), but not GD ($P = 0.281$) at LO.

Conclusions: The finding that a large majority of eyes had FD or GD prior to treatment with ocriplasmin indicates that EZ disruptions are common in sVMA and suggest that FD/GD are likely part of the natural history of this disorder. Presence of EZ disruptions at baseline were associated with persistent disruptions at LO. Given the high prevalence of FD/GD prior to treatment with ocriplasmin, it is likely that EZ disruptions arising after ocriplasmin treatment are at least in part due to the natural history of sVMA. Prospective analyses which include a sham control group would be required to test this hypothesis.

ABSTRACT BODY:

Purpose: Diabetic retinopathy, a common complication of diabetes has been associated with the downregulation of the Sirtuin 1(SIRT1) gene. SIRT1 is a nutrient-sensing deacetylase whose dysfunction can result in chronic metabolic abnormalities. Previously we showed that activation of SIRT1 signaling in vivo reduced diabetes-induced inflammation, neural and vascular degeneration, and impairment in visual function. In this study, we examined the effect of intravitreal SIRT1-AAV therapy on reversal of diabetic retinopathy.

Methods: db/db mice were given either control virus (GFP-AAV2) or SIRT1-AAV2 via intravitreal injection at 9 months. Mice were euthanized at 12 months. Retina, peripheral blood cells and bone marrow cells were collected. Vascular changes were assessed by enumeration of acellular capillaries and retinal immune cells were assessed using flow cytometry. Immunohistochemistry was performed for SIRT1 to confirm upregulation, caspase 3 for apoptosis and IBA-1 for microglial activation. Neural function was assessed using electroretinogram responses and optomotor responses.

Results: SIRT1-AAV2 treated db/db mice showed increased retinal SIRT1 mRNA compared to control virus treated db/db mice (3 ± 0.9 vs 0.5 ± 0.1 respectively) and the number of SIRT1 positive cells in the retina was higher in SIRT1-AAV2 db/db mice (28.4 ± 6) compared to control virus treated db/db mice (13.9 ± 2). The number of acellular capillaries were reduced in SIRT1-AAV2 treated db/db mice (8.8 ± 3) compared to db/db mice (11.1 ± 4). Retinal Iba1⁺ cells were increased in db/db mice injected with control virus (9 ± 2) and reduced in SIRT1-AAV2-treated db/db mice (4 ± 1). Caspase-3 expression was reduced in SIRT1-AAV2-treated db/db mice (15 ± 5) compared to db/db mice (8 ± 3). There was a significant improvement in the b-wave in the ERG scotopic response in SIRT1-AAV2 db/db mice (326 ± 43) compared to db/db (188 ± 39). The retinal visual function as determined by optokinetic responses was improved in SIRT1-AAV2 treated db/db mice (0.39 ± 0.01) compared to the db/db mice (0.28 ± 0.02).

Conclusions: We demonstrate that diabetic retinopathy can be prevented using a SIRT1-AAV2 intravitreal administration. We show that in addition to reduction in retinal inflammation and apoptosis, SIRT1 treatment preserved retinal bipolar cells and retinal visual function and response can be restored using this therapy.

SUBMITTER (NAME ONLY): Cynthia McClard

TITLE: Utility of Genetic Testing for Inherited Retinal Diseases in a Real-world Clinical Setting

SESSION TITLE: Genetics of Retinal dystrophies and Functional Genomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. McClard, F. Jamshidi, D. Pollalis, S. Lee, Ophthalmology, Dean McGee Eye Institute, Oklahoma City, Oklahoma, UNITED STATES|S. Lee, Physiology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Cynthia McClard: Commercial Relationship: Code N (No Commercial Relationship) | Farzad Jamshidi: Commercial Relationship: Code N (No Commercial Relationship) | Dimitrios Pollalis: Commercial Relationship: Code N (No Commercial Relationship) | Sun Young Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Attention to genetic testing for patients with inherited retinal diseases (IRD) has increased among patients and clinicians due to significant advances in genomics and gene therapy. However, routine genetic testing for clinically diagnosed IRD is not currently common practice for reasons including extra cost and clinicians' limited familiarity with its utility. In the current study, we share our experience in genetic testing of clinically diagnosed IRD patients using no-charge panel genetic testing.

Methods: Retrospective case analysis was performed of patients clinically diagnosed with IRD, who elected to undergo molecular genetic testing from 2019 to 2020 at a single academic center. Testing was performed with a saliva kit, in which 248 genes were assayed from a kit provided by Invitae (San Francisco, CA, USA) and sponsored by Spark Therapeutics (Philadelphia, PA, USA).

Results: Forty-seven patients (M 21: F 26) were included. The following diagnoses were represented:

1) photoreceptor disease (30/47, 63.8%), including retinitis pigmentosa (RP) (21/47, 44.7%), cone and cone-rod dystrophy (4/47, 8.5%), and syndromic RP (5/47, 10.6%); 2) macular diseases (11/47, 23.4%), including Stargardt's (5/47, 10.6%); and 3) other diseases (6/47, 12.8%), including choroideremia (3/47, 6.4%) and X-linked retinoschisis (2/47, 4.3%). Disease-causing genotypes were identified in 46.8% of patients (22/47), 42.3% in RP (11/26), 80% in Stargardt's (4/5), and 100% in choroideremia (3/3). Undetermined genotypes in 53.2% (25/47) patients were due to identifying either one recessive pathogenic mutation or multiple variants of unknown significance (VUS). Common VUS identified in our cohort were USHA2A(7), TUBGCP6 (6), CDH23(6), FSCN2(6), PCDH15(6), WHRN(6), ABCA4(5), and EYS(5).

Conclusions: Here, we report the results of currently available no-charge panel genetic testing to explore its utility in an established IRD clinic setting. We further plan to examine how testing utility may change depending on demographics or in phenotypic subdivisions in our cohort. Further studies interpreting the frequency of VUS and whether and how VUS are related to disease in our cohort will be pursued. In doing so, we aim to provide early guidance for retina specialists on the value of genetic testing in the practical management of IRDs.

ABSTRACT BODY:

Purpose: Mounting evidence suggests that Alzheimer's disease (AD) neuropathological changes are also present in the retinae of patients. These include the proteinaceous accumulation of amyloid- β (A β) and hyperphosphorylated tau (pTau) assemblies, gliosis, vascular abnormalities, pericyte loss, and neurodegeneration. Electroretinogram and visual deficits, likely driven by these retinal pathologies, are also documented. Among the main neuropathological hallmarks of AD, tauopathy remains considerably understudied in the retina. Given that cerebral tauopathy is closely linked to neuronal loss and the severity of cognitive deficits in AD patients, it is possible that similar relations exist in the retina between pathologic tau burden, synaptic loss, and neurodegeneration. These may serve as biomarkers of not only retino-visual irregularities but also brain disease and cognitive status.

Methods: Here, using immunohistochemical approaches we visualized and quantified the spatial burden of various AD-related tau species, including pTau, oligomeric and citrullinated tau, and neurofibrillary tangles (NFTs) in the central and peripheral regions of post-mortem retinae from mild cognitive impairment (MCI) and AD patients, relative to cognitively normal controls (NC). Levels of synaptic biomarkers in the retina, as well as the thickness of retinal layers, were also measured in the same cohort of human donors.

Results: Elevated levels of various pTau sites were found in a geometric-dependent manner in the retinae of MCI and AD patients compared to NC. Increased burden of NFTs and citrullinated tau were also identified in retinal layers that were associated with higher retinal synaptic loss and neuronal atrophy. Investigations of retinal cell type susceptibility to tauopathy, including oligomeric tau accumulation in early and late disease stages, reveals the vulnerability of certain retinal neurons in MCI and AD patients.

Conclusions: To date, our results provide new evidence for the presence of AD-specific tauopathy and related synaptic loss as well as neuronal-specific susceptibility in the AD retina, similar to those observed in the brain.

ABSTRACT BODY:

Purpose: Diabetic keratopathy affects up to 70% of patients with diabetes. Mitochondrial dysfunction is considered a central feature underlying diabetic complications. The purpose of this study was to characterize mitochondrial and metabolic alterations in primary cultured diabetic human corneal epithelial cells (HCECs) and in telomerase-immortalized human corneal epithelial (hTCEpi) cells exposed to hyperglycemic and hyperosmotic stress.

Methods: To determine the effects of diabetes on mitochondria and metabolism, donor human corneas from diabetics were obtained from Tissue Transplant Services at UT Southwestern Medical Center. Primary cultures were generated using an established lab protocol. HCECs and hTCEpi cells were cultured in a defined serum-free keratinocyte growth media containing 6 mM glucose. To determine the effects of hyperglycemia on hTCEpi cells, cells were cultured for 24 hours, 7 or 14 days in media containing an additional 19 mM glucose. Cells supplemented with 19 mM mannitol were used as an osmotic control. Mitochondrial morphology and polarization were assessed using MitoTracker and TMRE, respectively. Metabolic changes were quantified in real time using a Seahorse metabolic flux analyzer. Cell cycle was determined by staining with Propidium Iodide and analyzed using a Celigo imaging cytometer. Reactive oxygen species were measured using Amplex red. Expression of the mechanistic target of rapamycin (mTOR) and downstream effectors were assessed by western blot.

Results: Diabetic HCECs demonstrated variable growth rates in culture. Similarly, mitochondrial morphology varied greatly among diabetic HCECs ranging from mild to severe with robust fragmentation and depolarization. Exposure of hTCEpi cells to high glucose shifted cells towards a respiratory phenotype. Cell cycle was unaltered at 24 hours and at day 7. After 14 days of culture, hTCEpi cells in mannitol arrested in G2/M and this was associated with a decrease in mTOR expression.

Conclusions: These findings confirm the presence of mitochondrial and metabolic abnormalities in the diabetic corneal epithelium. Further studies are needed to determine the molecular mechanisms that underly these changes.

ABSTRACT BODY:

Purpose: The proper development of cone and rod photoreceptors (PRs) requires the timed activation of different genetic programs. Alterations in these specific programs trigger developmental defects of cell fate specification, that are likely to yield visual impairments.

Methods: Previous reports show that ONECUT1 (OC1) is involved in the repression of gene regulatory networks that trigger rod genesis (Emerson et al., 2013). To explore its contribution in the early decision of photoreceptor (PR) specification, we electroporated CrxEnh1::GFP (active in both cone and rods) and CAG::OC1Enr (a repressor form of OC1), at E5 in the chick retina (Jean-Charles et al., 2018). Transcriptomes of these cells were generated after culturing whole retinas for 2 day in vitro. Several rod-related genes were upregulated, while most cone-related genes were downregulated. We next screened candidate genes to test their involvement in the repression of rod programs, taking the following approach: retinas were electroporated at E5 with a reporter plasmid that drives GFP expression after the activation of the Rhodopsin promoter (Rho::GFP) (Jean-Charles et al., 2018), with either CAG::Enr or CAG::OC1Enr, in addition to an overexpression plasmid, that allowed the forced expression of each candidate genes.

Results: We identified that overexpression of SALL1 was able to reduce the early induction of Rhodopsin triggered by OC1 repression. We confirmed the expression of SALL1 in the cones of the chick retina as well as in the developing human retina, using retinal organoids. In addition, overexpression of SALL1 showed an increase number of RXRG-positive PRs.

We also analyzed SALL1 loss-of-function in the developing chick retina using CRISPR/Cas9. We determined that upon SALL1 gene editing, the Rhodopsin promoter was activated and the rod pathway was turned on.

Conclusions: We report for the first time that a cone-enriched gene, SALL1, that acts downstream of OC1 to repress the rod genesis pathway.

ABSTRACT BODY:

Purpose: As most features in the retina are found in the posterior pole, including the optical nerve head (ONH), the performance of registration algorithms when applied to widefield fundus images is generally sub-optimal in the periphery. In this research, we propose a weighted feature matching (WFM) to improve registration over the entire field of view of the widefield image.

Methods: Figure 1 shows the steps of the proposed algorithm. Both fixed and moving image pairs for registration are channel separated. Green channel is used for ONH detection [1]. Cornerness map from multi-scale Harris corner detection is multiplied with w_i before thresholding. If the fixed image is of size $m \times n$ and d_i is pixel distance from either the ONH (if detected) or from the center of the image (if ONH is not detected), the weighting factor is $w_i = d_i / (m \times n)$. Weighted vector distances between histogram of oriented gradients (HOG) descriptors (16×16 patches) are used for the feature point matching. Two registered images with and without WFM are generated for comparison.

Baseline and follow up images from 44 subjects (22 healthy and 22 with choroidal tumors, therapy-induced retinopathy, diabetic retinopathy and glaucoma) are acquired using CLARUSTM 500 (ZEISS, Dublin, CA). For each pair of images, cselect function in MATLAB is used to label 10 landmarks/points per image (5 in the center and 5 in the periphery). The angular distance between the points in the registered images should be zero degrees for perfect registration. The mean angular distance with and without WFM are calculated for the quantitative evaluation.

Results: The mean angular distance between the points in the registered images with and without WFM are $0.60 \pm 0.31^\circ$, $0.73 \pm 0.38^\circ$ (all points), $0.56 \pm 0.25^\circ$, $0.54 \pm 0.28^\circ$ (central points) and $0.63 \pm 0.35^\circ$, $0.92 \pm 0.38^\circ$ (peripheral points). With WFM, the overall performance of the registration is improved by 17.8% while the performance in the center of the image is decreased by 2.2%. Figure 2 shows the registered image with and without WFM.

Conclusions: The proposed registration with WFM improves the overall registration of the widefield fundus image by improving the performance in the periphery with minimum reduction to the performance in the center of the image.

ABSTRACT BODY:

Purpose: DNA-sequencing is not readily available in countries with little research resources or where health insurance does not cover the costs even for those who have it. This is especially true for very rare (orphan) inheritable retinal diseases. We wanted to develop a rapid targeted-sequencing protocol for eight genes involved in Familial Exudative Vitreo-Retinopathy (FEVR), Norrie Disease, and Retinoschisis, at greatly reduced cost. Furthermore, we desired a workflow which could be deployed locally and support training in human genomics for science and medical students

Methods: DNA is extracted from 100 uL samples of whole frozen blood. An Ampliseq targeted-panel (180 amplicons) for 8 genes was designed with illumina's DesignStudio Sequencing Assay Designer, distributed into three pools (PCR reactions) per patient sample for complete coverage of 83 exons with 25 bp adjacent intron sequence. Target Genes were: NDP (ChrX), RS1 (Chr10); CTNNB1 (Chr3); TSPAN12 (Chr7); KIF11 (Chr10), FZD4 (Chr11), LRP5 (Chr11), ZNF408 (Chr11). Ampliseq libraries were quality controlled by capillary electrophoresis (Agilent Bioanalyzer) and several sample pool sizes were tested for capacity and coverage using sequencing and variant calling on the Illumina iSeq-100 platform.

Results: An average 2500-times read coverage was obtained for a pool of 16 patient libraries and 800-times for a pool of 48 patient libraries. Numerous potential disease-associated variants were detected in targeted libraries from patients diagnosed with Norrie Disease, FEVR, and Retinoschisis. Average numbers of variants per patient for the 48 patient pool were: 19.5 ± 1.6 SNVs, 0.6 ± 0.2 Inserts, and 0.6 ± 0.2 Deletions.

Conclusions: We developed a targeted exome-sequencing protocol using Illumina Ampliseq reagents and the iSeq-100 platform for three rare pediatric retinal diseases. Coverage validated the ability to pool 40-50 patients per run for eight genes and provides for excellent base call accuracy ($>Q30$). Over 90 patient samples were successfully sequenced during validation. Potential mono and digenic variant contributions in FEVR patients are detectable by testing multiple genes. Research analysis costs were reduced to \$250 per patient and now involve an academic eye research institute / retinal clinic research partnership.

TITLE: Evaluation of Cytotoxicity of Anti-VEGF Molecules on Vascular Endothelial Growth Factor Enriched Choroidal Vascular Endothelial Cells

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Mynampati Arunadithya, S. grover, Ophthalmology, University of Florida Health, Jacksonville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bharani Krishna Mynampati Arunadithya: Commercial Relationship: Code N (No Commercial Relationship) | Sandeep grover: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Anti-VEGF therapy is currently an effective standard treatment for AMD; exploring the other possible pathways may provide an alternative strategy in the treatment of AMD. This includes combination of various anti-VEGF molecules such as Pazopanib, Palomid 529 and Bevacizumab (avastin) for targeting vascular endothelial growth factor (VEGF). However, the dose, time and combination effects of these molecules on VEGF-enriched choroidal vascular endothelial cells (CVECs) has not been well established in invitro. We evaluated the cytotoxicity of combination doses of Pazopanib, Palomid 529 and bevacizumab on CVECs.

Methods: Choroidal vascular endothelial cells (CVECs) were treated with VEGF (50ng/ml) and were treated with Bevacizumab, Palomid529, Pazopanib, Bevacizumab +Palomid 529, Bevacizumab +Pazopanib, Pazopanib+Palomid 529. Cell proliferation changes analyzed with water-soluble tetrazolium salts (WST-1) assay. Cytotoxicity was evaluated by trypan blue exclusion assay at different time intervals i.e 48h, 72h, 1 week. Simultaneously reactive oxygen species levels were also measured using dihydrorhodamine 123 at similar intervals. Apoptotic marker such as caspase 3 was also measured at 72h interval.

Results: VEGF-enriched CVECs treated with Bevacizumab, Palomid 529, Pazopanib, Bevacizumab+Palomid 529, Bevacizumab+Pazopanib, Pazopanib+Palomid 529 inhibited the proliferation of CVECs. CVECs showed a significant decrease in the cell proliferation rates when treated with combination of anti-VEGF molecules in comparison to single anti-VEGF molecules and to controls ($p < 0.0001$). Similarly, cell viability numbers also significantly reduced in combination of anti-VEGF molecules in comparison to single anti-VEGF molecule and to controls ($p < 0.0001$). Further, ROS levels were found to be significant in combination of anti-VEGF groups compared to drugs alone and controls ($p < 0.01$). Similarly, apoptotic marker caspase 3 levels were found to be increased by 10 folds in (Palomid 529+ Pazopanib) group compared to any other groups and control.

Conclusions: Although anti-VEGF molecules are effective in controlling the proliferation and cell viability rates of VEGF-enriched CVECs, a combination of these anti-VEGF molecules are more effective in inhibiting the cell proliferation rates than any one anti-VEGF molecule alone in comparison to control.

ABSTRACT BODY:

Purpose: Cell-cell adhesion and cell-polarity protein complexes coordinate crucial processes that ensure epithelial integrity. Among these, the cell-cell adhesion molecule E-cadherin and the polarity protein PAR3 serve important functions in epithelial tissues and its loss is associated with dermal melanoma progression and elevated metastasis. The role of PAR3 or E-cadherin in conjunctival melanoma (CM) and in conjunctival squamous cell carcinoma (SCC) remains open. This study aims to analyze the expression of these central markers for cell-cell adhesion and cyto-architecture to gain insight into molecular changes during ocular surface tumor progression.

Methods: The expression of epithelial PAR3 and E-cadherin in 32 patients with human SCC, CM and the corresponding precancerous lesions have been analyzed immunohistochemically in formalin-fixed paraffin-embedded tissues.

Results: In SCC and its precancerous lesions conjunctival intraepithelial neoplasia (CIN) I-III, E-cadherin expression was significantly decreased compared to controls. Melanocytes and keratinocytes in healthy conjunctiva were E-cadherin positive. In CM E-cadherin expression was reduced. Conjunctival carcinomas switch their E-cadherin expression from extra- to intracellular. PAR3 was statistically significantly decreased expressed in the epithelium of CIN I-III, SCC, CM, and the melanoma in situ probes compared to controls.

Conclusions: In CIN, SCC, and CM a reduction of the cell-cell adhesion molecule E-cadherin and the polarity protein PAR3 is seen. This indicates that during carcinogenesis even the premalignant lesions lose expression of these markers. Loss of PAR3 and extracellular E-cadherin expression might be used as additional diagnostic tools to separate premalignant from benign lesions in the future and as a potential therapeutic target.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has had a substantial impact on society but has disproportionately affected the disability population. The CNIB COVID-19 Impact Survey was distributed throughout Canada in May 2020 to gather information on the experiences of adults with visual impairments during the pandemic. This cross-sectional study identified key aspects in which those with vision loss have been impacted by the pandemic and associated policies and procedures.

Methods: Analyses were conducted using IBM SPSS version 22 statistical software. Conventional descriptive statistics were used to describe the sample. Data were cross-tabulated by age, age of sight loss onset, severity of sight loss, other disability or health condition, employment status, and education.

Results: Approximately half (51%) of the sample had concerns about their healthcare, and just over half (58%) said they did not know where to get tested for SARS-CoV2.

Key concerns reported by respondents included:

1. Touching things in public such as elevator panels, self-serve kiosks, or restroom doors to check signage (68% agreed).
2. Due to social distancing, they feel more depressed, sad, and lonely (64% agreed).
3. Because the individual does not drive, they will not be able to get themselves or a family member to a COVID-19 test centre or to a hospital or healthcare facility if they present with severe COVID-19 symptoms (61% agreed).
4. Getting access to accurate and current information about those who may be infected in their area (59% agreed).
5. Concern about accessing emergency medical services (50% agreed).
6. Unsure how to maintain appropriate social distance in public (48% agreed).

Conclusions: The COVID-19 pandemic has impacted those with sight loss in many ways and in many different aspects of their lives. This study gave key insights into barriers affecting the societal participation of those with sight loss. While the findings of this study may have evolved over the course of the pandemic, these concerns are important for all levels of policy and advocacy leads to take into account while developing and revising existing policies. This study has provided evidence for the development of new policies and procedures, and the evaluation of existing policies and public health procedures to ensure those with sight loss are not put at an even greater disadvantage during these times and are able to receive the necessary supports.

ABSTRACT BODY:

Purpose: Tears of the retinal pigment epithelium (RPE) occur in age-related macular degeneration (AMD) as part of normal disease progression or after injections with anti-VEGF. This provides opportunity to investigate two questions: does the presence of an intact pigmented RPE interfere with our ability to measure choriocapillaris (CC) flow deficits (FDs) and is the survival of the CC dependent on an intact overlying RPE. To answer these questions, we compared our CC FD measurements before and after a RPE tear and followed the change in CC FDs over time once the overlying RPE was removed.

Methods: Patients with AMD who developed RPE tears were enrolled in a prospective, swept source OCT (SS-OCT) imaging study and 6x6 mm scans centered on the fovea were acquired (PLEX^o Elite 9000, Carl Zeiss Meditec, Dublin, CA). Scans were obtained before and after the RPE tear formation, and during follow-up visits. CC FDs were measured at the site of the tear and within a control region symmetrically positioned to the fovea.

Results: Three AMD patients were followed before and after the RPE tear developed for 18 months. Two patients had a history of type 1 macular neovascularization and anti-VEGF therapy, and one patient had non-neovascular AMD. All three had macular CC FD that were previously determined to be within the 95% normal limits for age-adjusted eyes. When CC FD before the RPE tear were compared with those at the first post-tear visit, the average CC FD percentage decreased -0.7% in region of tear and -1.0% in control region ($p=0.92$, paired t-test). When CC FD from the first post-RPE tear visit were compared to 18-month follow-up visit, the average CC FD percentage decreased -1.9% in region of tear and increased +2.0% in control region ($p=0.31$, paired t-test).

Conclusions: SS-OCTA imaging of eyes with RPE tears indicate that there were no significant changes in CC FD before and after the RPE tears. Although the sample size was small, it appears that our CC algorithm for measuring FDs is reliable demonstrated by consistent measurements before and after the RPE was removed. Furthermore, removal of the RPE did not lead to significant changes in the CC over 18 months. This differs from animal studies demonstrating that RPE removal resulted in rapid loss of CC. The relationship between CC and RPE may not be absolute as previously believed.

TITLE: UTX demethylase function is required to decondense chromatin to create a “window of opportunity” for reprogramming to a fibrotic fate

SESSION TITLE: Posterior Capsular Opacification and Fibrosis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Basta, H. Paulson, S. Petruk, A. Mazo, J.L. Walker, Thomas Jefferson University, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Morgan Basta: Commercial Relationship: Code N (No Commercial Relationship) | Heather Paulson: Commercial Relationship: Code N (No Commercial Relationship) | Svetlana Petruk: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Mazo: Commercial Relationship: Code N (No Commercial Relationship) | Janice Walker: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to determine how a cell becomes epigenetically reprogrammed to a myofibroblast fate associated with lens fibrotic disease. For cell reprogramming to occur, transcription factors (TF) must overcome a condensed chromatin barrier typically marked by H3K27me3. Here, we investigated how chromatin structure becomes re-established shortly after DNA replication in myofibroblast progenitor cells to identify the “window of opportunity” for the adoption of a new pro-fibrotic transcription program.

Methods: Studies were performed in an ex-vivo mock cataract surgery wound healing/fibrosis chick embryo model to examine cell reprogramming to a myofibroblast fate, which occurs by 72hr post-injury. The chromatin assembly assay (CAA) was used to study how chromatin structure becomes re-established at the time of replication during cell reprogramming. To determine if TF binding occurs during replication, S phase entry was blocked by thymidine treatment. We examined how blocking ubiquitously transcribed tetratricopeptide repeat, X chromosome (UTX) demethylase function impacts both wound healing and reprogramming to a fibrotic phenotype.

Results: CAA revealed a delay in the accumulation of H3K27me3 on nascent DNA at 28hr post-injury, while at 48hr post-injury H3K27me3 accumulation was rapid. Thus, revealing a “window of opportunity” when chromatin is decondensed and amenable to new TF binding for cell reprogramming. The status of H3K27 is controlled by H3K27 modifying enzymes, the demethylase UTX and the methyltransferase enhancer of zeste homolog 2 (EZH2). By CAA, both UTX and EZH2 were recruited to nascent DNA at 28hr post-injury. However, blocking UTX function led to an accumulation of H3K27me3 to nascent DNA. This suggests that UTX masks EZH2 function to maintain a decondensed chromatin state for cell reprogramming. Recruitment of the pro-fibrotic TF, myocardin related transcription factor A (MRTF-A) to nascent DNA occurred during the “window of opportunity” and specifically at the time of replication. Lastly, we found that UTX demethylase function was required for MRTF-A binding to nascent DNA and transition to a fibrotic phenotype without preventing wound healing.

Conclusions: UTX demethylase activity is required to decondense post-replicative chromatin structure to make it amenable to the adoption of a new fibrotic transcription program.

ABSTRACT BODY:

Purpose: Early detection of diabetic retinopathy (DR) and glaucoma is crucial to preventing vision loss. Previous studies have evaluated teleretinal screening programs for DR in well-insured populations. The purpose of this retrospective, observational study was to evaluate a teleretinal screening program in a population of uninsured and underinsured patients.

Methods: We conducted a retrospective chart review of patients (age \geq 18) who underwent teleretinal imaging (TRI) at a federally qualified health center between January 1, 2015 and September 4, 2019. TRI gradings, patient demographic information, relevant medical history, laboratory data, and information from subsequent ophthalmology visits were abstracted. Generalized estimating equations were used to identify factors associated with ophthalmology referral and adherence to ophthalmology referral.

Results: 3130 TRI were graded in 2216 eyes from 1108 patients. Only 47.4% (N=184) of the 388 patients referred for a dilated fundus examination based on TRI followed up with ophthalmology as recommended. Adherence to the recommended ophthalmology exam was not associated with any of the baseline clinical or demographic characteristics ($p>0.10$). Referral to ophthalmology based on TRI gradings was associated with a greater likelihood of also having diabetic nephropathy, diabetic neuropathy, hypertension, proteinuria, $GFR<60$, older age, and higher hemoglobin A1c (all $p<0.05$). Female (odds ratio [OR], 0.75; $p=0.001$) and Hispanic patients (OR, 0.79; $p=0.009$) were less likely to receive an ophthalmology referral compared with male and non-Hispanic patients respectively. In a multivariable model, older age, male sex, proteinuria, and A1c remained significantly associated with a greater likelihood of ophthalmology referral (all $p<0.05$). There was high agreement between TRI gradings for glaucoma or DR and final diagnoses for patients who underwent subsequent ophthalmology examination (88.9% and 92.1% respectively).

Conclusions: In this study of uninsured/underinsured patients, those referred to ophthalmology based on TRI were more likely to have other complications of diabetes. However, fewer than 50% of patients attended the recommended follow-up examination. Improved care coordination is critical to ensure patients adhere to follow-up recommendation for a dilated fundus examination following teleretinal screening.

TITLE: Temporal relationship between ERG waveforms and the firing patterns of rat retinal ganglion cells

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Johnson, Molecular Physiology and Pharmacology, USF Health Morsani College of Medicine, Tampa, Florida, UNITED STATES|Y. Mohamed, C.L. Passaglia, Medical Engineering, University of South Florida College of Engineering, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nicholas Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Youssef Mohamed: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Passaglia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The contribution of retinal ganglion cell (RGC) activity to noninvasive measures of retinal health such as the electroretinogram (ERG) is a topic of clinical interest. We simultaneously recorded RGC spike trains and the full-field ERG for various stimulus paradigms to directly determine how ERG waveforms relate to the timing and pattern of activity in different RGC types.

Methods: Adult Brown Norway rats were kept at an anesthetic plane under a mixture of ketamine and xylazine. A craniotomy was performed at Bregma and a tungsten-in-glass electrode was advanced into the optic nerve to record the RGC spike trains. A gold ring electrode was placed on the limbus of the eye to record the ERG. Visual stimuli consisted of full-field flashes (10 – 500ms duration) of light ($0.018 - 1800 \text{ cd/m}^2/\text{s}$) or darkness ($1.8 \text{ cd/m}^2/\text{s}$ background) and full-field flicker (4 – 64 Hz) of 0.5 – 2 s duration presented via an LED-illuminated Ganzfeld dome. Tetrodotoxin (TTX; $6\mu\text{M}$) was used to block spiking activity.

Results: Spike trains from ON RGCs cluster into 'spike volleys' that correspond to oscillatory potentials in the ERG to bright flashes ($n=15$; $R^2>0.95$, $p<0.05$). Under these conditions, spike trains from OFF cells do not cluster into volleys but fire during the descending phase of the b-wave. Dark flashes produce a weak negative ERG wave analogous to the b-wave ($n=6$). Spike trains from OFF RGCs occur near the peak of the negative wave. The first harmonic amplitude of ON-transient ($n=1$) and OFF transient ($n=9$) RGC responses differed for short-duration flicker ($p<0.05$) but not for long-duration flicker. It did not differ for either short- or long-duration flicker for ON sustained ($n=14$) and OFF sustained ($n=3$) RGCs. TTX altered the ERG but did not eliminate OPs. Furthermore, cross correlation between the spontaneous activity of RGCs and the ERG did not reveal significant correlation ($n=9$).

Conclusions: OP generators in the retina drive oscillatory spike patterns in RGCs. Contrary to prior studies, there were no significant differences in the flicker responses of ON- and OFF-pathways.

ABSTRACT BODY:

Purpose: COVID-19 has created a strong need for telemedicine and remote monitoring. Remote monitoring is especially important for diseases such as age-related macular degeneration (AMD), because prompt detection of subtle changes indicating neovascularization is critical to prevent blindness. This describes a novel, digital, handheld standalone device that delivers at-home AMD monitoring for patients and a hardware validation of that new device.

Methods: A prototype device (KalEYEdoscope) was developed consisting of an injection-molded 3D printed shell with a graduated focusing mechanism with a 10x magnifying 22mm biconcave lens, two tactile buttons, a battery, a processing unit, and a small OLED screen (Figure 1). The electronics include a battery powered small single-board computer (Raspberry Pi 3) connected to a 1.5-inch RGB OLED screen and two pushbuttons. The device is inherently monocular. The software uses the concept of shape discrimination hyperacuity to identify the patient's minimum distortion-detection threshold (MDDT). Upon use, the screen displays a series of circle-like images and, after each image, asks the user whether the image previously displayed appeared to be a perfect circle. The software then converges to the user's MDDT based on user input. Data is collected longitudinally and analyzed to determine a change in patient condition, which is then communicated as a message on the screen.

Results: Hardware validation was performed. The device had a weight of 0.211 kg and diameter of 61 mm. There was an appropriate push button resistance of 1.52 N, meeting the required engineering specifications of 1.4 to 5.6 N. The screen transition time was 0.7 seconds, and it took 1.834 seconds for the circle to appear on the screen. The total boot time of the software was 20.21 seconds, which was below the target of 30 seconds.

Conclusions: A digital, hand-held standalone device can be created that is compact, lightweight, and meets targeted engineering and design specifications for hardware and software. This device could have potential in performing home monitoring of AMD progression using shape discrimination hyperacuity to identify the patient's minimum distortion-detection threshold.

ABSTRACT BODY:

Purpose: Recent literature suggests that average retinal vessel diameter is decreased in patients with open-angle glaucoma. We performed a prospective, observational cross-sectional study to determine whether changes in retinal vessel diameters were associated with steady state pattern electroretinogram (ssPERG) and Foveal Avascular Zone (FAZ) area parameters in patients with pre-perimetric glaucoma (PPG).

Methods: Five patients (8 eyes) with normal Humphrey 24-2 visual field tests, suspicious optic nerve head findings and with refractive errors $< \pm 5.0$ Diopters were enrolled in the study conducted at Manhattan Eye Ear and Throat Hospital. Participants underwent comprehensive ophthalmological examination and tests on Humphrey Field Analyzer (HFA) , Diopsys NOVA PERG and the Cirrus HD OCT-A Angioplex devices. Average vessel diameter of retinal arteries and veins was calculated using the vessel analysis plug-in on ImageJ. FAZ area was determined using ImageJ. Correlation analyses among vessel diameters, FAZ area and ssPERG parameters [Magnitude (Mag), MagnitudeD (MagD) and MagD/Mag ratio], were assessed to characterize these associations (Pearson's). P values < 0.05 considered statistically significant.

Results: Results were gathered from 8 eyes of 5 patients aged 59.90 ± 14.20 years of age, with mean IOP 18.30 ± 4.50 and HFA 24-2 mean deviation 0.21 ± 0.94 . Average vessel diameter was negatively correlated with FAZ area ($r = -0.955$, $p < 0.01$) and positively correlated with both ssPERG parameters MagD ($r = 0.733$, $p < 0.05$) and MagD/Mag ratio ($r = 0.819$, $p < 0.05$). No associations were observed between vessel diameter and Mag. FAZ area was negatively associated with MagD, however, this relationship was not significant ($r = -0.347$, $p = 0.055$).

Conclusions: To best of our knowledge, this is the first study to confirm the relationship between reductions in average vessel diameter measurements with abnormal ssPERG and enlarged FAZ area parameters in patients with PPG. These results suggest that retinal vascular abnormalities and retinal ganglion cell dysfunction may be present before changes in visual field tests. Future investigations are needed to better understand the relationships between arteriolar and venular diameters, as well as the effects of systemic diseases on vessel diameters.

ABSTRACT BODY:

Purpose: Mechanistic target of rapamycin (mTOR) signaling is central to trophic factor responses and nutrient sensing pathways. mTOR complex 1 (mTORC1) containing the regulatory-associated protein of mTOR (Raptor) regulates cell metabolism, growth and survival. Recently, we found that expression of mTORC1 components are relatively high in retinal ganglion cells (RGC, PMID:32622801). Here we examined the necessity of mTORC1 on RGC survival by conditional knockout (cKO) of mTOR and Raptor in the adult mouse retina.

Methods: mT/mG Cre-reporter mice were used to test the effectiveness of intravitreal (ivt) injection of AAV2Cre and a novel control virus encoding inactive Cre (AAV2CreΔC) on recombination in retinal cells. Adult *mtor*^{f/f} and *rptor*^{f/f} mice were ivt injected with these vectors to cause cKO of mTOR and Raptor, respectively, in cells within the ganglion cell layer (GCL). Activity of the mTORC1 pathway was evaluated by immunofluorescence (IF) analysis of phosphorylation of S6 ribosomal protein (p-S6, Ser240/244) and eukaryotic translation initiation factor 4E-binding protein 1 (p-4EBP1, Thr37/46) in retinal sections. RGC populations were examined using IF of the RGC marker RNA binding protein multiple splicing (RBPMS) and Hoechst staining in retinal sections.

Results: IvT injection of AAV2Cre caused effective recombination in cells within the GCL, whereas AAV2CreΔC did not. AAV2Cre-mediated cKO of mTOR or Raptor decreased mTORC1 activity in the GCL, as indicated by significant reductions of p-S6 and p-4EBP1 positive cells. At 12 wk after AAV2Cre injection, cKO of mTOR or Raptor did not change RGC or total GCL cell densities. However, at 24 wk after AAV2Cre injection, cKO of mTOR or Raptor caused 47% (p<0.01) and 43% (p<0.01) reductions in RBPMS-positive cells, respectively, relative to the contralateral eye injected with AAV2CreΔC vector. RBPMS IF intensities in RGC were also generally decreased. Densities of nuclei in the GCL decreased by 12% (p=0.2) and 26% (p<0.5), respectively, confirming cell loss.

Conclusions: Although some of the total decrease in RBPMS-positive cells may be attributed to down-regulation of RBPMS expression in mTORC1-deficient RGC, the results suggest that cKO of mTOR or Raptor caused an eventual loss of RGC in adult mice. mTORC1 function may thus be necessary for maintaining both RGC differentiation and long-term viability.

TITLE: Variation in visual outcomes for neovascular age-related macular degeneration within and between practitioners

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Nguyen, M.C. Gillies, The University of Sydney Save Sight Institute, Sydney, New South Wales, AUSTRALIA|D. Barthelmes, UniversitätsSpital Zurich, Zurich, SWITZERLAND|

Commercial Relationships Disclosure (Abstract): Vuong Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Barthelmes: Commercial Relationship(s);Bayer:Code F (Financial Support);Novartis:Code F (Financial Support) | Mark Gillies: Commercial Relationship(s);Bayer:Code F (Financial Support);Novartis:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Clustering of visual outcomes for neovascular age-related macular degeneration (nAMD) within practitioners is likely to occur due to a combination of shared patient demographics and adherence, practitioner treatment strategy including choice of treatment and re-treatment intervals, and access to resources. Such clustering would subsequently result in variation in outcomes between practitioners. We report both the intraclass correlation and variation in 12-month outcomes within and between practitioners in a large cohort of patients from routine clinical practice.

Methods: Treatment-naïve patients in the Fight Retinal Blindness! registry initiating treatment with anti-vascular endothelial growth factor (anti-VEGF) injections from 2012 onwards with at least 12 months of follow-up were identified. Only practitioners with at least 10 eligible eyes were included. Data from Australia, France, Italy, Netherlands, New Zealand, and Spain were included.

The primary outcome was the practitioner intraclass correlation (ICC) for the change in visual acuity (VA) at 12 months. Other outcomes included the standard deviation of the 12-month VA change within and between practitioners. Mixed-effects modelling with the practitioner specified as a nested random-effect and baseline age and vision as fixed effects was used to estimate these outcomes.

Results: There were 7191 eyes from 6023 patients treated by 94 practitioners that met the inclusion criteria. The mean 12-month VA change and 95% confidence interval for each practitioner is shown in Figure 1. The ICC for the 12-month VA change was 0.016, which is negligible, and the between practitioner standard deviation was 2.25. In contrast, the within practitioner standard deviation was much higher at 14.8. This result was consistent across countries. The between practitioner standard deviation ranged from 0.73 in France to 4.14 in New Zealand.

Conclusions: We found a negligible practitioner ICC in VA change due to the substantial variation in outcomes within practitioner relative to the variation between practitioners. This indicates that the patient-level response is contributing far more to the variation in outcomes than the practitioner. It is possible that most practitioners these days are treating nAMD patients fairly similarly, at least in the short-term.

ABSTRACT BODY:

Purpose: Compared to visual acuity, contrast sensitivity function (CSF) better correlates with vision-related quality of life and subjectively perceived visual impairment, and may be affected earlier in the course of age-related macular degeneration (AMD). Inherent imperfections of the existing contrast tests have prevented its adoption in the clinical practice. Our aim is to characterize CSF in different stages of non-neovascular AMD (nnAMD) compared to healthy controls employing a novel active learning quick CSF (qCSF) method.

Methods: This prospective cross-sectional study included nnAMD patients graded by consensus grading (clinical exam, color fundus photos, and OCT) and healthy controls. Contrast was measured using the Manifold Contrast Vision Meter (Adaptive Sensory Technology, San Diego, CA). Outcomes included Area under the Log CSF (AULCSF), contrast sensitivity (CS) thresholds at 1, 1.5, 3, 6, 12, and 18 cycles per degree (cpd). Mixed-model multiple linear regression analyses were performed to evaluate the association between presence and stage of nnAMD (vs controls) and the CSF outcome measures.

Results: A total of 363 eyes were included, 249 nnAMD eyes (68 Early, 154 Intermediate, 27 Advanced) and 114 control eyes. Mean BCVA for controls was 0.020 versus 0.040 in early ($P > 0.05$), 0.140 in intermediate ($P = 0.002$) and 0.550 in advanced nnAMD eyes ($P < 0.001$). When controlling for age and lens status, early nnAMD was significantly

associated with reduced CSF thresholds at low spatial frequencies (1, 1.5, 3 cpd) ($\beta = -0.09$, $\beta = -0.09$, and $\beta = -0.11$, respectively, all $P < 0.01$) compared to controls, despite no difference in BCVA. Intermediate and advanced nnAMD were significantly associated with reduced CSF at 1, 1.5, 3, 6 and 12 cpd and reduced AULCSF (all $P < 0.01$). On trend analysis, nnAMD progression was associated with corresponding significant progressive decline in AULCSF (Early $\beta = -0.06$, Intermediate $\beta = -0.18$, Advanced $\beta = -0.64$ vs controls)(Figure 1).

Conclusions: Early nnAMD was associated with reduced CSF compared to controls as measured by the novel qCSF method, despite no difference in BCVA. Worsening nnAMD stages were associated with a progressive decline in AULCSF. The qCSF may emerge as a promising visual function endpoint in the routine clinical practice and future nnAMD clinical trials.

ABSTRACT BODY:

Purpose: To evaluate the microbiological spectrum of corneas from septicemic donors and whether these corneas can be utilised for corneal transplantation. Study tested the hypothesis that cornea being an avascular tissue carries minimum risk of transmission of systemic infection from donor to recipient

Methods: In this prospective study, corneas donated to the eye bank of a tertiary eye care centre of Central India over a period of 2 years were included. During the corneal retrieval procedure based on the reports of blood culture, septicemic donors were defined as those whose blood culture tested positive. Donor corneas were allocated to either group I (septicemic donors) or group II (non-septicemic donors) based on blood culture reports and death certificate summary. Donor tissue in group I was subjected to a culture of the corneal tissue, scleral rim, aqueous and vitreous samples after retrieval, while in group II was subjected within 72 hours of retrieval. A microbial work-up flow chart was prepared and used for the sterility check of all the donor tissues. Variables were analysed using Fisher's exact test for probability and statistical significance

Results: A total of 264 corneas from 136 donors were analysed, 42 corneas of which were from septicemic donors. The microbial growth rates of the corneal tissue from group I and group II donors were close (7.142% vs 9.010%, $p=0.30$). Most common isolated organism was gram positive cocci. Only one corneal tissue showed similar bacterial growth as those from the blood culture. The rest of the contaminated corneas did not grow the same bacterial strains as those from their blood cultures. Results of the culture analysis of scleral (9.52% in Group I vs 10.81% in Group II), aqueous (4.76% in Group I and 2.25% in Group II), and vitreous (2.38% in Group I vs 1.35% in Group II) samples were statistically insignificant between both the groups

Conclusions: The study showed that corneas from septicemic donors have equally low infection rates as compared to non-septicemic donors hence can be utilised for corneal transplantation.

TITLE: Photoacoustic determination of methicillin resistance in Staphylococcus aureus in ocular infections

SESSION TITLE: Antimicrobials and Immunomodulators

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Jhanji, R.P. Kowalski, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|R. Edgar, A. Samson, J. Viator, Duquesne University, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Vishal Jhanji: Commercial Relationship: Code N (No Commercial Relationship) | Robert Edgar: Commercial Relationship: Code N (No Commercial Relationship) | Anie-Pier Samson: Commercial Relationship: Code N (No Commercial Relationship) | Regis Kowalski: Commercial Relationship: Code N (No Commercial Relationship) | John Viator: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Antibiotic resistance is an ever growing problem in clinical management of infections of the eye, including keratitis. We used photoacoustic flow cytometry to detect and classify keratitis as methicillin sensitive or resistant by testing clinical samples from patients.

Methods: We developed photoacoustic flow cytometry to detect light absorbing particles under flow. This method induces acoustic waves in pigmented particles using laser irradiation, allowing for detection, enumeration, and capture. We acquired samples of Staphylococcus aureus from keratitis in 13 patients in the clinic. These Staphylococcus aureus samples were grown in the presence and absence of Oxacillin and were tested using photoacoustic flow cytometry. In order to create optical absorption in the S. aureus bacteria, purified bacteriophage SP1 virions were modified to incorporate Direct Red 81 dye. Bacteriophage SP1 has a broad host range and has been shown to infect approximately 98% of clinical S. aureus strains. We split each patient sample into two groups, those treated with oxacillin and those not treated. Modified bacteriophage SP1 were added to each group in equal amounts. Using photoacoustics, we then counted the number of bacteria with the expectation that methicillin sensitive samples treated with oxacillin would have greatly reduced numbers of bacteria.

Results: We counted the photoacoustic events in all 13 treated and untreated samples. Detections ranged from 2 to 818 counts. We took the ratio of treated over untreated detections and performed k-means clustering into two groups. The two groups corresponded exactly to the methicillin sensitive and resistant groups determined by PCR for the MecA gene in all 13 strains.

Conclusions: Photoacoustic flow cytometry has the ability to detect Staphylococcus aureus bacteria. By treating samples with antibiotic, it is possible to classify infections as sensitive or resistant, thus allowing for improved management of keratitis.

TITLE: The effect of exogenous TGF β on regulating the fibrotic response of resident immune cells in distinct wound environments

SESSION TITLE: Posterior Capsular Opacification and Fibrosis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.L. Walker, M. Basta, H. Paulson, Pathology, Anatomy and Cell Biology, Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Janice Walker: Commercial Relationship: Code N (No Commercial Relationship) | Morgan Basta: Commercial Relationship: Code N (No Commercial Relationship) | Heather Paulson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vimentin/CD44-rich leader cells, which we now identify as resident immune cells, are immediate responders to cataract surgery wounding and can mediate either a wound healing or a fibrotic response to injury depending upon the wound environment they encounter. The purpose of this study is to investigate the impact of two distinct wound environments on the transforming growth factor-beta (TGF β)-mediated fibrotic response of leader cells with properties of resident immune cells.

Methods: An ex vivo mock cataract surgery wound healing chick embryo model was used to follow the injury response within two distinct wound environments: 1) cell-denuded posterior lens capsule basement membrane and 2) the rigid tissue culture substrate surrounding the explant (extracapsular zone (ECZ)). To determine the effect of the distinct wound microenvironments on the TGF β -mediated fibrotic response of leader cells, ex vivo cataract surgery explant cultures were incubated +/- 10ng/ml TGF β , fixed, and labeled for the leader cell protein CD44 and/or markers of fibrosis. Proliferation was assessed by EdU labeling. Immunolabeling was analyzed by confocal microscopy imaging.

Results: In contrast to untreated ex vivo cataract surgery explants, the addition of TGF β induced leader cells located on the lens capsule to produce and deposit a fibrotic matrix that included tenascin-C and was rich in fibronectin EDA (FN-EDA). On day 3 post-injury, when wound healing on the lens capsule has completed, TGF β induced the appearance of pro-collagen I producing cells without an increased presence of alpha-smooth muscle actin (α SMA) stress-fiber+ myofibroblasts. Lens epithelial cells retained their cuboidal epithelial phenotype. In the environment of the ECZ, exogenous TGF β induced an accelerated and exacerbated fibrotic response by leader cells compared to controls. Exogenous TGF β also promoted CD44+ leader cell proliferation and the earlier transition of leader cells to α SMA+ myofibroblasts. Furthermore, TGF β treatment in the ECZ wound environment accelerated the appearance and the amount of pro-collagen I-producing cells as well as led to the increased accumulation of a FN fibrillar matrix network.

Conclusions: The wound microenvironment that resident immune cells encounter shapes their TGF β -mediated fibrotic response to injury.

ABSTRACT BODY:

Purpose: There is a great need for non-invasive diagnostic tools to screen, diagnose, and track patients with Mild Cognitive Impairment (MCI) and Alzheimer's disease (AD). In AD, the brain accumulates β -amyloid ($A\beta$) as plaque detectable by amyloid-PET brain scans. $A\beta$ accumulates in lenses from AD patients but not patients with other neurodegenerative diseases (Goldstein et al., 2003). Identical $A\beta$ lens pathology has been identified in patients with Down syndrome (Moncaster et al., 2010), a chromosomal disorder in which $A\beta$ brain pathology is an invariant feature. We developed an non-invasive drug-device eye scanner to evaluate lens $A\beta$. The Sapphire II platform (Cognoptix) combines a topically-applied $A\beta$ -binding fluorescent ligand with a molecular spectroscopy ophthalmoscope that distinguishes normal subjects from those with probable AD (Kerbage et al., 2014). Sapphire II scan shows greater sensitivity and specificity than amyloid-PET scans vs clinical diagnosis for AD. This study evaluated Sapphire II screening vs amyloid-PET scans in earlier MCI and mild AD subjects.

Methods: 48 participants: 28 MCI, 16 Mild AD patients, 4 Normal Control subjects were studied. All MCI and AD subjects underwent cognitive testing and amyloid-PET scans. The Sapphire II system couples a medical imaging ointment that contains the $A\beta$ -binding fluorescent ligand, Aftobetin, and a Fluorescent Laser Eye Scanning (FLES) device that detects a spectral shifted fluorescent signature signal of bound Aftobetin- $A\beta$ complexes in the lens. Each scan takes <1 sec and multiple readings can be obtained in a single sitting.

Results: 43 subjects have been evaluated to date. No serious adverse events were reported. There was no instance where Sapphire II was negative and amyloid-PET scans were positive, indicating of a high degree of diagnostic specificity. Of the 39 Sapphire II positive subjects, positive amyloid-PET scans were noted in 26. Evaluation of individual PET scans and cognitive testing suggests that Sapphire II is more sensitive than amyloid-PET scans compared to clinical criteria.

Conclusions: Sapphire II is a convenient, inexpensive, rapid non-invasive screening tool that detects AD-related $A\beta$ accumulation in the lens of subjects with MCI and mild AD. We are exploring the utility of Sapphire II in patients with early prodromal asymptomatic AD ("preclinical AD").

ABSTRACT BODY:

Purpose: Dynamic changes in ocular shape during embryonic development have been observed in foveated vertebrates including humans, other primates and recently lizards. Areas that develop a fovea elongate shortly after retinal differentiation and then undergo ocular retraction or a return to ocular symmetry, during which time retinal remodeling occurs (pit formation, photoreceptor cell packing). We propose that fovea development is a protracted process that begins early in embryonic development and that ocular elongation followed by retraction are necessary steps for fovea formation. To better understand this, we investigated the role of morphological changes in eye shape in the foveated chameleon, *Chamaeleo calytratus*, and the bifoveated brown anole lizard, *Anolis sagrei*, before examining albino anoles with tyrosinase mutations. Wildtype chameleons have a central fovea while anoles have both a central and temporal fovea. Albino lizards with tyrosinase mutations fail to develop their temporal fovea.

Methods: Embryonic eyes were dissected and then measured along 3 different anatomical planes in chameleons as well as wildtype and albino anoles. Albino (*tyr*^{-/-}) lizards were created using a CRISPR gene editing approach.

Results: Between early and mid-embryonic development, the central and temporal regions of the wildtype anole eye elongate. Later, both regions retract, returning the eye to its' spherical shape, at which point the fovea develops. A similar process occurs in chameleons but only the central region undergoes ocular elongation, retraction, and fovea formation. Preliminary results of the albino anoles, which exhibit temporal fovea hypoplasia, suggest embryonic albino eyes exhibit a reduction in temporal ocular elongation but not in central elongation during development.

Conclusions: These results support the premise that ocular elongation and retraction are necessary steps in fovea formation and the idea that the onset of fovea development may occur much earlier than previously believed. Together these findings indicate that the anole lizard is a promising model system for studies investigating human ocular developmental disorders.

ABSTRACT BODY:

Purpose: To assess the association between quantitatively assessed, higher-order optical coherence tomography (OCT) features, such as ellipsoid zone (EZ) integrity and sub-RPE compartment features, evaluated at baseline with visual outcomes in subjects with non-neovascular age-related macular degeneration (AMD) treated with subcutaneous elamipretide.

Methods: ReCLAIM was an open-label, phase 1 clinical trial of daily subcutaneous elamipretide (40 mg) in NNVAMD, stratified into pre-defined nonfoveal geographic atrophy (GA) and high-risk drusen (HRD) subgroups. The primary endpoint was change in low-luminance best corrected visual acuity (LLBCVA). Higher-order OCT features were evaluated via automated machine-learning augmented multilayer retinal segmentation with expert reader manual verification to quantify outer retinal integrity [e.g., EZ-RPE thickness, percent EZ attenuation, outer retinal parameters (i.e., outer nuclear layer (ONL) to RPE thickness)] and sub-RPE anatomical metrics. Post hoc analysis assessed correlation of baseline higher order OCT Features with change in LLBCVA from baseline to end of treatment (week 24).

Results: A total of 40 patients were evaluated (19 in the nonfoveal GA subgroup and 21 in the HRD subgroup). In the nonfoveal GA subgroup, the baseline macular percentage of total EZ attenuation ($r=-0.72$; $p=0.002$) and baseline panmacular EZ-RPE volume ($r=0.62$; $p=0.01$) were significantly correlated to change in LLBCVA from baseline to week 24. Eyes gaining 2 lines or more had significantly less macular total EZ attenuation at baseline (9.0% vs 27%; $p=0.03$) and significantly less percentage area of macular GA (4.7% vs 15.6%; $p=0.004$).

In the HRD subgroup, mean central macular (e.g., central 2 mm) retinal thickness positively correlated with improvement in LLBCVA ($r=0.58$; $p=0.009$). Eyes gaining 2 lines or more had significantly greater baseline preservation of the central macular outer retina (ONL-RPE thickness, 137 μ m vs 117 μ m, $p=0.006$) trended towards

less baseline macular partial EZ attenuation (1.1% vs 5.0%; $p=0.06$).

Conclusions: Baseline higher order OCT parameters, such as EZ integrity, were correlated with functional response and improved LLBCVA in eyes treated with subcutaneous elamipretide. Further research is needed to better characterize these potential imaging biomarkers.

ABSTRACT BODY:

Purpose: Epiretinal prosthetic systems have been developed to restore sight to the blind; however, the spatial resolution of current devices is still limited. Previous studies have demonstrated that long stimulus pulses (~ 25 ms) or low sinusoidal frequencies (5-25 Hz) can selectively target retinal bipolar cells (BCs) and, therefore, improve the spatial resolution of epiretinal implants by avoiding axonal activation of retinal ganglion cells (RGCs). In this study, we present a computational modeling framework that captures the biophysical factors that influence the stimulus threshold of BCs to long stimulus pulse durations.

Methods: Using the Admittance Method (AM)/NEURON computational platform, we implemented a model of spiking BCs, diffuse bipolar cell subtypes (DB4), that was verified with experimental and modeling data from the literature. We analyzed the response of BCs over a range of stimulus pulses, including cathodic monophasic and anodic-first biphasic pulses. We investigated the role of the hyperpolarization-activated, cyclic nucleotide-gated (HCN) channels at the presynaptic terminals in the high sensitivity of BCs to long stimulus pulse durations.

Results: We tested a range of pulse durations from 0.1 ms to 25 ms and compared the response of BCs to cathodic monophasic and anodic-first biphasic pulses. Our data show that long anodic-first biphasic pulse durations (> 8 ms) significantly reduce the stimulus threshold of BCs relative to long cathodic-first pulses from 98 μ A to 57 μ A. We further explored that the absence of HCN channels at the presynaptic terminals of BCs increases the stimulus threshold of BCs and, therefore, HCN channels contribute to the higher sensitivity of BCs to long anodic-first stimulus pulse widths.

Conclusions: Our computational findings suggest that the presence of long anodic pulses prior to cathodic pulses likely contributes to selective activation of BCs and the reported rounder shape of phosphene with epiretinal implants using long stimulus pulse widths. The reduced threshold and high sensitivity of BCs to low-frequency stimulation and long pulse durations are likely mediated by the high concentration of HCN channels at the terminals of BCs.

ABSTRACT BODY:

Purpose: Melatonin is synthesized mainly in the pineal gland and is important for circadian function. It is also produced in retina, lens, gastrointestinal tract and skin. It displays strong anti-oxidative properties and plays a protective role in human pathologies associated with oxidative stress, including retinal diseases. Cobalt chloride (CoCl₂) mimics hypoxic conditions and can affect cell viability. The present study evaluates and compares the protective effects of melatonin on ARPE-19 and MIO-M1 cells stressed with CoCl₂ in vitro to determine if the drug can modulate the inflammatory/oxidative stress systems and reduce the damage caused by retinal diseases.

Methods: Human ARPE-19 and MIO-M1 cells were cultured separately for 24 hours in 96-well plates. Cells were pretreated for 6 hours with melatonin (200µM, 400µM and 800µM) and then stressed with CoCl₂ in different concentrations: 350 µM for ARPE-19 cells and 500 µM for MIO-M1 cells for 48 hours. Cultures were analyzed for cell viability (MTT assay), reactive oxygen species (ROS/H₂DCFDA assay), and mitochondrial membrane potential (MMP, JC-1 assay). The conditions were: untreated, solution-control, and the melatonin in different concentrations.

Results: CoCl₂-treated ARPE-19 cells incubated with 400µM and 800µM melatonin had (a) increased cell viability with p=0.0352 and p=0.0016, respectively; and (b) increased MMP with p=0.0131 and p=0.0096, respectively. The cell viability and MMP were not altered after treatment with 200µM melatonin.

MIO-M1 cells stressed with CoCl₂ and rescued with melatonin 200µM and 400µM showed increased cell viability with p=0.0341 and p=0.0009, respectively. The MMP increased when treated with 800µM melatonin (p=0.0082), while the melatonin 200µM and 400µM cultures were not altered. No significant changes were seen in ROS levels for either cell line.

Conclusions: Each CoCl₂-stressed cell line had distinct responses with the melatonin at different concentrations. Our results suggest that melatonin improves cell viability and mitochondrial membrane potential but does not affect ROS production in CoCl₂-stressed cells. Our approach may be helpful to identify novel pathways to protect against retinal diseases and show differential responses by different cell lines to one drug.

ABSTRACT BODY:

Purpose: To estimate prevalence of eyelid cancers in the AAO IRIS® Registry and evaluate associated factors.

Methods: All patients with ICD-9/10 codes for eyelid cancers(basal cell carcinoma [BCC],squamous cell carcinoma[SCC],malignant melanoma[MM],melanoma in-situ[MIS], sebaceous cell carcinoma/other specified malignant neoplasm[SBCC] and unspecified malignant neoplasm[UMN]),in the IRIS® registry between 12/1/2010-12/1/2018, were included. Prevalence was estimated overall, by age (categorical),race(White[W],Hispanic[H],African-American[A-A], Asian[A],Other[O],Unknown[UK]), sex (Male[M], Female[F]), and smoking status. Prevalences were compared using χ^2 tests or Fisher's exact tests. Odds ratios (ORs) and 95% confidence intervals (CIs) were estimated using multivariable logistic regression.

Results: 81,802 eyelid cancer patients were identified. Prevalence of Any Eyelid Cancer (AEC) was 0.14%. Tumor-specific prevalences ranged from: 0.088% (BCC), to 0.026% (UMN), 0.011% (SCC), 0.005% (SBCC), 0.004% (MM), and 0.0004% (MIS). Prevalence increased with increasing age for AEC and each tumor type (all $p < 0.0005$), was higher in M than F for any eyelid cancer and BCC, SCC, MM (all: $p < 0.0001$) and MIS ($p = 0.03$), but not UMN or SBCC. Prevalence was highest in W's compared with any other race for BCC, SCC, and SBCC (all $p < 0.0001$). Prevalence was also higher in current/former smokers vs. non-smokers for AEC and all tumor types (all $p < 0.01$). In the model, having AEC was associated with older ages [< 20 yrs (ref.); OR (CI): 20-39 yrs: 3.6 (3.2-4.0); 40-65 yrs: 16.0 (14.7-17.6); > 65 yrs: 25.6 (23.4-28.0)], M sex [F (ref.); 1.2 (1.2-1.2)], former/current smoking [never (ref.); former: 1.1 (1.1, 1.1), current: 1.2 (1.2-1.2)] and W race (inverse associations with A-A (0.1 (0.1-0.1), A (0.3 (0.3-0.3)) H (0.6 (0.5-0.6)) and O (0.6 (0.5-0.7)). Older age was associated with all tumor types, while other factors varied by type.

Conclusions: This is the first study to report on overall and tumor-specific prevalence of eyelid cancers from a large national clinical population. Associations with older age, male sex and white race are consistent with prior studies. The association with smoking for eyelid tumors offers guidance for disease prevention. This epidemiologic "real-world" data on eyelid cancers is valuable for risk factor assessment, planning treatment strategies, allocating medical resources, and improvements in cancer care.

ABSTRACT BODY:

Purpose: To determine the ability of an engineered corneal endothelium to restore corneal clarity in an animal model.

Methods: Corneal endothelial cells were isolated from three 3 months old New Zealand rabbits and harvested with a two-step approach. Collagen membranes were elaborated using bovine collagen type I ($5.6 \mu\text{L}/\text{mm}^2$ of the culture plate surface or 2X) dissolved in DMEM-F12 medium, 22 mM HEPES solution, 8% FBS, and 1 % antibiotics. The mixture was incubated 2h at 37 °C for gelation then placed in a 40 °C and 40% RH for 37 days. The corneal endothelial cells were seeded at a density of 1250 cells/ mm^2 overnight over 8 mm^2 membranes. Five male New Zealand rabbits 20 months old were used as models. Corneal endothelium was removed under local and general anesthesia and the membrane/cells constructs were transplanted into the anterior chamber of the right eye of 4 rabbits. One rabbit was transplanted using a collagen membrane elaborated with $8.4 \mu\text{L}/\text{mm}^2$ collagen (3X). The transplanted eyes were photo-documented for 30 days.

Results: The five eyes developed opacity after 5 min of corneal endothelium removal. The eyes transplanted with 2X membrane constructs (rabbits 1, 2, 3, and 4) recovered partially the peripheral clarity after 3 weeks. After 5 weeks, rabbits 1, 2, and 4 showed central corneal clarity. Central opacity remained in rabbit 3. The eye transplanted with 3X membrane construct remained with mild opacity after 5 weeks of transplantation.

Conclusions: Engineered corneal endothelium produced with corneal endothelial cells cultivated with a two-step approach and 2X collagen membranes restores the corneal clarity in old White New Zealand rabbits. The concentration of collagen in the fabrication of the membrane could affect the recovery of corneal clarity.

TITLE: Effect of enhanced lighting on detection of targets with artificially reduced acuity

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Freedman, G.E. Legge, Psychology, University of Minnesota Twin Cities, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrew Freedman: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Legge: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To design visually accessible spaces, it is important to understand how illumination and target-background luminance contrast affect detection of key features in the environment. Simply increasing overall room illumination ignores the crucial role of contrast in determining visibility, and directional lighting may reduce the contrast between an object and its background. This study examined the effects of illumination and luminance contrast on the detectability of objects in the environment for those with reduced acuity.

Methods: 13 normally sighted subjects, wearing blur goggles that reduced their acuity to approximately 20/900, completed a visual search task. Under typical ambient indoor lighting, subjects walked along a path, following a guideline, and visually searched for targets adjacent to the path. Subjects verbally identified the shape of targets as they walked. Performance was quantified with detection rate, the percent of targets subjects attempted to identify. Targets were white or grey Styrofoam objects on the floor, in a room with walls painted white or black. Spotlights were used to increase the illumination of targets placed against the walls to three fold their ambient illumination, creating two lighting conditions: ambient and enhanced. This served to either increase contrast (e.g. grey targets against black walls), or decrease contrast (grey targets against white walls). This created targets with high or low contrast with their background under both lighting conditions, for independent manipulation of both lighting and contrast. A multiple binomial logistic regression was performed to analyze the probability that a target would be detected.

Results: The model was statistically significant ($\chi^2(3)=92.89$, $p<.001$), and showed that detection odds were significantly increased by 3.41 fold for high vs low contrast targets (CI =1.80-6.44; $p<.001$). While increased illumination significantly increased detection rate by 29.2% for grey targets against a black background (CI=10.4-48.1%; $p=.006$), it did not significantly improve performance under other conditions, and was not statistically significant in the model.

Conclusions: Under low-acuity conditions in the environment tested here, luminance contrast was more predictive of object detectability than illumination. Notably, in some cases, increased illumination from directional lighting enhanced detectability by increasing target-background contrast.

ABSTRACT BODY:

Purpose: Corneal scarring is a major clinical problem worldwide that results in reduced vision and blindness. The development of new regenerative therapies to address corneal scarring and blindness requires a reliable, reproducible, and clinically relevant pre-clinical model of corneal scarring.

Methods: We have developed a method of creating a corneal scar of controlled diameter and depth on rabbit eyes through a transient microdose (TMD) of sodium hydroxide (NaOH). TMDs of varying time intervals and volumes were applied up to 30 seconds and 5 microliters, respectively. The eyes were then rinsed thoroughly with phosphate buffered saline for 10 seconds. The pH of the surface is checked to make sure no residual alkalinity remains. Optical coherence tomography (OCT) was used to evaluate the resulting depth and diameter of epithelial and stromal opacity formed, along with slit lamp images. A circular trephine is then used to perform an anterior lamellar keratectomy to remove the scar tissue and fill it with an in situ-forming hydrogel material to occupy the space where the scar was removed.

Results: We found that 0.2 microliters of 1M sodium hydroxide (NaOH) added to the surface of an ex vivo rabbit cornea for 20 seconds results in an approximately 50% depth opacity that is 3 mm in diameter. This size scar presents a visually significant corneal scar covering the visual axis that typically requires corneal transplantation. With OCT to aid in visualization, we found that the entirety of the scar with minimal surrounding transparent stroma can be removed via controlled-depth, trephine-assisted manual keratectomy and substituted with a transparent, in situ-forming gel matrix.

Conclusions: The technique described serves as a corneal opacity tissue model that can be utilized to evaluate regenerative therapies such as engineered, in situ-forming, pre-formed, and/or cell-based biomaterial therapies designed to avoid the need for penetrating keratoplasty. Future directions include translation of this technique into the in vivo setting and the testing of candidate therapies.

ABSTRACT BODY:

Purpose: Sjögren's Syndrome (SS) is a systemic autoimmune disease associated with lymphocytic infiltration and loss of function of the lacrimal gland (LG). The cysteine protease, cathepsin S (CTSS), is increased in LG and tears in a murine model of SS; moreover, the protease's activity is elevated in SS patients' tears. Inhibition of CTSS activity in a murine model also suppressed ocular symptoms of SS. Protein phosphatase 2A (PP2A), through dephosphorylation of tristetraprolin (TTP), destabilizes CTSS mRNA; conversely, inhibition of PP2A leads to increased stability and expression of CTSS mRNA. To understand more about the mechanisms responsible for LG CTSS upregulation in SS, we have explored the expression of effectors of the PP2A-TTP pathway in LG from SS model and healthy control mice.

Methods: Age-matched (12-18 weeks) male NOD mice and male BALB/c mice LG were used to compare gene and protein expression of the PP2A-TTP axis components. Primers for PP2A catalytic subunit, TTP, SET (an endogenous PP2A inhibitor), and CIP2A (an endogenous PP2A inhibitor) were used for analysis by RT-qPCR of lysed LG cDNA. CIP2A protein expression in LG lysates from male NOD and BALB/c mouse LG were compared by Western Blotting. PP2A and CTSS activities were measured from male mouse BALB/c LG incubated ex vivo with either okadaic acid (OKA, 1uM), a commercially available PP2A inhibitor, or DMSO (vehicle) for 2 hr using commercially available kits PP2A (Milipore Cat # 17-313) and CTSS (Biovision Cat # K144).

Results: NOD mouse LG showed significantly less expression of PP2Ac mRNA compared to BALB/c mouse LG (n=4, p=0.0054). A comparable trend to increased expression of CIP2A, an endogenous PP2A inhibitor, was seen in NOD mouse LG (n=6, p=0.0663). This trend to increased expression was verified by Western blotting for CIP2A, showing an increase of 1.6 fold CIP2A (n=6, p=0.011) in NOD mouse LG lysates relative to BALB/c mouse. No significant changes in gene expression of SET or TTP were seen between strains. Lysates from BALB/c mouse LG ex vivo incubated with OKA showed a 2.2 fold increase in CTSS activity (n=5, p=0.0013) and a 0.6 fold decrease in PP2A activity (n=3, p=0.0395) compared to control.

Conclusions: Changes in expression of effectors of the PP2A-TTP pathway regulating CTSS mRNA stability suggest this as a possible mechanism governing increased expression of CTSS in SS.

ABSTRACT BODY:

Purpose: Inherited Retinal Degenerative diseases (IRDs) are a major cause of blindness mainly caused by premature death of rod photoreceptor cells in the retina. As a heterogeneous group of pathologies, IRDs can either be congenital or have early/mid-onset where progressive degeneration has severe impact in quality of life among patients. Although more than 270 different genes and loci have been implicated, disease mechanisms remain obscure resulting in little hope for therapy. In this study we use a multi-omics approach to elucidate gene network and pathways underlying disease pathogenesis in the rd1 mice model which mimics human pathology and has the most aggressive form of degeneration.

Methods: We designed this unique study to focus on the early stages of the rd1 retina - Postnatal day (P) 2 to P10 - to identify the molecular events in rod photoreceptors before cell death begins at P12. We performed time course RNAseq of purified rods and integrated it with mass-spectrometry based proteomics and metabolomics from rd1 and WT retina. Validations were performed with ultrastructural analysis and functional assays.

Results: Transcriptomic analysis revealed co-expression modules of oxidative phosphorylation (OXPHOS) genes to be significantly associated with rd1. Proteomic comparisons between WT and rd1 retina confirmed differential abundance of core subunits of OXPHOS complexes at P6, with further exacerbation by P10. Electron microscopy analysis of the rd1 retina between P6 and P10 highlighted loss of mitochondrial cristae, corroborating molecular findings of OXPHOS dysregulation as cells get close to disease onset. At the same time, metabolomics uncovered reduced flux in central carbon metabolism and additionally showed deregulation of essential biosynthetic pathways such as nucleic and amino acid metabolism. Furthermore, Seahorse assays validated lower mitochondrial reserve capacity and energy metabolism in ex vivo mutant retina.

Conclusions: This study for the first time describes molecular changes in rod photoreceptors before they succumb to apoptosis in IRDs. Through an omics driven approach we identify mitochondrial energy metabolism as a molecular converging point, leading us to hypothesize a critical role of metabolism and the mitochondria in IRDs. Identification of these disease related pathways will aid therapy development and disease management.

ABSTRACT BODY:

Purpose: The retraction of retinal ganglion cell (RGC) dendrites is one of the earliest pathological changes leading to functional deficits. We demonstrated that insulin, administered after arbor retraction, promotes RGC dendrite and synapse regeneration. Endogenous insulin and related molecules are naturally found in the retina. Thus, we asked the following questions: 1) is reduction of high intraocular pressure (IOP) sufficient to promote dendrite regeneration in the absence of exogenous insulin? 2) what are the signalling components downstream of insulin promoting RGC dendrite regeneration in glaucoma?

Methods: Thy1-YFP mice, which allow visualization of RGC dendritic arbors, received an intracameral injection of magnetic microbeads to induce ocular hypertension. Daily topical application of brinzolamide, a carbonic anhydrase inhibitor with negligible effects on neurons or vascular cells, was used to reduce IOP. RGC dendrites were imaged with confocal microscopy and 3D reconstructed using Imaris software. RGCs were isolated by Fluorescence Activated Cell Sorting (FACS) from insulin- or vehicle-treated glaucomatous retinas as well as non-injured controls, followed by RNA sequencing analysis.

Results: Brinzolamide effectively reduced IOP relative to vehicle treated controls (sham: 10.7 ± 0.3 mmHg, brinzolamide: 11.3 ± 0.4 mmHg, vehicle: 20.5 ± 0.8 mmHg, $n=12$ mice/group, Student's t-test, $p < 0.001$). Total RGC dendritic length and complexity increased in glaucomatous eyes treated with insulin ($4,515 \pm 149$ μ m) to values similar to those found in non-injured controls ($4,566 \pm 233$ μ m), but not in eyes treated with brinzolamide ($2,534 \pm 164$ μ m) or vehicle ($2,981 \pm 169$ μ m) ($n=6$ mice/group, ANOVA, $p < 0.001$). RNA-seq analysis of insulin- and vehicle-treated glaucomatous retinas identified key regulatory pathways that might be implicated in insulin-induced RGC dendrite regeneration including the mammalian target of rapamycin (mTOR), glycolysis, fatty acid metabolism, DNA repair, and myc-targets (FDR <0.05).

Conclusions: We conclude that: 1) IOP reduction alone is not sufficient to promote RGC dendrite regeneration, and 2) multiple downstream pathways are activated during insulin-mediated regeneration. These findings support a critical role for exogenous insulin administration, and identify differential gene expression of potential targets to restore RGC function in glaucoma.

TITLE: Macular rod function in retinitis pigmentosa (RP): Comparison of scotopic microperimeter to modified Humphrey field analyzer

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Krishnan, A. Roman, M. Swider, S.G. Jacobson, A.V. Cideciyan, Perelman School of Medicine, Scheie Eye Institute, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Arun Krishnan: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Roman: Commercial Relationship: Code N (No Commercial Relationship) | Malgorzata Swider: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Jacobson: Commercial Relationship: Code N (No Commercial Relationship) | Artur Cideciyan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate validity and reliability of macular rod photoreceptor function estimated with a retina-tracking microperimeter in dark-adapted eyes of patients with RP.

Methods: Twenty-two eyes of eleven patients (ages:7–66 yrs) with RP, and five eyes of five normal subjects (ages:22–55 yrs) were included. Dark-adapted chromatic perimetry (DACP) was performed with a modified Humphrey field analyzer (mHFA) in dilated eyes. Monochromatic mHFA stimuli were 500 nm blue and 650 nm red with 200 ms duration and 1.7 deg diameter. In addition, MP-1S microperimeter was used to obtain sensitivities to broad-band blue stimuli filtered through 0, 1, 2, 3 or 4 ND to expand the effective dynamic range from 20 dB to 60 dB. Test locations were along the two principal meridians at eccentricities of 6, 8, 10, 12, and 14 deg. Sensitivity loss (SL) was defined as the difference from the average normal value at each locus. mHFA results were used to censor those locations that showed cone mediation or greater than 30 dB of rod sensitivity loss. In addition, loci near transitions to deep scotomas (papillary boundary or retinal degeneration) were censored to allow a fair comparison between free-viewing mHFA and retina-tracking MP-1S results. All RP eyes were evaluated similarly with both methods during two visits separated by 6 months.

Results: Normal effective MP-1S sensitivities with blue stimuli were 43.5 ± 1.0 dB (mean \pm s.d.). In RP patients, after censoring, there were 241 evaluable loci. The range of SL was 2.2 to 30.2 dB for mHFA and 2.5 to 38.5 dB for MP-1S, respectively. SL estimates obtained with MP-1S were highly correlated ($r = 0.81$) with those obtained with mHFA; the relationship could be explained well by a line with an offset of 3.9 dB and a slope of 0.93. Assuming no disease progression during the 6-month interval, 95% coefficient of repeatability was 5.96 dB for mHFA and 7.34 dB for MP-1S, respectively. There was no evidence of a relationship of variability with mean sensitivity.

Conclusions: In a macular annulus extending from 6 to 14 degrees, rod sensitivity losses with the scotopic microperimeter MP-1S closely track those of the mHFA – long-standing gold-standard for DACP in RP patients. There is a tendency for MP-1S losses to be slightly larger and more variable than those of mHFA.

TITLE: Abnormal Renal Profiles and Diabetic Eye Disease in Latino and African American Cohorts

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Carrasquillo, J. Levine, Ophthalmology, BronxCare Health System, Bronx, New York, UNITED STATES | J. Levine, Ophthalmology, Hadassah Academic College, Jerusalem, Jerusalem, ISRAEL |

Commercial Relationships Disclosure (Abstract): Onelys Carrasquillo: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Levine: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the association between abnormal renal profiles and presence of diabetic retinopathy (DR) and diabetic macular edema (DME) in Latino (LA) and African American (AA) patients of our South Bronx community. This will be an expanded version of our original pilot study of 100 patients to now include an n of over 1200.

Methods: This is a retrospective chart review of adult diabetic LA and AA patients seen in our hospital's eye clinic within the last 5 years. Demographic information and most recent renal profiles including serum creatinine levels, eGFR, and urinary microalbumin to creatinine ratios (ACR) will be recorded. In addition we will record hemoglobin A1C and cholesterol levels. Patients will be stratified based on presence or absence of Diabetic Macular Edema and/or Diabetic Retinopathy. Log values of ACR will be used for data analysis as the ACR values are not normally distributed. Lab values will be compared between groups and the unpaired Student's t-test will be used to calculate statistical significance.

Results: We have over 1200 diabetic patients included in our study, 439 AA and 809 in the LA cohort. We have reviewed nearly 200 charts thus far from the AA cohort, 55 with DR of some degree, and 142 with no DR. The DR group had a significantly higher mean ACR compared to the no DR group. (1.823 vs 1.269 p <.0005) The DME subgroup (n=14) also had a higher mean ACR than the no DR group but values did not reach statistical significance. (1.659 vs. 1.269 p > 0.05).

Conclusions: After reviewing 200 of the 1200 charts in our current study, we have already found significantly elevated ACR values among our African American patients with DR compared to non DR. We hope that a larger n will substantiate an association between ACR and DME as well. If so, then perhaps future studies could evaluate using abnormal ACR values as a prognostic indicator of future diabetic eye disease in these cohorts.

ABSTRACT BODY:

Purpose: Consideration of posterior vitreous detachment (PVD) status is highly clinically relevant for managing a host of vitreoretinal disorders and in planning for vitreoretinal surgery. However, the translucent nature of vitreous humor makes definitive clinical assessment of PVD challenging. The goal of this study was to define patterns of posterior vitreous cortex (PVC) changes using circumpapillary spectral-domain optical coherence tomography (SD-OCT).

Methods: The vitreoretinal interface of 1685 eyes of 879 clinical retina patients were retrospectively analyzed using 100 ART HS circumpapillary OCT and 6mm² macular OCT (Heidelberg OCT2) by 3 masked graders. The primary outcome was the vitreoretinal interface status, graded using a modified staging system (initially described by Uchino et al, 2001); 0) no PVD: tight vitreoretinal adhesion with no discernible separation 1) insignificant separation: partial vitreoretinal separation, with no separation of the PVC within the papillo-macular bundle 2) Clinically relevant separation: separation of the PVC within the papillo-macular bundle with persistent vitreofoveal attachment 3) vitreofoveal separation with persistent vitreoretinal adhesion at the optic disc 4) Full PVD: Dark absence of signal anterior to the retina or with pinpoint translucence consistent with vitreous cells or hemorrhage.

Results: Complete separation between the circumpapillary retina and PVC was detected by circumpapillary OCT in 706 of 1678 eyes (41.90%). Of 1685 scans analyzed in this study, 4 (0.24%) were deemed to have an indeterminate PVD status. By age, PVD was detected in 0/42 eyes age 1-18 ($P < 0.001$), 2/72 eyes (2.78%) age 19-29 ($P < 0.001$), 11/127 eyes (8.66%) age 30-39 ($P < 0.001$), 17/203 eyes (8.37%) age 40-49 ($P < 0.001$), 106/307 eyes (34.53%) age 50-59 ($P < 0.05$), 229/461 eyes (49.67%) age 60-69 ($P < 0.01$), 211/324 eyes (65.12%) age 70-79 ($P < 0.001$), 110/128 eyes (85.94%) age 80-89 ($P < 0.001$), and 20/21 eyes (95.24%) age 90+ ($P < 0.001$).

Conclusions: Analysis of the PVC with routine circumpapillary OCT scans is shown to be an effective, readily available means of evaluating PVD status; circumpapillary OCT may be valuable in discerning the vitreoretinal interface status for cases in which it may be clinically ambiguous. Results corroborate well-established progression of PVD with age while showing evidence that PVD initiates at earlier ages than previously reported.

TITLE: Comprehensive study of immune landscape in aging retina

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Elahi, P. Mattar, Ottawa Hospital Research Institute, Ottawa, Ontario, CANADA|P. Mattar, Cellular and Molecular Medicine, University of Ottawa Faculty of Medicine, Ottawa, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Seerat Elahi: Commercial Relationship: Code N (No Commercial Relationship) | Pierre Mattar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aging is the one of the major risk factors for degenerative retinal disorders. While a role for immune cells in the progression of the degenerative process has been implicated, studies on the retinal immune landscape, mostly due to sparsity and lack of markers to identify various cell populations, and how these cells are affected by aging are scattered. In this study, we aimed to comprehensively explore the dynamics of innate and adaptive immune cells of the murine retina from birth to death. To this end, we designed a multi-color flow cytometry panel and identified various populations of innate and adaptive immune system, including different types of microglia, dendritic cells (DCs), neutrophils, monocytes, T and B cells, and analyzed their changes over time.

Methods: In this study, we performed multi-color flow cytometry analysis on retinal cells of CD1 and C57/B6 mice at various time points from birth (P0) to up to 2 years.

Results: Our study revealed that CD45⁺ hematopoietic cells were surprisingly frequent within the retina. Interestingly, we found that the frequency of both myeloid (CD45⁺/CD11C⁺/MHCII⁺/CD11B⁺) and lymphoid (CD45⁺/CD11C⁺/MHCII⁺/CD11B⁻) DCs increased strikingly with age. The higher expression of MHCII complex on dendritic cells over time was echoed by an elevation in the frequency of CD11c⁺ microglia (CD45⁺/CD11C⁺/MHCII⁻/CD11B⁺), while CD11c⁻ microglia (CD45⁺/CD11C⁻/CD11B⁺/LY6G⁻/LY6C⁻) were not affected. This data suggests different roles for CD11C positive and negative microglia in homeostasis and sub-clinical inflammation. In contrast to previous studies that tried to capture the dynamics of lymphocytes over time by immunofluorescence staining, our flow cytometry approach revealed that CD4⁺ T cells (CD45⁺/CD19⁻/CD3⁺/CD4⁺/CD8⁻) are present within the retina immediately after birth while CD8⁺ T cells (CD45⁺/CD19⁻/CD3⁺/CD4⁻/CD8⁺) begin to present themselves after 6 months. Interestingly, the frequency of both of CD4⁺ and CD8⁺ T cells increased continuously as the mice aged, while B cells were not observed.

Conclusions: Here we introduce a flow cytometry strategy to capture a global image of various and rare populations of immune cells residing in retina effectively and simultaneously. Moreover, our data suggest that while para-inflammation state of aged retina is thought to arise via microglia/complement activation, activated DCs may also contribute to neuroimmune inflammatory processes.

ABSTRACT BODY:

Purpose: Most babies born prematurely do not develop retinopathy requiring treatment. Complications in this specific population are known to occur in adults. To assess the vasculature in these adult patients with a history of premature birth, we analyzed swept source optical coherence tomography angiograms (SS-OCTA) to identify potential novel imaging biomarkers.

Methods: This is a retrospective IRB approved study. Seventeen eyes from ten adult patients with a history of prematurity (mean age 44 years; range 23-76) imaged with SS-OCTA (Zeiss Plex Elite) were compared to 19 age matched control eyes. SS-OCTA superficial capillary plexus en face 3x3 mm and 6x6 mm scans were analyzed. The border of the foveal avascular zone (FAZ) was traced manually, and FAZ metrics of total area, perimeter, and circularity index (given as a number between 0 and 1, 1 indicating a perfect uniform circle) were calculated with ImageJ software (NIH, Bethesda, MD). Spectral domain OCT (SD-OCT) metrics were also evaluated. Independent t tests were used to compare OCTA and OCT features.

Results: Adults born prematurely had significantly smaller FAZ area ($p=0.001$) of less uniform shape as indicated by circularity index ($p<0.001$) than controls. The mean FAZ area (mm^2), perimeter (mm), and circularity index (0-1) on SS-OCTA were 0.11 ± 0.084 , 1.7 ± 0.72 , and 0.46 ± 0.17 , respectively, in adults with premature birth and 0.21 ± 0.079 , 2.0 ± 0.41 , 0.67 ± 0.11 in controls. There was no significant difference in the mean central subfield thickness (CST, mm), central volume (CV, μm^3), and cube average thickness (CAT, mm) on SD-OCT in adults born prematurely (293 ± 32.5 , 9.92 ± 1.07 , and 276 ± 29.3) and in controls (277 ± 22.6 , 10.4 ± 0.370 , 290 ± 10.3).

Conclusions: SS-OCTA in adult patients with a history of premature birth without treated retinopathy demonstrated significantly smaller and less uniform FAZ than controls. This increased vascularity as seen within the fovea on SS-OCTA may be a useful imaging modality to identify these patients.

ABSTRACT BODY:

Purpose: To evaluate the diagnostic performance of the 8x8 grid of the posterior pole algorithm with two different fovea-to-disc inclinations to discriminate between healthy and primary open-angle glaucoma (POAG).

Methods: 85 eyes of 85 glaucomatous patients and 74 eyes of 74 early POAG patients were included. All underwent macular OCT scans (Spectralis, Heidelberg) using the 8x8 posterior pole algorithm with an automatic 7-degree inclination of the fovea-to-disc axis. Ganglion cell complex (GCC) thickness was obtained for the 64 superpixels of the grid. Then, horizontalization of the grid in each eye was performed and the results of GCC were also exported. The areas under the receiver operating characteristics curves (AUROC) values were obtained for the GCC thickness in the 64 cells for 7-degree inclined grid and for horizontalized grid. Heat maps were plotted to represent the AUROC values. The thickness of superpixels with AUROC values ≥ 0.75 were combined for each inclination obtaining a global index for the 7-degree inclined grid (7degINDEX) and the horizontalized grid (horINDEX).

Results: AUROC values were ≥ 0.75 in 25 superpixels in the 7-degree inclined grid (the highest was the superpixel 2.8, AUROC=0.821) and 24 superpixels in the horizontalized grid (the highest was also the superpixel 2.8, AUROC=0.807). We found no significant difference between 7degINDEX AUROC (0.827) and horINDEX AUROC (0.824) ($p > 0.05$, DeLong test).

Conclusions: The 7-degree inclination of the 8x8 grid of the posterior pole algorithm measuring GCC thickness does not seem to outperform the horizontalized grid when discriminating between POAG and healthy eyes.

ABSTRACT BODY:

Purpose: The presence of subretinal fluid (SRF) in central serous chorioretinopathy (CSCR) separates the photoreceptors from the blood supply of the choroid, which could lead to disruptions of the cells in the outer retina especially when CSCR is chronic or recurrent. In this retrospective study, we sought to determine the functional and anatomical outcomes of CSCR based on standard treatment methods as well as experimental normobaric hyperoxia (NBH), which has been proposed to reduce macular edema and improve vision.

Methods: Clinical outcomes and ocular coherence tomography findings were compared for patients with CSCR undergoing observation, laser/photodynamic therapy (PDT), or NBH. A total of 47 patients with active CSCR, acute (≤ 6 months) or chronic (> 6 months), were included and underwent either observation ($n=23$), laser/PDT therapy ($n=7$), 3-hour NBH sessions ($n=13$), or nocturnal NBH ($n=4$). Best corrected visual acuity (BCVA), recurrence, and the thickness of the central macula (CMT), SRF, photoreceptor layer (PL), and outer nuclear layer (ONL) were assessed.

Results: A total of 49 eyes were classified as acute ($n=39$) or chronic ($n=16$) and non-recurrent ($n=26$) or recurrent ($n=15$). Time for complete resolution of SRF was 3.5 ± 1.5 months for acute patients and 11 ± 4.2 months for chronic patients. BCVA improved from baseline for all resolving patients regardless of treatment type. None of the patients in the laser therapy group experienced a recurrent episode after an average follow-up of 38.7 ± 19.7 months (range of 3.6 – 56.6 months) while 48% of observation-only patients experienced a recurrence within an average of 24.9 ± 23.7 months (range of 1.7 to 68.8 months). Patients in the 3hr NBH group showed no statistical difference in any of the parameters tested before and after treatment. When compared to observation patients, resolving nocturnal NBH patients demonstrated a decrease in the time for resolution of SRF (4.5 ± 3.1 and 3.8 months, respectively). In resolving patients, there were consistent decreases in CMT and PL thickness, and little to no change in the thickness of the ONL.

Conclusions: We show that patients with CSCR have a high probability of recurrence and that this may be reduced by laser/PDT therapy. Nocturnal NBH may facilitate earlier resolution of SRF and vision loss. Together, these treatment strategies may improve clinical outcomes for CSCR.

ABSTRACT BODY:

Purpose: Achromatopsia (ACHM) is an autosomal recessive retinal disease characterized by absence of cone photoreceptor function. Clinical manifestations include reduced visual acuity, complete loss of color discrimination, and photophobia under daylight conditions. Gene therapy drugs, AGTC-401 and AGTC-402, are being developed to compensate for the mutated genes responsible for over 80% of the ACHM cases, CNGA3 and CNGB3. This is an initial report on the twelve-month safety and efficacy findings from two ongoing, Phase 1/2, open-label, dose-escalation trials using recombinant adeno-associated virus (rAAV) viral vectors.

Methods: A single subretinal injection of either AGTC-401 (rAAV2tYF-PR1.7-hCNGB3) or AGTC-402 (rAAV2tYF-PR1.7-hCNGA3) was administered to participants (n=24), age ≥14, into the macula region of the study eye. Participants were sequentially assigned to one of four dose groups in both studies. The safety and efficacy outcomes were measured by best-corrected visual acuity (BCVA) using ETDRS, light discomfort testing (LDT) by ocular photosensitivity analyzer (OPA), ERG/mfERG, retinal sensitivity by static perimetry and microperimetry, color vision testing by Farnsworth D15 and CAD, and patient-reported outcomes (PROs) using a QoL questionnaire (VLSQ-8).

Results: Both drugs were well-tolerated across all dose ranges. Most AEs were mild-moderate. No SAE was drug-related, and 2 participants had SAEs related to raised IOP due to concomitant steroids. AEs due to ocular inflammation were controlled after modification of the steroid regimen. Immunological response to AAV and genes CNGA3 or CNGB3 were not indicative of a safety concern. Among the 24 treated participants, 4 had a 5-letter improvement on BCVA at month 12. Five participants had a 1-log₁₀ lux or more improvement for light sensitivity threshold on OPA analysis. PROs showed patient improvement in outdoor light sensitivity, severity of worst light

sensitivity, and headache. There were small changes for most assessments at month 12 compared to baseline.

Conclusions: Safety results suggest AGTC-401 and AGTC-402 are safe and well tolerated in ACHM patients. There were no indications of significant immunological responses to the vector or capsid. Data across both studies show encouraging signs of biologic activity. Additional patients will be enrolled in both studies and followed through 5 years.

Commercial Relationships Disclosure (Abstract): Bridget Peterson: Commercial Relationship: Code N (No Commercial Relationship) | Tomislav Glavan: Commercial Relationship: Code N (No Commercial Relationship) | Kenny Huang: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Chan: Commercial Relationship: Code N (No Commercial Relationship) | Jurja Bratko: Commercial Relationship: Code N (No Commercial Relationship) | Nebyou Mergia: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Selian: Commercial Relationship: Code N (No Commercial Relationship) | Justyna Szczygiel: Commercial Relationship: Code N (No Commercial Relationship) | Hanna De Bruyn: Commercial Relationship: Code N (No Commercial Relationship) | Ivana Mihalek: Commercial Relationship: Code N (No Commercial Relationship) | Anne Fulton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The phenotypic information surrounding ABCA4-related Stargardt's disease most commonly available in the literature is the age of onset. Based on that information only, we note that the genotypes where neither ABCA4 allele produces a functional protein result in the early onset of the disease (Fig 1A and 1B). However, to begin to understand the disease progression, the longitudinal data are of particular value, Fig. 1C.

Methods: We have collected the disease progression data from 38 patients diagnosed with ABCA4-related Stargardt's disease. The medical literature search resulted in further 600 genotype-phenotype pairs. Therein the longitudinal data, we note, remains scarce.

Results: Based on our dataset, we propose the model in which the rapid decline in the visual acuity is a consequence of the feedback interplay between the photoreceptors (PRs) and the retinal pigment epithelium (RPE). In a nutshell, we argue that if the RPE declined over time in a simple proportion to the number of its cells under the toxic attack by A2E, the byproduct of dysfunctional ABCA4 in the PRs, the decline would be exponential. However, because the PRs themselves depend on the RPE for their viability, the decline must be faster, leading to super-exponential decline in the RPE and, consequently, in visual acuity (VA). This corresponds well with the clinical observation, Fig 1D.

Conclusions: Our hope is that the model will serve as the starting point for discussion of the Stargardt's disease phenotype as a function of ABCA4 genotype (rather than individual alleles). The hope is also that it will motivate systematic collection and publication of Stargardt's disease progression data, and further experimental characterization of the disease-related variants needed for the development of detailed models applicable in the clinical setting.

TITLE: Performance of an Artificial Intelligence model in retinal fluid quantification for patients with diabetic macular edema and retinal vein occlusions.

SESSION TITLE: AI in the retina: Clinical Applications

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Kaakour, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|W. Song, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|A. Kalur, A. Iyer, J. Muste, R.P. Singh, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|R.P. Singh, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Abdul-Hadi Kaakour: Commercial Relationship: Code N (No Commercial Relationship) | Weilin Song: Commercial Relationship: Code N (No Commercial Relationship) | Aneesha Kalur: Commercial Relationship: Code N (No Commercial Relationship) | Amogh Iyer: Commercial Relationship: Code N (No Commercial Relationship) | Justin Muste: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Computational image recognition and machine learning techniques have been used to develop algorithms that distinguish normal retinal morphological features from distorted contours occurring due to the presence of fluid between and within tissue layers. A deep neural network has previously demonstrated efficacy for the detection and quantification of exudative fluid in age-related macular degeneration. However, it lacks validation in diabetic macular edema (DME) or retinal vein occlusion (RVO). This study aims to externally evaluate the performance of NOA against expert graders for the classification and quantification of fluid in DME and RVO.

Methods: Retrospective, non-randomized cohort study performed at Cole Eye Institute, Cleveland, OH. Scans were graded by the Notal OCT Analyzer (NOA, Notal Vision Ltd, Tel Aviv, Israel) machine learning and image recognition algorithm and manually measured by two expert graders who assessed the quantification of fluid using OCTExplorer (Iowa Institute for Biomedical Imaging, Iowa City, IA). The results from manual and NOA reading were compared to determine interclass correlation and Pearson's correlation coefficient. Categorical variables were described using frequencies and percentages, and continuous variables using medians, interquartile ranges, means, and standard deviations.

Results: Twenty DME and 20 RVO Cirrus SD-OCT B-scan macular cubes with retinal fluid were analyzed. In the DME cohort, the overall fluid grader-grader agreement (GGA) was 91.9%, while the NOA-grader agreement (NGA) was 76.5%. This further stratified into 92.2%, 98.9% GGA and 82.3%, 80.8% NGA for intraretinal and subretinal fluid (IRF, SRF) respectively. RVO overall fluid GGA was 96.6% and 68% NGA, differentiating into 96.4%, 99.8% GGA and 42.2%, 42.9% NGA in the IRF and SRF categories.

Conclusions: Manual expert graders exhibited high levels of agreement in both the DME and RVO cohorts, generally higher in evaluating SRF. Between the manual graders and the NOA algorithm a satisfactory level of agreement was found, albeit relatively lower in comparison to human graders. Additionally, there was higher machine-human agreement in the DME cohort than the RVO group. The NOA algorithm is helpful in the classification and quantification of retinal fluid may be a useful clinical diagnostic and management tool to augment decision making.

TITLE: Characteristics of patients receiving intravitreal injections during COVID-19

SESSION TITLE: Impacts of Covid on patients and practice

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.F. Hyacinthe, S.A. Sadiq, A. Clingerman, R. Desai, A.T. Lyon, R. Mirza, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Christian Hyacinthe: Commercial Relationship: Code N (No Commercial Relationship) | Saena Sadiq: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Clingerman: Commercial Relationship: Code N (No Commercial Relationship) | Ria Desai: Commercial Relationship: Code N (No Commercial Relationship) | Alice Lyon: Commercial Relationship: Code N (No Commercial Relationship) | Rukhsana Mirza: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: After the Illinois shelter-in-place COVID-19 mandate was instituted on March 16, 2020, outpatient ophthalmology care was limited to patients with vision-threatening conditions. In order to better understand the impact of the mandate on patients receiving intravitreal injections (IVIs), we compared key demographic and clinical features of patients seen before and after quarantine measures.

Methods: Retina patients receiving IVIs at Northwestern Medicine sites between 12/1/19 and 6/30/20 were identified and divided into “pre-COVID” (PC) and “Strict-Quarantine” (SQ) groups (12/1/19-3/15/20 and 3/16/20-6/30/20, respectively). A subset of patients lost to follow-up (LTFU), defined as having been seen at least once in the PC period but not at all during the SQ period, were also identified. Comparison of primary diagnoses and self-reported demographic data was performed between these three sub-groups. Primary diagnoses necessitating IVIs were identified as age-related macular degeneration (AMD), diabetic retinopathy (DR), retinal vein occlusion (RVO), and other causes of neovascularization (other).

Results: 1426 injections were administered to 716 patients during the PC period compared to 1121 injections to 637 patients during the SQ period. More injections per patient were performed in the PC period compared to the SQ period (1.99 ± 1.00 vs 1.76 ± 0.87 , $p = 5.87E-06$). There were no significant differences in primary diagnosis or demographic characteristics between these two groups ($p = 0.852$, 0.974 , respectively). 24.2% of PC patients (173 patients) were identified as LTFU. Of the LTFU patients, a lower percentage identified as White and higher percentages identified as Black, Asian and Other in comparison to the PC ($p = 0.0413$) and SQ ($p = 0.00853$) groups. LTFU patients proportionally had a higher percentage of DR (35.88%) and RVO (20.59%) primary diagnoses and a lower proportion of AMD (33.53%) primary diagnoses than patients in the PC ($p=0.0011$) and SQ ($p=0.0014$) groups.

Conclusions: The COVID-19 pandemic resulted in disruption of normal ophthalmic clinic operations. Because Black and other non-white patients and patients with diabetic retinopathy made up higher percentages of the LTFU group, efforts should be made to understand and address any barriers to medically necessary follow-up during this unprecedented public health crisis.

SUBMITTER (NAME ONLY): Cadmus Rich

TITLE: Development of AU-011 for Choroidal Metastasis

SESSION TITLE: Advances in intra and extra ocular pathologies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C.C. Rich, A. Savinainen, R. Kines, Aura Biosciences, Inc, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Cadmus Rich: Commercial Relationship(s);Aura Biosciences:Code E (Employment);Aura Biosciences:Code S (Non-remunerative) | Anneli Savinainen: Commercial Relationship(s);Aura Biosciences:Code E (Employment) | Rhonda Kines: Commercial Relationship(s);Aura Biosciences:Code E (Employment)

ABSTRACT BODY:

Purpose: AU-011 is an investigational virus-like drug conjugate composed of a virus-like particle conjugated to a photosensitizer. AU-011 binds to tumor cells by selectively targeting specifically modified heparan sulphate proteoglycans (HSPGs) on the tumor cell surface. Upon light activation, AU-011 is designed to cause membrane disruption leading to acute cellular necrosis and tumor regression in vivo. The HPV derived VLPs have a tumor tropic nature and have been previously described to have the ability to target a large panel of tumor types. As such, AU-011 has the potential to treat choroidal metastasis using the same treatment paradigm. The most common primary tumors known to metastasize to the choroid are breast and lung. The purpose of this study was to evaluate the potential to treat choroidal metastasis by evaluating the effect of AU-011 in these cancer types both in vitro and in vivo.

Methods: In vitro efficacy was evaluated in a panel of human breast and lung cancer cell lines. Cells were treated with AU-011, and cell binding and cell killing were evaluated by flow cytometry. HSPG targeting and tumor specificity were assessed by inhibiting binding to HSPGs with exogenous heparin. In vivo efficacy was evaluated by utilizing 4T1 and EMT6 syngeneic mouse models for breast cancer. Tumor cells were implanted subcutaneously. AU-011 treatment was initiated when tumors reached approximately 50 mm³. Treatment consisted of a single intravenous administration of AU-011 followed 12 hours later by external exposure to near-IR light. Tumor volumes were measured over time.

Results: In both panels of cancer cell lines, the in vitro cell binding and cell killing potency were in the picomolar range (EC₅₀: 17-250pM). Cell binding and subsequent AU-011 mediated cell death was inhibited by heparin, demonstrating that AU-011 can bind to these tumor cell types in an HSPG dependent manner. In vivo AU-011 treatment demonstrated activity and reduction of growth in 4T1 and EMT6 murine breast tumor models, further corroborating data previously obtained in other murine cancer models.

Conclusions: These data demonstrated that AU-011 can bind to, and kill, cells derived from the most common cancer types known to metastasize to the choroid. Furthermore, AU-011 showed activity in vivo using cognate tumor models. The studies herein support further development of AU-011 for choroidal metastasis.

TITLE: Activation of NADPH oxidase 4 Promotes Angiogenic Progenitor Dysfunction in Diabetic Retinopathy

SESSION TITLE: Diabetic retinopathy/retinal pharmacology/physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.X. Zhang, C. Liao, J.J. Wang, Department of Ophthalmology and Ross Eye Institute, University at Buffalo, Buffalo, New York, UNITED STATES|S.X. Zhang, Department of Biochemistry, University at Buffalo, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sarah Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Chunfen Liao: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress resulting from excessive reactive oxygen species (ROS) generation is a major cause of angiogenic progenitor dysfunction that contributes to the development of persistent vascular damage in diabetic retinopathy (DR). Main sources of ROS in blood vessels include mitochondria and NADPH oxidases. However, the expression and role of NADPH oxidases in diabetic angiogenic progenitors and their implication in DR remain poorly understood. Herein, we investigate the role of NADPH oxidase 4 (Nox4) in diabetic angiogenic progenitor dysfunction and DR.

Methods: Diabetes was induced in Tie2-cre mediated Nox4 conditional KO (cKO) mice and wild type (WT) mice. Expression of Nox isoforms (Nox1, Nox2, and Nox4) was examined in bone marrow-derived endothelial outgrowth cells (EOCs) at 1, 3, 6, or 9 months after the induction of diabetes. Cell proliferation, colony formation, apoptosis, senescence, migration, and ROS generation were examined in EOCs from 6-month diabetic Nox4 cKO and WT mice. Signaling pathways of oxidative stress, ER stress, and expression of integrins were investigated.

Results: At 6 and 9 months after diabetes, Nox4 expression in EOCs was significantly increased, while Nox2 expression in EOCs was increased only after 9 months diabetes and no change was observed in Nox1 expression at any time points. In addition, ROS levels were significantly increased in 6 month-diabetic EOCs and the increase was largely abolished in Nox4 cKO cells. Compared to non-diabetic controls, EOCs derived from 6-month diabetic WT mice demonstrated reduced proliferation and colony formation, enhanced apoptosis, increased senescence, and impaired migration in response to VEGF, all of which were significantly improved in EOCs from diabetic Nox4 cKO mice. Mechanically, Nox4 deletion remarkably reduced endoplasmic reticulum (ER) stress and alleviated CHOP and caspase-3 activation in diabetic EOCs. Furthermore, downregulation of Nox4 or inhibition of ER stress significantly alleviated diabetes-induced reduction of integrin b1 improving mobilization of EOCs.

Conclusions: Our results suggest that the aberrant upregulation of Nox4 in diabetic EOCs resulting in increased ROS, enhanced ER stress and disrupted integrin expression may play an important role in angiogenic progenitor dysfunction and DR development.

ABSTRACT BODY:

Purpose: Usher Syndrome type II (USH2A) is a retinal degenerative disease leading to hearing and vision loss that is most commonly caused by recessive mutations in exon 13. USH2A protein is localized in the connecting cilium between inner and outer segments, supporting inner/outer segment formation in photoreceptors. A human iPSC-derived retinal organoid model was developed to test the hypothesis that deleting or inverting USH2A exon 13 (redundant protein domain) could restore deficits caused by USH2A mutation.

Methods: Human iPSC lines were generated from a USH2A patient containing homozygous c.2299delG mutation in exon 13 and healthy control individuals. In patient iPSC clones, exon 13 was deleted (or inverted) by high fidelity CRISPR gene editing. iPSCs from control (n=2), patient (n=5), exon 13-deleted (n=3) and exon 13-inverted (n=3) clones were differentiated at least for 250 days to form high-quality retinal organoids. These organoids were characterized at various time points during organogenesis by gene expression (RT-qPCR), immunohistochemistry (IHC), and morphology.

Results: Control and exon 13-deleted and inverted iPSC clones showed similar gene and protein expression patterns and overall retinal organoid morphologies that are consistent with normal development and published results. In contrast, USH2A mutant iPSC-derived organoids showed irregularity in photoreceptor morphology and deficits in cilia and inner/outer segment organization. Moreover, USH2A, Whirlin and Vldlr proteins were stably expressed in WT but not in mutant retinal organoids. These USH2A mutant abnormalities were rescued by exon 13 deletion (and inversion) using precision gene editing.

Conclusions: USH2A-c.2299delG homozygous mutation caused deficits in photoreceptor morphology, cilia and inner/outer segment formation and destabilization of Usher protein complex (Whirlin/Vldlr/USH2A) during retinal organogenesis. These abnormalities were rescued by precision CRISPR-mediated deletion (and inversion) of exon 13, providing strong support for our exon 13-deletion therapeutic strategy for the treatment of USH2A-associated retinal degenerative diseases.

TITLE: Heritability, concordance and prevalence of epiretinal membrane (ERM) in a twin population

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O.A. Mahroo, NIHR Biomedical Research Centre at Moorfields and the UCL Institute of Ophthalmology, UNITED KINGDOM|Z. Jarrar, K. Williams, O.A. Mahroo, C.J. Hammond, King's College London Section of Ophthalmology, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Zakariya Jarrar: Commercial Relationship: Code N (No Commercial Relationship) | Katie Williams: Commercial Relationship: Code N (No Commercial Relationship) | Omar Mahroo: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Hammond: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore the heritability, concordance and prevalence of ERM in a twin population.

Methods: Macular OCT scans (Optovue iVue 100, Optovue, Freemont, CA) taken between 2014-2019 from participants of the TwinsUK cohort were graded for signs of ERM. Zygosity was ascertained using the “peas in a pod” questionnaire. Casewise concordance was calculated for mono- (MZ) and dizygotic (DZ) twin pairs using $2C/(2C + D)$, where C=number of twin pairs concordant and D=number of twin pairs discordant for ERM. The covariance of ERM within MZ and DZ twin pairs was compared, and genetic modelling techniques were used to determine the relative contributions of genes and environment to the variation in ERM and adjusted for age using OpenMx (<http://openmx.psyc.virginia.edu/>) package in R.

Results: OCT scans from 1098 twin pairs (704 monozygotic [MZ] and 394 dizygotic [DZ]) aged 18-89 (mean 54 SD ± 17) were analysed. ERMs were present in 250 individuals, prevalence 11.4%. 35 MZ and 13 DZ twin pairs were concordant for ERM. 80 MZ and 74 DZ twin pairs were discordant for ERM. Concordance was 0.47 and 0.26 for MZ and DZ twins, respectively, suggesting a role for genes. A model combining additive genetic and unique environmental effects provided the best fit and resulted in an ERM heritability estimate of 0.49 (95% CI, 0.38–0.64).

Conclusions: This is the first classic twin study describing the concordance and heritability of ERM. The findings suggest that ERM has significant underlying genetic influences. Further research to better understand these genetics influences is needed.

TITLE: The influence of reading medium on braille reading speed

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Martiniello, W. Wittich, School of Optometry, Universite de Montreal, Montreal, Quebec, CANADA|N. Martiniello, W. Wittich, Centre de recherche interdisciplinaire en readaptation du Montreal metropolitain, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Natalina Martiniello: Commercial Relationship: Code N (No Commercial Relationship) | Walter Wittich: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The use of braille is associated with higher levels of education and more positive employment outcomes. Braille is read by individuals with visual impairments either in hard copy (paper) or through the use of electronic refreshable braille displays, which provide instant access to information. Braille displays have dots of greater height than traditional paper based formats and may thus provide benefits for older adults with reduced tactile sensitivity. As the cost of braille technologies decline, there is a need to understand how such devices may influence braille reading outcomes. The goal of this study was to explore the influence of reading medium on braille reading speed among a sample of experienced working-age and older adult braille users.

Methods: Forty-six participants (age 23-88, M=52.3, SD=14.9, 15 male) who began learning braille between the ages of 4 and 63 (M=11.75, SD=9.46) read two braille passages from the International Reading Speed Test (IReST) on paper and two passages on display. Demographic information including age and frequency of braille use was collected. Descriptive statistics, Pearson correlations, paired two-sample t-tests and Kruskal-Wallis analyses were conducted.

Results: Reading speeds of 34 to 600 characters/min (M=245.31, SD=157.85) were achieved, with reading on an electronic display being marginally slower (M=241.19, SD=157.71) than reading on paper (M=249.43, SD=164.31). Frequency of braille use led to significant differences in braille reading performance on both paper, $H(4) = 14.317$, $p = .006$, and display, $H(4) = 16.207$, $p = .003$. The age at which braille was first learned was significantly negatively correlated with reading speed on both a display, $r(84) = -0.59$, $p < .001$, and paper, $r(84) = -.63$, $p < .001$.

Conclusions: This study is one of the first to report on differences in reading performance between electronic and paper braille. Results suggest that among experienced readers, there are no significant differences in reading speed when reading on paper versus a refreshable display. Future research should examine differences based on the nature of reading task and whether the benefit of refreshable braille displays may be more pronounced for older adults with reduced tactile sensitivity.

SUBMITTER (NAME ONLY): Ethan Buhr

TITLE: Opsin 5 (OPN5) photoreceptors are induced in the mouse cornea following epithelial debridement.

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Buhr, N.M. Diaz, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ethan Buhr: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Diaz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The cornea is typically transparent to most wavelengths of light. Following dissection and organotypic culture, the cornea begins to express the photoreceptor, Opsin 5 (Opn5) which absorbs short-wavelength light. This confers a light sensitivity to the cornea, particularly to wavelengths in the UVA to violet range. These cells are found primarily in the epithelial layer and co-stain with known epithelial cell markers. We wished to replicate ex vivo observations of photoreceptor induction in vivo using a cornea wounding model.

Methods: Mice which express a fluorescent reporter for Opn5 expression (Opn5^{Cre}; Ai14) were anesthetized and given cornea epithelial debridement using an algerbrush. Cells of these mice will produce red fluorescent protein (RFP) when Opn5 is transcriptionally active. Mice were between 1 and 6 months of age and were of both sexes. Three mice were euthanized and corneas collected at 0, 6, 12, 24, and 48 hours post-surgery. Observed fluorescent cells were used as a representation of OPN5 positive cells. The untreated eyes were used as a control group.

Results: OPN5 cells were observed in the epithelial layer of debrided corneas in a manner consistent to what we previously observed ex vivo. Opn5-positive cells were induced by 6 hours after debridement and were no longer present by 48 hours. The peak number of cells was observed at 12 hours post-surgery. This is a much faster induction than we had measured ex vivo, in which the OPN5 cells begin to appear approximately 18 to 24 hours post-dissection. The induced cells were found close to the healing perimeter, but also throughout the epithelium. No induction of Opn5-positive cells was observed in the untreated corneas.

Conclusions: A photoreceptive system is induced in the mouse cornea after epithelial debridement. These photoreceptive cells express the opsin OPN5 and confer direct light sensitivity to the cornea both in vivo and ex vivo. In the future we hope to assess any role these cells play in the healing process.

ABSTRACT BODY:

Purpose: Contact lens care (CLC) products require robust activity against microorganisms in order to clean and disinfect contact lenses (CL). CLC products are required to meet criteria for disinfection of CLs against bacteria, yeast and mold. However, contamination of CLs is not limited to microorganisms, as viruses can also cause keratitis in patients. Herpes simplex virus type 1 (HSV-1) is the leading infectious cause of keratitis and reoccurrences are common. This study assesses multipurpose and hydrogen peroxide CLC products for antiviral efficacy against HSV-1 in the presence and absence of contact lenses.

Methods: A modified version of ISO 14729 was utilized to assess the antiviral activity of CLC products against Human herpes virus 1 ATCC VR 260 with stand-alone and/or regimen testing. Three multipurpose solutions containing polyquaternium-1 and myristamidopropyl dimethylamine (MPS-1,-2,-3), and two hydrogen peroxide products containing 3% hydrogen peroxide (HP-1,-2) were utilized. For stand-alone tests, all three MPS were inoculated with 10^{5-10^8} TCID₅₀/mL of HSV-1 and allowed to disinfect for six hours prior to recovery of viable virus particles. For regimen tests with MPS-1, HP-1 and HP-2, soft contact lenses (Groups 1 and 4) were inoculated with 10^5-10^7 TCID₅₀/lens, cleaned and/or rinsed, and soaked in lens cases according to label instructions. Following disinfection time, samples were serially diluted and plated on VERO cells in order to determine the titer of viable virus. Log and percent (%) reductions were determined based differences between starting counts and survivors at DT. There are no criteria for the antiviral efficacy of CLC products tested with Herpes simplex virus.

Results: For MPS-1, MPS-2 and MPS-3, the log and percent reduction in the stand-alone test (without lenses) at disinfection time was 3.2 (99.9%), 1.7 (90%) and 1.5 (90%) respectively. For the regimen test (with lenses in lens cases), no viable virus particles were recovered from the lenses or from MPS-1, HP-1 or HP-2 solutions after completing the cleaning, and/or rinsing, and disinfection steps resulting in an avg. log reduction of 5.0 (99.999%).

Conclusions: Contact lens care products tested with and without contact lenses showed antiviral activity in tests for Human herpesvirus 1. This information could be useful when counseling contact lens patients with a history of HSV-1 keratitis.

ABSTRACT BODY:

Purpose: Blur signals play an important role in emmetropization. The purpose of this study was to measure retinal responses and perceptual sensitivity to different types and levels of simulated optical blur across the visual field in young children with normal vision.

Methods: Children ($n=27$, 7.83 ± 0.96 yrs) with functional emmetropia ($SE\ OD +0.91 \pm 0.41D$) participated in 2 tests. (1) Pattern ERGs (pERGs) were recorded using a dead leaves stimulus, previously used in adults. The stimulus was computationally blurred with defocus (DEF) or primary spherical aberration (SA) at three retinal eccentricities (beyond 0° , 6° , and 12°). The stimulus was viewed from a distance of 40 cm and subtended 30° of visual angle. (2) Blur discrimination thresholds were measured with an adaptive 4AFC task previously used in adults. Dead leaves stimuli were blurred with different pedestal levels and increments of DEF or SA beyond 0° , 6° , or 12° eccentricity at a viewing distance of 40 cm. Participants chose which quadrant appeared blurriest. Blur discrimination thresholds were fit with a 2-parameter (Intrinsic Blur, Blur Criterion) dipper function. The data were analyzed using a parametric 2-way ANOVA (pERGs) and nonparametric Friedman's 2-way ANOVA (Blur perception) with Bonferroni corrections for post hoc analyses.

Results: (1) Generally, there was an effect of blur eccentricity on the pERG amplitude, with higher amplitude for the 12° condition compared to the 0° (DEF: $p < 0.0001$, SA: $p = 0.011$) and 6° condition (DEF: $p < 0.0001$, SA: $p = 0.544$), but no differences between the 6° and 0° deg conditions (DEF: $p = 1.0$, SA: $p = 0.827$). (2) The psychophysical data show the same trend as the ERG data, i.e., a significant increase in the intrinsic blur between the 0° and 12° conditions (DEF: $p < 0.0001$, SA: $p = 0.001$) and between the 6° and 12° conditions (DEF: $p = 0.004$, SA: $p = 0.021$). There was also a significant increase in Blur Criterion between the 0° and 12° conditions for DEF ($p = 0.01$), but not for SA ($p = 0.134$) and not between the 6° and 12° conditions for both DEF and SA (DEF: $p = 0.089$, SA: $p = 0.088$).

Conclusions: Blur discrimination data and pERGs using simulated optical blur show similar trends, i.e. higher retinal responses correspond to lower perceptual blur discrimination. Generally, the perceptual blur discrimination data and retinal responses independently indicate that an area between 6° and 12° plays a significant role in blur encoding.

TITLE: Unintended Placement of Intraocular Lens Haptics in the Sulcus and Association with Posterior Capsular Opacification

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Denis, G. Nassrallah, A.B. Dias, H. Ito, C. Mastromonaco, N. Saheb, M.N. Burnier, McGill University, Montreal, Quebec, CANADA]

Commercial Relationships Disclosure (Abstract): Raphaëlle Denis: Commercial Relationship: Code N (No Commercial Relationship) | Georges Nassrallah: Commercial Relationship: Code N (No Commercial Relationship) | Ana Dias: Commercial Relationship: Code N (No Commercial Relationship) | Hiroaki Ito: Commercial Relationship: Code N (No Commercial Relationship) | Christina Mastromonaco: Commercial Relationship: Code N (No Commercial Relationship) | Nabil Saheb: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Unintended sulcus placement of intraocular lens (IOL) haptics following cataract surgery can lead to severe glaucoma secondary to hemorrhage or inflammation from iris chafing. The occurrence of posterior capsular opacification (PCO), which is the most common complication of cataract surgery, is less well studied in these cases. This study aims to assess the prevalence of sulcus haptics and their potential association with PCO.

Methods: A total of 429 post-mortem human eyes with IOLs, obtained from the Minnesota Eye Bank, were used in this cross-sectional cohort study at the MUHC-McGill University Ocular Pathology & Translational Research Laboratory. Each eye was assessed for sulcus placed IOL haptics using digital images, and PCO, as well as Soemmering's Ring (SR) density, were quantified using Automated Detector Opacification Software (ADOS) as a factor of intensity and area. Two-tailed T-test was used to assess the mean difference in PCO and SR between eyes with sulcus haptics and controls. SR distribution pattern was also assessed and qualified as either focal, diffuse or absent. Odds ratios were calculated to determine if some patterns were more prevalent in each group.

Results: Nineteen (4.4%) eyes contained IOLs with sulcus haptics. PCO was significantly more present in eyes with sulcus haptics (0.910 vs 0.680; mean difference 0.229, 95% CI 0.069-0.390, $p = 0.019$). Similarly, SR was also more present (13.751 vs 8.287; mean difference 5.464, 95% CI 2.336-8.592, $p < 0.001$). When compared to eyes with both haptics in the capsule, eyes with sulcus haptics were more likely to have focal SR opacity (OR 11.98, 95% CI 4.09-35.06) and far less likely to have diffuse opacity (OR 0.049, 95% CI 0.006-0.371).

Conclusions: The prevalence of IOLs with haptics placed in the sulcus was significant in this study. Moreover, the occurrence of PCO and SR is more common in these eyes, with a more distinct pattern of opacification when compared with in bag haptics IOL. Given the significant ocular morbidity associated with sulcus haptics, this study offers signs suggesting their occurrence which may prompt earlier appropriate intervention.

ABSTRACT BODY:

Purpose: To establish a biobank at the Hospital for Sick Children (SickKids) that catalyzes innovative research in pediatric ophthalmology, and document its first 6 months of operations.

Methods: The biobank leveraged the structural and technological foundation of the SickKids central biobank, which includes state-of-the-art liquid nitrogen facilities, CentraXX data management software, and technical experts trained in biobank operations. Eligible participants, identified in the electronic medical record, included any SickKids patient scheduled to have a tissue removed as part of standard of care that would otherwise be discarded. A broad informed consent model was adopted, allowing storage of tissues for future use in unspecified research; patients were provided with the option to opt-out of specific research components and contact preferences, as per standard SickKids broad consent practice. With patient informed consent, tissues were collected by the patient's circle of care, then processed and stored according to international standards. Clinical annotated data associated with the tissues were collected from the patient's electronic medical record and stored in CentraXX.

A governance structure to oversee sharing of specimens with scientists was developed. The biobank was approved by the SickKids Research Ethics Board.

Results: From June to December 2020, 16 eligible patients were identified; 14 were approached and 13 provided written informed consent (13/14=93% consent rate). Of consented patients, 13 agreed to whole genome sequencing research, 10 to sharing genomic sequencing data with industry, 13 to development of cell lines, 10 to sharing cell lines with industry, and 12 to other research by industry partners; 12 wished to be informed of carrier status and 10 agreed to future research contact. Patients covered 3 diagnoses (retinoblastoma, Coat's disease, von-Hippel Lindau syndrome) and contributed 10 specimens (including tumor, retinal tissue, vitreous humor, aqueous humor and subretinal fluid), resulting in 18 aliquots for use in future research.

Conclusions: This is the first pediatric ophthalmology biobank of its kind. Future steps include registration with relevant biobank databases, and collaboration with additional clinical sites to increase tissue collection, patient partners to enhance recruitment, and scientists to promote use of the tissues.

ABSTRACT BODY:

Purpose: Endophthalmitis is a sight threatening condition due to inflammation after microbial infections affecting posterior parts of the eye. Treatments including repeated intravitreal injections of antimicrobial agents may exacerbate complications. However, eye drop/gel system or systemic administration is unable to cross the ocular barriers resulting in reduced bioavailability of drugs in the eye. There is a need for non-invasive drug delivery system (DDS) that can maintain therapeutically relevant intraocular concentration of drugs for a sufficient period of time. Thus, we hypothesized that a slow degrading DDS formulated as eye drop possessing high permeability across the ocular barriers could be an effective non-invasive method of drug (antimicrobial and anti-inflammatory) administration for endophthalmitis.

Methods: Nanoparticles (NPs) with hydrophobic core of slow degrading poly-L-lactide (PLA) loaded with macrolide-antibiotic, azithromycin (AZM) and a corticosteroid, triamcinolone acetonide (TCA) anti-inflammatory drugs were coated with a hydrophilic shell of chitosan (CHI) having mucoadhesive and penetration enhancing properties. The NPs were characterized for size, zeta potential, surface morphology, hydrophilicity, cytocompatibility, hemocompatibility, plasma recalcification, whole blood clotting, antibacterial and anti-inflammatory activity. Additionally, we investigated localization of the coumarin loaded NPs as eye drops in C57BL/6 mice.

Results: The NPs were spherical, ~250nm, moderately hydrophilic, mucoadhesive and cyto-/hemo-compatible. When the NPs were administered as eye drops in C57BL/6 mice, PLA-CHI NPs showed higher bioavailability in retina when compared to PLA NPs. Surprisingly, PLA-CHI itself showed antibacterial properties in both gram positive and gram-negative bacteria and both PLA-CHI-TCA and PLA-CHI-AZM showed higher antibacterial and anti-inflammatory properties than the drug or NPs alone. It showed anti-inflammatory effect against LPS activated BV-2 microglia cells.

Conclusions: The dual drug delivery system showed cyto-/hemo-compatibility, antibacterial and anti-inflammatory properties, adequate bioavailability and provided sustained drug release making it suitable for retinal drug delivery. It also showed synergistic effect than either of the drugs or NPs alone making it more applicable for endophthalmitis, though further evaluation of in vivo diseases model is needed.

ABSTRACT BODY:

Purpose: Keratitis is a painful inflammation of the cornea commonly treated with immunosuppressive drugs. However, additional treatments are needed for patients in whom keratitis is not responsive to standard therapies. Repository corticotropin injection (RCI, Acthar[®] Gel) has anti-inflammatory and immunomodulatory effects through interaction with melanocortin receptors. The goal of this multicenter, open-label, phase 4 study was to evaluate the efficacy and safety of RCI in patients with refractory severe non-infectious keratitis (Clinicaltrials.gov, NCT04169061).

Methods: Patients ≥18 years of age with severe keratitis that is refractory to standard of care received 80 U RCI subcutaneously twice weekly for 12 weeks. Initial assessments included Impact of Dry Eye on Everyday Life (IDEEL) score, Visual Analogue Scale (VAS) for burning/stinging and eye discomfort, corneal fluorescein staining, and conjunctival lissamine green staining as measured by Ora Calibra[™] scales. One-sample binomial tests (null hypothesis: 5%) or one-sample t tests (null hypothesis: no change) were used to perform statistical analyses, as appropriate; significance vs baseline was determined as p<0.05. Adverse events (AEs) were also evaluated.

Results: Topline results in 35 patients showed that a significant proportion (41%-65%) of patients improved ≥20% at weeks 2, 4, 6, and 12 (all measured time points) on the symptom bother score module of the IDEEL questionnaire. A clinically meaningful ≥12-point improvement on the symptom bother score module was achieved in a significant proportion (50%-56%) of patients at all measured time points. VAS score for burning/stinging significantly improved at weeks 2, 6, and 12, as did the VAS score for eye discomfort at all measured time points. Inferior, superior, and central corneal fluorescein staining detecting corneal damage significantly decreased at weeks 4, 6, and 12. Both temporal and nasal conjunctival lissamine green staining for dry eyes were significantly reduced at week 6. Most AEs were rare, with hypertension being the most common, occurring in 2 patients. No serious AEs were related to the study drug.

Conclusions: Topline results of this open-label study showed that RCI significantly reduced the signs and symptoms of refractory severe non-infectious keratitis, in alignment with patient perceptions.

ABSTRACT BODY:

Purpose: Usage of small animal models has become a common practice in understanding pathological conditions. The purpose of this work is to develop a non-invasive, high-speed, and high-resolution optical coherence microscopy (OCM) combined with a dual-channel scanning fluorescence microscopy (FM) to enable longitudinal studies of the cornea in mouse models.

Methods: A high-resolution OCM was developed using a source (central wavelength at 850 nm and FWHM of 165 nm) that offers a theoretical axial resolution of $\sim 1.5 \mu\text{m}$ (in tissue). A dual-detection channel FM system with two excitation peaks at 488 nm and 594 nm for green and red fluorophore variants was integrated with OCM. Beams from both systems were combined and focused onto the sample using a 10X objective, which yields a lateral resolution of $\sim 2 \mu\text{m}$. To evaluate this system, a conditional knockout mouse model to express tdTomato transgene that converts into green fluorescent proteins (GFP) on exposure to Cre recombinase was developed using the tet-O-Cre system. Rosa mT/mG reporter mice were crossed with the Keratocan rtTA/ tet-O-Cre transgenic mice to express the tdTomato gene in the corneal stroma. On treatment with doxycycline, part of the tdTomato transgene in the stroma gets converted to GFP over time. Both red and green fluorescence, as well as structural information of the stroma, were simultaneously imaged on a sacrificed mouse using the combined system.

Results: OCM achieved an axial resolution of $\sim 2.4 \mu\text{m}$ in the cornea, which was slightly lower than the theoretical value due to dispersion. A $2.2 \mu\text{m}$ lateral resolution was demonstrated with the combined system. Reflectance and fluorescence were registered simultaneously with the speed of 250 kHz. Fig.1 shows a $1.3 \times 1.3 \text{ mm}^2$ image of the mouse cornea. A $0.3 \times 0.3 \text{ mm}^2$ field of view of the different layers of the cornea is shown in Fig.2, highlighting the epithelial cells, the keratocytes, and endothelial cells.

Conclusions: A combined system integrating a high-resolution OCM and a dual-channel FM was developed and evaluated in imaging mouse cornea. Future work will focus on improving the depth sectioning of FM to enable 3D reflectance and fluorescence in vivo imaging of the mouse cornea.

ABSTRACT BODY:

Purpose: Infectious keratitis is a leading cause of blindness worldwide. Efforts to address this burden are limited by clinically significant gaps in our ability to rapidly diagnose the causative pathogen. Culture results are delayed and have poor sensitivity, and prior studies demonstrate that human experts are only accurate 66% of the time when differentiating bacterial from fungal keratitis based on clinical appearance. This results in delayed initiation of appropriate antimicrobial therapy and worsened visual outcomes. Herein we address this gap by developing and evaluating a deep learning artificial intelligence system to distinguish culture-proven bacterial and fungal keratitis using corneal photographs.

Methods: We established an image database by collating 1,010 external photographs from handheld digital cameras obtained as part of several randomized clinical trials conducted by the Aravind Eye Care System in India and the Proctor Foundation in San Francisco since 2006. 940 images were used to train the deep learning system, and 70 were reserved as an independent testing set. 50% of the training image set consisted of images from bacterial ulcers, and 50% were from fungal ulcers. We used a transfer learning approach adapting a pre-trained deep learning system (EyeMeter) built on the ResNet-50 convolutional neural network architecture.

Results: This deep learning system demonstrated 76% overall accuracy for differentiating bacterial and fungal corneal ulcers from photographs alone. For detecting bacterial keratitis, the system had 70% sensitivity and 80% specificity. For detecting fungal keratitis, the system had 80% sensitivity and 70% specificity.

Conclusions: A deep learning system trained using photographs from inexpensive handheld cameras was able to distinguish bacterial from fungal keratitis with greater accuracy than the published performance of expert human cornea specialists. Future incorporation of similar technology into mobile telemedicine platforms may reduce blindness from infectious keratitis, particularly in low- and middle-income countries where disease burden is highest but clinical and microbiologic expertise are scarce. Future directions include collection of additional images from geographically diverse sources to optimize and validate this technology.

ABSTRACT BODY:

Purpose: The retina provides a valuable system for studying neuronal lineages and differentiation through development. Using a novel method we have designed for combining single-cell transcriptomics and lineage tracing, we aim to improve the resolution of developmental mapping of retinal cells as well as to provide comparative analysis of retinal lineages between mice and human iPSC-derived retinal organoids. With this technology, we hope to provide new insights into the transcriptional changes that accompany individual retinal cell-fate decisions and yield a deeper understanding of the mechanisms of retinal development and disease.

Methods: We have developed DREAM-seq (DNA/RNA extraction, amplification, and multiplexing), a high-throughput, multi-omic method for reading transcriptomic and targeted genomic output from single cells. Human iPS cells and mice have been barcoded using the homing guide RNA (hgRNA) system (Kalhor et al. Science 2018), thereby making possible continuous lineage tracing of individual cells throughout development. We are using DREAM-seq to read out single-cell transcriptomes and lineage barcodes at timepoints throughout development from both murine retinas and hPSC-derived retinal organoids. Novel bioinformatic strategies are being implemented in order to generate high-resolution single-cell lineage maps of retinal development.

Results: The methodology and model systems have been developed and validated for performing these lineage tracing studies. We are collecting data from organoids and murine retinas at a range of developmental timepoints, while concurrently developing and testing the necessary bioinformatic tools using in silico modeling and simulation of the data to reconstruct single-cell lineage relationships.

Conclusions: Using DREAM-seq for the parallel analysis of single-cell transcriptomes and lineages will provide us with a deeper understanding of developing retinal cell fates. This will allow us to identify the timing of cell fate decisions, detect rare or intermediate cell types that occur during retinal development, understand the mechanisms of developing cellular subtypes, and potentially identify targets for trans-differentiation. This level of detail will add to our current understanding of retinal development and have implications for treating retinal disease.

TITLE: Detailed binocular scotoma mapping reveals adaptive saccades in macular degeneration

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Vullings, Z. Lively, P. Verghese, Smith-Kettlewell Eye Research Institute, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Cécile Vullings: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Lively: Commercial Relationship: Code N (No Commercial Relationship) | Preeti Verghese: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: When the scotoma is binocular in macular degeneration (MD), objects can be obscured and individuals are often unaware that they are missing information. Current methods of detailed scotoma mapping are mainly monocular; very few methods offer the same level of precision for binocular scotoma. We propose a new method to map precisely the binocular scotoma and use this detailed map to investigate adaptive saccade strategies in visual search.

Methods: Six individuals with MD and 4 age-matched controls participated in our study. First, we measured the peripheral fixation locus, the location of the foveal pit and the extent of the monocular scotoma in each eye using an OCT/SLO. Then, we extensively mapped the monocular and binocular scotomata with an eyetracker while fixation was carefully monitored. Participants fixated a cross and responded whenever they detected a briefly flashed dot. The flashes were first presented on a coarse grid, and then at manually selected points to examine the edges of the scotoma in finer detail (Fig 1A). Finally, participants completed a visual search task where they had to report the number of Gaussian blobs randomly distributed across a natural scene.

Results: Monocular scotomata measured in the SLO and eyetracker were highly similar (mean d' value = 2.54), validating the eyetracking method to map scotoma. Moreover, all participants used clustered fixation loci corresponding to their dominant preferred fixation locus. Importantly, the binocular map from the eyetracker was consistent with the overlap of the monocular scotoma profiles from the SLO. In the visual-search task, all participants made mostly horizontal saccades, but individuals with MD made significantly more saccades toward their scotoma than controls for the same directions (Fig 1B). However, their median amplitude was smaller, and therefore a single saccade was not sufficient to fully uncover the region hidden by a large scotoma (Fig 1C). Instead of making sequential saccades toward the scotoma, participants frequently made backward saccades directed to newly uncovered regions.

Conclusions: Our eyetracker method offers a reliable and sensitive tool for measuring the functional binocular scotomata. Determining the location and extent of the binocular scotoma with respect to the fixation locus reveals oculomotor adaptations in daily life such as backward saccades to explore newly uncovered regions during visual search.

ABSTRACT BODY:

Purpose: Glucagon-like peptide-1 receptor (GLP1R) agonists are a class of incretin mimetics used to treat type 2 diabetes by augmenting insulin release and sensitivity. Despite improved glycemic control, clinical trials have shown a transient worsening of diabetic retinopathy in some patients treated with GLP1R agonists. We examined this paradoxical worsening and assessed risk for progression of nonproliferative diabetic retinopathy (NPDR) to vision-threatening diabetic retinopathy (VTDR), and in particular, proliferative diabetic retinopathy (PDR) and diabetic macular edema (DME).

Methods: A retrospective cohort of patients with NPDR newly started on a GLP1R agonist from a national insurance claims database was compared to a cohort of patients treated with other oral agents and matched for age, sex, race, index year, and number of active diabetic medications. Exclusion occurred for <2 years in database before diagnosis; prior diagnosis of PDR, DME, vitreous hemorrhage, other retinal vascular diseases; or prior VTDR treatment. Primary outcomes were incidence of VTDR, PDR, and DME. Inverse probability of treatment weight (IPTW) was used within a multivariable Cox proportional hazard regression model to test the association between GLP1R agonist exposure and progression to VTDR, PDR and DME. IPTW was derived from a propensity score model based on Diabetic Complications Severity index, hemoglobin A1c (HbA1c), demographic factors and systemic health conditions. HbA1c was modeled in a time-updating fashion.

Results: 3,668 GLP1R users meeting inclusion criteria were matched to 4,821 unexposed controls. In the GLP1R cohort, 132 (3.6%), 22 (0.6%) and 118 (3.2%) patients progressed to VTDR, PDR and DME, respectively. This compared to 353 (7.3%) VTDR, 156 (3.2%) PDR, and 242 (5.0%) DME patients in the control group. Accounting for underlying DM severity with IPTW, GLP1R agonist use conferred a reduced hazard of developing VTDR (hazard ratio [HR] = 0.44, 95% CI: 0.38-0.50, p<0.001), PDR (HR = 0.16, 95% CI: 0.12-0.22, p<0.001), and DME (HR = 0.57, 95% CI: 0.49-0.66, p<0.001).

Conclusions: GLP1R agonist use was associated with statistically significant and clinically meaningful reductions in progression from NPDR to VTDR, PDR, and DME. These results may have implications in treatment choice for patients with diabetic retinopathy.

TITLE: Diagnosis and histopathological evaluation of soft drusen in patients that underwent evisceration and enucleation

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.S. Dias, H. Ito, S. Bergeron, J. Coblentz, A.A. Goyeneche, M.N. Burnier, MUHC – McGill University Ocular Pathology & Translational Research Laboratory, McGill University Faculty of Medicine, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Anelise Dias: Commercial Relationship: Code N (No Commercial Relationship) | Hiroaki Ito: Commercial Relationship: Code N (No Commercial Relationship) | Sabrina Bergeron: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Coblentz: Commercial Relationship: Code N (No Commercial Relationship) | Alicia Goyeneche: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Soft drusen is large dome-shaped, hyaline granular deposits with poorly demarcated boundaries beneath the (Retinal Pigment Epithelium) RPE. This drusen increases the risk for advanced Age Macular Degeneration (AMD), which can result in vision loss. Soft drusen lifecycle includes growth, anterior migration of RPE atop drusen, followed by collapse, and atrophy. The aim of this study is to correlate the prevalence of soft drusen in histopathological sections of macular region, obtained from enucleated and eviscerated eyes.

Methods: A total of 158 eyes from 158 patients were examined, from the MUHC – McGill University Ocular Pathology & Translational Research Laboratory, Montreal, Canada (2013-2019). Of the 158 eyes, 79 (50%) were enucleated and 79 (50%) were eviscerated. The specimens were considered for the study based on the following inclusion criteria: 1. patients over 50 years of age; 2. histopathologically preserved macular area; 3. presence of sufficient residual tissue for additional cuts; 4. identification by histological criteria of macular area; 5. concrete data of patients, such as age and diagnosis that led to enucleation or evisceration. Histopathological review was performed in digitalized H&E slides (Zeiss AxioScan.Z1) in all patients. Each case was assessed based on the presence of soft drusen and divided by age in decades in both eviscerated and enucleated eyes.

Results: Histopathological analysis of soft drusen was possible in both groups. There was no difference in the frequency of soft drusen between enucleated and eviscerated eyes in patients aged 50 to 59 years [$\chi^2(1)=0,046$, $p = 0,829$], 60 to 69 years [$\chi^2(1)=0,130$, $p = 0,719$], 70 to 79 years [$\chi^2(1)=0,142$, $p = 0,706$] and ≥ 80 years [$\chi^2(1)=0,027$, $p = 0,870$]. The presence of soft drusen increased with age in eviscerated or enucleated patients that were submitted.

Conclusions: The presence and characteristics of soft drusen could be analyzed in both enucleated and eviscerated eyes with similar results. It was possible to find soft drusen using the same histopathological criteria, both in enucleation and evisceration eyes. Prevalence of macular drusen from enucleated and eviscerated ocular specimens in patients over 50 years of age is comparable to the incidence of age-related macular degeneration in this population.

Commercial Relationships Disclosure (Abstract): Darlene Miller: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Maestre-Mesa: Commercial Relationship: Code N (No Commercial Relationship) | Jean-Marie Parel: Commercial Relationship: Code N (No Commercial Relationship) | Harry Flynn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Information on the metabolic and functional diversity of the ocular surface fungal-associated microbiota and their role in fungal keratitis is just beginning to be explored Fungal associated microbiomes may help modulate carbon substrate utilization, signaling pathways and mycotoxins production at the ocular surface.

Purpose: To compare and document the impact on the functional diversity, carbon utilization profile (n=31) and mycotoxin production of Fusarium keratitis isolates with unique microbiomes after growth on chocolate agar (choc), potato dextrose agar (pda) and sabouraud agar (sab) with antibiotics (gentamicin and chloramphenicol).

Methods: We used a combination of Whole Genome Sequencing (CosmosID) and Biolog EcoPlates to identify and compare a) Fusarium associated microbiomes; b) percent functional diversity and c) carbon substrate utilization profiles of three Fusarium isolates- Fusarium solani (n=2, FS1, FS2), and Fusarium oxysporum (n=1, FO) recovered from patients with Fusarium keratitis.

Results: The three fungal microbiomes, FS1, FS2 and FO were unique but dominated by 3 phyla, Actinobacteria (57.3% vs 86% v 46.5%), Firmicutes (41.3% vs 9.4% vs 23%) and Proteobacteria (1.2% vs 4.5% and 23%) respectively. Phylum Bacteroidetes was more commonly associated with the FO community (6.8%) than FS1 or FS2 (both <1%). Modulating species for each community (>1%) included Bacillus species and Cellulosimicrobium cellulans for F1, Staphylococcus epidermidis and Brevundimonas diminuta, FS2, Cutibacterium acnes, Citrobacter koseri, Cellulosimicrobium cellulans, Corynebacterium species and Streptomyces species for FO. Functional diversity and carbon utilization profiles differed by isolates and growth environment. In general, functional diversity was highest for the FS1 and FS2 isolates recovered on sabouraud agar (54.8%, 70.7% vs 25.8%) for FO. Community functional diversity was highest for the FO community when recovered on chocolate (45.6% vs 19.5% vs 38.7%) respectively. Complex polymers and carbohydrates were the preferred carbon substrates for all three communities. Genes for fumonisin and trichothecene expression were more likely to be associated with the two fungal microbiomes harboring minimal numbers of Brevundimonas diminuta

Conclusions: Fusarium associated microbiota may impact functional diversity, carbon metabolic profiles and fungal-bacterial interactions at the ocular surface.

ABSTRACT BODY:

Purpose: Intravitreally-administered therapies for retinal vascular diseases impose a significant treatment burden due to injection frequency. To address this, we have developed an antibody biopolymer conjugate (ABC) platform, in which a high molecular weight (800 kDa), hydrophilic, zwitterionic, and branched phosphorylcholine based biopolymer is site-specifically conjugated to a full length, humanized, and highly potent anti-VEGF antibody. We investigated the biophysical properties of an ABC in advanced clinical trials, KSI-301, using a series of spectroscopic and biochemical characterization assays.

Methods: Intermolecular interactions of KSI-301 or its payload antibody alone were assessed by size exclusion chromatography, dynamic and static light scattering, and zeta potential, under a range of pH and ionic conditions. Protein secondary and tertiary structure and stability were evaluated by circular dichroism (CD). The relative structural orientations of the antibody and biopolymer portions of KSI-301 were visualized by electron microscopy (EM). KSI-301 and protein FcRn binding and recycling properties were characterized using bioluminescence and endothelial cell-based assays.

Results: Light scattering measurements indicated polymer modifies antibody colloidal properties by reducing nonspecific interactions between protein molecules. These data coupled with CD analysis supported high thermal and steric stabilization of the ABC with preserved antibody secondary and tertiary structure. The 1:1 antibody:biopolymer conjugation ratio was supported by SEC-MALS, SDS-PAGE and EM. FcRn assays indicated that biopolymer conjugation to the antibody prevents FcRn recycling, contributing toward fast plasma clearance of ABCs.

Conclusions: The ABC platform stabilizes antibody structure and imparts favorable clinical properties, such as low nonspecific interactions and reduced antibody recycling through FcRn. These underlying biophysical properties may also contribute to the observed enhanced tissue penetration and improved treatment durability seen for ABC-based therapeutics such as KSI-301. In addition to KSI-301, various ABC platform based biologic or biologic + small molecule therapeutics are in earlier stages of development. Altogether, our continuing studies support the potential of the ABC platform to meaningfully improve or enable the treatment of a myriad of retinal diseases.

ABSTRACT BODY:

Purpose: To assess whether longitudinal changes in central visual field increase the risk of visual acuity (VA) loss in patients with Primary Open Angle Glaucoma (POAG).

Methods: VA loss was defined as a loss of 0.2 logarithm of the minimum angle of resolution (logMAR) or more in 2 consecutive exams. The mean value of the 4 innermost paracentral point locations from the total deviation (TD) plot of a 24-2 standard automated perimetry (SAP) test, threat to fixation area (TTF), was calculated and a joint longitudinal survival models were used to evaluate the rates of changes in the TTF area for predicting VA loss over time, adjusting for confounding variables, such SAP mean deviation (MD), age and central corneal thickness (CCT) at baseline, and intraocular pressure (IOP) measurement during follow-up. A separated analysis was performed in a subgroup that included only pseudophakic eyes.

Results: This study included 4,131 SAP tests and 17,704 clinical visits of 1,207 eyes of 900 POAG patients followed for an average of 4.0 ± 3.2 years. The rates of change of paracentral points in TD plot were significantly predictive of VA loss with an increase of 2.6-times the risk of developing VA loss for each 1 dB/year decrease in the slope (HR 2.56, CI, 1.73, 3.82; $P < 0.001$), after adjusting for age, SAP MD and CCT at baseline, and for IOP measurements during follow-up. The risk for VA loss was also higher for the pseudophakic eyes. For this group, rates of change on mean TD of the 4 central points were associated with VA loss with a HR of 4.63 (95% CI:2.38, 8.93; $P < 0.001$) the multivariable analysis.

Conclusions: In our study longitudinal changes on the mean of 4 central points from SAP TD was predictive of development of VA loss in glaucoma patients and should be included in the assessment of risk for visual impairment.

ABSTRACT BODY:

Purpose: To investigate the impact of corneal culture results on the management of patients treated for suspected microbial keratitis at a tertiary-care academic institution.

Methods: The Penn State College of Medicine Institutional Review Board reviewed the study protocol and determined the study was exempt from further review. Medical records were reviewed of patients who underwent corneal culture (CPT code 65430) at Penn State Eye Center between 01/01/2015 and 09/01/2020.

Results: A total of 59 corneal cultures from 54 patients were reviewed. The overall culture positivity rate was 46%. Forty-four percent of the positive cultures and 69% of the negative cultures were obtained from eyes treated with topical antibiotics prior to the culture being taken. Bacteria were isolated most commonly (82%), followed by fungi (11%), and Acanthamoeba (7%). The most common bacteria isolated were Staphylococcus aureus (33%), Staphylococcus epidermidis (25%), coagulase negative Staphylococcus (12%), and Pseudomonas aeruginosa (8%). Fungal species isolated included Candida albicans, Candida parapsilosis, Gorodonia species and Fusarium species with equal prevalence. Of the Staphylococcus species isolated, one was resistant to moxifloxacin (S. aureus) and seven were resistant to oxacillin (S. aureus and S. epidermidis). Initial therapy included fortified vancomycin and tobramycin in 61% of eyes and moxifloxacin in 22 % of eyes. Culture results resulted in a management change in 38% of eyes: In 10% of eyes, treatment was escalated, defined as adding or changing to fortified antibiotics, antifungal or anti-acanthamoeba agents, and in 28% of eyes, treatment was de-escalated, defined as discontinuing either vancomycin or tobramycin or changing from fortified antibiotics to commercially available fluoroquinolones.

Conclusions: Culturing corneas with suspected microbial keratitis can impact management in a significant proportion of cases.

ABSTRACT BODY:

Purpose: To develop a list of everyday items based on the Common Objects in Context (COCO) dataset, that are highly useful among people with native and artificial ultra-low vision (ULV) so that successful computer vision algorithms can be developed for object identification.

Methods: 10 participants with ULV (VA 20/1600) and 5 Argus II users were given 150 items from the COCO dataset and asked to rate the objects as very useful, useful, neutral, not useful, definitely not useful and the scores were 2, 1, 0, -1, -2 respectively. They were also asked about their preferences for system notifications (visual, speech, sound and haptic) for passive (general scanning) and active modes (scanning for a specific object).

Results: Participants with native ULV and Argus II users rated more than 50% of the items on the dataset as useful and very useful. The objects that were reported to be most useful were similar in both groups, the top 5 useful objects reported that would benefit from using an object finder device were phone, empty seat, remote control, person and toilet. The category that was rated the highest was person and the category with the lowest rating was animal (Fig 1). All participants preferred speech and sound notifications compared to visual or haptic notifications for both passive and active modes irrespective of their level of residual vision (between 1.4 and 3.5 log MAR).

Conclusions: We developed a priority list of useful objects from everyday life based on the COCO dataset among people with native ULV and Argus II users. This list of objects will be used to develop an object finder system using machine learning algorithms for people with ULV. Using the subjective ratings from this study, performance measures will be developed to determine the effect of an object finder system on functional performance and accessibility in people with ULV and visual prosthesis. Future studies will compare the effect of different modalities of notifications on functional performance in people with ULV and visual prosthesis.

TITLE: The impact of image processing algorithms on quantitative optical coherence tomography angiography metrics in diabetic retinopathy

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.C. Wang, I. Freedman, L. Hui, E. Li, K.H. Nwanyanwu, Ophthalmology & Visual Science, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|E. Li, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|L. Hui, Ophthalmology, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jay Wang: Commercial Relationship: Code N (No Commercial Relationship) | Isaac Freedman: Commercial Relationship: Code N (No Commercial Relationship) | Lucy Hui: Commercial Relationship: Code N (No Commercial Relationship) | Emily Li: Commercial Relationship: Code N (No Commercial Relationship) | Kristen Nwanyanwu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the impact of using different image processing algorithms to calculate commonly reported quantitative metrics in optical coherence tomography angiography (OCTA) images in patients with various stages of diabetic retinopathy.

Methods: Single center, retrospective, observational study. Patients with diabetes from September 2017 to December 2018 were included. Complete ophthalmological exams and OCTA imaging with the Cirrus HD-OCT 5000 AngioPlex (Carl Zeiss Meditec, Inc., Oberkochen, Germany) were performed at each visit. Patients with coexisting chorioretinal disease were excluded. Scans with poor signal strength or significant motion or segmentation artifact were excluded. Demographic and clinical variables including age, gender, visual acuity, stage of diabetic retinopathy (DR), and presence of diabetic macular edema (DME) were recorded. 8 x 8 mm superficial slab images were thresholded using the Huang, Otsu, or Niblack algorithms in ImageJ (NIH, Bethesda, MD). The vessel density (VD) and skeletonized VD (SVD) were calculated for each image. Mixed-effect uni- and multivariate linear regressions were performed using the Stata statistical package (StataCorp LLC, College Station, TX). P-values < 0.05 were considered statistically significant.

Results: 144 scans from 48 patients were included. 54 were excluded for poor signal strength or significant artifact. Of the remaining 90, 26 had no DR, 47 had nonproliferative diabetic retinopathy (NPDR), and 17 had proliferative diabetic retinopathy (PDR). 24 of 90 scans had DME. The thresholding algorithm used significantly impacted VD and SVD even when controlling for age, DME, and DR stage (p-values < 0.001). The Otsu and Niblack algorithms gave significantly lower measurements of VD and SVD than the Huang algorithm (p-values < 0.001). DME was significantly associated with lower VD and SVD across all algorithms (p-values < 0.015). PDR was borderline significant for lower VD (p = 0.056) and significant for lower SVD using the Huang algorithm (p = 0.010) but not significant using Otsu and Niblack.

Conclusions: Caution must be taken when quantitatively analyzing OCTA images, as the specific thresholding algorithm used may impact the results of any given study. There is a need for standardization of image processing algorithms to ensure robust and consistent analysis of OCTA imaging.

TITLE: Automated analysis of large vessel blood flow using AOSLO

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Zamoun, S. Ongun, S. Houston, J. Greenwood, A. Dubis, Department of Ophthalmology, University College London, London, London, UNITED KINGDOM|A. Dubis, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Ines Zamoun: Commercial Relationship: Code N (No Commercial Relationship) | Sevim Ongun: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Houston: Commercial Relationship: Code N (No Commercial Relationship) | John Greenwood: Commercial Relationship: Code N (No Commercial Relationship) | Adam Dubis: Commercial Relationship(s); Boston Micromachines Corp: Code C (Consultant)

ABSTRACT BODY:

Purpose: Several studies have shown ocular blood flow anomalies in vascular disorders (diabetes, multiple sclerosis, and dementia) disorders using adaptive optics scanning ophthalmoscopy (AOSLO). One AOSLO method for studying vascular change been XT, where spatial data is acquired for part of the scan, then freezing the fast scanner to measure cells coming past the scanner (Figure 1). The challenge is that while data is becoming easier to acquire, analysis routines that stabilize eye motion, extract vessel features, and flow data are still manual and time-consuming.

Methods: Blood flow video sequences were acquired using a bespoke multimodal AOSLO (Boston Micromachines Corp, Boston, MA). The AOSLO simultaneously acquires up to four video sequences at 26Hz. Image motion stabilization and removal of bad frames is the first step, accomplished through a novel template matching algorithm. Next, line and edge detectors were employed to detect the vessel to scan direction angle. Cell speed was extracted by line detection techniques that detected the slope of the cell tracks in the Time portion (Figure 1). Lastly, to assess the validity of our extraction automated measures were compared to frames quantified manually by two graders.

Results: The comparison of manual and automated methods was made over 100 images. For this image set, 98% were manually measurable compared to 80% using automated methods. For this shared dataset, the most experienced grader had a slight bias (-2.61; limits: -12.5 to 7.3 mm/s, with greater variability at higher velocities) between trials, with poorer repeatability to the less experienced grader (bias: - 13.07; limits -33.8 to 7.7 mm/s). In comparison, automated methods showed results with 70% accuracy (bias: 2.42; limits -15 to 13 mm/s). The greatest benefit was in time-saving where manual processing took 43 ± 5 min to complete, automated methods took 2.83 sec to extract up to 96 cell profiles per frame.

Conclusions: The method presented here simplifies the processing pipeline from three steps to a single workflow. In addition, there is a drastic reduction in time consumption for data extraction, while providing comparable results. These processing improvements will allow this technology to proliferate and potentially. We aim at developing tools to quantitatively model the changes in blood velocity profiles in the human eye, non-invasively.

ABSTRACT BODY:

Purpose: To describe the use of synchronous audio-visual telemedicine at Wills Eye Hospital (WEH) during the COVID-19 pandemic.

Methods: A retrospective chart review was performed on visits coded as synchronous, audio-visual telemedicine, covering March 15th to May 15th, 2020. Telemedicine software reported the length of synchronous patient and physician time in the visit. Patient satisfaction surveys were completed at the conclusion of each visit. Results are analyzed with descriptive statistics.

Results: During the study period, WEH performed synchronous, audio-visual telemedicine for 495 patients. Patients averaged 51 years of age, with a range from 1 to 98 years. 61% of patients were female and 44% identified as white. The Primary Eyecare Service performed the plurality of evaluations (40%), with the remainder performed by the departments of Ocular Oncology (20%), Cornea (12%), Neuro-Ophthalmology (11%), Oculoplastics (6%), Pediatric Ophthalmology (6%), Glaucoma (5%), and Retina (1%). The most common diagnosis categories were blepharitis or dry eye (10%); stye, chalazion or other eyelid pathology (8%); glaucoma (6%); anterior uveitis (4%); choroidal melanoma (4%); corneal abrasion (3%); allergic conjunctivitis (3%); herpetic dermatitis (3%); viral conjunctivitis (2%); and strabismus (2%). Median synchronous patient-physician time in the visit was 9 minutes. Patients, on average, answered 9.2 out of 10 as their likelihood of recommending the service to a friend.

Conclusions: During the initial phase of the COVID-19 pandemic, WEH employed synchronous audio-visual telemedicine across a wide range of clinical indications with acceptable operational efficiency and high patient satisfaction.

ABSTRACT BODY:

Purpose: Histone deacetylases (HDACs) 1 and 2 are highly conserved nuclear enzymes that are the core components of the corepressor complexes. HDAC1 and 2 regulate the chromatin structure and function and play a key role in critical biological processes like aging, oxidative stress, autophagy, and proteinopathy. Although these cellular processes are risk factors for several age-related eye diseases, the role of HDAC 1 and 2 are not well defined in the context of the eye and eye-related disorders. The current study explores a previously unrecognized role for HDAC1 and HDAC2 in regulating chromatin modifying enzymes in mouse RPE.

Methods: We used CRISPR/Cas9 genome editing system to generate single or combinatorial depletion of HDAC 1 and 2 in ARPE19 cells. Also, in vivo effects of HDAC 1 and 2 on chromatin modifying enzymes were determined using a transgenic mouse that expresses Cre recombinase in the RPE with floxed HDAC 1 and 2. RNA was isolated from both the ARPE19 and mouse RPE cells (at 4 and 8 weeks). qPCR was conducted to transcriptionally profile a panel of 84 epigenetic chromatin modifying genes that included DNA and histone methyltransferases, DNA and histone demethylases, histone acetyltransferases, deacetylases, phosphorylases, and set domain proteins.

Results: Ablation of HDAC 1 or 2 leads to compensatory upregulation of other HDACs. Simultaneous deletion of HDAC 1 and 2 leads to repression of several chromatin modifying enzymes. The mouse RPE showed differential expression of approximately 16 % genes at 4-week, and this drastically increases to 50 % genes at 8-week. This is concordant with the qPCR data as 8-week old mouse RPE had lower levels of HDAC1 and 2 transcripts than 4-week old RPE. Interestingly, except class II MHC transactivator (Ciita) gene, all the other genes were downregulated. Some of the genes which display altered expression as early as 4 weeks and continue the trend in 8-week mouse RPE include Atf2, Kat2b, Ncoa1, Ube2b, Usp21, and Hsp90ab1. Interestingly, HDAC 1 and 2 depleted RPE cells show downregulation of many HDACs with the maximum depletion of HDAC11 amounting to nearly 50 % of control. Thus the data shows that combined depletion of HDAC1 and HDAC2 can alter the transcript levels of many chromatin modifying enzymes.

Conclusions: In conclusion, these data show that HDAC1 and HDAC2 play an essential role in the transcriptional regulation of chromatin modifiers.

ABSTRACT BODY:

Purpose: To present recent advancements in measurements, interpretation, and modeling of the light-evoked functional retinal imaging with Optical Coherence Tomography. To endorse use of the term Optoretinogram (ORG).

Methods: Albino (Balb/c) mice were imaged in vivo with a custom Scanning Light Ophthalmoscopy / Optical Coherence Tomography (SLO/OCT) retinal imaging system. Before the ORG experiments, mice were dark-adapted for over 6 hours. In addition to our standard OCT intensity-based ORG analysis (time-dependent changes of the depth scattering profiles of retinal layers), we have also extracted phase-based ORG signals (time-dependent changes of the phase difference (path length) between retinal layers) from the same data sets. To test the impact of retinal water homeostasis on the light-evoked retinal response, we have induced a mild, diffuse central retinal edema by intraperitoneal (IP) injection of distilled water.

Results: The depth scattering ORG profiles extracted from the OCT data reveal correlations between depth positions and intensity of different outer retina bands. The phase-based ORG signals extracted from the same data sets, although more sensitive to retina motion and more computationally demanding, provided an order of magnitude higher sensitivity of detecting changes in retina layer positions. The comparison between ORG responses during mild, diffuse central retinal edema and the normal retina without water injection shows several differences in the kinetics of the retina layers swelling and OCT scattering, suggesting that water movements play an important role in standard light-evoked PRC-NVU functional response. These results also indicate that ORG could be used to assess alterations in retinal water homeostasis

Conclusions: Successful implementation of phase-based ORG signal analysis in mice provided higher sensitivity for detecting changes in retina layer positions, what should potentially allow separation of Cone and Rod based ORGs in mice. Changes in the ORG signals caused by a mild, diffuse central retinal edema further confirmed the water movement between different compartments of the outer retina as the origin of measured ORGs. The use of "ORG" term draws an instructive parallel to the ERG (electroretinogram), which has long been used to assess retinal function in vivo. Specifically, the ORG, like the ERG, comprises multiple components arising from distinct cells and mechanisms.

TITLE: Functional relevance of hyper-reflectivity in macular telangiectasia type 2 (MacTel)

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Tzaridis, M. Friedlander, The Lowy Medical Research Institute, La Jolla, California, UNITED STATES|S. Tzaridis, M. Friedlander, Molecular Medicine, The Scripps Research Institute, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Simone Tzaridis: Commercial Relationship: Code N (No Commercial Relationship) | Martin Friedlander: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A common finding associated with disease progression in macular telangiectasia type 2 (MacTel) is the presence of hyper-reflective changes on optical coherence tomography (OCT). However, an association between hyper-reflectivity and any functional impairment has not yet been evaluated. In a retrospective, cross-sectional cohort study, we quantify hyper-reflectivity on en face-OCT and study its functional relevance to MacTel.

Methods: Baseline image and functional data from participants of a phase 2 clinical trial (NCT01949324) that studied the effect of Ciliary Neurotrophic Factor in patients with MacTel were analyzed. The projection of hyper-reflectivity within different layers on OCT was used to generate an en face view and measure the en face size of hyper-reflectivity. Ellipsoid zone (EZ)-loss was additionally evaluated, and en face images were superimposed onto microperimetry sensitivity maps permitting an estimate of mean retinal sensitivity within areas displaying hyper-reflectivity and EZ-loss, respectively. Best-corrected visual acuity (BCVA) and reading speed were also analyzed.

Results: 52 eyes from 52 patients were analyzed. Hyper-reflectivity was present in 32 (62%), and EZ-loss in 50 (96%) eyes. Mean lesion size was 0.11mm² (range 0.01-0.26) for hyper-reflectivity and 0.51mm² (range 0.02-1.34) for EZ-loss, and lesion sizes correlated strongly (Spearman $r=0.79$, $p<0.001$). While both lesions were associated with a significant decrease in retinal sensitivity, comparison of mean sensitivity thresholds in hyper-reflective and EZ-loss lesions differed significantly (0.9 ± 2.6 dB vs 16.3 ± 5.8 dB [mean \pm SD]; $p<0.001$), demonstrating an almost complete loss of sensitivity in hyper-reflective areas.

No correlations were found between the size of hyper-reflectivity and BCVA ($r=0.09$) or reading speed ($r=-0.17$).

Conclusions: We present a method to quantify hyper-reflectivity on en face OCT in MacTel. The en face projection of hyper-reflectivity enables a direct correlation with retinal function as evaluated by microperimetry. We demonstrate that hyper-reflectivity in MacTel is associated with severe functional impairment, resulting in an almost complete loss of retinal sensitivity within those lesions.

ABSTRACT BODY:

Purpose: Controversy exists in the field regarding the extent of heterogeneity in microglial responses in a damage dependent context in the eye. We investigated the hypothesis that mutations in genes involved in the visual cycle, namely rpe65, can be used to study changes in damage kinetics and immune cell recruitment by modulating the extent of phototoxicity

Methods: Using mice containing the wildtype Rpe-65(Leucine at aa450) and the low activity variant (L450M), we used light-induced retinal damage (LIRD) to study how changes in Rpe-65 affects damage kinetics in the C57BL6/J line. Mice were aged to P60+. We used both L450 and L450M animals that were exposed to LIRD at 50,000 lux for 5 hours during the dark phase of their circadian rhythm (ZT12-ZT17). Animals were then grouped into day 3, 5, 7, and 10 post LIRD groups, at which time retinal thickness and morphology were measured via SD-OCT and cSLO. Animals were sacrificed immediately after terminal in vivo data collection and ocular tissue was collected for RPE flat mounts. RPE flat mounts were stained with markers for microglia (IBA-1), zonula occludins (ZO-1), and cell nuclei (Hoescht). The IBA-1 positive cells that were deposited into the RPE sheet were then counted and examined for morphology.

Results: Preliminary data suggest that post LIRD mice expressing the L450 wildtype version of Rpe65 exhibit early signs of morphological changes in fundus images and SD-OCT images compared to animals expressing the L450M variant. The L450 animals have an increased presence of autofluorescent dots (postulated to be microglia) in cSLO images that are detectable at ~ 3 days within the RPE layer. Additionally, quantification of IBA-1- positive cells in the RPE layer by immunohistochemistry show that there is a significant difference between IBA+ cell deposition between L450 and L450M mice at days 3, 5, and 7 (p-value <0.05). The most significant differences in IBA+ cell counts at the RPE were on day 7 (p-value < 0.001) post LIRD (n=3/group).

Conclusions: The L450M Rpe65 variant has 60% of the wildtype Rpe65 (L450) activity level. Here we show that the L450 are more susceptible to LIRD damage as characterized by SD-OCT, cSLO, and IHC images. This data suggests that changes in RPE function via reduction of Rpe65 can change both the extent of damage and the kinetics of damage resolution.

ABSTRACT BODY:

Purpose: Leber congenital amaurosis (LCA) is a group of retinal diseases characterized by severe visual impairment. One form of LCA is caused by mutations in the RPE65 gene, which encodes the retinal pigment epithelium (RPE) isomerase. The aim of this study is to evaluate an impact of RPE65 deficiency on retinal glial cells response.

Methods: Retinas of middle-aged normal and RPE65 mutant dogs were processed for morphologic evaluation and immunohistochemistry using cell-specific markers.

Results: In RPE65 mutant dogs, active migration of IBA1⁺/CD18⁺ microglia and GFAP⁺/VIM⁻ astrocytes toward the outer retinal layers was found in peripheral, mid-peripheral and to a lesser extent in central part of superior retina. We further observed disease associated changes in expression pattern of glutamine synthetase (GS) and excitatory amino acid transporter 1 (EAAT1), the key proteins in glial-neuronal transmitter recycling. In normal retina GS and EAAT1 are expressed in Müller cell bodies and processes. In RPE65 deficient retinas expression of GS and EAAT1 was significantly reduced in Müller cell processes in the ONL that extended toward the OLM. Furthermore, we observed in Müller glia induction of axon guidance receptor ROBO1 expression and upregulation of type III intermediate filament protein VIM, indicating an activation of gliotic responses. Interestingly, the disease associated changes in ROBO1 expression were accompanied by upregulation of its ligand SLIT2 in PAX6⁺ amacrine cells.

Conclusions: The study data provides new insight into RPE65 disease pathology and can be applied to the interpretation of outcomes of retinal gene therapy in animal models and humans.

ABSTRACT BODY:

Purpose: Yearly rising emergency department (ED) visits, especially for nonemergent conditions, create significant strain on hospital systems. This study aims to determine the percentage of nonemergent ophthalmology ED consults at a Level 1 trauma center and identify associated risk factors.

Methods: All ED encounters at Memorial Hermann Hospital (Houston, TX) from 1/2015-1/2020 with ophthalmology consultation were reviewed to determine the principal ophthalmic ICD10 diagnosis code. Ophthalmic ICD10 codes were categorized as emergent, nonemergent, or unspecified based on whether it represented an immediate threat to vision or could be managed outpatient. Procedures performed, patient demographics including home zip code, and insurance type were recorded. The zip code was used to calculate distance to the hospital and obtain published median income data for that area. Risk factors that affect the incidence of nonemergent visits were identified using stepwise logistic regression analysis.

Results: There were 6789 encounters of which 5075(75%) were emergent, 1275(19%) were nonemergent, and 437(6%) were unspecified. The mean age was 41.6 years (± 21.2) and 3942(58%) were males. The most frequent diagnosis was a fracture related diagnosis such as orbital floor or medial wall fracture 1170(17%), followed by eyelid laceration 507(7%) and corneal abrasion 373(5%). 1293 procedures were performed with the most frequent procedures being repair of open globe 284(22%), margin laceration 232(18%), and simple eyelid laceration 205(16%). Risk factors for nonemergent encounters were: females (Odds ratio (OR)=1.9 vs males, $P<0.001$), seniors 65+ (OR=1.5 vs adult 18–34 years, $P<0.001$), median income $>100k$ (OR=1.4 compared to \$40–\$60k, $P=0.021$), patients who live <10 miles from the hospital (OR=1.5 vs >30 miles, $P<0.001$) and patients who had commercial insurance (OR=1.6 vs self pay, $P<0.001$).

Conclusions: Most encounters resulted in an emergent diagnosis underscoring the importance of ophthalmic emergency triage. The most frequent diagnosis (fracture) however did not correspond to most frequently performed ophthalmic interventions illustrating that a large portion of ED ophthalmic care does not result in surgical intervention. This data and the demonstrated risk factors for non-emergent use may help identify areas for intervention to optimize ED efficiency.

TITLE: Activated microglia target specific ganglion cell types in experimental glaucoma

SESSION TITLE: Neurodegeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A.K. Yu, L. Della Santina, M. Soliño, Y. Ou, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alfred Yu: Commercial Relationship: Code N (No Commercial Relationship) | Luca Della Santina: Commercial Relationship: Code N (No Commercial Relationship) | Manuel Soliño: Commercial Relationship: Code N (No Commercial Relationship) | Yvonne Ou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While it is well known that pathological consequences of glaucoma involve degeneration of retinal ganglion cells (RGCs) and their axons, increasing evidence has pointed to selective vulnerability of specific RGC types. We have previously shown that microglia activation increases following glaucomatous injury, but their role in synapse disassembly in the inner plexiform layer (IPL) and specific RGC type vulnerability is unknown. Here we determined whether microglia are positioned to play a role in the selective vulnerability of alpha OFF-transient RGCs.

Methods: Laser-induced ocular hypertension (LIOH) was performed unilaterally on adult CD-1 mice expressing Cx3cr1-GFP, in which microglia are fluorescently labeled. Mice were sacrificed 7 days-post LIOH and individual RGCs were labeled by ballistic delivery of dextran dye. Immunolabeling was used to detect expression of postsynaptic protein, PSD95. Z-stacks were acquired using confocal microscopy. Microglia contact with individual RGCs was analyzed with VolumeCut (<https://lucadellasantina.github.io/VolumeCut/>) and colocalization of PSD95 with RGCs and microglia were evaluated throughout the IPL using ObjectFinder (<https://lucadellasantina.github.io/ObjectFinder/>). Statistics were performed using the Wilcoxon rank-sum test and one-way ANOVA.

Results: After IOP elevation, contact points made between microglia and individual alpha RGCs increased for OFF-sustained (OFF-S), OFF-transient (OFF-T), ON-sustained (ON-S), and ON-transient (ON-T) RGCs (42.5%, $p=0.34$; 189%, $p=0.03$; 264%, $p=0.02$; 215%, $p=0.003$, respectively). The percent change was significantly greater in OFF-T compared to OFF-S RGCs ($p=0.04$). This increase in contact points also resulted in greater colocalization of microglia with PSD95 sites on individual RGCs: for OFF-S (75.4%, $p=0.02$), OFF-T (298%, $p=0.02$), ON-S (155%, $p=0.06$), and ON-T (282%, $p=0.007$). The percent change was significantly greater in OFF-T compared to OFF-S ($p=0.03$), and in ON-T compared to ON-S ($p=0.04$).

Conclusions: Following IOP elevation, microglia in the IPL increase their contact with individual RGCs. Microglia contact favored OFF-T over OFF-S RGCs and targeted PSD95 sites to a greater degree in the transient vs. sustained RGC types, suggesting that microglia may play a role in the selective vulnerabilities of specific RGC types.

TITLE: Novel Virtual-Reality Perimetry in normal children compared to Humphrey Field Analyzer

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.L. Groth, E. Linton, E. Brown, S. Donahue, Ophthalmology, Vanderbilt University, Nashville, Tennessee, UNITED STATES|F. makadia, Ophthalmology, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sylvia Groth: Commercial Relationship: Code N (No Commercial Relationship) | Edward Linton: Commercial Relationship: Code N (No Commercial Relationship) | Eric Brown: Commercial Relationship: Code N (No Commercial Relationship) | Frini makadia: Commercial Relationship: Code N (No Commercial Relationship) | Sean Donahue: Commercial Relationship(s); Olleyes: Code I (Personal Financial Interest); Olleyes: Code C (Consultant)

ABSTRACT BODY:

Purpose: Perimetry in children is an invaluable modality for assessing afferent function. Current threshold perimeters demonstrate relatively poor reliability and satisfaction. The Olleyes VisuALL (OV) is a commercially available video-game based automated static threshold perimeter that uses a Virtual Reality headset, and a wireless remote.

Methods: Fifty normal subjects ages 9-17 (mean=13 years, 50% female) performed Humphrey Visual Field (HVF) 24-2 and Olleyes VisuALL pediatric threshold perimetry. Test time, reliability parameters, and effects of age, gender, and ethnicity were evaluated. Normative threshold sensitivities were established by percentile. Patient satisfaction surveys were administered.

Results: Median time to completion for OV and HVF was 7.06 and 5.25 min/eye respectively. Age-adjusted thresholds were similarly distributed between OV and HVF (Mean sensitivity 31.8 ± 1.11 dB OV, 31.0 ± 1.53 dB HVF), mean inter-subject variability was no different as measured by Gini's Mean Difference (2.7 ± 0.4 OV and 2.7 ± 0.6 HVF, $p > 0.25$). Mild age-effects on threshold sensitivity in OV were similar to HVF ($R^2 = 0.10$ $p < 0.01$ OV; $R^2 = 0.08$ $p < 0.01$ HVF). Mean threshold sensitivities in the same eye were compared by linear regression ($R^2 = 0.11$ $p < 0.001$), and 5th percentile values were derived empirically at each location. Geographic effects on sensitivity and variability were concentric in the HVF as expected, and more sporadic for the OV. Patient satisfaction scores favored the OV device experience (1-5 scale, Wilcoxon matched-pairs signed rank test $p < 0.01$).

Conclusions: Attention to the task has long been a challenge in pediatric visual field testing. This game-based perimeter has higher patient satisfaction as well as tight correlation to the standard of care perimeter. Direct comparison of the two demonstrates less variability and tighter thresholds with the portable instrument which should translate into better ability to detect defects. The portability of the test allows it to be done in myriad environments lending to flexibility that can benefit children.

ABSTRACT BODY:

Purpose: Aging of the retina results in a gradual visual loss due to the dysfunction and ultimately death of cells within the neural retina and retinal pigment epithelium (RPE). Importantly, aging is the highest risk factor for severe eye diseases, such as glaucoma and AMD. As the increased susceptibility of aging cells to pathological insults is a major root-cause for disease development, cell rejuvenation may prevent disease onset and/or progression. We recently reported that partial epigenetic reprogramming in vivo using AAV2-OSK (Oct4, Sox2, Klf4) reversed the biological age of retinal ganglion cells (RGCs) in 12-month-old mice as determined by their epigenetic clock, increased visual function, and “youthful” methylome and transcriptome profiles. In the current study we examined whether in vivo epigenetic reprogramming can be applied to RPE and reverse aging of the outer-retina complex.

Methods: 24-month-old mice received subretinal injections of AAV2-OSK. Negative controls included mice that received AAV2-GFP, or no injections. Young mice (4-6 months) were used as positive controls. Visual acuity was measured via optomotor reflex (OMR), and phototransduction assessed by scotopic ERG. Morphological examinations were conducted on retinal sections via TEM and by immunostaining of RPE whole mounts.

Results: Compared to young mice, aged mice showed reduced visual acuity ($p < 0.05$, $n = 12$) with marked loss of photoreceptor, bipolar and RPE ERG responses (a and b wave $p < 0.0001$, c wave $p < 0.001$, $n = 10$). Subretinal injection of AAV2-OSK transduced approximately 50% of the RPE and did not alter cell number, area and nuclei/cells at two weeks. Histological analysis showed improved retinal morphology in the OSK+ regions of experimental aged mice compared to the controls (AAV2-GFP, or uninjected). Ultrastructural imaging confirmed reduced phenotypic markers of RPE dysfunction and aging in OKS-treated eyes characterized by decreased dysmorphic RPE, reduced lipofuscin and undigested outer-segment accumulation, increased choriocapillaris fenestrations and reduced basal laminar deposits.

Conclusions: In vivo epigenetic reprogramming with OSK reversed these age-induce morphological changes, restoring RPE to a youthful morphology. These data imply epigenetic reprogramming can reverse the effects of aging and restore function to aging RPE, which may lead to a new approach to therapeutically treat AMD.

Vetter, Department of Psychology, Universite de Fribourg, Fribourg, Fribourg, SWITZERLAND|J. Bergmann, Department of Psychology, Max-Planck-Institut fur Kognitions- und Neurowissenschaften, Leipzig, Sachsen, GERMANY|

Commercial Relationships Disclosure (Abstract): Belén Montabes de la Cruz: Commercial Relationship: Code N (No Commercial Relationship) | Clement Abbatecola: Commercial Relationship: Code N (No Commercial Relationship) | Petra Vetter: Commercial Relationship: Code N (No Commercial Relationship) | Johanna Bergmann: Commercial Relationship: Code N (No Commercial Relationship) | Lucy Petro: Commercial Relationship: Code N (No Commercial Relationship) | Lars Muckli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sound content can be decoded from brain activity patterns in the early visual cortex of blindfolded (Vetter et al. 2014) and congenitally blind (Vetter et al., 2020) participants, especially in the periphery. What is the role of visual imagery in this effect? We explored this question by replicating Vetter et al.'s (2014) experimental design on a sample of aphantasic individuals who experience no visual imagery.

Methods: We controlled 5 self-reported aphantasics (4 females, Mage=34, SD=15.65) with the voluntary visual imagery questionnaire (VVIQ; Marks, 1973) and for involuntary imagery with the spontaneous use of imagery scale (SUIS; Kosslyn et al., 1998). We also used a behavioural test assessing the degree to which imagery can prime a binocular rivalry display (Bergmann et al., preprint).

In a 3T fMRI experiment we presented our blindfolded participants with 3 natural sounds in a block design. We functionally localised auditory (positive control) and motor areas (negative control), early visual areas (V1, V2 and V3) and their respective eccentricities (fovea, periphery, far periphery). We fed each area's Z-normalised beta weights signal into a linear support vector machine classification algorithm (LIBSVM) contrasting auditory scenes. We assessed the statistical significance of our classification with a permutation test.

Results: Our participants scored low on the VVIQ (Mean=19.8, SD=1.92), SUIS (Mean=19.4; SD=3.85) and had close to chance priming scores (Mean=0.54, SD=0.07).

Our positive ($p < 0.001$) and negative ($p > 0.05$) controls performed as expected. Two participants had significant classification accuracies in visual areas. However, at the group level our permutation analysis rendered non-significant accuracies in all retinotopic areas (whole early visual cortex: 43%, V1: 42%, V2: 40% and V3: 42%; all $p > 0.05$) and in their respective eccentricities (all $p > 0.05$).

Conclusions: Since our participants scored low for spontaneous visual imagery, and because Vetter et al.'s (2014) reported deactivation patterns and eccentricity differences do not fit a voluntary visual imagery account, we suggest that our lack of findings arose from our participants' inability to engage in involuntary imagery. Moreover, we propose that auditory feedback to the early visual cortex may stand as a form of involuntary imagery which does not necessitate awareness, being elicited through previously integrated multisensory associations.

ABSTRACT BODY:

Purpose: To determine if the inner diameter of a tube-shunt device for IOP lowering in glaucoma has a significant impact on outflow, and thus IOP.

Methods: A series of benchtop experiments were conducted using tubes with same dimensions as commercial tube-shunt products: Ahmed Clear Path (305µm); Ahmed Glaucoma Valve (305µm); Baerveldt Glaucoma Implant (305µm); PAUL (127µm). For the valved device (Ahmed Glaucoma Valve), the flow regulator was removed to isolate the effect of tube inner diameter on IOP. All tubes were tested at the commercially available length of 16mm.

Theoretical (expected) IOP was calculated using the Hagen Poiseuille Equation based on each tube's dimensions: 305µm tube (0.02mmHg); 127µm tube (0.6mmHg). Water was then run through each tube at a fixed flow rate of 2.75 µL/min to determine the steady-state IOP. This mimics the early postoperative period before a capsule has formed to provide flow resistance.

Results: The observed benchtop IOPs were as follows: 0.03mmHg for the 305µm tubes and 0.6mmHg for the 127µm tube. A small rise in IOP (from 0.02mmHg to 0.6mmHg) was derived by reducing the tube's inner diameter from 305µm to 127µm.

Conclusions: Hypotony occurs when IOP falls to 5-6mmHg or below, which means that a theoretical IOP of at least 5mm Hg is required for a tube to be considered restrictive to prevent hypotony. None of the tubes tested in these experiments maintained IOP above this threshold. Thus, none of these devices would be expected to prevent early postoperative hypotony based on tube diameter alone.

These laboratory findings are published clinical studies: Ahmed Clear Path 7.1%; Ahmed Glaucoma Valve 5.7%; Baerveldt Glaucoma Implant 8.3%; PAUL Glaucoma Implant 9.5%.

All 4 tube-shunt devices are associated with some incidences of early postoperative hypotony (~6-10%). These rates appear independent of tube inner diameter, although the Ahmed Glaucoma Valve shows the lowest rate of hypotony likely due to a benefit from the presence of a flow-restriction valve.

Both benchtop testing and clinical data, show that none of the devices evaluated show flow restrictive properties that would prevent hypotony, including the device with the smallest diameter tube (PAUL Glaucoma Implant). Instead, early postoperative hypotony is likely attributable to other factors than device selection.

ABSTRACT BODY:

Purpose: This study aims to develop a deep learning approach that can automatically detect retinopathy in ultra-widefield (UWF) retinal images with limited training data. It can serve as the steppingstone for large scale deployment of real-time automated retinopathy detection tools using UWF images where no similar approach has been developed.

Methods: The dataset used to train and validate the approach includes 324 3-channel images obtained using the ultra-widefield fundus camera (UWF Primary, Optos) on 162 diabetic patients at Duke Endocrinology. An image preprocessing method that did affine transformation and added noise to raw images was developed to increase data amount. A Residual Neural Network (ResNet) was trained to detect retinal pathology. Specifically, 75% of ultra-widefield retinal images were used to train the ResNet, and the rest 25% of the images were used for the test. Figure 1 shows an overview of our approach.

Results: Our approach achieved 87.97% (95% CI [85.88%, 90.05%]) accuracy in detecting referable retinopathy, along with the False Negative Rate of 13.23% (95% CI [11.06%, 15.41%]), Recall of 86.77% (95% CI [84.59%, 88.94%]), Precision of 86.82%(95% CI [84.65%, 88.99%]), F1 Score of 86.79% (95% CI [84.62, 88.96]), and AUC-ROC of 86.77% (95% CI [84.59%, 88.94%]). The confusion matrix is shown in Figure 2.

Conclusions: Our model, trained with limited data, can successfully detect retinopathy in ultra-widefield retinal images. It could be used as a useful real-time automated tool in clinical practice. Future studies will improve detection performance by collecting more UWF images and combining demographics information as model input.

ABSTRACT BODY:

Purpose: In mammals, neurons in the central nervous system (CNS) lose their axon growth abilities as they mature. On the contrary, mature neurons in the peripheral nervous system (PNS) still possess such an ability and can spontaneously regenerate axons upon axonal injury by initiating a regenerative response. Emerging evidence suggests that such a response largely involves epigenetic regulation of chromatin accessibility. Here we first characterized the role of Ezh2, a H3K27 methyltransferase, in PNS axon regeneration, and then tested if its modulation could induce CNS axon regeneration.

Methods: Western blot and immunostaining were used to compare protein levels. Dorsal root ganglion (DRG) neuronal culture and sciatic nerve regeneration were used as in vitro and in vivo PNS regeneration models, respectively. Optic nerve regeneration was used as an in vivo CNS axon regeneration model. Fluorescence-activated cell sorting was used to enrich RGCs from dissociated retinal cells. RNA-seq of RGCs was conducted to explore molecular mechanisms by which Ezh2 supports axon regeneration.

Results: Ezh2 was significantly upregulated in mouse lumbar 4 and 5 (L4/5) DRGs 3 days after sciatic nerve transection. Functionally, Ezh2 knockdown (KD) or knockout (KO) in cultured DRG neurons impaired axon growth in vitro. In consistence, KD or KO of Ezh2 in L4/5 DRGs or conditional KO of Ezh2 in sensory neurons impaired sensory axon regeneration after sciatic nerve crush. More importantly, we found that Ezh2 overexpression in RGCs significantly promoted optic nerve regeneration and RGC survival after optic nerve crush. Interestingly, the axon regeneration promoting effect of Ezh2 was not solely dependent on its methyltransferase function, as overexpression of a mutant form of Ezh2 lacking the methyltransferase function also produced RGC axon regeneration, although to a lesser extent. RNA-seq revealed that mRNA levels of a large number of genes involved in synaptic transmission were downregulated by Ezh2 overexpression. Overexpression of Slc6a13 (encoding Gat2), a gene suppressed by Ezh2, partially blocked RGC axon regeneration induced by Ezh2 overexpression.

Conclusions: Our study demonstrated that Ezh2 was necessary for the successful spontaneous axon regeneration in the PNS, and that Ezh2 gain-of-function in RGCs could promote optic nerve regeneration by silencing synaptic transmission-associated genes.

Cole, Neuroscience Graduate Program, University of Virginia, Charlottesville, Virginia, UNITED STATES|D.A. Miller, H. Zhang, Biomedical Engineering, Northwestern University, Evanston, Illinois, UNITED STATES|X. Liu, Ophthalmology, University of Virginia, Charlottesville, Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): James Cole: Commercial Relationship: Code N (No Commercial Relationship) | Marta Grannonico: Commercial Relationship: Code N (No Commercial Relationship) | Mingna Liu: Commercial Relationship: Code N (No Commercial Relationship) | David Miller: Commercial Relationship: Code N (No Commercial Relationship) | Hao Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Xiaorong Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aniridia is a devastating panocular eye disease that affects 1 in every 50,000 to 100,000 newborns, typically caused by heterozygous mutations in the PAX6 gene. Patients with aniridia exhibit a diverse range of ocular abnormalities, each to differing extents, including corneal opacification, cataract, optic nerve hypoplasia, and foveal hypoplasia. Little is known about how the disease impacts retinal health during early development. We performed a series of in vivo assessments of retinal health and visual function and tracked their changes in aniridia mice.

Methods: We used the Pax6^{Sey+/-} mouse model of aniridia, as it possesses a nonsense mutation identical to those in most cases of human aniridia. We whole mounted 15 retinas in 4 key age groups (P10, P60, P100, P200) and immunostained them with markers such as SMI-32 for subtype RGCs and DAPI for nuclei of retinal cells. 6 retinal sagittal sections were also examined to assess changes in retinal layer structures. Intraocular pressure (IOP) was measured regularly using rebound tonometry to monitor glaucomatous damage which is a common symptom of aniridia. Visual behavior was monitored using the qOMR system which projects a virtual cylinder with moving black and white bars. The subject's innate ability to perceive the movement of these bars at varying frequencies measure their visual acuity. Finally, we used visible-light optical coherence tomography (Vis-OCT), an imaging technique with post imaging data analysis established by our laboratories, to examine cross-sectional and en face retinal scans in vivo.

Results: IOP was found to increase with age in Pax6^{Sey+/-} mice, averaging ~25mmHg as opposed to ~15mmHg in WT mice. Visual acuity measurements confirm that this visual deficit continues to worsen with age. The mean acuity for WT mice was 0.41 ±0.02cyc/deg, while the mean acuity for Pax6^{Sey+/-} was 0.21 ±0.05 cyc/deg. Confocal imaging of flat-mount retinas and retinal sections confirmed that the retina continues to degrade with age in Pax6^{Sey+/-} mice. Our initial vis-OCT imaging data also confirms that retinal structure is impaired in Pax6^{Sey+/-}, particularly in the optic nerve head.

Conclusions: Our data shows that neural damage and vision deteriorates with age in Pax6^{Sey+/-} mice. The combination of in vivo assessments makes it possible to track changes in individuals, which enables a better understanding of retinal developmental defects in aniridia.

ABSTRACT BODY:

Purpose: To describe the experience of tele-ophthalmology at a large academic medical center during the COVID-19 pandemic.

Methods: This is a retrospective review of tele-ophthalmology encounters conducted at the Duke Eye Center between March 13th and July 15th, 2020. Collected data includes patient demographics, mode of communication (video or telephone), visit type (new, routine return, or urgent), diagnoses, prescribed medications, management plan, and follow-up care.

Results: Five hundred and ninety-two routine return visits, 75 urgent visits, and 75 new patient visits were conducted over 742 tele-ophthalmology encounters spanning nine ophthalmology sub-specialty services: pediatric ophthalmology (224), oculoplastics (118), glaucoma (115), vitreoretina (69), cornea (67), inherited retinal disease (45), comprehensive ophthalmology (37), neuro-ophthalmology (34), and ocular oncology (24). The average patient age was 44.2 years (range, 1 month - 100 years). Figure 1 shows the most common diagnoses addressed. Video was the preferred mode of communication over telephone (439 versus 276 encounters). The show rate was 97.4%. The average time spent with patients was 18.0 minutes. The longest average visits occurred during inherited retinal disease (38.2 minutes) and neuro-ophthalmology (23.2 minutes) encounters. An active management decision was made in 36 of the new patient encounters (47.3%), 51 urgent encounters (70.8%), and 116 routine return encounters (20.2%). Figure 2 shows the top prescribed medication classes by subspecialty. In-person follow-up within 4 weeks was required for 28.0% urgent visits, 12.0% new patients, and 4.2% routine return visits.

Conclusions: Tele-ophthalmology was utilized during the COVID-19 pandemic across a wide range of patient ages and ophthalmology sub-specialties. A substantial percentage of virtual encounters led to an active management decision, and the majority of encounters did not require a sooner than scheduled in-person follow-up. More research and follow-up are needed to determine if the accuracy of tele-ophthalmology diagnosis and management matches that of in-person encounters.

TITLE: Effects of ascorbic acid on mechanical and optical properties of cultured porcine lenses

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Rich, Z. Chen, D. Mackessy, T. Brandt, D. Valenzuela, B. Kumar, K.E. Swindle-Reilly, M.A. Reilly, Biomedical Engineering, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Wade Rich: Commercial Relationship: Code N (No Commercial Relationship) | Zhuo Chen: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Mackessy: Commercial Relationship: Code N (No Commercial Relationship) | TC Brandt: Commercial Relationship: Code N (No Commercial Relationship) | Diego Valenzuela: Commercial Relationship: Code N (No Commercial Relationship) | Bharat Kumar: Commercial Relationship: Code N (No Commercial Relationship) | Katelyn Swindle-Reilly: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Reilly: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mechanical and optical properties of patient's lenses are known to change after vitrectomy, potentially contributing to diseases such as cataract and posterior capsule opacification. Ascorbic acid (AA) is highly concentrated in the vitreous. This study evaluated whether AA protected cultured lenses against changes in mechanical and optical properties.

Methods: Pairs of fresh porcine eyes were acquired then intact, encapsulated lenses removed. Lenses were cultured in one of four environments consisting of (1) M199 cell culture media alone (control), as well as M199 supplemented with (2) vitreous humor, (3) 365 mg/mL ascorbic acid (AA), or (4) AA and vitreous humor. Media was changed every 24 hours. Paired lenses were cultured in similar conditions except one lens was cultured with supplementary AA while the other was not. Whole lenses were removed from culture after incubation periods of 12 hours to 8 days. Optical transmission and elastic modulus were estimated using photography and a spinning test, respectively. The nucleus of each lens was also analyzed with Raman spectroscopy and shear rheometry.

Results: Rheologic data from some lens pairs showed decreased lens stiffening over time in the presence of vitreous when compared to control lenses. Optical transmittance from shorter incubation times were improved with vitreous , AA, and vitreous with added AA. Lenses cultured for longer times were always stiffer in rheologic analysis.

Conclusions: We previously found that inclusion of vitreous in lens tissue culture experiments improved lens viability over time. These findings suggest that AA may be the active ingredient in the vitreous preserving the lens' viability and material properties during culture.

ABSTRACT BODY:

Purpose: Capillary perfusion is spatially and temporally heterogeneous in the retina, and likely plays a role in the pathogenesis of human retinal vascular diseases, for example Diabetic Retinopathy. We propose that variation in sequentially acquired OCT angiography (OCTA) volumes can be measured to estimate retinal perfusion heterogeneity, and investigate the sensitivity of the measurement to the OCTA acquisition parameters and OCTA processing methods used.

Methods: Ten porcine eyes were perfused with red blood cells for OCTA image acquisition by cannulation of the central retinal artery. For each eye, 20 OCTA volumes were sequentially acquired under two imaging protocols with a custom developed 200 kHz SS OCT: 2BM and 4BM, where 'BM' denotes the number of repeated B-scans acquired at each location. Each OCT data set was processed independently using four different methods for generating the angiography signal: subtraction, decorrelation, speckle-variance, and complex-variance. OCTA volumes were then layer-wise segmented to generate 2D superficial vascular complex (SVC) and deep vascular complex (DVC) en face images. The coefficient of variation (CoV; defined as the standard deviation of a signal divided by its mean value) was calculated for each pixel in the temporally stacked SVC and DVC images. The mean CoV for each BM acquisition and OCTA processing method combination was then calculated.

Results: The mean CoV differed significantly ($P < .05$) between each BM acquisition/OCTA processing method combination, as well as between each vascular complex. Mean CoV was, on average: higher for 2BM acquisition than 4BM; higher for complex- and speckle-variance OCTA than either of decorrelation or subtraction OCTA methods; and lower in the SVC than in the DVC. Quantitative CoV results are summarized in Figure 1, and these results are presented qualitatively in Figure 2 as CoV-based heat maps.

Conclusions: Retinal perfusion heterogeneity may be measured with OCTA, but measurements differ based on the OCTA acquisition and processing methods used. These differences should be further investigated to determine the optimal OCTA image acquisition and processing method for detecting retinal perfusion heterogeneity. Future work will combine this method with 3D motion correction to perform perfusion heterogeneity analysis on human OCTA data.

ABSTRACT BODY:

Purpose: Endophthalmitis is a devastating complication of intraocular surgery; however, there is limited data on the rates of endophthalmitis in cataract surgeries combined with additional intraocular surgery. We performed a retrospective analysis to determine the incidence and characteristics of endophthalmitis for cataract surgery with a combined procedure in the United States.

Methods: This was a retrospective analysis using 100% Medicare fee-for-service claims data for endophthalmitis after cataract surgery from 2011 to 2019. Retina surgeries included retinal detachment repair and posterior vitreous procedures; glaucoma surgeries included trabeculectomy, tube shunt implant and minimally invasive glaucoma surgery; cornea surgeries included penetrating keratoplasty, endothelial keratoplasty, and keratoprosthesis; other surgeries included anterior chamber washout, ruptured globe repair, and iridotomy. Patients with prior intraocular surgery or intravitreal injection within 3 months and diagnosis of endophthalmitis within 12 months were excluded.

Results: 19,552 cases of endophthalmitis occurred following 14,396,438 cataract surgeries from 2011 to 2019. 289,778 (2.01%) of cataract surgeries were performed with glaucoma surgery, 51,131 (0.35%) with retina surgery, 20,918 (0.15%) with cornea surgery, and 57,752 (0.40%) with other intraocular surgery. The overall rate of endophthalmitis per 1000 cataract surgeries was 1.36. Cataract surgery endophthalmitis rates per 1000 surgeries was 1.30 for cataract surgery alone, 7.33 for combined retina surgery, 2.72 for combined cornea surgery, 2.20 for combined glaucoma surgery, and 7.12 for other combined surgery. In a multivariate model, the adjusted odds ratio of endophthalmitis with combined surgery versus cataract surgery alone was 2.51 (95% CI, 2.03, 3.10) for retina surgery, 1.08 (95% CI, 0.78, 1.51) for cornea surgery, 0.78 (95% CI, 0.63, 0.97) for glaucoma surgery and 2.13 (95% CI, 1.76, 2.58) for other intraocular surgery.

Conclusions: Rates of endophthalmitis were higher in patients who had cataract surgery with a combined procedure of cataract and retina or other intraocular surgery. These findings can improve patient counseling and future research should focus on endophthalmitis prevention in these higher risk cases.

SUBMITTER (NAME ONLY): Megan Straiko

TITLE: Modification of an eye bank pre-loaded DMEK graft preparation protocol to accommodate “flat” grafts

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.M. Straiko, T. Hikes, P.K. Dye, K.D. Tran, Lions VisionGift, Portland, Oregon, UNITED STATES|M.A. Terry, Cornea, Legacy Devers Eye Institute at Legacy Good Samaritan Medical Center, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Megan Straiko: Commercial Relationship: Code N (No Commercial Relationship) | Tucker Hikes: Commercial Relationship: Code N (No Commercial Relationship) | Philip Dye: Commercial Relationship: Code N (No Commercial Relationship) | Khoa Tran: Commercial Relationship: Code N (No Commercial Relationship) | Mark Terry: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During DMEK graft processing, eye bank technicians occasionally encounter “flat” grafts that do not spontaneously scroll easily and are difficult to load without causing damage to the graft. In this eye bank laboratory-based study, we sought to determine if modification to the standard pre-loaded DMEK preparation technique resulted in additional damage or a characteristic pattern of damage to the graft after short-term storage.

Methods: Six pairs of human donor corneas (age 65-80, with comparable cell counts and pre-processing damage) were prestripped, punched and loaded as a single scrolled graft by two experienced processing technicians. The OD graft was drawn into a Straiko modified Jones tube filled with Life4C using suction (standard loading procedure for our eye bank). The OS graft was picked up with forceps and dropped into a Life4C filled Straiko modified Jones tube. Grafts were stored in a Life4C filled Krolman viewing chamber for 24 hours at 4°C and then ejected onto a bed of calcein AM-supplemented viscoelastic, imaged with a fluorescent light microscope and analyzed for endothelial cell loss by FIJI segmentation. Mean endothelial cell loss was determined for standard loading and drop-in loading grafts and statistical significance determined using an unpaired Student’s t-test.

Results: There was no difference in endothelial cell counts as determined by specular microscopy prior to graft processing (standard loading grafts, 2728.4 ± 333.8 cells/mm²; drop-in loading grafts, 2635.6 ± 369.2 cells/mm², $P = 0.6877$). Mean ECL for standard loading protocol grafts was $21.4\% \pm 4.8\%$; mean ECL for drop-in loading grafts was $18.9\% \pm 4.6\%$, $P = 0.4310$. There was no consistent pattern of damage noted in DMEK grafts that underwent either standard loading or drop-in loading.

Conclusions: Modification to the standard technique of preloading DMEK grafts by grasping the stripped, punched graft and dropping it into a storage media filled Straiko modified Jones tube does not result in additional damage to a DMEK graft as measured by vital dye staining, nor does it result in a characteristic pattern of cell death. This technique may be useful with flat DMEK grafts that are difficult to load without excessive contact with the edge of the Straiko modified Jones tube.

TITLE: Comparison of glaucoma diagnosis by ophthalmologist, optometrist, and telemedicine with OCT

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Atik, T.A. Swain, G. McGwin, C. Owsley, C.A. Girkin, L.A. Rhodes, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|A. Atik, T.A. Swain, G. McGwin, C. Owsley, C.A. Girkin, L.A. Rhodes, Department of Ophthalmology and Visual Sciences, UAB Callahan Eye Hospital, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alp Atik: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Swain: Commercial Relationship: Code N (No Commercial Relationship) | Gerald McGwin: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Owsley: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Girkin: Commercial Relationship: Code N (No Commercial Relationship) | Lindsay Rhodes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Telemedicine is a novel, emerging medium addressing the challenges of accessing in-person glaucoma care by utilizing objective tools such as optical coherence tomography (OCT) for remote diagnosis. This study assessed the agreement of the diagnosis of glaucoma performed by an in-person ophthalmologist (MD), in-person optometrist (OD) and 2 telemedicine ophthalmologists (TMD1 and TMD2) with that of OCT alone.

Methods: This was a cross-sectional study of patients presenting to an academic tertiary referral glaucoma clinic who were independently examined for glaucoma with a dilated exam and optic nerve testing (visual field, optical coherence tomography, and photos) by both an MD and OD. Optic nerve testing was then reviewed by TMD1 and TMD2 with blinding to the MD and OD diagnoses. The OCT software labelled each scan as within normal limits, borderline or outside normal limits. "Borderline" was considered as both outside normal limits (OCT1) and within normal limits (OCT2). Agreement between each method of diagnosis (MD, OD, and TMD1 and TMD2) of normal vs. glaucoma (open angle glaucoma, normal tension glaucoma, other type of glaucoma, ocular hypertension, glaucoma suspect) compared to OCT1 and OCT2 for each eye was calculated using Cohen's unweighted Kappa statistic and 95% confidence intervals. The predictive ability of OCT alone compared to TM2 was assessed by the area under the curve (AUC) of the receiver operating characteristics curve.

Results: 100 study participants (200 eyes) with a mean age of 66.7 years (IQR 59-72) were 40% male and 62% white. There was moderate agreement between OCT1 and telemedicine (TMD1: $K=0.45$ [95% CI 0.32-0.57], TMD2: $K=0.46$ [0.34-0.58]) in determining a diagnosis of normal from glaucoma. There was only fair agreement between OCT1 and in-person review by an MD ($K=0.32$ [0.19-0.45]) and OD ($K=0.35$ [0.22-0.48]). These results were similar for OCT2 agreement with telemedicine (TMD1, $K=0.39$ [0.28-0.51], TMD2, $K=0.40$ [0.28-0.51]), MD ($K=0.34$ [0.22-0.46]), and OD ($K=0.29$ [0.17-0.41]). When assessing the ability of OCT1 to diagnose glaucoma as compared to TMD2, the AUC was 0.73 (95% CI: 0.67-0.79) (Figure 1).

Conclusions: Although OCT is an important tool, it is not sufficient for the diagnosis of glaucoma in a telemedicine model as other parameters such as visual fields and optic nerve photos provide key information.

ABSTRACT BODY:

Purpose: This study aimed to assess axial length and choroidal thickness changes following short-term peripheral myopic defocus sessions.

Methods: 20 visually-normal subjects (13 females and 7 males) of mean age 25.5 years (range 19-31) with mean spherical equivalent refractive error of -2.02 D (range 0 to -4.13 D, cyl < 0.75 D) were enrolled. 14 subjects were Asian and 6 were Caucasian. Subjects underwent defocus sessions by watching projected (ViewSonix PX706 projector) color movies (screen dimensions: 8 ft H X 12 ft W) 4 meters away under controlled conditions (room illumination of approximately 80 lux) while wearing standard spectacle lenses corrected for distance refraction (both eyes) for 4 hours between 8:00 am to 12:00 pm. The right (test) eye was peripherally defocused using a Fresnel lens overlay of +3.50D with a central clear aperture of 15 degree diameter, which was centered for the subject’s pupillary axis on primary gaze, while the fully-corrected left eye served as the control. A subset of 10 subjects from the same cohort also further underwent similar defocus sessions with +5.00D of peripheral defocus supplied through the Fresnel lenses on a different day following a wash-out of at least 1 day. Axial length was measured with a Lenstar APS 900 from Haag-Streit Holding, and radial choroidal scans were obtained from Heidelberg SD-OCT with EDI, before and after the defocus sessions.

Results: The test eye was approximately 11 µm shorter than the control eye when measured after 4 hours of defocus for both +3.50D and +5.00 D peripheral myopic defocus conditions (corrected p<0.05). The thickening of choroidal thickness after defocus was more robust for the +5.00D condition compared to the +3.50 condition (p>0.05 for both conditions).

Conclusions: We have shown, for the first time, that short-term peripheral myopic defocus is capable of inhibiting eye-elongation, which gives additional insight towards the physiological effect of peripheral myopic defocus.

TITLE: Evaluation of Sleep, Activity, and Burnout after Implementation of Night-Float and Post-Call Relief in PGY-2 Ophthalmology Residents

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Yi, J. Huang, S. Feng, Ophthalmology, University of Washington School of Medicine, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jonathan Yi: Commercial Relationship: Code N (No Commercial Relationship) | Johnson Huang: Commercial Relationship: Code N (No Commercial Relationship) | Shu Feng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lack of sleep and activity are commonly associated with resident burnout. Proposed strategies to address resident burnout include restructuring traditional call schedules to provide time for sleep recovery post call. This study examines the effects of implementing night-float and post-call relief on sleep, activity, and burnout in post-graduate year (PGY)-2 ophthalmology residents at the University of Washington (UW) between 2017-2021 using wrist actigraphy and standardized burnout surveys.

Methods: Data from 20 PGY-2 ophthalmology residents at UW were collected with Fitbit Alta HR wrist actigraphers between 2017-2020. Three residents were excluded due to insufficient sleep or activity data. From 2017-2019, residents took home call every 5 nights and returned to full clinical duties on their post-call workday. From 2019-2021, a night-float resident without daytime clinical duties took call for 3 nights a week while remaining residents rotated call duties for the remaining 4 nights of the week with no clinical duties assigned past noon on their post-call day. Burnout was evaluated by Maslach Burnout Inventory surveys and Depression Anxiety Stress scales. T-tests were used to compare average sleep, activity, and sedentary time between residents before and after implementing night-float and post-call relief. Pearson correlation was used to associate sleep and activity metrics with averaged median burnout scores.

Results: PGY-2 residents with night-float and post-call relief (N=8) had greater average daily activity (17.1 ± 10 min vs 5.60 ± 3.5 min, $p=0.02$) and lower average sedentary time (14.1 ± 2.5 hours vs 17.5 ± 2.7 hours, $p=0.02$) compared to residents without night-float and post-call relief (N=9). No statistically significant differences in sleep or burnout were found in the two cohorts, though residents with night-float and post-call relief trended toward lower emotional exhaustion ($p=0.10$) and stress ($p=0.10$). For all PGY-2 residents, there was a negative correlation between activity and stress, and a positive correlation between sedentary time and emotional exhaustion, anxiety, and stress.

Conclusions: Night-float and post-call relief led to greater average physical activity and lower average sedentary time in PGY-2 ophthalmology residents. Increased physical activity and decreased sedentary time correlates to decreased emotional exhaustion, anxiety, and stress.

TITLE: Gonioscopy Findings in a Childhood Variant Angle Closure Glaucoma after Laser Peripheral Iridotomy

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.V. Nguyen, School of Osteopathic Medicine, University of the Incarnate Word, San Antonio, Texas, UNITED STATES|W.E. Sponsel, Director, WESMDPA, San Antonio, Texas, UNITED STATES|G. Slagle, Clinical Research, Sponsel Foundation, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Angela Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Grant Slagle: Commercial Relationship: Code N (No Commercial Relationship) | William Sponsel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pediatric Eversional Angle Closure with Headache (PEACH) is a childhood variant intermittent angle closure glaucoma characterized by 1) recurrent frontal headache, 2) iris laxity on dynamic gonioscopy, and 3) concentric visual field loss on Frequency Doubling Technology perimetry. Prior reports demonstrate nearly universal symptom improvement with laser peripheral iridotomy (LPI), but gonioscopy findings in these patients have not been reported. This retrospective observational study evaluates gonioscopy findings in PEACH eyes pre- and post- LPI.

Methods: We retrospectively analyzed 166 eyes of 91 subjects (5 to 18 years) with PEACH who had LPI (VISULAS YAG III, Zeiss, Jena, Germany) between March 2011 and September 2020. Dynamic gonioscopy was performed using a 4-mirror gonio lens and graded using the Spaeth system before (n=166) and after (n=98) LPI. Frequency percentages were calculated for all variables. Iris insertion, angle width, and pigment were evaluated with Wilcoxon's signed-rank test and iris configuration with chi-square.

Results: Iris configuration of Q was the most sensitive index (92%) for PEACH diagnosis, most commonly presenting as (R)Q (82.7%). Other common findings: 75.95% of eyes had iris insertion deep to the ciliary body (Spaeth D, range A-E), 50.6% had iris angle width of 40 degrees (range 0-55°), and 54.2% of subjects had concentric iris folds. Significant portions of eyes had pigment dust anterior to Schwalbe's line (42.8%) with only a minority showing synechiae (15.7%). Iris insertion became less deep after LPI ($p<0.001$), mean angle width decreased from 40 ± 7 to 34 ± 6 degrees ($p<0.001$), and mean pigment increased from 1 ± 1 to 2 ± 1 ($p=0.03$). Significantly, in eyes in perpetual Q pre-LPI, 87.5% reverted to Spaeth R post-LPI. In baseline (R)Q eyes, 93.7% reverted to R [$\chi^2(20, N=96)=33.6, p<0.001$]. Thus LPI may impart resistance to reverse pupillary block in PEACH.

Conclusions: Gonioscopy is a sensitive tool essential to the diagnosis and monitoring of PEACH patients, and must be considered alongside historical and perimetric factors to arrive at an accurate diagnosis and verify effective therapy. The iridocorneal angle structures change in response to LPI and may be mechanistically related to improvements in PEACH symptomatology.

TITLE: Zebrafish PCDH15 (USH1F) mutants display visual and audiovestibular defects

SESSION TITLE: Models to study retinal degeneration and remodeling

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.B. Phillips, S. Buchner, M. Westerfield, Institute of Neuroscience, University of Oregon, Eugene, Oregon, UNITED STATES|M. Ivanchenko, D.P. Corey, Department of Neurobiology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jennifer Phillips: Commercial Relationship: Code N (No Commercial Relationship) | Maryna Ivanchenko: Commercial Relationship: Code N (No Commercial Relationship) | Sara Buchner: Commercial Relationship: Code N (No Commercial Relationship) | David Corey: Commercial Relationship: Code N (No Commercial Relationship) | Monte Westerfield: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mutations in PCDH15 cause severe early onset visual dysfunction, along with profound congenital deafness and loss of vestibular function. *pcdh15b*, previously shown by morpholino knock-down to be critical for photoreceptor function and survival with no observed effect on hearing or balance, but no zebrafish mutant studies have been published to date.

Methods: Mutations induced by CRISPR/Cas9 injection into zygotes were verified by Sanger sequencing and propagated. We assayed hearing, balance, mechanosensory hair cells, photoreceptor morphology, and cell death with behavioral and histological methods. Light exposure experiments were performed using broad-spectrum light and petri dishes treated with tinted window film. Western blot analysis was performed on extracts from enucleated larval retinas.

Results: Optokinetic response was detected at reduced levels in 5 day postfertilization (dpf) mutant larvae, and immunohistochemical, SEM and TEM analysis of mutant photoreceptors revealed morphologically abnormal calyceal processes and outer segments. An antibody recognizing zebrafish *pcdh15* labeled the region of the calyceal processes in wild-type photoreceptors with no specific labeling in mutants. We observed elevated cell death, assayed by Caspase-3, in the outer nuclear layer. We examined levels of *e1fa* and CHOP by Western blot to determine whether ER stress was induced by *Pcdh15b* dysfunction and found no elevation in either. We observed enhanced photoreceptor death by rearing larvae in bright light, and that filtering out short wavelength while keeping Lux values constant resulted in lower rates of cell death. Although mutants exhibited normal startle responses, indicative of acoustic function, they had impaired balance. Consistent with this finding, stereocilia of the inner ear were perturbed more in the utricle than the saccule, and expression of the orthologous gene *pcdh15a* was enriched only in the saccule of 5dpf mutants compared to wild-type levels.

Conclusions: The zebrafish model of visual and vestibular defects in USH1F exhibits severe, early defects consistent with human symptoms. Our data indicate that both *pcdh15a* and *pcdh15b* are required for hearing and balance, and that genetic compensation by *pcdh15a* is evident in the acoustic hair cells of *pcdh15b* mutants. These characterizations provide numerous measures of disease progression and an advantageous system to test potential pharmacological interventions.

ABSTRACT BODY:

Purpose: We have previously shown that Neutrophil Extracellular Traps (NETs) are present on the ocular surface of oGVHD patients and they contribute to inflammation and surface disease. Therefore, we performed a clinical trial using DNase eye drops to test the hypothesis that reducing the abundance of NETs from the ocular surface will reduce signs, and symptoms of oGVHD.

Methods: A prospective, phase I/II, randomized, placebo-controlled, double-masked clinical trial was performed to compare the safety and preliminary efficacy of DNase (0.1%) eye drops four times a day for 8 weeks in patients with oGVHD (n=51). Available data and intent-to-treat analyses were performed to determine the change in safety outcome measures (drug tolerability and proportion of adverse events) and efficacy outcome measures (OSDI score and corneal staining) between baseline and week 8. The clinical trial was performed under a IND assigned by the FDA and a protocol approved by UIC IRB.

Results: Tolerability and adverse events were similar in Vehicle group and DNase group. Within the DNase group (but not Vehicle group), corneal staining showed a statistically significant and clinically meaningful reduction at week 8 (3.50 [2.75; 5.00]) compared to baseline (5.00 [3.00; 7.00]). The OSDI score also showed a significant median reduction of 18.4 [9.16; 33.1, p<0.001] at week 8 compared to baseline (45.5 [31.8; 50.0]) within the DNase group. Proportion of eyes that had improvement in Subjective global assessment (SGA) and mucous discharge were significantly greater in the DNase group (55.6% and 57.7% at weeks 4 and 8, respectively; p < 0.0001 at both time points) as compared to the Vehicle group (35.7% and 34.0% at weeks 4 and 8, respectively). Proportion of eyes that had improvement on CGI at week 8 were significantly greater in the DNase group (94.2%; p < 0.0001) as compared to the Vehicle group (22.0%).

Conclusions: Treatment of patients with oGVHD using DNase eye drops is safe and demonstrates a preliminary efficacy. DNase eye drops have the potential to reduce the severity of signs and symptoms of ocular surface disease in oGVHD patients.

TITLE: Effects of Dexamethasone on Wnt Signalling Expression in Human Trabecular Meshwork

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Sislyan, C. Han, L.U. Sanchez, C. Zhang, J.J. Zheng, University of California Los Angeles, Los Angeles, California, UNITED STATES|E. Cohen, Weill Cornell Medicine, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sarkis Sislyan: Commercial Relationship: Code N (No Commercial Relationship) | Christiana Han: Commercial Relationship: Code N (No Commercial Relationship) | Emily Cohen: Commercial Relationship: Code N (No Commercial Relationship) | Luis Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Chi Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Jie Zheng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Damage to the trabecular meshwork (TM) is commonly thought to lead to elevated intraocular pressure (IOP) and glaucoma development, but the exact mechanisms that increase IOP remain unresolved. Prior studies indicate Dexamethasone(Dex)-induced glaucoma may involve increased Wnt signaling activity. This study employs RNA sequencing to investigate the specific changes in gene expression that can result from Dex treatment of human TM cells.

Methods: The TM from 3 human corneal tissue (TM 3, TM 4, and TM 5) were isolated and plated with 20% fetal bovine serum (FBS) media. After reaching confluency, each TM cell line was treated with dexamethasone (D) or ethanol vehicle (V). RNA was isolated from each group, and the data was sequenced using Illumina HiSeq 3000. The data was demultiplexed using Illumina Bcl2fastq2 v. 2.17. Using Bowtie2 v. 2.1.0, the reads were mapped, and gene expression was determined using RSEM v. 1.2.15. The data was normalized using the trimmed mean of M-values. Data analysis was performed using Rstudio. Heatmaps were generated using the pheatmap R package and were scaled by row.

Results: RNA sequencing data was converted into heatmaps on Rstudio. Both figures displayed similar relationships across genes and treatment groups. DKK1 had lower expression in Dex treated groups, particularly TM 5 cells. SFRP1 and SFRP 4 expression was lower in Dex treated groups. FZD4 showed a stark increased expression in Dex treated groups, especially TM 5 cells.

Conclusions: Overall, Dex treatment caused wide-ranging changes in the expression of Wnt signaling genes, consistent with the idea that Wnt signaling plays a key role in the human TM's function of regulating IOP. This is supported by a decreased expression of DKK1, SFRP1 and SFRP4, which are Wnt signaling inhibitors, in Dex-treated groups. Similarly, FZD4 is a receptor in the canonical Wnt pathway, where increased expression leads to greater Wnt signaling. Together, these results indicate a potential mechanism which involves the reduction of Wnt inhibition in glaucomatous TM cells.

ABSTRACT BODY:

Purpose: To determine if the detection of choroidal hyper-transmission defects (hyperTDs) on en face OCT images serve as a risk factor for the formation of nascent geographic atrophy (nGA) or GA in eyes with intermediate AMD (iAMD), we compared the onset and persistence of hyperTDs with the gold-standard detection of nGA using averaged OCT B-scans

Methods: Patients with bilateral large drusen were enrolled in a natural history study and imaged with both Spectralis SD-OCT (Heidelberg Engineering, Heidelberg, Germany) and Cirrus SD-OCT (Carl Zeiss Meditec, Dublin, CA) instruments at 6-month interval over 36 months. The Spectralis SD-OCT B-scans were used to grade for nGA at the Centre for Eye Research Australia. En face Cirrus SD-OCT images were graded for the presence of hyperTDs in a masked fashion at the Bascom Palmer Eye Institute. HyperTDs with greatest linear dimensions (GLDs) $\geq 125\mu\text{m}$ were measured and tracked throughout all available visits. The size cut-off for persistent and non-persistent hyperTDs was determined based on baseline GLD measurements. Over 36 months, the association between these HTDs and the presence of nGA was assessed.

Results: A total of 157 eyes from 81 patients were available to be graded. At baseline, Cirrus SD-OCT scans were available on 133 eyes, and 39 hyperTDs from 27 eyes of 22 subjects were classified as either persistent (26 lesions) or non-persistent (13 lesions) over 36 months. Receiver Operating Characteristic curve analysis suggested hyperTDs with baseline GLDs above a threshold of $250\mu\text{m}$ to $300\mu\text{m}$ fulfilled the definition of persistent lesions. After grading the entire population of 157 eyes, a significant association ($p < 0.001$) was found between nGA gradings and the masked gradings of hyperTDs with $\text{GLD} \geq 250\mu\text{m}$ (OR, 14.5, 95% CI: 4.8, 54.0) or $300\mu\text{m}$ (OR, 15.2, 95% CI: 5.0, 56.7). HyperTDs with $\text{GLD} \geq 250$ or $300\mu\text{m}$ had an excellent negative predictive value of $\geq 94\%$, but a poor positive predictive value (PPV) of $\leq 40\%$ for detecting nGA. The poor PPV appeared to be due to the earlier detection of lesions that would become nGA.

Conclusions: Choroidal hyperTDs detected on en face SD-OCT images with a $\text{GLD} \geq 250\mu\text{m}$ or $300\mu\text{m}$ were strongly associated with the presence of nGA and may serve as a useful risk factor for the early detection of disease progression of iAMD to GA.

ABSTRACT BODY:

Purpose: The role of inflammation and neurosensory abnormalities in dry eye disease (DED) has been defined by dry eye workshop II report. The etiologic role of autoimmune diseases, such as Sjögren's syndrome, mixed connective tissue diseases, sarcoidosis, and related nerve loss has been established in DED. However, dysimmune neuropathies, which are caused by specific autoantibodies (Abs) against peripheral nerve axons and myelin have not been investigated. Therefore, our purpose was to evaluate the potential systemic etiologies in DED, by assessing serological Abs used for dysimmune neuropathies as well as autoimmune diseases.

Methods: Patients with moderate to severe DED (n=37) underwent serological testing for inflammatory (ESR, CRP), autoimmune, and dysimmune neuropathy Abs (anti-TSHDS, anti-FGFR3, anti-sulfatide IgM, anti-Histone H3, Anti-GD1a).

Results: At least one abnormal result was detected in 24 patients (64.8%) with 54.0% showing at least one positive dysimmune neuropathy Ab. Anti-TS-HDS and anti-FGFR3 were positive in 48.6% and 21.6% of patients, respectively. Acute inflammation markers ESR and CRP were positive in 24.3% and 16.2%, respectively. ANA was positive in 32.4% of patients. SS-A (13.5%) and SS-B (13.5%) were the most common disease specific autoimmune Abs followed by RF (5.4%). At least one positive Celiac Ab (anti-gliadin IgA, IgG, tissue transglutaminase IgA, IgG) was detected in 2.7% of patients.

Conclusions: Our findings suggest that dysimmune neuropathy may play a crucial role in DED etiology. Detailed serological evaluation detects higher positivity rates for dysimmune neuropathy Abs compared to well-known systemic etiologies, such as Sjögren's syndrome and rheumatoid arthritis Abs, suggesting that neurosensorial abnormalities need further investigation in the course of DED.

ABSTRACT BODY:

Purpose: Delay in outpatient chronic care management can lead to a rise in acute complications. COVID-19 related clinic and ambulatory shutdowns came into effect in South Texas by the end of 3/2020. Recent studies have shown delays in care and more severe disease presentations during the COVID-19 shutdown. We evaluate trends in ophthalmic pathologies in relation to patient follow-up behaviors after ED and inpatient encounters in South Texas.

Methods: A retrospective study used electronic medical records to collect consultation logistics, patient clinical data, and clinical follow up for ophthalmic inpatient and emergent encounters from 7/2019 - 7/2020. Proliferative disease-associated vitreous hemorrhage (VH) and neovascular glaucoma (NVG) were used as markers for acute on chronic complications. Patient follow-up rate and time were compared to recommended follow-up during the two eras to analyze trends in patient behavior.

Results: 501 records were evaluated. Pre- and post-shutdown weekday (14 hour) volume of encounters were 5.7 ± 3.2 and 3.7 ± 2 , respectively. Weekend (24 hour) encounters changed from 12.7 ± 4.6 to 9.9 ± 5.5 . Pre-shutdown average weekday time of encounter was $21:36 \pm 4.6$ hrs compared to $20:59 \pm 4.0$ hrs post-shutdown, and for weekend time of encounter was $19:49 \pm 6.2$ hrs compared to $19:23 \pm 5.6$ hrs. Pre-shutdown recommended follow-up was 6.9 ± 8.7 days compared to 9.9 ± 10.5 days post-shutdown, with patients delaying the originally recommended appointment by 11.3 ± 50.9 days pre-shutdown and 7.1 ± 25.3 days post-shutdown. Missed appointment rate was 35% pre-shutdown and 47% post-shutdown. Of the 216 pre-shutdown encounters, 9% needed urgent surgery and 5% needed a bedside procedure. Post-shutdown, 8% needed surgery and 6% needed a bedside procedure. Pre- and post-shutdown incidence respectively was 4% and 4% for NVG, and 5% and 7% for VH.

Conclusions: During the COVID-19 shutdown, the volume of ophthalmic ED evaluations decreased, but not significantly. Patient encounter time and procedural intervention rate were also not significantly altered, suggesting that the urgency profile of pathologies did not change significantly. More patients missed clinic follow-up but appointment delays were comparable to the pre-shutdown era. There was a slightly higher incidence of acute on chronic proliferative pathologies.

TITLE: Using a handheld facial vibration device is associated with reduction in pain associated with onabotulinumtoxinA injections for Benign Essential Blepharospasm

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.P. DeRuyter, B. Barahimi, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|Y. Liu, Q. Chen, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nicolaas DeRuyter: Commercial Relationship: Code N (No Commercial Relationship) | Yuhan Liu: Commercial Relationship: Code N (No Commercial Relationship) | Qingxia Chen: Commercial Relationship: Code N (No Commercial Relationship) | Behin Barahimi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Strategies to mitigate pain associated with periorbital onabotulinumtoxinA (BOTOX) injections for Benign Essential Blepharospasm (BEB) are insufficient in the current era. We conducted a randomly controlled trial to test the hypothesis that using a handheld facial vibration device would improve BOTOX injection associated pain for patients with BEB.

Methods: Adults 18 or older with a clinical diagnosis of BEB were randomized to receive facial vibration with the handheld Yeamon vibration device (frequency = 100Hz) to only one side of their face (right vs. left) during periorbital BOTOX injections. Following treatment, subjects completed a pain rating survey scaled 1-10 (1 = no pain, 10 = worst pain) for each side of the face. Baseline demographic data was collected. Pain rating between treatment and control was compared using linear mixed effect model regression.

Results: 21 patients participated in the trial. Median age and years since diagnosis was 65 and four years, respectively. For treatment pain rating, the median score was 4.0; for no treatment, the median score was 5.0. Mean score and standard deviation between treatment and control was 4.4 ± 2.1 vs. 5.7 ± 2.1 . Vibration stimulation was associated with a statistically significant lower score when controlling for age of patient and number of injected units during treatment ($p=0.0198$).

Conclusions: Using a handheld facial vibration device is associated with reduction in patient pain during periorbital BOTOX injections for BEB. This can be considered for use in the injection specialist's armamentarium to improve patient comfort.

ABSTRACT BODY:

Purpose: Deficits in vergence and accommodation are commonly reported following concussion. We explored if the frequency and subtypes of vergence deficits (VD) and accommodation deficits (AD) vary between subacute (>15 days to 12 weeks) and chronic (> 12 weeks to < 1 year) phases of concussion recovery along with sex-based differences.

Methods: Retrospective cross-sectional study. Chart review of patients with concussion evaluated at Boston Children's Hospital between August 2012 and March 2020. Inclusion criteria: 7-18 years; 20/30 vision or better in each eye; complete assessment of vergence and accommodation; no strabismus, amblyopia, or other ocular pathology. Results were compared to a non-concussed control group (n= 30; median age: 9.2, IQR: 8.1 -10.6 years) recruited and evaluated from April to October 2016. VD and AD were characterized based on clinical findings falling outside of the 95th percentile of the control group. Chi-square and Fischer's exact test (FET) were used to assess diagnosis and subtype differences.

Results: A total of 256/423 (61%) patients fit inclusion criteria with 115 evaluated in the subacute (median age: 15 IQR: 13.6 - 16 years; 60% females) and 141 in the chronic (median age: 15.4; IQR: 13.7 -16.8 years; 67% female) phases of concussion recovery. Frequency and subtype of VD and AD were not significantly different between subacute and chronic cohorts (45% vs 52% and 84% vs 83%, respectively). In the subacute phase, the frequency of AD was lower in females compared to males (65.3% vs 82.6%, $\chi^2 = 4.15$, $p=0.04$). In the chronic phase, frequency of AD was similar in both sexes (67% vs 75%), but there was a difference in subtype of AD (FET, $p<0.001$) with accommodative insufficiency in 56% vs. 23% ($\chi^2 = 14.48$, $p<0.001$), accommodative excess in 7.4% vs 15% ($\chi^2 = 2.1$, $p=0.15$) and accommodative dysfunction in 10.5% vs. 26.1% ($\chi^2 = 5.69$, $p=0.017$) females vs males, respectively. This difference is likely due to a trend towards higher failure rate with accommodation amplitude in females (64% vs 50%, FET $p=0.07$) and higher failure rate of accommodative facility in males (52% vs 25%; FET, $p=0.002$).

Conclusions: We found no difference in the frequency of VD or AD in the subacute and chronic phases of concussion recovery. In the chronic phase sex-based differences were noted in subtype of AD. Low accommodative amplitude drove AD in females but poor accommodative facility drove AD in males.

TITLE: The Impact of the Affordable Care Act on Eye-Related Emergency Department Utilization in the United States

SESSION TITLE: Public Health

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T.A. Mir, S. Mehta, K. Qiang, I. Freedman, J. Chow, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tahreem Mir: Commercial Relationship: Code N (No Commercial Relationship) | Sumarth Mehta: Commercial Relationship: Code N (No Commercial Relationship) | Karen Qiang: Commercial Relationship: Code N (No Commercial Relationship) | Isaac Freedman: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Chow: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the impact of the affordable care act (ACA) on nationwide eye-related emergency department (ED) utilization

Methods: Nationally representative data from the US Nationwide Emergency Department Sample (NEDS) were used to analyze eye-related ED visits before (2010-2013) and after (2014-2017) the ACA was mandated. The primary outcome was to compare the nationwide and regional incidence of eye-related ED visits per 100,000 US population before and after the ACA was mandated. Secondary outcomes measures included change in payor status, relative proportion of urgent versus non-urgent eye-related ED visits and charges per ED visit.

Results: A total of 16,808,343 eye-related ED visits occurred in the United States during the study period from 2010-2017. Of these, 8,088,203 ED visits occurred before the ACA was mandated (2010-2013) and 8,720,766 ED visits occurred after the ACA was mandated (2014-2017). The median age of individuals presenting to the ED with eye-related problems was 30 years and 53.4% of them were male. After the ACA was mandated in 2014, there was an initial decline in incidence of eye-related ED visits from 652.4 per 100,000 in 2013 to 593.0 per 100,000 in 2014, followed by a rapid increase in incidence to 658.5 per 100,000 population in 2015, with a further increase to 746.6 per 100,000 population in 2016. The percentage of uninsured patients decreased from 19% to 14.3% and those with Medicaid coverage increased from 29.4% to 36.0%. The increase in ED utilization was greatest for individuals belonging to the lowest income quartile (895.1 per 100,000 population in 2013 to 964.0 per 100,000 in 2017). Overall, only 38.3% of the ED visits during the study period were due to emergent eye conditions. The inflation adjusted median charge per ED visit increased from \$718.4 to \$999.5 after the ACA was mandated.

Conclusions: Although the ACA increased insurance coverage for Americans belonging to low socioeconomic status and minorities, it did not translate into improved and more equitable access to outpatient ophthalmic care. Emergency department utilization for non-emergent ophthalmic conditions continues to increase, resulting in more costly and less specialized care. Additional measures beyond expanding insurance coverage may be necessary to provide high quality, efficient and equitable healthcare to all Americans.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is linked in part to genetic defects in complement system proteins as well as inflammatory markers of the innate immune system. Previously, our laboratory reported that AMD platelets have increased surface levels of complement component C3b at baseline and after platelet activation. In this study, we measured platelet levels of proteins from all three complement pathways as well as several innate immune proteins with associations to AMD.

Methods: Whole blood was obtained from 13 pre-advanced AMD and 6 age-matched control subjects after receiving IRB approval and informed consent. Platelet-rich plasma was isolated by centrifugation and samples were prepared in buffer containing fibrin inhibitor Gly-Pro-Arg-Pro. Fluorescently-conjugated antibodies against complement proteins C1R, C3b, CFH, MASP-1/3, and Ficolin-2, as well as innate immune proteins Toll-like receptor 4 (TLR4) and TIMP-3, were measured at baseline and after activation with dual platelet agonists thrombin and convulxin (T/C) using a Beckman Coulter CytoFLEX S flow cytometer. Inhibitors of the TLR4 pathway resveratrol, quercetin, and curcumin were evaluated in combination (RQC) for their potential to reduce systemic vascular complement activation.

Results: In AMD platelets, C1R ($P=0.003$), C3b ($P=0.02$), and innate immune receptor TLR4 ($P=0.01$) were significantly increased at baseline compared with controls. CFH, a negative regulator of complement activity, was decreased at baseline ($P=0.04$). Platelet activation with T/C increased surface levels of all measured proteins. Pre-treatment with RQC significantly inhibited the activation-induced increase in C1R ($P=0.001$), C3b ($P=0.001$), CFH ($p=0.0001$), MASP-1/3 ($P=0.008$), Ficolin-2 ($P=0.0004$), TLR4 ($P=0.01$), and TIMP-3 ($P=0.0008$).

Conclusions: Systemic levels of complement and TLR4-associated innate immune system proteins are increased in AMD. Platelet complement and innate immune pathways may be a new target for AMD treatment.

TITLE: Assessment of the Readability, Accessibility and Quality of Online Source Material for Myopia and Myopic Degeneration

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Wang, J. Fallon, D. Harris, New York Eye and Ear Infirmary of Mount Sinai, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Daniel Wang: Commercial Relationship: Code N (No Commercial Relationship) | Julia Fallon: Commercial Relationship: Code N (No Commercial Relationship) | David Harris: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myopia is a common cause of visual impairment globally with its prevalence set to rise over the next several decades, particularly in Asian nations. Patients increasingly rely upon Google searches on the internet to provide supplemental information regarding their ophthalmic and medical conditions. This study seeks to compare the quality, readability, and accessibility of online content available to the public regarding myopia and myopic degeneration.

Methods: A cross-sectional analysis of the top 15 google sites using a general search strategy (terms: Myopia and Myopic Degeneration) was performed between November 2020 and December 2020. Identified sites were stratified into either private or academic sources. Website quality was assessed using the internationally recognized DISCERN and the Health on the Net (HONcode) criteria. Readability was graded using an online readability tool. Website accessibility features available to patients were also evaluated.

Results: Eight academic and seven private websites were included in the analysis. Academic websites had a significantly higher quality index (43.4 ± 9.2) compared to the private sites (29.3 ± 7.6 ; $P < 0.007$) determined by the DISCERN criteria. Similarly, the average quality score based on the HONcode criteria for academic websites (8.1 ± 2.6) was statistically significantly higher compared to the private websites (3.6 ± 1.4 ; $P < 0.001$). The mean consensus reading grade level was similar between the academic (11.4 ± 1.8) and private websites (11.6 ± 1.5 ; $P = 0.82$). Language translation and accessibility features for visual impairment was offered by only 7 of the 15 identified websites.

Conclusions: The quality of freely available online information regarding myopia and myopic degeneration is variable by source, but in general is of poor quality according to the specified criteria. Online content provided by academic sites was of significantly higher quality compared to private websites. Improving the readability of online source content and implementing universal accessibility features is needed to aid patients in their understanding of ophthalmic conditions.

ABSTRACT BODY:

Purpose: Ocular blast injuries result from a variety of damage mechanisms. Primary blast waves can cause damage with local increases in pressure. Secondary injuries from projectiles can cause penetrating and blunt trauma. Current injury models study a single mechanism and do not consider possible additive effects of multifactorial damage. The goal of this study is to produce and test a repeatable and controllable combined injury model in ex vivo porcine eyes and in in vivo rabbits.

Methods: A custom injury model device was fabricated that produces a primary blast wave, secondary corneal puncture injury, and blunt trauma in a simultaneous event. The physical effects of pressure, blade length, and blunt force were measured or calculated with a pressure transducer, microscopy, and projectile velocity, respectively. Immediate pathological effects were measured on fresh, intact porcine eyes, which were obtained from a local slaughterhouse. Blade lengths of 200, 400, and 600 μm were tested. Porcine corneas were analyzed with cornea strip extensometry and histology. The injury model was further tested in New Zealand white rabbits. Wound healing was observed with ophthalmic exams at regular intervals and with histology at days 3 and 14 following injury.

Results: The injury device produced consistent and controllable peak pressure, blade length, and blunt force. In porcine eyes, corneal strip extensometry showed a decrease in elastic modulus ($p < 0.01$, ANOVA) and ultimate stress ($p < 0.0001$, ANOVA) with increased blade length ($n = 6$). Histology showed that the wound depth correlated with blade length. In the in vivo study, fluorescein staining in ophthalmic exams and collagen imaging in histological analysis revealed a consistent location and depth of injury. By day 3, epithelial cells migrated and proliferated in the wound, and by day 14, scar tissue was observed through alpha-smooth muscle actin staining.

Conclusions: Our results demonstrate a novel model that combines damage mechanisms underlying blast injury. The model produces consistent and controllable damage in ex vivo porcine eyes and in in vivo rabbits. The model could be used to assess compounding effects of blast injury mechanisms and to test multipronged therapies for these injuries.

TITLE: Rab11, the TRAPP II complex, and phosphorylation regulate Rabin8 during ciliary trafficking of rhodopsin

SESSION TITLE: Biochemistry and molecular biology of the retina

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Deretic, T. Fresquez, Ophthalmology and Visual Sciences, University of New Mexico Health Sciences Center, Albuquerque, New Mexico, UNITED STATES|B.M. Tam, O.L. Moritz, Ophthalmology, The University of British Columbia, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure (Abstract): Dusanka Deretic: Commercial Relationship: Code N (No Commercial Relationship) | Beatrice Tam: Commercial Relationship: Code N (No Commercial Relationship) | Orson Moritz: Commercial Relationship: Code N (No Commercial Relationship) | Theresa Fresquez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sorting into rhodopsin transport carriers (RTCs) is regulated by the Rab8 GEF Rabin8, the backbone of the Rab11-Rabin8-Rab8 ciliogenesis complex. Rabin8 phosphorylation by NDR2 (aka STK38L), a canine early retinal degeneration (erd) gene, regulates its membrane association and function. The role of Rabin8 is not clear, however its interactions with multiple ciliary complexes suggest a central role in ciliary pathways of rhodopsin and other sensory receptors.

Methods: A GFP-Rabin8 WT and C (AA 251-460) fragment of human Rabin8 were constructed by site-directed mutagenesis and cloned into the XOP0.8 eGFP-N1 expression vector for the generation of transgenic *X. laevis*. The following mutants were generated: GFP-Rabin8 S272E and GFP-Rabin8 S272A; GFP-Rabin8 E192A and F201A GEF domain mutants and GFP-Rabin8 Δ 300-305 Rab11 binding mutant. The resulting phenotypes were analyzed by confocal microscopy.

Results: GFP-Rabin8 WT co-localized with rhodopsin in the Golgi and on RTCs, similar to the known localization of endogenous Rabin8 in photoreceptors cells. GFP-Rabin8 WT concentrated at the Golgi exit sites (GES), and at the RTC fusion sites. GFP-Rabin8 C was completely cytosolic, indicating that the binding of its N-terminal domain to the TRAPP II complex is essential for localization. GFP-Rabin8 S272E mutant, a phosphomimetic that decreases Rabin8 binding affinity for phosphatidyl serine (PS) but increases affinity for the Sec15 component of the exocyst ciliary complex, was predominantly localized at the base of the cilium, indicating that NDR2 phosphorylation directs Rabin8 to this location. The GFP-Rabin8 S272A mutant accumulated at the GES, where Rabin8 phosphorylation likely occurs. The phenotype of GFP-Rabin8 E192A and F201A mutants, which cannot activate Rab8, was similar to that of the S272E mutant, suggesting that Rabin8 phosphorylation and Rab8 activation occur at the similar site. The GFP-Rabin8 Δ 300-305 mutant was completely cytosolic, indicating that Rabin8 binding to Rab11 is also essential for its localization.

Conclusions: Our results implicate Rab11, the TRAPP II complex and the NDR2 kinase in the control of Rabin8 localization and function during the targeting of rhodopsin from the Golgi to the cilium and ROS. Ongoing experiments will establish the linkages between Rabin8 regulatory interactions and the discrete steps in rhodopsin ciliary trafficking.

ABSTRACT BODY:

Purpose: Hematopoietic stem/progenitor cells (HS/PCs) play a vital role in retinal injury and repair. Studies have shown that the egress of HS/PCs from the bone marrow via circulation to target tissues is influenced by both sympathetic and sensory nerves whose neurotransmitters activate adrenergic and sensory receptors expressed on HS/PCs and regulate HS/PC migration and proliferation (Gao et al, 2020). However, the role HS/PCs play in retinal development and the role of the sympathetic and sensory neurons in physiological recruitment during retinal development remains unclear. We sought to investigate the earliest time point at which HS/PCs are recruited into the neonatal retina in mice and to characterize the phenotype of the recruited cells. We also investigated whether HS/PC recruitment is associated with the sympathetic or sensory innervation of the neonatal retina.

Methods: Wild-type C57BL/6J mice at postnatal days 0, 3, 5 and 7 were euthanized and their eyes enucleated. The retinas were isolated and processed for immunohistochemistry. Bone marrow-derived cells in the retina were identified with the hematopoietic-specific marker VAV1. Vascular endothelial cells, sympathetic and sensory neurons were labelled with CD 31, tyrosine hydroxylase and calcitonin gene-related peptide, respectively. The number and phenotype of hematopoietic cells was quantified and the density of sympathetic and sensory neurons assessed at each time point.

Results: HS/PCs (VAV1-positive) were observed in the retina less than 24 hours after birth (P0) and did not increase significantly between P0 and P3 ($p=0.114$), P5 ($p=0.114$) and P7 ($p=0.057$). Between P0 (67.16%) and P7 (68.09%, $p=0.601$), the majority of hematopoietic cells in the developing retina were F4/80-positive, indicating a macrophage/microglial phenotype. Sympathetic neurons were not observed until at P3 in the inner nuclear layer and increased rapidly at P5 ($p=0.028$) and P7 ($p=0.029$). However, cells expressing CGRP were observed from P0 to P7 in the nuclear layers of the retina, and only reduced significantly at P7 ($p=0.008$).

Conclusions: Our data suggests that HS/PCs may be recruited into the developing healthy retina prenatally as predominantly phagocytic cells, and their recruitment may be facilitated by sensory innervation to the retina.

TITLE: Ten Year Experience of Optical Keratoplasty in Mexican Children

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Morales, A. Navas, L. Pedro Aguilar, A. Ramirez Miranda, E.O. Graue-Hernandez, Cornea, Instituto de Oftalmologia Fundacion Conde de Valenciana IAP, Mexico City, Mexico City, MEXICO|

Commercial Relationships Disclosure (Abstract): Norma Morales: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Navas: Commercial Relationship: Code N (No Commercial Relationship) | Lucero Pedro Aguilar: Commercial Relationship: Code N (No Commercial Relationship) | Arturo Ramirez Miranda: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Graue-Hernandez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the indications and outcomes associated to keratoplasty in children.

Methods: This is a retrospective descriptive study performed at the Instituto de Oftalmologia Conde de Valenciana.

The medical records of all patients under 18 years of age that underwent keratoplasty from 2009 to 2019 were reviewed. The data reviewed was: patients demographics, indication for keratoplasty, visual acuity at presentation and at last visit, surgeries previous, during or after keratoplasty, glaucoma incidence and time to graft failure

Results: A total of 46 patients (53 eyes) under the age of 18 were included in this review. The mean age was 13.75 ± 3.89 years. The most common indication was keratoconus in 26 eyes (49%). The most common procedure was penetrating keratoplasty in 47 eyes (89%). Mean logMAR vision acuity at presentation was 2.05 ± 0.99 and at last visit 0.82 ± 1.33 ($p < 0.05$). The mean follow up time was 56.98 ± 42.83 months while the mean survival time was 130.34 months. The survival rate was 86.79% per year. The survival time of the eyes with previous surgery and the eyes that had concomitant surgery was different compared to the eyes without previous surgeries ($p = 0.02$). The survival time of the 15 eyes that had surgery after the keratoplasty was not different ($p = 0.601$). A total of 17 eyes (32.1%) had ocular hypertension of which 8 (15.1%) had confirmed diagnosis of glaucoma. Mean survival time of patients without glaucoma was 116.

Conclusions: The most common indication for keratoplasty was keratoconus and the survival rate of the grafts over a mean follow up time of 56.98 ± 42.83 months was 86.79% per year. This survival rate was worse in patients who had had previous surgeries or concomitant surgeries at time of keratoplasty. The most common complication was ocular hypertension. Interestingly, even though many studies have reported that glaucoma affects the survival rate in adults and children, in this study, there was no difference in survival time between eyes that had glaucoma and the ones without glaucoma.

ABSTRACT BODY:

Purpose: To investigate associations between patient-related factors, provider-related factors, and the risk of postinjection endophthalmitis.

Methods: Retrospective nationally-representative sample of Medicare beneficiaries undergoing ≥ 1 intravitreal injection between January 1, 2013 and December 31, 2017. Logistic regression analysis was performed to assess whether patient-related factors (age at injection, race, sex, agent injected, injection-associated diagnosis, year of injection), and provider-related factors (retina subspecialist versus non-subspecialist, board certification status) were associated with an increased or decreased risk of postinjection endophthalmitis. Main outcomes were measured with odds ratio (OR) with 95% confidence intervals of receiving a diagnosis of endophthalmitis in the 14 days after intravitreal injection.

Results: 2,907,324 intravitreal injections were performed on 219,640 patients by 4,315 ophthalmologists, 3,196 (74%) who were retina specialists and 4,021 (92%) who were certified by the American Board of Ophthalmology (ABO). The mean (SD) age of the patients was 78.2 (10.2), there were 131,284 females (59.8%), and 192,544 whites (87.7%), and 13,220 blacks (6.0%). Overall, there were 1,088 (0.037%) cases of postinjection endophthalmitis, 1,024 (0.037%) among patients receiving injections by ABO certified ophthalmologists and 64 (0.050%) by non-ABO-certified ophthalmologists ($p=0.01$). Patients receiving injections by ABO-certified ophthalmologist had a 28% reduced odds of endophthalmitis (OR=0.72; 95% CI: 0.523-0.996, $P = 0.047$). Subspecialty training in retina was not associated with the rate of endophthalmitis (OR=1.00; 95% CI: 0.734-1.362 $P = 1.00$).

Conclusions: ABO board certification was associated with decreased odds of endophthalmitis after intravitreal injection. While some risk factors are not modifiable, restricting intravitreal injection to board certified ophthalmologists may reduce the risk of sight-threatening postinjection endophthalmitis.

TITLE: Effect of Alternating and In phase flicker occlusion on vergence eye movements

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Ramakrishnan, S.B. Stevenson, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bhavatharini Ramakrishnan: Commercial Relationship: Code N (No Commercial Relationship) | Scott Stevenson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Rapid alternate occlusion of the eyes has been shown to improve stereoacuity and visual acuity in some amblyopic subjects¹. Previously we looked at the effect of alternate occlusion on vergence eye movements in subjects with normal ocular health. In this current study, we want to compare the effect of alternate vs. in phase occlusion of different frequency on vergence eye movements and to see if it is the presence of flicker per se or alternate occlusion of the eyes that has an effect on vergence.

Reference:

¹ A flicker therapy for the treatment of Amblyopia, Fuensanta. A. Vera-Diaz, Bruce Moore, Eric Hussey, Gayathri Srinivasan, Catherine Johnson, Vision development and Rehabilitation, Volume 2 Issue 2, June 2016.

Methods: Vergence eye movements were measured using a dual Purkinje image eye tracker. The stimulus used for the testing was a filtered noise pattern of spatial frequency 0.25 or 2 c/deg with a bandwidth of 1 octave and variable contrast. Trials were 2 seconds long, with a near or far 1 deg disparity step at either 250 or 350 msec into the trial. Both alternating and in-phase flickers of different frequencies (2, 4, 8, 16, 32 Hz) were used. Data were collected in blocks of 240 trials (6 contrast x 5 flickers x 2 directions x 2 onset times x 2 phases) in shuffled order. Data were collected in 2 subjects and for two spatial frequencies (2 and 0.25 cycles per degree) in separate sessions. Three variables were analyzed and compared between the two phases of flickers: Latency to reach half the amplitude, Peak velocity, and the final amplitude.

Results: At higher flicker rates of 16 and 32 Hz, Vergence responses were robust, with peak velocities of 4 to 6 degrees per second and reaching the 1-degree demand within one second. At lower flicker rates, 2 and 4 Hz, and to a lesser extent at 8Hz, alternating flicker reduced vergence amplitude and increased latency dramatically while in phase flicker had only a small effect.

Conclusions: The results of this study show that vergence responses are disrupted by alternate flicker more than in phase flicker, particularly at lower frequencies. With alternate occlusion at 8 Hz, which has been used in Amblyopia treatment, vergence is intact but somewhat impaired. Results of this study will be helpful in refining Flicker glasses as a therapy for Amblyopia.

ABSTRACT BODY:

Purpose: The choroid is a vascular structure of the ocular posterior segment which serves a number of crucial metabolic and homeostatic functions. Choroidal dysfunction is implicated causally in several macular diseases, so there is considerable interest in characterizing choroidal structure in terms of specific biomarkers, using in vivo imaging. However, clinical studies have so far been based on optical coherence tomography (OCT) images corresponding to 6mm × 6mm macular scanning area. A wide-field swept-source OCT (SS-OCT) imaging system provides denser raster scans over a larger, 12mm × 12mm scanning area that includes the optic nerve. The aim of this study was to achieve automated segmentation of the choroid in wide-field SS-OCT scans. A deep learning architecture based on residual encoder-decoder modules proved efficacious for this purpose.

Methods: A retrospective dataset of 613 wide-field SS-OCT B-scans with a resolution of 12mm × 3mm (1024×1536 in pixels) taken from healthy eyes was used in this experiment. Images were captured using a wide-field SS-OCT device (Carl Zeiss Plex Elite 9000). Inspired by the ability of deep residual networks to propagate the information without loss and the success of encoder-decoder architecture in image segmentation, we adopted residual U-Net (ResUnet) for choroidal segmentation (Fig. 1). A random 70:30 data split was considered for training and testing (unseen). Ground truth annotations (masks) required for training the model were obtained by a previously validated segmentation tool and all annotations were verified by clinicians. Images were resized to 256x256. Further, the model was trained for 80 epochs, with a batch size of 8, to minimize Dice coefficient (DC) loss. The DC criterion was also used for performance evaluation.

Results: Training and Testing DC values were found to be 99.42% and 97.81%, respectively, which were desirably high. Segmentation results on representative test images, depicted in Fig.1, visually demonstrate the efficacy of the ResUnet architecture.

Conclusions: The proposed ResUnet approach demonstrated performance close to the ground truth. We next plan to extend the methodology to diseased datasets. Further, we envisage extending the 2D approach to train directly on 3D volumes.

ABSTRACT BODY:

Purpose: Mutations in the rhodopsin (RHO) gene are the most common cause of autosomal dominant Retinitis Pigmentosa (adRP), a retinal disease that results in blindness due to photoreceptor degeneration. Over 150 autosomal dominant mutations have been identified in the RHO gene. Therefore, we are developing a CRISPR-Cas9-based mutation-independent therapeutic strategy that simultaneously 'knocks out' endogenous RHO, and 'replaces' it with exogenous functional RHO using a dual AAV system.

Potent, highly specific guide RNAs and an optimized RHO expression vector have been identified and used in studies to address the following questions:

- 1.Could the novel alleles generated as a consequence of on-target editing be dominant negative?
- 2.What is the optimal ratio of the two AAV vectors?

Methods: An in vitro overexpression system was developed to quantify the effect of novel, editing-induced, alleles on cell viability. Three novel alleles were tested, one in each open-reading-frame as an indicator of potential novel alleles generated by on-target editing. The system was benchmarked using RHO-P23H as the dominant negative allele and WT RHO as the normal allele. To confirm in vitro results, and to identify the optimal ratio of the two AAVs, the dual AAV system was tested at multiple ratios in humanized RHO mice. The optimal ratio of vectors and percentage of potential novel deleterious alleles was determined by quantifying on-target editing by NGS at 6 and 13-weeks post subretinal injection.

Results: Examination of the on-target editing site in humanized mice by NGS revealed low percentage of potential deleterious allele and a consistent INDEL profile at 6 and 13-weeks post injection, demonstrating that the risk of generating novel dominant negative alleles is minimal. Different ratios of dual AAV vectors showed corresponding change in the level of RHO KO and replacement. The configuration that provides the highest level of RHO replacement and sufficient on-target editing has been identified as the 'optimal ratio' for future studies.

Conclusions: We have demonstrated minimal risk of generating novel dominant negative alleles and the feasibility of achieving therapeutically relevant levels of editing and replacement using an optimized ratio of the two AAV vectors. We are moving forward to preclinical studies for further characterization of dual AAV system in vivo.

ABSTRACT BODY:

Purpose: The usefulness of zebrafish for examining molecular mechanisms of lens development could be enhanced by producing consistent terminology for abnormal lens phenotypes. Here we characterize a variety of lens abnormalities stemming from knockout of crystallin, transcription factor and RNA-binding protein genes after CRISPR/Cas9 editing.

Methods: We used two approaches to disable individual genes with CRISPR/Cas9 editing. First, we produced two gRNAs designed to delete a region spanning a gene's promoter and first exon to prevent translation of any resulting mRNA. Second, we designed a mix of four gRNAs to produce multiple gene mutations in the coding region of a targeted gene. In each case, we co-injected one nanoliter into one-cell stage zebrafish zygotes containing a total of 500 picograms of gRNA and 250 picograms of recombinant Cas9 protein. For the first method, we raised the injected embryos to adulthood, outcrossed them to wildtype individuals, and genotyped offspring to identify null mutants, which were then used to produce lines of homozygous mutant fish. In the case of the four guide mix, we examined phenotypes directly in injected embryos.

Results: We generated zebrafish missing ~800 basepairs of the cryaa gene and confirmed by western analysis a decrease in α A-crystallin protein levels. Seventy-eight embryos from a cross of injected fish with this large cryaa deletion showed a decreased proportion of normal lenses compared to wildtype embryos at four dpf (46.2% versus 94.3%; p-value<0.0001). Lenses in these cryaa mutant embryos showed a mix of three different abnormalities (prevalence shown in parentheses): a central roughness (43.6%), disorganization of the concentric fiber cell rings (20.5%), and excessive pitting (6.4%). Mixes of four guides targeting several genes resulted in observable lens phenotypes directly in injected embryos. Targeting of both zebrafish γ N-crystallin genes (crygn1 or crygn2) produced lenses with excessive gaps between fiber cells. Similar gaps were seen after targeting the transcription factor gene prox2. A unique lens abnormality affecting the central lens was seen after targeting the ribonuclease endou2.

Conclusions: These data demonstrate that gene disruption can produce diverse phenotypes in the lens. We suggest that future studies using zebrafish as a model for lens development carefully characterize these abnormalities so that they can be compared between studies.

ABSTRACT BODY:

Purpose: Diabetic macular oedema (DMO) is the commonest cause of vision loss in patients with diabetes. As per the Royal College of ophthalmologists of the UK guidelines during the 2020 COVID-19 pandemic, in an effort to reduce injection and clinic visit frequency, and to minimize the risk of exposure of patients and healthcare staff many patients attending the eye unit had their appointments and treatment postponed. Patients with diabetic retinopathy were offered clinic review and treatment during this time but many of these patients chose not to attend their appointments because they were at high risk from the virus.

To evaluate the impact of delays in anti-VEGF treatment during the pandemic at a single university hospital clinic. Specifically, to identify the gap in treatment, and to examine the impact of this on visual acuity and anatomical outcomes.

Methods: Retrospective data collection from the electronic medical record system (medisoft ophthalmology), and OCT scans of patients with DMO. Patients were included if they have active diagnosis of DMO with Anti-VEGF treatment in the 12 weeks prior to national lockdown and restriction of services. Exclusion criteria included patients with no follow up visits.

Results: Average gap in treatment is 16.5 (range) weeks and Average reduction of the best corrected visual acuity from last recorded before treatment gap to visual acuity when patient was reviewed, or treatment restarted was -0.15. ($P > 0.05$). One patient showed progression of his diabetic retinopathy to proliferative stage.

Conclusions: Information was gathered for 328 patients (125 F, 203 M), who were treated with Anti-VEGF between 01/01/2020 & 01/09/2020

Preliminary data analysis of 134 eyes of 105 consecutive patients showed average gap in treatment of 13.2 (10-31) weeks. The average reduction of the best corrected visual acuity from last recorded before treatment gap to visual acuity when patient was reviewed, or treatment restarted was -0.05 LogMar. ($P > 0.05$) with mean VA 0.4 (range 0-1.6 LogMar) pre break and mean VA post treatment of 0.45 LogMar (range 0.06-1.6). 27/134 lost 5 letters or more of vision, 6 eyes lost 15 letters, 63 were within ± 5 letters of baseline vision.

One patient showed progression of his diabetic retinopathy to proliferative stage, and two patients showed improvement in their DMO after their treatment gap, and their Anti-VEGF treatment was stopped.

ABSTRACT BODY:

Purpose: We have recently shown that plasmacytoid dendritic cells (pDCs) play a significant role in corneal homeostasis. The current study aims to determine the efficacy and safety of local adoptive transfer of pDCs for the treatment of corneal epithelial wounds.

Methods: Splenic pDCs from 6-8-week-old wild-type (WT) C57BL/6 or DPE-GFP \times RAG1^{-/-} mice, receiving FLT3L-secreting B16 melanoma cells to enhance pDC density, were isolated by flow cytometric sorting. Central corneal epithelial debridement using a 2 mm trephine was performed on WT mice to assess the density of labelled pDCs. Epithelial debridement of central corneas was performed on PSGL-1 KO mice using a 1.5 mm trephine in order to assess the effect of pDC therapy on corneal wounds, ruling out the effect of infiltrating cells. Mice received topical fibrin sealant (sham-transfer) or 10,000 splenic pDCs. Corneal fluorescein staining was conducted 24, 48, and 72 hours after the procedure to assess wound healing. Wound areas were measured using ImageJ. Corneal wound-mounts were imaged on day 2, 5, 7, and 14 after the adoptive transfer to measure the density of transferred cells. T test was used to determine differences and $p < 0.05$ was considered significant.

Results: Adoptive transfer did not result in corneal opacity or neovascularization. Adoptively-transferred GFP⁺ pDCs were observed in the central cornea on day 2 and remained in the cornea 14 days following adoptive transfer, although in reduced numbers compared to day 2 ($p < 0.05$). We observed that one-time adoptive transfer of pDCs significantly decreased epithelial defect size by 1.7-, 3.0- and 6.1-fold, at 24, 48, and 72 hour following corneal epithelial wounding, as compared to sham-transfer ($p < 0.05$).

Conclusions: Local adoptive transfer of pDCs is a safe procedure, which significantly improves corneal wound healing.

ABSTRACT BODY:

Purpose: Failure of primary rhegmatogenous retinal detachment (RRD) repair is an unwanted clinical outcome associated with decreased final visual outcomes compared to successful primary RRD repair. The current study characterized surgical approaches and rates of recurrent RRD (re-RRD) repair.

Methods: Data was retrospectively collected from electronic health records from a large, urban retina practice with 14 physicians. Inclusion criteria were failed primary RRD repair with ≥ 2 RRD repairs from 2016 through 2020. Exclusion criteria were non-rhegmatogenous etiologies of RD, previous vitreoretinal surgery in the study eye, and proliferative diabetic retinopathy. Analyzed parameters included epidemiological data, surgical information, and post-operative outcomes. Statistical analysis was performed using Pearson's chi-squared test and one-way ANOVA analysis with Tukey's HSD to assess the relationship of surgical procedure with re-RRD rates and recurrence time. Statistical significance was defined as $P < 0.05$.

Results: 195 among 2,187 eyes undergoing primary RRD repair developed re-RRD (8.9%). Among this population, the mean number of RRD repairs performed was 2.4 ± 0.7 (range 2-5). During initial RRD repair, 9.2% of eyes received an encircling scleral buckle (SB) without pars plana vitrectomy (PPV) while 90.8% of eyes underwent PPV \pm SB. The likelihood of repair success following the second RRD repair was 72.3% while 27.7% of eyes required ≥ 3 RRD surgeries (Table 1), and the risk of subsequent RRD repair with respect to the number of pre-existing RRD repairs is summarized in Table 2. Eyes undergoing one RRD repair were less likely to undergo further procedures (8.9%) than eyes undergoing ≥ 2 RRD repairs; after the second RRD repair, the risk for further RRD repairs appeared to remain constant (20.4-27.7%) (Table 2). Moreover, repair of the presenting RRD with an encircling SB alone was associated with a lower rate of need for additional repairs than initial repair by PPV \pm SB ($P < 0.05$).

Conclusions: This study, limited by its retrospective design and inherent biases, describes the rates of re-RRD repair among all patients presenting with RRD. An association was observed between the primary surgery type and need for re-RRD repair which may be valuable for patient counseling. Additional work regarding risk factors for undergoing re-RRD repair may allow for mitigating strategies to be considered.

ABSTRACT BODY:

Purpose: Recent evidences indicate that (R)-DOI, a 5-HT_{2R} agonist, can modulate inflammatory processes and prevent allergic asthma in mice. In addition, (R)-DOI reduced complications from Herpes Simplex Virus-associated ocular disease. Given the foreseen applications in ophthalmology for a new immuno-modulatory drug class, we set out to investigate the therapeutic viability of topical eye drops (R)-DOI for ocular inflammatory diseases.

Methods: 1/ Ocular and plasma pharmacokinetics of a single topical administration of (R)-DOI 0.1% were determined using LC-MS/MS (LLOQ of 0.1ng/g) in DB rabbits.

2/ Compound 48/80 was used to induce an anaphylactic response, pruritis, and inflammation modeling allergic conjunctivitis in NZW rabbits. Animal groups were pretreated with topical (R)-DOI 0.05%, 0.01% or 0.001%.

3/ Topical (R)-DOI 0.01% was applied TID subsequent to disease induction in the antigen TB-induced recurrent intermediate uveitis model in NZW rabbits.

Results: 1/ The observed C (ng/mL-ng) values were: cornea-10900, iris-ciliary body-7810, conjunctiva-5680, choroid-1240, aqueous humor-297, retina-195, vitreous humor-3.47 and plasma-1.82. The terminal half-life ranged from 35 to 11 hrs in ocular tissues and was 1.9 in plasma. A follow up study established the ability of R-DOI to interact with melanin pigments.

2/ (R)-DOI 0.01% demonstrated the most significant inhibition of the allergic response (64% mean inhibition of total clinical score).

3/ R)-DOI treatment prevented worsening of vitreous haze (VH) in eyes presenting a mild uveitis disease at treatment initiation. Treatment improved time to resolution (VH) in moderate to severely graded eyes by 35% on the primary induction and by ~50% following re-induction. Histopathology assessments at Day 35 revealed decreased intensity of inflammatory cell infiltrates involving the choroid and retina in treated animals as well as a reduced frequency of retinal degeneration.

Conclusions: Topical ophthalmic (R)-DOI is readily absorbed into the rabbit eye and effectively reaches both anterior and posterior segments at therapeutically relevant concentrations.(R)-DOI demonstrated antiinflammatory efficacy and protection in both anterior and posterior ocular tissues against acute and chronic disease states in allergic conjunctivitis and intermediate uveitis models in rabbits.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) is characterized by inflammation and microvascular abnormalities leading to vision loss. Muller cells (MC) are a major source of cytokines whose vitreous elevation correlates with DR progression. We previously showed that, after direct stimulation of human retinal microvascular endothelial cells (hRMEC) with IL1 β , TNF α , IL8, and IL6, only TNF α and IL1 β significantly affected cytokine auto-amplification and cell adhesion molecule expression in hRMEC. Now, we explore paracrine effects of inflammatory cytokine-stimulated human MC (hMC) on NF-kB translocation, and expression of inflammatory cytokines and cell adhesion molecules in hRMEC.

Methods: Primary hMC were stimulated with IL1 β , TNF α , IL8, and IL6 vs vehicle for 2 hours and the media replaced. 6 hrs after replacement, hMC-conditioned media was collected. hRMEC were stimulated directly with 1ng/mL of IL1 β , TNF α , IL8, and IL6 vs vehicle, or with conditioned media from stimulated hMC. hRMEC were fixed after 30 min stimulation and assayed by immunocytochemistry for NF-KB P65 nuclear translocation. hRMEC were lysed 4hr after stimulation with hMC-conditioned media, mRNA isolated, and cDNA generated and subjected to qRT-PCR with IL1 β , TNF α , CXCL8/IL8, IL6, ICAM, VCAM, SELE versus TBP (housekeeping control) TaqMan probes.

Results:

NFkB nuclear translocation was observed after direct hRMEC stimulation with either TNF α or IL1 β (P<0.0001) but only after hRMEC treatment with conditioned media from IL1 β - (and not TNF α , IL8 or IL6-) stimulated hMC (P<0.0001). Likewise, only conditioned media from IL1 β -stimulated hMC significantly increased hRMEC expression of IL1 β , TNF α , CXCL8/IL8, and IL6 by 31.2, 17.9, 10.4 and 8.8 fold, respectively (P<0.0001) and of ICAM, VCAM, SELE by 8, 200, and 70 fold, respectively (P< 0.001). IL6 and IL8 stimulation did not significantly affect any outcomes measured.

Conclusions: We observed NFkB nuclear translocation and increased expression of IL1 β , TNF α , IL8/CXCL8, IL6, ICAM, VCAM, and E-SELECTIN in hRMEC only after direct TNF α and IL1 β stimulation or after stimulation with conditioned media from IL1 β -stimulated hMC. This data suggests that NFkB activation may be involved in hRMEC pro-inflammatory transcriptome alterations and that IL1 β may be a key regulator of inflammatory amplification and a valuable target for early DR therapies.

ABSTRACT BODY:

Purpose: Gene therapy is an emerging treatment modality. The cornea is an ideal tissue for gene therapy approaches owing to its easy accessibility and immune-privileged status. Earlier, we have shown that AAV5-Decorin gene therapy treats corneal haze (Invest Ophthalmol Vis Sci., 2011;52:4833-41) and retards corneal neovascularization (PLoS One 2011; 6:e26432) in established preclinical rabbit disease models. This study investigated the long-term tolerability of AAV5-Decorin gene therapy in vivo. Tolerability studies documenting safety are essential for drug development.

Methods: New Zealand White rabbits were used in three groups (naïve, naked vector, and AAV5-Decorin gene delivered) as per ARVO guidelines. Six eyes of rabbits were topically administered AAV5-Decorin gene therapy and followed for six months. Six eyes each for naïve and naked vector groups were used as controls. Eyes were periodically (3 days-6 month) examined clinically with the slit lamp, stereo-microscope, pachymetry, fluorescein eye staining, tonometry, and in vivo confocal microscopy with HRT3-RCM. Modified Hackett-McDonald scale was used to record the findings of clinical examinations. At the end of six months, rabbits were humanely euthanized and corneal tissues were collected for histological, immunofluorescence, and qPCR analyses.

Results: AAV5 decorin gene delivered eyes did not show any significant change in corneal thickness and intraocular pressures until six months when compared to that in the naïve and naked vector group ($p>0.05$). AAV5-Decorin gene delivered eyes revealed normal pupillary reflex, no conjunctival congestion, swelling, and discharge, no signs of corneal opacity, and neovascularization. HRT3-RCM biomicroscopy showed normal corneal architecture at the surface epithelium, stromal and endothelial levels in naïve and AAV5-decorin gene delivered eyes at the sixth month. Histological, immunofluorescence, and qPCR analyses are underway.

Conclusions: Topical AAV5 decorin gene therapy appears tolerable to the cornea in the long term and has potential for bench-to-bedside translation.

ABSTRACT BODY:

Purpose: Vitreous seeding is a common cause of tumor relapse and poor ocular survival in patients with intraocular retinoblastoma. Intravitreal chemotherapy (IVC) is predominantly employed as salvage treatment for persistent or recurrent vitreous seeding. The purpose of this study was to determine the feasibility of primary IVC for the treatment of intraocular retinoblastoma with vitreous seeding.

Methods: We identified patients treated on a single institution phase II clinical trial for the treatment of retinoblastoma (NCT00186888). RET CAM images of each patient were retrospectively reviewed to identify eyes amenable to IVC at diagnosis and at subsequent examinations. Event-free survival (EFS) was defined as length of time to external-beam radiotherapy (EBRT) or enucleation. A log-rank test with p-values based on marginal computation was used for statistical analysis.

Results: 27 patients (54 eyes) were reviewed. Eyes were classified as Reese-Ellsworth group I-III (n=12) and IV-V (n=42) and International Classification of Retinoblastoma group A-B (n=17) and C-E (n=37). 27 eyes (50%) were deemed eligible for IVC at diagnosis. Of these 27 eyes, 6 (22%) had vitreous seeding. Of the 27 eyes deemed not eligible for IVC at diagnosis, 1 was excluded due to diffuse vitreous seeding, 1 due to phthisis bulbi, and 25 due to extensive subretinal detachment. Of these 27 eyes, 7 (26%) had vitreous seeding. After the completion of two courses of systemic vincristine and topotecan, 21 of these 27 eyes became eligible for IVC prior to the 3rd cycle of systemic chemotherapy.

Two additional eyes were deemed eligible prior to the 6th cycle of chemotherapy. 4 eyes (7%) did not reach eligibility due to either a persistent retinal detachment (n=1) or progressive disease (n=3). The EFS rate was 100% in eyes that were eligible for injection at time of diagnosis compared to 81% of those who reached eligibility at course 3 (p=0.019) and 0% of those who became eligible at course 6 or did not reach eligibility (p<0.0001).

Conclusions: Our retrospective study suggests that IVC can be incorporated early in the treatment of intraocular retinoblastoma to mitigate risk of recalcitrant vitreous disease. 89% were eligible for IVC prior to the 3rd course of chemotherapy. As expected, clearing of vitreous seeding correlated to improved EFS.

ABSTRACT BODY:

Purpose: Recent literature has shown that retinal ganglion cell (RGC) dysfunction is reversible in early glaucoma after 3 months of topical intraocular pressure (IOP) lowering treatment, but no studies reported those effects beyond that period in pre-perimetric glaucoma (PPG). The purpose of this cross-sectional study was to evaluate the utility of Pattern Electroretinogram (PERG) for quantifying RGC functional improvement in PPG after IOP lowering treatment over a period of over a year.

Methods: Six subjects (8 eyes) underwent topical IOP lowering treatment based on their clinical examination were observed at Manhattan Ear, Eye, and Throat Hospital over an average of 16.1 months. During this time, participants underwent full ophthalmological exam and were evaluated with Diopsys NOVA PERG [Magnitude (Mag), MagnitudeD (MagD), and MagnitudeD/Magnitude ratio (MagD/Mag ratio)] at three different timepoints: pre-treatment, 4 months (4.2 ± 0.82 months) and 16 months (16.1 ± 3.0) after treatment was started. Goldman applanation tonometry was used to measure IOP at each visit. One-way repeated measures ANOVA were conducted to determine statistical significance.

Results: One-way repeated measures ANOVA was conducted to determine whether there were statistically significant differences in PERG parameters at 4 months and 16 months. Both timepoints demonstrated significantly improved MagD and MagD/Mag ratios ($F(1, 7) = 6.351$, $p = 0.04$, partial $\eta^2 = 0.476$) and ($F(1, 7) = 7.843$, $p = 0.027$, partial $\eta^2 = 0.528$). Additionally, MagD and MagD/Mag ratio showed significant increases from pretreatment at both 4 months ($47.32\% \pm 52.91\%$ and $22.46\% \pm 46.53\%$) and 16 months ($20.02\% \pm 20.72\%$ and $8.43\% \pm 21.25\%$). As expected, the IOP lowering treatments resulted in significant decreases in IOP at both 4 months ($-18.10\% \pm 12.08\%$) and 16 months ($-16.43\% \pm 8.98\%$).

Conclusions: PERG is an effective method of measuring RGC functional recovery following administration of topical IOP lowering treatments. Reduction in IOP at both the 4-month and 16-month timepoint correlated with an improvement in MagD and MagD/Mag ratio, with a more pronounced effect during early stages of treatment.

TITLE: Access to healthcare, medication and daily help for Canadians with vision loss.

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Sukhai, C. Robbins, Research, CNIB, Kingston, Ontario, CANADA|M. Sukhai, Ophthalmology, Queen's University, Kingston, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Mahadeo Sukhai: Commercial Relationship: Code N (No Commercial Relationship) | Christine Robbins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Canadian Survey on Disability (CSD) 2017 is a nationwide assessment of the lived experience of persons with disabilities, across a variety of social determinants of health. Here, we examined the impact of demographic characteristics (age, severity of vision loss, other disabilities) on access to healthcare services, prescription drugs, and help with daily living tasks for Canadians living with vision loss.

Methods: The population sample for the CSD was derived from individuals who indicated they had difficulty with activities of daily living in the 2016 Canadian Census. Respondents were 15 years of age and above, and identified with a functional limitation, and represented more than 6 million (n = 6,246,640) Canadians. A subset of the larger dataset was created with individuals with seeing disability (n = 1,519,840) and weighted descriptive analyses were performed using SPSS.

Results: Access to allied healthcare services. Respondents with vision loss were most likely to receive physiotherapy, massage or chiropractic services (27.9%), compared to 17.2% accessing psychology or social work services, 6.8% accessing support group services, 4.5% accessing nursing care at home, and 2.9% accessing occupational therapy services. Adults under 65 were more likely to access physiotherapy, massage, chiropractic, psychology or social work services; conversely, adults over 65 were more likely to access support group services or nursing care at home. 54.5% of those with sight loss did not access healthcare services.

Prescription medication. 72.8% of the Canadian vision loss population take prescription drugs at least once per week; 66% of respondents under 65 compared to 85.2% for those over 65. 13.1% of Canadians with vision loss were unable to purchase prescription medications because of cost. 13.3% of Canadians with vision loss took prescription medications less often because of cost.

Help with daily living tasks. 54.9% of respondents received help with daily activities (average of 3.5 activities). Age, age of onset and number of disabilities were positively correlated with receiving help with daily activities.

Conclusions: Age, age of onset and number of disabilities correlated significantly with access to allied healthcare services, prescription medication, and help with daily living tasks for Canadians with vision loss.

TITLE: Cultured human uveal melanocytes express/secrete CXCL1 and CXCL2 constitutively and are increased by lipopolysaccharide via activation of Toll-like receptor 4

SESSION TITLE: Cornea, cytokines, anti-inflammatory

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Hu, R. Zhang, R.B. Rosen, Ophthalmology, Icahn School of Medicine at Mount Sinai, New York, New York, UNITED STATES|W. Yang, Chung Shan Medical University, TAIWAN|S. Yang, Chung Shan Medical University, TAIWAN|

Commercial Relationships Disclosure (Abstract): Dan-Ning Hu: Commercial Relationship: Code N (No Commercial Relationship) | Ruihua Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Wei-En Yang: Commercial Relationship: Code N (No Commercial Relationship) | Richard Rosen: Commercial Relationship: Code N (No Commercial Relationship) | Shun-Fa Yang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: CXCL1 and CXCL2 are potent chemoattractants of neutrophils. Their levels are significantly increased in intraocular fluids or serum specimens from patients suffering from infectious endophthalmitis and non-granulomatous uveitis. We tested the hypothesis that lipopolysaccharide (LPS, agonist of TLR4) can stimulate the expression/secretion of CXCL1 and CXCL2 by cultured human uveal melanocytes via the activation of TLR4.

Methods: Effects of LPS on the expression of TLR4 were tested by using real time PCR, flow cytometry and fluorescence immunostaining. Effects of LPS-induced expression/secretion of CXCL1, -2 were studied by using real time PCR in cell lysates and ELISA in conditioned media of cultured uveal melanocytes. NF- κ B in nuclear extracts and phosphorylated MAPK signals were tested in cells with and without LPS treatment. Effects of various signal inhibitors on p38, ERK1/2, JNK1/2 and NF- κ B on the secretion of CXCL1 and CXCL2 were tested by using ELISA analysis.

Results: LPS stimulation increased the expression of TLR4 mRNA (3.34 ± 0.93 fold, mean \pm SD, $P < 0.05$) and protein ($36.9 \pm 4.5\%$, $P < 0.05$) in culture uveal melanocytes. LPS (100 ng/ml, 24 hr) stimulated the secretion of CXCL1 and CXCL2 proteins by 15.1 ± 2.0 fold and 7.51 ± 0.6 fold (mean \pm SD), respectively ($P < 0.05$); and increased the expression of CXCL1 and CXCL2 mRNA by 22.7 ± 3.5 fold and 15.7 ± 1.3 fold, respectively ($P < 0.05$). LPS mainly increased the activated NF- κ B (3.68 ± 0.14 fold) and phosphorylated JNK1/2 (3.43 ± 0.2 fold) (both $P < 0.05$). NF- κ B and JNK1/2 inhibitors significantly blocked LPS-induced expression of CXCL1 and CXCL2 in uveal melanocytes.

Conclusions: The present study validates our hypothesis that LPS can stimulate the expression/secretion of CXCL1 and CXCL2 by cultured human uveal melanocytes via the activation of TLR4. This result indicated that uveal melanocytes may play a role in the immune reaction to eliminate invading pathogens and also in the pathogenesis of non-granulomatous uveitis.

TITLE: Correlation of Corneal & Retinal Thickness Ratio At Annular Points Aligned to Astigmatic Axis

SESSION TITLE: Multidisciplinary imaging technologies and applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Abdel-Maseih, Rutgers The State University of New Jersey, New Brunswick, New Jersey, UNITED STATES|F. Shafik, New York Medical College, Valhalla, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jerome Abdel-Maseih: Commercial Relationship: Code N (No Commercial Relationship) | Farid Shafik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop algorithms and protocols for Ophthalmic Evaluations as they pertain to different disease states and pre-operative evaluations.

Methods: Corneal tomographic & retinal OCT thicknesses in millimeters were directly correlated along rings at 5 and 7 mm from the central axis in correspondence from the cornea and the retina along the astigmatic steep axis; N=120. The steep axis was chosen as a peak point and hypothesized as aspect of vector summation of internal forces acting in a fashion to tissue planes: anterior & posterior. Analysis and comparison by Student T-Test

Results: There appears to be a direct correlation between the corneal and retinal thicknesses as a ratio in regard to the isolated rings segments (Sup & Inf) as highlighted in the table.

Conclusions: It is believed that the forces as they relate to pressing aspects to the anterior portion of the eye, ie, the cornea carry a proportional and effecting aspect to the posterior portion of the eye, ie, the retina. Physiologically there may be other factors, but on a relative basis of comparison this holds for the given statement of proportionality and a promise for quick clinical correlates for decision making.

TITLE: Detailed phenotypic investigation of HtrA1 transgenic mice model

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Shihabuddeen, Y. Yanagi, R.Y. Chuan, V.A. Barathi, X. Wang, G.C. Cheung, Retina, Singapore Eye Research Institute, Singapore, SINGAPORE]

Commercial Relationships Disclosure (Abstract): Waseem Ahamed Shihabuddeen: Commercial Relationship: Code N (No Commercial Relationship) | Yasuo Yanagi: Commercial Relationship: Code N (No Commercial Relationship) | Richard Chuan: Commercial Relationship: Code N (No Commercial Relationship) | Veluchamy Barathi: Commercial Relationship: Code N (No Commercial Relationship) | Xiaomeng Wang: Commercial Relationship: Code N (No Commercial Relationship) | Gemmy Cheung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: High-temperature requirement 1 (HtrA1) is linked with age-related macular degeneration(AMD)/polypoidal choroidal vasculopathy (PCV). Reportedly, polypoidal lesions, choroidal neovascularization(CNV) and lipid deposition are some of the common phenotypes of HtrA1 transgenic mice model. Moreover, overexpressed HtrA1 in mice RPE cells is associated with change in Bruch membrane composition. This study aims to clarify the phenotype of HtrA1 Tg mice in detail and to investigate the underlying pathophysiological mechanism of AMD and PCV.

Methods: In-vivo imaging was performed using funduscopy and optical coherence tomography (Micron,Phoenix), fluorescein angiography (FA: Micron), indocyanine green angiography (ICGA: HRA2, Heidelberg),and optical coherence tomography angiography (OCT-A: Plex Elite, Carl Zeiss). Eyes were sectioned or flat-mounted for Hematoxylin and eosin (H&E) and Immunofluorescence staining using CD31 (endothelial marker), APOE (drusen component), F4/80 (macrophage marker) and vitronectin antibodies to investigate the neovascularization, drusen formation, and infiltration of macrophage. Laser-induced CNV model was used to evaluate the role of HtrA1 on CNV activity.

Results: We examined 60 Tg and 15 wild type aged mice (23 – 30 months). Abnormal subretinal lesions [(Tg -33% (20/60) and WT – 7% (1/15)] were detected on color fundus photography and OCT. ICGA images represent from middle to late phase hyperfluorescent nodules corresponding to the areas of white material deposition [Tg - 40% (4/10)], whereas no leakage was observed in FA. En-face OCT-A and cross-sectional OCT-A failed to confirm vascular flow signals. In addition, IHC stains showed no difference in APOE and CD31 between HtrA1 Tg and wild type mice groups which is supported by the mRNA sequencing data. From H&E stains, we confirmed that lesions are in fact RPE cell migrations. Retina and RPE flatmount demonstrated increase macrophage infiltration and activation in HtrA1 Tg mice. Laser induced CNV in young HtrA1 Tg mice(n=12 for HtrA1 and WT) showed increased leakage from CNV compared to wild type mice (P<0.05).

Conclusions: The subretinal lesions from mice have different composition compared to that of humans observed in PCV. Hence, these drusen-like deposits might be the representation of immune cells which have been migrated into the subretinal space. Such subclinical inflammation may have resulted in the increased activity of laser-induced CNV.

ABSTRACT BODY:

Purpose: Loss of retinal metabolic homeostasis can lead to the development of diabetic retinopathy (DR). Post-translational modification (PTM) of proteins by the addition of a malonyl groups to lysine residues (MalK) fine tune the activities of metabolic enzymes to match nutritional conditions. To understand how the retina adapts to over-nutrition, as in metabolic syndrome and diabetes, we examined how high fat diets (HFD) and a high sucrose diet (HSD) affects retinal MalK content.

Methods: C57BL6/J mice were divided into seven groups (n=6/group). Groups were fed continuously for 24 wk HFDs with 60% of calories coming from either lard or sunflower oil (SFO), a HSD (10% calories from fat, 35% calories from sucrose), or a standard chow diet (SD, 10% calories from fat, low sucrose) Additional groups were fed the lard-based HFD for 16 wk and then switched to one of the other three diets for the final 8 wk. An antibody that specifically binds to MalK residues was used to probe retinal sections; fluorescence microscopy and image analysis was used to quantify retinal MalK content.

Results: Feeding mice HFDs containing lard or SFO for 24 wk significantly decreased the amount of MalK PTM in retinal tissue, when compared to low fat diets with either high or low sucrose. Feeding HSD had no significant effect on retinal MalK content compared SD fed controls. The decreases in malonylation caused by HFD feeding occurred in both the ganglion cell layer and the entire retina, and ranged from 30% to 41% relative to the SD fed group. Mice fed the lard-HFD for 16 weeks and then switched to any other diet (SD, HSD, oleate-HFD) for the final 8 weeks, exhibited normal MalK PTM.

Conclusions: The studies suggest that the retina alters its protein malonylation to adapt to nutrient conditions imposed by HFDs containing either highly saturated fat (lard) or monounsaturated fat (SFO). Future studies will examine how removal of saturated fat from the diet led to normal MalK levels and determine if loss of MalK represents a beneficial adaptation or a maladaptation that could contribute to the risk of developing DR.

TITLE: Individualized finite element (FE) models demonstrate stress concentration in optic disc and peripapillary tissue caused by variations in globe and orbital size during adduction tethering.

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Park, S. Jafari, J.L. Demer, Ophthalmology, Stein Eye Institute, UCLA, Los Angeles, California, UNITED STATES|J. Park, Bioengineering, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joseph Park: Commercial Relationship: Code N (No Commercial Relationship) | Somaye Jafari: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Demer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) with normal intraocular pressure (IOP) has been proposed to be caused by repetitive stress on the optic nerve (ON) when it becomes tethered during adduction, and is more common in East Asians than Caucasians. We hypothesized that variations in globe and orbital dimensions may influence stress concentration on the globe-optic nerve (ON) junction during adduction.

Methods: Surface coil magnetic resonance imaging was employed to collect axial images of the orbits of 22 normal controls (Male: 8, Female:14, 59.2 ± 13.4 yrs) and 23 POAG patients (Male: 7, Female:16, 63.7 ± 10.4 yrs) with IOP never exceeding 21mmHg. Globe equatorial diameter, axial length (AL), and orbital length (OL) from globe center to orbital apex were measured to specify individualized mesh models of the globe and ON. FE simulations were repeated performed in each of 45 individual cases using 6° additional adduction from an initial 26° adducted configuration employing identical average human tissue material properties and boundary conditions.

Results: The ratio of OL to AL ratio in subjects with POAG was 1.46 ± 0.20 (\pm SD) was significantly less than in controls at 1.59 ± 0.20 ($P=0.005$). FE simulations showed that stresses caused by adduction tethering were mostly concentrated at the temporal globe-ON junction near the retro-lamina region and peripapillary sclera encircling the optic disc. Subjects with POAG had 44.2 ± 6.0 kPa mean stress in the entire finite element model, significantly higher at 40.7 ± 5.2 kPa than normal subjects ($P=0.022$). Mean stress on the peripapillary ring was 34.0 ± 4.9 kPa for POAG, significantly greater than 30.6 ± 4.2 kPa for normal subjects ($P=0.008$). However, the mean stress on the optic disc was similar ($P=0.4$) for both POAG (15.3 ± 1.4 kPa) and controls (15.3 ± 1.7 kPa).

Conclusions: Subjects with POAG at normal IOP tend to have shorter orbits relative to globe axial lengths than healthy subjects. These morphological characteristics are predicted to cause higher stress on the globe-ON junction when ON tethers during adduction.

ABSTRACT BODY:

Purpose: Mutations in the ABCA4 gene are responsible for recessive Stargardt (STGD1), a central blinding disease similar to AMD. STGD1 patients and Abca4^{-/-} mouse model exhibit deposition of bisretinoids in the retinal pigment epithelium (RPE) and photoreceptor degeneration. Bisretinoid-mediated complement activation was reported in cultured RPE cells and detected in the RPE of Abca4^{-/-} mice and STGD1 donor eye. Here, we used induced pluripotent stem cell (iPSC) derived RPE from a STGD1 patient to investigate the role of complement in disease pathogenesis.

Methods: STGD1 patient, with two ABCA4 mutations on different alleles: (1) c.3386G>T; p.Arg1129Leu and (2) c.[5461-10T>C;5603A>T]; p.[Thr1821Aspfs*6,Thr1821Vals*13;(Asn1868Ile)], and control (no ABCA4 mutations) fibroblasts were reprogrammed into iPSCs and differentiated to RPE cells using standard protocols. iPSC-RPE cells were grown on filters and analyzed at 3- and 12-mo by confocal and electron microscopy. Cell count and height were determined by morphometric analysis. Transepithelial resistance (TER) was measured to evaluate the RPE monolayer integrity. Immunohistochemistry was performed on the flatmount of iPSC-RPE cells with antibodies against ZO1, 4-hydroxynonenal (4HNE), complement negative regulators (CD46 and CD59), C3/C3b/iC3b, C3aR, and membrane attack complex (MAC).

Results: At 3-mo, control and STGD1 iPSC-RPE cells displayed normal morphology with silimar ZO1 staining, TER measurements, and cell count. Over time, STGD1 iPSC-RPE cells accumulated autofluorescence at ~1.2- and ~1.6-fold higher levels vs control at 3- and 12-mo respectively. 4HNE immunostaining was also enhanced in STGD1 RPE cells. While levels of C3aR and CD59 were similar, CD46 levels were reduced by half in the RPE of STGD1 vs control. In contrast, C3/C3b/iC3b and MAC levels were ~1.5-fold higher in the RPE of STGD1 vs control. At 12-mo, STGD1 RPE cells height and number were reduced by ~30% vs control. Changes in morphology correlated with ~80% reduction of TER in STGD1 vs control RPE, consistent with cell membranes disruption.

Conclusions: Using STGD1 patient iPSC-derived RPE cells, we provide evidence of complement dysregulation triggered by the buildup of autofluorescence material. Additionally, ongoing complement activation led to MAC-mediated cellular death in 12-mo cultured STGD1 iPSC-RPE cells. These findings strongly support a common inflammatory etiology of AMD and STGD1 maculopathy.

ABSTRACT BODY:

Purpose: Microvascular permeability is a fundamental property of blood vessels. The protein plasmalemma vesicle-associated protein (PLVAP) is a key structural protein in fenestrated capillaries, stomatal diaphragms in caveolae, and transendothelial channels. PLVAP assembles as heterodimers to form radial fibers in a spoke-like endothelial barrier. One theory for age-related macular degeneration (AMD) is the vascular theory in which fenestrated vessels in the choriocapillaris form ghost vessels leading to underperfusion of the overlying macula. The protein (PLVAP) is critical for the normal functioning of vascular fenestrations and plays a role in angiogenesis and vessel integrity. In this study, we measured platelet PLVAP protein content by western blot in AMD and healthy control subjects.

Methods: Whole blood was obtained from 12 AMD and 5 age-matched control subjects after IRB approval and informed consent. Platelet-rich plasma was isolated by centrifugation and lysed in lysis buffer. PLVAP protein content was analyzed under reducing conditions using standard western blot protocols and non-reducing conditions using blue-native gel electrophoresis. PLVAP was detected using a monoclonal antibody against PLVAP (Abcam, 1:1000) and a secondary polyclonal antibody (Cell Signaling, 1:1000) labeled with horseradish peroxidase using a GE ECL system and Coomassie blue staining. Relative quantification of PLVAP was performed by densitometry. Pre-advanced AMD, nascent GA, and advanced GA were defined as the presence of drusen $\geq 63 \mu\text{m}$ in width, hypofluorescent regions of macular atrophy greater than 0.015 mm^2 , and hypofluorescent regions of atrophy no greater than 0.015 mm^2 , respectively.

Results: Three PLVAP-positive bands were observed at apparent molecular weights of 70, 60, and 12 kDa. AMD subjects with both nascent and advanced GA had significantly higher levels of the 60 kDa band ($p=0.03$) and 12 kDa ($p=0.04$) compared with controls. Notably, under non-reducing conditions, subjects with GA had minimal heterodimer formation, indicating a possible defect in PLVAP assembly.

Conclusions: Platelet PLVAP expression is altered in GA under reducing and non-reducing conditions. Consequently, the function of fenestrated capillaries in the choriocapillaris in GA may be impaired, leading to defective microvascular permeability. Therefore, PLVAP may be a viable therapeutic target in GA.

ABSTRACT BODY:

Purpose: While intravitreal anti-vascular endothelial growth factor (VEGF) therapy revolutionized the treatment of diabetic macular edema (DME), there remains a proportion of afflicted eyes that do not achieve optimal visual acuity (VA) outcomes. Previous studies have shown that the amount of fluctuation in macular thickness may be associated with worse VA outcomes in multiple exudative retinal diseases. The current study assessed this relationship among patients with DME undergoing prolonged anti-VEGF therapy.

Methods: Medical records were retrospectively reviewed for patients diagnosed with treatment naïve DME between January 2016 and August 2017. Eyes were included if they had an anti-VEGF injection ≤ 31 days of initial diagnosis, a follow up period ≥ 44 weeks, and ≥ 3 central subfield thickness (CST) measurements. Fluctuations in CST were determined by standard deviation (SD) of CST measurements across visits. Statistical analysis included Chi-squared test and one-way analysis of variance (ANOVA).

Results: 242 eyes from 170 subjects were included in the current study. Mean CST at baseline and final visit was 353.1 μm (95% CI, 341.3-364.8) and 285.6 μm (95% CI, 276-296), respectively; mean SD was 46.2 μm (95% CI, 39.9-52.4). Mean number of visits was 21.8 (range, 4-67) and mean length of follow up was 149 weeks (range, 51-230.3). 41.7% of eyes received laser treatment with a mean 17.2 anti-VEGF injections (95% CI, 15.9-18.5). Eyes were stratified into quartiles based on CST SD. From the first (lowest SD) to fourth (highest SD) quartile, final VA was 0.32 (20/40 Snellen equivalent), 0.34 (20/40), 0.43 (20/50), and 0.62 (20/80) logMAR ($p=0.0004$), respectively, with a mean 13.8, 17.1, 18.4, and 19.5 anti-VEGF injections ($p=0.01$). Pairwise comparisons showed quartile 1 received significantly fewer injections and quartile 4 demonstrated significantly worse final VA compared to other quartiles ($p<0.05$). There were no significant differences between quartiles in length of follow up, number of visits, or laser treatment status ($p>0.05$).

Conclusions: The current study demonstrated increased CST fluctuations resulted in worse VA outcomes, consistent with other studies involving exudative retinal diseases. Also, decreased CST fluctuations was associated with fewer anti-VEGF injections, while length of follow up, number of visits, and laser treatment status were not similarly associated.

TITLE: Perioperative outcomes of carotid endarterectomy for retinal artery occlusion versus cerebrovascular accident

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I.G. Freedman, J.C. Wang, Ophthalmology & Visual Sciences, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Isaac Freedman: Commercial Relationship: Code N (No Commercial Relationship) | Jay Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare perioperative outcomes in patients who undergo carotid endarterectomy (CEA) for retinal artery occlusion (RAO) versus for cerebrovascular accident (CVA) in the United States and to determine comparative predictors of 30-day perioperative outcomes.

Methods: A retrospective, multicenter nationwide study of the American College of Surgeons National Surgical Quality Improvement Program database in the eight-year period 2010-2017 of all patients with a diagnosis of RAO or CVA who underwent CEA. Patients were selected based on primary international classification of diseases-9 (2010-2015) or 10 (2015 or later) codes corresponding to RAO or CVA and had a primary procedural current procedural terminology code of CEA. Ideal caliper width 1:1 propensity score (PS) matching was performed on age and sex to yield balanced cohorts. Demographic characteristics, preoperative and intraoperative variables, length of stay (LOS), and 30-day adverse events (AEs) were recorded. Nonparametric hypothesis tests and uni- and multivariate linear and logistic regressions were constructed to determine independent predictors of prolonged LOS or AE.

Results: 52 (1.9%) underwent primary CEA for RAO and 2,757 (98.1%) for CVA. After PS-matching the cohorts were balanced on age ($p=1.0$) and sex ($p=1.0$). The median age in both groups was 72.5 years (IQR: 63-78.5 years) and both were 38.5% female. RAO patients were more likely to have a history of COPD (26.8% vs. 4.0%, $p=0.015$) but there was no significant difference between the two groups in any other demographic characteristics, preoperative, or intraoperative variables. The median hospital LOS was significantly longer in the CVA group (3 [IQR 1-6] vs. 6 [3-8], $p=0.005$). The most common AEs were pulmonary, myocardial infarction, bleed, and stroke. There was no significant difference in AEs between the two groups, though subsequent stroke was more common in the CVA group (3.8% vs 1.9%). When controlling for other variables, CVA (RR 3.0, 95% CI 1.4-4.7 days, $p<0.001$) and history of COPD (RR 2.8, 0.3-5.3, $p=0.030$) significantly predicted prolonged LOS.

Conclusions: In this comparative analysis of patients who received CEA for RAO vs. CVA, CVA and history of COPD were associated with significantly prolonged LOS. As other perioperative measures were similar between the groups, the prolonged LOS in the CVA group may reflect lengthier recovery from the CVA itself.

TITLE: Early Feasibility Study for Substantial Equivalence Testing and Design Evaluation of the OcuFLOW-Composite Ocular Circulatory Analyzer (COCA) for Measuring and Monitoring Ocular Circulation to Guide Therapeutic Intervention and Prevent Glaucoma Blindness

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.M. Kirstein, Harper's Point Eye Associates, Cincinnati, Ohio, UNITED STATES|T. Kramer, R. DuBois, R. Grebe, M. Brink, OcuFLOW, Inc., Glen Arm, Maryland, UNITED STATES|R. Xian, Political Science, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|R. Xian, Annenberg School for Communication, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elliot Kirstein: Commercial Relationship: Code N (No Commercial Relationship) | Theresa Kramer: Commercial Relationship(s);OcuFLOW, Inc.:Code I (Personal Financial Interest) | Robin DuBois: Commercial Relationship(s);OcuFLOW, Inc.:Code I (Personal Financial Interest) | Rhonda Grebe: Commercial Relationship(s);OcuFLOW, Inc.:Code I (Personal Financial Interest) | Matthew Brink: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Xian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In addition to intraocular pressure (IOP), measurement of vascular risk factors is now key in the management of glaucoma. The OcuFLOW-composite ocular circulatory analyzer (COCA) is a reinvented pneumatonometer that measures IOP, pulse amplitude (PA), pulsatile ocular blood flow (POBF), ocular perfusion pressure (OPP) and an autoregulation index (AI). It is the only device that measures global choroidal blood flow, equivalent to 90% of ocular blood flow. The purpose of this study is to assess the safety of measuring IOP, pulse amplitude (PA), pulsatile ocular blood flow (POBF), and ocular perfusion pressure (OPP). A secondary purpose is completion of early feasibility clinical studies comparing the investigational OcuFLOW-COCATM (OcuFLOW) to the Goldmann applanation tonometer (GAT), the CATSTM tonometer prism (CATS), and the Dynamic Contour TonometerTM (DCT) for the measurement of IOP, devices that have prior FDA 510(k) clearance.

Methods: This study was a prospective, open-label study. Human IRB approval was completed by Sterling IRB, Inc. Eight healthy subjects underwent informed consent and review of inclusion and exclusion criteria. Brachial blood pressure was measured and recorded in the software. After instillation of topical proparacaine anesthesia, multiple ocular circulation parameters were measured in each subject, as defined by the known device applications.

Results: The OcuFLOW-COCATM was successfully able to measure the IOP, PA, POBF and calculate the OPP. The range of IOP paired differences for all four devices was between -5 and 4. The IOP paired difference range for the OcuFLOW was smallest of the four test devices at 5.2, compared to 7 (GAT), 8 (CATS), and 6.4 (DCT).

Conclusions: The OcuFLOW-COCATM was successfully able to safely and efficaciously measure the IOP, PA, POBF and OPP. For IOP measurement, the OcuFLOW is substantially equivalent to the GAT, the CATS, and the DCT, and appears to be more accurate for measuring IOP, especially. The early feasibility study design limits the data set. Further study is needed.

TITLE: Dexamethasone mediates MYOC expression in primary human trabecular meshwork cells modulated by small-molecules Wnt inhibitors

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Zhang, J.J. Zheng, Ophthalmology, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|C. Zhang, J.J. Zheng, Ophthalmology, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chi Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Jie Zheng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Steroid treatments including the use of dexamethasone (Dex) has been shown to increase the intraocular pressure (IOP) and the risk of ocular hypertension, which can cause the steroid-induced glaucoma. It has been reported that Dex treatment can lead to irregular TM structure and potentially reduce outward flow of intraocular fluid through altering Wnt signaling. To further elucidate the role of Wnt signaling in the Dex-induced glaucomatous phenotype, we studied the mRNA expression patterns across MYOC, AXIN2, and extracellular matrix (ECM) genes. Furthermore, we used novel Wnt small molecule regulators to investigate whether these modulators would affect Dex-mediated phenotype on primary human TM cells.

Methods: Primary human TM cells cultured from corneal-scleral rims were treated every day for 5-days or 7-days, with 100 nM Dex, DMSO vehicle, or Dex in combination with Wnt signaling regulators. RNA was isolated and followed by quantitative PCR analysis to measure MYOC, AXIN2, and ECM genes expression.

Results: Dex-treated TM cells showed increased levels of MYOC, AXIN2 and ECM gene expression compared to their vehicle counterparts. Combination of the Wnt inhibitors with Dex abolished the effects of Dex on the TM cells, whereas Wnt activators maintained the Dex-induced phenotype. Furthermore, Wnt modulators has distinct effects on different passages of the primary TM cells.

Conclusions: Dex-induced phenotypic changes in primary human TM cells are consistent with previously reported phenotypes contributing to ocular hypertension, therefore leading to glaucoma progression. Regulating the activity of Wnt alleviates these Dex-mediated effects indicates that Dex-induced glaucomatous TM cell activities is associated with aberrant Wnt signaling. The different effects among Wnt modulators exhibited on the TM cells suggests that proper balanced Wnt signaling is required to maintain the homeostasis of the TM tissue.

TITLE: The RAP study, Report 4: Discoloration of the macular region in patients with macular neovascularization type 3

SESSION TITLE: AMD: clinical research - biomarkers and outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Haj Najeeb, G. Deak, U. Schmidt-Erfurth, B. Gerendas, Eye Department, Medical University of Vienna, Vienna, Vienna, AUSTRIA]

Commercial Relationships Disclosure (Abstract): Bilal Haj Najeeb: Commercial Relationship: Code N (No Commercial Relationship) | Gabor Deak: Commercial Relationship: Code N (No Commercial Relationship) | Ursula Schmidt-Erfurth: Commercial Relationship: Code N (No Commercial Relationship) | Bianca S Gerendas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore the prevalence and pattern of distribution of macular hemorrhage and exudate in macular neovascularization type 3 (MNV3), previously known as retinal angiomatous proliferation, and to find out whether they can be valuable diagnostic markers for MNV3 in patients with neovascular age-related macular degeneration.

Methods: 83 eyes of 83 consecutive treatment naïve patients with stage 3 MNV3 were enrolled. The diagnosis was based on fluorescein angiography (FA) and optical coherence tomography (OCT). Sub- and intraretinal hemorrhage and dense exudates were evaluated on color fundus photography. FA images and OCT scans were used to identify the axial location of the hemorrhage. 83 patients with MNV1 and 83 with MNV2 were included as two control groups.

Results: In the MNV3 group 62 (75%) eyes had intraretinal hemorrhage and 52 (63%) had dense exudates. 73 (88%) eyes had intraretinal hemorrhage and/or dense exudates. 41 (49%) had both pathologies. The intraretinal hemorrhage was flame shaped over the lesion and punctate or semi-punctate further away from it and directed to the fovea. No subretinal hemorrhage was noticed. In the MNV1 and MNV2 groups 11 (13%) and 24 (29%) eyes had subretinal hemorrhage or dense exudates, respectively. No intraretinal hemorrhage was seen in the two control groups. The incidence of exudates and hemorrhage (irrespective of its location) was greater in MNV3 than in MNV1 or 2 ($p < 0.0001$).

Conclusions: The existence and pattern of distribution of intraretinal hemorrhage is pathognomonic of MNV3. It makes (alone or with dense exudates) the diagnose MNV3 possible using fundoscopy or color fundus photo and without further diagnostic expenditure.

TITLE: Depletion of optic nerve microglia does not improve visual function in experimental glaucoma

SESSION TITLE: Neurodegeneration and neuroprotection

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Tan, Y. Guo, M. Shrestha, M.S. Gregory-Ksander, T.C. Jakobs, Ophthalmology, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|Z. Tan, Ophthalmology, Xi'an Jiaotong University, Xi'an, Shaanxi, CHINA|

Commercial Relationships Disclosure (Abstract): Zizhu Tan: Commercial Relationship: Code N (No Commercial Relationship) | Yinjie Guo: Commercial Relationship: Code N (No Commercial Relationship) | Maleeka Shrestha: Commercial Relationship: Code N (No Commercial Relationship) | Meredith Gregory-Ksander: Commercial Relationship: Code N (No Commercial Relationship) | Tatjana Jakobs: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Microglia become reactive in response to pathological stimuli, such as an increase in IOP. It has been reported that depending on the nature and the duration of the insult activated microglia in the brain can instruct neighboring astrocytes to assume a predominantly neuroprotective or a predominantly neurotoxic phenotype (Liddelow et al, 2017). We tested whether depletion of microglia with the CSF1R inhibitor PLX5622 has an effect on the visual function or ganglion cell loss during experimental glaucoma. We also compared the gene expression profile of isolated astrocytes from microglia-depleted and control nerves over a 4-weeks course of IOP elevation.

Methods: Two groups of C57BL/6 mice were placed on microglia depletion diet (n=32) or control diet (n=26) for 3 weeks. Magnetic microbeads were injected into the anterior chamber of the right eye. Visual function was measured by pattern ERG and observation of the optomotor reflex. Retinal ganglion cells and axons were counted. In addition, a cohort of mice received either depletion or control diet and microbead injection. At 7 days, 14 days, 21 days, and 28 days after injection the optic nerve heads were dissociated and individual astrocytes from were collected under microscopic control. The gene expression profile was assayed by quantitative PCR.

Results: Treatment with PLX5622 led to complete depletion of microglia from the retina over the time course of the study. However, there was a small population of cells with microglial morphology that remained in the myelinated portion of the optic nerve even after 7 weeks total on the PLX5622 diet. IOP elevation led to a significant decrease of visual acuity (0.296 ± 0.072 versus 0.42 ± 0.017 cycles/degree in the control group, $p < 0.001$), whereas saline injection had no effect on the IOP or the visual acuity. Pattern ERG amplitude was decreased from 21.46 ± 4.9 uV at baseline to 14.33 ± 4.6 uV after microbead injection ($p < 0.001$). However, there was no significant difference between the microglia depleted and the control groups. Genes associated with the putative neuroprotective astrocyte phenotype were up-regulated under control conditions. In astrocytes from microglia-depleted nerves this up-regulation was attenuated.

Conclusions: Our preliminary results suggest that microglia depletion does not appear to be a promising strategy to improve visual function in experimental glaucoma.

TITLE: Feasibility of Ophthalmic telemedicine Consultation in Urgent Settings (FOCUS)

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Murchison, Emergency Medicine, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|J.R. Bilyk, Oculoplastic and Orbital Surgery, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ann Murchison: Commercial Relationship: Code N (No Commercial Relationship) | Jurij Bilyk: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ophthalmologist are not always available for on-site consultation in emergency departments. We performed a prospective, double-masked pilot study to determine the feasibility for an ophthalmologist to provide triage consultation virtually.

Methods: This study used a convenience sample of adult patients from an eye emergency department. Ophthalmic telemedicine consultation was provided by an ophthalmology attending physician (OAP) using a synchronous telehealth interface and in-person consultation was provided by second OAP. The remainder of the visit followed usual care. The primary outcomes were feasibility and urgency of recommended in-person ophthalmic examination. Feasibility was measured as the ability to enroll patients and transmit the necessary audiovisual information. Urgency of recommended full ophthalmic examination was collected from both the in-person and virtual ophthalmic triage providers. The secondary outcome was time to perform ophthalmic consultation. An exploratory outcome was concordance of triage-based diagnoses between the in-person and telehealth OAPs. Descriptive statistics were used for evaluation.

Results: This pilot study enrolled 31 of 33 (93.9%) patients. The majority (74.2%) were female and the median age was 57 years (range 24-86; mean 54.2). The majority of patients identified as African American (48.4%) followed by Caucasian (45.2%). There were no dropped calls or audiovisual problems reported with the telemedicine interface. The recommended urgency of in-person full examination between the in-person and telemedicine consultation was concordant 90.3% of the time. The duration range of the consultation was 1.5-6 minutes via telemedicine and 2-7 minutes in person with a mean of 2.5 and 2.7 minutes, respectively. The exploratory outcome of diagnostic concordance was 93.5%.

Conclusions: Telemedicine emergency ophthalmic consultation appear to be feasible, with good patient acceptance and ability to obtain necessary audio and visual data. The duration of the visits was similar for in person and telemedicine consultations, supporting the potential feasibility. The diagnostic concordance was high between both the telemedicine and in person ophthalmic consultation compared to the full ophthalmic evaluation. More data on this approach in general emergency room settings would be useful to aid in expediting urgent ophthalmic care and make ophthalmic consultation more widely available.

TITLE: Real-world efficacy and safety of brolucizumab

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.D. Walter, Retina Consultants, P.C., Hartford, Connecticut, UNITED STATES|S.D. Walter, N.J. Saba, Surgery, University of Connecticut School of Medicine, Farmington, Connecticut, UNITED STATES|N.J. Saba, Medicine, Eastern Connecticut Health Network, Manchester, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Scott Walter: Commercial Relationship(s);Novartis:Code C (Consultant);Genentech:Code C (Consultant);Castle Biosciences:Code C (Consultant);Spark Therapeutics:Code C (Consultant);Allergan:Code C (Consultant) | Nicholas Saba: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Brolucizumab (Beovu) is a novel anti-vascular endothelial growth factor (VEGF) drug approved for the treatment of neovascular age-related macular degeneration (NVAMD). In this post-marketing surveillance study, we evaluated the efficacy and safety of brolucizumab in our practice during the initial 7.5 months following its commercial release.

Methods: Retrospective consecutive case series of 544 patients with NVAMD who were treated with intravitreal injections (IVI) of brolucizumab in a private retina practice between 10/1/2019 and 5/15/2020. The study population included NVAMD patients who were treatment-naïve and others who were switched from an alternate anti-VEGF therapy. Visual acuity (VA) was compared before initiation of brolucizumab therapy and at the end of the study period. Anatomic outcomes were assessed with spectral-domain optical coherence tomography and included central subfield thickness (CST), macular volume (MV), presence of intraretinal fluid (IRF), presence of subretinal fluid (SRF), and presence of serous pigment epithelial detachment (sPED) on foveal line scans. The cumulative incidence of drug-related adverse effects during the study period was also reported.

Results: 544 patients received a total of 1438 brolucizumab IVIs during the study period. A statistically significant improvement in VA was observed in treatment-naïve eyes (+3.7 letters, $p=0.038$) but not in eyes switched from another anti-VEGF agent (-0.5 letters, $p=0.41$). For both groups of patients, there were significant reductions in CST (-47.8 μ m), MV (-0.40mm³), presence of IRF (-18.5%), presence of SRF (-28.6%), and presence of sPED (-7.3%; all $p<0.001$). Drug-related adverse events occurred in 26 patients (4.8%), including intraocular inflammation (25), retinal vasculitis (3), retinal artery occlusion (1), and urticarial rash (1) after an average of 2.0 IVIs.

Conclusions: Brolucizumab proved to be a potent drying agent in both treatment-naïve and previously anti-VEGF treated eyes. However, no VA improvement was observed when eyes were switched to brolucizumab from an alternate anti-VEGF agent. The incidence of brolucizumab-related inflammatory events observed in this post-marketing surveillance study corroborates a recent reanalysis of clinical trial data by the Safety Review Committee.

TITLE: Accelerated corneal cross-linking in pediatric patients with keratoconus from the northeast of Mexico: A 3-year follow-up

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.A. Rodríguez, V. Holguin, D. Loya, Ophthalmology, Instituto Tecnológico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, MEXICO]

Commercial Relationships Disclosure (Abstract): Luis Rodríguez: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Holguin: Commercial Relationship: Code N (No Commercial Relationship) | Denise Loya: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the 3 year follow-up clinical characteristics, visual and topographic outcomes of pulsed-light accelerated crosslinking (A-CXL) protocol in a northeastern Mexican pediatric population with progressive keratoconus

Methods: Retrospective case series study of pediatric patients with keratoconus in whom crosslinking was performed between January 2016 and December 2020. Inclusion criteria comprised patients aged 18 or under with progressive keratoconus treated with epi-off pulsed-light A-CXL protocol (30mW/cm² x 8 min, total energy dose of 7.2J/cm²). Medical history, BCVA, slit lamp examination, endothelial cell count (ECC), spherical equivalent (SE) and Scheimpflug corneal tomography previous and after crosslinking were analyzed. Statistical analysis was performed using the paired t-test with the STATA software

Results: A total of 28 eyes of 17 patients, 15 (88.2%) males and 2 (11.8%) females were included. Mean follow-up time was 646±411 days since the diagnosis of keratoconus. Mean Body Mass Index was 25.7± 9.5 (overweight). Allergic conjunctivitis was present in 65% of patients, and 47% of patients reported rubbing their eyes. Mean age at surgery was 13.8±2.72 years (range, 9-18). Mean BCVA was 0.64±0.59 logMAR at baseline and 0.34±0.32 logMAR at the last follow up (p=0.0019). Baseline SE was -3.88 and -4.12 at the last follow up, refractive cylinder values were -3.72 at baseline and -4.38 at the last follow up. Mean baseline K1, K2, and Km values were 47.54 D, 54.97 D, and 50.71 D, respectively; at the last time follow up these values decreased to 47.37 D (p=0.62), 54.56 D (p=0.42) and 50.65 D (p=0.58) respectively. Preoperative central and thinnest pachymetry by Pentacam were 475.48 um and 460.77 um respectively, compared to post-operative values of 470.00 um (p=0.90) and 456.63 um (p=0.80). The most common topographic pattern was inferotemporal steepening 32.1%, ECC decreased from a mean preoperative value of 2903 cells to 2886 cells (p=0.81). Two eyes developed infectious keratitis after the procedure, and 1 eye had hydrops after crosslinking

Conclusions: There seems to be an association between allergic conjunctivitis, overweight patients and keratoconus progression in these patients. A-CXL seems to be safe and effective to halt progression in this population with improvement of BCVA. Further follow up is necessary to measure long-term effects

CONTROL ID: 3547250

SUBMITTER (NAME ONLY): Ujjaldeep Jaggi

TITLE: Effect of further shifting the M2-like macrophage responses by cellular adjuvant on primary and latent HSV-1 infection

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: U. Jaggi, H. Matundan, J. Yu, H. Ghiasi, Surgery, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ujjaldeep Jaggi: Commercial Relationship: Code N (No Commercial Relationship) | Harry Matundan: Commercial Relationship: Code N (No Commercial Relationship) | Jack Yu: Commercial Relationship: Code N (No Commercial Relationship) | Homayon Ghiasi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Macrophages are one of the dominant infiltrates in the corneas of ocularly infected mice. Previously, we demonstrated that M2 macrophages have a protective effect on ocular virus, eye disease, latency, and reactivation than M1 macrophages using HSV-1 infected WT mice. To further explore the role of M1 and M2 macrophages on the HSV-1 responses, we used M2^{-/-} (GATA3 deleted) and M2-OE (GATA3 overexpressed) mice and infected them with HSV-IL4 (to further push toward M2) or HSV-IFNg (to further push toward M1).

Methods: M2^{-/-} and M2-OE mice were ocularly infected with 2×10^5 pfu/eye of HSV-1 recombinant viruses expressing IL4 or IFNg or parental control virus. Following ocular infection with each virus, primary virus replication in the eye, viral and cellular expressions in the cornea and trigeminal ganglia (TG) on various times post-infection (PI) and survival, corneal scarring (CS) and latency-reactivation on day 28 PI were determined.

Results: Primary infection in the eye was significantly reduced in HSV-IL4 infected mice on day 3 PI compared to mice infected with either HSV-IFNg or control viruses. CS was higher in HSV-IFNg infected mice compared with HSV-IL4 or control viruses. Latent infection in TG was reduced in both HSV-IL4 and HSV-IFNg groups compared with the parental virus, while the level of latency in HSV-IL4 infected mice was significantly lower than HSV-IFNg infected mice. In addition, reactivation was also lower in HSV-IL4 infected mice as compared with HSV-IFNg and control infected mice.

Conclusions: Our findings demonstrate that: 1) Both HSV-IL4 and HSV-IFNg viruses shifted macrophage polarization toward M2 and M1, respectively; and 2) HSV-IL4 was more effective in providing protection against both primary and latent infection and reactivation compared to HSV-IFNg or parental virus. Our results suggest that inclusion of cellular factor(s) as part of a vaccination regiment to coax responses of macrophages toward M2 polarization, as compared to the M1 polarization, may further improve vaccine efficacy against ocular HSV-1 replication and latency-reactivation in the ocularly infected mice.

ABSTRACT BODY:

Purpose: To describe clinical features of infectious keratitis following keratoplasty

Methods: A 17-year (2001-2018) retrospective review of clinical records. Analyzed variables included: microbiology, previous ocular surgeries and medications, history of contact lens use, ocular surface disease, and lid abnormalities. Also treatment characteristics, indications for surgery and clinical outcomes were noted. Descriptive statistics, means, and SD were used for continuous variables; percentages were used to describe categorical variables. P, 0.05 was regarded as evidence of significance. All analyses were done with STATA v.10 software.

Results: A total of 105 eyes of 105 patients were included in this study. Mean age was 52.64 years, 48% were female. Mean time to infection after PKP was 20.11 (range 0.5 - 114 months). The mean number of previous grafts was 1.24 (range 1-7). Of the 105 cases 16 patients (15.24%) had 2 or more PKPs, and 89 patients (84.76%) had just one graft. 23 patients (21.90%) had clinical signs of blepharitis and 3 (2.83%) had palpebral alterations. 13 patients (12.50%) had glaucoma drainage device and just 10 patients (9.52%) were contact lens users.

Indications for corneal transplantation were bacterial keratitis in the 20% (n = 21) and trauma in 15.23% (n = 16). The corneal graft had failed in: 52 patients (49.52%), clear graft in 37 patients (35.23%) and 14 patients (14.7%) had rejection episode at the time of infection. Of those grafts that were clear only 19 cases remained clear (51.35%). 76 patients (72.38%) had sutures at the time of the episode, and of these, 25% the infection was judged to be related to sutures. Gram positive organism were responsible for 42% of the cases, gram negatives 30% , Herpetic 20% and fungi 8%. The most common gram+ bacteria was Staphylococcus epidermidis in 17 cases (16.19%) and the most common gram- was pseudomonas aeruginosa in 11 cases (10.47%).

Conclusions: Infectious keratitis following PKP is an important cause of graft failure, specifically bacterial. Patients with PKP require close monitoring to identify risk factors for developing infectious keratitis and posterior failure of the graft.

ABSTRACT BODY:

Purpose: Infectious bacterial keratitis and infectious crystalline keratopathy (ICK) are both serious and visually threatening ocular infections. We hypothesise corneal nerves, and their derivatives, are important in the pathogenesis of both bacterial keratitis and ICK. We performed a systematic review into the role of corneal nerves during infectious bacterial keratitis and ICK to highlight areas of interest, or possible future research, for the development of new and improved treatment regimens for infectious bacterial keratitis and ICK.

Methods: A systematic literature search of the PubMed database was performed, identifying 64 articles relating to the role of corneal nerves in bacterial keratitis or ICK. Articles were screened and selected, leaving a total of 23 papers included for review.

Results: The results of our study detail the alterations of nerve structure during infection, demonstrate the influence of corneal nerves on bacterial keratitis, and suggest the consequences of the lack of nerves in ICK. Neurochemistry was shown to have a distinctive influence on inflammation, chemotaxis of inflammatory cells, and resolution of infection. In addition to this, MicroRNA and tear cytokines were associated with corneal nerves, their structural changes, and disease response. Corneal nerves and their neurochemistry also altered the corneal healing response during infection.

Conclusions: Corneal nerves are imperative in the immune response towards infectious bacterial keratitis. Corneal nerves influence and coordinate a spectrum of host responses to infection, including cytokine production, immunomodulation, and corneal healing. Therapeutic agents targeting corneal nerves and ocular neurochemistry should be studied and considered as possible treatments for the infection and recovery of infectious bacterial keratitis. More research into physiological mechanisms is also needed to improve our understanding of corneal nerves during infection.

ABSTRACT BODY:

Purpose: Coronavirus disease 2019 (COVID-19) is caused by infection with severe acute respiratory syndrome coronavirus 2 (SARS-CoV2). While the ocular surface is considered one of the major SARS-CoV2 transmission routes, SARS-CoV2 specific tropism in ocular epithelial cells is not fully understood. In the current study, we evaluated the expression of two SARS-CoV2 viral entry proteins, ACE2 and TMPRSS2, in human ocular epithelial cells. Additionally, we investigated the role of an eye-specific transcription factor PAX6 in regulating the expression of ACE2 and TMPRSS2.

Methods: Human donor corneas were obtained from the Saving Sight eye bank, Kansas City, MO. Flow cytometry was performed to detect ACE2 and TMPRSS2 in ABCB5-positive LSCs and ABCB5-negative limbal epithelial cells. RNAseq data of conjunctival swab samples were obtained from GSE135455 Gene Expression Omnibus datasets, and Spearman's rank correlation coefficients between PAX6, ACE2 and TMPRSS2 were calculated using R version 4.0.3. RNAseq analyses of PAX6 overexpressing oral mucosal epithelial cells were obtained from the DNA Data Bank of Japan Sequence Read Archive (DRA002960). PAX6 knockdown (KD) was performed in cultured immortalized conjunctival epithelial cells using five distinct siRNAs. PAX6, ACE2, and TMPRSS2 expression was analyzed by qRT-PCR and Western blotting.

Results: Flow cytometry analyses revealed enhanced expression of ACE2 and TMPRSS2 in PAX6 low-expressing ABCB5-positive LSCs compared to PAX6 high-expressing ABCB5-negative limbal epithelial cells. Intriguingly, TMPRSS2 mRNA expression negatively correlated with PAX6 in conjunctival swab samples ($R=-0.48$, $p<0.0001$). Mechanistically, PAX6 overexpression in oral mucosal epithelial cells decreased TMPRSS2 mRNA levels by 76.8%, while PAX6 KD in immortalized conjunctival epithelial cells resulted in induction of TMPRSS2 RNA and protein expression suggesting a possible functional role of PAX6 in regulating TMPRSS2.

Conclusions: High expression of ACE2 and TMPRSS2 in LSCs raises the possibility of specific COVID-19 cellular tropism to this cell population. Based on the here reported novel role of PAX6 as a negative regulator of TMPRSS2 expression, lower levels of PAX6 might contribute to the induction of TMPRSS2 in LSCs. Our study points to the importance of COVID-19 testing of donor corneas before clinical transplantation to patients with limbal stem cell deficiency.

Commercial Relationships Disclosure (Abstract): Marie Elise Torm: Commercial Relationship: Code N (No Commercial Relationship) | Christina Eckmann-Hansen: Commercial Relationship: Code N (No Commercial Relationship) | Flemming Skovby: Commercial Relationship: Code N (No Commercial Relationship) | Michael Larsen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe fundus optical imaging and vision characteristics in a patient with Niemann-Pick disease.

Methods: Retrospective chart review of the case of a young adult male who was incidentally found, in relation to a spectacle prescription consultation, to have a bilateral white perifoveolar ring in both eyes. He was subsequently found to have homozygosity for a pathogenic missense variant in SMPD1 and diagnosed with Niemann-Pick disease, a sphingomyelin lysosomal neural storage disease.

Results: Visual acuity was 1.0/1.0 in both eyes with correction for myopia -1.0/-0.25 diopters. The patient had no subjective pericentral scotoma. Intraocular pressure was 12 mmHg, and photopic microperimetry was normal in both eyes. Color fundus photography was normal except for the presence of a white ring of inner retinal hyperreflectivity encircling the foveola in both eyes. Optical coherence tomography showed a slight signal reduction of the retina behind the ring, but otherwise the retina and choroid were normal. On infrared scanning laser ophthalmoscopy, the white material was invisible and entirely transparent. The ring was also transparent on adaptive optics fundus photography in 850 nm illumination (rtx1, Imagine Eyes, Orsay, France), but when the cone photoreceptors on either side of the ring were in focus, the photoreceptors behind the ring were out of focus, and vice versa.

Conclusions: The sphingomyelin in the perifoveolar inner layers of the retina that obstructs the imaging of the deeper layers of the retina in visible light is transparent in infrared, but it shifts the focal plane of the rtx1 adaptive optics camera sufficiently to require an adjustment of its focal plane, possibly because the material increases the refractive index of the nerve fiber layer in the inner retina.

ABSTRACT BODY:

Purpose: Mutations in retinal secreted serine protease PRSS56 and transmembrane glycoprotein MFRP, a factor predominantly expressed in the retinal pigment epithelium (RPE) constitute major causes of nanophthalmos, a condition characterized by severe reduction in ocular axial length/extreme hyperopia. Interestingly, common variants of these genes have been implicated in myopia, a condition associated with ocular axial elongation. In fact, mice with loss of function mutation in PRSS56 or MFRP exhibit a reduction in ocular axial length. We found that Adamts19 expression is significantly upregulated in the retina of mice lacking either Prss56 or Mfrp. Here, we test the hypothesis that retinal Adamts19 upregulation compensates for lack of PRSS56 or MFRP in supporting ocular axial growth. Additionally, we test the requirement of Prss56 or Mfrp in supporting excessive ocular elongation caused by a null mutation in the gene coding for Interphotoreceptor retinoid-binding protein (IRBP).

Methods: We crossed Prss56 or Mfrp mutant mice with mice deficient in Adamts19 to determine the effect of Adamts19 inactivation on ocular size reduction caused by loss of Prss56 or Mfrp function. In parallel, Prss56 and Mfrp mutant mice were crossed to Irbp deficient mice. A detailed ocular biometric ocular assessment was conducted on the progeny of various genotypes using the SD-OCT.

Results: Ocular axial length and vitreous chamber depth (VCD) exhibited a significantly greater reduction in double mutants (Prss56^{-/-};Adamts19^{-/-} or Mfrp^{-/-};Adamts19^{-/-}) as compared to respective Prss56 or Mfrp single mutants. Overall, we demonstrate that while ADAMTS19 is not required for ocular growth during normal development, its inactivation exacerbates ocular axial length reduction in Prss56 and Mfrp mutant mice. Furthermore, we demonstrate that inactivation of either Prss56 or Mfrp prevented ocular axial elongation in Irbp mutant mice (Irbp^{-/-};Prss56^{-/-} and Irbp^{-/-};Mfrp^{-/-}, respectively). Thus, both PRSS56 and MFRP are necessary for supporting excessive ocular elongation due to a null mutation in Irbp.

Conclusions: We identified ADAMTS19 as a novel factor involved in ocular size regulation and demonstrate that the retinal Adamts19 upregulation is part of an adaptive response to overcome impaired ocular growth. Furthermore, our findings support a role for molecular crosstalk between the retina and RPE involved in refractive development.

ABSTRACT BODY:

Purpose: Cancer is a major public health problem in North America and many other parts of the world. Cancer care has greatly improved in the last few decades, as evidenced by a 22% decline in the overall cancer-related death rate in the United States since 1991, translating to more than 1.7 million deaths averted through 2012. Our goal is to perform complete clinical ophthalmologic exam in patients receiving treatment (radiation, chemotherapy, or combinations) in order to assess adverse ocular events.

Methods: This study was conducted at the McGill University Health Centre. Necessary approval by the hospital ethics regulatory board was obtained prior to recruitment of patients and commencement of the study. The details of the study were explained to patients prior to securing informed consent. Inclusion criteria: all patients receiving any modality of treatment for any type of cancer, with or without ocular complaints. Exclusion criteria: inability to or difficulty in visiting the eye clinic for subsequent follow-ups. A thorough ophthalmologic examination, including measure of visual acuity, slit lamp biomicroscopy, intraocular pressure measurement, dilated fundus examination, and OCT of both anterior and posterior segments were performed. Data gathered from the initial visit served as baseline for the patient's symptoms and health status of the patient's eye, as well as type of cancer and treatment modality.

Results: We analyzed data for 118 patients with cancer diagnosis. Median age was 67 years old (29-93 years old). Regarding gender, 73 (61.86%) were female and 45 (38.14%) were male. Among all patients, 51 (43.22%) had breast cancer, 29 (24.58%) had lung cancer, 21 (17.80%) had hematological cancer and 17 (14.41%) had gastrointestinal cancer. Eighty-two patients (69.49%) received chemotherapy as main treatment, whereas 36 (30.51%) received radiation therapy. We identified 69 patients (58.47%) with alterations in the ocular examination, which consisted of dry eyes in 41 patients (34.75%) and cataracts in 28 patients (23.73%).

Conclusions: Cancer treatment may lead to ocular signs and symptoms including affecting visual acuity. Early recognition of these side effects is important to minimize ocular manifestations and to improve quality of life throughout the treatment. Specific associations between ocular findings and a particular cancer treatment need yet to be determined.

ABSTRACT BODY:

Purpose: Microglia-mediated inflammation plays a significant role in neuronal and vascular damage in diabetic retinopathy (DR), but the mechanism linking inflammation, neurodegeneration, and impaired vascular integrity is still unclear. Our previous studies from diabetic mouse models exhibiting systemic inflammation showed that fractalkine (FKN), a neuronal-derived chemokine, and its microglial receptor, CX3CR1, exert neuroprotective roles in the retina. Our main goal is to elucidate the role of fibrinogen in CX3CR1-mediated inflammation during DR. We hypothesize that aberrant CX3CR1 signaling and fibrinogen-mediated microglial activation leads to inflammation and neuronal loss, followed by blood-retinal barrier damage, which can be ameliorated by reducing fibrinogen levels. We also hypothesize that DR pathology in human retinas mirrors observations from mouse models.

Methods: To analyze DR pathology hallmarks, we used a murine model of diabetes and obtained post-mortem human retinas from nondiabetic and diabetic patients. To characterize retinal pathology, microglial number and morphology, vascular damage, and fibrinogen extravasation were evaluated by immunohistochemistry. To determine effects of reducing fibrinogen in diabetic mice, the defibrinogenating agent ancrod was administered, after which retinal pathology and visual acuity were assessed.

Results: Histopathological analyses revealed increased microglial activation, vascular aberrations, and fibrinogen deposition in both diabetic patients and mouse retinas. After ancrod treatment, diabetic mice appeared to improve visual acuity, with reduced retinal inflammation and extravasated fibrinogen.

Conclusions: Our results show that pathological hallmarks observed in diabetic human retinas are corroborated in retinas from experimental diabetic models and that CX3CR1 signaling plays a key role in mediating neuroprotection in DR. Furthermore, ancrod administration to diabetic mice appears to dampen inflammation and vascular damage, with improvement in visual acuity. Together, these findings suggest that fibrinogen can be uniquely targeted as a novel therapeutic strategy for diabetic patients.

ABSTRACT BODY:

Purpose: Adaptive optics line-scan OCT offers high speed, resolution and sensitivity for imaging retinal structure and function. Here we report its implementation with reflective mirror based telescopes, optimized for improved resolution of fast light-induced retinal activity and weak retinal reflections.

Methods: Two wavelength bands from a supercontinuum light source were used for illumination - OCT (λ : 820 ± 40 nm) and line-scan ophthalmoscope (λ : 750 ± 6 nm), while a superluminescent diode (λ : 980 ± 10 nm) was used for wavefront sensing. A cylindrical lens created a linear illumination at the entrance pupil. In the sample arm, the entrance pupil was optically conjugated to a 1D galvo scanner, deformable mirror and the eye's pupil via three spherical-mirror telescopes. In the reference arm, the OCT beam was propagated via three spherical-mirror telescope relays to minimize the diffraction resulting from the 8.5 meter long travel, intended to match the sample arm optical path length. Non-planar telescope folding was followed and Zemax optimization was performed for the entire optical design, including the sample, reference and detection arms. In detection, band-pass filters separated OCT, LSO and wavefront sensing channels. An anamorphic telescope composed of two positive cylindrical lenses enabled efficient optimization of spatial and spectral resolution simultaneously in detection. The system's performance was assessed by imaging the structure of foveal cones, retinal ganglion cells and the functional response of parafoveal cones to a 660 nm flash stimulus.

Results: Over a 2.2 deg field-of-view and 3.2 D vergence range, the system's optical performance was optimized to remain under the diffraction-limit. The anamorphic configuration significantly improved signal collection efficiency and roll-off. Cones at ~ 0.2 deg from the foveal center, and retinal ganglion cells at 10 deg eccentricity were resolved in the OCT en face images. The temporal evolution of phase difference between individual cone inner/outer segment junction and outer segment tips provided a measure of light-induced activity in cones and was resolvable at ~ 0.2 deg. eccentricity from the foveal center.

Conclusions: We implemented the first reflective mirror-based line-scan OCT and demonstrated its feasibility for foveal cone optoretinography and visualizing retinal ganglion cell structure.

ABSTRACT BODY:

Purpose: It is exceedingly rare for sinonasal papillomas, which typically originate from nasal mucosa, to develop from the lacrimal sac. We performed a retrospective chart and literature review to categorize the demographic, clinical, and histopathological findings associated with this unusual pathogenesis with potential for malignant transformation.

Methods: A literature search in PubMed was performed to include all articles published in English between 1980 and June 2020. A series of 12 case reports of lacrimal sac papillomas were identified for review. The authors contribute 3 novel cases, including one illustrative case of a contiguous papilloma arising from the lacrimal sac and protruding through both upper and lower lacrimal puncta (Figure 1). We also review 5 patients with primary malignancies of the lacrimal sac in the setting of papilloma, including 1 novel case. (Table 1)

Results: All patients with benign lacrimal sac papillomas presented with epiphora (86%), swelling (76%), or both (71%). Their ages ranged from 24 to 73 with a median of 45. Seven (47%) were male, and eight (53%) were female, including one transgender woman.

Diagnosis was made with histologic analysis in all cases. The majority of papillomas were of the inverted subtype (60%), with three cases of exophytic (20%) papillomas. Three patients (20%) also presented with features of both. Treatment was with surgical excision in all cases, almost always via dacryocystorhinostomy (DCR, 92%) though additional surgery was required in 46% of cases.

All five cases of malignant transformation were inverted subtype. A majority (60%) were squamous cell carcinomas. Patients' ages ranged from 35 to 58 with four males and one female. All patients underwent DCR, and three required concurrent maxillectomy or ethmoidectomy for adequate removal. Radiotherapy and exenteration were further utilized in two cases of recurrence.

Conclusions: We present 15 cases of lacrimal sac papillomas and 5 cases of malignancy, including 4 of our own. These tumors may masquerade as chronic dacryocystitis. Inverted subtype papillomas are at greatest risk of malignant transformation. Surgeons and pathologists should be aware of this rare entity, and consideration should be given towards routine histopathologic examination of DCR specimens. Recurrence is rare but can be devastating, and prognosis following excision is generally good.

TITLE: Keratoconus-like Changes After Descemet Membrane Endothelial Keratoplasty in Patients with Fuchs' Dystrophy

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Tapley, A. Bauer, M. Straiko, M.A. Terry, Legacy Devers Eye Institute at Legacy Good Samaritan Medical Center, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jeffrey Tapley: Commercial Relationship: Code N (No Commercial Relationship) | Alex Bauer: Commercial Relationship: Code N (No Commercial Relationship) | Michael Straiko: Commercial Relationship: Code N (No Commercial Relationship) | Mark Terry: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Descemet membrane endothelial keratoplasty (DMEK) rapidly deturgescence a cornea that is edematous due to endothelial dysfunction. In some cases, the central cornea deturgescence reveals localized posterior corneal steepening similar to that of keratoconus. Our aim was to describe changes in corneal thickness and identify the incidence of posterior corneal changes characteristic of keratoconus after DMEK surgery.

Methods: A retrospective chart review was conducted for 50 eyes that received cataract surgery and 50 eyes that received DMEK for Fuchs' Dystrophy. 6 month and 1 year follow-up images were reviewed for the DMEK group using an Oculus Pentacam. The central corneal thickness (CCT) of the preoperative cataract surgery eyes served as normal controls and was compared to the CCT of the postoperative DMEK eyes at 6 months and 1 year. Pentacam images in the DMEK group were also reviewed for characteristics resembling keratoconus. Statistical significance comparing CCT was determined using the Student's T-test.

Results: The normal CCT from 50 eyes at our center was $543\mu\text{m} \pm 35\mu\text{m}$. The 6 month postoperative CCT in the DMEK group was $534\mu\text{m} \pm 35\mu\text{m}$ ($P=0.23$) and the 1 year CCT was $536\mu\text{m} \pm 35\mu\text{m}$ ($P=0.33$). 19 out of 50 DMEK eyes (38%) had posterior steepening resembling keratoconus at the 6 month visit. A subgroup analysis of the preoperative CCT from those 19 eyes vs 31 eyes without keratoconus-like changes was not statistically different ($611\mu\text{m} \pm 51\mu\text{m}$ vs $615\mu\text{m} \pm 56\mu\text{m}$, $P=0.80$). All 19 of those eyes had the same posterior corneal changes at the 1 year visit.

Conclusions: CCT after DMEK was not statistically different compared to normal corneas at 6 months and 1 year postoperative. The posterior corneal steepening seen in 38% of DMEK corneas may be a consequence of stromal keratocyte apoptosis due to chronic edema. The localized steepening persists out to 1 year postoperative, suggesting that there may be structural loss in the stroma.

TITLE: Tyrosinase Immobilized to Ni-NTA Magnetic Beads Shows Improved Protein Thermostability

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Varghese, M. Abu-Asab, E. Dimitriadis, M.B. Dolinska, G. Morcos, Y.V. Sergeev, Biochemistry, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Paul Varghese: Commercial Relationship: Code N (No Commercial Relationship) | Mones Abu-Asab: Commercial Relationship: Code N (No Commercial Relationship) | Emilios Dimitriadis: Commercial Relationship: Code N (No Commercial Relationship) | Monika Dolinska: Commercial Relationship: Code N (No Commercial Relationship) | George Morcos: Commercial Relationship: Code N (No Commercial Relationship) | Yuri Sergeev: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Tyrosinase (Tyr) initiates the melanogenesis pathway by producing dopachrome (DC). The isolation of DC is essential to having a quantitative characterization of Tyr function with regard to mutations linked to oculocutaneous albinism 1 (OCA1). Previously we offered a method of DC isolation to allow current research to obtain this quantitative analysis by immobilizing Tyr to magnetic beads (Tyr-MB). Here we show increased thermostability of Tyr bound to Ni-NTA magnetic beads (MB) and have characterized and performed experiments on Tyr-MB to further our understanding of the role of wildtype and OCA1-related mutant Tyr within the melanogenesis pathway.

Methods: Whole T. ni larvae expressing recombinant truncated human Tyr (residues 19-469) was purified using Immobilized Metal Affinity and Size Exclusion Chromatography. 100 μ L of MB were incubated with Tyr for 30 minutes at room temperature to allow Tyr to bind. L-DOPA substrate (12, 6, 3, 1.5, 0.75, 0.38, 0.19, or 0.09 mM) was then incubated (1:1) with Tyr-MB complexes for 30 min. at different temperatures (25, 31, 37, 43, or 50 $^{\circ}$ C) to produce DC. After isolating DC with a magnetic separator, Tyr activity for DC formation was tracked by colorimetric activity (475 nm). Bare MB and Tyr-MB were imaged and analyzed using Atomic Force Microscopy (AFM) and Transmission Electron Microscopy (TEM).

Results: A dose-dependent hill plot ($R^2 = 0.99$) using different L-DOPA concentrations confirmed similar behavior between Tyr-MB and native Tyr (positive cooperativity; hill coefficient: 1.65 and 1.71 respectively; L-DOPA concentration that produces 50% of maximal DC production: 3.18 and 3.01 mM respectively.) A temperature dependence curve revealed a direct correlation ($R^2 = 0.97$) of Tyr-MB DC production with temperature. Under 50 $^{\circ}$ C, Tyr-MB remained functional and produced significantly more orange-brown DC than native Tyr (clear solution) as the MB increased Tyr thermostability. AFM and TEM showed the "texture and roughness" of bare MB and Tyr-MB and the relative diameter of Tyr-MB (168.2 ± 24.4 nm).

Conclusions: The analysis suggests using MB for DC isolation to obtain a quantitative characterization of Tyr function is an efficient approach as it increases the thermostability of Tyr. This approach will further illuminate the role of OCA1 mutant Tyr with regard to melanogenesis and open doors for treating albinism-related disorders.

AUTHORS/INSTITUTIONS: C.E. Douglas, E. Roztocil, C. Hammond, M. Gonzalez, S.E. Feldon, C. Woeller, Ophthalmology, University of Rochester Medical Center, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Christina Douglas: Commercial Relationship: Code N (No Commercial Relationship) | Elisa Roztocil: Commercial Relationship: Code N (No Commercial Relationship) | Christine Hammond: Commercial Relationship: Code N (No Commercial Relationship) | Mithra Gonzalez: Commercial Relationship: Code N (No Commercial Relationship) | Steven Feldon: Commercial Relationship: Code N (No Commercial Relationship) | Collynn Woeller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Thyroid Eye Disease (TED), also referred to as Graves' orbitopathy, is a disfiguring and sight threatening autoimmune disease that involves inflammation and remodeling of the orbit. TED can present with mostly orbital fat (Type 1), connective tissue (Type 2) or a combination of both. Patients with thyroid autoimmune diseases are at risk for developing TED; however, only 50-60% of Graves' disease patients will also show symptoms of TED. Currently, it is unclear why certain patients develop TED and whether the disease will manifest into either Type 1 or Type 2 phenotypes. New biomarkers may help identify patients who are at risk for TED. MicroRNAs (miRNAs) are a class of small, non-coding RNAs that play a role in the development of autoimmune diseases and are readily detectable in blood samples making them ideal candidate biomarkers.

Methods: Blood samples from control, non-TED patients and patients with Type 1 or Type 2 disease were collected in heparinized tubes and processed. Small RNAs, including miRNAs, were isolated from 0.25 mL of plasma. MiRNA samples were treated with heparinase and cDNA was generated. The levels of specific miRNAs were measured using TaqMan based real-time quantitative PCR. MiRNA expression was normalized using NormFinder software and then compared between non-TED and TED patients (both Type 1 and Type 2).

Results: The expression of several miRNAs including: miR-155-5p, miR-146a-5a, miR-130a-3p, miR-130b-3p were readily detected in control and TED patient plasma. Several of the miRNAs identified have been reported to be differentially expressed in TED orbital tissue compared to non-TED orbital tissue. MiR-130a, which was recently found to contribute to Type 1 disease phenotype, was upregulated in TED patient plasma.

Conclusions: MiRNAs associated with TED are readily detected in patient plasma samples. The expression of miR-130a is elevated in TED patient samples and may be indicative of Type 1 disease. The identification of novel miRNA biomarkers could be important for patients at risk for TED, and could lead to additional strategies that may mitigate disease before severe symptoms appear.

ABSTRACT BODY:

Purpose: Reactive dicarbonyls, glyoxal (GO) and methylglyoxal (MGO), react with proteins and nucleotides, eventually leading to the formation of advanced glycation end products (AGEs). AGEs are associated with aging-related diseases, including age-related macular degeneration and cataracts. We recently identified GATD3A as a novel mitochondrial specific deglycase, with similar activity to the Parkinsonism associated deglycase DJ-1/Park7. Notably, loss of DJ-1 results in retinal associated phenotypes. This project aimed to validate GATD3A's biochemical activity and elucidate its necessity for retinal function.

Methods: Subcellular fractionation was utilized to determine organelle compartmentalization. Enzyme activity assays using recombinant GATD3A were used to confirm deglycation of amino species. A novel CRISPR-mediated Gat3da knockout mouse was generated, and complete loss of mature protein was confirmed via retinal and heart immunoblot. Retinal function was assessed via scotopic and photopic ERG. Histological and electron microscopy imaging were used to examine both retinal and heart structure. Using mouse embryonic fibroblasts (MEFs) from the Gatd3a knockout mice, mitochondrial biogenesis was quantified with qPCR and mitochondrial morphology was examined using confocal image-based morphometric analysis.

Results: GATD3A has glyoxalase activity primarily against GO and localized to the mitochondrial matrix. Gatd3a knockout resulted in disrupted mitochondrial dynamics in the heart and MEFs, with mitochondria displaying more rounded morphology and electron lucent cristae. Gatd3a knockout mice displayed a 3-4-fold increase in dicarbonyl and AGE immunoreactivity in the heart. Knockout mice exhibited left ventricular heart fibrosis. Surprisingly, 4-month-old and 18-month-old retinas did not display any reduced functionality in either scotopic or photopic ERG. The retina did not display changes in morphology or levels of fibrosis.

Conclusions: GATD3A exhibits glyoxalase activity which functions in the prevention of AGE accumulation and fibrosis in the heart. However, Gatd3a knockout displayed no detectable changes in the retina under normal physiological conditions. Future directions include stress induction via provision of a high-glycemic diet in order to increase the prevalence of AGEs and exacerbate previously identified phenotypes in Gatd3a knockout mice. We will further quantify AGE species using LC-MS/MS based methods.

ABSTRACT BODY:

Purpose: A large proportion of the world's population harbors latent herpes simplex virus type 1 (HSV-1). Crosstalk between antiviral CD8⁺ T cells and HSV-1 appear to control latency/reactivation cycles.

Methods: In the present study, we compared the transcriptome, phenotype, and function of memory CD8⁺ T cells, sharing the same HLA-A*0201-restricted HSV-1 epitope-specificities freshly isolated from peripheral blood and trigeminal ganglia (TG) of HSV-1 infected ASYMP and SYMP patients and HLA transgenic (Tg) mice, respectively.

Results: We report that HSV-specific CD8⁺ T cells from SYMP patients are phenotypically and functionally exhausted, highly co-expressing LAG-3 with three others inhibitory receptors while being defective in expression of functional markers. Moreover, the blocking of LAG-3 and PD-1 synergistically restored anti-viral CD8⁺ T cell responses, reduced HSV-1 reactivation from latently-infected TG, and reduced UV-B induced recurrent ocular herpetic infection and disease in latently-infected HLA-A*0201 transgenic mice.

Conclusions: These findings confirm antiviral CD8⁺ T cell exhaustion during symptomatic herpes infection and pave the way to targeting immune checkpoints to combat recurrent ocular herpes.

ABSTRACT BODY:

Purpose: Central Retinal Artery Occlusions (CRAOs) are occlusions of the central retinal artery, which often presents clinically as sudden, painless loss of vision in one eye. The central retinal artery is the primary blood supply to the inner retinal layers of the macula, and therefore CRAOs result in irreversible loss of vision in the affected eyes. Currently, there is no established treatment that can alter the course progression of the disease other than to prevent subsequent neovascularization. The purpose of this study is to use the imaging instrument Laser Speckle Flowgraphy (LSFG), a relatively novel diagnostic tool to help quantify the degree of loss of blood flow in CRAO patients, using the metric relative blood flow (RBF). RBF allows for a unitless ratio comparison of blood flow from the patients' healthy eye to the affected eye and establish the degree of ischemia.

Methods: Three separate LSFG scans were performed on seven patients with clinical history of CRAOs and twenty control patients to measure the mean blur rate (MBR) in the optic nerve head (ONH) of both healthy and affected eyes. MBR is a measurement of laser scatter directly correlated with the flow of red blood cells through tissue and vasculature. RBF, a unitless ratio of respective MBRs was then calculated to measure the average loss of blood flow through the ONH due to the CRAO.

Results: A Welch two sample t-test was used to calculate statistical significance, resulting in indicating strong significant difference in RBF between healthy control patients and CRAO patients. In control patient's RBF was calculated to be 1.021332 ($p = 0.6843$) indicating no significant difference in RBF between healthy eyes. In CRAO patients, RBF was calculated to be 0.503304 ± 0.1433871 ($p = 1.06 \times 10^{-5}$), indicating on average a 50 percent loss in blood flow to the ONH in eyes with CRAOs.

Conclusions: These results support our current understanding of the pathophysiology of CRAOs, and provides researchers and clinicians with a diagnostic tool capable of truly quantifying loss of blood flow. RBF measurements of CRAO patients confirm a dramatic loss in blood flow in affected eyes due to occlusive injury. Prospective studies could utilize LSFG measurements to longitudinally analyze blood flow in affected eyes throughout disease progression and determine the possibility of a correlation between the return of blood flow and a return of visual acuity.

ABSTRACT BODY:

Purpose: Vogt-Koyanagi-Harada (VKH) disease is bilateral and granulomatous uveitis. At the acute phase, the VKH-patients often suffer from decrease in the visual acuity (VA), and metamorphopsia because of serous retinal detachment (SRD), undulations of the retinal pigment epithelium (RPE), or choroidal fold at the fovea. Systemic steroid therapy for the inflammation is often effective, however, it is problematic that the inflammation can be recurrent generally when the dose of the steroid agent is reduced. Optical coherence tomography (OCT) is clinically useful for diagnosing and quantitatively evaluating the chorioretinal pathologies, however, there have been no valid OCT markers for predicting the recurrence. In this study, we focused to examine the OCT-reflectivity of the RPE at the acute phase, and the association with the future recurrence of the VKH-disease.

Methods: We included 40 eyes (both eyes of 9 men and 11 women) with treatment naïve acute VKH-disease whom we can observe for more than 12 months. We excluded patients with uveitis other than VKH disease, and patients who had received steroid therapy for other pathologies. Using OCT B scans at the fovea, we measured the RPE-reflectivity by calculating the ratio of the difference in the reflectivities between the RPE and the vitreous body to that in the reflectivities between the retinal nerve fibers and the vitreous body. We defined the recurrence as the reappearance of inflammations in the anterior segment, or those in the posterior segment including SRD, undulation of the RPE, and thickening of the choroid on OCT during the observational period.

Results: During the mean observational period of 37.2 months, 22 eyes of the 11 patients (55 %) had the recurrence. Logistic analysis using factors of age, retinal and thicknesses at the fovea, and RPE-reflectivity showed that the only RPE reflectivity was significantly associated with the recurrence (adjusted odds ratio: 40.560, 95% confidence interval: 1.20-1372.40, $p = 0.039$). Compared to eyes without the recurrence, the logMAR VA was poorer (0.08 ± 0.17 vs. 0.63 ± 0.70 , $p = 0.002$), and the RPE reflectivity was greater at the initial visit in eyes with the recurrence (1.25 ± 0.19 vs. 1.54 ± 0.43 , $p = 0.010$).

Conclusions: In addition to the initial poor VA, the greater RPE-reflectivity on OCT may be a prognostic marker for the future recurrence of the VKH-disease.

TITLE: Treatment Decentration in Small Incision Lenticule Extraction (SMILE)

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Asroui, W.J. Dupps, J. Randleman, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lara Asroui: Commercial Relationship: Code N (No Commercial Relationship) | William Dupps: Commercial Relationship: Code N (No Commercial Relationship) | James Randleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the percentage of visually significant decentered treatments in SMILE, and the impact of treatment decentration on patient-reported visual outcomes.

Methods: A retrospective evaluation of 31 eyes that underwent SMILE over the past year was conducted. Treatment decentration was determined on both pachymetry difference maps and Scheimpflug anterior tangential curvature difference maps, derived from preoperative and 3-month postoperative maps. Decentration was determined as the vector magnitude from the center of the visual axis, or center of the respective difference map, to the center of treatment. The center of treatment was determined by means of superimposing a schematic of concentric circles with a grid at the center, on the difference maps. The schematic was overlaid such that the treatment zone was best-fit into one of the circles. The center of the grid was taken as the center of treatment.

Results: Average treatment decentration in all eyes was 0.45 ± 0.24 mm based on the pachymetry difference maps, and 0.36 ± 0.16 mm based on the anterior tangential curvature difference maps ($p=0.005$). 22 (70.97%) eyes demonstrated good patient-reported visual outcome, while 9 (29.03%) eyes had suboptimal results, some of which requiring an enhancement surgery. Based on the pachymetry maps, average decentration was 0.45 ± 0.25 mm in the group with good visual outcome, and 0.46 ± 0.21 mm in the group with suboptimal visual outcome ($p=0.8$). Based on the anterior tangential curvature maps, average decentration was 0.32 ± 0.16 mm in the group with good visual outcome, and 0.43 ± 0.14 mm in the group with suboptimal visual outcome ($p=0.09$).

Conclusions: The magnitude of treatment decentration in SMILE differs depending on whether decentration is determined using pachymetry maps or anterior tangential curvature maps. The magnitude of decentration, as determined by use of either anterior tangential curvature maps or pachymetry maps, does not differ between eyes with good patient-reported visual outcomes and those with suboptimal outcomes.

ABSTRACT BODY:

Purpose: Age related macular degeneration (AMD) is the leading cause of vision loss in developed countries. Propranolol is a commonly used, nonspecific β_1/β_2 adrenergic receptor antagonist (BARA) that has been shown to have a neuroprotective effect on various mouse retinal injury models. We hypothesize that systemic propranolol will exhibit a protective effect against retinal degeneration in the mouse model and has potential to protect from vision loss related to AMD in the future.

Methods: BALB/c albino mice were divided into 2 groups: vehicle-treated mice and propranolol treated. Light injury mice were exposed to 8,000 lux-cool, white, fluorescent light for 2 hours to induce light injury. Vehicle (4% v/v citrate buffer in normal saline) or propranolol (20 mg/kg/dose freshly prepared in normal saline solution before injection, stock solution at 50mg/ml in citrate buffer) was injected subcutaneously following light injury for 4 days. Scotopic electroretinography (ERG) was recorded before light injury and 5 days following light injury.

Results: Following retinal light injury, ERG a- and b-wave amplitudes were significantly reduced in the control mice. Propranolol treatment significantly attenuated light-induced loss of retinal function as compared to control treated mice. Before treatment, scotopic ERG a- and b-wave amplitudes were an average of 347.9 μ V and 616.4 μ V, respectively, in the control group and 368.6 μ V and 618.9 μ V, respectively, in the propranolol treatment group. Following retinal light injury, ERG a-wave amplitudes were 71.75 μ V in the control group and 161.2 μ V in the propranolol treatment group ($p < 0.01$). Following retinal light injury, ERG b-wave amplitudes were 142.4 μ V in the control group and 360.2 μ V in the propranolol treatment group ($p < 0.01$).

Conclusions: Propranolol treatment of mice demonstrated a substantial effect on preserving ERG a- and b-wave amplitudes following retinal light injury as compared to a control group. These initial findings suggest that propranolol may represent a novel therapy for retinal degenerative conditions.

ABSTRACT BODY:

Purpose: Vitamin D has an important role in immune systems. Association of hypovitaminosis D and non-infectious inflammatory ocular diseases have been showed previously but this association was not studied in inflammatory infectious ocular diseases and area with high sun exposure. Our aim is to determine whether there is any association between vitamin D levels and infectious and non-infectious ocular diseases in Florida.

Methods: In this retrospective study, 1468 patients (28.9% male) and 490 controls (27% male) were recruited. Cases were diagnosed by an ophthalmologist with infectious (endophthalmitis, cellulitis, keratitis, infectious uveitis) and non-infectious ocular inflammation (uveitis and scleritis) after exclusion of neoplastic causes. Controls had no history of eye inflammation. They had recorded 25 hydroxy (OH) vitamin D levels. Clinical and demographic data were collected from patients 's record. Logistic regression models were created to examine the association between ocular inflammation and hypovitaminosis D using Stata (college Station, TX). Age, gender, race, smoking, and history of systemic diseases were included in multivariate model.

Results: Vitamin D levels means and standard deviations were 33 ± 12.7 and 28 ± 13.9 nanograms per milliliter in controls and cases. The odds of having infectious and non-infectious ocular inflammation was 2.2 higher in patients with hypovitaminosis D compared to normal vitamin D level [(odds ratio (OR) =2.2, 95% Confidence Interval (CI) = 1.76-2.67, $P= 1.8 \times 10^{-13}$). The association remained significant in multivariate regression, after adjusting for age, gender, race and smoking (OR =2.7, 95%, CI = 2.19-3.44, $P= 8.17 \times 10^{-19}$). The odds of developing infectious and non-infectious inflammation was 3% lower for every unit increase in vitamin D level (OR =0.97, 95%, CI = 0.97-0.98, $P= 6.35 \times 10^{-9}$).

Conclusions: Low vitamin D is associated with increased risk of infectious and non-infectious ocular inflammation in a large population in Florida in a retrospective study.

ABSTRACT BODY:

Purpose: To evaluate the impact of PCR sampling on diagnosis and treatment of infectious uveitides at a large tertiary care facility

Methods: This is a retrospective chart review of patients with at least one PCR sample performed from 2014-2019 at New York Eye and Ear Infirmary of Mount Sinai. At least one follow up visit following results of PCR testing was required for inclusion. If a patient had multiple PCR samples taken, only the first sample was included. The samples were divided into three categories based on pre-PCR diagnosis: those where pre-sampling diagnosis was presumed not infectious (group 1), those where pre-sampling diagnosis was presumed infectious (group 2) and those where pre-sampling diagnosis was concerning for infection but still unknown (group 3).

Results: 108 cases were available for analysis in the study. 25 of the 108 samples yielded a positive PCR result (23%). Majority of patients fell into group 3 where diagnosis was unknown (56%). Presumed infectious and noninfectious cases made up 22% of the population each. Table 1 summarizes treatment and diagnostic changes made in response to PCR sampling results. A chi square analysis was performed. The results of PCR testing had a more significant impact on diagnosis in those cases where pre-sampling diagnosis was unknown versus those where it was presumed infectious or presumed noninfectious (77% vs. 21%; 77% vs. 13%, $p<0.0001$). In cases where the presumed diagnosis was infectious, the rate of diagnosis change was similar to those where the diagnosis was presumed noninfectious (21% vs. 13%, $p>0.05$). Similarly, treatment changes were made based on PCR results more frequently in cases where the diagnosis was unknown compared to when an infectious entity is presumed (38% vs. 25%, $p<0.0001$). There were no cases where treatment was changed in relation to PCR when a noninfectious entity was the pre-sampling diagnosis.

Conclusions: In our experience, PCR sampling is undertaken in various clinical scenarios, including when an infectious entity is not suspected, when an infectious entity is suspected, and when diagnosis is unknown. As expected, it has the greatest impact on diagnosis and treatment when the clinical diagnosis is unknown. When PCR sampling is confirmatory in nature, it has a minimal impact on diagnosis and treatment, especially when compared to unknown cases.

ABSTRACT BODY:

Purpose: Coronavirus disease (COVID-19) has escalated to a global pandemic with increasing reports of ophthalmic disease. We report ophthalmic observations of hospitalized COVID-19 patients and correlate retinal disease findings with clinical and laboratory data.

Methods: Retrospective review of COVID-19 patients who underwent ophthalmic exam during hospitalization within Emory Healthcare between April-July 2020.

Results: Thirty-seven patients were examined with 23 (62%) females and a mean age of 54 years. 35 patients were admitted to the ICU. Ophthalmic manifestations included conjunctival injection in 12 eyes (17%), chemosis in 8 (11%) and retinopathy in 20 eyes (27%) with bilateral retinopathy in 6 patients (16%). No difference in baseline comorbidities or COVID-19 complication development was observed between patients with and without retinopathy. However, patients with retinopathy required ICU care for 1 week longer than those without retinopathy (27.6 vs 19.9 days $p=0.19$). The mean sequential organ failure assessment score at ICU admission was 6.18. All patients with retinopathy required both mechanical ventilation and vasopressors, while in patients without retinopathy, 15 (65%) and 12 (52%) required mechanical ventilation and vasopressors respectively ($p=0.015$, $p=0.002$). 6 patients with retinopathy required extracorporeal membrane oxygenation compared to 1 without retinopathy ($p=0.0070$). While the mean peak D-Dimer was elevated at 18477, in the entire cohort, the peak D-Dimer was higher in patients with retinopathy (28,971 vs 12,575, $p=0.0298$). The fibrinogen nadir during hospitalization was on average 338 for the entire cohort, and reduced in patients with retinopathy (262 vs 381, $p=0.029$). Peak D-dimer analyses with a threshold of 16,508 showed an odds ratio of 16.7 (95% CI 3.11-89.3) for retinopathy. Fibrinogen nadir with a threshold of 367 showed odds ratio of 0.06 (95% CI 0.01-0.53) with 0.75 concordance.

Conclusions: Retinopathy was the most common ophthalmic manifestation in a critically ill COVID-19 population, exceeding 25% of patients. Elevated D-dimers and a lower fibrinogen nadir in patients with retinopathy suggest a pathogenic relationship between coagulation pathways and retinal microangiopathy.

ABSTRACT BODY:

Purpose: We have recently reported that deamidations associated with cataracts increase aggregation. The purpose of this study was to quantify the disulfides in wild type and deamidated gammaS-crystallin upon oxidation and correlate levels to aggregation.

Methods: Wild type gammaS and deamidated gammaS (N14D, N76D, N143D) crystallins were reduced and then rapidly exchanged into phosphate buffer containing amounts of GSH:GSSH ranging from 5 mM:0 mM to 0 mM:2.5 mM. This approximated the loss of both reduced and total glutathione in normal vs cataractous lenses and mimicked the oxidative environment found during cataract formation. Proteins were then incubated for 2-24 hours at 37 or 60 degrees C before whole mass measurement using an Orbitrap Fusion mass spectrometer (Thermo Scientific). The overall numbers of disulfide bonds and glutathione adducts were determined and correlated to changes in aggregation. Aggregation was measured by dynamic light scattering using a DynaPro NanoStar Reader (Wyatt Tech. Co.).

Results: We identified an increase in non-native disulfide bonds in oxidized, deamidated gammaS-crystallin. The intermolecular C24-C24 crosslink was increased in deamidated gammaS during oxidation in vitro, as was the C144-C114 crosslink. After 2 h incubation at 1:1 ratio of GSH:GSSH, the deamidated gammaS had increased radii of the main monomer peak and increased aggregates at radii > 10 nm compared to wild type. The monomer peak was 3.2 nm compared to 2.5 nm of the wild type and the higher radii species contributed 3% of the mass compared to none detected in the wild type. The overall shape of the light scattering autocorrelation curves suggested multimodal distribution for both proteins, but the curves were distinctly different with the curve for the deamidated gammaS not reaching baseline as fast suggesting larger species.

Conclusions: Our findings support that deamidation predisposes crystallins to further modifications that then lead to higher-ordered oligomers and eventually large light scattering aggregates associated with cataracts.

ABSTRACT BODY:

Purpose: X-linked retinitis pigmentosa (XLRP) is an inherited retinal disease (IRD) characterized by night blindness beginning in adolescence, and progressive loss of peripheral vision that eventually leads to central vision loss. Gene therapy approaches for treating XLRP have explored the use of recombinant adeno-associated viral (rAAV) vectors to deliver a normal copy of the mutated gene responsible for retina cell loss. This is an initial report from an ongoing, Phase 1/2, open label, dose escalation clinical trial using an rAAV2 viral vector to deliver a functioning gene copy of

retinitis pigmentosa GTPase regulator (RPGR) via subretinal injection.

Methods: Male participants (n=29), age ≥ 6 , received subretinal injection of AGTC-501 (rAAV2tYF-GRK1-RPGR) into the central or peripheral macula region of the study eye. Participants were sequentially assigned to one of five dose groups to assess safety (primary outcome) and changes in visual function (secondary outcome), measured by MAIA microperimetry and best-corrected visual acuity (BCVA) as assessed by ETDRS. Patient data was analyzed 6 months post-treatment.

Results: Subretinal administration of AGTC-501 was well-tolerated across a wide dose range. The majority of adverse events were mild-moderate in severity, consistent with the subretinal injection and vitrectomy procedures, and/or concomitant prophylactic steroid regimen used to mitigate inflammation. Among the 21 centrally dosed participants, 18 had evaluable microperimetry data of which there were 8 responders, classified as a ≥ 7 decibel improvement in at least 5 loci within the central 36 loci macular area ($p \leq 0.05$). Eleven of the 20 participants with evaluable BCVA data demonstrated improvement of ≥ 5 letters in the treated eyes compared to the fellow eyes ($p = 0.001$). Among peripherally treated patients, BCVA remained stable.

Conclusions: Robust safety and efficacy signals in the study eyes of participants who underwent subretinal administration of AGTC-501 were observed through month 6. There was clinically meaningful improvement in macular sensitivity and statistically significant improvement in BCVA for the study eyes vs. untreated fellow eyes. Follow-up is ongoing through 5 years to assess long-term safety and durability of response.

TITLE: Ocular Symptoms in COVID-19 infection: A Survey Study

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Kodati, M. McHarg, Y. Wang, M. Yakin, H. Sen, National Eye Institute, Bethesda, Maryland, UNITED STATES|S. Caplash, University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Shilpa Kodati: Commercial Relationship: Code N (No Commercial Relationship) | Matt McHarg: Commercial Relationship: Code N (No Commercial Relationship) | Yujuan Wang: Commercial Relationship: Code N (No Commercial Relationship) | Sonny Caplash: Commercial Relationship: Code N (No Commercial Relationship) | Mehmet Yakin: Commercial Relationship: Code N (No Commercial Relationship) | H Nida Sen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular findings have been reported in association with the novel severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Despite these reports, less is known on the frequency, spectrum and duration of associated ocular symptoms and their onset in the disease course. The purpose of this study is to systematically characterize ocular symptoms in participants with COVID-19 infection.

Methods: An online Research Electronic Data Capture (REDCap) survey designed to characterize ocular symptoms was developed and the study information distributed to NIH employees who had tested positive for SARS-CoV-19. The survey was also advertised to the public through social media and patient recruitment mailing lists. All responses were anonymous, and participants were asked to consent to completing the survey, confirm a positive SARS-CoV PCR test and that they were 18 years of age or older. This study was approved as exempt by the National Institutes of Health (NIH) Office of IRB Operations.

Results: Following exclusion of ineligible participants and incomplete responses, 181 (20.4% male and 79.0% female) complete survey responses were included for analysis including from hospitalized (9.9%) and non-hospitalized (90.1%) respondents as well NIH employees (27.1%). Ocular symptoms were reported by 77.9% of participants (mean number of ocular symptoms per participant: 2.19+/- 2.36). The most commonly reported ocular symptoms were light sensitivity 28.1%, itchy eyes (26.0%), tearing (25.4%), eye redness (24.9%), mucous discharge (20.1%), foreign body sensation (17.1%), and new onset floaters (15.4%). With the exception of itchy eyes, no significant differences in eye symptoms were found between age groups. The onset of ocular symptoms occurred mostly frequently at the same time as systemic symptoms (53.8%) compared to before (18.9%) and after systemic symptoms (27.3%). Notably, 10.6% of respondents with ocular symptoms sought medical attention by an eye care professional and 21.2% reported eye symptoms lasting ≥ 14 days.

Conclusions: Our results show that the majority of survey respondents experienced ocular symptoms though only a minority required ophthalmic examination and our study is likely biased towards respondents with eye symptoms. Consistent with other reports, ocular surface related symptoms were more common and vision affecting symptoms were rare. Further work is needed to identify the sequelae of ocular symptoms associated with SARS-COV-2.

ABSTRACT BODY:

Purpose: Drusen size is a hallmark of AMD progression to geographic atrophy (GA) or choroidal neovascularization (CNV) leading to loss of vision. Drusen formation accompanies retinal pigment epithelium atrophy and is a risk factor for disease progression. Although the cause remains unclear, drusen size predicts the likelihood of progression to advanced AMD. In this study, we evaluated the effect of oral curcumin, an inhibitor of the innate immune receptor TLR4, on drusen size and disease progression over the course of one year in a cohort of pre-advanced AMD subjects.

Methods: Participants with pre-advanced AMD (n=18) were recruited from the office of Zaporackas and Knepper, Ltd. in Chicago, IL after IRB approval and informed consent. Pre-advanced AMD was defined as the presence drusen ≥ 63 μm in width without GA or CNV. Participants were provided oral curcumin at a dose of 2660 mg/day and imaged using ocular coherence tomography (OCT) at baseline and every 3 months for 1 year. The primary outcome was macular drusen volume. As an internal control, drusen size was measured up to 6 months prior to beginning oral administration of curcumin. Drusen volume was measured manually using ImageJ software. Macular regions were defined using the 1, 3, and 6 mm grid. The cohort was classified as responder or non-responder using an arbitrary cutoff of $\pm 10\%$ change.

Results: After one year, total macular drusen volume decreased from 0.0204 to 0.0184 mm^3 (-9.8%, $P=0.009$), foveal drusen volume decreased from 0.0092 to 0.0079 mm^3 (-13.9%, $P=0.03$), parafoveal volume decreased from 0.0086 to 0.0078 mm^3 (-9.1%, $P=0.10$), and perifoveal volume increased (30.9%, $P=0.08$). In the 6 months prior to beginning the study, the growth rate of total macular drusen volume was 0.0035 mm^3/year , consistent with natural history studies in the literature (Folgar, 2016) and significantly higher than the rate after beginning curcumin of -0.0020 mm^3/year ($P=0.002$). The percent of responders and non-responders was 56% and 19%, respectively, which was significantly different from the expected percentages of 12% and 48%, respectively, found in the literature ($P=0.0005$; Yehoshua, 2011). Importantly, no subjects developed GA or CNV after 1 year.

Conclusions: These preliminary results, though limited, may demonstrate the efficacy of RQC in slowing the growth of drusen in AMD – a finding that would be very promising as it may reduce the risk of disease progression.

ABSTRACT BODY:

Purpose:

Junctional epidermolysis bullosa laryngo-onycho-cutaneous (JEB-LOC) is an overlap multisystem disorder characterised by extensive granulation tissue formation in the dermis, submucosa, larynx, and eyes. Ocular complications in JEB-LOC remain devastating and recalcitrant to many available treatment modalities.

Methods: We report the results of an interventional clinical study on the novel use of oral thalidomide and doxycycline in a case of an 18-year-old male JEB-LOC. Ocular and cutaneous tissue samples were collected pre- and post-treatment and underwent histopathological and immunofluorescence analysis.

Results:

Ocular involvement was observed to begin in this male at 15 months of age with eyelid ulcerations and granulation tissue formation in the conjunctiva bilaterally. By 13 years of age, this had progressed to recurrent, painful corneal erosions with associated cicatrising conjunctivitis leading to symblepharon, epiphora, severe photophobia, and visual loss (Right: 1/60, Left: 2/36). This occurred despite multidisciplinary management with numerous ocular surgical excisions and maximal medical therapy of antibiotics, anti-inflammatory medications, ocular lubricants, and steroids. He was commenced on thalidomide (50mg/day) and doxycycline (100mg/day) at 15 years of age. Within 3 months, he experienced significant improvement of his photophobia, epiphora, and pain. There was also significant improvement of his vision (Right: 6/12, Left: 6/18), accelerated physical growth, and no new cutaneous lesions formed. However, wary of long-term safety, treatment was ceased temporarily which resulted in a resurgence of symptoms. This was controlled by reintroduction of the therapy every second day, which was well tolerated and monitored by nerve conduction studies. Immunofluorescent and histopathological analysis demonstrated significant decrease in inflammatory marker (tumour necrosis factor) and laminin V expression in both ocular and cutaneous tissues after treatment initiation.

Conclusions:

Oral thalidomide and doxycycline therapy may have potential in managing the cutaneous and ocular complications of JEB-LOC. Its use may be warranted in patients with other forms of epidermolysis bullosa refractory to treatment.

ABSTRACT BODY:

Purpose: Inter-individual variations in the optical properties of the sclera and ciliary body may be a factor in the variability of treatment outcomes of transscleral and transpupillary laser therapies, such as cyclophotocoagulation. The goal of this study is to quantify inter-individual variations of the attenuation of the sclera and ciliary muscle with OCT.

Methods: The sclera and ciliary body of the left eye of 41 healthy subjects (age range: 16 to 60 years) were imaged using a commercial spectral domain OCT system following an IRB-approved protocol ($\lambda_c = 1325$ nm, Telesto I, Thorlabs, NJ). Rectangular regions of interest (ROI) consisting of 100 A-lines (width = 0.35 mm) were identified in the sclera from the episcleral - sclera to the sclera - ciliary muscle boundary (depth: 0.43 ± 0.06 mm) and in the ciliary muscle from the sclera - ciliary muscle boundary to the muscle inner boundary (depth: 0.29 ± 0.07 mm). The attenuation coefficient (AC) along each A-line of the ROI was calculated from an exponential fit of the axial intensity profile (Fig 1). A-lines with ACs that were outside 2 standard deviations from the mean were discarded. This step was repeated and the truncated mean and standard deviation of the AC within the ROI, with outliers removed was calculated.

Results: The ACs of the sclera and ciliary muscle ranged from 1.38 to 4.55 mm^{-1} and 1.88 to 5.00 mm^{-1} (mean: $3.26 \pm 0.95 \text{ mm}^{-1}$ and $3.74 \pm 0.76 \text{ mm}^{-1}$), respectively (Fig 2).

Conclusions: There is a large inter-individual variation of the scleral and ciliary muscle attenuation which produces significant variations in the energy reaching the ciliary body. The results suggest that a personalized laser treatment that takes into account scleral attenuation might improve treatment outcomes across individuals.

TITLE: Longitudinal Retinal Blood Flow Changes Associated with Unilateral Central Retinal Vein Occlusions

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.A. Lemire, N. Hazra, R. Koch, B. Seto, K. Yamada, J.G. Arroyo, Ophthalmology, Beth Israel Deaconess Medical Center, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Colin Lemire: Commercial Relationship: Code N (No Commercial Relationship) | Nina Hazra: Commercial Relationship: Code N (No Commercial Relationship) | Rachelle Koch: Commercial Relationship: Code N (No Commercial Relationship) | Brendan Seto: Commercial Relationship: Code N (No Commercial Relationship) | Keiko Yamada: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Arroyo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal blood flow is reduced in patients with vascular occlusions and can be quantified by comparing blood flow between the affected eye and the fellow eye. In this prospective study, we describe short- and long-term changes in retinal blood flow in patients with unilateral central retinal vein occlusions (CRVOs).

Methods: The eyes of patients with acute, less than 1 month old ($n = 8$), and chronic, greater than 2 years old ($n = 18$), unilateral CRVOs were imaged using laser-speckle flowgraphy at the optic nerve head. For each patient, the relative blood flow (RBF) was calculated by dividing the mean blur rate of the occluded eye by the mean blur rate of the unaffected fellow eye. Patients with follow-up measurements ($n = 11$) were used to compare the change in RBF within 6 months in acute and chronic CRVOs. Additionally, the RBF in CRVO patients was compared to control subjects without any ocular disease ($n = 18$). RBF measurements were also compared to visual acuity and central macular thickness obtained at the time of measurement as well as to the number of injections each patient required after measurement. Data was analyzed using the Wilcoxon Rank Sum Test.

Results: Eyes with acute CRVO showed a reduction in relative blood flow of 33% (SE: 15%, $p < 0.001$), compared to 27% (SE: 11%, $p < 0.001$) in eyes with chronic CRVO. There was a significant difference in the average 6-month change in RBF between acute and chronic CRVOs, with acute eyes increasing by 9.7% and chronic eyes decreasing by 1.2% (SE: 5%, $p < 0.01$).

Conclusions: CRVOs can cause a marked reduction in blood flow that persists for years. Eyes with acute CRVOs are more likely than chronic CRVOs to experience increased perfusion over time, which may be correlated with improved functional and anatomical outcomes. These results also highlight the need for animal models of CRVOs to consider the long-term complications that can arise from chronic reductions in retinal blood flow.

ABSTRACT BODY:

Purpose: To report long term outcomes of corneal wavefront guided PRK followed by same day accelerated crosslinking in keratoconus patients.

Methods: Retrospective review of clinical records. Grade I and II keratoconus (Amsler-Krumeich classification) with evidence of clinical progression were included. In all cases, corneal wavefront guided PRK (Sirius corneal tomographer and Amaris 750 Hz Schwind) combined with accelerated. corneal crosslinking 0.1% riboflavin (Vibex RapidTM) for 10 minutes.UVA pulsed radiation (365 nm) for 8 minutes at 30mW/cm2 with an interval of one second (Avedro). Measured variables included UCVA, CDVA, Sphere, Cylinder, pachymetry, and spherical aberration, coma, trefoil and MTF and RMS. Follow-up was performed at 1 day, 1 week, month 1, 3, 6, 12, 48 and 72. Results are presented using waring standard graphs and statistical analysis with STATA v.12.

Results: 30 eyes of 16 patients were treated. Mean age was 29.53. Mean follow-up 32 ± 9.7 months (range 9-44) Mean central ablation was 37.63 microns. Preoperative values and postoperative values at the last follow-up were: LogMAR UDVA $0.86 \pm .34$ vs $0.18 \pm .19$; LogMAR CDVA 0.5 ± 0.8 vs 0.04 ± 0.08 ; sphere (D) 1.09 ± 1.45 vs 0.25 ± 0.8 ; Cylinder -2.76 ± 1.45 vs 1.5 ± 1.1 ; MRSE -2.46 ± 1.17 vs 1.19 ± 1.4 ; corneal thinnest point(μ) 501.7 ± 25.95 vs 459 ± 31.4 ; K1 42.9 ± 1.15 vs 41.74 ± 1.30 ; K2 45.95 ± 1.19 vs 43.9 ± 2.2 ; WFE RMS (μ) 2.01 ± 0.1 vs 1.44 ± 0.8 ;HOA(μ) 0.64 ± 0.4 vs 0.54 ± 0.2 ; Spherical Aberration(μ) 0.09 ± 0.6 vs 0.9 ± 0.1 ; Trefoil 0.4 ± 0.3 vs 0.33 ± 0.2 and Coma (μ) 0.33 ± 0.26 vs 0.27 ± 0.18 . All comparisons of pre and post op values were statistically significant with $p < 0.05$ with the exception of CDVA $p 0.68$, Spherical aberration 0.9, and Coma 0.31. Only 1 eye (3.3%) lost 2 lines of CDVA and 16 eyes (53%) gained at least 1 line of CVDVA. Refraction remained stable over the followup period. Complications: 6 eyes had irregular conreal surface that resolved in the first month and mild corneal haze (Grade I) was observed in all eyes and resolved spontaneously by 3 months.

Conclusions: Combination of photorefractive keratectomy and corneal cross linking is a safe and effective treatment that produces corneal and refractive changes that remain stable 3 years after the procedure. No signs of progression were observed in patients keratoconus grade I and II.,

ABSTRACT BODY:

Purpose: Clinical and basic studies implicate the retinal pigment epithelium (RPE) as the primary site of two related central blinding maculopathies such as AMD and Stargardt disease (STGD1). Links of epigenetics to aging have been proposed but a specific epigenetic-mediated mechanism responsible for the RPE cellular death is yet to be identified. Preliminary data suggest a role of Methyl-CpG-binding protein 2 (MeCP2), an epigenetic factor, in mitochondria dynamics of aged and diseased RPE cells. Using *Abca4*^{-/-} mice and human STGD1 iPSC-derived RPE cells, we correlated the MeCP2 protein profile and mitochondrial functions. We employed proteomics analysis to identify MeCP2-regulated molecular targets responsible for age-dependent mitochondrial changes.

Methods: 1-, 3-, and 6-mo old background-matched wild-type (WT) and *Abca4*^{-/-} mice and human normal and STGD1 iPSC-derived RPE cells homogenates were used to measure the levels of MeCP2 by quantitative immunoblotting (normalized to beta-actin; n=3). By LC-MS proteomics analysis, we determined oxidative phosphorylation (OXPHOS) and glycolysis proteins using 4 mouse RPE sheets (n=3). Mouse and human primary RPE cultures (n=4) were used to evaluate mitochondria functions by Seahorse respirometry. Statistical analysis was done using t-test or One-way ANOVA.

Results: By immunoblotting, we found a ~2- and ~4-fold increased MeCP2 level in 3-mo- and in 6-mo-old respectively when compared to 1-mo-old *Abca4*^{-/-} RPE cells. Importantly, RPE cell homogenate from 6-mo-old *Abca4*^{-/-} mice showed ~2-fold higher MeCP2 level vs age-matched WT mice. Analysis of human iPSC-derived RPE grown for 2-mo in culture indicated increased MeCP2 level in STGD1 vs normal cells. Proteomics analysis revealed significantly (p<0.05 to p<0.001) reduced levels of the OXPHOS complexes (I, II, III, and V) and elevated levels of the glycolysis proteins. Consistently, Seahorse respirometry analysis indicated increased glycolytic activity in *Abca4*^{-/-} vs WT RPE cells.

Conclusions: Our data evidenced an age-dependent MeCP2 protein changes that correlated with altered mitochondrial functions in the RPE cells of the STGD1 models. These studies inform on a specific regulatory role of MeCP2 and its targeted molecular players in the RPE cells that are involved in disease progression. Importantly, modulation of MeCP2 in the RPE cells may potentially rescue the mitochondria deficiency to mitigate RPE functions and prevent blindness.

ABSTRACT BODY:

Purpose: Purpose: Glaucoma patients experience irreversible vision loss that affects activities of daily living including reading, driving and mobility. Published literature has shown that a quarter of glaucoma providers follow the American Academy of Ophthalmology practice guidelines of referring patients to low vision service when visual acuity in the better seeing eye drops to 20/40 or worse. Data on referral rates and completion of low vision services in this patient group is lacking. A retrospective chart review in a tertiary care center was completed to identify the number of low vision referrals from the glaucoma service and the number of those patients who attended their low vision exams.

Methods: Methods: A retrospective record review of patients seen in the glaucoma service of an academic medical center from 7/2 - 7/18/18 was conducted. Patients with visual acuity of 20/40 or worse in the better eye were identified. The following data were gathered: age, gender, visual acuities of both eyes, completed low vision exams, documented discussion of low vision services, how long the patient had 20/40 or worse in the better eye prior to receiving services and referral source (OD vs MD). Descriptive statistics were used.

Results: Results: 509 charts were reviewed, 29 patients with 20/40 or worse in the better eye were identified. Mean age was 78 [16.9] years of age, with a range of 24-96 years of age. Male/female distribution was 13/16 (45% male and 55% female). Average visual acuity in the better seeing eye was 0.639logmar, in the worse eye 0.929logmar. Low vision consultation was completed for 15/29 (52%) patients, all of which had documentation of low vision service discussion and referrals. Of the patients who did not receive low vision services 14/29 (48%) only two had documented discussions about low vision care. 11/15 (73%) of the patients who received low vision services, had vision worse than 20/40 for > 2 years before being seen by a low vision specialist. Of the 15 completed examinations, 6 were referred by ophthalmologists and 9 were referred by optometrists.

Conclusions: Conclusion: 52% of low vision patients seen by glaucoma providers were referred and received low vision care. This is higher than referral rates reported in the literature, in addition to self-reported rates by glaucoma providers. However, the majority of low vision patients had their vision loss for > 2 years before seeing a low vision specialist

ABSTRACT BODY:

Purpose: The recession of the ellipsoid zone (EZ) and more generally the thinning of the outer zone have become potential structural surrogates for disease severity in retinitis pigmentosa (RP). During a Phase 2b trial conducted to evaluate the intravitreal injection of allogeneic hRPC for treatment of RP, spectral-domain optical coherence tomography (SD-OCT) baseline characteristics of subjects were explored to identify predictors of efficacy in a more responsive target population.

Methods: In a post hoc analysis, a target subgroup of patients with less measurement variability was identified (n=37). From this subgroup, readable SD-OCT volumetric data (n=29; sham, n=10, low dose, n=9, high dose, n=10) was analyzed. Frame by frame macular cube scans were processed using automated segmentation followed by EZ mapping with manual correction for segmentation errors by masked graders. A three-dimensional volume map of the EZ-RPE for the entire macular cube generated measures of mean foveal thickness within the subfield or mid-subfield, mean central foveal thickness (CFT), EZ-RPE subfield or mid-subfield volume and thickness (with or without fluid). Correlational analysis was performed between each OCT parameter and change in each of the phase 2b trial endpoints from baseline to 12 months (Best Corrected Visual Acuity, Contrast Sensitivity, Kinetic Visual Fields, Low Luminance Mobility Test, and a VFQ).

Results: Two parameters from the OCT analysis demonstrated moderate to strong correlations in all trial endpoints in the high dose (single injection of 6×10^6 cells) target group with most relationships being statistically significant despite the small sample size. The parameters were mean CFT ($p < 0.05$ for BCVA, VF, CS, LLMT, VFQ) and mid-subfield mean EZ thickness ($p < 0.05$ for VF, CS, VFQ) with greater values in each parameter corresponding to greater improvement in endpoints. The low dose (3×10^6 cells) did not demonstrate a significant relationship.

Conclusions: Given the small number of subjects in the target population subset and the post hoc nature of the analyses, these results should be viewed cautiously. However, we believe that having a certain minimum EZ or mean CFT thickness will facilitate selection of a population with the greatest chance for response in a phase 3 study from the neutrophic effects of hRPCs

TITLE: Longitudinal Changes of Macular Vessel Density in Preclinical Diabetic Retinopathy: An Optical Coherence Tomography Angiography (OCTA) Study

SESSION TITLE: Imaging of posterior segment II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Sun, F. Tang, Z. Tang, D. Yang, D. Ng, C. Cheung, Ophthalmology and Visual Sciences, The Chinese University of Hong Kong, Hong Kong, HONG KONG

Commercial Relationships Disclosure (Abstract): Zihan Sun: Commercial Relationship: Code N (No Commercial Relationship) | Fangyao Tang: Commercial Relationship: Code N (No Commercial Relationship) | Ziqi Tang: Commercial Relationship: Code N (No Commercial Relationship) | Dawei Yang: Commercial Relationship: Code N (No Commercial Relationship) | Danny S. Ng: Commercial Relationship: Code N (No Commercial Relationship) | Carol Y. Cheung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To prospectively characterize the longitudinal changes of macular vessel density (VD) imaged by optical coherence tomography angiography (OCTA) in diabetic subjects without clinically detectable retinopathy.

Methods: We recruited diabetic subjects without diabetic retinopathy (DR) from an ongoing prospective, observational study conducted at a tertiary center in Hong Kong. DR progression was defined as a 2-step increase in severity level according to the modified Airlie House classification system. All subjects underwent OCTA with a swept-source OCT platform (DRI-OCT Triton, Topcon, Inc, Tokyo, Japan) with a 3mm*3mm volumetric scan centered at the macula. OCTA images of the superficial capillary plexus (SCP) and deep capillary plexus (DCP) were generated by IMAGENet6. After image quality control, we calculated VD by using a customized MATLAB program. In statistical analysis, we used the linear mixed-effect model to estimate the rates of VD changes over time in the SCP and DCP with adjustment of confounding factors.

Results: Over a median follow-up duration of 2.97 years, 16 eyes showed DR progression. After excluding these eyes with DR progression, a total 180 eyes of 111 subjects were included in the final analysis. In the longitudinal analysis, VD of the DCP significantly decreased ($P<0.0001$) over time after adjusting for age, duration of diabetes, axial length, mean arterial blood pressure, intraocular pressure, HbA1c, and image quality score. On the contrary, there was no detectable VD reduction in the SCP ($P=0.3$). The estimated rate of VD reduction at the DCP was $-0.41\%/year$ (standard error: 0.09; $P<0.0001$).

Conclusions: Macular vessel density of the DCP progressively decreased over time among eyes without DR, whereas that of the SCP did not show significant change. This longitudinal study adds to current cross-sectional evidence and suggests that OCTA can detect microvascular changes before clinically detectable signs occur, and hence may challenge the existing paradigms of disease monitoring of DR.

ABSTRACT BODY:

Purpose: Adaptive optics has enabled in vivo imaging of the living human retina with diffraction limited spatial resolution and thereby can image the retinal structure at the cellular level. However, adaptive optics may not readily be available for all imaging modalities, and in some cases its performance may be compromised by incomplete compensation of ocular wave aberrations. We investigate a deep learning based method to enhance the spatial resolution of retinal images without or with adaptive optics.

Methods: Twelve high resolution retinal images were obtained using an adaptive optics near-confocal ophthalmoscope (AONCO) as the ground truth. To model the image blur induced by ocular optical defects, we introduced various wave aberrations (with varying Zernike coefficients up to the 7th order). To expand the dataset, the AONCO images were split into small patches (2820 patches/image on average). With 8 different blurring kernels applied, there were 270,736 image patches in total for training and testing. In application of the trained networks, the corrected patches were combined to form images of their original sizes.

The artificial neural network was based on a U-net architecture. We performed a 4-fold cross validation study with a quarter of the images reserved for testing per cross validation.

The normalized mean squared error (NMSE) and structural similarity index measure (SSIM) were calculated for the images before and after correcting for the blurring effects, using the ground truth images as the reference.

Results: After correction with the neural networks, the NMSE was reduced by 36% on average, from 0.063 ± 0.026 to 0.040 ± 0.013 . The SSIM was improved by 89% on average, from 0.22 ± 0.10 to 0.40 ± 0.14 . The improvements were significant (by paired t-tests, $p < 0.001$ for both the NMSE and the SSIM). Image examples are shown in Figures 1 and 2.

Conclusions: Our preliminary results showed that deep learning may be useful in correcting the retinal image blur caused by ocular wave aberrations. Further optimization with larger datasets and more types of blurring effects are underway to improve its performance and the generalizability of the network.

ABSTRACT BODY:

Purpose: A progressive chorioretinopathy is associated with Long-chain 3-Hydroxyacyl-CoA Dehydrogenase Deficiency (LCHADD). The pathophysiology of LCHADD retinopathy is incompletely understood. We have established a cell model of LCHADD to explore disease mechanisms.

Methods: Four LCHADD fibroblast lines (HADHA c.1528G>C) were reprogrammed into iPSCs. Two wild type iPSC lines were purchased as controls. iPSCs were differentiated into RPE and assayed for several RPE markers, transepithelial electrical resistance (TEER), and ability to phagocytose labeled outer segments. RPE were fed palmitate (C16) and FAO was measured with the Seahorse bioanalyzer. Acylcarnitines were measured with tandem mass spectrometry. Beta-hydroxybutyrate (BOH) was assayed from transwells. Neutral lipids were detected using LipidTOX and triglycerides were measured. RPE were treated with H₂O₂ and C16, viability monitored by alamarBlue.

Results: All RPE lines showed similar expression of RPE markers. Wild type and LCHADD RPE were able to phagocytose outer segments. TEER in wild type ($288 \pm 13 \Omega/\text{cm}^2$) and LCHADD ($277 \pm 14 \Omega/\text{cm}^2$) RPE was similar. The basal oxygen consumption rate (OCR) for wild type RPE increased after C16 compared to BSA alone (41 ± 6.7 BSA to 68 ± 8.5 BSA-C16, $p < 0.0001$). In contrast, no change was observed in LCHADD (45 ± 7.7 BSA, 51 ± 4.7 BSA-C16). Apical levels of BOH increased in wild type RPE when treated with BSA-C16 ($p < 0.002$) with no significant change in LCHADD RPE. Increased triglycerides and neutral lipid staining were observed only in LCHADD RPE after C16 exposure. Media from LCHADD RPE accumulated palmitoyl (C16) and 3-hydroxypalmitoyl-carnitine (C16-OH). When treated with H₂O₂ in the presence of C16, LCHAD RPE showed a decrease in viability compared to wild type RPE ($p < 0.0001$).

Conclusions: LCHADD RPE have impaired FAO and ketone body production. Acylcarnitine profiles from LCHADD RPE are similar to those of LCHADD patients. The viability of LCHADD RPE decreased when treated with H₂O₂ in the presence of long-chain fats. LCHADD RPE may be more susceptible to oxidative stress due to the accumulation of toxic metabolic intermediates such as C16-OH.

TITLE: Direct comparison of in vitro retinal organoids with in vivo eye development using Rax-Cre;tdTomato mice and iPSC-derived retinal organoids

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Louie, A. Miltner, S.K. Cheema, A. La Torre, N.L. Brown, Cellular Biology and Human Anatomy, University of California Davis, Davis, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mikaela Louie: Commercial Relationship: Code N (No Commercial Relationship) | Adam Miltner: Commercial Relationship: Code N (No Commercial Relationship) | Simranjeet Cheema: Commercial Relationship: Code N (No Commercial Relationship) | Anna La Torre: Commercial Relationship: Code N (No Commercial Relationship) | Nadean Brown: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our understanding of the molecular steps of mammalian eye development remains incomplete. This holds especially true for early eye development where in vivo experiments are difficult due to the small size of the tissue. Here, we directly compared in vitro differentiation of stem cells into retinal tissue or, retinal organoids (ROs), to in vivo eye development, using BAC transgenic Rax-Cre and flox-stop tdTomato (Ai9) lineage reporter mice. Embryos of the same genotype were used to make the stem cell lines for RO differentiation. The Rax/Rx transcription factor is one of the earliest genes to demarcate the eye field. The time-course and characteristics of ROs arising from these lines were directly compared to in vivo eye formation.

Methods: Embryos containing both Rax-Cre and Ai9 transgenes were previously reported to recapitulate Rax spatiotemporal expression during early eye formation eye (Bosze et al., 2020). We extended the time course of Ai9 expression during embryogenesis using live imaging and immunofluorescence. The morphologic and molecular progression of ROs, derived from double-transgenic iPSC lines, using established protocols (Sasai et al 2011, La Torre et al. 2016), was analyzed by the same methods, plus RT-qPCR.

Results: Rax-Cre;Ai9 (Rc;Ai9) embryos show Ai9 expression from the embryonic day 7.5 (E7.5). At E9.5 and E11.5, the developing ventral diencephalon -including the optic vesicle- and telencephalon express high levels of Ai9. Rc;Ai9 undifferentiated stem cell colonies are indistinguishable from mouse embryonic stem cells (mESCs). When differentiated into ROs, retinal markers increase in expression while markers of pluripotency are down-regulated, comparable to differentiated mESCs. Ai9 expression began on day 4 and, by day 6, all ROs expressed Ai9. Interestingly, these cells respond to well-known morphogens such as Sonic Hedgehog (Shh). Hence, the addition of Shh changes proliferation rates compared to control ROs.

Conclusions: The Rc;Ai9 mice have been shown a to be a powerful tool for retinal lineage tracing. Similarly, Rc;Ai9 ROs mimic normal developing retinas in gene expression, cell morphology, and Ai9 expression. Importantly, these ROs can be used to study molecular mechanism early development, and also to inform strategies to advance the current protocols to generate ROs.

TITLE: The relationship in binocular summation between high and low contrast letter acuities

SESSION TITLE: Eye Movements and Binocular Vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E. Watson, D. Yu, The Ohio State University, The Ohio State University, Columbus, OH, US, academic, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Emily Watson: Commercial Relationship: Code N (No Commercial Relationship) | Deyue Yu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Binocular summation is a well-known phenomenon in letter acuity measurement. This study is to examine the relationship in binocular summation between high and low contrast letter acuities using common commercially available visual acuity charts and investigate whether people who exhibit stronger binocular summation at high contrast tend to have greater summation at low contrast.

Methods: Corrected high and low contrast letter acuities were assessed monocularly and binocularly in 325 normal vision observers aged 18 to 40 years using Bailey-Lovie charts. All observers had high contrast acuities of 0.1 LogMAR or better and no known eye disease. Binocular summation was calculated as the difference in LogMAR between the better eye acuity and binocular acuity.

Results: At high contrast, letter acuities for right, left and both eyes were -0.066 ± 0.004 (SE), -0.065 ± 0.004 , and -0.130 ± 0.003 , respectively. The corresponding acuities at low contrast were 0.087 ± 0.006 , 0.087 ± 0.006 and -0.007 ± 0.005 . Consistent with previous studies, we found binocular summation at both contrast levels with higher magnitude of summation at low contrast (0.045 ± 0.002 for high and 0.068 ± 0.003 for low contrast). Binocular summation at high contrast had a weak correlation with summation at low contrast ($r = 0.116$, $p = 0.036$), whereas it had a strong inverse relationship with the change in binocular summation between the two contrast levels ($r = -0.614$, $p < 0.001$).

Conclusions: Using common commercially available letter acuity charts, we replicated the findings on binocular summation for acuity in normal vision for both high and low contrast letters. While overall binocular summation is greater for low contrast acuity, people who exhibit stronger binocular summation at high contrast tend to have less enhanced (or even reduced) summation for low contrast acuity.

ABSTRACT BODY:

Purpose: Human color vision is based on the spectral sensitivities of S, M, and L cone photoreceptors, yet methods to objectively measure cone sensitivity as a function of wavelength over the entire visible light spectrum in the living human eye still do not exist. Here, we demonstrate a new, high resolution method based on phase-sensitive adaptive optics optical coherence tomography (AO-OCT) for measuring spectral sensitivities of the three different cone types.

Methods: AO-OCT volumes of $1^\circ \times 0.8^\circ$ at 3.8° temporal retina were acquired over 5 s for two color normal subjects. At 2.5 s, a 5 ms flash of 450 nm, 520 nm or 635 nm light with variable strength was delivered to the retina. The resulting temporal changes in the cone outer segment optical path length (ΔOPL) were extracted from the volume images and used to determine the spectral type [1] and sensitivity of each cone. Sensitivity was determined by fitting the cones' average peak response at each wavelength to a power function of stimulus photon strength after compensating for lenticular and macular absorption. We then separately scaled the measured sensitivity function for each cone type to best align with widely accepted psychophysical measurements [2]. In both subjects, spectral sensitivity 95% confidence intervals (CI) were calculated for S, M, and L cone types at the three stimulus wavelengths by computing the average and standard deviation values of S, M and L cone average peak response per stimulus flash strength and using the resulting probability distributions to estimate the CIs via a Monte Carlo simulation.

Results: For both subjects, CI were $<6.0\text{e-}3$ at all wavelengths and for all cone types (except we had insufficient response to calculate a CI for S cones at 635 nm). After aligning our data to the psychophysical results, the least-squares error across 450 nm, 520 nm, and 635 nm wavelengths for S, M, and L cones, respectively, was $[5.50\text{e-}4, 2.62\text{e-}4, 2.4\text{e-}3]$ for Subject 1, and $[1.04\text{e-}4, 3.4\text{e-}2, 1.23\text{e-}4]$ for Subject 2.

Conclusions: We demonstrate the first objective measurements of cone spectral sensitivities using phase-sensitive AO-OCT. Excellent agreement is obtained with Stockman & Sharpe's psychophysical measurements.

TITLE: The Use of Optogenetics to Study Inhibition in the Ex Vivo Mouse Electroretinogram

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.D. Maley, E. Eggers, Physiological sciences GIDP, University of Arizona, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Timothy Maley: Commercial Relationship: Code N (No Commercial Relationship) | Erika Eggers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The mouse Electroretinogram is a well characterized tool used to measure hyperpolarization of photoreceptors followed by excitatory activation of bipolar cells and ganglion cells across the entire retina. While the interaction of inner retinal neurons can be measured, we are not able to measure inhibition in isolation across the entire retina. Previous data has shown that inhibition likely plays an important role in light adaptation. Finding a way to measure inhibition across the entire retina could be an important tool to understanding the mechanisms of light adaptation and the role inhibition plays.

Methods: Retinas were isolated from 7-10 week old B6.Cg-Tg(Slc32a1-COP4*H134R/EYFP) male and female mice and placed in a custom ERG chamber. Retinas were perfused with Ringers solution and bubbled with 95% O₂-5% CO₂. These mice contain ChR2 in the inhibitory amacrine and horizontal cells under the VGAT promoter and were optogenetically activated with 5ms, (20 hz frequency) light stimulations (λ 470 nm) at 3.19×10^9 photons/ μm^2 . ERGs were recorded under ambient room light. Photoreceptor inputs were pharmacologically blocked with CNQX (25 μM), APV (50 μM), ACET (1 μM), and L-AP4 (50 μM). Inhibitory responses were blocked with TPMPA (50 μM), Gabazine (20 μM), and Strychnine (5 μM). D1 receptors were agonized with SKF-38393 (20 μM). Normalized peak amplitudes of the 1st (fast) and 2nd (slow) responses were calculated for each response before and after antagonizing the GABA_C, GABA_A and Glycine receptors.

Results: Treatment with GABA_C, GABA_A and Glycine receptor antagonists (n=5) did not cause significant changes to the fast response. This suggests the response is a measurement of the depolarization of amacrine and horizontal cells. However, the inhibitory block did cause a significant decrease in the normalized peak amplitude of the slow response. This suggest the slow response is likely a measure of inhibition generated by the activation of amacrine cells in the INL. Furthermore, the application of a D1 agonist (n=4) did not cause a change in the normalized peak amplitude of the slow response.

Conclusions: Optogenetic activation of ChR2 in the inhibitory amacrine and horizontal cells may be a novel way to measure inhibition across the entire retina. It is also possible to isolate the amacrine cell mediated inhibitory circuits in the mouse retina by blocking upstream photoreceptors and recording from bipolar cells.

TITLE: Dense Optic Nerve Head Deformation Estimated using CNN as a Structural Biomarker of Glaucoma Progression

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Salehi, M. Balasubramanian, Electrical and Computer Engineering, The University of Memphis Herff College of Engineering, Memphis, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ali Salehi: Commercial Relationship: Code N (No Commercial Relationship) | Madhusudhanan Balasubramanian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucomatous structural changes are observable non-invasively using optical imaging techniques. The aim of this study is to test the hypothesis that our newly designed convolutional neural networks (CNN) trained for estimating transformations in generic image sequences can be useful for estimating glaucomatous progression from confocal image sequences of the optic nerve head (ONH).

Methods: Optical flow provides a dense pixel-wise estimate of a scene transformation from an image sequence. We propose the average magnitude of flow velocities within the ONH region as a structural biomarker of glaucoma progression. Dense ONH structural transformation between a baseline scan and the most recent follow-up scan was estimated using various pre-trained CNNs namely FlowNet Correlation and FlowNet2¹, Teney², and our newly designed compact deep-dilated CNN (DDCNet) framework³. Diagnostic accuracy of the proposed flow-based structural biomarker was evaluated using longitudinal HRT-II exams of study participants in the UCSD Diagnostic Innovations in Glaucoma Study. 36 eyes progressed by stereophotos or visual field guided progression analysis, and 21 eyes were longitudinal normal eyes. Diagnostic sensitivity and specificity were estimated using a maximum likelihood classifier.

Results: The area under the ROC curve, sensitivity, and specificity of our deep-learning methods for estimating ONH structural transformations and other legacy computational methods (POD framework and TCA⁴) are presented in Table 1.

Conclusions: CNNs trained to estimate dense transformations in generic scenes were able to detect glaucomatous progression from HRT scans of the ONH with higher diagnostic accuracy. We anticipate that fine-tuning these networks using ONH sequences may further improve their diagnostic performance. Further, we conclude that the average magnitude of ONH structural changes estimated using the CNNs is a robust candidate biomarker for detecting glaucoma progression.

TITLE: Risk Factors for lens opacities in African Americans: The African American Eye Disease Study (AFEDS)

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Burkemper, R. McKean-Cowdin, X. Jiang, Preventive Medicine, University of Southern California Keck School of Medicine, Los Angeles, California, UNITED STATES|M. Torres, R. Varma, Ophthalmology, Southern California Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bruce Burkemper: Commercial Relationship: Code N (No Commercial Relationship) | Roberta McKean-Cowdin: Commercial Relationship: Code N (No Commercial Relationship) | Xuejuan Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Mina Torres: Commercial Relationship: Code N (No Commercial Relationship) | Rohit Varma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine independent risk factors (RFs) for lens opacities (LOP) in a population-based study of African Americans (AAs) ages 40 and older.

Methods: AFEDS participants, residents of Inglewood, Los Angeles County, California, completed a detailed questionnaire and comprehensive ophthalmic examination. Clinical ophthalmologists performed slit lamp exams and diagnosed LOP according to the Lens Opacities Classification System II (LOCS II). Cases were subdivided into 4 mutually exclusive categories based on opacity type present in either eye: nuclear only (NUC), cortical only (COR), post-subcapsular only (PSC) and mixed (MIX: >1 LOP type present). Multivariable logistic regression models identified factors independently associated with each LOP category (except PSC, due to too few cases).

Results: After excluding those with bilateral cataract surgery and missing LOCS II grades, LOP among the remaining 5867 AFEDS participants were distributed as follows—NUC: 602 (10.3%), COR: 622 (10.6%), PSC: 21 (0.4%), MIX: 1386 (23.6%); 3200 subjects with no LOP in either eye were the reference group for each model. Higher waist-hip ratio (WHR) was an RF for each LOP category: after controlling for all covariates, 4th vs 1st WHR quartile subjects were 47% more likely to have NUC (OR 1.47, 95% CI 1.09-2.00), 46% more likely to have COR (OR 1.46, 95% CI 1.12-1.92), and 59% more likely to have MIX (OR 1.59, 95% CI 1.23-2.04). Older age and being unemployed were additional RFs shared among all LOP categories. Protective factors included taller height (COR) and alcohol use (NUC). Greater comorbidities and smoking were additional RFs for NUC. Additional RFs for MIX included female sex, low education, diabetes, glaucoma, shorter axial length and high systolic blood pressure (alcohol use was protective, as with NUC).

Conclusions: AFEDS is the largest population-based study exclusively of AAs and provides a unique opportunity to identify RFs for ocular diseases such as LOP. Three RFs are common to each category of LOP examined, one of which (WHR) represents a modifiable risk factor. Factors leading to greater WHR, such as a sedentary lifestyle and poor diet, likely increase LOP risk in AAs. RFs for the most prevalent LOP category (mixed) also include high systolic blood pressure and diabetes, providing additional evidence for a link between obesity and increased LOP risk in AAs.

TITLE: Evaluation of chorioretinal vascular changes in diabetic kidney disease using optical coherence tomography angiography

SESSION TITLE: OCT Angiography - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Tan, C. Sabanayagam, T.Y. Wong, G. Tan, Ophthalmology, Singapore National Eye Centre, Singapore, Singapore, SINGAPORE|B. Tan, L. Schmetterer, Imaging, Singapore Eye Research Institute, Singapore, SINGAPORE|

Commercial Relationships Disclosure (Abstract): Rose Tan: Commercial Relationship: Code N (No Commercial Relationship) | Charumathi Sabanayagam: Commercial Relationship: Code N (No Commercial Relationship) | Bingyao Tan: Commercial Relationship: Code N (No Commercial Relationship) | Tien Wong: Commercial Relationship: Code N (No Commercial Relationship) | Leopold Schmetterer: Commercial Relationship: Code N (No Commercial Relationship) | Gavin Siew Wei Tan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the retinal and choroidal vasculature changes in type 2 diabetic patients with and without chronic kidney disease using optical coherence tomography angiography (OCTA).

Methods: Cross-sectional study. One hundred and two diabetic patients without diabetic kidney disease (DKD) and 28 with DKD recruited from a tertiary eye clinic in Singapore, were included in this study. All subjects aged 40 years old and above. DKD was defined as an estimated glomerular filtration rate (eGFR) below 60mL/min/1.73m^2 . All subjects underwent $3\times 3\text{mm}^2$ scans using a swept-source optical coherence tomography angiography (PlexElite 9000, Zeiss Meditec). Vessel density (VD) and perfusion density (PD) were evaluated separately for large vessels and capillaries in the superficial vascular plexus (SCP). For the choroidal vasculature, flow void density was evaluated on the choriocapillaris slab. All OCTA metrics were compared between the two groups using a t-test.

Results: The VD was significantly higher in the DKD group compared with the non-DKD group only for large vessels (4.0 ± 0.7 vs 3.6 ± 0.6 , $p = 0.005$). There was no significant change in VD for capillaries between the two groups (14.7 ± 3.6 vs 15.1 ± 2.8 , $p = 0.58$). The PD of large vessels and capillaries was not significantly different between the two groups (all $p > 0.1$). Choriocapillaris flow void density was significantly higher in the DKD group compared with the non-DKD group (18.2 ± 1.8 vs 17.2 ± 1.3 , $p = 0.01$).

Conclusions: Type 2 diabetic subjects with chronic kidney disease have increased vessel density in the large retinal vessels and increased choriocapillaris flow void density compared with subjects without DKD. Larger sample size is required to understand if these chorioretinal vasculature changes are independent of diabetic retinopathy.

SUBMITTER (NAME ONLY): Brittini Scruggs

TITLE: Transient vision loss associated with aflibercept pre-filled syringes

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Scruggs, D.J. Lee, M. Thomas, A. Faridi, Department of Ophthalmology, Oregon Health & Science University Casey Eye Institute, Portland, Oregon, UNITED STATES|A. Faridi, Department of Ophthalmology, Veterans Affairs Portland Health Care System, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Brittini Scruggs: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Lee: Commercial Relationship: Code N (No Commercial Relationship) | Merina Thomas: Commercial Relationship: Code N (No Commercial Relationship) | Ambar Faridi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe cases of significant vision loss following intravitreal aflibercept (Eylea™; Regeneron) injections using pre-filled syringes (PFS), which were approved by the Food and Drug Administration (FDA) in 2019.

Methods: All retina specialists (N=13) at Oregon Health & Science University and the Veterans Affairs Portland Medical Center were queried in December 2020 to determine their experience with aflibercept PFS. The specialists were asked to report any episodes of post-injection severe vision loss with or without the need for an anterior chamber paracentesis after administering aflibercept PFS. Medical records of all patients who had this complication were reviewed for demographics and pertinent ocular history.

Results: All specialists reported using aflibercept PFS starting in February 2020 when the PFS was made available at our institutions. Three specialists had no cases of vision loss with PFS use, whereas 10 specialists (76.9%) reported a perceived increase in post-injection vision loss with aflibercept PFS. There were 16 reported events of no light perception (NLP) or light perception (LP) vision immediately after aflibercept PFS. Seven physicians reported one case each; another specialist described two cases; one reported three events; and one reported four events. Chart review was performed for 12 of these events. The indication for aflibercept was exudative age-related macular degeneration (N=8), diabetic macular edema (N=3), or central serous retinopathy (N=1). The median age of the affected patients was 71 years (range 49-94). Two patients were being treated for glaucoma (N=1) or ocular hypertension (N=1); one patient was a glaucoma suspect. Three patients required anterior chamber paracentesis, and the remaining patients had improved vision without procedural intervention.

Conclusions: Pre-filled syringes have several advantages over traditional vial packaging (e.g., reduced total injection time, decreased endophthalmitis rates). However, retina specialists in our institution have noted numerous cases of transient central retinal artery occlusions with the recent adoption of aflibercept PFS. As a result, the majority of affected patients have reported increased injection-related anxiety. Further studies by our team include comparing PFS and traditional 1mL syringes as well as developing a national survey for query of retinal specialists performing aflibercept injections using pre-filled syringes.

TITLE: Patient Knowledge of Potential Ocular Toxicity from Systemic Medications in a Veterans Administration Eye Clinic

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.J. Donegan, Department of Ophthalmology and Visual Sciences, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|P.J. Donegan, Vanderbilt University School of Medicine, Nashville, Tennessee, UNITED STATES|A. Chomsky, VA Tennessee Valley Healthcare System, Nashville, Tennessee, UNITED STATES|A. Chomsky, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Patrick Donegan: Commercial Relationship: Code N (No Commercial Relationship) | Amy Chomsky: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of the study is to determine the patient knowledge rate of potential ocular toxicity from systemic medications, specifically hydroxychloroquine, amiodarone and ethambutol. Secondly, the study aims to determine if there are certain patient characteristics or prescribing provider types that may impact that knowledge rate.

Methods: A cross-sectional survey was carried out among 37 patients presenting to the Nashville Veterans Affairs Medical Center Eye Clinic between November 2020 and January 2021 using a questionnaire. Patients taking amiodarone, ethambutol, or hydroxychloroquine were asked if they could identify what medication they were taking, if they knew it could cause eye toxicity, and if they recall receiving education from the prescriber. Data were summarized with descriptive statistics while Fisher's exact test was used for categorical variables at $p < 0.05$.

Results: Among 37 patients surveyed to date, 73% knew why they were having an eye exam that day, 78% correctly identified the medication they were taking, and 46% were aware of the medication's potential ocular toxicity. Age over 70 years was significantly associated with not knowing their medication could cause ocular toxicity ($p=0.007$), while correctly identifying which medication they were on failed to show a statistical significance ($p=0.44$). Greater knowledge of medication toxicity among patients with trainee prescribers (defined as resident physicians or fellows) was found to be statistically significant compared to nurse practitioners ($p=0.01$) and non-trainee physicians ($p=0.04$). Among all groups, no comparisons showed statistical significance in correctly identifying the medication they were taking.

Conclusions: Our results suggest that there are significant differences in knowledge of medication ocular toxicity in a Veterans Affairs patient population depending on patient age and prescribing provider. Non-elderly patients and those prescribed their medication by a trainee were more likely to know that their medication could cause ocular toxicity. This study is limited by its small sample size.

TITLE: Age as a prognostic factor for the visual or surgical outcome after scleral buckle (SB) or pneumatic retinopexy (PR) for primary macula-off rhegmatogenous retinal detachment (RRD)

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.H. Sohn, G. Sanchez, J. McGinnis, D. Mantopoulos, Ophthalmology, Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire, UNITED STATES]

Commercial Relationships Disclosure (Abstract): Ashley Sohn: Commercial Relationship: Code N (No Commercial Relationship) | George Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Jacob McGinnis: Commercial Relationship: Code N (No Commercial Relationship) | Dimosthenis Mantopoulos: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine whether a patient's age changes the visual or surgical outcome following SB or PR for repair of a primary macula-off RRD.

Methods: Retrospective, consecutive case series. The charts of patients who presented to our institution with a primary macula-off RRD between January 2012 and October 2020 were reviewed. Those who underwent treatment with SB or PR were included. These patients were divided into the following two age groups: (A) ≤ 60 years-old and (B) ≥ 61 years-old. The primary outcome was postoperative BCVA. The secondary outcome was single-surgery anatomic success (SSAS) rate.

Results: Of the 193 patients who underwent PR or SB, 45 met inclusion criteria. Twenty-seven of them were male. The mean age \pm SD was 57.1 ± 15.1 years-old. The mean follow-up period was 9.4 ± 14.2 months. From these, 21 (47%) were in age group A and 24 (53%) were in age group B. In the SB group, the final mean logMAR (Snellen) BCVA was 0.72 (20/100) for group A and 0.51 (20/63) for group B ($p = 0.36$). In the PR group, the final mean logMAR (Snellen) BCVA was 0.14 (20/25) in group A and 0.33 (20/40) in group B ($p = 0.09$). From those who underwent PR, the SSAS rate was 80% in group A compared to 57% in group B ($p = 0.24$). The SSAS rate of SB was 91% in group A compared to 80% in group B ($p = 0.47$).

Conclusions: Despite the strong trend for different outcomes between the different subgroups, the patient's age was not found to have a prognostic significance for the final surgical or visual outcome after RRD repair with SB or PR. More studies with a larger sample size are needed to confirm or reject this hypothesis.

ABSTRACT BODY:

Purpose: Mice deficient in *Wwtr1*, the gene that encodes transcriptional co-activator with PDZ-binding motif (TAZ), show softer Descemet's membrane and decreased corneal endothelial cell (CEnC) density reminiscent of late-onset Fuchs' endothelial dystrophy in humans. The purpose of this study was to evaluate the expression of proteins critical to barrier and pump functions of CEnC in wildtype (WT) and homozygous TAZ (*Wwtr1*^{-/-}) and heterozygous TAZ deficient (*Wwtr1*^{+/-}) mice over time.

Methods: At least 3 corneas from different animals were collected for each genotype from various age groups (2, 6, 12, and 16 months old). After fixation, corneas were dissected from enucleated globes. Corneal flatmounts were sectioned into several pieces and incubated with primary antibodies against zonula occludens-1 (ZO-1) and Na/K-ATPase separately for evaluation of barrier and pump function of corneal endothelium, respectively. Subsequently, tissues were incubated with fluorophore conjugated secondary antibodies and nuclei were counterstained with DAPI. Whole-mount corneal tissues were mounted endothelial side up on a slide and were imaged using a fluorescent microscope with 20X and 40X objectives.

Results: In WT mice, ZO-1 staining demonstrated a typical hexagonal pattern with a zig-zag distribution along the cell border while Na/K-ATPase demonstrated expected finger-like projections along the basolateral membrane. The *Wwtr1*^{+/-} mice showed an expression pattern similar to WT for both markers over time. However, the *Wwtr1*^{-/-} exhibited different patterns of expression although high variability existed between animals and regions of the cornea. Specifically, ZO-1 staining was disrupted or absent resulting in partial loss of hexagonal appearance from 2 months old and Na/K-ATPase staining had a more diffuse and lobulated staining pattern lining the cell membrane from 6 months old in *Wwtr1*^{-/-} mice when compared with WT controls.

Conclusions: Data demonstrated that homozygous TAZ deficiency caused partial loss of ZO-1 expression and altered immunolabeling of Na/K-ATPase in the corneal endothelium of mice. These findings could potentially affect the barrier and pump function and further study is needed to explain the pathophysiologic mechanism and clinical significance for these findings.

TITLE: Uveitic Macular Edema: OCT Anatomic and Temporal Biomarkers

SESSION TITLE: Imaging of posterior segment II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Kapik, T.A. Ciulla, Clearside Biomedical Inc, Alpharetta, Georgia, UNITED STATES | D.A. Goldstein, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES |

Commercial Relationships Disclosure (Abstract): Debra Goldstein: Commercial Relationship(s);clearside biomedical:Code C (Consultant);abbvie:Code C (Consultant);allergan:Code C (Consultant) | Barry Kapik: Commercial Relationship(s);Clearside Biomedical, Inc.:Code E (Employment);Clearside Biomedical, Inc.:Code I (Personal Financial Interest) | Thomas Ciulla: Commercial Relationship(s);Clearside Biomedical, Inc.:Code S (Non-remunerative);Clearside Biomedical, Inc.:Code E (Employment);Clearside Biomedical, Inc.:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: To evaluate a potential correlation between best corrected visual acuity (BCVA) and optical coherence tomography (OCT) anatomic and temporal features in macular edema (ME) due to noninfectious uveitis (NIU). This analysis builds on a prior analysis which showed moderate correlation between BCVA and central subfield thickness (CST).

Methods: This post hoc analysis of uveitic eyes evaluated the relationship between BCVA and the presence of cystoid spaces, presence of subretinal fluid (SRF), and ellipsoid zone (EZ) integrity collected during two Phase 3, 24-week clinical trials. Correlation analyses evaluating baseline and change from baseline relationships were conducted. A longitudinal treatment-response analysis was created to model the temporal relationship between change in BCVA and CST. Early CST anatomic response, defined as a reduction in CST of 50 μ m or greater at 4 weeks, was assessed for relationship to BCVA prognosis.

Results: The analyzed data set included a total of 198 uveitic eyes. For EZ at baseline, mean BCVA progressively worsened with each EZ grade, trends which were not evident for cystoid space or SRF gradations. Eyes with normal EZ experienced greater 24-week change in BCVA than those with abnormal baseline EZ (11.9 vs 9.4 letters, $p=0.006$). In contrast, eyes without cystoid spaces and/or SRF with center-involvement at baseline showed less improvement (5.5 letters or 9.5 letters, respectively) improvement at 24 weeks, compared to those eyes with center-involvement (13.7 letters, $P=0.012$ or 17.2 letter, $P<0.001$, respectively). Longitudinal modeling in uveitic eyes showed a more rapid effect for CST than BCVA, with CST requiring approximately 3 weeks to reach over 90% of full response and BCVA requiring approximately 9 weeks to reach the same magnitude of response. Eyes that showed an early anatomical response, experienced a greater 24-week improvement in BCVA, compared to those without an early response (12.6 vs 4.9 letters, $P=0.007$ for difference).

Conclusions: Important and clinically meaningful relationships exist between BCVA and OCT anatomic and temporal features in eyes with uveitic macular edema, with anatomic improvement preceding BCVA improvement.

ABSTRACT BODY:

Purpose: To investigate in vivo effects of high myopia on the deformation response of the anterior scleral canal opening (ASCO) area and lamina cribrosa (LC) depth with acute changes in IOP.

Methods: Juvenile tree shrews were randomly assigned to two groups: normal visual experience (n = 6) and monocular -10D lens treatment to induce high myopia (n = 6). Lens treatment started at 24 days of visual experience (DVE). At 59 DVE, eyes were cannulated and the optic nerve head was imaged via optical coherence tomography (Spectralis OCT2, Heidelberg Engineering) at four IOP levels (5, 15, 30, 45mmHg) with at least 5 minutes rest after IOP changes. A deep learning algorithm (Reflectivity, Abyss Processing) was trained with 489 manually segmented OCT scans and used for auto-segmentation of the anterior LC surface. ASCO points were manually segmented. ASCO area and central LC depth were computed in 3D and analyzed after nonlinear distortion correction (Grytz R, et al. IOVS 2020; 61: ARVO E-Abstract 4778) from 48 radial B-Scans per OCT scan. Mixed design analysis of variance split-plot ANOVA and Wilcoxon analysis were used to test for significant IOP-group interactions and group differences at each IOP level, respectively.

Results: ASCO deformations were small across all groups with significant changes in IOP-group interactions between treated and control eyes. For IOPs 30 and 45 mmHg, ASCO area changes were significantly higher in treated vs control eyes ($p < 0.05$). In a large number of eyes, ASCO area was decreasing with IOP (9/12 normal, 5/6 control, 3/7 treated). No significant differences were found for central LC depth changes.

Conclusions: Our results suggest that high myopia has a small but measurable effect on ASCO area changes with IOP in juvenile tree shrews. This increase in optic nerve head compliance during juvenile myopia may contribute to subsequent ONH remodeling and increased risk of glaucoma later in life.

ABSTRACT BODY:

Purpose: We measured the thickness of the circumpapillary retinal nerve fiber layer (RNFL) in normal rhesus macaques (*Macaca mulatta*) and also in animals with a single nucleotide polymorphism (SNP) in the OPA1 gene predicted to be pathologic. We hypothesized a decreased RNFL thickness in OPA1 mutants compared to normal counterparts. There is no treatment for Dominant Optic Atrophy (DOA) associated with mutations in OPA1 and a large animal disease model could accelerate clinical trials.

Methods: Seven primates with a SNP in the OPA1 gene and 51 wild type animals underwent ophthalmic exams that included a circumpapillary OCT scan of the RNFL. Electroretinography (ERG) was performed, including photopic negative response (PhNR) to assess retinal ganglion cell (RGC) function. Results of the RNFL scans were analyzed using a two-way ANOVA and Sidak's multiple comparison test. The PhNR results were analyzed with a Mann-Whitney non-parametric test.

Results: Female NHPs have thicker RNFL than males in the inferotemporal region at location 270 Degrees ($P=0.039$). There was no significant difference in the RNFL thickness between the OPA1 and wildtype groups at any location. However, when OPA1 animals were compared to age- and sex-matched individuals (Fig 1), two of the oldest OPA1 animals had RNFL thinning in the temporal and nasal regions. OPA1 animals as a group had reduced RGC function (Fig 2) as measured by PhNR at 72 ms ($P=0.0121$) and at the PhNR minimum ($P=0.0098$).

Conclusions: The RNFL of rhesus monkeys shows significant regional differences between sexes, as seen in humans. There were no RNFL differences between OPA1 animals and controls. However, when comparing the individual OPA1 mutants to age- and sex-matched wildtype counterparts, there was RNFL thinning in older OPA1 individuals. OPA1 animals had reduced RGC function when compared to wild type controls suggesting reduced function at all ages. Since DOA can have a relatively late onset of disease, it is possible animals with this OPA1 polymorphism represent an NHP model of hereditary optic neuropathy.

ABSTRACT BODY:

Purpose: To describe the performance of scleral lenses (SL) for visual rehabilitation in patients with corneal irregularities.

Methods: Retrospective review of clinical records of patients with corneal irregularities fitted with SL for visual rehabilitation. Data analyzed included demographics, medical history, spherical equivalent, keratometry measurements and SL parameters. Visual outcomes in logMAR and aberrometric parameters were assessed using paired t-tests before and after SL fitting. The level of statistical significance was taken as $p < 0.05$.

Results: Thirty-Three eyes of nineteen participants are included in this study. Mean age was 33.39 ± 13.44 years. 64.71% were male. The most frequent diagnosis was keratoconus (66.67%), followed by irregular astigmatism either by corneal grafts or scarring and post-LASIK ectasia. History of corneal crosslinking and keratoplasty was present in 41.18% and 5.88% of the patients respectively. Mean spherical equivalent was -9.70 D, Mean K1 46.10 ± 3.82 and K2 50.62 ± 6.33 D. Mean SL base curve was 7.43 and a mean power of -7.51D, all SL had a 15 mm diameter. Mean logMAR VA significantly improved from 1.03 ± 0.66 to 0.067 ± 0.14 ($p=0.0001$). Total Root Mean Square (RMS) values reduced from $10.065 \mu\text{m}$ to $0.710 \mu\text{m}$ ($p=0.03$) measured after SL fitting. No complications associated with SL use were reported.

Conclusions: Scleral lenses are effective in improving quantitative and qualitative optimal visual function in patients with irregular corneas by improving visual acuity and reducing ocular aberrations.

ABSTRACT BODY:

Purpose: To assess the correlation between traditional metrics used for glaucoma assessment and ocular blood flow (OBF) metrics obtained with high temporal resolution using the XyCAM RI (Vasoptic Medical, MD, USA).

Methods: Unilateral imaging of duration six seconds using the XyCAM RI was done in a total of twenty healthy subjects, seventeen glaucoma suspect subjects, and ten subjects with moderate to severe glaucoma, as determined by the Hodapp-Andersen-Parrish criteria. As illustrated in Fig. 1, pulsatile OBF waveforms were obtained by averaging blood flow velocity index (BFVi) values in retinal vessels within the optic disc ("Disc Vessels"), and region of the optic disc with retinal vessels masked out ("Disc Perfusion"). From these waveforms, each cardiac cycle (from Dip to Dip) was isolated and three measurements were considered – Dip BFVi, Peak BFVi, and the mean BFVi over the cardiac cycle ("Cycle Mean"), and an average of each across all cardiac cycles from each subject. Pearson correlation coefficients were computed between these BFVi measurements and clinical data, including age, intraocular pressure (IOP), cup-to-disc ratio (CDR), OCT metrics such as minimum rim width (MRW) and retinal nerve fiber layer (RNFL) thickness, and visual field (VF) metrics including mean deviation and pattern standard deviation.

Results: As shown in Fig. 2, significant negative correlations were observed between all BFVi measurements and CDR, while correlations were inconclusive between BFVi measurements and IOP. BFVi in the Disc Vessels was significantly correlated with all considered OCT and VF metrics, whereas BFVi in the Disc Perfusion was significantly correlated only with MRW. Correlation between each of OCT and VF metrics and Dip BFVi is greater than their correlation with Peak BFVi.

Conclusions: OBF metrics obtained using the XyCAM RI may hold insights that are useful for glaucoma assessment and their clinical value should be investigated in greater detail in a prospective clinical trial.

ABSTRACT BODY:

Purpose: Many techniques have been described for the repair of lower eyelid cicatricial ectropion and large lower eyelid defects following Mohs surgical repair. A significant obstacle can be the incidence of post-operative cicatricial ectropion when repairing this area. The bi-pedicle Tripiier flap or “bucket handle” provides bulk, excellent vascularization, and support from the upper eyelid. We describe our surgical experience to previously described techniques.

Methods: A retrospective chart review was performed of two surgeon’s charts over a two year period. All patients’ charts that underwent a bucket handle flap were selected. Outcomes measured included underlying pathology, Mohs defect area, and total number of procedures performed on the individual patient. All patients were followed through postoperative month three.

Results: A total of 11 bucket handle flaps were performed. Five patients had a diagnosis of basal cell carcinoma, three patients had a diagnosis of squamous cell carcinoma, and the remaining three had cicatricial ectropion from previous lower eyelid surgery following Mohs surgery. The average defect area was 12.72 cm². One patient required a lateral tarsorrhaphy for neurotrophic keratopathy. Otherwise, no patients developed post op cicatricial ectropion, and no patients required further procedures.

Conclusions: The bucket handle flap is a useful technique for repair of cicatricial ectropion and large lower eyelid defects following Mohs repair. This technique allows for reconstruction of a challenging area with a low complication rate.

TITLE: Characteristics of Nationwide ED Presentations of Acute Angle-Closure Glaucoma from 2008-2017

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.K. Mehta, T. Mir, I.G. Freedman, A. Sheth, S. Sarrafpour, J. Liu, C. Teng, Ophthalmology and Visual Sciences, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sumarth Mehta: Commercial Relationship: Code N (No Commercial Relationship) | Tahreem Mir: Commercial Relationship: Code N (No Commercial Relationship) | Isaac Freedman: Commercial Relationship: Code N (No Commercial Relationship) | Amar Sheth: Commercial Relationship: Code N (No Commercial Relationship) | Soshian Sarrafpour: Commercial Relationship: Code N (No Commercial Relationship) | Ji Liu: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Teng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Acute angle closure glaucoma (AACG) is an ophthalmologic emergency with a rising incidence in the United States. Nationwide data on the epidemiology and clinical characteristics of AACG are lacking despite the significant morbidity and costs associated with the condition. We performed a nationally-representative, retrospective cross-sectional study using the Nationwide Emergency Department Sample (NEDS).

Methods: NEDS was queried by ICD-9/10 code for cases of AACG in a ten-year study period from 2008 to 2017. Cases with AACG as primary ED diagnosis were included. Weights specified in NEDS were used to compute nationally representative estimates. Linear regression analysis and seasonality (Edwards and Hewitt's) tests were used to identify significant trends. Reported outcomes include trends in the incidence, demographics, seasonality, and economic impact of AACG.

Results: A total of 29,645 AACG related ED visits were identified nationally over the study period. AACG was found to occur most frequently among female patients in the seventh decade of life. Incidence increased significantly over the study period (average increase of 0.044 cases per 100,000 individuals per year, $p=0.01$). The most common systemic comorbidity was hypertension, and the most common procedures were iridotomy and iridectomy. The Northeast U.S. geographic region had the highest average incidence of AACG (1.18 per 100,000), followed by the West (0.96 per 100,000), South (0.93 per 100,000), and Midwest (0.73 per 100,000). Significant seasonal variation was seen nationally and in each region ($p<0.01$), with increased national incidence from July to December ($p=0.048$). Inflation adjusted charges associated with AACG related ED visits over the study period totaled \$152.8 million.

Conclusions: The rising incidence of AACG poses an increasing burden on the U.S. healthcare system. High-risk groups that may benefit most from preventative strategies include women, individuals of low socioeconomic status, and those between ages 50 and 70. Ophthalmologists should be aware of significant regional and seasonal trends in the presentation of AACG.

ABSTRACT BODY:

Purpose: Vision degradation caused by damage to the phototransduction circuitry of retina in dry-age-related macular degeneration (dry-AMD) represents the most common cause of irreversible vision loss in the ageing society. To date, no single mouse strain developing all the features of AMD exist. Also, there often is a need to target specific or multiple retinal cell types to emulate the disease model such as RGC associated damage in Glaucoma. In order to generate spatiotemporal rodent model for dry-AMD and other layer specific injury model, we integrated an irradiation laser with the optical coherence tomography (OCT) where temperature rise at micro-focused spots is significant enough to allow site and layer-specific injury.

Methods: We utilized real-time depth-resolved imaging by OCT for guidance of the microirradiation laser. OCT allows live imaging guidance to target specific area and enables live monitoring of the injury. Therefore, we improved the spatiotemporal aspect of the laser irradiation ablation model. With scanning control of the irradiation beam, arbitrarily shaped injury to selected retinal layer could be achieved. For selective damage of different cell types, the wavelength of irradiation laser was varied from visible to near infrared. In addition, to target specific layer and cell type, we tuned the focal plane of the microirradiation spot. The laser can be focused on specific layer by tuning the variable focal lens in the integrated system.

Results: Instantaneous swelling of the targeted layer occurred in response to the laser microirradiation, followed by change in OCT image contrast. Longitudinal OCT measurements of laser-injured retina exhibited progressive degeneration of targeted layer: photoreceptors or RPE without damaging other layers. Thinning of retina of laser-injured site correlated with focal ERG measurements.

Conclusions: Our results demonstrate successful development of OCT guided laser microirradiation system and its implementation for spatially targeted injury to specific retina layers and cell types. OCT guided laser based targeted microirradiation will enable development of animal models of retinal degenerative diseases while characterizing the disease progression and therapeutic intervention.

TITLE: Long-term Outcomes of Fellow Eyes in Patients with Non-traumatic Rhegmatogenous Retinal Detachments due to Giant Retinal Tears

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Sengillo, A.L. Kunkler, H. Al-khersan, N.A. Yannuzzi, W.E. Smiddy, H.W. Flynn, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jesse Sengillo: Commercial Relationship: Code N (No Commercial Relationship) | Anne Kunkler: Commercial Relationship: Code N (No Commercial Relationship) | Hasenin Al-khersan: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Yannuzzi: Commercial Relationship: Code N (No Commercial Relationship) | William Smiddy: Commercial Relationship: Code N (No Commercial Relationship) | Harry Flynn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine clinical characteristics and long-term outcomes for fellow eyes of patients with a prior rhegmatogenous retinal detachment (RRD) due to a giant retinal tear (GRT)

Methods: Retrospective, observational analysis of patients evaluated at the Bascom Palmer Eye Institute for RRD secondary to GRTs. Patients with one or more years of follow-up were included. Patients with retinal detachments occurring in the setting of trauma were excluded.

Results: Of 44 patients who underwent retinal detachment repair for a non-traumatic GRT-associated RRD, 39 met inclusion criteria. The majority of patients were men in this cohort (n = 25, 64%). Average age at the time of initial retinal detachment repair was 67 (range 10-81). Mean follow-up time was 7 years (range 1-16 years). Risk factors for retinal detachment included lattice degeneration in 6 patients (15%) and myopia in 8 patients (21%). Eleven fellow eyes (28% of patients) in this cohort were pseudophakic. During follow-up of the fellow eye, 3 patients (8%) received prophylactic laser retinopexy for retinal tears (n=2) and a progressing schisis cavity (n=1). Six patients (15%) were diagnosed with retinal detachments that required surgery in the fellow eye during follow-up. One patient already had a prior history of retinal detachment in the fellow eye at presentation. Visual acuity of the fellow eye at the most recent visit was 20/40 or better in 33 patients (85%) and in just 2 of 6 (33%) patients who developed an RRD in the fellow eye.

Conclusions: In the current series we identify retinal tears and/or detachments to be relatively common in the fellow eyes of patients with a history of GRT associated RRD during follow-up. Regular dilated fundus exams are warranted for patients with a history of giant retinal tears.

TITLE: An evaluation of the use of 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase inhibitors (statins) and progression of age-related macular degeneration

SESSION TITLE: AMD: Clinical and translational research II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Smith, C. Kirk, S. Kirk, P. Bu, E.B. Stubbs, F. de Alba, Ophthalmology, Loyola University Health System, Maywood, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Erica Smith: Commercial Relationship: Code N (No Commercial Relationship) | Clayton Kirk: Commercial Relationship: Code N (No Commercial Relationship) | Suzanne Kirk: Commercial Relationship: Code N (No Commercial Relationship) | Ping Bu: Commercial Relationship: Code N (No Commercial Relationship) | Evan Stubbs: Commercial Relationship: Code N (No Commercial Relationship) | Felipe de Alba: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although age-related macular degeneration (AMD) is the leading cause of irreversible vision loss in the U.S. adult population, only vitamin supplementation and risk factor modulation are used to prevent progression of this disease from non-neovascular to neovascular. Prior studies have demonstrated a beneficial effect of 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase inhibitors (statins) on retinal physiology (Barathi 2014, Tian 2017, Zheng 2015). We performed a retrospective, observational clinical study to evaluate if statins protect against the progression of AMD from the non-neovascular to the neovascular form.

Methods: A retrospective chart review was performed for patient encounters with the ICD-9 and ICD-10 codes for non-neovascular or neovascular AMD from 2009 to 2019. Patients were included if they initially presented with non-neovascular AMD and if they were followed for at least two clinic visits. The resulting 1,631 patients were then divided into two groups based on whether or not they were on statin therapy—935 (57.3%) were on statin therapy and 696 (42.7%) were not. Patients were then evaluated for progression to neovascular AMD in at least one eye based on ICD-9 and ICD-10 codes for follow up encounters. A chi-square and odds ratio statistical analysis was used to evaluate if a difference exists between the patients on statin therapy and patients not on statin therapy with respect to progression from non-neovascular to neovascular AMD.

Results: Preliminary data analysis demonstrated that 57.3% of patients with non-neovascular AMD were taking a statin. Of these patients, 12.6% developed neovascular AMD. For patients who were not taking a statin, 11.2% progressed to neovascular AMD. This analysis did not demonstrate a protective effect of statins against progression from non-neovascular to neovascular AMD: χ^2 (2, N=1,631) = 0.75, p=0.39. The odds ratio for this analysis was 1.14 with a 95% confidence interval of 0.84-1.54.

Conclusions: Approximately half of our patients with non-neovascular AMD were on statin therapy. In this analysis, use of statins did not provide a protective benefit against progression from non-neovascular to neovascular AMD. Further studies regarding the relationship between statins and AMD as well as other treatment options for AMD are important due to the prevalence of this sight-threatening disease.

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is the most common primary eye cancer and remains uniformly fatal. In contrast to cutaneous melanoma, UM is an immunologically “cold” tumor that is poorly responsive to immunotherapy. The purpose of this study was to bioinformatically deconvolute the tumor immune microenvironment (TIM) after stratification for key molecular biomarkers associated.

Methods: RNA-seq data were downloaded from The Cancer Genome Atlas Uveal Melanoma (TCGA-UVM) dataset (n=80). Samples were stratified by gene expression profile (GEP) class 1 versus class 2, PRAME expression (negative versus positive), and LAG3 expression (low versus high). TIM deconvolution was performed using Quantiseq from the Immunedecconv R package.

Results: Class 2 UM were inferred to comprise 2.64-fold fewer CD4+ T cells ($p=0.0013$), 2.3-fold fewer myeloid dendritic cells ($p=0.026$), 1.74-fold more M2 macrophages ($p=4.37E-9$), 2.02-fold more NK cells ($p=1.2E-6$), and 53-fold more CD8+ T cells ($p=0.0007$) compared to class 1 UM. PRAME-positive UM contained 1.26-fold more M2 macrophages ($p=0.022$), 1.39-fold more NK cells ($p=0.005$), and 2.29-fold fewer CD4+ T cells ($p=0.0054$) than PRAME-negative UM. LAG3 expression was strongly associated with class 2 UM ($p=0.0026$), increased M1 ($p=0.00057$) and M2 macrophages ($p=5.6E-6$), NK cells ($p=0.016$), CD8+ T cells ($p=1.77E-11$), Tregs ($p=2.27E-5$), and decreased CD4+ T cells ($p=0.0045$).

Conclusions: The two strongest predictors of metastasis in UM – class 2 GEP and PRAME expression – are strongly associated with an inhibitory TIM. LAG3, which we recently showed by single cell RNA sequencing to be the predominant T cell exhaustion marker in UM, was associated with an increased global inflammatory signature. The data suggest that a subset of Class 2 Tumors are prime candidates for LAG3 Immune Checkpoint Inhibition. Correlation between key molecular biomarkers and TIM will facilitate the development of targeted immune therapy for patients with UM.

ABSTRACT BODY:

Purpose: We investigated the relationship between retinal nerve fiber layer (RNFL) thickness and visual field loss among Latino, African, and Chinese American eyes with a clinical diagnosis of glaucoma.

Methods: We obtained data from 50+-year-old participants with a clinical diagnosis of glaucoma from three multiethnic population-based studies of eye diseases in the Los Angeles area: the Los Angeles Latino Eye Study (LALES), Chinese American Eye Study (CHES), and the African American Eye Disease Study (AFEDS). Imaging was completed using the Cirrus HD-OCT with the Optic Disc Cube 200x200 protocol. Scans with low signal strength (<6) were excluded. Associations between RNFL thickness and visual field loss (mean deviation) and potential covariates were assessed using multivariable linear mixed regression.

Results: There were 1742 OCT scans available from 966 individuals with glaucoma, including 263 Latinos, 348 Chinese Americans, and 355 African Americans. 58% were female. The average RNFL thickness was 86 μm (95% CI: 76-95 μm) among all glaucoma eyes. Average RNFL was lower in African American eyes than Chinese and Latino eyes, even after accounting for age, waist-hip ratio, axial length, and visual field mean deviation. Also, a significant interaction was observed between race/ethnicity and visual field defect on the average RNFL thickness and the inferior quadrant RNFL thickness ($P < 0.05$). With each decibel of loss in visual field mean deviation among glaucoma eyes, Chinese eyes and Latino eyes had more reduction in RNFL thickness (-1.03 and -1.00 μm , respectively) than African American eyes (-0.77 μm). This pattern was observed in the inferior quadrant as well.

Conclusions: This multiethnic population-based study suggests that the relationship between visual field loss and RNFL thickness in glaucoma varies by ethnicity/race. It indicates that race/ethnicity should be considered for the use of OCT in diagnosing glaucoma.

TITLE: Spatial pattern of the retinal activation by frequency modulated electrical stimuli

SESSION TITLE: Retinal prostheses

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Yue, P. Lo, M. Humayun, Ophthalmology, University of Southern California, Los Angeles, California, UNITED STATES|L. Yue, J. Castillo, P. Lo, M. Humayun, Ginsburg Institute for Biomedical Therapeutics, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lan Yue: Commercial Relationship: Code N (No Commercial Relationship) | Johnny Castillo: Commercial Relationship: Code N (No Commercial Relationship) | Pei-An Lo: Commercial Relationship: Code N (No Commercial Relationship) | Mark Humayun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the investigation of the electrically-elicited color perception in the blind Argus II patients, we found that increase of the stimulation frequency led to not only blue-shifted color percepts but also elongated shapes of the phosphene sensation in some patients. Here we studied the spatial characteristics of the retinal activation under frequency modulation (FM), seeking to decode the changes in the phosphene shape observed clinically.

Methods: We used Ca^{2+} imaging to visualize spatial responses in wholemount mouse retina (wildtype C57BL/6 mice). AAV2-CAG-GCaMP6f was used to impart Ca^{2+} -dependent fluorescence on mouse retinal ganglion cells (RGCs). The retina was acutely dissected 3-4 weeks after intravitreal injection of the viral vectors and the wholemount was placed in an electrode array embedded chamber for simultaneous electrical stimulation and optical recording. Biphasic stimuli of 1-ms pulse width were delivered repetitively for 1-s at the frequency ranging between 5 and 120 Hz, similar to those tested in humans. A cocktail of synaptic blockers was applied to pharmacologically isolate the ganglion cell. Changes in the fluorescence ($\Delta F/F$) of the pixels in the cells were analyzed.

Results: The resulting $\Delta F/F$ maps show that increased stimulation frequency led to marked enhancement in the RGC activation in the direction along the axons of passage opposite to the optic disc. In comparison, increased amplitude resulted in a uniform expansion of a focal activation in all directions. Increasing the stimulation frequency from 5 Hz to 120 Hz reduced the standard deviation of the activation angle ($\Delta\theta$) by an average of 60%, whereas increasing the stimulation amplitude while keeping a 5Hz stimulation rate did not result in a significant change in $\Delta\theta$. When the synaptic input to the RGCs was blocked, the directional activation resulting from FM was largely maintained whereas the focal activation resulting from amplitude modulation (AM) was substantially eliminated.

Conclusions: Increased stimulation frequency resulted in increasingly directional activation map of the RGCs, consistent with the elongated phosphene sensation reported by some Argus II patients. The insensitivity of the directional activation to synaptic blockers and the alignment between the activation direction and the axon orientation strongly suggest an antidromic mechanism that may involve enhanced activation by axonal multi-pulse integration.

TITLE: Incidence of Second Primary Malignancy in Primary Optic Nerve Glioma: A US National Database Analysis

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Khan, Z. Hussain, F. Dihowm, Texas Tech University Health Sciences Center El Paso Paul L Foster School of Medicine, El Paso, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jawad Khan: Commercial Relationship: Code N (No Commercial Relationship) | Zain Hussain: Commercial Relationship: Code N (No Commercial Relationship) | Fatma Dihowm: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Advanced understanding of screening and therapeutic modalities acts as provision for increased survival in patients diagnosed with optic nerve gliomas. Second primary malignancies (SPM) and latency periods is currently an uncharacterized frontier. This US national database analysis showcases incidences of SPMs and latency periods in patients with optic nerve gliomas.

Methods: The Surveillance, Epidemiology, and End Results (SEER) database was executed for procurement of nationally de-identified cases of first primary optic nerve glioma. Standardized incidence ratios (SIR) and excess absolute risk (EAR) were calculated using the SEER-specific multiple outcome analysis. 95% SIR confidence intervals are demonstrated with statistical significance achieved at $p < 0.05$.

Results: 622 patients with primary optic nerve glioma were selected. Mean age was 14.6 ± 19 years (range 00–80). 315 (50.6%) patients and 307 (49.4%) patients were female and male, respectively. Relative to the US national population, patients afflicted with primary optic nerve gliomas demonstrated significantly increased risk for multiple SPMs. Primary malignancies originating from soft tissues (including the heart) (SIR 33.2, CI 6.9–97.1, EAR 5.1), breast (SIR 4.99, CI 1.4–12.8, EAR 5.6), female breast (SIR 5.0, CI 1.4–12.9, EAR 5.6), brain (SIR 105.4, CI 65.2–161.1, EAR 36.2), cranial nerves (SIR 103.3, CI 12.5–373.1, EAR 3.5), non-lymphocytic leukemia (SIR 15.6, CI 1.9–54.4, EAR 3.3), myeloid and monocytic leukemia (SIR 16.3, CI 1.97–58.8, EAR 3.3), and Kaposi sarcoma (SIR 79.9, CI 2.0–445.1, EAR 1.7) demonstrated significantly increased SIR as SPMs as showcased in Table 1. In totality, cumulative SPM (SIR 6.04, CI 4.3–8.2, EAR 59.6) showcases overall significance in incidence rates of SPM in patients diagnosed with optic nerve gliomas.

Conclusions: As compared to the US national population, diagnosis of first primary optic nerve gliomas prognosticates increased chances for formation of second primary malignancies, including tumors of all sites, soft-tissue, brain, cranial nerve, non-lymphocytic leukemia, myeloid and monocytic leukemia and Kaposi's sarcoma. Advancements related to diagnosis and treatment modalities may sustain survival. Yet, some treatments may increase incidence of malignancies. Clinical decision-making should reconcile enhanced propensities for development of second primary malignancies.

ABSTRACT BODY:

Purpose: To train and validate a convolutional neural network (CNN) to segment nonperfusion areas (NPA) in three retinal plexuses on wide-field OCTA.

Methods: We obtained consecutive 6×6-mm OCTA scans at central macular, optic disc, and temporal regions on one eye from 202 participants in a clinical diabetic retinopathy (DR) study with a 70-kHz OCT commercial system (RTVue-XR; Optovue, Inc). Projection-resolved OCTA algorithm was applied to remove projection artifacts in voxel. We designed a deep convolutional neural network [Fig. 1 D] to detect NPA [blue in Fig. 1 E] and distinguish from signal reduction artifacts [yellow in Fig. 1 E] from superficial vascular complexes (SVC), intermediate capillary plexuses (ICP) and deep capillary plexuses (DCP). The input to the network contains the inner retinal thickness map [Fig. 1 A], reflectance mean projection [Fig. 1 B] and en face angiograms of montaged scans at three regions [Fig. 1 C]. In the temporal region where the ICP merges with the DCP, we treated the ICP and the DCP as a single slab for segmentation and NPA measurement. Expert graders manually determined the ground truth for NPA and signal reduction artifacts. Six-fold cross-validation was used to evaluate our algorithm on the entire dataset.

Results: This study had 202 participants, including 39 healthy controls, 25 participants with diabetes without retinopathy, 59 participants with mild to moderate nonproliferative DR (NPDR) and 79 participants with severe NPDR or proliferative DR (PDR). The signal strength index (SSI) ranged from 55 to 87. On the test set, the proposed algorithm had high agreement with ground truth on NPA detection in three retinal plexuses on montaged wide-field OCTA (F-score (mean±standard deviation): SVC 0.83±0.08, ICP 0.81±0.10, and DCP 0.78±0.12). The algorithm showed high performance on both healthy controls and eyes with varying severities of DR [Fig. 2]. Shown by all scans from healthy controls, the proposed method was independent of SSI (Pearson correlation, p-value = 0.146).

Conclusions: A deep learning network can accurately segment NPA in individual retinal capillary plexuses and distinguish from signal reduction artifacts prevalent on wide-field OCTA.

ABSTRACT BODY:

Purpose: Glaucoma is the leading cause of irreversible blindness in the general population. End-stage glaucoma carries a relevant challenge in its clinical management. Some scientific evidence has suggested that citicoline can be used as a supplement to preserve vision in glaucoma patients. The aim of this study is to investigate the effect of systemically administered citicoline in the visual function in patients with end-stage glaucoma in a real-world setting.

Methods: A retrospective assessment of 134 electronic medical records of consecutive patients with end-stage glaucoma under treatment with citicoline (orally, 500 mg BID) for at least three months was performed. Clinical data including best-corrected visual acuity (BCVA), IOP, number of glaucoma medications, visual field indexes (VFI) evaluated by applanation tonometry, cup-to-disc (CD) ratio, peripapillary retinal nerve fiber layer (RNFL) and perimacular ganglion cell complex (GCC) thickness by OCT. Tolerability and safety issues were also recorded.

Results: From 134 patients under oral citicoline treatment, 27 were excluded; therefore, 206 eyes from 107 patients were analyzed in this study (58 females, 49 males). This population had a mean age of 68.0 ± 17.6 years and a greater proportion of primary open-angle glaucoma (60.7%), as well as at least two glaucoma medications (70.8%) for topical administration. Mean time of citicoline administration was 5.1 ± 0.7 months. Baseline measurements of IOP of both eyes (RE, 13.6 ± 6.3 mmHg; LE, 13.4 ± 5.8 mmHg; $P=0.80$) was not significantly different as compared to the last follow-up quantification (RE, 13.4 ± 6.1 mmHg; LE, 13.3 ± 6.0 mmHg; $P=0.86$). BCVA, VFI (with exception of LE mean deviation), CD ratio, CFNR and GCC were not statistically different when baseline mean values were compared to the ones measured in the last visit ($p>0.05$). Only mean deviation for the left eyes was different after comparison (-21.53 ± 10.36 mmHg; LE, -24.32 ± 8.4 mmHg; $P=0.005$). Minor headache (12.1%) and intermittent diarrhea (2.8%) were the only tolerability issues recorded. Twenty three patients (21.5%) claimed to have a subjective improvement in their vision.

Conclusions: In this retrospective "real world" study of end-stage glaucoma patients, no significant improvement was observed when citicoline was orally administered during a short-term period. Safety and tolerability were acceptable. A subjective improvement perception was uncommon.

ABSTRACT BODY:

Purpose: The loss of the central visual field in macular disease means that patients must use peripheral vision to conduct most visual tasks. With time, most patients develop a preferred retinal locus (PRL) outside of their scotoma for visual tasks. To date, it is unclear how the PRL develops, especially in response to asymmetric progression of the disease in the two eyes. This study investigated how participants with normal vision develop a "PRL" in response to simulated bilateral central field loss; in particular, when the field loss is asymmetric in the two eyes.

Methods: We simulated central field loss with a gaze-contingent paradigm by tracking participants' gaze position as they performed a training task viewed through a stereoscope, and occluding a 2 degree circle around their gaze positions (the artificial scotoma) on the computer screens. Training consisted of repeated trials of identifying the orientation of a Tumbling-E. Participants performed multiple days of training. Oculomotor responses, including fixation stability, saccade latency and accuracy, were continuously monitored. To simulate the asymmetric progression of macular disease, we increased the size of the scotoma to 4 degrees in one eye after participants' oculomotor responses to the bilateral artificial scotoma reached a plateau.

Results: Participants' gaze positions were analyzed using a kernel density estimator to determine the location of the "PRL", defined as the most probable stimulus location relative to central gaze position. Each participant's "PRL" was initially within the scotoma, but over time shifted outside the artificial scotoma (regression coefficients for time and distance were positive, $p < .03$). When the size of the scotoma was increased in one eye, the distance between the PRL and central gaze did not increase with time like in the first phase of training, indicating that participants did not change the location of the PRL in response to binocular asymmetry.

Conclusions: Participants with normal vision are able to shift their "PRL" from central vision to outside a scotoma in response to bilateral simulated central field loss. Subsequent changes in the size of a scotoma, causing a binocular asymmetry, have little effect on the distance of the "PRL" from central vision. This finding suggests that the location of a PRL for patients with bilateral macular disease is likely governed by the better eye.

ABSTRACT BODY:

Purpose: The purpose of this research was to test the hypothesis that PNU-282987 (PNU) causes regeneration of neurons lost to damage in adult mice.

Methods: Male and female 129/SvJ wild-type and Rbp1-CreERT2;Rosa26-tdTomato transgenic mice (3 to 6 months) were used. Glaucoma-like damage was elicited using episcleral vein injections of hypertonic saline. Retinitis pigmentosa (RP)-like damage was induced with single intraperitoneal injection of 60mg/kg N-methyl-N-nitrosourea (MNU). Animals were treated bilaterally, once daily, with eye drops containing 1mg/mL BrdU with 1mM PNU added in experimental groups. MNU-injected mice were treated with PNU for 7 days, starting 3 days after MNU injection (Group M1) or treated with PNU for 3 days, starting 10 days post MNU injection (Group M2). After 3-14 days treatment, retinas were immunostained for BrdU incorporation, expression of differentiated cell markers, and lineage tracing. Statistical analysis between control and experimental cell counts was performed using ANOVA.

Results: Hypertonic saline injections significantly increased intraocular pressure, from 8.86 ± 0.8 mmHg to 14.38 ± 1.9 mmHg (SEM; $p < 0.05$; $n = 11$) and significantly decreased Thy1.2+ RGCs ($28.31 \pm 1.5\%$ (SEM; $p < 0.001$, $n = 8$) at 28 days post injection. Glaucomatous eyes treated with PNU and BrdU for 72 hours had an average of $8.29 \pm 1.05\%$ (SEM; $p < 0.05$; $n = 4$) RGCs double labeled for BrdU and Thy1.2, whereas glaucomatous eyes treated with BrdU only contained no BrdU+ cells. In glaucomatous eyes treated for 14 days with PNU, $22.06 \pm 2.28\%$ (SEM; $p < 0.001$; $n = 4$) of Thy1.2+ RGCs were tdTomato positive. At 10 days following MNU injection, the ONL was significantly thinner, decreasing from $65.041 \pm 3.69 \mu\text{m}$ in control retinas to $52.089 \pm 1.27 \mu\text{m}$ (SEM; $p < 0.01$; $n = 4$) at 10-days post injection. The ONL in Groups M1 and M2 was thicker in PNU treated eyes vs. control MNU-injected eyes but was still thinner than uninjured control retinas. In Group M2, new cells were detected following PNU treatment, and $12.43 \pm 2.1\%$ (SEM; $p < 0.01$; $n = 4$) of cells in the ONL BrdU+, of which 88.25% were ($10.97 \pm 1.1\%$ SEM; $n = 4$) double labeled for BrdU and a differentiated photoreceptor marker.

Conclusions: Induction of glaucoma and RP-like damage caused a significant loss of RGCs and photoreceptors in this study. With PNU-282987 treatment, regeneration of disease-specific damaged cells was demonstrated.

TITLE: Micropump Device Capable of Measuring Outflow Facility in Awake Freely Moving Rats

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Mohamed, C.L. Passaglia, Medical Engineering, University of South Florida, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Youssef Mohamed: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Passaglia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Most animal models of hypertensive glaucoma elevate pressure by experimentally disrupting aqueous drainage pathways, which alters the outflow facility and intraocular pressure (IOP) of the eye in an imprecise and unpredictable manner. This study presents the continued development of a micropump system capable of continuously measuring and controlling IOP through a cannula implanted in the anterior chamber. Furthermore, the device allows for repeated outflow facility measurement in conscious free-moving rats.

Methods: The system is comprised of an implantable cannula and tether system, a pressure sensor, a micropump, and a flow restrictor. MATLAB was used to create a model of the eye and simulate the device to verify theory and optimize the feedback algorithm. The device pressure calibration and resistance were measured daily over a month to check for drift. Bench testing was conducted with an inline flow meter to verify flow rates produced by the device. The device was then tested on rats anesthetized with ketamine and xylazine using one of two paradigms (constant flow or feedback-controlled flow) to measure outflow facility. Finally, the system was deployed in an awake rat to demonstrate proof of concept.

Results: The device showed no drift in flow-restrictor resistance, pressure generation, or pressure sensor readings over 30+ days when subjected to flow rates between 0 and 2 ul/min. It was bench tested with a small-diameter cannula and reported an outflow facility of 1.109 ± 0.041 ul/min/mmHg, which was not significantly different from the value of 1.134 ± 0.094 ul/min/mmHg measured using a commercial pump. MATLAB simulations indicated a feedback control algorithm would allow for over 5X faster measurements and later confirmed during testing in anesthetized animals. When tested on anesthetized rats utilizing the feedback algorithm, mean outflow facility was 0.0228 ± 0.003 ul/min/mmHg as measured by the device and 0.0233 ± 0.0032 ul/min/mmHg as measured with an inline flowmeter (N=14, p=0.29). In the awake animal (n=2) a diurnal rhythm was recorded, with outflow facility lowest at night (~ 0.01 ul/min/mmHg) and highest during the day (~ 0.025 ul/min/mmHg).

Conclusions: The system displayed reliability in outflow facility measurements over multiple weeks and can be used to study outflow facility in conscious freely-moving rats. The feedback algorithm provides an increased temporal resolution.

TITLE: Remote diagnosis of referable retinal pathology in diabetic patients visiting primary care clinic

SESSION TITLE: Diabetic Retinopathy Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Hadziahmetovic, J. Amason, S. Cousins, Ophthalmology, Duke University, Durham, North Carolina, UNITED STATES|T. Lee, Duke Medicine, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Majda Hadziahmetovic: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Amason: Commercial Relationship: Code N (No Commercial Relationship) | Terry Lee: Commercial Relationship: Code N (No Commercial Relationship) | Scott Cousins: Commercial Relationship(s);NotalVision:Code I (Personal Financial Interest);Stealth:Code C (Consultant);PanOptica:Code C (Consultant);Merc Pharm.:Code C (Consultant);Clearside:Code C (Consultant)

ABSTRACT BODY:

Purpose: To test the feasibility of remote ophthalmic imaging technology for early identification of referable retinal pathology in the setting with relatively low disease prevalence.

Methods: Prospective, non-randomized study on 635 patients (1270 eyes) conducted on diabetic patients in Duke primary care clinic. Adult patients with type 1 and 2 diabetes underwent retinal screening using color fundus (CFP) and optical coherence tomography (OCT) camera (MaestroCare, Topcon) on un-dilated pupils. Obtained images were graded by masked readers for interpretability and the presence of predetermined retinal pathology, with each eye graded independently. Retinal pathology was defined as referable to a retina specialist, requiring further intervention or follow-up, and incidental findings referable to the retina or comprehensive ophthalmology.

Results: The mean age of screened patients was 66.1 (SD±13.5), the mean A1c 7.6 (SD±1.7), with an average disease duration of 5.9 years (demographics presented in Table 1). Remote image interpretability was significantly better by the OCT relative to CFP (97.9% vs. 83.5%, $p<0.0001$). We have identified 58 patients with different stages of Diabetic Retinopathy (Table 1 and Table 2 A), 114 patients with other retinal pathologies that required further retina evaluation, and 50 patients with incidental retinal findings that needed comprehensive ophthalmology follow-up (Table 1 and the most common incidental findings are presented in Table 2 B). Considerable agreement in the final diagnosis was found between the gold standard (dilated exam by the Duke ophthalmology) and the screening outcome for a limited number of patients assessed at Duke. The screening significantly improved providers' HealthCare Effectiveness Data and Information Set (HEDIS, from 4 to 5 star; 74% to 84%).

Conclusions: Ophthalmic imaging technologies at the point of service may harbor sufficient diagnostic information to enable accurate referral and timely treatment of retinal pathology. In return, this might lead to improved clinical and cost-effectiveness. Additionally, this approach might be attractive to primary care and endocrinology clinics, as it might significantly improve their quality performance (HEDIS) measures and bonus insurance reimbursements.

ABSTRACT BODY:

Purpose: Glaucoma is a complex multifactorial disease where apoptosis and inflammation represent two key pathogenic mechanisms. However, the relative contribution of apoptosis versus inflammation in axon degeneration and death of retinal ganglion cells (RGCs) is unknown. We previously demonstrated that Fas-FasL signaling is required for the development of glaucoma. While triggering of the Fas receptor is best known for inducing apoptosis through the activation of caspase-8, activated caspase-8 can also induce the production of pro-inflammatory mediators and caspase-8-mediated inflammation has been linked to the death of RGCs in glaucoma. The recent development of a caspase-8 mutant mouse (Casp8^{DA/DA}) in which a point mutation in the auto-cleavage site blocks caspase-8-mediated apoptosis but does not block caspase-8-mediated inflammation, will allow us for the first time to uncouple the two pathways and definitively determine the extent to which caspase-8-mediated inflammation and/or apoptosis contributes to the death of RGCs in glaucoma.

Methods: Intracameral injection of magnetic microbeads (control: saline) was used to elevate the intraocular pressure (IOP) in Casp8^{DA/DA} mutant mice and WT littermates. IOP was monitored by rebound tonometry twice a week and RGC function was monitored by pattern ERG (pERG). At 4 weeks post microbead injection, RGC density was measured in retinal whole mounts stained with a RGC-specific anti-Brn3a antibody.

Results: Rebound tonometry showed equivalent elevation of IOP in microbead-injected Casp8^{DA/DA} mutant mice and WT littermates. At 2 weeks post microbead injection, pERG amplitude was significantly decreased in both Casp8^{DA/DA} mutant mice (22.60 ± 1.2 uV at baseline to 16.27 ± 1.0 uV, $p < 0.05$) and WT mice from (21.99 ± 3.1 uV at baseline to 15.27 ± 1.2 uV, $p < 0.05$). At 4 weeks post microbead injection, quantification of RGCs revealed a significant decrease in RGC density in both microbead-injected Casp8^{DA/DA} mutant mice (3359.4 ± 95.1 RGCs/mm²) and WT littermates (3768.4 ± 212.4 RGCs/mm²) when compared to saline-injected WT controls (4428.6 ± 114.0 RGCs/mm², $p < 0.05$).

Conclusions: Our preliminary results indicate that caspase-8-mediated apoptosis is not required for the death of RGCs in a microbead-induced mouse model of glaucoma, indicating that caspase-8-mediated inflammation, but not apoptosis is the driving force in the development of glaucoma.

TITLE: Arterial Length as a predictor for Glaucoma Status

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.F. Shafik, J. Abdel-Maseih, Ophthalmology, New York Medical College School of Medicine, Valhalla, New York, UNITED STATES|F.F. Shafik, Ophthalmology, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Farid Shafik: Commercial Relationship: Code N (No Commercial Relationship) | Jerome Abdel-Maseih: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Using primary arterial lengths as an indicator of overall macular fibers. We hypothesize that the arterial lengths delineate the macular area. With decrease in macular fibers there would be less binding and expected expansion of the major arterioles of the superotemporal (ST) and inferotemporal (IT).

Methods: Arteriolar lengths were measured in a standardized system from first branching at the optic nerve to the first bifurcation. Comparison was made between Normal (N=25) vs the given open angle glaucoma states of: mild (N=47), moderate (N=49), severe (N=43). A ratio was carried out between Normal to given disease state, Student T-Test carried out for comparison.

Results: Glaucoma Categories show a difference from normal arterial lengths. There is a lengthening of the arterial segment.

Conclusions: With the lengthening of the arterial segment relative to glaucomatous status, it is sensed that this purports to widening of the macular arcades due to decreased anchoring from the nerve fiber layer as it relates to glaucoma, ie, with more glaucomatous change there is a resultant decrease in NFL. More development and testing will be needed to develop such algorithms.

ABSTRACT BODY:

Purpose: Group-Based Trajectory Modeling (GBTM) is a statistical approach that clusters persons with similar behavioral and developmental trajectories. When applied to administrative claims data which document the frequency of ocular hypotensive prescription refills, GBTM has revealed distinct patterns of medication adherence. In this study, we applied GBTM to electronically monitored data which document daily eye drop use in order to identify distinct patterns of medication adherence in glaucoma patients.

Methods: We performed GBTM with ancillary adherence data from 100 participants enrolled in an NIH-funded glaucoma progression study at the University of Alabama at Birmingham. Participants were included if they were above age 18, used hypotensive eye drops, had 2 or more reliable visual field tests, and had visual acuity better than 20/40 at baseline. Adherence was monitored for 6 months using Medication Event Monitoring Systems (Aardex, Switzerland) which record the date and time at which the devices are opened to use the eye drops stored inside. Using the Proc Traj macro (SAS Institute, Cary NC), quadratic functions [RL(1) [sp2] were fitted to weekly mean adherence data to estimate trajectory models with 2, 3, 4, 5, and 6 groups. The trajectory model that included 5% or more of participants in each group and had the highest Bayesian Information Criterion (BIC) was identified as optimal.

Results: Mean age was 68.6 ± 8.3 years, and mean baseline intraocular pressure was 25 ± 4.8 mmHg (right eye) and 23.9 ± 6.5 mmHg (left eye). Mean adherence was $80 \pm .21\%$ and the BIC for the final model was -437.5. Five trajectory groups were estimated: Near-perfect adherence (30.7% of participants), Good adherence (32.7%), Initially Good but Declining adherence (6% of participants), Consistently Poor adherence (18.7% of participants), and Poor and Declining adherence (11.9% of participants).

Conclusions: We identified "Near-perfect" adherence and "Initially Good but Declining" adherence as two patterns that had not been previously captured in administrative data. Utilizing different metrics to quantify adherence may provide additional insight into the dynamic nature of medication adherence, which may help to predict adherence to prescribed hypotensive therapy.

TITLE: Eyelid Blinking Dynamics in Adults with Facial Paralysis Using High Speed Video Photography

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Habeel, M. Chen, P. MacIntosh, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Samer Habeel: Commercial Relationship: Code N (No Commercial Relationship) | Michael Chen: Commercial Relationship: Code N (No Commercial Relationship) | Peter MacIntosh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Eyelid blinking serves to protect against drying through continuous tear distribution. Facial paralysis can lead to paralytic lagophthalmos, resulting in exposure of the ocular surface that can lead to corneal dryness, infection and ulceration. There are few studies of eyelid blinking dynamics. We are studying subjects with facial paralysis to better understand and treat it.

Methods: We studied five adult subjects with facial paralysis but without adnexal, ocular or other, neurologic pathology that may affect blinking. One minute of spontaneous, bilateral blinking was recorded at 240 frames per second in upright and supine positions. Eyelid closure velocity, amplitude, and closure percentage (relative to the palpebral fissure) were calculated in horizontal (x) and vertical (y) axes for each eye using the Tracker® Video Analysis and Modeling Tool program.

Results: Average age amongst patients was 57.2 years, with an average duration of facial paralysis of 56.2 months (SD 53.88 months). Compared to non-paralyzed eyes, paralyzed eyes moved vertically with 62.7mm/s slower velocity and 4.28mm less amplitude in upright and 50.27mm/s slower velocity and 3.97mm less amplitude in supine position. In the horizontal plane, the eyes moved with 34.57mm/s slower velocity and 2.40mm less amplitude in upright and 20.72mm/s slower velocity and 1.90mm less amplitude in supine position. Mean percent closure for paralyzed eyes was 44% less in upright and 45% less in supine position compared to non-paralyzed eyes.

Conclusions: Facial paralysis led to decreases in all vertical and horizontal measurements, except percent closure, by greater than 50% relative to non-paralyzed eyes, in both upright and supine positions. The decrease in percent closure was almost the same in both positions, suggesting that gravity did not have as much of an effect on the closure percentage as paralysis did. Furthermore, paralyzed eyes often displayed a horizontal wobbling motion during closure rather than the medial movement seen in normal eyes, which could have implications in tear film spread and tear drainage. Future studies should include analysis of larger numbers of subjects as well as subjects with surgical interventions for paralytic lagophthalmos to better understand approaches to reanimating the eyelid.

ABSTRACT BODY:

Purpose: Context: The US Census Bureau's American Community Survey (ACS) estimates a national prevalence of visual disability, defined as "being blind or having serious difficulty seeing even when wearing glasses" of 2.6% in adults ≥ 40 years (y). The prevalence of visual disability has not been assessed specifically across diverse Hispanic/Latino groups. Objective: To characterize the prevalence of visual disability in Hispanic/Latinos of diverse backgrounds by age.

Methods: Design, Setting and Participants: Multicenter, prospective, population-based Hispanic Community Health Study/Study of Latinos (HCHS/SOL) including 9663 participants aged ≥ 40 y who completed Visit #2 (2014-2017). Age-adjusted, sex-specific prevalence of visual disability was calculated weighting for study design and non-response. Analyses included those with Cuban (n=1455), Dominican (n=804), Mexican (n=3746), Puerto Rican (n=1485), Central American (n=965), South American (n=669) and Other (n=199) backgrounds. Main outcome measure: Prevalence and 95% confidence interval (95%CI) of self-reported visual disability defined using national ACS definitions assessed at Visit #2.

Results: Analysis included 9324 with complete data (35.9% men), with a mean age of 55.4y in men and 56.5y in women. Prevalence (%) was associated with increasing age in both men [estimate and 95%CI; 40-49y: 6.1(3.7-8.5); 50-59y: 10.5(8.3-12.6); 60-69y: 12.0(9.3-14.6); 70+y: 19.5(13.8-25.2] and women [40-49y: 10.5(7.9-13.1); 50-59y: 12.1(10.1-14.2); 60-69y: 16.5(13.9-19.1); 70+y: 18.8(15.0-22.7)]. Age-adjusted prevalence varied significantly by Hispanic/Latino background. In men, prevalence was highest in Puerto Ricans 14.6(10.7-18.5) and lowest in Mexicans 6.6(4.7-8.6); in women, prevalence was highest in Dominicans 24.5(19.8-29.2) and lowest in Cubans 8.8(6.4-11.2).

Conclusions: Sex-specific results demonstrate significant variability in the prevalence of visual disability by age and across diverse Hispanic/Latino backgrounds. Results support objectives of SOL Ojos, an ancillary HCHS/SOL study that will examine 3000 participants to systematically assess associations of lifestyle exposures (e.g., CVD risk factors, acculturation, sociocultural variables, healthcare access, physical activity, diet) with objectively measured chronic eye disease in a diverse cohort of Hispanics/Latinos.

TITLE: Tonic ErbB signaling underlies TGF β -induced activation of ERK and is required for lens cell EMyT

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Musil, Chemical Physiology & Biochemistry, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Linda Musil: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In primary lens cell cultures, inhibitors of either ErbBs (EGF receptor family members) or ERK kinases prevent TGF β from inducing epithelial-to-myofibroblast transition (EMyT). Despite its relevance for fibrotic PCO, we do not understand why ErbB activity is essential for TGF β -induced EMyT of lens cells.

Methods: Western blotting and immunofluorescent microscopy were used to assess the expression of markers of lens cell differentiation in serum-free primary cultures of embryonic chick lens epithelial cells grown on laminin (DCDMLs). Activation of ErbBs, Smad3, ERK, and p38 was assessed using phospho-specific antibodies.

Results: Inhibitors of either ERK or ErbB signaling block TGF β from upregulating both early (fibronectin) and late (α SMA) markers of myofibroblast differentiation. TGF β stimulates ERK in DCDMLs within 1.5 h. Kinase inhibitors of ErbBs, but not of other growth factor receptors active in lens cells, reduce the phosphoERK signal to below basal levels in either the absence or presence of TGF β . This effect is attributable to constitutive ErbB activity playing a major role in regulating the basal levels pERK. Additional studies support a model in which TGF β -generated reactive oxygen species serve to indirectly amplify ERK signaling downstream of tonically active ErbBs to mediate EMyT.

Conclusions: By mechanistically linking TGF β , ErbB, and ERK signaling to myofibroblast differentiation, our data elucidate a new role for ErbB in the lens and reveal a novel mode by which ERK directs lens cell fate.

ABSTRACT BODY:

Purpose: To report the characteristics of inflammatory features seen in EYS-associated ARRP.

Methods: We retrospectively identified 20 subjects (M=8/F=12, age 23-80), all of whom had undergone a complete eye examination, inclusive of visual fields (VFs) and flash ERGs, macular (n=20) and optic nerve (n=13) spectral domain optical coherence tomography (SD-OCT) and, in 12 of them, fluorescein angiography (FA) and CLIA-certified testing for circulating auto-antibodies (AABs) against retinal and/or retrobulbar optic nerve antigens by either immunoblot or Western blot, as well as retinal immunohistochemistry (IHC).

Results: All 12 patients who underwent FA showed optic nerve head leakage, involving also the vascular arcades in 4 cases. RNFL was thickened, most often sectorally, in 12 of 13 patients assessed, and correlated well with FA leakage, helping explain disproportionate visual acuity losses compared to foveal findings or disproportionate VF loss compared to retinal imaging or functional findings. Cystoid macular edema (CME) was seen by SD-OCT in only 3 patients. AABs were identified in all tested subjects. Anti-retinal AABs were found in 11 of the 12 tested patients [most common: anti enolase (8/12) and TULP1 (4/12)]. AABs recognizing anti-optic nerve antigens were found in 8 out of 9 tested patients. AABs against both tissues were seen in 6 patients. Retinal IHC showed positive staining in 9 of 12 cases, predominantly labeling photoreceptors (8/12) and less frequently ganglion cells and RNFL. Altogether, 70% (14/20) of patients exhibited signs of overt inflammation and, in 12 of them, they were associated with an autoimmune component that correlated closely with imaging and functional findings. These patients received intravitreal and/or sub-Tenon steroid injections, with both subjective and measurable increase in vision (acuity, visual field, or both), associated with improved OCT and IVFA characteristics achieved in most.

Conclusions: Inflammation involving both retina and/or optic nerve (disc, RNFL, RGC) appears to be a common yet underdiagnosed feature of EYS-associated ARRP, affecting the majority of patients. These changes can be readily detected with OCT and FA, and can be further confirmed by AAB/IHC testing. Identification of these complications is clinically and prognostically important, as meaningful vision improvement can be achieved with peri/intraocular steroid injections.

ABSTRACT BODY:

Purpose: We recently reported a multimodal, imaging-based classification classifying Central Serous Chorioretinopathy (CSCR) into simple and complex types depending upon the extent of the disease. In this retrospective, multi-center, observational clinical study, we aimed to investigate subfoveal choroidal thickness (SFCT) among different types of CSCR and its predictive role for treatment outcomes for each subgroup.

Methods: 104 patients with CSCR underwent retrospective chart review focusing on date of initial presentation followed by 3, 6 and 12 month follow-up. Patients were classified into simple or complex CSCR based on a priori clinical criteria and then further classified into primary, recurrent or resolved depending on their clinical course. Various OCT parameters including SFCT, outer retinal atrophy, and central macular thickness (CMT) were evaluated at each visit by masked observers.

Results: Of all studied patients, average age was 52.7 ± 10.6 years with 66.7% being male. The odds ratio of developing recurrent CSCR versus primary CSCR between simple and complex initial presentations was 0.115 (95% CI 0.040-0.350). The mean initial CMT in simple primary was 446.19 ± 136.51 versus 360 ± 48.56 ($p < 0.05$). The mean initial SFCT between simple CSCR and complex CSCR was 384.95 ± 97.48 and 419.05 ± 106.64 ($p < 0.10$).

Conclusions: Preliminary data suggests that there is prognostic and diagnostic value in SFCT and CMT on initial presentation. The future implication for this project is to use clinically objective data to guide treatment as per a new multimodal classification. Further retrospective chart review is underway to increase statistical power and there is ongoing analysis to investigate the relationship between SFCT and CMT to treatment response.

TITLE: Emergency Department Ophthalmology Consultation Trends at Two Level-One Trauma Centers

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Williams, A. Marin, H. Neves da Silva, J. Patnaik, R. Pieterick, N. Fischer, J. Smith, Ophthalmology, University of Colorado, Denver, Colorado, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eric Williams: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Marin: Commercial Relationship: Code N (No Commercial Relationship) | Helio Neves da Silva: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Patnaik: Commercial Relationship: Code N (No Commercial Relationship) | Ryan Pieterick: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Fischer: Commercial Relationship: Code N (No Commercial Relationship) | Jesse Smith: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Limited outcome and descriptive data exist regarding ocular complaints that presents to Emergency Departments (ED) within the United States. We performed a retrospective review of ophthalmology consults at two level-one trauma centers in Colorado to identify trends for ophthalmic consultation and factors associated with urgent and emergent pathology.

Methods: This study consisted of a retrospective chart review of ED consults to the ophthalmology service that occurred between Feb 25th, 2016 and Feb 25th, 2018. Characteristics such as patient age, sex, race/ethnicity, illicit drug use, and medical insurance status were recorded. Encounter measures included chief complaint, diagnostic steps, diagnosis at the ED, timeframe to follow-up, final ophthalmologic diagnosis as well as intervention and disposition. We categorized consultations into three groups depending on the final ophthalmic diagnosis: emergent, urgent, and non-emergent. Emergent diagnoses were defined as those requiring a procedure or surgery during the encounter. Urgent diagnoses were pre-defined conditions that required prompt treatment such as uveitis, orbital fracture, and corneal ulcer among others. Non-urgent diagnoses did not require further treatment or intervention.

Results: A total of 695 charts were identified, 288 at the University of Colorado Hospital and 407 at Denver Health Medical Center. Females comprised 247 (35.5%) of the encounters. The average age at presentation to the ED was 42 years old. Most ED visits were emergent, 53.7%, followed by non-urgent, 29.8%, and 15.8% were urgent. Only 465 (67.5%) of all visits had a visual acuity checked. Males were significantly more likely to present with trauma (33.9% vs 15.4%, $p < 0.0001$) and more likely to have emergent or urgent diagnoses (67.0% and 75.4% male, $p = 0.0001$) compared to females. Of the 473 patients that were discharged from the ED with ophthalmology follow-up, only 283 (59.8%) were seen within 30 days of their initial presentation.

Conclusions: Ophthalmology consultation analyses in the emergency room allow us to identify areas for improvement in care of our patients related to urgent complaints. Inconsistency of initial ED exams may account for high numbers of unnecessary ophthalmology consultations. More information is needed to understand why there is poor ophthalmology follow-up after ED consultations.

TITLE: Endpoint management in central serous chorioretinopathy

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Shekoh, V. Gonzalez, Valley Retina Institute, McAllen, Texas, UNITED STATES|V. Gonzalez, Gulf Coast Eye Institute, Texas, UNITED STATES|Q. Shekoh, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Noor-UI-Ain Shekoh: Commercial Relationship: Code N (No Commercial Relationship) | Quratulain Shekoh: Commercial Relationship: Code N (No Commercial Relationship) | Victor Gonzalez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Central serous chorioretinopathy (CSCR) is a disorder characterized by hyperpermeability of choroid and accumulation of serous fluid between retinal pigment epithelial (RPE) and outer photoreceptors, with RPE focal defects and detachments. It is mostly a self-limiting disease but sometimes results in chronic accumulation of fluid and consequent visual dysfunction.

Several treatment modalities are available including focal Argon photocoagulation, micropulse therapy, endpoint management with thermal laser, and reduced fluence photodynamic therapy (PDT). The purpose of our study was to see the effect of endpoint management (EPM) with thermal laser on the resolution of subretinal in CSCR. We chose this modality because it is efficient in stimulating RPE to pump fluid out of the retina and safe because it does not damage RPE as evident on retinal imaging.

Methods: Seventeen patients diagnosed with CSCR on clinical exam and multimodal imaging- Fluorescein angiography (FA), fundus autofluorescence (FAF), and optical coherence tomography (OCT), with center involving subretinal fluid (SRF), were selected. Patients with any other central retinal problems were excluded from the study. After obtaining informed consent, a light intensity burn was applied outside the vascular arcades then the laser power was titrated to 30%. The affected area was treated. Patients were followed up on post-op week 1, month 1, and month 3 for the clinical exam. OCT testing with Heidelberg Spectralis was done to evaluate treatment results.

Results: Patients were followed up to see the effect of laser on the resolution of fluid. In the case of partial resolution/recurrent SRF, retreatment was done on month 3.

SRF resolved in 52.9%, improved in 23.5%, and remained stable in 23.5% of patients.

Visual Acuity improved in 52.9%, deteriorated in 17.6%, and remained stable in 29.4% of patients.

The absence of RPE scarring or atrophy attributable to laser was confirmed on OCT in all patients.

Conclusions: Endpoint management is an effective and efficient method of treating center involving CSR with vision loss. It speeds up sub-retinal fluid absorption and improves visual rehabilitation without damaging retinal pigment epithelium.

TITLE: The suppressive effect of ICP22 on CD80 promoter is altered by a recombinant virus lacking CD80 binding site

SESSION TITLE: Antimicrobials and Immunomodulators

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Matundan, S. Wang, U. Jaggi, J. Yu, H. Ghiasi, Surgery, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Harry Matundan: Commercial Relationship: Code N (No Commercial Relationship) | Shaohui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Ujjaldeep Jaggi: Commercial Relationship: Code N (No Commercial Relationship) | Jack Yu: Commercial Relationship: Code N (No Commercial Relationship) | Homayon Ghiasi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently reported that ICP22 plays a major role in downregulating the host CD80 expression upon HSV-1 ocular infection in mice. Our previous report demonstrated that using D22 virus which has a complete deletion of full length ICP22, maintained CD80 expression and still remained virulent despite lower viral replication and ex vivo reactivation. To further study the effect of ICP22 on viral replication and disease severity, we mapped the ICP22 binding site to CD80 and constructed a mutant HSV-1 which is not binding to CD80. We now have characterized the effect of the absence of ICP22 binding to host CD80 in vitro and in vivo. expression.

Methods: To identify the binding region of ICP22 to CD80 promoter, ICP22 gene was fragmented to shorter regions and the effect of these fragments on suppression of CD80 promoter were analyzed with luciferase assay. Based on these assays, we have constructed a recombinant HSV-1 which is not binding to CD80 (KOS-ICP22Δ40). We compared KOS-ICP22Δ40 virus replication in vitro with parental control virus. Following corneal scarification, BALB/c mice were ocularly infected with 2×10^5 pfu/eye of KOS-ICP22Δ40 and parental viruses and primary virus replication in the eye, corneal scarring and latency-reactivation in the infected mice were determined.

Results: Western blot analysis of 293 HEK cells infected with KOS-ICP22Δ40 virus expressed a smaller fragment of ICP22 as compared to parental virus infected cells. CD80 expression was restored in the mice infected with KOS-ICP22Δ40 virus as compared with the parental control virus. Interestingly, primary viral replication in the eye and corneal scarring was slightly reduced in KOS-ICP22Δ40 virus infected mice as compared to the parental KOS infected mice. The level of latency and reactivation remained the same in both the infected mice groups.

Conclusions: We have identified HSV-1 ICP22 binding site to cellular CD80 and shown that blocking this interaction using a recombinant HSV-1 lacking CD80 binding site reduced primary virus replication in the eye and eye disease but had no effect on latency-reactivation. As there is currently no effective treatment for HSV-1 recurrences, interfering with ICP22-CD80 interaction may represent a clinically effective and expedient target in developing HSV-1 therapeutics.

ABSTRACT BODY:

Purpose: Geographic atrophy (GA) is a progressive form of AMD characterized by sharply defined oval-to-round areas of retinal atrophy which increase in size and coalesce to cause loss of vision affecting more than 5 million people worldwide. Currently, there is no effective treatment for GA. In this study, we evaluated the effects of oral supplementation with resveratrol, quercetin, and curcumin (RQC) on the size and annual GA growth rate in subjects with advanced dry AMD over one year.

Methods: AMD patients with nascent (n=3) or advanced (n=7) GA were recruited from Zaparackas and Knepper, Ltd after IRB approval and written consent. A total of 12 eyes were included in the study consisting of 3 with nascent GA and 9 with advanced GA. Each patient received 200 mg resveratrol, 240 mg quercetin, and 2000 mg curcumin per day for twelve months and had fundus autofluorescence (FAF) images recorded with the Heidelberg Spectralis OCT at three-month intervals. Advanced GA was defined as hypofluorescent regions of macular atrophy greater than 0.15 mm² and was confirmed on OCT images using hyperreflectivity in the choroid region. Nascent GA was defined as regions of atrophy no greater than 0.015 mm². GA area was quantified using a precise and reproducible post-processing procedure with ImageJ software. GA growth rate was reported in mm²/year and square root transformed mm/year.

Results: The annual growth rate for advanced GA was 0.35 ± 0.66 mm²/year (square root transformed 0.10 ± 0.11 mm/year). The growth rate for nascent GA was 0.01 ± 0.02 mm²/year (square root transformed 0.02 ± 0.03 mm/year). Compared with the natural GA growth rate reported by Yehoshua, et al. (2011) of 1.20 ± 0.90 mm²/year (square root transformed 0.18 mm/year), the GA growth rate of subjects taking oral RQC was significantly lower (P=0.003).

Conclusions: The annual rate of GA growth was significantly decreased in subjects taking oral RQC. Our results indicate that RQC may be the first safe and efficacious therapy for the slowing or prevention of GA progression.

Commercial Relationships Disclosure (Abstract): Jose Paczka: Commercial Relationship: Code N (No Commercial Relationship) | Sara Aurora Garcia y Otero Sánchez: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Ibañez Sandoval: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Tornero-Jimenez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The micropulse transscleral cyclophotocoagulation (MP-TSCPC) has been proven to treat refractory glaucomas, mainly with very limited vision. Very scarce information is present regarding results with this relatively new treatment on patients with good vision. The aim of this study is to investigate the short-term efficacy and safety of MP-TSCPC on a consecutive case series of refractory glaucoma cases in eyes with good vision.

Methods: A retrospective review of consecutive case series of adult patients with refractory glaucoma and BCVA \geq 20/40 which underwent MP TSCPC in a specialized center in Western Mexico. All consecutive cases with complete clinical information during at least 6 months of follow up were included. A surgical procedure success was defined if the following standard criteria were met: (1) the postoperative OP remained in a range of 5-21 mm Hg and was reduced at least 30% compared to the baseline IOP with or without medication (complete or qualified success), (2) there was no loss of light perception or vision threatening severe complications, and (3) no additional glaucoma surgery was required. Minor and major complications as well as their outcomes were also registered. A p value \leq 0.05 was considered statistically significant.

Results: Fourteen eyes of 14 patients (mean age, 58.5 ± 21.6 years; 8 female, 6 male) were included in the study. All eyes had a logMAR BCVA above 0.4. Mean power and time of MP TSCPC were $2,550 \pm 208.4$ mW and 146.3 ± 45.6 seconds, respectively. Preoperatively, the mean intraocular pressure (IOP) was 36.42 ± 9.81 mm Hg. Postoperatively, the mean IOP significantly decreased at all follow up points: 24.6 ± 7.9 mm Hg at 1 day ($P=0.0004$), 14.12 ± 5.9 mm Hg at 7 days ($P<0.0001$), 13.2 ± 6.5 mm Hg at 1 month ($P<0.0001$), 14.9 ± 6.2 mm Hg at 3 months ($P<0.0001$), and 16.3 ± 5.4 mm Hg ($P<0.0001$) at 6 months. The success rate was 85.7% at 6 months. Two cases required reoperation during the 6 months of follow up. Two cases with prior macular edema had a self-limited recurrence.

Conclusions: This study provides short-term evidence that MTS-CPC when used in eyes with good vision is a clinically useful procedure that effectively reduces IOP maintaining a very good safety profile.

TITLE: Optical coherence tomography offers a new window into newt lens regeneration

SESSION TITLE: Lens Development and Differentiation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Salles, G. Tsissios, W. Chen, H. Wang, K. Del Rio-Tsonis, Miami University, Oxford, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Anthony Salles: Commercial Relationship: Code N (No Commercial Relationship) | George Tsissios: Commercial Relationship: Code N (No Commercial Relationship) | Weihao Chen: Commercial Relationship: Code N (No Commercial Relationship) | Hui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Katia Del Rio-Tsonis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In adult newts lens regeneration is especially fascinating as the regenerated lens originates from a completely different tissue through reprogramming of the iris pigmented epithelium. However, this process has never been visualized in real time or 3D. Our goal was to establish optical coherence tomography (OCT) as an in vivo imaging platform to characterize the process of lens regeneration.

Methods: Two separate studies were performed in adult red spotted newts, *Notophthalmus viridescens*. In the first study, the lens was surgically removed from 39 newts. Over the course of 80 days 3 newts were taken per time point, imaged by OCT, then immediately sacrificed and the eyes processed for histology. The second study consisted of acquiring OCT images over 60 days from a single newt. At the 60th day, the newt eye was collected and processed for histology. OCT images were acquired at 800nm with ~8µm lateral resolution and ~3µm axial resolution.

Results: OCT captured key morphological changes associated with lens regeneration in live newts such as corneal wound healing, accumulation of ECM, migratory cells, lens vesicle formation and its differentiation into a lens with clear lens epithelium and lens fibers as well as dilation of blood vessels. These OCT images were validated with corresponding histological images collected from the same newt eye. The 3D view provided by OCT demonstrated the regenerating lens vesicle adopts an elliptical form extending along the dorsal iris tip. The lens vesicle became spherical in shape around 4 weeks post lentiectomy. From the 3D reconstructions, we calculated the changes in volume size enabling a quantitative measure to monitor the progression of the lens regeneration process with time.

Conclusions: This is the 1st report describing both in vivo and 3D imaging of the newt lens regeneration process using OCT. As verified by histological analysis, OCT is a reliable imaging tool to monitor the regenerating lens and the dynamic changes that occur in the eye during this process. Detecting the lens vesicle in as little as two weeks after lentiectomy highlights the power of OCT. Future work includes characterizing the identity and function of the migrating cells detected by OCT, and to establish OCT as a semi-high throughput quantitative platform to screen inhibitors and activators of lens regenerative potential in the newt eye.

TITLE: Timing of Orbital Fracture Repair in Children

SESSION TITLE: Neuro-Ophthalmology and Oculoplastics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K. Revere, E. Meer, Y. Schein, A. Spiller, G. Binenbaum, Ophthalmology, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, UNITED STATES|K. Revere, Y. Yu, G. Ying, Ophthalmology, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Karen Revere: Commercial Relationship: Code N (No Commercial Relationship) | Elana Meer: Commercial Relationship: Code N (No Commercial Relationship) | Yinxi Yu: Commercial Relationship: Code N (No Commercial Relationship) | Yvette Schein: Commercial Relationship: Code N (No Commercial Relationship) | Alyssa Spiller: Commercial Relationship: Code N (No Commercial Relationship) | Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship) | Gil Binenbaum: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Delaying repair of orbital fractures without muscle entrapment has recently been advocated in adults. Observation may result in recovery without a need for surgery, and outcomes following later surgery appear similar to earlier surgery. However, studies addressing this issue in children are limited. We sought to determine the preferred timing for orbital fracture repair in children.

Methods: Retrospective cohort study of children with orbital fracture, classified into groups based on presence of entrapment and timing of repair. Early repair was defined as surgery within 3 weeks of injury. A successful clinical outcome was defined as absence of both enophthalmos and strabismus at latest follow-up. Presenting findings, including muscle entrapment, enophthalmos, motility restriction, and fracture size, were considered as potential confounding factors or indications for surgery.

Results: We studied 147 children with orbital fracture (median age 12 years, range 0.2-18; median follow up 3.1 months, range 0.3-103). 11(7.5%) had entrapment and had surgery at median 1 day post-injury (range 0-15). Among 136 without entrapment, 30 had early repair (median 12.6 days, range 1-18) and 106 did not, of which 5 eventually had surgery (median 57 days, range 47-157) and 101 had no surgery. Successful outcomes were seen in 91% of children with entrapment, 93% of early repair, and 95% late/no repair ($p=0.65$). Success did not differ between early and late surgery (93% vs. 80%, $p=0.38$). Among 31 children with fracture size $>50\%$ and no entrapment, successful outcomes occurred in 19/21 (90.5%) with early surgery, 2/2 (100%) with late surgery, and 10/11 (91%) of children with no surgery. Among patients without entrapment, enophthalmos and motility limitation at baseline resolved without surgery in 6/8 (75%) and 9/10 (90%) cases, respectively.

Conclusions: Muscle entrapment is an indication for urgent orbital fracture repair. Otherwise, pediatric orbital fractures without entrapment should be observed for 3 months or more, as many patients will eventually not require surgery, and early surgery does not appear to improve outcomes. Contrary to long-held belief, extraocular motility limitation without entrapment, enophthalmos, or fracture size $>50\%$ are not indications for early surgery, as motility limitation and enophthalmos may resolve without surgery in a majority of cases, even when fracture size is large.

ABSTRACT BODY:

Purpose: To determine whether hypotony in patients with histories of intraocular inflammation is associated with anatomic changes in the ciliary body (CB) on high-frequency ultrasound biomicroscopy (UBM).

Methods: In this pilot study, we performed a retrospective chart review of patients with histories of intraocular inflammation, seen by 3 uveitis providers (2016-20), who underwent UBM, performed with the VuMAX HD (SonomedEscalon) using immersion technique (an exception was a child intolerant of the immersion shell, who underwent direct contact technique). Using ImageJ (National Institutes of Health), we measured CB thickness, and ciliary process (CP) length, thickness, density, and area for available high-quality scans of each quadrant. Patients were categorized into 2 groups based on UBM indication: hypotony (IOP \leq 5mmHg) or other. Linear regression with clustered robust standard errors at the patient-eye level were used to assess group differences in CB measurements.

Results: A total of 159 scans (35 eyes, 28 patients) were included. Each patient underwent a median of 4 scans (range 3–12). Mean age at time of UBM was 48.1 \pm 24.5 years (range 10–78 years), and 20 patients (71.4%) were female. Seventeen patients (60.7%) underwent UBM for hypotony and 11 (39.3%) for evaluation of intraocular lens position or preoperative planning. Categories of disease were: anterior (n=19, 67.9%), intermediate (n=2, 7.1%), posterior (n=2, 7.1%), and pan- (n=4, 14.3%) uveitis, and chronic post-operative endophthalmitis (n=1, 3.6%). Median disease duration at time of UBM was 2.7 years (range 14 days–23.0 years); the hypotony group had longer median duration of disease (5.0 vs. 1.3 years). Mean CB thickness was increased in the hypotony group versus the non-hypotony group (0.660 \pm 0.041 vs. 0.559 \pm 0.024 mm, p=.038). Means of all CP measures were decreased in the hypotony group versus the non-hypotony group, including length (0.502 \pm 0.066 vs. 0.738 \pm 0.039 mm, p=.004), thickness (0.254 \pm 0.031 vs. 0.370 \pm 0.014 mm, p=.001), density (2.9 \pm 0.3 vs. 3.8 \pm 0.1 processes/2 mm, p=.011), and area (0.920 \pm 0.12 vs. 1.44 \pm 0.08 mm², p=.001).

Conclusions: Hypotony as a late complication of intraocular inflammation appears to be related to anatomic changes in the ciliary body, which may result in decreased aqueous humor production. This hypothesis should be tested in a longitudinal study of uveitis patients who do and do not develop hypotony.

ABSTRACT BODY:

Purpose: The genes and pathways that contribute to early eye development are not well known. We hypothesize that screening of the International Mouse Phenotyping Consortium (IMPC) database for unique knockout mouse lines with embryonic eye defects will yield novel genes and pathways important for eye embryogenesis.

Methods: The IMPC web portal (impc.org) was interrogated for mouse embryos with ocular defects. Most of the eye abnormalities in knockout mouse embryos were small or absent eyes, findings most relevant to microphthalmia, anophthalmia, and coloboma (MAC) spectrum disease in humans. A literature search was performed to determine which of these mouse knockouts have been reported previously and if there were eye abnormalities associated with them. In addition, a "gold standard" list was created based on clinical literature of established genes associated with congenital MAC spectrum disease in humans. Gene ontology, protein-protein interaction networks, and functional annotation bioinformatics microarray analysis were used to analyze the predicted relationship between 1. human orthologs of the IMPC mouse genes and 2. the gold-standard MAC spectrum human disease genes to identify biochemical pathways involved in eye embryogenesis.

Results: Screening of the IMPC database of over 7,000 knockout lines resulted in 63 unique genes associated with embryonic eye defects. The literature search showed that 41 of the 63 had previously published knockout mouse models, and 22 did not. Out of the 41 published knockout mouse models, only 13 of them noted ocular defects in the original publication, and 28 of them did not. Therefore, the 28 published knockouts which did not previously detect ocular abnormalities and the 22 unpublished knockouts together represent 50 novel genes that contribute to early eye development in mice. The literature search also resulted in 114 gold standard human MAC disease genes, which were vetted against the 63 IMPC genes to show that several of the IMPC genes reveal a critical role for serine-glycine biosynthesis in early eye formation.

Conclusions: The genetic underpinnings of MAC spectrum disease are incompletely understood, however, serine-glycine biosynthesis may be a novel pathway associated with early eye development. Analysis of this pathway may hasten the diagnosis and treatment of this congenital blinding disease.

TITLE: Evaluation of in vivo murine modeling of Staphylococcus aureus bacterial keratitis

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Meijome, L. Azzouz, L.M. Niziol, M. Kriegel, M.A. Woodward, Ophthalmology and Visual Sciences, W K Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|R. Wozniak, Ophthalmology, University of Rochester Medical Center, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tomas Meijome: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Wozniak: Commercial Relationship: Code N (No Commercial Relationship) | Lyna Azzouz: Commercial Relationship: Code N (No Commercial Relationship) | Leslie Niziol: Commercial Relationship: Code N (No Commercial Relationship) | Matthias Kriegel: Commercial Relationship: Code N (No Commercial Relationship) | Maria Woodward: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Staphylococcus aureus, a predominant pathogen in bacterial keratitis (BK), is a significant contributor to worldwide disease burden of corneal vision loss and blindness. Validated animal models have historically played a critical role in the study of BK; however, a direct correlation to human disease has yet to be thoroughly established. We propose to advance our understanding of an established murine model of BK by correlating advanced image analysis, disease severity, and bacterial burden.

Methods: Twenty BALB/c strain mice underwent three parallel scratches of the left corneal epithelium and anterior stroma with subsequent inoculation of 5×10^6 S. aureus cells (50ml of 10^8 S. aureus cells/ml). At 48 hours post-infection, subjective clinical disease severity was graded based on an established scale from 0 (no clinically evident disease) to 4 (corneal perforation). Slit-lamp photography and image annotation with ImageJ were used to measure stromal infiltrate area (mm^2). Eyes were homogenized, and the bacterial load (colony forming units or CFU) was determined. Pearson and Spearman correlations were used to estimate the linear association between severity grade, ulcer size and CFUs.

Results: The average ulcer size was 1.3 mm^2 (SD = 0.9) and 50% were identified as grade 2 clinical severity (0: 5%, 1: 10%, 2: 50%, 3: 25%, 4: 10%). Bacterial burden was evaluated in twenty mice with mean of 8×10^5 CFU/ml (SD = 1.4×10^5 CFU/ml). A strong linear association was found between bacterial burden (CFUs) and stromal infiltrate measurements (Pearson correlation = 0.72, p = 0.0026,) and between CFUs and severity grade (Spearman correlation = 0.79, p = 0.0005). No significant correlation was found between severity grade and stromal infiltrate measurements (p = 0.17).

Conclusions: Clinical severity and corneal infiltrate size were both strongly correlated with the bacterial corneal load, suggesting that both clinical grading and image annotation approaches have potential to estimate disease severity in this murine model of BK. Further research in animal models will be important in developing risk stratification models and standardized treatment methods for human disease.

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) is a rare monogenic retinal disease that causes the atrophy of photoreceptor, cone and rod cells. Based on the defect of even a single causal gene converging at the same disease, we hypothesized that all of the genes that cause RP must be connected to each other through protein-protein interactions (PPIs) in this computational correlation study.

Methods: A final list of 161 genes that are known to cause RP was compiled using RetNet (<https://sph.uth.edu/RetNet/>) on Feb. 15, 2019. Of 161 genes, 159 were recognized and mapped by Search Tool for the Retrieval of Interacting Genes/Proteins (STRING), which uses PPIs as the measure of association. On the basis of the hypothesized interconnectedness among RP genes, we defined novel genes as the genes that may cause RP by interacting with the genes already attributed to the disease. The novel genes, which connect the ten previously disconnected genes, were then identified based on the PPI confidence levels to complete the network of RP genes. Further reorganization based on subcellular localization and previous literature of the 169 genes was conducted for analysis.

Results: Ten novel genes were discovered through PPIs at a minimum of 40% confidence for the initial 161 genes (Figure 2a). The categorization of cells based on subcellular localization showed that the genes with protein products localized in the rod outer segment (ROS) have the greatest number of PPIs. With the inclusion of these novel genes, all known causal genes of RP were connected to each other as hypothesized.

Conclusions: The successful establishment of PPIs among all documented genes and the discovery of novel genes for Retinitis Pigmentosa strongly support the global interconnectedness of the genes that cause the disease on the molecular level as hypothesized. Furthermore, the additional findings such as the greatest number of PPIs with respect to ROS and previous literature on the association of novel genes to RP support the hypothesis that all genes that cause Retinitis Pigmentosa must be interconnected.

ABSTRACT BODY:

Purpose: Chronic eye diseases (CED) share risk factors (RF) with cardiovascular disease (CVD). HCHS/SOL showed marked variation in 5 major CVD RFs (diabetes mellitus-DM, hypertension-HTN, smoking-SM, obesity-OB, hypercholesterolemia-HChl) by Hispanic/Latino group. Estimates of CED in Hispanics/Latinos without considering RF heterogeneity (e.g., only Mexican-Americans) yield inaccurate estimates of disease prevalence. We characterize the prevalence of visual disability and associated CVD RFs in HCHS/SOL.

Methods: Design, Setting and Participants: Multicenter, prospective, population-based HCHS/SOL subjects (n=9663), ≥40y age, completing Visit #2 (2014-2017). Age-adjusted prevalence of visual disability and CVD RFs were calculated weighting for study design. Adverse CVD RFs were defined using national guidelines. Main outcome measure: Age-adjusted prevalence of self-reported visual disability defined by the US Census Bureau's American Community Survey definition, "being blind or having serious difficulty seeing even when wearing glasses."

Results: 9324 subjects with complete data were analyzed. Sex-specific prevalence of CVD RFs and adverse CVD RF profile varied significantly by Hispanic/Latino group. Visual disability prevalence (%) was higher in men with DM (estimate and 95%CI) 13.4% (10.4-16.4), HTN 11.3% (9.5-13.1), HChl 11.7% (9.8-13.7), OB 11.8% (9.5-14.1) and SM 12.5% (9.1-15.9) versus the overall estimate 10.6% (9.2-12.1). In women, visual disability prevalence was higher with DM 16.1% (13.5-18.8), HTN 15.5% (13.5-17.6), HChl 14.6% (12.3-16.9), OB 13.9% (12.0-15.7) and SM 16.8% (12.6-21.0) versus the overall estimate 13.5% (12.0-14.9). In men, visual disability prevalence was similar with 0-1 adverse CVD RFs [8.0% (3.9-12.1); 7.1% (5.1-9.1)] but increased with 2-3 adverse CVD RFs [10.9% (8.3-13.5); 13.5% (10.8-16.2)]. In women, visual disability prevalence increased with increasing adverse CVD RFs [0 RF, 9.5% (6.5-12.5); 1 RF 11.8% (9.4-14.2); 2 RFs 13.4% (10.8-16.0); 3 RFs 16.7% (14.0-19.5)].

Conclusions: A sizeable burden with marked variation exists for the prevalence of visual disability and adverse CVD RFs in Hispanic/Latinos. Results support SOL Ojos, an ancillary study that leverages HCHS/SOL heterogeneity, to assess CED-CVD risk factor associations in Hispanic/Latinos of diverse backgrounds.

ABSTRACT BODY:

Purpose: Whilst diabetic eye disease (DED) has long been a leading cause of certifiable visual impairment in the working age, hereditary eye disease (HED) has also become a leading cause in some countries. We explored trends in these causes of visual impairment registration in England and Wales over 10 years.

Methods: Individuals who meet specific criteria are eligible for a Certificate of Visual Impairment (CVI), at one of two levels, sight-impaired (SI) or severely sight-impaired (SSI). A single main cause is listed, together with additional causes where applicable. We explored CVI registrations for the 10 years between 2009 and 2019, where DED or HED were listed as main cause, in the working age (16-64 years) in particular, and also proportions of males in HED CVIs.

Results: In 2009-10, similar numbers of CVIs had DED and HED as the main cause (1334 and 1338 respectively). In 2018-19, respective numbers were 904 and 1539. Since 2014-15, CVIs due to DED were consistently <1000 annually, whilst those due to HED were >1400. In the 16-64 age group, DED and HED were the main causes for 600 and 720 CVIs respectively in 2009-10, and for 499 and 963 CVIs in 2018-19. In this age group, slightly more SI registrations were due to DED (n=355) than HED (n=350) in 2009-10. From 2013-2014 onwards, HED SI registrations were consistently higher; in 2019-19, 278 and 407 SI registrations were due to DED and HED respectively. For SSI registrations, these were consistently higher for HED, but the numbers diverged over the period: 279 SSI registrations were due to DED in 2009-10, and 347 in 2018-19; for HED, the numbers were 387 and 602. Over the period, males accounted for 53% of working age HED CVI registrations (95% CI, 0.52-0.54), for 55% of HED SSI registrations (0.53-0.56) and 51% of HED SI registrations (0.49-0.52).

Conclusions: In England and Wales, annual CVI registrations due to DED have fallen whilst those due to HED have risen. HED was consistently the leading cause of SSI registration in the working age, and overtook DED as leading cause of SI registration from 2013-14 onwards. Males accounted for just over 50% of HED CVI and HED SSI registrations (confidence intervals did not cross 50%). This might relate in part to males more severely affected by X-linked disease. Our findings highlight the increasing burden of visual impairment due to HED and the need for developing therapies.

Commercial Relationships Disclosure (Abstract): Matthew Wilneff: Commercial Relationship: Code N (No Commercial Relationship) | Rinald Paloka: Commercial Relationship: Code N (No Commercial Relationship) | Allison Wuller: Commercial Relationship: Code N (No Commercial Relationship) | Dashiell Wuller: Commercial Relationship: Code N (No Commercial Relationship) | Christian Miller: Commercial Relationship: Code N (No Commercial Relationship) | Shannon Wuller: Commercial Relationship: Code N (No Commercial Relationship) | David Miller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the incidence of post-injection endophthalmitis in patients wearing facemasks. We hypothesize that the incidence of post-injection endophthalmitis in patients wearing facemasks would be significantly greater than patients who were not wearing facemasks.

Methods: A retrospective cohort study was performed at a private retinal practice in Ohio. The practice management database was searched using CPT codes for endophthalmitis over two, six-month periods. The first cohort from 6/01/2019-12/31/2019, and the second, following universal facemask usage due to COVID 19, from 6/01/2020-12/31/2020. Patients who developed endophthalmitis post-intravitreal injection during the study period had their charts reviewed. Data collected included: age, sex, visual acuity, medication injected, administering physician, date of diagnosis, length of follow up, intervention, and cultured organism. Means of variables and chi-squared analyses were performed to determine statistical difference between non-masked and masked cohorts.

Results: A total of 25029 intravitreal injections were performed in the first study period with 34019 injections in the second. Of those injections, endophthalmitis occurred in 8 and 12 patients respectively. Incidence of post-injection endophthalmitis in the 2019 was .00039 and .00041 in 2020 (p-value= 0.8289). The mean age of patients was 69 years in 2019 and in 68 years in 2020. Average length of follow up in 2019 was 472 days, and 74 days in 2020. Average change in visual acuity from diagnosis to last follow up was .707 in 2019 and .945 in 2020. In 2019 all six positive cultures grew coagulase negative staph, in 2020 the three positive cultures yielded Streptococcus mitis, gram positive cocci, and rare skin flora.

Conclusions: We reject our hypothesis of, if patients were wearing masks during intravitreal injections, then there would be a significantly greater incidence of post-injection endophthalmitis. There was no significant association between wearing facemasks and post-injection endophthalmitis within our six-month study periods in 2019 and 2020. However, cultures between the two cohorts yielded different organisms, with one culture in 2020 presenting an organism typically found in oral flora.

TITLE: Effect of genipin on the metabolic activity of porcine lamina cribrosa cells

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.P. Vande Geest, J. Liou, Bioengineering, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|J.P. Vande Geest, Ophthalmology, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jonathan Vande Geest: Commercial Relationship: Code N (No Commercial Relationship) | Jr-Jiun Liou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the effect of scleral stiffness on the susceptibility to glaucoma, Kimball et al. treated mouse eyes with glyceraldehyde alone via subconjunctival injections and found no effect on retinal structure or function. However, in mice with experimental glaucoma, glyceraldehyde significantly increases intraocular pressure and axon loss at 6 weeks. It therefore may be that de-stiffening of the sclera can rescue or halt glaucomatous damage. The effect that stiffening or de-stiffening agents have on the health of lamina cribrosa cells has not been fully quantified in the literature. In this preliminary study, we evaluated the effects of genipin on optic nerve head cells, specifically, lamina cribrosa cells.

Methods: Porcine lamina cribrosa (LC) cells were isolated from three fresh pig eyes purchased commercially. Cell characterization was performed using anti-alpha smooth muscle actin (α SMA) and anti-glial fibrillary acidic protein (GFAP) antibodies from Abcam. Cells at passage 3 were seeded onto a 24-well plate and cultured in DMEM medium with 10% Fetal Bovine Serum, 2.5% HEPES, 1% Amphotericin B and 1% Penicillin-Streptomycin. Genipin was reconstituted in medium at a final concentration of 10 mM. MTS assays were performed on day 3, day 7, and day 10 to quantify the metabolic activity of these cells.

Results: Porcine LC cells are characterized as α SMA positive and GFAP negative (Figure 1A). Genipin at 10 mM significantly reduces the metabolic activity of LC cells in monolayer cultures on day 3, day 7, and day 10 (Figure 1B). The metabolic activity of genipin group is no different than the negative control (Figure 1B).

Conclusions: Genipin at 10 mM reduces the metabolic activity of LC cells. Future investigations are needed to examine the effects of genipin at a lower concentration (1 mM or 5 mM) in order to conclude the cytotoxic effects of genipin. We are currently working on eye culture with genipin treatment and examine the stiffening effects via whole globe inflation tests.

ABSTRACT BODY:

Purpose: Metal oxide nanoparticles (NPs) zinc oxide (ZnO) and titanium dioxide (TiO₂) are routinely applied near the eye via cosmetics and sunscreens. Despite the high probability of exposure there remains a paucity of research as to the ocular consequences. The biomechanics of the corneal stroma are altered during wound repair, indicating a need to examine mechanics in ocular toxicity. We hypothesize that ZnO and TiO₂ NPs increase the mechanical stiffness of corneal fibroblast cells, and thus contribute to keratocyte-fibroblast-myofibroblast transformation.

Methods: Rabbit Corneal Fibroblasts (RCFs) at passage 6 were cultured with and without 10 ng/mL Transforming Growth Factor Beta 1 (TGFβ-1) for 48 h at which time phosphate buffered saline (PBS-control), 10 µg/mL ZnO or 250 µg/mL TiO₂ NPs were added, and cells incubated for an additional 24 hrs. After incubation cells were then gently washed 3x with PBS and live cell stiffness measured by Atomic Force Microscopy (AFM). For each experimental condition, 5 force curves per cell were collected from 10 individual cells. Force curves were taken with PNP-TR-50 silicon nitride cantilevers that were calibrated for the deflection inverse optical lever sensitivity by indentation in PBS on glass and the spring constant determined using the Asylum Research software at a scan velocity of 1.98 µm/s. Data were analyzed to determine elastic modulus and were obtained by mathematically fitting the indentation curves to the Hertz model for spherical geometry and then subjected to a one-way analysis of variance (ANOVA) followed by Tukey's test.

Results: RCFs exposed to ZnO and TiO₂ NPs had a significantly ($p < 0.001$) greater elastic modulus than control cells to a degree that approximated the effect seen with TGFβ-1 alone. For ZnO, the degree of stiffening was not augmented by the presence of TGFβ-1. RCFs treated with TiO₂ NPs were stiffer and in contrast to results obtained with ZnO NPs, the effect was significantly augmented by TGFβ-1.

Conclusions: ZnO as well as TiO₂ NPs increased stiffness of RCFs. The degree of stiffening induced by ZnO NPs was unaffected by the presence or absence of TGFβ-1. For TiO₂, TGFβ-1 further increased the stiffness of cells. These results suggest that ZnO and TiO₂ NPs alter cytoskeletal dynamics and further studies of the NPs on KFM transformation during stromal wound healing are warranted.

TITLE: Retinal Microglia Depletion as a Tool to Determine the role of Microglia-Mediated Inflammation in the Diabetic Retina

SESSION TITLE: Retinal diseases: molecular and biochemical mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Church, D. Vanegas, A. Cardona, Biology, The University of Texas at San Antonio, San Antonio, Texas, UNITED STATES|A.S. Mendiola, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kaira Church: Commercial Relationship: Code N (No Commercial Relationship) | Difernando Vanegas: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Mendiola: Commercial Relationship: Code N (No Commercial Relationship) | Astrid Cardona: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR), an incurable eye disease caused by prolonged high glucose levels in the retina, is a leading complication of diabetes mellitus and the leading cause of blindness amongst working age adults. Chronic hyperglycemia damages retinal blood vessels leading to hemorrhages, ischemia and ultimately vision loss. Microglia, the resident immune cells of the central nervous system, are believed to contribute to the development of DR. Microglial activation is largely regulated via the CX3CR1-fractalkine (FKN) signaling axis in which microglia express the CX3CR1 receptor, and neurons express it's only ligand, FKN. A polymorphic variant of the CX3CR1 gene, present in 25% of the population, causes the CX3CR1 receptor to be adhesive defective to FKN. Previous studies have shown that aberrantly activated microglia in the diabetic retina are responsible for increased vascular damage, microglial clustering around vascular lesions, fibrinogen leakage, microgliosis, and up-regulation of proinflammatory mediators in CX3CR1-KO and human CX3CR1^{I249V/M280} expressing mice. Microglia appear to play an important role in mediating neuroretinal inflammation and degradation in DR. To understand the role of microglia in DR progression we depleted microglia to determine if strategies to downregulate microglia mediated inflammation can prevent neuronal damage and hence vision loss.

Methods: Utilizing a genetic model using mice expressing an inducible Cre under the CX3CR1 promoter and the DTR gene under the Rosa 26 promoter (CX3CR1^{CreER}:R26^{iDTR}), expression of DTR by CX3CR1-expressing cells only occurs upon tamoxifen (TAM) treatment, rendering microglia susceptible to the effects of diphtheria toxin.

Results: Following acute microglia depletion in diabetic CX3CR1^{CreER}:R26^{iDTR} mice, we depleted ~90% of microglia in the retina without depleting CX3CR1-expressing cells in the periphery. We observed an increase in neuronal cell loss and astrogliosis, without significant axonal damage. These results reveal that we can successfully deplete microglia in the retina without effecting peripheral immune cells or eliciting neurotoxic effects in the murine diabetic retina.

Conclusions: Further studies looking at chronic depletion of activated microglia and aberrantly activated CX3CR1-M280 microglia in DR retinas are crucial to potentially to ameliorate inflammatory-mediated damage to neurons.

ABSTRACT BODY:

Purpose: Müller cells, the major retinal macroglia, contribute to maintain vascular integrity as well as retinal fluid and ion homeostasis. Although PDGF receptor expression in Müller glia has been reported earlier, their actual role for Müller cell function and intimate interaction with cells of the retinal neurovascular unit remains unclear.

Methods: Müller cell-specific PDGF receptor alpha (PDGFR α) knockout (KO) were generated by crossbreeding a tamoxifen-inducible Glast-CreER^{T2} driver line with PDGFR α ^{fl/fl} mice. We isolated Müller cells (4 weeks post-tamoxifen injection) by MAC sorting and analyzed the efficiency of Müller cell-specific deletion of PDGFR α at mRNA and protein level by qPCR and immunofluorescence. To analyze the functional role of PDGF in Müller cell physiology, we performed volume regulation experiments in vital retinal slices. We also evaluated the retinal functional integrity by electroretinogram recordings (ERG). To investigate the role of PDGF signaling in Müller glia in retinal diseases, we subjected Müller cell-specific PDGFR α KO mice to a model of choroidal neovascularization (CNV) and analyze the retinal vasopermeability.

Results: We demonstrated the usability of double transgenic Glast-CreER^{T2};PDGFR α ^{fl/fl} (PDGFR α KO) mice to induce Müller cell-specific PDGFR α knockout. The vast majority of isolated Müller cells from those mice were lacking immunoreaction for PDGFR α and the mRNA levels of Pdgfra were also significantly downregulated in comparison to wild type controls. PDGFR α -deficient Müller cells could not counterbalance hypoosmotic stress as efficiently as their wildtype counterparts. In wildtypes, the PDGFR α ligand PDGF-BB prevented Müller cell swelling induced by administration of barium ions. This effect could be blocked by the PDGFR family inhibitor AC710. PDGF-BB could not restore the capability of an efficient volume regulation in PDGFR α KO Müller cells. Additionally, PDGFR α KO mice displayed reduced ERG response. Remarkably, Müller cell-specific PDGFR α KO resulted in less vascular leakage and smaller lesion area in the CNV model.

Conclusions: In sum, our data support the hypothesis that PDGF signaling is central for retinal functions under physiological conditions. These data imply that targeting PDGF to treat retinal neovascular diseases may have short term beneficial effects, but may elicit unwarranted side effects given the putative negative effects on Müller cell homeostatic functions.

ABSTRACT BODY:

Purpose: Refractive surgery, although it causes very few complications and a rapid recovery of the patient, very little attention has been given to the issue of corneal temperature during this type of surgical procedure. The temperature becomes something important to be evaluated because an ablation laser is used during the procedure, which can cause injuries to the tissue due to the thermal energy inserted locally in the ablation region. Thus, the idea of this study is to deepen this knowledge using a digital infrared thermal image to evaluate how invasive this procedure can be from a perspective of the thermal energy inserted in this process and its relationship with the physiology of cornea.

Methods: Thermal digital images were obtained at a distance of 40cm from the ocular surface and performed at a rate of 30 frames/s using infrared cameras, model: T540 (sensitivity <40mK/resolution 464 x 348 pixels) and A6753sc (sensitivity <30mK/640x512 pixels Flir System), the data were analyzed via software and we used infrared radiation intensity and temperature of regions of interest, ablation site, pre and post procedure eye temperature, and all areas of interest were analyzed the maximum, minimum and average temperature, and also calculated the dissipated energy in Watts. Surgery was performed in an environment with controlled temperature and humidity, ablation of the corneal surface was performed with Excimer laser, with a spherical profile of 6-7mm and maximum ablation time of 16s.

Results: Thirty uneventful surgical procedures were analyzed, with the patients acclimatized in a room at 23°C and 50% relative humidity. The average global ocular surface temperature was 30.33±0.45°C after flap-elevating in LASIK procedures or epithelial debridement in PRK procedures, before the ablation; energy input was 0.26 Watts/s exposure. The tissue returned to pre-exposure temperature 3.5s after the application of laser, on average. The peak temperature is closely linked to the laser exposure time, and the maximum peak observed was 36.11°C.

Conclusions:

In this research, in photo-refractive procedures, where peaks of almost 6 ° C on the corneal surface were observed, the 30 corneas studied were able to return to the temperature before the procedure very quickly, 3.5 seconds on average, showing a prepared physiology for these temperature variations, avoiding tissue damage. Larger diopters led to a longer recovery time.

ABSTRACT BODY:

Purpose: To investigate the intrinsic autofluorescent (AF) granules in the retinal epithelium (RPE) cells of mouse retina and their AF emission properties using multicolor confocal fluorescent microscopy (MCFM). Compare the in vivo recorded spectra with ex vivo measured spectra with MCFM for the mouse model of Stargardt's disease (*Abca4*^{-/-} [129S4]) and agouti WT control.

Methods: In situ imaging of RPE flat-mounts from agouti *Abca4*^{-/-} (129S4) and agouti WT (129S1/SvImJ) controls, was performed with a Nikon A1 confocal microscope. High-resolution confocal image z-stacks of the RPE cell mosaic were acquired with four different excitation wavelengths (405nm, 488nm, 561nm, and 640nm). In vivo AF spectra for same four excitation wavelengths are acquired with a spectrometer-integrated SLO system from both mice strains. The autofluorescence images of RPE, including voxel-by-voxel emission spectra, were acquired, and processed with Nikon NIS-AR Elements software.

Results: MCFM provided an enhanced visualization of the RPE cell mosaic, including melanosomes and lipofuscin granules, and their variations in *Abca4*^{-/-} and agouti WT control mice. MCFM allowed the extraction of AF emission spectrum from the individual granules. Acquired in vivo spectra are compared with the ex vivo measured spectra for both mice strains.

Conclusions: MCFM can delineate individual RPE autofluorescent granules and provide their characteristics AF emission spectra. Lipofuscin granules and melanosomes are the two major pigmented granules. Lipofuscin granules are identified as the major source of AF from RPE whereas, melanosomes completely lack fluorescence in visible excitation ranges. The in vivo acquired spectra are in good agreement with the ex vivo spectra. This comparison also revealed the source of FAF and their changes in disease model.

TITLE: Utility of a postoperative hour one intraocular pressure evaluation to predict postoperative day one management changes after uncomplicated pars plana vitrectomy

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.S. Borkar, F. Brodie, A. Ponugoti, A. Song, A. Ayala, X. Zhang, Duke University Eye Center, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Durga Borkar: Commercial Relationship: Code N (No Commercial Relationship) | Frank Brodie: Commercial Relationship: Code N (No Commercial Relationship) | Arathi Ponugoti: Commercial Relationship: Code N (No Commercial Relationship) | Ailin Song: Commercial Relationship: Code N (No Commercial Relationship) | Alexandria Ayala: Commercial Relationship: Code N (No Commercial Relationship) | Xinxin Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The current COVID-19 pandemic has emphasized the need for streamlining in person office visits while maintaining clinical outcomes and patient safety. Prior studies have shown that an intraocular pressure (IOP) increase at postoperative day one (POD1) is the primary clinical finding necessitating an unexpected management change after uncomplicated pars plana vitrectomy in asymptomatic patients. The purpose of this study was to evaluate whether a postoperative hour one (POH1) IOP measurement in the postoperative recovery area can predict a POD1 IOP elevation.

Methods: Retrospective chart review was performed at an academic medical center of all cases of uncomplicated pars plana vitrectomy (with or without scleral buckle) for which POH1 IOP was measured between November 2019 and May 2020. The preoperative evaluation, operative report, and POD1 visit were reviewed. Relevant clinical characteristics were recorded including history of glaucoma or ocular hypertension, administration of intraoperative acetazolamide, POH1 IOP, POD1 IOP, and any additional unexpected management changes at the POD1 visit.

Results: During the study period, 63 cases of 62 eyes had POH1 IOP evaluated. The most common indications for surgery were rhegmatogenous retinal detachment (61.9%) and macular hole repair (25.4%) After excluding eyes with a history of glaucoma or ocular hypertension, 5 patients had a POD1 IOP measurements over 30mmHg. All of these eyes had a POH1 IOP measurement over 20 mm Hg. No other significant unexpected management changes were prescribed at the POD1 timepoint in asymptomatic eyes.

Conclusions: In non-glaucomatous eyes, POHR1 IOP measurements provide a promising tool to predict POD1 IOP elevations that would necessitate changes in management. As a result, POHR1 IOP data may help us streamline postoperative care for asymptomatic patients after uncomplicated vitreoretinal surgery during the COVID-19 pandemic.

Zhu, Optometry and Visual Science, West China Hospital of Sichuan University, CHINA|

Commercial Relationships Disclosure (Abstract): SO GOTO: Commercial Relationship: Code N (No Commercial Relationship) | Qiurong Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Kelly Jensen: Commercial Relationship: Code N (No Commercial Relationship) | Josue Torres: Commercial Relationship: Code N (No Commercial Relationship) | Christine Wildsoet: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To establish reference ophthalmic findings, which include seven months follow-up data from one guinea pig diagnosed with heterotopic bone formation (HBF).

Methods: Slit lamp biomicroscopy, gonioscopy, optical biometry, rebound tonometry, anterior segment optical coherence tomography (AS-OCT), and posterior segment spectral domain optical coherence tomography (SD-OCT) were all performed on a 3.8-year-old male guinea pig suspected of having heterotopic bone formation. The eyes of this animal underwent further evaluation 7 months after the initial evaluation.

Results: Slit lamp biomicroscopy revealed vascularized, white masses in the anterior chamber, adjacent to the limbus, both nasally and temporally in the right eye, and both superiorly and temporally in the left eye. Their apparent locations, between the posterior corneal (endothelium) surface and anterior iris, were confirmed by gonioscopy and AS-OCT examinations. The right eye showed slightly elevated intraocular pressure compared to the left eye (18.3 vs. 13.3 mmHg) and recorded a slightly longer axial length (10.40 vs. 10.29 mm). However, SD-OCT showed no obvious differences in the shape or appearance of the optic nerve heads of the two eyes. Measurements made 7 months after the initial examination revealed significant progression in both eyes, in terms of the areal extent of the HBF lesions, as revealed by slit-lamp biomicroscopy and AS-OCT imaging. In the right eye, the lesions had extended into both superior and inferior limbal regions and in the left eye, into the nasal region. Recorded IOPs were only slightly higher than the earlier readings and still within a normal range, although a disparity between right and left eyes was again in evidence, with the right eye recording being 5.3 mmHg higher. Nonetheless, no changes in either nerve fiber layer thickness or total retinal thickness in the vicinity of the optic nerve heads were observed.

Conclusions: Advanced ophthalmic imaging techniques including OCT can provide important clinical insights into the pathophysiological changes in HBF. This case report provides reference time course data for ocular HBF in the guinea pig.

TITLE: Redox Regulation of Endothelial Progenitor Function and Senescence in Aging Retina

SESSION TITLE: Retinal diseases: molecular and biochemical mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.J. Wang, C. Liao, S.X. Zhang, University at Buffalo School of Medicine and Biomedical Sciences, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joshua Wang: Commercial Relationship: Code N (No Commercial Relationship) | Chunfen Liao: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aging is a significant risk factor for neurovascular injury in diseases such as diabetic retinopathy. This is in part attributable to declined function of progenitor cells to repair and replenish damaged endothelium resulting in sustained damage and loss of blood vessels. Herein, we investigated the role of NADPH oxidase 4 (Nox4), a key regulator of redox homeostasis, in endothelial progenitor function and senescence associated with retinal changes during aging.

Methods: Bone marrow-derived endothelial outgrowth cells (EOCs) were isolated and cultured from Tie2-specific human Nox4 overexpression (Nox4-Tg) mice or Nox4 KO mice at ages 5, 8, 12, and 24 months. EOC cell proliferation, migration, senescence, apoptosis, ROS generation were determined. Gene expression of signaling pathways underlying the cellular events were examined.

Results: The mRNA and protein levels of Nox4 were markedly increased, accompanied by enhanced ROS levels, in EOCs from mice of age 12 months, and to a significantly greater extent in EOCs from 24 month-old mice, when compared to young adults. Substantial increase of Nox4 and ROS were confirmed in EOCs from Nox4 Tg mice and reduction in Nox4 KO EOCs. Age or overexpression of NOX4 showed no effect on cell proliferation, but led to a significant increase in apoptosis and senescence of EOCs. Nox4 deletion significantly attenuated apoptosis, reduced pro-apoptotic gene CHOP expression, and inhibited caspase-3 activation in aging EOCs. Nox4 deletion also significantly decreased p53 and p21 expression, and demonstrated a trend in reducing senescence of aging EOCs. In addition, knockout Nox4 markedly improved the basal level and stromal derived factor-1 (SDF-1)-stimulated EOC migration through upregulation of CXCR4. Consistent with the changes in EOCs, Nox4 Tg mice demonstrated significantly increased acellular capillary formation in the retina compared to age-matched wild type.

Conclusions: Our results suggest that Nox4-derived ROS is implicated in age-related endothelial progenitor cell apoptosis and senescence. Approaches that manipulate Nox4 and ROS production may improve the function of endothelial progenitor cells thus reducing the risk of vascular damage in retinal diseases.

ABSTRACT BODY:

Purpose: The pathophysiology of drusen formation in dry age-related macular degeneration (AMD) is incompletely understood. Studies have found common molecular components of the complement system in drusen of dry AMD and dense deposit disease (DDD) of the kidney. To understand the pathophysiology of AMD we compared the morphological features of the two diseases by light (LM) and immunofluorescence (IF) microscopy.

Methods: Human donor eyes with dry AMD (n=3) and kidney biopsies from patients diagnosed with DDD (n=2) were studied in compliance with the institutional guidelines. Formalin-fixed and snap-frozen fresh samples from both eye and kidney specimens were cut at 2 and 5 microns, respectively, and stained with H&E, PAS, Masson's trichrome, Jones silver, Verhoeff's stains, and anti-C3 antibody. Unstained sections were used as controls for autofluorescence. Slides were analyzed under bright field and confocal fluorescence microscope.

Results: Morphological similarities were observed between drusen and DDD deposits: Significant thickening of the Bruch's membrane (BrM) and glomerular basement membrane (GBM) was found in both diseases by PAS stain, suggesting the presence of excess matrix formation composed of polysaccharides and mucins. While multiple large laminar deposits of drusen were diffusely dispersed alongside the BrM, by LM, the GBM in DDD did not reveal the deposits by LM. By PAS stain, the cleavage edge – splitting of BrM between the basement membrane of the RPE and the inner collagenous layer – was observed in AMD specimens, while the DDD specimens revealed double contouring of the GBM. Abundant notched inter-capillary pillars were seen in AMD, mirroring increases in mesangial matrix seen in DDD specimens. Jones silver staining revealed extracellular matrix (abundance of oxidized carbohydrates), particularly around capillaries in both specimens. By IF, linear deposits of C3 were found in dry AMD along the BrM compared to strong deposits of C3 seen along the GBM in DDD sections.

Conclusions: We show similarities in the structural defects in the membranes of dry AMD eye and the DDD kidney. Moreover, C3 deposition in the BrM and GBM in drusen and DDD have similarities in terms of pattern and intensity. As DDD has a complement-mediated pathogenesis, hypothetically, it is possible that the pathogenesis in AMD is also related to complement system dysfunction.

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the association between retinal microanatomy at 36 weeks postmenstrual age and Teller card grating visual acuity (VA) at 9 months in preterm infants.

Methods: For each infant and for each eye, we analyzed optical coherence tomography (OCT) images from one bedside imaging session captured at 35-37 weeks postmenstrual age. We also analyzed retinopathy of prematurity (ROP) stage (the same day as OCT imaging), infant demographics, and Teller card grating VA at 9 months corrected age. We captured all measures prospectively from preterm infants enrolled in the Study of Eye imaging in Preterm infants (BabySTEPS; NCT02887157). Expert graders, masked to other study data except for age, extracted OCT microanatomy features (e.g., presence/severity of macular edema) and retinal thicknesses, including: inner layer complex (retinal nerve fiber layer [RNFL], ganglion cell, and inner plexiform layer) thickness at the foveal center; inner nuclear layer thickness at the foveal center; total retina thickness at the foveal center; choroid thickness averaged across the foveal 1mm; and RNFL thickness at the papillomacular bundle (PMB). We analyzed for associations of OCT retinal microanatomy features with categorized VA (normal vs. subnormal, using a threshold of 3.70 cycles/degree) using logistic regression models and with continuous logMAR VA using linear regression models. We accounted for inter-eye correlation by using generalized estimating equations.

Results: Of the 130 eyes of 65 infants with both OCT and VA data, 71 (55%) eyes of 40 infants had subnormal VA (<3.70 cycles/degree), and 12 (9%) eyes of 6 infants had prior ROP treatment. On univariable linear regression, low gestational age, low birthweight, prior ROP treatment, and RNFL thinning at the PMB were associated with higher logMAR. On multivariable linear regression, ROP treatment ($p=0.006$) and RNFL thinning at the PMB ($p=0.007$) were independently associated with higher logMAR. On logistic regression, only prior ROP treatment ($p=0.021$) was associated with subnormal VA, though RNFL thinning at the PMB ($p=0.097$) approached significance.

Conclusions: RNFL thinning at the PMB is associated with poorer 9-month VA in preterm infants, independent of ROP severity and demographic features.

TITLE: Activation of A₁ and A₃ adenosine receptors protect zebrafish photoreceptors from neurodegeneration in a light-induced retinal degeneration model

SESSION TITLE: Retinal neurodegeneration and protection

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.L. Stella, T.D. Friemel, A.S. Khan, Neural and Behavioral Sciences, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|T.D. Friemel, Basic Biomedical Sciences, University of South Dakota Sanford School of Medicine, Sioux Falls, South Dakota, UNITED STATES|A.S. Khan, Division of Anatomy, Albany Medical College, Albany, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Salvatore Stella: Commercial Relationship: Code N (No Commercial Relationship) | Taylor Friemel: Commercial Relationship: Code N (No Commercial Relationship) | Amanda Khan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal diseases that damage photoreceptors, particularly those that affect cones such as the “dry” form of age-related macular degeneration (AMD), have dire consequences for vision. Models of light-induced retinal degeneration (LIRD) recapitulate some of the damage observed in dry AMD. One strategy for treating AMD is to utilize a “druggable” therapy targeted to neuroprotective mechanisms in photoreceptors. Adenosine has neuroprotective properties at neurons within the central nervous system and prevents neurodegeneration. The purpose of this study was to determine which adenosine receptors mediate neuroprotection of photoreceptors in a zebrafish LIRD model.

Methods: Adult wild-type and Tg(nrd:GFP) zebrafish were dark-adapted for 24 hours, followed by intravitreal injections of adenosine or adenosine receptor agonists (A₁R, A_{2A}R, A_{2B}R, A₃R). Controls were injected with saline in both eyes. All zebrafish were exposed to high-intensity light (28,000 lux) and collected at 0 and 96 hours post dark-adaptation. Immunohistochemical analysis with cell specific markers, TUNEL assays, and optomotor response measurements were performed on zebrafish in order to assess the impact of adenosine and adenosine receptor agonists on LIRD.

Results: Treatment of retinas with adenosine resulted in a dose-dependent survival of both rod and cone photoreceptors after LIRD that was mediated by both A₁R and A₃R in the retina. Any damage observed in adenosine-treated retinas was not enough to stimulate a regenerative response, arguing in favor of a neuroprotective mechanism. Moreover, higher concentrations of adenosine prevented structural damage and apoptosis of rods and cones while preserving both visual acuity and contrast sensitivity in zebrafish retinas, suggesting that adenosine has the capacity to preserve photoreceptor function.

Conclusions: These findings clearly demonstrate that adenosine acting on A₁R and A₃R has a significant capacity for neuroprotection and provides evidence of a potential novel therapeutic target for the treatment of the dry form of AMD.

ABSTRACT BODY:

Purpose: To compare efficacy and treatment burden of a treat-and-extend (T&E) anti-VEGF treatment of age-related macular degeneration (AMD) against fixed and pro re nata (PRN) schedules.

Methods: MEDLINE, CENTRAL, and EMBASE were searched from 2004 to August 2020. Randomized-controlled trials and observational studies comparing T&E to PRN or fixed dosing for treatment-naïve AMD patients were included. Mean difference (MD), and 95% confidence intervals (CI) for visual acuity (VA) and injection frequency are presented. Risk of bias was assessed according to Cochrane guidelines. Methodology was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA).

Results: 6 RCTs and 5 observational studies were identified. VA improvement was similar for eyes receiving T&E and fixed dosing at one (743 eyes T&E, 725 eyes fixed; MD -0.08 letters, 95% CI -2.52-2.36, $p = 0.95$, $I^2 = 69\%$) and two years (260 eyes T&E, 249 eyes fixed; MD 0.58 letters, 95% CI -1.74-2.90, $p = 0.62$, $I^2 = 0\%$). In contrast, visual acuity improvements were significantly greater for T&E eyes when compared against a PRN regimen at one (525 eyes T&E, 748 eyes PRN; MD 3.95 letters, 95% CI 2.13-5.77, $p < 0.0001$, $I^2 = 40\%$) and two years (85 eyes T&E, 187 eyes PRN; MD 4.08 letters, 95% CI 1.67-6.49, $p < 0.001$, $I^2 = 0\%$). Significantly fewer ranibizumab injections were administered in the T&E arm at one (628 eyes T&E, 604 eyes fixed; MD -2.42 injections, 95% CI -2.71 to -2.14, $p < 0.0001$, $I^2 = 0\%$) and two years (267 eyes T&E, 249 eyes fixed; MD -6.06 injections, 95% CI -6.79 to -5.34, $p < 0.00001$, $I^2 = 17\%$) relative to fixed dosing. Fewer aflibercept injections were likewise administered to patients on a T&E regimen versus fixed dosing at one year (127 eyes T&E, 124 eyes fixed; MD -0.78 injections, 95% CI -1.14 to -0.42, $p < 0.0001$, $I^2 = 53\%$). No studies compared T&E to fixed aflibercept at two years. Significant heterogeneity precluded meta-analysis of injection frequency among studies comparing T&E to PRN dosing.

Conclusions: T&E preserves VA similar to fixed schedules with significantly fewer injections at one and two years. Patients on a PRN regimen receive fewer injections than those on T&E dosing, but with less favourable visual outcomes. Additional studies are required for more robust meta-analysis of anti-VEGF injection frequency at 1 year and beyond.

ABSTRACT BODY:

Purpose: Mutations in optineurin (OPTN) are associated with familial normal tension glaucoma and other neurodegenerative diseases. It remains unclear how OPTN loss or mutation alters visual function during aging. Here, we used transgenic mouse models and in vivo assessments to test the hypothesis that OPTN dysfunction contributes to progressive visual impairment through a toxic gain of function mechanism.

Methods: Mice with C57BL/6 background were used (Fig 1): wildtype (WT; n=19), homozygous OPTN knock-out (mOPTN-KO; n=13), hemizygous mouse E50K OPTN knock-in (mE50K-het; n=8), homozygous mouse E50K OPTN knock-in (mE50K homoz; n=10), and human E50K OPTN bacterial artificial chromosome overexpression (hE50K BAC; n=6) (PMID: 31076632, 25818176). Intraocular pressure (IOP), total retinal thickness (TRT), visual acuity (VA), and contrast sensitivity (CS) were measured at 6, 12, and 18 months of age in the same mice using the TonoLab rebound tonometer, Bioptigen spectral-domain optical coherence tomography imaging, and OptoMotry optokinetic virtual reality system, respectively. Left and right eye data were averaged and analyzed using ANOVAs followed by posthoc tests between genotype and age groups, as well as linear regressions for VA versus contrast threshold (CT).

Results: Our longitudinal study of the same mice during the aging process showed that IOP remained normal between 10-15 mmHg (Fig 2A). Small to no difference in TRT over time or compared to WT was observed (Fig 2B). mE50K-homoz, mE50K-het, and hE50K BAC mice exhibited greater age-dependent decline in VA and CT than WT or mOPTN-KO mice (Fig 2C, 2D, 2E). In contrast, mOPTN-KO mice showed preservation of VA and CT over time compared to WT. Consistently, mice with one copy of E50K OPTN (mE50K het) experienced less deterioration of VA and CT compared to mice with two copies (mE50K homoz) or mild overexpression (hE50K BAC).

Conclusions: Despite limited IOP and TRT changes between age and genotype groups, E50K OPTN was associated with differential age-dependent visual impairment (greater for CS than VA). Surprisingly, OPTN deficiency preserved visual function such that CS in knockout mice was better than WT mice. Our results suggest visual loss associated with E50K OPTN is due to a toxic gain of function mechanism, and that suppression of OPTN might constitute a therapeutic strategy for glaucomatous neurodegeneration.

TITLE: Etiologic Spectrum, Disease Severity, and Vision Outcomes in Pediatric Uveitis: A Single Referral Center Experience

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Samson, J.M. Samson, C.M. Samson, Ophthalmology, Manhattan Eye Ear and Throat Institute, New York, New York, UNITED STATES|J.M. Samson, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Caitlin Samson: Commercial Relationship: Code N (No Commercial Relationship) | James Samson: Commercial Relationship: Code N (No Commercial Relationship) | C Samson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the characteristics and outcomes of pediatric uveitis seen and managed at a tertiary care center in New York City.

Methods: Charts of pediatric patients (<18 years of age) with a diagnosis of uveitis seen on the Uveitis Service at the Manhattan Eye, Ear, and Throat Hospital between 2017 and 2020 were reviewed. Gender, anatomical location of uveitis, laterality, uveitis etiology, age of uveitis onset, visual outcome, need for immunomodulatory therapy, need for surgery, and drug free remission, were collected.

Results: A total of 78 patient charts were reviewed. Most patients were female (71.8%). Anterior uveitis was the most common type (78.2%). The most common etiologies were idiopathic (48.7%) and JIA (37.2%). 80.8% children had undergone treatment with immunomodulatory therapy (IMT) during their disease course. Of these, 46% have discontinued their IMT during the follow-up period: 89.7% remained in drug-free remission at 5 years. 24.4% of children required surgery. Most of the children (94.3%) had vision of 20/40 or better in at least one eye, and no patients were legally blind.

Conclusions: Pediatric uveitis patients managed at a tertiary care center often required immunomodulatory therapy, and 1/4 required surgery. Great visual outcomes were achievable, and many children remain inflammation free after discontinuation of IMT.

ABSTRACT BODY:

Purpose: Mutations in the beta subunit of phosphodiesterase 6 expressed in rod photoreceptors have been shown to cause rapid retinal degeneration in mouse models such as rd1. In this study we demonstrate that the D167A mutation in PDEA leaves rods with less than 10% of normal PDE expression, but this is enough to protect the cells from precipitous degeneration.

Methods: The CRISPR-Cas system was used in mouse to convert the aspartic acid at position 167 of PDE6A to alanine. Protein content was measured by serial-dilution Western blots, and PDE activity was quantified with a biochemical assay. Retinal morphology was assessed and quantified with light microscopy. Single cell photocurrents were recorded from the outer-segment of mouse rods with suction-electrode recording, and a mathematical model was used to fit the collected data.

Results: The D167A mutation in the PDE6A results in a greater than 10-fold reduction in PDE6B, with PDE6A almost undetectable. A significant reduction in basal PDE6 catalytic activity as well as trypsin-activated PDE6 activity was observed in these retinas. Degeneration was slow, with 70% of rod nuclei still remaining at 6 months. No detectable changes were observed in the sensitivity of single cells, though activation and recovery of the photoresponse were both significantly slower. These changes could be mathematically modeled by a reduction in the dark rate of PDE (b_d), a reduced rate of PDE activation, and a small elevation in dark Ca^{2+} concentration, all of which are compatible with a reduction in PDE activity.

Conclusions: The changes observed in the temporal properties of rod photoreceptors in the D167A animal can be explained by the reduction in PDE concentration and activity. The small PDE6B expression seems to be forming sufficient functional phosphodiesterase enzyme to provide protection against rapid degeneration.

ABSTRACT BODY:

Purpose: The retina, as the only visually accessible tissue in the central nervous system, has attracted significant attention for evaluating it as a biomarker for neurodegenerative diseases. Yet, most of studies focus on characterizing the loss of retinal ganglion cells (RGCs) and degeneration of their axons. There is no integrated analysis addressing temporal alterations of different retinal cells in the neurovascular unit (NVU) in particular retinal vessels. Here we assessed NVU changes in two mouse models of tauopathy and evaluated the therapeutic effects of a tau oligomer monoclonal antibody (TOMA).

Methods: Studies were performed in P301S and P301L transgenic mice which overexpress the human tau mutated gene. Optical coherence tomography, scanning laser ophthalmoscopy and electroretinography were applied to non-invasively analyze retinal structural and functional changes. Vascular leakage was determined by analyzing FITC-BSA extravasation into the retina. Leukocyte adhesion was assessed by Concanavalin A labeling. Alterations of adhesion junction, microglia, leukocytes and RGCs were assessed by immunostaining in retinal flatmounts. TOMA was utilized to treat tauopathy.

Results: Retinal edema and breakdown of blood-retina barrier were observed at the very early stage of tauopathy. Leukocyte adhesion/infiltration, and microglial recruitment/activation were constantly increased in the retinal ganglion cell layer of tau transgenic mice at different ages, while Müller cell gliosis was only detected in relatively older tau mice. Concomitantly, the number and function of RGCs progressively decreased during aging although they were not considerably altered in the very early stage of tauopathy. Moreover, intrinsically photosensitive RGCs appeared more sensitive to tauopathy. Remarkably, TOMA treatment in young tau transgenic mice significantly attenuated vascular leakage, inflammation and RGC loss.

Conclusions: Our data provide compelling evidence that abnormal tau accumulation can lead to pathology in the retinal neurovascular unit, and vascular alterations occur more manifest and earlier than neurodegeneration in the retina. Oligomeric tau-targeted immunotherapy has the potential to treat tau-induced retinopathies. Retinal NVU may serve as a potential biomarker for diagnosis and staging of tauopathy as well as a platform to study the molecular mechanisms of neurodegeneration.

ABSTRACT BODY:

Purpose: Detection of specific features of interest on OCT is strongly linked to training data composition. For many targeted features, large comprehensive ground-truth annotated datasets are not available. Smaller datasets may be more susceptible to class imbalance potentially affecting the machine learning (ML) performance. The purpose of this study was to evaluate the impact of the variable ratios of positive to negative training data on ML performance based on quantitative and qualitative parameters on segmentation of subretinal material (SRM).

Methods: : A U-Net architecture convolutional model was executed and evaluated on training datasets with varying ratios of annotated OCT images containing (positive) and not containing (negative) SRM in neovascular age-related macular degeneration. ML performance based on 5 different ratios of positive (P) and negative (N) data: 30P-70N, 40P-60N, 50P-50N, 60P-40N, 70P-30N was assessed. The quantitative performance evaluation was calculated using F-scores. Qualitative performance evaluation was based on multiple experts' reviews of the model outputs in a tiled configuration for assessment of optimal segmentation (Figure 1).

Results: The results demonstrated variable model performance related to the training dataset ratio. Based on quantitative model performance, the F-scores ranged from 0.59 to 0.72. The highest performing model based on F-score was the 70P-30N training set. However, qualitative model performance assessment demonstrated that the 30P-70N (F-score = 0.61) was the preferred training set. In qualitative review, the 70P-30N model demonstrated excellent detection of subretinal material with few false negatives, but with an excess of false positives that was clinically impactful (Figure 1). Conversely, the 30P-70N demonstrated a more conservative segmentation with dramatic reduction in false positives while maintaining minimal false negatives.

Conclusions: This study demonstrates the important of dataset composition and positive/negative sampling ratios in datasets of limited size. In addition, this analysis identifies the potential disconnect between qualitative/practical model performance and quantitative performance metrics.

TITLE: Avacincaptad Pegol, A Novel C5 Inhibitor, Demonstrates a Continued Reduction in the Mean Rate of Geographic Atrophy Growth: 18-Month Results from the GATHER1 Clinical Trial

SESSION TITLE: AMD: Clinical and translational research II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Sheth, University Retina, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Veeral Sheth: Commercial Relationship(s);Iveric Bio:Code C (Consultant)

ABSTRACT BODY:

Purpose: Avacincaptad pegol, a polyethylene glycol-conjugated oligonucleotide, is a potent C5 inhibitor delivered via a 100 µl intravitreal injection. The 18-month results of GATHER1, a randomized, double-masked, multi-national, sham-controlled clinical trial evaluating avacincaptad pegol for treatment of geographic atrophy (GA) secondary to age-related macular degeneration, are reported here.

Methods: Patients were randomized to avacincaptad pegol 1 mg, avacincaptad pegol 2 mg, avacincaptad pegol 4 mg or sham injection. GA progression was evaluated as a change in GA lesion area over 18 months measured by fundus autofluorescence; square-root transformation was applied to mitigate the impact of baseline factors on GA growth. Other assessments included visual function (best-corrected visual acuity and low-luminance visual acuity) and safety analysis.

Results: The least-squares mean change from baseline to month 18 in square-root GA lesion area was 0.599 mm in sham-treated patients vs 0.430 mm in avacincaptad pegol 2 mg-treated patients (28% reduction; $p < 0.0014$). The least-squares mean change from baseline to month 18 in square-root GA lesion area was 0.559 mm in sham-treated patients vs 0.391 mm in avacincaptad pegol 4 mg-treated patients (30% reduction; $p < 0.0021$). There were no significant differences in best-corrected visual acuity or low-luminance visual acuity between avacincaptad and sham-treated patients. Avacincaptad pegol was generally well tolerated after 18 months of administration, with no drug-related adverse events or trial discontinuations.

Conclusions: Intravitreal avacincaptad pegol resulted in a decrease in the rate of GA lesion growth over 18 months of treatment versus sham injection. GATHER2, a second pivotal clinical trial comparing avacincaptad 2 mg vs sham, has been initiated and is currently enrolling patients.

TITLE: The value of OCT angiography (OCTA) to discriminate neovascular central serous chorioretinopathy (nCSC)

SESSION TITLE: OCT Angiography - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Zhang, B. Sun, C. Yan, Shanxi Eye Hospital, Taiyuan, Shanxi, CHINA|

Commercial Relationships Disclosure (Abstract): Zhaoxia Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Bin Sun: Commercial Relationship: Code N (No Commercial Relationship) | Chunfang Yan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Central serous chorioretinopathy (CSC) mainly affects middle-aged men and is characterized by serous detachment of neurosensory retina and retinal pigment epithelium (RPE). Although choroidal neovascularization (CNV) is a well-known complication in eyes with chronic CSC, CNV can also be detected in acute CSC, named as neovascular central serous chorioretinopathy (nCSC). This study is aimed to evaluate neovascular CSC with OCTA.

Methods: Twenty-three eyes presenating with CSC (35~50 years, 18 male and 5 female) were included in this study. Macular angiograms (3×3 mm) were obtained using spectral-domain OCT (SD-OCT, RTVue XR; Optovue). CNV was defined as flow in the outer retinal slab between the outer plexiform layer and Bruch's membrane. Eyes with nCSC were treated with anti-VEGF therapy (aflibercept 2.0mg/0.05ml intravitreal injection, 3+PRN). Clinical characteristics and OCTA were performed at the time of no more than two months after diagnosis of CSC and follow-up.

Results: Of twenty-three eyes with CSC, three eyes (13.04%) with the flat, irregular RPE elevation or PED were determined as type 1 CNV in outer retina of OCTA, even though symptomatic macular detachments resolved spontaneously. All the patients with nCSC were female, who showed a significantly worse initial best corrected visual acuity (BCVA) (Snellen 20/40) compared to eyes with non-neovascular CSC (Snellen 20/25) ($p<0.05$). BCVA, central macular thickness, subretinal fluid significantly decreased, while the CNV area and vessel density did not change after treatment.

Conclusions: OCTA provides a promising CNV detection rate in CSC. Eyes with nCSC may have acute CSC, not chronic CSC, and should be carefully examined with OCTA to determine. Anti-VEGF therapy can stabilize the nCSC.

TITLE: Central and Peripheral Corneal Pachymetry, measured by Fourier-Domain Optical Coherence Tomography and Scheimpflug Topometry in Healthy, Keratoconic, and Post-LASIK eyes

SESSION TITLE: Keratoconus and biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Asimellis, M. Stergiou, College of Optometry, University of Pikeville, Pikeville, Kentucky, UNITED STATES|M. Stergiou, Medical School, Demokriteio Panepistemio Thrakes, Komotini, East Macedonia and Thrace, GREECE|

Commercial Relationships Disclosure (Abstract): George Asimellis: Commercial Relationship: Code N (No Commercial Relationship) | Marianthi Stergiou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate corneal pachymetry accuracy and precision by two different devices, a Fourier Domain Optical Coherence Tomography (AS-SD OCT) and a Scheimpflug Topography (Pentacam), in healthy, keratoconic, and post-LASIK eyes.

Methods: 140 eyes were examined (76 female and 64 male). Group A 80 healthy, Group B 20 keratoconic, and Group C 40 post-LASIK eyes. We used Anterior Segment-Fourier Domain Optical Coherence Tomography (OCT) and Scheimplug imaging (Pentacam). Measurements were taken at center (2 mm), periphery (5 mm average of superior, inferior, nasal, and temporal) and the thinnest location. Statistical analysis evaluated mean, STDV, and interquartile range.

Results: There was a statistically significant difference between the OCT and the Pentacam, with the Pentacam results at an average of 5% higher than those obtained by OCT.

A) In Healthy eyes the mean central by OCT is 550.35 ± 21.84 and by Pentacam which is 572.30 ± 21.66 , the mean peripheral by OCT is 573.35 ± 21.93 and by Pentacam is 626.45 ± 24.79 and the mean thinnest by OCT is 545.40 ± 21.62 and by Pentacam is 568.4 ± 20.74 . T-test is less than zero (0) with ($p < 0.001$) so there is a statistical significant difference.

B) In Keratoconic eyes the mean central OCT is 442.5 ± 21.90 in contrast to Pentacam which is 458.4 ± 23.31 , the mean peripheral OCT is 489 ± 20.44 and by Pentacam is 558.1 ± 20.36 and the mean thinnest by OCT is 434.2 ± 22.17 and by Pentacam is 453.25 ± 25.72 . In all parts the T-test is less than zero (0) with ($p < 0.001$) so there is a statistical significant difference.

C) In post-LASIK eyes the mean central OCT is 455.6 ± 26.06 in contrast to Pentacam which is 458.15 ± 27.39 , the mean peripheral by OCT is 493.5 ± 18.64 and by Pentacam is 543.45 ± 18.56 and the mean thinnest location by OCT is 428 ± 29.37 and by Pentacam is 443.95 ± 27.25 . The T-test in central is 0.43 ($p > 0.05$), in contrast to peripheral and pachymetry in thinnest location which is less than zero (0) ($p < 0.001$). The data suggest a statistical significant difference between OCT and pentacam at the periphery and thinnest location.

Conclusions: The Pentacam shows thicker corneas than OCT, attributed to the different principles of imaging. While the clinical trend in corneal pachymetry is shifting towards optical imaging, there are considerable cross-device differences in pachymetry data that need to be evaluated.

TITLE: Transcriptional Dynamics of Retinal Endothelial cells underlying Blood-Retinal Barrier (BRB) alteration in Diabetic Retinopathy

SESSION TITLE: Regulating endothelial cell homeostasis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Rangasamy, C. Legendre, Neurogenomics Division, Translational Genomics Research Institute, Phoenix, Arizona, UNITED STATES|F. Monickaraj, A. Das, University of New Mexico School of Medicine, Albuquerque, New Mexico, UNITED STATES|A. Das, New Mexico VA Health Care System, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sampathkumar Rangasamy: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Legendre: Commercial Relationship: Code N (No Commercial Relationship) | Finny Monickaraj: Commercial Relationship: Code N (No Commercial Relationship) | Arup Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Endothelial cell dysfunction and increased vascular permeability constituting the blood–retinal barrier (BRB) alteration is the hallmark of diabetic macular edema (DME). Using next generation sequencing (NGS), we investigated the gene expression and transcriptional regulatory network dynamics across human and mouse retinal endothelial cells to understand the molecular mechanisms of DME

Methods: Retinal Endothelial (ECs) from the non-diabetic and diabetic (n=12) mouse retina were obtained through fluorescent activated cell sorting (FACS) using endothelial cell specific marker (CD31-FITC) staining. RNA sequencing of isolated E retinal ECs was done using paired-end Illumina sequencing (NovaSeq 6000 System). Single-cell RNA sequencing (scRNA) of in vitro human retinal endothelial microvessel model was performed under low and high- glucose conditions. DESeq2 analysis was performed to identify the differentially expressed genes (DEGs) set, followed by gene set enrichment analysis (GSEA) analysis and the top genes were identified using custom functional analysis tools.

Results: Transcriptomic analysis of isolated retinal ECs from diabetic animals showed differential expression of genes linked to barrier maintenance and prosurvival. We also identified enrichment of divergent transcriptional clusters connected to cellular stress response pathway in the diabetic retinal EC. In vitro expression analysis of human retinal ECs revealed early upregulation of proinflammatory and angiogenic factors such as IL-6, ICAM-1, CCL2, ANG2, which are well documented to play a critical role in BRB alterations. Integrated analysis of human and mouse retinal endothelial cells revealed identification of novel upstream signaling mediators and transcription factors such as BRK1, PKIG, HEXIM1, AND DDIT4 involved in the regulation of proinflammatory and angiogenic factors involved in the retinal vascular permeability alterations. Further, using single-cell transcriptome analysis, we characterized retinal endothelial specific robust cell markers.

Conclusions: Our study highlights the importance of endothelial cell-specific transcriptomic analysis to understand the pathogenesis of diabetic retinopathy. A detailed understanding of the transcriptional landscape of endothelial cells in diabetes will help in the development of novel molecular targets and therapies for DME.

ABSTRACT BODY:

Purpose: Independent from one another, both acute retinal necrosis (ARN) and ocular syphilis are rare ocular infections that can present in healthy individuals as well as immunocompromised patients. To our knowledge, ARN with concurrent ocular neurosyphilis has not been reported. Herein, we describe a case of a male with newly diagnosis human immunodeficiency virus (HIV) present with ARN from herpes simplex virus-1 (HSV1) with a second co-infection of ocular syphilis.

Methods: A detailed retrospective review was conducted of a case who presented in Los Angeles County, USA with ARN confirmed with positive ocular fluid HSV1 polymerase chain reaction (PCR) and co-infection of ocular syphilis confirmed with positive cerebrospinal fluid (CSF) venereal disease research laboratory (VDRL) antibody and serum fluorescent treponemal antibody absorption (FTA-ABS).

Results: A 54-year-old previously healthy male with a gradual three month decline in vision of the left eye, presented with acute painless vision loss of the right eye. On exam, the right eye had count fingers vision with active anterior chamber inflammation, dense vitritis, and a well-demarcated wedge-shaped peripheral chorioretinal lesion. Left eye was light perception vision with a quiet anterior chamber but with heterochromia of the iris and dense white uveitic cataract obscuring the view to posterior pole but ultrasound confirmed dense vitritis. Laboratory workup revealed a new diagnosis of HIV-1 and neurosyphilis confirmed with positive VDRL of the CSF. Anterior chamber fluid of the right eye was HSV1 positive, whereas anterior and vitreal samples of the left eye were HSV1 negative. The patient underwent a series of intravitreal foscarnet injections of the right eye and oral valacyclovir and two-week course of intravenous penicillin. The vitritis and vision improved in both eyes with the right eye recovering back to 20/40 vision.

Conclusions: Though a rare infection, the rate of ocular syphilis continues to rise especially in the Los Angeles County health network. Over the past five years the Los Angeles County ophthalmology service has treated roughly 55 patients with ocular syphilis, and as far as the authors are aware, this is the first case of ocular syphilis with a co-infection of viral acute retinal necrosis. Given the rise in these ocular infections, it is important to recognize and effectively treat the various clinical presentations of infectious panuveitis.

TITLE: Histological comparison of cytoplasmic AQP5-containing structures in bovine and mouse ocular lens fiber cells

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.B. Gletten, K.L. Schey, Biochemistry, Vanderbilt University, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Romell Gletten: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Schey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aquaporin-5 (AQP5) is the second most abundant aquaporin in ocular lens fiber cells. Previously we have shown that in bovine outer cortical lens fiber cells, cytoplasmic AQP5 localizes to spheroidal, tubular compartments. Transmission electron microscopy revealed morphologically similar autophagosomes with degrading mitochondria. The connection between, and conservation of, these structures in mammalian lenses is unclear. The purpose of this work is to histologically define AQP5-associated cytoplasmic structures in bovine and mouse lenses to better understand lens AQP5 function and regulation.

Methods: High resolution immunofluorescence (IF) confocal microscopy was conducted on bovine and mouse lens cryosections. Colocalization analyses of cytoplasmic AQP5 and biological markers of various organelles including TOMM20 (mitochondrial marker), calnexin (endoplasmic reticulum [ER] protein), and DiI_{C₁₈}(3) (DiI; marker dye of lipid membranes) were conducted. Colocalization analysis of LC3B (autophagosomal marker) and TOMM20 was also conducted.

Results: In the bovine lens outer cortex, AQP5-associated, TOMM-20 positive cytoplasmic compartments are juxtaposed to calnexin-positive compartments. In mouse outer cortical lens fiber cells, AQP5-positive cytoplasmic structures and TOMM20-positive cytoplasmic structures were detected in separate assays. Both of these mouse lens structures are spheroidal, tubular in morphology. In mouse lenses, calnexin-positive compartments are not juxtaposed to AQP5-associated cytoplasmic compartments. In mouse and bovine lenses, TOMM20-positive cytoplasmic structures become LC3B-positive late in fiber cell maturation.

Conclusions: Bovine lens outer cortical fiber cells contain spheroidal, tubular AQP5-associated, cytoplasmic structures comprised of mitochondrial membranes that associate with the ER. These structures likely undergo autophagic degradation with fiber cell maturation. Similar AQP5-associated cytoplasmic structures are present in the mouse lens but the association of these structures with ER compartments is unclear. Future experiments will focus on further defining the relationship between AQP5, mitochondria, autophagy, and fiber cell differentiation in the mammalian lens.

ABSTRACT BODY:

Purpose: To assess bilateral ganglion cell layer-inner plexiform layer (GCL-IPL) thickness changes in patients with unilateral neovascular age-related macular degeneration (nAMD) treated with anti-vascular endothelial growth factor (aVEGF)

Methods: Single center, retrospective, cohort study. The medical records of patients with unilateral nAMD treated with aVEGF were reviewed. The treatment group included eyes with newly diagnosed nAMD that subsequently underwent treatment with intravitreal aVEGF injections. The control group was the fellow eye with dry age-related macular degeneration (dAMD). Eyes that received at least 10 intravitreal injections were included. Measurement of the GCL-IPL thickness was performed at different timepoints using spectral domain-optical coherence tomography (SD-OCT).

Results: A total of 216 eyes/108 patients met the inclusion criteria. The mean age [\pm standard deviation] was 80.1 years [\pm 10.7 years]. Eyes in the treatment group underwent a mean of 20.2 ± 7.2 injections in 43.2 ± 13.9 months. The mean GCL-IPL thickness decreased from $74.8 \pm 6.6 \mu\text{m}$ to 69.6 ± 9.5 ($p < 0.001$) in the treatment group and from $74.4 \pm 6.2 \mu\text{m}$ to 72.8 ± 8.2 [DM1] μm in the control group ($p = 0.013$). Other variables such as age, duration of treatment, number of injections, IOP, and central retinal thickness did not correlate with GCL-IPL thickness change.

Conclusions: The GCL-IPL thickness decreased in the treatment group and the control group. The mechanism and the clinical significance of this observation warrant further study.

TITLE: Factors Associated with Obtaining a Faculty Position at Well-Regarded U.S. Ophthalmology Programs

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Li, J. O'Fee, S. Kang, B.C. Toy, USC Roski Eye Institute, University of Southern California Keck School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joy Li: Commercial Relationship: Code N (No Commercial Relationship) | John O'Fee: Commercial Relationship: Code N (No Commercial Relationship) | Sara Kang: Commercial Relationship: Code N (No Commercial Relationship) | Brian Toy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Careers in academic ophthalmology are highly competitive. The purpose of our study was to identify factors that may be associated with obtaining a faculty position at a well-regarded program.

Methods: Full-time academic ophthalmology faculty from 123 institutions with Accreditation Council for Graduate Medical Education-approved ophthalmology residency programs were included. Ophthalmology residency programs were categorized into "Top" (top 25 programs) and "Other" (non-top 25 programs) using Doximity Residency Navigator 2020-2021. Medical school rankings were determined using U.S. News and World Report 2021 and similarly categorized into "Top" and "Other" programs. Preliminary data from 38 programs (8 Top programs and 30 Other program) are reported below.

Results: A total of 979 faculty from 38 programs were included (Table 1). Compared to Other programs, Top programs had a greater number of faculty ($P = 0.0002$), proportion of fellowship-trained faculty ($P < 0.0001$), and faculty with at least one or more non-medical graduate degrees ($P < 0.0001$). Compared to Top programs, Other programs had a greater proportion of pediatric ophthalmology fellowship-trained faculty ($P = 0.0494$). Compared to Other programs, Top programs had significantly higher proportions of faculty who trained at Top medical schools ($P < 0.0001$), Top residency programs ($P < 0.0001$), and who were fellowship-trained at their current institution (Fig. 1, $P < 0.0001$). There were no significant differences between Top and Other programs in the proportion of faculty who completed at least part of their training outside the United States ($P = 0.3944$), or who completed a research fellowship ($P = 0.3274$).

Conclusions: In this preliminary study, we found faculty at top-ranked programs were significantly more likely to be fellowship-trained, have completed a fellowship at their current institution, and have had prior training at their current institution or at other top-ranked programs.

TITLE: Outcomes of Cataract Extraction with Kahook Dual Blade Goniotomy Versus iStent Trabecular Micro-Bypass Device With Minimum Two Year Follow-Up

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. David, J.A. Tran, Z. Fang, L.J. Al-Dujaili, Ophthalmology, LSU Health New Orleans, New Orleans, Louisiana, UNITED STATES|C. Grenier, M. Morgan, Ophthalmology, Ochsner Health System, Baton Rouge, Louisiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): James David: Commercial Relationship: Code N (No Commercial Relationship) | Jamie Tran: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Grenier: Commercial Relationship: Code N (No Commercial Relationship) | Michael Morgan: Commercial Relationship: Code N (No Commercial Relationship) | Zhide Fang: Commercial Relationship: Code N (No Commercial Relationship) | Lena Al-Dujaili: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Kahook Dual Blade (KDB) goniotomy and iStent trabecular micro-bypass device implantation are two minimally invasive glaucoma surgical (MIGS) procedures used at time of cataract extraction to reduce intraocular pressure (IOP), but there are limited head-to-head comparisons and limited long-term data regarding their efficacy. We performed a retrospective chart review to determine long-term success rates of both devices and identify variables predictive of surgical success as well as safety profiles.

Methods: A retrospective chart review of all mild-to-moderate open angle glaucoma patients whom had cataract extraction combined with KDB or iStent with a minimum two year follow up by two surgeons. 138 eyes were treated with iStent and 50 eyes were treated with KDB. Success was defined as intraocular pressure (IOP) reduction of at least 20% of baseline IOP or reduced use of at least one IOP-lowering medication. Secondary analyses included decrease in IOP from baseline, decrease in number of IOP medications, evaluation of variables predictive of surgical success, and complication rates. Statistical analyses included paired t-test, two-group t test, Wilcoxon signed rank test, Chi-square test, and Chi-square approximation.

Results: The groups were well balanced other than slightly larger cup-to-disc ratio in iStent group (0.55 vs 0.47, $p < 0.01$). Success rates for iStent and KDB at two years were 64% and 55% ($p = 0.28$) and at three years they were 63% and 76% ($p = 0.28$), respectively. At two years, IOP decreased from baseline in the iStent group (-2.8, $p < 0.01$) but not the KDB group (-0.9, $p = 0.78$), while number of medications decreased in both groups (-0.3 for iStent with $p < 0.01$ and -0.3 for KDB with $p = 0.02$). No variables were consistently predictive of success across multiple time points. KDB had a higher incidence of prolonged postoperative iritis (8% vs 0%, $p = 0.01$), while all other complications were similar between groups.

Conclusions: These data suggest that overall, iStent and KDB are similar in terms of success rates at two and three years for patients with mild-to-moderate open angle glaucoma, although iStent may lower IOP slightly more than KDB. There are no variables that consistently predicted surgical success. Both devices had low complication rates. Further data with larger sample sizes should confirm these results.

ABSTRACT BODY:

Purpose: PAI-1, through its inhibition of urokinase-type and tissue-type plasminogen activators (uPA, tPA), plays a key role in fibrosis, inhibiting cellular degradation of extracellular matrix proteins. Elevated levels of PAI-1 have previously been found in studies of liver, kidney, heart and lung fibrosis. The aim of this study was to analyse the difference in gene expression between normal and glaucoma lamina cribrosa (LC) cells, in particular focusing on genes involved in fibrosis.

Methods: We obtained LC cells from 2 normal and 2 confirmed glaucoma donors. Cells were cultured and dissociated using papain dissociation method. The suspension viability was >90%. Cells from all 4 individuals were pooled and the suspension was processed on the 10x Genomics platform at Queens University Belfast (QUB) Genomics Core Technology Unit to capture a total of ~5000 cells. Sequencing was performed on an Illumina Novaseq which generated ~800 million reads. Bioinformatic analysis was performed in QUB, with SNP data used to demultiplex the individuals using the Demuxlet package.

Results: We found that the expression levels of PAI-1 and related proteins such as Vitronectin (VTN), Thrombospondin 1 (THBS1) and Somatomedin B and Thrombospondin Type 1 Domain Containing (SBSPON) are significantly enhanced in glaucomatous LC cells. tPA was overexpressed in normal LC cells compared to glaucoma LC cells.

Conclusions: Single cell RNA sequencing has revealed glaucomatous LC cells show a differential expression of pro-fibrotic genes. Increased PAI-1 leads to excess collagen accumulation and reduced extracellular matrix proteolysis, thus contributing to LC fibrosis and optic disc cupping. The overexpression of tPA in normal LC cells and its relevance to the fibrinolysis pathway may represent a novel therapeutic path.

ABSTRACT BODY:

Purpose: Abnormalities in the mechanical stiffness of corneal tissue as in the cases of fibrosis, keratoconus, or excessive crosslinking can remodel the corneal architecture and significantly impair vision. Optical coherence elastography (OCE) is an emerging imaging technique that has shown potential for the acquisition of high-resolution spatial information of corneal stiffness directly in vivo. Accurate assessment of tissue stiffness, however, relies on a more comprehensive understanding of elastic wave propagation through corneal tissue. Here, we assess the effects of intraocular pressure on the elastic wave propagation and the accuracy of OCE-acquired stiffness measurements.

Methods: An OCE system was custom-built and consisted of a spectral domain-OCT (SD-OCT) coupled with a mechanical piezo actuator. OCT imaging was timed with the mechanical stimulation of the piezo so that elastic wave propagation could be tracked. The raw OCT phase data was processed in MATLAB software. System calibration was performed using phantoms made of gelatin-methacrylate prior to any corneal experiments. Once calibrated, whole porcine globes were used to study elastic wave propagation in ex vivo corneal tissue. The porcine globes were cannulated, and the intraocular pressure (IOP) was controlled using a custom-built apparatus and a pressure sensor. The elastic wave speed was measured at different IOPs. Computational models were constructed using COMSOL software to assess the effect of IOP and tensile prestress on wave propagation.

Results: Preliminary results suggest that IOP has a significant effect on the propagation speed of elastic waves traveling through porcine corneal tissue. Computational models demonstrate that the increase in tensile prestress from higher IOPs increases the wave speed and lowers the accuracy of OCE-based corneal stiffness measurements.

Conclusions: Significant changes in intraocular pressure create tensile prestress within the corneal tissue, resulting in inaccurate measurements of corneal mechanical properties. Our computational model helps to understand and correct the OCE measurements. The development of OCE for clinical application may allow for direct monitoring of corneal stiffness and other mechanical properties during disease progression or after clinical therapies.

ABSTRACT BODY:

Purpose: Structural changes of the optic nerve head (ONH) such as lamina cribosa defects, prelaminar schisis, and peripapillary retinal schisis have been associated with glaucoma. We describe cases of previously undescribed ONH cavernous voids that were found on routine optic nerve head imaging (spectral domain optical coherence tomography [SD OCT], Spectralis, Heidelberg Engineering).

Methods: We include a case series (n=5 eyes, 4 patients) of ONH cavernous voids with demographic and clinical information. Visual field (SITA Standard 24-2 or 30-2) progression was defined by the clinician's analysis of the final scan and averaged 13 years of follow up. Visual acuity, recorded cup to disc ratios, and intraocular pressures (IOP) were noted.

Results: The SD OCT images (Figure 1) demonstrate cystic, hyporeflective spaces that are sharply delineated from surrounding tissue. They appear to be located anterior to the lamina cribosa. Cases 1,2, and 3 may be situated within Bruch's membrane opening (BMO), while case 4 is clearly situated lateral to BMO. They are all located inferonasally and can extend ~3 clock hours (cases 1 and 4) or ~6 clock hours (cases 2 and 3). In cases 1, 3, 4 this is found exclusively in the right eye. Case 2 had simultaneous nasal presentation of similar size in the left eye. In all cases there was no clinically significant global RNFL tissue loss over time. Vision remained stable in cases 1,3,4, except case 2 who developed macular degeneration requiring anti-VEGF injections. Visual field progression was observed in Case 1 and 4, while Case 2 and 3 had stable and/or full fields over 13 and 20 years of follow up, respectively. IOP averaged 15.9 +/- 4.7 mmHg across patients and all timepoints. Cup to disc ratio remained stable in all cases, except case 2.

Conclusions: Large optic nerve head cavernous voids can present in glaucoma suspects and glaucoma patients. Longitudinal volumetric analysis may shed light on whether the size of these voids change over time.

ABSTRACT BODY:

Purpose: Visual field loss in glaucoma patients is optimized to maximize the binocular field of vision via reciprocally asymmetric scotomal patterns in fellow eyes. (Jigsaw Effect; TVST 3.3.1, 2014). We now observe similar maximization of monocular fields arising over a physiologic time-frame. Discrete scotomal regions appear to be switched on and off via CNS coordinated alternation over a period of minutes. With MD tending to remain stable, one set of scotomal zones become visually active while adjacent segments of the previously intact visual field are switched off. These findings were discovered during a post-hoc analysis of prospective test-retest (TR) reliability of a new virtual reality perimeter.

Methods: Prospectively enrolled glaucoma patients with ≥ 5 years of highly reliable (FL, FP, and FN < 20%) and stable ($\Delta MD < 5$ dB over 5yr) Humphrey SITA visual field testing history were tested with the VisuALL virtual reality perimeter (Ollyes Inc., Summit, New Jersey, USA) using its 24-2 normal threshold algorithm twice, back-to-back. Monte Carlo simulations were used to test the hypothesis that test-retest (TR) variability within ipsilateral visual field measurements could be contributing to improved function and visual field survival in these diseased eyes. Visual fields were randomized 1,000,000 times and compared using a published method respecting the hill of vision (see TVST 3.3.1, 4.2.8 and 4.3.7).

Results: 44 eyes of 22 patients were included in the analysis. The best composite uniocular TR measurements were significantly worse than the mean randomized composite for the same eye ($p < 0.05$). However, when combined, the resulting oscillating monocular fields were significantly better than the mean from 1,000,000 randomizations ($p < 0.0001$; +1.37 dB), better than the best randomly-generated field (+0.17 dB).

Conclusions: Composite visual field patterns were significantly better than random variation, indicating CNS-directed throttling of neuronal function to maximize time-averaged visual field function in glaucomatous eyes, optimizing metabolic activation and recovery and minimizing apoptosis. Short-term fluctuation in perimetrically reliable patients may thus be a positive finding reflecting the existence of this dynamic protective phenomenon.

ABSTRACT BODY:

Purpose: The invariant natural killer (iNKT) cells are among the first innate immune cells to elicit early protective immunity that control invading viral pathogens. The role of iNKT cells and of their three major subsets, iNKT1, iNKT2, and iNKT17, in herpes immunity remains to be fully elucidated. In this study, we examined the protective role of corneal-resident iNKT cell subsets, using the mouse model of ocular herpes infection and disease.

Methods: Wild type (WT) C57BL/6 mice and CD1d knockout (KO) mice were infected ocularly with HSV-1 (strain McKrae). Cornea, spleen and liver were harvested at 2, 5, 8 and 14-days post-infection (p.i.) and the frequency and function of the three major iNKT cell subsets were analyzed by immunostaining and flow cytometry. The profiles of sixteen major cytokines were analyzed in corneal lysates using western blot and Luminex assays.

Results: Early during ocular herpes infection (i.e. day 2), the PLZF^{lo} RORgt^{lo} iNKT1 cell subset, was the predominate iNKT cell subset in the infected asymptomatic corneas. Asymptomatic mice (with reduced corneal herpetic disease) had more functional IFN-g-producing PLZF^{lo} RORgt^{lo} iNKT1 cells, compared to symptomatic mice. Moreover, compared to HSV-1 infected WT mice, the CD1d KO mice, with iNKT cell deficiency, are more susceptible to HSV-1 ocular infection and disease. This was associated with a decrease in: (i) IFN-γ production, and (ii) activation of MAPK (ERK1/2) and NFκB pathways in the cornea.

Conclusions: Our findings suggest that the IFN-γ-producing PLZF^{lo} RORgt^{lo} iNKT1 cells play a protective role against ocular herpes.

Commercial Relationships Disclosure (Abstract): Edwin Sarver: Commercial Relationship(s);Alcon:Code C (Consultant) | Max Hall: Commercial Relationship(s);Alcon:Code E (Employment)

ABSTRACT BODY:

Purpose: Purpose: An intraoperative Talbot-Moire interferometer uses Fourier analysis of captured images to generate exam data. The quality of the processed data can be degraded by the presence of artifacts in the images. A two-stage software module combined a convolutional neural network (CNN) front end with a deep neural network (DNN) back end capable of detecting in real time the artifacts appearing singly or in combination.

Methods: Methods: The first stage of the detection module employed pre-trained weights for a VGG16 CNN model, and the second stage was a fully connected DNN. The CNN weights were fully specified. Only the DNN and weights needed to be determined. The CNN inputs the image to be analyzed and outputs a length-512 real-valued vector. This vector is a collection of image features suitable for classification tasks for a large range of image types. The DNN inputs the output vector from the CNN and produces a vector estimating the probability of the presence of each of the artifacts. The data set consisted of 287 hand-labeled interferometer images. Each image could contain one or more artifacts. These image artifact labels included: one or more bubbles present, one or more floaters present, and corneal glint present. The data set was randomly split into 229 images for training the model and 58 images for testing the model.

Results: Results: 99% of the training set images were classified correctly for the presence of glint and 97% were classified correctly for the presence of floaters and bubbles. 91% of the test set images were classified correctly for the presence of glint, 95% were classified correctly for floaters, and 97% were classified correctly for bubbles. 97% of training images were correctly identified as being free from artifacts or having one or more artifacts, compared to 91% of the test images being correctly identified as being free from artifacts or not.

Conclusions: Conclusion: The CNN/DNN module developed was reasonably successful at identifying the artifacts in the image test set. We believe further training with a much larger image data set will increase performance. In addition, optimizing the threshold for the output layer values would allow customization of likelihood of detecting a "bad" image at the expense of increasing the likelihood of rejecting an artifact-free image.

ABSTRACT BODY:

Purpose: Describe the distribution of area of non-perfusion (NP) and neovascularization (NV) on ultra-widefield fluorescein angiography in patients with diabetic retinopathy (DR).

Methods: This retrospective, cross-sectional study included all ultra-widefield fluorescein angiograms taken for DR at the Kellogg Eye Center after approval from the UM IRB from January 2009 to May 2018 that included 651 eyes. Exclusion criteria included previous panretinal photocoagulation and images with significant media opacity (e.g. vitreous hemorrhage or significant cataract). These images were manually segmented for retinal surface areas of NP and NV. The total area per patient were organized by frequency in a histogram, and which were tested against power law and exponential distributions.

Results: Analysis of areas of NV across a population of 189 patients with proliferative DR demonstrates a power law distribution with an R2 fit of 0.9672 and shown by least squares method to be a superior fit to an exponential distribution with $p < 0.05$. Areas of NP over 794 patients with DR demonstrated a fit with an exponential distribution, with a superior fit compared to the power law distribution with $p < 0.05$. When the far periphery was excluded, the R2 fit for the exponential distribution was 0.9618.

Conclusions: NV in patients with diabetes follows a power law distribution, and NP follows an exponential distribution. The difference in event distribution suggests that though the two phenomena are related, they are of fundamentally different. While exponential distributions are seen in many gradual, progressive phenomena in nature, the power law distribution tends to occur in constructs which follow the principle of self-organized criticality, suggesting that NV may propagate as a catastrophic local event in an unpredictable manner.

TITLE: Cone mitochondria act as microlenses to enhance light delivery and confer Stiles-Crawford-like direction sensitivity

SESSION TITLE: Photoreceptors

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W. Li, J. Ball, S. Chen, NEI/RNS, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Wei Li: Commercial Relationship: Code N (No Commercial Relationship) | John Ball: Commercial Relationship: Code N (No Commercial Relationship) | Shan Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The vertebrate retina features an inverted structure with multiple neural layers through which photons must pass—risking premature absorption or scattering—prior to detection by light-sensitive opsin molecules located in photoreceptor outer segments (OS). Intriguingly, mammalian photoceptors hold numerous mitochondria in their ellipsoid region immediately before light reaching the OS. These mitochondria, likely supporting the high metabolic needs of phototransduction, however, could potentially impair light delivery to the OS due to their high membrane contents that might cause excessive light scattering. Conversely, they might enhance the delivery of light to the OS, taking up a potential optic role, which is not unprecedented for retinal structures (e.g. rod nuclei, Müller glia, and cone oil droplets). We thus set out to investigate the potential optic role of mitochondria in photoreceptor ellipsoid region.

Methods: Here, using a horizontal slice preparation from the ground squirrel retina, in which plentiful cones contain mitochondria in a bundled arrangement closely resembling those in primate, we directly imaged light transmitted through the mitochondria bundle (MtB). In addition, we performed electromagnetic simulations of light transmission based on the MtB structures translated from reconstructions of Blockface Scanning EM images.

Results: We directly demonstrated that such MtB concentrates light several fold onto the OS for detection. In addition, this “microlens”-like feature of cone mitochondria produces an angular dependence of light intensity quantitatively consistent with the Stiles-Crawford effect, a psychophysical phenomenon believed to improve visual resolution.

Conclusions: Thus, in addition to their function as a necessary powerhouse, cone mitochondria play a critical optical role. These findings provide needed insights into their role in interpreting results from noninvasive optical tools in ophthalmology.

ABSTRACT BODY:

Purpose: Corneal neuro-immune crosstalk has been of interest given advances in in vivo confocal microscopy (IVCM) imaging, given that IVCM is able to capture the presence of both immune cells and nerves. However, correlations between nerve alterations and dendritiform immune cell (DC) parameters in dry eye disease (DED) have not been investigated to date, which is the aim of the current study.

Methods: This retrospective cross-sectional cohort study included 105 patients with DED. Patients were included in the study if they had symptoms of DED, a tear break-up time (TBUT) of less than 10 seconds and/or corneal fluorescein staining score of at least 1 on the Oxford scale. Three representative images were selected for the study eye for analysis using ImageJ. Morphological alterations of DCs per image was quantified by Image J. NeuronJ was used to quantify corneal nerve density for each image for main and total nerves.

Results: The average age of the patients was 58.8 ± 1.7 years, and 76.2% of them were female. The average DC size was $108.54 \pm 5.70 \mu\text{m}^2$, and the average number of dendrites was 0.59 ± 0.08 per immune cell. The mean immune cell density was $47.73 \pm 5.43/\text{mm}^2$. Main, total, and branch nerve densities were $8,011.58 \pm 269.74 \text{ mm}/\text{mm}^2$, $12,516.58 \pm 450.89$, and 4504.99 ± 264.20 , respectively. DC size was inversely correlated to total nerve density ($\rho = -0.339$, $p = 0.001$) and branch nerve density ($\rho = -0.386$, $p < 0.001$). In addition, number of dendrites had an inverse correlation to total nerve density ($\rho = -0.212$, $p = 0.035$) and branch nerve density ($\rho = -0.211$, $p = 0.036$). The inverse correlation of DC size and dendrite number and nerve density suggest that larger, more mature DCs are associated with nerve loss or vice versa.

Conclusions: IVCM reveals an increased density and morphologic changes of corneal DCs in DED. There is a strong and significant correlation between the increase in DC size and number of dendrites and the decreased subbasal corneal nerves, suggesting a potential interaction between the immune and nervous system in the cornea during DED.

TITLE: Validation of a Low Luminance Mobility Test for Retinitis Pigmentosa

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. KAMMER, J. Yang, H. Klassen, Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|A.K. Bittner, Jules Stein Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|B. Mills, Mills Consulting, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): REBECCA KAMMER: Commercial Relationship(s);jCyte:Code C (Consultant) | Ava Bittner: Commercial Relationship(s);jCyte:Code C (Consultant) | Bonnie Mills: Commercial Relationship(s);jCyte:Code C (Consultant) | Jing Yang: Commercial Relationship(s);jCyte:Code I (Personal Financial Interest);jCyte:Code S (Non-remunerative);jCyte:Code R (Recipient) | Henry Klassen: Commercial Relationship(s);jCyte:Code I (Personal Financial Interest);jCyte:Code R (Recipient);jCyte:Code S (Non-remunerative)

ABSTRACT BODY:

Purpose: To rigorously assess the test-retest repeatability, content validity and construct validity of a novel Low Luminance Mobility Test (LLMT) and scoring algorithm to determine whether this new performance task is a suitable endpoint to include in clinical trials of retinitis pigmentosa (RP).

Methods: A prospective, observational study, included both subjects with RP (n=20), mean best corrected visual acuity (BCVA) of 1.05 logMAR (range 0.55-1.56 logMAR), and without RP (NoRP, n=16, normal BCVA <0.05 logMAR). The LLMT used 13 light levels from 0.12 lux in increasing steps of 0.3 log units up to 500 lux. A novel scoring algorithm utilized MNREAD principles and R programming to develop a Critical Illumination Level (CIL) and Maximum Step Speed (MSS) score. The CIL is the lowest light level prior to a significant drop in adjusted step speed. MSS is the mean speed for the fastest trials on the plateau of the curve. Subjects completed the LLMT monocularly twice over two weeks, and video recordings of the trials, which were masked to visit and light levels, were sent to trained raters for scoring. For inter-rater and intra-rater reliability, grading of video trials of the LLMT across two studies using three raters allowed for the largest sample. In addition, BCVA, contrast sensitivity (CS), kinetic visual fields (KVF), and the VA LV VFQ-48 were compared to CIL scores to establish content validity.

Results: The LLMT differentiated between NoRP and RP since NoRP subjects had a median CIL of 0.12 lux and mean MSS of 61.0 ± 11.01 steps per minute (spm), whereas RP subjects varied widely in performance with a median CIL of 32 lux (range 0.12-1000 lux) and mean MSS of 33.6 ± 14.93 spm. There was no change in the CIL between test sessions for 75% of RP subjects (n=15), and the five with variability all had constricted KVF diameter $<12^\circ$. All visual function measures were significantly related to the CIL in a multiple regression model, $R^2=0.75$ (p=0.004) but CS was the greatest contributor. Bland Altman plots for inter-rater and intra-rater video grading indicated biases close to zero, and there were no significant differences between graders (p>0.05).

Conclusions: The LLMT is a novel low luminance clinical trial endpoint validated for RP with strong test-retest reliability, good content and construct validity, and an objective scoring system. The LLMT is a useful and reliable endpoint for studying low luminance mobility function in RP.

ABSTRACT BODY:

Purpose: Independent of one another, endogenous bacterial endophthalmitis (EBE) and uveal lymphoma are extremely rare. Herein, we describe two cases of EBE secondary to group B streptococcus (GBS) in eyes with secondary uveal lymphoma confirmed on histopathology. Understanding the characteristics of these presentations is critical to informing our approach to patients with EBE in the setting of underlying systemic leukemia / lymphoma.

Methods: A retrospective review was conducted of two cases who presented with endogenous bacterial endophthalmitis secondary to GBS who underwent enucleation and histopathology confirmed concurrent intraocular manifestation of systemic lymphoma.

Results: A 65-year-old male with a history of a lymphoproliferative disorder treated previously presented with a red, painful left eye and loss of vision. He was found to have endogenous endophthalmitis secondary to GBS bacteremia as determined by blood and vitreous cultures. Enucleation was performed. Histologically, the ocular specimen showed gram positive cocci in pairs in addition to atypical lymphocytic infiltrate in both the uvea and conjunctiva. Tumor cells were positive for CD20 and focally co-expressing CD43 on immunohistochemistry. A diagnosis of bacterial endophthalmitis and extranodal marginal zone B-cell lymphoma involving the uvea and conjunctiva was made. A 70-year-old male with a history of Hepatitis B, facial squamous cell carcinoma, and diabetes mellitus type II, similarly presented with acute, painless vision loss of the left eye, and was also found to have endogenous endophthalmitis secondary to GBS bacteremia as confirmed on blood, anterior chamber and vitreous cultures. Enucleation was performed, and immunohistochemistry of the uveal and retinal tissues was positive for CD20 and CD5, with co-expression of CD23, CD43, and BCL2. The patient was diagnosed with CD5+ small B-cell lymphoproliferative disorder with chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) immunophenotype.

Conclusions: To our knowledge, no reports have discussed EBE with concurrent secondary intraocular malignancy. The clinical course of both patients' EBE was rapidly progressive. It may be that the presence of uveal lymphoma weakens the intraocular immune system and increases the eye's susceptibility to infection.

TITLE: Surgical Phase Identification and Pupil Tracking in Phacoemulsification Cataract Surgery as a Foundation for Surgical Guidance

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Garcia Nespolo, C. Luciano, Y. Leiderman, Bioengineering, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|R. Garcia Nespolo, E. Cole, N. Valikodath, Y. Leiderman, Ophthalmology, University of Illinois at Chicago College of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rogerio Garcia Nespolo: Commercial Relationship: Code N (No Commercial Relationship) | Emily Cole: Commercial Relationship: Code N (No Commercial Relationship) | Nita Valikodath: Commercial Relationship: Code N (No Commercial Relationship) | Cristian Luciano: Commercial Relationship: Code N (No Commercial Relationship) | Yannek Leiderman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As a foundation to develop tools for surgical guidance, we sought to develop an agent capable of autonomously identifying the various steps and phases of phacoemulsification cataract surgery in real-time together with pupil segmentation, such that the generated output is capable of informing surgical decision making.

Methods: Heterogeneous videos were annotated by ophthalmic surgeons in order to achieve robustness of pupil detection, phase identification and tissue segmentation by the algorithm.

The application acquires video frames, in real time, from a surgical microscope-based video capture device. Then, a Region Based Convolutional Neural Network (R-CNN) performs the following functions for each analyzed frame (figure 1):

i) pupil location and area

ii) surgical phase identification according to the instruments in use

Results: 1. We evaluated the performance of the R-CNN via comparison with annotation of surgical videos performed by ophthalmic surgeons (Table 1). We achieved high values in accuracy, precision, and sensitivity across each of the four phases (idle, capsulorhexis, phacoemulsification and cortex removal), leading to F1-scores above 90%.

2. There was also strong correlation among the graders' assessment of the size of the pupil with the pupil area detected by the algorithm, yielding precision, sensitivity, and intersection over union area (IoU) of 82.07%, 87.19%, and 95.14%, respectively.

3. The algorithm executed these tasks at an average processing speed of 82 ± 20 frames per second (FPS), well above the output of 60 FPS at which most contemporary surgical visualization systems display images.

Conclusions: It is important to state that no current machine learning solution combines phase identification with pupil tracking. We have developed a platform that provides the foundations for a real-time surgical guidance tool for phacoemulsification cataract surgery by using object detection and classification for surgical phase classification. Future machine learning-based tools can utilize these capabilities for the creation of novel surgical guidance tools and feedback mechanisms.

ABSTRACT BODY:

Purpose: Functional characterization at cellular resolution is key to the advancement and evaluation of new therapeutic interventions such as gene and cell replacement therapies. Here, we report development of optical coherence tomography (OCT) guided micro-focal multi-color light stimulated electroretinogram (ERG) platform for highly localized monitoring of retina function. Functional evaluation of wild type and animals with degenerated retina was carried out using OCT guided micro-focal ERG (μ fERG) with selected stimulation wavelengths for S, M and L cones as well as rod photoreceptors.

Methods: The stimulation light beam was fiber coupled and combined with the OCT imaging beam. Using Nanoscope Instrument's NS-Neel OCT guided μ fERG platform, μ fERG responses from different retinal locations were recorded. Light flashes were elicited by pre-selected wavelengths (Blue: 455 nm; Green: 530 nm; and Red: 630 nm) of the micro-focused beam on wild type mice and pigs as well as animals with photoreceptor degeneration caused by gene mutation or laser-injury. Micro-focal ERG from multiple strobe light flashes were averaged and filtered to obtain the final waveform.

Results: Functional deficits in mice and pigs with photoreceptor degeneration was observed via micro-focal ERG measurements. Further, μ fERG recordings from different types of cones produced unique characteristic responses when stimulated by blue, green, or red micro-focused beam at targeted locations. No micro-focal cone ERG response was observed with red light stimulation (since mice and pigs lack red sensitive-cones). Using low intensity stimulation, μ fERG measurements from rod photoreceptors could be detected and isolated from cone response.

Conclusions: Our results show that OCT guided μ fERG allows functional evaluation of retinal degeneration. Micro-focal ERG is able to not only characterize differences in rod and cone function but also distinguish different cones with selected stimulation wavelengths. Control of light adaptation and stimulation parameters in the OCT guided μ fERG such as intensity, wavelength, and pulsing allow distinguishing differences in functioning of different photoreceptors and cell types.

ABSTRACT BODY:

Purpose: Central retinal vein occlusion (CRVO) is a common cause of visual loss. Asymmetry among the 4 ETDRS quadrants (superior [SUP], nasal [NAS], inferior [INF] temporal [TEMP]) in terms of optical coherence tomography angiography (OCTA) metrics (e.g., superficial retinal layer [SRL] perfusion density [PD, total area of perfused vasculature/unit area], vessel density [VD, total length of perfused vasculature/unit area] inner thickness [IT] and outer thickness [OT]) exists in control eyes. Herein, we assess if the insult of a non-ischemic versus ischemic CRVO affects the quadrant asymmetry (QA) differentially.

Methods: 28 control eyes, 6 non-ischemic and 7 ischemic CRVO eyes underwent 3x3 mm OCTA scans with signal strength >7. Automated segmented scans with registration for the SRL. QA was defined as the maximum value among the 4 ETDRS quadrants minus the minimum value for a given eye. OCTA parameters were assessed by multivariate linear regression analysis including fixed effects for each individual-by-eye.

Results: There was no significant QA for the 4 OCTA metrics when comparing non-ischemic CRVO with control eyes ($p>0.05$). However, ischemic CRVO eyes had greater PD QA (+0.014, $p=0.006$), IT QA (+20.7, $p<0.001$) and OT QA (+6.3, $p<0.001$) than control eyes. Ischemic CRVO eyes had greater VD QA (+1.48, $p<0.001$), PD QA (+0.030, $p=0.003$), IT QA (+43.3, $p<0.001$) and OT QA (+17.6, $p<0.001$) than non-ischemic CRVO eyes. Within control eyes, OCTA metrics tended to be greatest in NAS, with INF and SUP having lower VD (2.55, $p=0.001$; 1.54, $p=0.002$), PD (0.04, $p=0.001$; 0.02, $p=0.011$), IT (10, $p<0.001$; 14.8, $p<0.001$) and OT (29.6, $p<0.001$; 32.0, $p<0.001$), and TEMP having lower IT (5.2, $p=0.008$) and OT (17.7, $p<0.001$). In contrast, in CRVO eyes, the max quadrant was not consistent ($p>0.05$) aside from NAS IT in non-ischemic CRVO eyes higher than INF (6.8, $p=0.041$) and SUP (10.3, $p=0.015$) and NAS OT in ischemic CRVO eyes higher than INF (30, $p=0.008$) and SUP (39.1, $p=0.003$).

Conclusions: Although QA does not differ between nonischemic CRVO and control eyes, ischemic CRVO affects PD, VD, IT and OT more asymmetrically across the 4 ETDRS quadrants when compared to non-ischemic CRVO eyes, and affects PD, IT and OT more asymmetrically than control eyes. QA of OCTA metrics in control eyes tended to be driven by the largest values found in the nasal quadrant, but were more evenly distributed in CRVO eyes.

TITLE: Simultaneous combination steroid anti-VEGF therapy for monotherapy resistant macular disease

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Warter, M. Cavichini Cordeiro, D.G. Bartsch, S.R. Singh, D.R. Freeman, Ophthalmology, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alexandra Warter: Commercial Relationship: Code N (No Commercial Relationship) | Melina Cavichini Cordeiro: Commercial Relationship: Code N (No Commercial Relationship) | Dirk-Uwe Bartsch: Commercial Relationship: Code N (No Commercial Relationship) | Sumit Singh: Commercial Relationship: Code N (No Commercial Relationship) | Dr. William Freeman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our purpose was to analyze the safety and efficacy of the use of combined anti-VEGF and long-acting steroid IV therapeutic agents in resistant macular fluid after conventional monotherapy. We performed a retrospective observational clinical study to assess anatomical and visual changes in a consecutive cohort of patients resistant to aggressive monotherapy in retinovascular (RVD) induced edema (ME) and choroidal vascular induced edema (CNV) in Wet-AMD.

Methods: This study included a total of 28 eyes (56 injections) with nonresponsive macular fluid after a standardized protocol consisting in escalation treatment with varied doses of alternating anti-VEGF or steroid injections. Resistance was defined as persistent fluid after escalation of anti-VEGF to 1mg Aflibercept every 4 weeks and additional monotherapy resistance to IV Triamcinolone Acetonide (TCA) or Dexamethasone in RVD. A prior mean of injections was 36.45[18-67] in Wet-AMD and 9.17[3-17] in RVD. Combination therapy consisted in the simultaneous administration of IV anti-VEGF and steroid. Slit lamp evaluation, VA, IOP, and Optical Coherence Tomography (Heidelberg Spectralis) measurements of central retinal thickness (CRT) were recorded every 4 weeks post injection. All eyes received prophylactic topical anti-glaucoma medication for 2 weeks (Timolol 0.5%/Dorzolamide 2%). Outcomes included reduction in CRT, VA, and IOP changes.

Results: Our initial analysis was performed post first injection of combined therapy in one eye of each patient. Safety data showed no evidence of infection. 14% of patients reported transient visual obscuration due to TCA particles. There was a modest rise in IOP in 19% of patients; no eyes required glaucoma surgery or showed vascular occlusions. Anatomic outcomes showed a statistically significant reduction in CRT in both groups; paired analysis showed an average CRT reduction of $45.55\mu\text{m}\pm\text{SD}20.656$ ($p<0.05$) in CNV and $145\mu\text{m}\pm\text{SD}31.651$ ($p<0.0003$) in RVD. There was a non-significant trend of VA improvement ($p=0.712$).

Conclusions: We found that combination of IV steroids and anti-VEGF produces clear anatomic improvement in CNV. Other studies have evaluated combination therapy in RVD and found vision improvement, but not in eyes resistant to monotherapy with both anti-VEGF and steroids. In such eyes, we found overall disease improvement. Combination therapy therefore may be useful in treating resistant Wet-AMD CNV and RVD ME.

ABSTRACT BODY:

Purpose: Ocular surface disease (OSD) is a defying condition affecting patients under preserved topical glaucoma therapy. Even when the safety and effectiveness of both short-term and long-term use of autologous serum (AS) eyedrops has been studied in a myriad of diseases affecting the ocular surface, there is scarce information regarding AS benefit on OSD derived from preserved topical glaucoma therapy. The aim of this study is to compare effectiveness and safety AS eyedrops (comparing 30%AS vs 50%AS concentrations) in glaucoma patients with severe/persistent OSD using topical hypotensive treatment.

Methods: A retrospective assessment of all consecutive patients under glaucoma treatment in a specialized center was performed. A total of 396 patients with severe OSD under glaucoma treatment were identified. Twenty-nine cases had AS eyedrops in concentrations 30%AS and 50%AS, as well as other treatment regimes. Variables included BCVA, TBUT, ocular surface staining (OSS) percentage, presence of Meibomian gland dysfunction and ocular-surface disease index (OSDI). A p value ≤ 0.05 was considered as statistically significant.

Results: Fifty-eight eyes from 29 patients were included in the study (22 females, 7 males) had a mean age of 67.0 ± 16.1 years. According to AS concentration, 56% of the eyes were treated with a 30%AS and 44% with 50%AS. Mean time of preserved topical treatment was 1.6 ± 1.0 years. Baseline IOP (RE, 19.2 ± 5.9 mmHg; LE, 19.1 ± 8.8 mmHg) was not different as compared to the measurements at the last visit (RE, 18.9 ± 6.1 mmHg; LE, 19.4 ± 7.3 mmHg; $p \geq 0.05$). Mean time of AS administration (RE, 8.9 ± 7.5 weeks; LE, 9.7 ± 8.3 weeks; $p = 0.5$). Overall, a comparative improvement was significant in regards of BCVA (RE, $p = 0.001$; LE, $p = 0.007$), OSS (RE, $p = 0.045$; LE, $p = 0.035$), OSDI (RE, $p = 0.04$; LE, $p = 0.03$). No significant change was demonstrated in TBUT (RE, $p = 0.12$; LE, $p = 0.08$). Comparative success rate between groups are not significantly different (30%AS, 84%; 50%AS, 86%). One non-infectious ulcer was present in the group treated with 30%AS eyedrops but it healed without further complication.

Conclusions: Current study results suggest that ASE of either concentration is effective and safe for treating severe ocular surface diseases caused by glaucoma eyedrops containing preservatives.

Commercial Relationships Disclosure (Abstract): Kathleen Heng: Commercial Relationship: Code N (No Commercial Relationship) | BaoXiang Li: Commercial Relationship: Code N (No Commercial Relationship) | Aakriti Singh: Commercial Relationship: Code N (No Commercial Relationship) | Rain Wen: Commercial Relationship: Code N (No Commercial Relationship) | Albert Wu: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goldberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Adeno-associated virus serotype 2 (AAV2) is a promising gene therapy platform for glaucoma and other retinal ganglion cell (RGC) degenerative diseases. Although pro-survival and pro-regenerative AAV2 gene therapies have been identified in mouse, advancement towards human therapeutics has been limited due to a lack of data in a large animal model. Here we test transduction of porcine RGCs with AAV2 in vivo while evaluating vector promoters and optimizing injection technique.

Methods: Yucatan minipigs (5.5-6 months old) were intravitreally co-injected with AAV2-UBC-eGFP and AAV2-CAG-TdTomato to compare promoter strength. In order to optimize vector delivery, three injection strategies were evaluated: (1) 1-point injection at the temporal aspect of the eye 4 mm posterior to the limbus, (2) 2-point injection at the temporal and nasal aspects, and (3) 4-point injection at the temporal, nasal, superior, and inferior aspects. Four weeks after injection, retinas were harvested, stained by immunofluorescence for Brn3a (RGC marker), flat-mounted, and imaged by confocal microscopy. Fluorescent cells were quantified on ImageJ, and transduction efficiency was determined by calculating the percentage of Brn3a+ cells that were eGFP+ or TdTomato+. All research was conducted in compliance with IACUC approval and the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research.

Results: Both UBC and CAG promoters drove high fluorophore expression in RGCs (75% and 74% transduction efficiency, respectively). The 2-point injection strategy resulted in high transduction efficiency across the retina, whereas 1-point injection resulted in high transduction in the temporal retina but moderate or low transduction elsewhere, and 4-point injection resulted in minimal transduction across the retina.

Conclusions: AAV2 is a viable technology for gene delivery in porcine RGCs in vivo. Both UBC and CAG promoters strongly promote transduced gene expression in porcine RGCs, and a 2-point injection method yielded optimal delivery efficiency.

ABSTRACT BODY:

Purpose: The goal of this study is to investigate the effect of Apolipoprotein A-I binding protein (AIBP; gene name APOAIBP) on mitochondrial structure and function in Müller glia in response to elevated pressure.

Methods: Retina tissues were prepared from wild-type (WT, C57BL/6J) and AIBP knockout (Apoa1bp^{-/-}) mice. Mitochondrial morphology and ATP production were assessed by serial block-face scanning electron microscopy (SBEM) and electron microscope (EM) tomography. Rat Müller glia cell line (rMC-1) cultures were pretreated with BSA or recombinant human AIBP (0.2 µg/ml) at 2 hours before exposure to elevated hydrostatic pressure (HP, 30 mmHg) for 2 hours. Mitochondrial respiration in rMC-1 cells was assessed by measuring oxygen consumption rate using a Seahorse XF24 analyzer. Mitochondrial activity and cell viability were measured by MTT and CellTiter-GloTM luminescent assays.

Results: Apoa1bp^{-/-} mice showed mitochondrial fragmentation and reduction of ATP production in Müller glia mitochondria. Quantitative analyses showed that there were no significant changes in mitochondrial volume, volume density, or mitochondrial number in the Apoa1bp^{-/-} Müller glia endfeet. The form factor for the Apoa1bp^{-/-} mitochondria was significantly lower than for the WT, meaning more mitochondrial rounding in the Apoa1bp^{-/-}. Mitochondrial length was significantly decreased in Apoa1bp^{-/-}. Similarly, the crista density and the modeled rate of ATP production per mitochondrial volume were lower in the Apoa1bp^{-/-}. In contrast, the modeled rate of ATP production per mitochondrion was not lower in the Apoa1bp^{-/-}, yet there was a significant decrease in cellular ATP production via mitochondria in the Apoa1bp^{-/-}. AIBP treatment promoted basal and maximal respiration along with an increase of ATP production and spare respiratory capacity, as well as mitochondrial activity in rMC-1 cells exposed to normal pressure compared to BSA treatment. In BSA treatment, elevated HP significantly reduced maximal respiration and spare respiratory capacity in rMC-1 cells compared to cells exposed to normal pressure. In addition, AIBP treatment enhanced basal and maximal respiration, as well as mitochondrial activity and cell viability in rMC-1 cells exposed to elevated HP.

Conclusions: These findings suggest that AIBP may protect retinal ganglion cells by promoting mitochondrial bioenergetics of Müller glia during glaucomatous neurodegeneration.

ABSTRACT BODY:

Purpose: To evaluate the diagnostic accuracy of a Retinal virtual multimodal-imaging clinic led by ophthalmic graders in the management of patients with retina diseases

Methods: Prospective comparative observational study. Patients who were known to have retinal diseases (including diabetic retinopathy (DR), age-related macular degeneration(AMD) or other retina conditions) were recruited from the Singapore National Eye Centre Retina Clinic, and underwent a clinical pathway, involving optical coherence tomography(OCT) [Cirrus Photo, Zeiss, Germany] and ultrawide wide field fundus image(UWF) [Clarus, Zeiss, Germany] which are reviewed by trained non-physician graders (Ophthalmic graders) to detect for active retinal disease that require treatment or further evaluation by ophthalmologist. Patients were subsequently reviewed on the same day in standard of care retina clinics by an ophthalmologist (resident to consultant level) blinded to the grader outcome with OCT performed as clinically indicated. The reference standard was evaluation of the clinical notes and multimodal imaging (OCT + UWF) by a masked Retina specialist. A composite outcome of active retinal disease was defined as the presence of either: 1)vision threatening diabetic retinopathy(VTDR) [severe non proliferative DR or active proliferative DR], 2) Centre involving diabetic macular edema, 3) Active neovascular AMD. The sensitivity and specificity of the new clinical pathway in identifying treatment requiring retinal disease was evaluated against the reference standard.

Results: There were 494 participants of which 38 (8.3%) patients had active retinal disease identified. The new clinical pathway had a sensitivity of 95.1 % (95% confidence interval [CI] 88.5-100%) and a specificity of 97.4% (95% CI 95.9-98.8%) to detect active retinal disease. The positive predictive value was 76.5% and the negative predictive value was 99.6% There were 2 cases of active retinal disease misclassified by the grader pathway as stable, and both had severe non-proliferative DR with no macular disease.

Conclusions: The new ophthalmic grader led multimodal imaging based clinical pathway had good sensitivity and specific for identifying active retinal disease that may require treatment. This pathway may be able to replace standard specialist outpatient clinic for the management of selected patients with retinal diseases.

ABSTRACT BODY:

Purpose: Neuropathic corneal pain NCP is commonly thought to present with discordant signs and symptoms with minimal to no ocular surface staining. However, the Schirmer's test result in patients with NCP have previously not been compared to patient with conventional dry eye disease DED. Thus, the purpose of the current study was to compare Schirmer's test results between patients with NCP as compared to DED.

Methods: This is a comparative, retrospective case-control study of age and sex matched NCP and DED patients, who were seen at the New England Eye Center between August 2018 and November 2020. NCP was diagnosed clinically and confirmed by in vivo confocal microscopy and the proparacaine challenge. Demographics, Schirmer's test results with anesthesia, tear-break-up time TBUT, corneal staining CFS, ocular pain scores, ocular and systemic comorbidities were recorded. Patients were included in the DED group, based on the inclusion criteria of CFS staining ≥ 4 and TBUT ≤ 7 .

Results: The mean age of patients with NCP was 45.7 ± 4.9 with $n=4$ males and $n=19$ females, and 63.1 ± 3.9 for the DED group with $n=5$ males, and $n=14$ females $p=0.199$ for age $p=0.707$ for gender. The mean Schirmer's tests results for the NCP group were $9.8\text{mm} \pm 1.8$ and $7.1\text{mm} \pm 1.1$ for the DED group, respectively with a p value of $p=0.450$. This indicated no significant difference in Schirmer's results between the DED and NCP patients, with both groups demonstrating decreased results compared to healthy subjects. There was no difference in Schirmer's results in the NCP group regardless of breakdown into peripheral $n=3$ mean 8.67 ± 5.78 , mixed $n=9$ mean 12.33 ± 2.73 and central $n=3$ mean 5.00 ± 1.16 $p=0.383$. The mean TBUT for the DED group was $4.0\text{sec} \pm 0.4$ and $10.2\text{sec} \pm 0.5$ for the NCP group $p= <.001$. The mean CFS was 4.1 ± 1.0 for DED, and 0.4 ± 0.2 for the NCP group $p=.011$. DED patients reported a mean pain level of 1.9 ± 0.7 on VAS, while NCP patients reported VAS of 4.5 ± 0.3 $p=.002$. DED patients reported a mean of 1.8 ± 0.7 on OPAS questions 5-7 indicating pain over the previous 24hr period, while NCP patients reported 5.0 ± 0.7 $p=.001$.

Conclusions: The results of this study shows that NCP patients may present with low values on Schirmer's tests in the absence of clinical signs of DED. The data suggests that abnormal Schirmer's test results may be due to nerve dysfunction and that abnormal Schirmer's tests results should not be used to exclude NCP.

ABSTRACT BODY:

Purpose: To assess the importance of subretinal hyperreflective material in nAMD visualized on structural OCT and its response to anti-VEGF treatment.

Methods: We analyzed eighteen eyes from twenty five subjects with nAMD. These were nAMD consecutive cases and we followed them for up to five years to investigate the incidence of subretinal hyperreflective material during nAMD treatment with ranibizumab and bevacizumab. The best visual acuity before treatment ranged from 20/40 to 20/100

Results: We found four cases of subretinal hyperreflective material (SHM) on the follow up of the treated subjects. Visual acuity had no improvement during the treatment of the the patients affected by the SHM. Two of the subjects presenting SHM had a initial improvement of visual acuity, developing retrogression after the development of the pathology.

Conclusions: The appearance of subretinal hyperreflective material on OCT during treatment with anti-vegf for nAMD is possible and suggests worse visual prognosis when compared to patients with no hyperreflective material

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is influenced by environmental and genetic factors. It is associated with multiple disease processes with primary open angle glaucoma (POAG) being the most prevalent. Due to its complex, multifactorial nature, genetic predisposition is not completely understood, and a standardized animal model has yet to be developed for POAG. Heterogenous stock (HS) outbred rats is a multigenerational outbred population derived from eight fully sequenced founder strains. This population is ideal for genome-wide association studies (GWAS) due to most genetic variants being common, access to a large collection of tissue samples, and the large allelic effect size compared to human studies. The purpose of this study was to use HS rats to identify genetic loci underlying elevated IOP.

Methods: Both male and female HS rats (N=1812) were used in the study with genotyping by sequencing conducted on all subjects. We mapped quantitative trait loci (QTLs) for IOP phenotypes and SNP heritabilities were estimated. We used permutation to determine the threshold for significance using an empirical p value of 0.05. Linear mixed model was used to control for the complex family relationships of the HS rats.

Results: GWAS identified three genome wide significant loci for elevated IOP located on chromosomes 1, 5, and 16. The QTLs contained 18 genes in total. Only one of these genes has been previously associated with human POAG.

Conclusions: This study highlights the efficacy of HS rats for investigating the genetics of elevated IOP and identifying potential candidate genes for future functional testing. GWAS is a powerful method for identifying genome regions which harbor variants responsible for the variation in quantitative traits, such as IOP. The identification of three independent QTLs in a relatively small sample size is promising for continued future findings as the sample population grows. Additional studies are ongoing to narrow the list of candidate genes in these intervals.

ABSTRACT BODY:

Purpose: The neuroprotective role of glial cells is a growing research focus in nervous system pathologies including glaucoma, which is one of the most common neurodegenerative disorders and the leading cause of irreversible blindness worldwide. Retinal astrocytes, along with those of the optic nerve, have been shown to play key roles in the survival of retinal ganglion cells, particularly in response to glaucomatous stress. The mechanisms regulating this protection, however, are poorly understood, as these cells populate the retina sparsely and are difficult to isolate acutely. By utilizing a novel isolation method and examining the transcriptomic data from retinal astrocytes exposed to elevated intraocular pressure (IOP), we aim to understand the response of these cells to glaucomatous stress.

Methods: Adult male C57/B6 mice underwent laser-induced episcleral vein cauterization, resulting in an elevation in IOP. After one week, treated animals and age-matched controls were euthanized and highly enriched populations of retinal astrocytes were isolated by a combination of enzymatic dissociation and mechanical separation. Purified RNA from these samples was used to generate cDNA libraries for next generation sequencing, and differential gene expression was analyzed after bioinformatic cleanup.

Results: After applying thresholds of 2-fold change in expression and $< .05$ for false discovery rate, 335 upregulated genes were identified in samples from experimental animals relative to those from controls. The most strongly correlated gene ontology category was 'GO:0006954: inflammatory response', with a $-\log_{10}(P)$ of 27.8. Furthermore, a number of these upregulated genes have been previously implicated as markers of astrocyte reactivity. The second most strongly correlated GO category was 0001568: blood vessel development, with a $-\log_{10}(P)$ of 25.1, likely reflecting the close association of astrocytes with the superficial retinal vasculature.

Conclusions: Our results are broadly consistent with studies of reactive astrocytes in the brain, while delivering new insight into the behavior of these cells in the retina; this may illuminate future directions for research into retinal neuroprotection. This outcome also demonstrates the utility of our approach to retinal astrocyte isolation, which requires little in the way of specialized equipment and benefits from a post-mortem interval of less than one hour.

ABSTRACT BODY:

Purpose: Primary-angle closure glaucoma (PACG) is the second most common form of glaucoma with over 23 million affected in 2020 globally. It is more common in Asian populations and may manifest sudden extreme IOP elevations with rapid optic nerve damage. However, identifying individuals who are at risk to provide appropriate clinical management is challenging. Given the disparity in prevalence across global populations, there is potentially a complex interplay among risk factors in inter-racial predisposition towards PACG. Two major Genome-Wide Association (GWAS) meta-analyses of PACG across global populations identified 17 variants in eight loci to be potentially causal. It is not clear how these variants mechanistically contribute to manifestation of the disease. We hypothesize that there are unique molecular factors that contribute to disparity observed for PACG based on ancestry.

Methods: Transcriptome-based predicted gene expression associations (TWAS) of PACG could provide powerful methods to prioritize genes involved in the etiology of the disease. We used three recently developed TWAS methods that provide a framework for directly estimating gene expression using GWAS summary data. We performed TWAS on global-multiethnic (n=40,070) and South-East Asian (SEA, n=12,743) summary PACG data across 49 GTEx tissues.

Results: We identified 78 genes in 42 loci associated with PACG, including genes in GWAS loci with subgenome-wide signals. Three prominent loci with multiple gene signals: GWAS PLEKHA7 locus (eight genes), and novel CYP2C9 (four genes) and ECM2 (eight genes) loci that were unique to SEA, we performed sequential conditional analysis in each tissue. We further rebuilt prediction models excluding variants in models of other genes in the loci that were in LD with any variants of the strongest signal. The strongest signals in these loci were NCR3LG1 ($p=4.4e-14$), CYP2C9 ($p=3.3e-15$) and ECM2 ($p=2.4e-26$), respectively, and all the other 17 gene signals were not independent of these signals. Multigenic score and comorbidity analyses in a large EHR-linked BioVU data (n=100,262) implicated dysregulation in inflammatory and blood pressure processes in PACG. Moreover, our results point to unique genetic factors and pathways in across-ancestry risk to PACG.

Conclusions: Unique inflammatory and blood pressure processes are involved in across-ancestry PACG etiology

ABSTRACT BODY:

Purpose: The diverse DNA variants found in human patients can differ not only in their pathogenicity but also in their response to therapeutic compounds. Both of these issues can prevent inherited retinal disease patients from receiving treatment. Our goal is to create high-throughput cell-based assays to categorize variants and their differential sensitivity to potential therapeutic compounds. For example, 9-cis retinal, a form of vitamin A, is a known molecular chaperone for misfolded mutant rhodopsin (RHO), and mutations in RHO are a major cause of autosomal dominant retinitis pigmentosa.

Methods: A library of 211 rhodopsin variants was created and transfected into HEK293 cells. After transfection, all variant-expressing cells were pooled. Cells were treated with 5 different doses of 9-cis retinal for 24 hours. The cells were fixed and stained with a monoclonal anti-rhodopsin antibody to detect rhodopsin that was successfully folded and transported to the cell surface. Using FACS, cells from each dose were sorted according to their rhodopsin surface expression. Residual transfected DNA inside the cells was extracted and the RHO amplicon amplified via PCR. The relative rhodopsin expression of each library variant for each dose was quantified by next-generation sequencing. Clustering algorithms partitioned the variants into clusters which behaved similarly across the experimental conditions.

Results: Sorted cells from 3 biological replicates were sequenced across 7 conditions using 4×10^6 total sequencing reads. Library coverage was 99-100%. Replicate experimental conditions showed low dispersion within clusters. Biologically, previously unclassified RHO mutations partitioned into either retinal responsive groups containing class II and III mutants, or a non-retinal responsive groups containing class I, IV, and VI mutants.

Conclusions: Functional genomics approaches can be used to classify the pathogenicity and the response to potential therapeutic compounds of a large number of RHO variants. Multiple mutations with no previously-known mechanism were identified that could be particularly amenable to chaperone treatment. This pharmacogenomic approach helps to better understand therapeutic options in RHO, and can also be applied to mutations in other genes.

ABSTRACT BODY:

Purpose: Eye injuries are the leading cause of vision loss for children in the US. Many of these injuries are preventable. We aim to determine whether the COVID-19 associated quarantine resulted in fewer and less severe pediatric ocular injuries.

Methods: We conducted a retrospective review of patients with adnexal, anterior segment, posterior segment, and penetrating ocular injuries requiring surgical repair presenting between March 1- June 1, 2019 and March 1-June 1, 2020 to a tertiary referral pediatric emergency center.

Results: 17 patients in 2019 compared to 15 in 2020 required surgery for ocular trauma during this time period. Average age was 7.27 (2019) and 9.58 (2020), and 15/17 (2019) and 11/15 (2020) were males. In both 2019 and 2020, the majority of cases were adnexal (88% and 53% respectively), most injuries were related to sharp objects (65% and 93%) and the most common etiology was animal related (35% and 53%, respectively). While not statistically significant, there was a trend toward a higher number of animal- and pencil-related injuries in 2020 compared to 2019. There was no significant difference in patient race/ethnicity, Medicaid status, age, or gender between 2019 and 2020, and, although there were fewer surgeries in 2020, the difference was not significant. However, there was a significant increase in number of patients in 2020 having last-recorded visual acuities worse than 20/40 in the injured eye with no patients in 2019, and 5 (33%) in 2020 having worse visual acuity.

Conclusions: Quarantine restrictions, with a decrease in organized sports and in-person school, did not significantly change characteristics of pediatric ocular injuries requiring surgical repair in our patient population, although a trend toward increased animal- and pencil-related injuries could be related to more indoor activity. Substantial risk of vision-threatening injury occurs even with the absence of in-person school and organized sporting activity which may be associated with increased eye injury severity.

ABSTRACT BODY:

Purpose: Choroideremia (CHM) is a disorder affecting the retinal pigment epithelium (RPE), photoreceptors (PR), and the outermost vascular layer, choroid (more specifically the choriocapillaris CC) [1]. OCTA technology uses laser light reflectance of the surface of moving red blood cells to depict vessels through different segmented areas of the eye, allowing non-invasive detailed imaging of the retina microvasculature that is not possible with conventional angiography [2]. We recently showed that micropulse laser of 1% and 3% duty cycle (DC) damages the RPE of Yucatan minipigs [3]. Here we extend this work to evaluate the effect of micropulse laser on pig CC and larger choroidal vessels using OCTA with conventional angiography, to develop an induced choroidal degeneration (choroideremia) pig model

Methods: A micropulse laser of 532 nm with 330 msec pulses was used with different DC (1, 1.5, 2, and 3%) in 8 eyes of Yucatan minipigs. Animals were evaluated every week for up to 12 weeks with Optical Coherence Tomography OCT, OCTA and conventional angiography (fluorescein angiography FA and indocyanine green-angiography ICGA)

Results: Data acquired with the different techniques are consistent and show that CC degeneration is visible 7 days post laser treatment for all DC, and the severity of degeneration is directly proportional to the laser power. The CC appear to progressively recover from the edges of the lesion for lower DC laser (1, 1.5, and 2%), leading to almost complete recovery in 1% DC in 12 weeks. Laser power of 1 and 1.5% DC leaves INL intact and ONL partially preserved; 2% DC laser more severely damaged the ONL, and mildly the INL; 3% DC leads to complete degeneration of ONL and INL. Our results indicate that lower power laser (1, 1.5, and 2% DC) induces CC and PR degeneration likely as a secondary effect of RPE loss. In comparison, higher power laser (3% DC) severely damages retinal and choroid structure causing complete CC, RPE, ONL, and INL loss

Conclusions: Our data suggest that laser power of 1.5% and 2% DC leads to RPE, PR, and CC damage in the Yucatan minipig retina comparable to late stage of CHM. The OCTA, combined with other imaging techniques (OCT, FA, and ICGA) allows for an accurate in vivo follow-up of the CC and the retinal layers and therefore a direct translation of the efficacy of potential therapy from the pig model to the patients

ABSTRACT BODY:

Purpose: Homelessness currently impacts 3.5 million Americans and costs the U.S. economy two trillion dollars annually. Homelessness is strongly associated with various comorbidities including cardiovascular disease, diabetes mellitus, and depression. However, our understanding of homelessness' impact on vision is limited. Vision is of specific importance due to its central role in maintaining individuals' quality of life and day-to-day functioning. In this study, we survey and record exam findings from over 150 homeless participants who presented to the Healthcare for the Homeless Eye Clinic in Baltimore, Maryland.

Methods: We surveyed over 150 homeless participants who presented for general ophthalmic examinations at Health Care for the Homeless in Baltimore, Maryland. Surveys collected information regarding vision related quality of life, past medical history, living conditions, and medical diagnoses. Surveys were offered in both Spanish and English.

Results: Our captured population was mostly composed of Blacks (49%) or Hispanics/Latinos (38%). We also captured a small number of Caucasians (10%). The most common self-reported vision problems were blurry vision (70%), wanting glasses (51%), eye pain (27%), and dryness (27%). The most frequent ocular diagnoses were refractive error (77%), cataracts (36%), glaucoma/glaucoma suspect (24%), and dry eye (23%). Forty-four% of participants were referred for further subspecialty ophthalmic care. Black patients were significantly older than Hispanic/Latino patients, predominantly male (63%), and had greater incidence of glaucoma and cataracts. In contrast, Hispanic/Latino patients were younger, predominantly female (66%), and more likely to be diagnosed with dry eye, allergies, and other corneal diseases.

Conclusions: In this study, we characterized the ophthalmic needs of a homeless population in Baltimore, Maryland. Within this population, we identified differences between the demographic characterization and ophthalmic needs of Black and Hispanic/Latino subpopulations experiencing homelessness. Overall, our data emphasizes that homelessness is a complex social factor with various subpopulations requiring unique ophthalmic considerations.

ABSTRACT BODY:

Purpose: To survey participant perceptions on the use of a tablet device for weekly home-monitoring of visual field (VF) by glaucoma and age-related macular degeneration (AMD) patients.

Methods: We recruited participants with either stable glaucoma in at least one eye, or intermediate AMD at a routine clinical review. Baseline perimetric examination was conducted with the Humphrey Field Analyzer (HFA, glaucoma) or Macular Integrity Assessment perimeter (MaIA, AMD). Test subjects were trained on how to undertake a home VF test facilitated by the Melbourne Rapid Fields (MRF) iPad application. They were tasked with performing weekly home examinations using the MRF for 12-months, assisted by a 'voice-over' that guided the testing process. At the completion of the study, participants were surveyed on the ease of use of the tablet device for home monitoring of vision, factors that would ensure the success of home monitoring, and their preference for using the iPad in assessing the visual field. Responses were scored using a 5-point Likert scale and the mean score [\pm SEM] was determined to gauge significance in preference.

Results: Eighty-seven participants were recruited to the survey (n=37 glaucoma, n=50 AMD, mean age 66.9 [range: 29-84]). Participants found the MRF app very easy to use (mean 4.4 [0.08]) and the 'voice-over' feature helpful in guiding them through the exam (mean 3.7 [0.13]). Previous experience using an iPad, as well as an information pamphlet provided at the training session were seen as most useful in enabling participants to use the iPad for visual field testing. A text message was the preferred method for reminding patients to perform their test. Undertaking a visual field examination with the iPad was much preferred over standard clinical devices (HFA/MaIA, mean 4.64 [0.08]). Those with a chronic eye disease favoured home monitoring their vision at either weekly (mean 3.80 [0.13]) or monthly (mean 3.92 [0.11]) intervals over the long term (weekly versus monthly, $p > 0.05$). A sub-analysis of different age groups found no significant difference in survey preferences from younger (< 70 yo) or older (≥ 70 yo) participants.

Conclusions: Home monitoring of the visual field under the guidance of tablet generated voice prompts was a positive experience for most participants with chronic eye disease. Participants were receptive to undertaking either weekly or monthly home monitoring in the long term.

SUBMITTER (NAME ONLY): Michael Puente, Jr.

TITLE: Ocular Manifestations of Ruptured Arachnoid Cysts in Pediatric Patients

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Puente, Jr., J.L. Jung, Ophthalmology, University of Colorado Denver School of Medicine, Aurora, Colorado, UNITED STATES|M.A. Puente, Jr., J.L. Jung, Ophthalmology, Children's Hospital Colorado, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Puente, Jr.: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Jung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Arachnoid cysts are intra-arachnoidal collections of cerebrospinal fluid, which may be congenital or secondary to head injuries, intracranial hemorrhage, or infection. Occasionally these cysts can rupture spontaneously or secondary to trauma, resulting in subdural hemorrhage or, more rarely, a subdural cerebrospinal fluid collection without hemorrhage. While the neurologic manifestations of ruptured arachnoid cysts have been well described, there is little published data examining the ocular manifestations in the setting of ruptured arachnoid cysts, particularly among patients with associated subdural hemorrhage or fluid collection. By examining the records of pediatric patients with documented radiographic evidence of ruptured arachnoid cysts as well as a formal ophthalmologic exam, we sought to better characterize the ocular findings associated with ruptured arachnoid cysts.

Methods: We performed a retrospective chart review of all patients treated for ruptured arachnoid cysts at Children's Hospital Colorado from 1 January 2006 to 1 August 2018 and recorded the findings of ophthalmology exams in these patients. Children who did not receive an eye exam during their initial admission were excluded.

Results: A total of 23 children were treated for ruptured arachnoid cysts at our institution during the study period, 17 of whom were eligible for this study due to receiving an eye exam during their admission. Age at time of rupture ranged from 9 months to 17 years (median age 5 years). Eleven children experienced spontaneous rupture of their arachnoid cyst, while the etiology was traumatic in the remaining six. Subdural hemorrhage or fluid was noted in 16 of the 17 patients on MRI. Funduscopic exams revealed papilledema in 10 patients, but no papilledema was noted in any of the 5 patients under 3 years old. Retinal hemorrhages were found only in the 2 patients who were under 2 years old, with non-accidental trauma highly suspected in one case. Best corrected visual acuity in verbal children ranged from 20/20 to 20/30.

Conclusions: Children with ruptured arachnoid cysts commonly develop papilledema, though this may be less likely in younger children. Retinal hemorrhages are less likely to develop but may be seen in especially young patients. Ophthalmology should be consulted in all cases of ruptured arachnoid cysts in children due to the likelihood of ocular manifestations, though the visual prognosis is generally good.

TITLE: Bioinformatically predicted, stress-associated mitogen-activated protein kinase 7 (PsMPK7) of *Pythium insidiosum* is significantly associated with infection progression in human cadaveric cornea

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.K. Ahirwar, S. Sharma, Jhaveri Microbiology Centre, LV Prasad Eye Institute, Hyderabad, Telangana, INDIA|L.K. Ahirwar, Manipal Academy of Higher Education, Manipal, Karnataka, INDIA|

Commercial Relationships Disclosure (Abstract): Lalit Ahirwar: Commercial Relationship: Code N (No Commercial Relationship) | Savitri Sharma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Keratitis caused by *Pythium insidiosum* is rare but severe and can lead to vision loss. To study its pathogenicity and determine its putative virulence genes, we investigated the genome of ocular *P. insidiosum* isolate using bioinformatics tools. The selected virulence genes of *P. insidiosum* were studied for mRNA expression in infected human cadaveric cornea (HCC)

Methods: The whole genome sequencing of *P. insidiosum* obtained from a patient with keratitis was performed for gene prediction (GeneMark-ES) and virulence genes identification (PHI base). Primers were designed for the identified genes [Aspartate aminotransferase 3 (PsAAT3), Stress associated mitogen activated protein kinase 7 (PsMPK7), ADP-ribosylation factor 2 (ARF2)] and a housekeeping gene (GAPDH) using Primer3. Ex-vivo cultures (n=6) of HCC were infected (intrastromal injection) with zoospores of a clinical isolate from a patient with severe *P. insidiosum* keratitis. Postinfection (PI) the HCC were incubated at 37°C, harvested (PI- 24hrs, n=3; 48hrs n=3) and preserved in RNAlater. The culture of *P. insidiosum* was used as control. RNA extraction, cDNA synthesis and RT-qPCR (QuantStudio 3) were performed for gene expression analysis. Data was analyzed using one-way ANOVA with Post-Hoc Tukey HSD test (p-value ≤0.05-significant).

Results: The gene prediction in *P. insidiosum* genome resulted in the identification of 27706 coding sequences. These coding sequences showed a total of 6812 distinct virulence genes. Among these, we selected 3 genes based on the least e-value (0 to 3.5e-56), >90% similarity matches and their function. The mRNA analysis, showed significant elevation of PsMPK7 expression after 48hrs PI [mean±SD (9.09±2.29)] compared to 24hrs (1.66±1.32), p-value ≤0.008. Although, the expressions of PsAAT3 [24hrs vs 48hrs (0.42±0.063 vs 0.55±0.26, p-value≤ 0.42)] and ARF2 (0.34±0.09 vs 0.74±0.31, p-value≤ 0.10) were not significantly different they were higher at 48 hrs.

Conclusions: This study demonstrates the expression of PsMPK7 gene in *P. insidiosum* in ex-vivo human corneal culture. This gene, known to play a crucial role in response to various stresses and reactive oxygen species detoxification, seems to play an important role in the pathogenicity of severe *P. insidiosum* keratitis.

TITLE: Optimal Follow-up and Medication Management for Traumatic Hyphema

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Baten-Tschan, C. Callahan, M.C. Chen, Ophthalmology, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alexander Baten-Tschan: Commercial Relationship: Code N (No Commercial Relationship) | Christine Callahan: Commercial Relationship: Code N (No Commercial Relationship) | Michael Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Acute hyphema is one of the most common ocular injuries that results in emergent ophthalmologic consultation. Associated complications, such as severely elevated intraocular pressure (IOP) and corneal blood staining, can cause vision loss. At our institution, patients are followed daily for a period of 5-7 days to ensure that re-bleeding and IOP elevations do not occur. As management strategies often vary by provider or institution, the purpose of this study is to determine at what point certain complications are most likely to occur to inform optimal management strategies.

Methods: Retrospective chart review of all traumatic hyphemas treated at Penn State Eye Center between January 2015 and October 2020 was performed. Data collected included age, injury mechanism, initial hyphema level, baseline IOP, maximum IOP, and re-bleed date. Hyphema associated with open globes, post-operative, and spontaneous hyphemas were excluded. IOP elevations were defined as a >5 mmHg elevated in IOP from initial examination or presenting IOP of >21 mmHg. The Penn State College of Medicine Institutional Review Board reviewed the study protocol and determined it exempt from further review.

Results: 100 eyes of 100 patients met the inclusion criteria. The mean age was 27.01 ± 20.4 (range 2-92) years and 75% were male. The most common mechanisms were high velocity projectiles (73%), blunt trauma (17%), and motor vehicle accidents (5%). The average presenting level of hyphema was 1.55 ± 1.94 (range 0-9.7) mm. Of the 78 patients were tested for sickle cell trait, two were positive. The mean presenting IOP was 19.65 ± 8.35 (range 7-52) mmHg and maximum IOP during the follow up period was 25.96 ± 10.92 (range 10-64) mmHg. IOP elevations were found to occur in 26 eyes and occurred from 1 to 15 days. 38 eyes required intervention for IOP during their clinical course. Re-bleeds were found to occur in 6 eyes and occurred from 2 to 8 days.

Conclusions: The clinical course of traumatic hyphemas is highly variable. As such, daily follow up should continue in order to diagnose re-bleeds and IOP elevations in a timely manner.

TITLE: Increased Cx43 and VEGF expression in acute nonarteritic anterior ischemic optic neuropathy induced with 577nm laser

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.R. Rangel, L.A. Mesentier-Louro, A. Shariati, R. Dalal, Y.J. Liao, Ophthalmology, Stanford Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Barbara Rangel: Commercial Relationship: Code N (No Commercial Relationship) | Louise Mesentier-Louro: Commercial Relationship: Code N (No Commercial Relationship) | Ali Shariati: Commercial Relationship: Code N (No Commercial Relationship) | Roopa Dalal: Commercial Relationship: Code N (No Commercial Relationship) | Yaping Liao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cx43, a gap junction protein expressed in astrocytes, is known to play an important role in modulating the response to CNS injury. Blocking Cx43 hemichannel opening in ischemia/reperfusion models has been shown to rescue RGCs by preventing secondary damage spread. Nonarteritic anterior ischemic optic neuropathy (NAION) is the most common acute optic neuropathy in those older than 50 years old and it presents as sudden, painless visual field loss. Here, we introduced and validated a novel photochemical thrombosis NAION animal model and investigated changes in Cx43 expression in retinal astrocytes.

Methods: We induced photochemical thrombosis NAION model in adult C57BL/6 mice using a 577nm laser (200µm spot size, 50mW power, 500ms, 15 spots). We assessed retinal and optic nerve in vivo imaging using spectral-domain optical coherence tomography (OCT) at baseline, day 1, 3 and 21 after NAION induction and used immunohistochemistry examine changes in Cx43, VEGF and Brn3a expression.

Results: One day after NAION induction, there was significant thickening of the peripapillary ganglion cell complex (GCC) (RNFL+GCL+IPL) compared with baseline (baseline: $80 \pm 1\text{mm}$, $n=10$; day-1: $88 \pm 3\text{mm}$, $n=10$, $p<0.05$). Immunohistochemistry showed that NAION also led to the increase in the levels of VEGF (Ctrl: 2319 ± 195 , $n=5$; day-1: 4549 ± 683 gray mean value, $n=5$, $p<0.05$) which correlates with retinal edema ($r=0.89$, $p=0.045$). NAION induced a significant increase in Cx43 expression (Ctrl: 1351 ± 80 , $n=4$; NAION day-1: 1791 ± 55 , $n=5$, $p<0.05$; NAION day-3: 2844 ± 148 puncta/ mm^2 , $n=4$, $p<0.0001$), which normalized within 3 weeks (NAION day-21: 1639 ± 100 puncta/ mm^2 , $n=4$). Twenty one days after NAION, OCT imaging showed a significant thinning of the GCC (69 ± 1 , $n=9$, $p<0.01$) indicating loss in RGCs, confirmed by a 30% decrease in Brn3a⁺ cells (Ctrl: 3131 ± 44 cells/ mm^2 , $n=4$; NAION: 2180 ± 217 , $n=8$, $p<0.01$).

Conclusions: A novel protocol of photochemical thrombosis using a 577nm laser induced elevation of VEGF positively correlated to GCC swelling and also led to significant RGCs loss at 21 days, reproducing the expected phenotype of a NAION model. The focal ischemia also led to an increase in Cx43 one day after NAION which was 1.5x more elevated by day 3. Early astrocytic changes in Cx43 expression could be relevant mechanism involved in NAION pathology and therefore a potential therapeutic target.

ABSTRACT BODY:

Purpose: To assess the prognosis of nAMD with hemorrhagic choroidal neovascularization treated with ranibizumab, bevacizumab and aflibercept

Methods: We investigated twelve nonconsecutive cases of nAMD with predominantly hemorrhagic neovascularization over the course of six years. During the investigation, we looked for signs of worsening or improvement in patient's vision and for difference between the chose drugs results

Results: During the treatment, we found a satisfactory response of the eyes suffering from nAMD with hemorrhagic choroidal neovascularization when treated with anti VEGF drugs. The first signs of improvement were noticed three months following the initial therapy and the patient who took the longest to show improvement after the begining of the treatment did so after eight months. No patient showed imediate response to the treatment and no difference between the drugs were noticed during the treatment.

Conclusions: These cases of nAMD with hemorrhagic choroidal neovascularization benefited from the treatment with anti VEGF, despite its first responses being held after three months of treatment. No difference in the result between drugs was noticed. 70% of the eyes treated showed improvement in the visual acuity. Two of the cases evolved to subretinal fibrosis. nAMD is still an important therapy in patients of nAMD

ABSTRACT BODY:

Purpose: To compare results obtained through the standard slit-eye examination of tear breakup time (TBUT) and Schirmer's test with the JENVIS Dry Eye Report software values in the diagnosis of dry eye.

Methods: Retrospective observational study. We used a random sample of 20 patients at Zambrano Hellion Medical Center, Tecnológico de Monterrey. All patients were diagnosed with dry eye syndrome between January and December 2020. Their TBUT was measured through slit-lamp examination and with the JENVIS software installed in the OCULUS Keratograph 5M. Three JENVIS values were compared with slit-lamp results (which acted as control): the total breakup time (NIK BUT, noninvasive breakup time), the time to first rupture (NIK BUT_f), and the average time of rupture (NIK BUT_{av}). Schirmer's test results were also compared with tear meniscus height (TMH) values given by the JENVIS software. A statistical analysis between values followed.

Results: Twelve patients were female (60%), and eight patients were male (40%). The age range was of 26 - 69 years with a mean of 45 years. Eight patients (40%) had a previous refractive surgery (LASIK). TBUT results obtained through slit-lamp had a mean of 5.89 seconds (range 3-9 seconds). The NIK BUT results had a mean of 10.53 seconds (range 1.53-24.98 seconds). The correlation between this value and slit-lamp TBUT was found to be moderately positive ($r=0.34$), statistically significant ($p=0.03$). The NIK BUT_f results had a mean of 6.74 seconds (range 2.17-17.21 seconds). A statistically significant ($p=0.04$), moderately positive ($r=0.38$) relation was also found. The third value was the NIK BUT_{av} with a mean of 8.52 seconds (range 3.39-21.58 seconds). The correlation between both of these values was not found to be statistically significant ($p=0.09$). TMH had a mean of 0.18 mm (range 0.1-0.34 mm). Its relation to Schirmer's test values was also not found to be significant ($p=0.8$).

Conclusions: We found that at least 2 values given by the JENVIS software had a significant correlation with slit-lamp examination values. This suggests that the software may be used as an automatic, more systemized way of measuring TBUT that is easier, faster and less prone to subjective interpretation for those who possess an OCULUS Keratograph 5M. Schirmer's test and TMH results should still be analyzed separately. The main disadvantage of this study is its small sample size, so repeating the study with a larger sample is warranted.

ABSTRACT BODY:

Purpose: Uveitis is a significant cause of severe visual handicap. Evidence links induction of experimental autoimmune uveitis to T cell mediated pathogenesis which is broadly regulated by the crosstalk between natural killer (NK) cells and dendritic cells (DC). Blockade of IL2Ra in uveitis patients lead to expansion of CD56^{bright} NK cells whose immunomodulatory effects inhibit activated T cell survival. The role of NK cells as however, as modulators of autoimmune responses in uveitis patients, has not been extensively explored. The purpose of this study is to present the analysis of major immune cell populations in the peripheral blood lymphocytes (PBMCs) of a large cohort of non-infectious uveitis patients with a focus on NK cell, DC and T cell crosstalk.

Methods: Bulk-RNA from PBMCs of 153 non-infectious uveitis patients and 51 age-, sex- and race-matched healthy individuals from a prospective clinical study (NCT02656381) were sequenced using Illumina NovaSeq 6000 platform. Multicolor flow panels were designed to interrogate subsets of T cells, NK cells and monocyte/DCs in freshly isolated peripheral blood and acquired on a BD LSR Fortessa cytometer.

Results: A clear distinction of transcriptome was observed between healthy donors and uveitis patients while analyzing their corresponding PBMCs. Introducing a cutoff of 1.2 folds and FDR 0.05 separated intermediate uveitis from posterior and pan uveitis based on their transcriptome signatures. High dimensional flow cytometric analysis revealed a significant upregulation of NK cells subsets ($p = 0.0023$) and a concomitant downregulation of DC subsets ($p = 0.003$) in PBMCs of uveitis patients. T cell subset analysis revealed a significant expansion of CD4⁺ T cells ($p = 0.0142$) as well as CD8⁺ T effector memory CD45RA⁺ cells ($p = 0.0183$) in uveitis patients.

Conclusions: Our observation indicates basal expansion of CD4⁺ T cells and NK cells in uveitis patients. Concomitant decrease of DCs and increase of terminally differentiated CD8⁺ T cells suggest both cytotoxic and regulatory roles of NK cells in uveitis patients, which need to be further examined.

Commercial Relationships Disclosure (Abstract): Marco Beccarini: Commercial Relationship: Code N (No Commercial Relationship) | Cristian Luciano: Commercial Relationship: Code N (No Commercial Relationship) | Yannek Leiderman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In vitreoretinal surgery, surgeons manipulate sharp surgical instruments in close proximity to the retina, with the potential for unintentional tissue-instrument interactions causing tissue damage. The principles of collision avoidance may be applied to ophthalmic surgery in order to minimize the potential for tissue damage. Accurate assessment of the position of the surgical instruments and intraocular tissues is requisite.

Methods: Tracking of surgical instruments and intraocular tissues may be performed via two approaches; optical tracking via surgical stereo cameras to track the retina, and electromagnetic sensing to track the surgical instrument. A rigid registration of the two reference systems allows for the determination of the distance between the tip of the instrument and the retina. We created a virtual and navigable three-dimensional environment, generated in real time, for the visualization of distances. We assessed the accuracy of a registered optical-electromagnetic tracking system in measuring distance in real time. The evaluation of the algorithm has been performed at the macroscale with a tracking volume size of 46x56x30 cm.

Results: With an exemplar chosen ground truth distance of 15cm, the optical tracker detected distances with an average accuracy of 97.15%, with a mean absolute error of 4.28mm and a standard deviation of 1.5mm. The registered camera-sensor system showed an average distance detection accuracy of 92.84%, with a mean absolute error of 1.07 cm and a standard deviation of 1.068cm.

Conclusions: These data indicate that this approach has the potential to provide reliable real-time surgical guidance by assessing surgical instrument positional data relative to intraocular tissues. Experiments at the microscale using a surgical microscope will yield additional data on the potential utility of this approach in the microsurgical environment.

ABSTRACT BODY:

Purpose: The involvement of severe acute respiratory syndrome related coronavirus 2 (SARS-CoV-2) in ocular tissue is currently poorly understood. This study examines the presence of SARS-CoV-2 in cornea tissue from postmortem donors with confirmed SARS-CoV-2 infection

Methods: We conducted a retrospective analysis of human cornea tissue from nine postmortem SARS-CoV-2 positive donors to examine for the presence of SARS-CoV-2 RNA and protein. All tissue donors were confirmed positive for SARS-CoV-2 via nasopharyngeal swab during tissue recovery. Real-time polymerase chain reaction (RT-PCR), immunofluorescence, and histopathologic evaluations were performed to examine for the presence of SARS-CoV-2 structural proteins (spike, nucleocapsid) and human viral ligands, angiotensin converting enzyme 2 (ACE2) and transmembrane protease serine type 2 (TMPRSS2).

Results: RT-PCR analysis of cornea tissue demonstrated 100% (9 of 9) positivity for SARS-CoV-2 RNA in right corneal tissue and 77.8% (7 of 9) positivity in left corneal tissue. Immunofluorescence demonstrated the presence of ACE2 and TMPRSS2 within the corneal epithelium and endothelium. SARS-CoV-2 spike and nucleocapsid proteins were present in 77.8% and 88.9% of corneal epithelial tissue and in 88.9% and 66.7% of corneal endothelial tissue, right and left respectively. ACE2 and TMPRSS2 expression co-localized with SARS-CoV-2 spike and nucleocapsid proteins. Histopathologic evaluation was unremarkable for all nine pairs of specimens.

Conclusions: This retrospective case series demonstrates the presence of SARS-CoV-2 RNA within cornea tissue using RT-PCR. Furthermore, we show by immunofluorescence that spike and nucleocapsid SARS-CoV-2 proteins within the cornea colocalized native ligands in the epithelium and endothelium. Further investigation is warranted for the possibility of SARS-CoV-2 transmission and the utilization of SARS-CoV-2 positive tissue in corneal transplant surgeries

TITLE: The ER membrane protein complex subunit Emc3 controls angiogenesis via the FZD4/WNT signaling axis

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Zhu, Sichuan Provincial People's Hospital, Chengdu, CHINA|

Commercial Relationships Disclosure (Abstract): Xianjun Zhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The ER membrane protein complex (EMC) regulates the synthesis and quality control of membrane proteins with multiple transmembrane domains and has been implicated in several disease conditions. However, the role of EMC in angiogenesis remains elusive. The purpose of this study is to investigate the role of Emc3 in retinal angiogenesis using genetic knockout mouse models.

Methods: Endothelial specific knockout model of Emc3 was generated by crossing conditional allele of Emc3 with Pdgfb-Cre ER line. Retinal vascular development was assessed using retinal whole mount staining. Tube formation and cell proliferation was analyzed in primary human retinal endothelial cells (HRECs) with EMC3 knockdown mediated by shRNA lenti-virus. Downstream target genes were assessed by transcriptome analysis.

Results: We show that the EMC subunit Emc3 plays critical roles in retinal vascular angiogenesis by regulating Norrin/Wnt signaling. Postnatal endothelial cell (EC)-specific deletion of Emc3 led to retarded retinal vascular development with a hyperpruned vascular network, the appearance of blunt-ended, aneurysm-like tip endothelial cells (ECs) with reduced numbers of filopodia at the vascular front and reduced numbers of tip cells. Leakage of erythrocytes was also prominent. Knockdown of EMC3 in primary human retinal endothelial cells (HRECs) impaired tube formation and diminished cell proliferation. Mechanistically, deletion of Emc3 reduced EC proliferation by reducing the expression level of the Wnt receptor FZD4. Knockdown of Emc3 decreased FZD4 expression and reduced β -catenin signaling, as revealed by luciferase reporter assay. Moreover, augmentation of Wnt activity via lithium chloride treatment partially reversed the angiogenesis defects in Emc3-cKO mice.

Conclusions: Our data reveal that Emc3 plays essential roles in angiogenesis through direct control of FZD4 expression and Norrin/ β -catenin signaling and provide a potential therapeutic target.

ABSTRACT BODY:

Purpose: While the ocular comorbidities of panuveitis are well documented, there is a dearth of literature analyzing the general health of these patients as represented by other systemic comorbidities. This investigation identifies the fifteen most common non-ocular comorbidities in patients with panuveitis.

Methods: TriNetX (Cambridge, MA, USA) is a real-time, federated healthcare database that was used in this study. At the time of the study, the database included 60 million unique electronic medical records (EMR) of patients from 41 healthcare organizations (HCOs). The TriNetX platform mostly receives EMR data from HCO's that are large academic centers across the USA. All data, when appropriate, were queried based on the International Classification of Diseases codes. The goal of this study was to analyze the prevalence of non-ocular comorbidities amongst panuveitis patients in this cohort. Inclusion criteria included patients with ICD-10 codes corresponding to panuveitis (H44.11) and the fifteen most prevalent ICD-10 codes associated with a disease diagnosis. Patients aged 18 years and older were included.

Results: 6126 patients with panuveitis were identified in the cohort. The mean age +/- standard deviation was 52.7 +/- 18.4 years old. 57% of the cohort was female (n=3490) and 43% male (n=2633). 52% of the study population identified as white (n=3219), 27% black or African American (n=1647), and 3% as Asian (n=158). The fifteen most common systemic comorbidities included essential hypertension 14% (n=1141), disorders of lipoprotein metabolism and other lipidemias 11.6% (n=712), diabetes mellitus 10.5% (n=647), other diseases of intestines 9.5% (n=584), gastroesophageal reflux disease 8.7% (n=535), benign neoplasms 7.7% (n=476), osteoarthritis 7.5% (n=464), nicotine dependence 7.3% (n=448), other headache syndromes 7.3% (n=445), major depressive disorder 7.1% (n=437), obesity 6.9% (n=428), anemia unspecified 6.6% (n=407), inflammatory polyarthropathies 6.5% (n=309), sleep disorders 6.3% (n=384), and other anxiety disorders 6.1% (n=374).

Conclusions: To our knowledge this is the first study looking at the prevalence of non-ocular comorbidities in panuveitis patients. Further research is necessary to determine which comorbidities are more prevalent than in the general population and which are possible secondary effects from therapies.

ABSTRACT BODY:

Purpose: Progress of deep learning (DL) research in medicine is often hampered by the time required to generate the large amounts of labelled data for model training. To address this, we propose an active learning method to optimize training efficiencies while minimizing labelling efforts. We employed model uncertainty as an objective metric for prioritizing the candidate training images. Intuitively, images giving rise to higher levels of model uncertainty during prediction would contain more informative features that could help accelerate the rate at which a DL model can learn. We evidence the benefit of active learning on retinal-layer segmentation in optical coherence tomography (OCT) images.

Methods: 20 AMD, 20 DME and 20 normal OCT volumes (16-61 scans/volume) were obtained using the Heidelberg Spectralis device. We used a 12-12-36 split over the volumes for training, validation and testing. We quantified gains from active learning by comparing segmentation performance (intersection-over-union (IoU)) of a DL model trained with images selected by high uncertainty against a baseline where training samples were selected at random. Starting with a DL model trained on a prior subset of training images, we employed the Bayesian Dropout method to estimate the trained model's uncertainty when deployed on the remaining candidates of unseen training images. We select an increment of additional images based on high uncertainty values for model retraining. In the baseline experiment, additional images were selected at random. We continue to iterate the process and record the test performance over 4 increments and over 3 experimental repeats.

Results: Active learning produce higher IoU at the lower training sets sizes. This trend was greatest for DME scans.

Conclusions: In general, active learning is a principled method that can help minimize the burden of expensive and time-consuming data labelling and, in the process, can help accelerate deep learning research in medicine. In our results, while active learning provides trends of efficiency, more experimental repeats are needed to determine significance.

ABSTRACT BODY:

Purpose: To determine the association between the severity of upper eyelid margin conjunctivization (CM) and trichomatous trichiasis (TT) severity as well as to evaluate the association between CM and entropion in TT surgical patients.

Methods: A cross-sectional study was conducted amongst adults with TT who were referred to surgical camps in Bahi District, Tanzania, for TT surgery. Participants underwent ocular examination. The presence and severity of CM was evaluated in photographs of the everted upper eyelid and the presence of entropion was evaluated in a subset of these photographs. TT severity was assessed at the time of the ocular exam based on the number of lashes touching the globe and/or evidence and extent of epilation. Ordinal logistic models were used to examine the association between the severity of CM and TT severity.

Results: A total of 627 eyes of 388 subjects were included. The participant's mean age was 64.6 years, 81% were females, and 62% had bilateral TT. 75.2% of the eyes had severe conjunctivization of the lid margin and 42% of the eyes had severe trichiasis. An increase in the severity of CM was associated with an increase in TT severity. Using as a reference eyes with none to mild CM, the odds of increased TT severity per one level increase in CM severity was 2.12 (95% CI: 1.56, 2.88).

Conclusions: In cases of trichomatous trichiasis presenting for surgery, TT severity was significantly associated with the severity of CM. Almost all cases of TT had moderate or severe CM. CM could be a useful adjunct in helping determine who needs trichiasis surgery.

ABSTRACT BODY:

Purpose: Recent advancements in surgical instrumentation have shifted physician preference toward use of PPV for treatment of primary RRD. Placement of a supplemental buckle, however, remains the subject of intense debate. The present review aims to synthesize evidence from randomized controlled trials (RCTs) that compared efficacy and safety of pars plana vitrectomy (PPV) with and without application of a supplementary scleral buckle (SB) for management of rhegmatogenous retinal detachment (RRD).

Methods: The authors searched MEDLINE, EMBASE, and CENTRAL on July 2, 2020 from their inception to identify RCTs published in English that compared safety and efficacy of PPV with and without supplemental SB. Risk of bias was assessed according to Cochrane Risk of Bias 2 tool. We present risk ratios (RRs), mean differences (MDs), and 95% confidence intervals (CIs) estimated using random effects meta-analyses.

Results: We identified six eligible RCTs (705 eyes). Primary reattachment (6 studies, 345 eyes PPV, 324 eyes PPV+SB; RR 0.99, 95% CI 0.93-1.06, I² = 0%, p = 0.78) and final anatomic success rates (4 studies, 272 eyes PPV, 267 eyes PPV+SB; RR 1.00, 95% CI 0.98-1.02, I² = 0%, p = 0.89) were similar between groups. Postoperative improvement in visual acuity (5 studies, 244 eyes PPV, 222 eyes PPV+SB; MD 6.09 letters, 95% CI -0.47-12.64, I² = 69%, p = 0.07) and frequency of adverse events (6 studies, 1294 observations PPV, 1221 observations PPV+SB; RR 0.76, 95% CI 0.57-1.01, I² = 25%, p = 0.06) likewise were not found to differ significantly between treatment arms.

Conclusions: Low-certainty evidence from RCTs did not demonstrate a benefit in placement of a supplemental scleral buckle during vitrectomy for management of RRD. Additional high-quality trials are needed to provide more precise estimates of effect.

ABSTRACT BODY:

Purpose: To develop and evaluate custom solutions for ophthalmologists when performing retinal examination on patients with airborne communicable disease.

Methods: Two solutions were developed for viewing and imaging patients with airborne communicable disease. The first solution was a custom indirect ophthalmoscope barrier shield consisting of a 3D printed bracket and laser cut shield. The shields were mounted using a rubber band fastening device to allow easy removal and cleaning. The bracket spaced the shield from the user to prevent fogging and heat generation. The central aperture allowed an unobstructed view of the retina. The second solution was a hand-held off the shelf portable fundus camera used with a Controlled Air-Purifying Respirator (CAPR) for providers examining patients in negative pressure rooms. Clinical viability was assessed with a survey completed by providers.

Results: Providers completed the survey after use. No fogging obscured view of the retina. Ergonomically, the provider was able to maneuver and perform indirect ophthalmoscopy to the periphery. Spacing of the shield allowed use with a N95 and prevented heat buildup. The portable fundus camera was used with a CAPR successfully allowing the user to maintain full PPE while taking fundus photos of patients on airborne precautions. It was possible to use an N95 mask with the CAPR to prevent transmission of airborne particles from the user.

Conclusions: There is a need for improved personal protective equipment due to the spread of COVID-19. Both solutions allowed ophthalmologists to maintain airborne precautions when examining patients. The first solution was compatible with a N95 mask and provided an additional face shield. This solution allowed viewing of the macula as well as far periphery. The second solution allowed use of a CAPR, making it suitable for providers who do not fit N95 masks. Photographs of the macula and mid-peripheral retina were possible with this option and dilation was not needed for examination. However, peripheral retinal viewing was more limited compared with the first option.

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the antimicrobial activity of peptide mimic 758 against a drug-resistant and biofilm-producing strain of *Pseudomonas aeruginosa* in solution and when surface immobilised onto contact lenses.

Methods: Minimal inhibitory concentration (MIC) and Minimum bactericidal concentration (MBC) of 758 was measured against the *P. aeruginosa* strain 6294. 758 was covalently attached to etafilcon A contact lenses via EDC (1-ethyl-3-[3-dimethylaminopropyl] carbodiimide hydrochloride) and NHS (N-hydroxysuccinimide) coupling. High salt (10% NaCl) treatment was carried out to extract any adsorbed peptide to ensure that the activity was only due to 758 peptide mimic attached to the lens surface. The antimicrobial activity of 758 was evaluated against *P. aeruginosa* by measuring the amount of cell death compared to control uncoated lenses.

Results: MIC and MBC of 758 against *P. aeruginosa* was $45.5 \mu\text{g ml}^{-1}$ and $91 \mu\text{g ml}^{-1}$ respectively. When allowed to adhere to contact lenses coated with 1mg ml^{-1} 758 *P. aeruginosa* adhered to $0.15 \log_{10}$ colony forming units (cfu/lens) whereas *P. aeruginosa* adhered to control lenses to $\geq 3. \log_{10}$ cfu/lens. Therefore, covalently attached 758 was active against drug-resistant and biofilm-producing strain of *P. aeruginosa*, giving $\geq 2.9 \log_{10}$ reduction in bacterial counts compared to control lenses.

Conclusions: The peptide mimic 758 showed excellent antimicrobial activity against *P. aeruginosa*. Future research will examine the activity of 758 against drug-resistant Gram-positive bacteria, to see the potential for development as a broad-spectrum antimicrobial coating for contact lenses.

ABSTRACT BODY:

Purpose: Retinal artery occlusions (RAOs) are rare and understudied in young patients, and the etiology of these events are thought to differ from older adults. We performed a retrospective, observational study to investigate risk factors associated with RAOs in young adults.

Methods: A retrospective chart review of patients under 40 was conducted of the medical record from 1/1/2003 through 10/28/2019. Patients were identified by the ICD-9/ICD-10 codes for central retinal artery occlusion (CRAO), branch retinal artery occlusion (BRAO), and partial retinal artery occlusion. Clinical data was obtained by manual chart review.

Results: 30 eyes from 28 patients were identified with a RAO. 8 patients were found to have CRAO, 19 had BRAO, and two patients had a hemiretinal artery occlusion. The average age at onset was 33.14 years. 71.4% of patients were female, and only 10.7% were non-White.

Systemic risk factors were discovered in 25 patients (89.3%), with 12 patients (42.9%) having a hypercoagulable state, 4 patients (14.3%) having a rheumatologic condition without hypercoagulability, 3 patients (10.7%) with significant cardiac risk factors, and 2 patients (7.1%) whose only risk factor was hormonal contraceptive use. One traumatic and one post-operative RAO were identified. One patient was diagnosed with Susac Syndrome.

6 patients (21.4%) were smokers at onset of the RAO. A large percentage of affected patients were overweight, with 14 patients (50%) having BMI >25, and 11 (39.3%) with BMI >30.

Two patients (7.14%) died within 1 year of RAO onset, and a third patient passed approximately 8 years after RAO onset.

Conclusions: Retinal artery occlusion in young adults is rare. Unlike the embolic nature in older adults, hypercoagulable conditions, such as Lupus, are frequently found in younger patients and is the most common etiology in this study. Conditions associated with vaso-occlusive events such as smoking, hormonal contraceptive use, and cardiovascular disease were less common.

A third of the patients were obese/morbidly obese, hinting at a possible association with RAO. Additionally, clinically significant vaso-occlusive events leading to death occurred in several patients after RAO. This may suggest that RAO in young adults may be a harbinger of poor outcomes. However, due to the extreme rarity of this disease entity, further study is required to draw definitive conclusions.

TITLE: Photodynamic therapy for the treatment of choroidal metastases: A case series and meta-analysis

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.T. Nguyen, A.W. Stacey, Department of Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Minh Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Stacey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Choroidal metastasis remains the most common type of ocular malignancy, affecting quality of life of patients who already carry poor prognosis from their primary cancers. Among the local treatment modalities for choroidal metastasis, photodynamic therapy (PDT) is an effective option and requires little time commitment. This study is a systematic review and meta-analysis aiming to investigate the efficacy and safety of photodynamic therapy in the treatment of choroidal metastasis.

Methods: We compiled all cases of choroidal metastases treated with PDT in literature, and included the unreported cases seen at our institution, a tertiary referral center, for a comprehensive meta-analysis.

Results: 50 tumors in 40 eyes of 34 patients were identified from the choroidal metastases treated with PDT at our institution and from 12 case reports in literature since 2004. Tumors became significantly flatter after an average of 1.4 PDT treatments (mean thickness was 1.9mm pre-operatively vs 1.0mm post-operatively, $p < 0.0001$). Similarly, there was a significant decrease in central macular thickness (CMT) post-operatively (mean CMT of 289 μ m vs 454 μ m, $p = 0.03$). After PDT, the majority of tumors completely flattened, had reduced thickness or stayed flat (82% of the tumors) and no longer had sub-retinal fluid (75% of the eyes). PDT also resulted in visual protection (stable or improved vision) in 77.5% of treated eyes, but there was no significant difference in vision between pre-PDT and post-PDT eyes ($P = 0.54$). There were no adverse events reported, and PDT was shown to be safe and effective in treating fovea and optic nerve involving tumors (tumor control efficacy of 86% and 75%, respectively), as well as metastases originating from the most common primary sites (tumor control efficacy of 94% in lung adenocarcinoma and 92% in breast carcinoma).

Conclusions: Although PDT requires less time consumption than other local treatment methods for choroidal metastasis, it showed effective tumor control and vision protection in our meta-analysis.

TITLE: Characteristics of Ophthalmology Procedural Care during the COVID-19 Pandemic

SESSION TITLE: Healthcare Delivery during Covid Pandemic

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Hamid, S. Rezaei, D. Goldman, R. Levine, P.A. Edwards, Henry Ford Hospital, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mariam Hamid: Commercial Relationship: Code N (No Commercial Relationship) | Sina Rezaei: Commercial Relationship: Code N (No Commercial Relationship) | David Goldman: Commercial Relationship: Code N (No Commercial Relationship) | Robert Levine: Commercial Relationship: Code N (No Commercial Relationship) | Paul Edwards: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Describing the procedures conducted during the peak of the COVID-19 pandemic in the department of ophthalmology at Henry Ford Hospital in Detroit, MI and understanding how the demographics of these patients compared to preceding years

Methods: Electronic medical record data at Henry Ford Hospital in Detroit, MI was queried for all operative procedures. The procedures must have met three criteria: 1) scheduled from March 15th to May 19th, 2020, 2) A staff ophthalmologist as the primary surgeon, 3) The procedure status was "completed." Parallel dates in the preceding three years 2017-2019 were queried to use as controls. Information obtained for each procedure included: date, procedure completed, age, race, sex, primary insurer, class of procedure (inpatient vs. outpatient). 2-tailed equal proportions tests and 2-tailed T tests were used to determine statistical significance of 2020 vs. preceding years 2017-2019.

Results: On average, there was a 94% decline in the number of procedures in 2020 compared to the average of the three preceding years. Over 800 surgical procedures were postponed during the pandemic. Retina procedures were most prevalent in 2020. Significantly younger patients were seen in 2020. There were no significant difference in race distributions by year. There was a significantly higher proportion of males who underwent operative procedures in 2020. Significantly more procedures were done with inpatient status compared to outpatient compared to preceding years

Conclusions: It is estimated that there is a 80-100% reduction in ophthalmologic surgical cases during COVID, which was consistent with our study of 94% decrease. The younger age group seen in 2020 was likely multifactorial, partially thought to be secondary to cancelling routine cataract and lens procedures on a largely older population skews the average age of procedures to the right, as well as a higher incidence of trauma requiring emergent procedural intervention in younger individuals such as for orbital floor fractures. Regarding a higher proportion of men, retinal procedures more commonly occur in men, and ambulatory procedures like cataract extraction which were cancelled during the pandemic are more commonly occur in women. We found no differences by race, which requires further study, and may possibly related to differences in baseline characteristics.

TITLE: Saccades during smooth pursuit in macular degeneration

SESSION TITLE: Visual Impairment - Assessment and Measurement

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.M. Shanidze, Z. Lively, R. Lee, A. Velisar, P. Verghese, The Smith-Kettlewell Eye Research Institute, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Natela Shanidze: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Lively: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Lee: Commercial Relationship: Code N (No Commercial Relationship) | Anca Velisar: Commercial Relationship: Code N (No Commercial Relationship) | Preeti Verghese: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Saccades and smooth pursuit are inextricably linked, particularly in cases of low gain, where saccades can help bring the fovea back on target. Individuals with macular degeneration (MD) have compromised foveas due to central field loss, which impacts both fixation stability and saccades, as well as the interaction between the saccade and pursuit systems. To investigate how saccades associated with pursuit are affected, we conducted a quantitative analysis of binocular smooth pursuit eye movement data collected for a prior study (Shanidze et al., 2016) of smooth pursuit in MD. Here we extend that work by characterizing saccadic intrusions in MD participants during pursuit and pre-pursuit fixation.

Methods: We examined saccade frequency, magnitude, and direction across viewing conditions for MD (7, 4F) and control participants (4, 1F). Participants were asked to pursue a 1° annular target, moving in a step ramp (6° step, 12° ramp) in one of 6 directions (4 cardinal & 2 oblique). Saccades were detected offline when eye velocity exceeded 40°/s, or acceleration exceeded 150 (°/s²) and confirmed manually by an experimenter during the fixation and pursuit portions of each trial.

Results: Individuals with MD made significantly more saccades during fixation and pursuit than controls (Fig F). During pursuit, both control and MD participants made saccades aligned with the target direction. However, MD participants also made saccades in non-target directions (Fig A-D). To quantify this difference, we computed the anisotropy index (a comparison of saccades aligned with and orthogonal to the target, Fig E). We found controls had a significantly higher anisotropy index than MDs, indicating greater alignment with target direction.

Conclusions: Our analysis suggests that despite higher frequency, a large number of saccades during pursuit in MD participants are not in the target direction, and thus are not catch-up saccades that serve to keep the eye on the target. The saccades in non-target directions appear to be associated with the significant increase in saccades during fixation. Thus, MD participants do not effectively use saccades to compensate for the lower pursuit gains reported previously.

ABSTRACT BODY:

Purpose: To investigate the cellular pathophysiology of Stargardt disease caused by the c.5882G>A p.(Gly1961Glu) in a patient-derived retinal organoid model system.

Methods: Human induced pluripotent stem cells (iPSCs) were reprogrammed from peripheral blood lymphocytes from 4 STGD1 patients and 2 two unaffected control subjects. One patient was homozygous for the p.Gly1961Glu variant, two were compound heterozygous, and one patient harbored two deleterious ABCA4 alleles. Mycoplasma testing and karyotyping was performed before differentiation, and pluripotent markers, LIN28, NANOG, OCT4, and SOX2 expression were confirmed by PCR. To begin differentiation, hiPSCs were cultured in neuron-inducing medium for 16 days and then switched to retina-inducing medium. At day 42, 10% FBS and 100uM taurine were added to the medium for long-term differentiation. Developing organoids were manually picked between days 25 and 30, and cultured in suspension. Cryosectioning and immunofluorescence (IF) microscopy were performed at days 90, 120, 150, and 230, followed by transmission electron microscopy (TEM) at day 260.

Results: At day 230, organoids from one compound heterozygous patient for the p.(Gly1961Glu) and c.4947del p.(Glu1650fs) variants, exhibited round contours with visible lamination of the neural retina. Rudimentary subcellular compartments of photoreceptors along the outer edge were discernible on IF by Hoeschst (nuclei), RHO (rods) and Opsin (Blue, Red/Green cones) staining. These distal structures were visualized by TEM and are consistent with short, nascent outer segments. Mutant ABCA4 protein was detected using two separate antibodies--ABCA4 RIM3F4 and RIM5B4, and co-localized with Opsin Blue, or Opsin Red/Green in photoreceptors.

Conclusions: Patient-derived retinal organoids recapitulate complex cellular features of the human retina and express mutant ABCA4 protein in the distal portions of developing photoreceptors. These findings provide a functional model system to characterize the physiological consequences of ABCA4 mutations in individual patients and simultaneously offers a broad window for understanding the mechanism of retinal degenerative diseases.

ABSTRACT BODY:

Purpose: Antimicrobial peptides (AMPs), including defensins, are key effector molecules of innate immunity expressed and secreted by corneal epithelial cells. Previous studies from our lab demonstrate a marked upregulation of human beta-defensin 3 mRNA (DEFB103) expression in corneal epithelial cells treated with herbal compounds andrographolide, oridonin, isoliquiritigenin. The current study focused on quantification of human beta-defensin 3 peptide (hBD3) after induction with the herbal compounds and determination of the induction kinetics.

Methods: hTCEpi cells were treated with increasing concentrations of andrographolide (10-100 μ M), oridonin (1-15 μ M), isoliquiritigenin (5-50 μ M) or negative control (vehicle: DMSO or EtOH) for 48 hours. After treatment, the supernatant was collected and 100 μ l was used to quantify hBD3 peptide concentration and performed in duplicate for each treatment. To determine kinetics of DEFB103 mRNA upregulation, hTCEpi cells were treated with andrographolide (75 μ M), oridonin (10 μ M), or isoliquiritigenin (25 μ M) for 2, 6, 12, and 24 hours prior to mRNA isolation and compared with vehicle control. Statistical significance was determined based on an ANOVA and appropriate post-hoc test.

Results: The level of hBD3 peptide was below the threshold of detection when hTCEpi cells were treated with vehicle, 10, 25 and 50 μ M of andrographolide, yet resulted in detectable levels of hBD3 peptide of 260 pg/ml and 488 pg/ml with 75 and 100 mM, respectively. Additionally, hBD3 peptide levels were below the level of detection in supernatants from hTCEpi cells treated with oridonin and isoliquiritigenin at all doses. Both isoliquiritigenin and oridonin had an initial upregulation of DEFB103 mRNA expression within 6 hours, peaking by 12 hours and returning to baseline levels by 24 hours post-treatment. Andrographolide had an initial upregulation of DEFB103 mRNA expression by 6 hours that continued to increase at 24 hours post-treatment.

Conclusions: Modulation of AMP expression with herbal compounds (andrographolide, oridonin, isoliquiritigenin) represent a novel approach to treating patients with resistant bacterial infections of the ocular surface. The kinetics of DEFB103 induction with each compound provides insight as to the frequency of application that may be required to sustain antimicrobial activity.

TITLE: A simplified nomogram for approximating intraocular lens (IOL) power in post-LASIK patients

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Lian, F. Malé, R. Sella, H. Gali, A. Chayet, N.A. Afshari, Viterbi Family Department of Ophthalmology, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rebecca Lian: Commercial Relationship: Code N (No Commercial Relationship) | Francisco Malé: Commercial Relationship: Code N (No Commercial Relationship) | Ruti Sella: Commercial Relationship: Code N (No Commercial Relationship) | Helena Gali: Commercial Relationship: Code N (No Commercial Relationship) | Arturo Chayet: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Afshari: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the ability of a simplified nomogram, that can be used as a mental calculation, to approximate IOL power in myopic eyes post LASIK.

Methods: Nomogram predictions were calculated by adding a set number of diopters to the pre- operative SRK/T (5 for KM 25-30, 4 for KM 30.01-35, 2.5 for KM 35.01-40, 1.5 for KM 40.01-42.99, 1 for KM 43-45). Records of 64 eyes of 51 myopic patients who underwent cataract surgery after LASIK were reviewed. The percentage of eyes with post-operative spherical equivalent (SE) within 0.5 D and 1D of preoperative target was calculated. The proportion of predictions within 0.5 D and 1 D of Optiwave Refractive Analysis (ORA) and Barrett True K (BTK) IOL values were calculated.

Results: Refractive outcomes showed 71.9% and 93.75% of eyes with post-operative SE within 0.5 D of target refraction respectively. The nomogram IOL prediction fell within 0.5 D of BTK value in 85.94% (n=55) of eyes and within 1 D in 93.75% (n=60) of eyes. The nomogram output fell within 0.5 D of ORA prediction in 68.75% (n=44) of eyes and within 1 D in 92.19% (n=59) of eyes. There were no significant differences between the nomogram and ORA IOL predictions (mean difference 0.07 D, p=0.86) or between the nomogram and BTK IOL predictions (mean difference 0.04 D, p=0.92).

Conclusions: This nomogram approximates IOL power in myopic eyes post LASIK and can be used for mental calculation of IOL power.

TITLE: TESTOSTERONE AND PROGESTERONE IN HUMAN MEIBOMIAN GLAND EPITHELIAL CELLS DETECTED USING LC-MS

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Golebiowski, M. Phan, M. Bucknall, M.C. Madigan, M. Willcox, F. Stapleton, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA]

Commercial Relationships Disclosure (Abstract): Blanka Golebiowski: Commercial Relationship: Code N (No Commercial Relationship) | Minh Anh Thu Phan: Commercial Relationship: Code N (No Commercial Relationship) | Martin Bucknall: Commercial Relationship: Code N (No Commercial Relationship) | Michele Madigan: Commercial Relationship: Code N (No Commercial Relationship) | Mark Willcox: Commercial Relationship: Code N (No Commercial Relationship) | Fiona Stapleton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sex hormones may regulate lipid production in the meibomian glands. Sex hormone receptors and mRNAs of key steroidogenic enzymes are present in human meibomian glands and in meibomian gland cells, suggesting these hormones are locally synthesised and metabolised. However, the presence of sex hormones in meibomian gland cells or tissue has not yet been reported. This study aimed to determine whether androgens or estrogens can be synthesized in immortalised human meibomian gland cells (iHMGEc) from the precursor dehydroepiandrosterone (DHEA).

Methods: Undifferentiated and PPAR γ -agonist-differentiated iHMGEc were cultured in serum-free media and treated for 3 days with DHEA (0.1 and 1 μ M). Culture supernatant and cell lysates were extracted with tert-butyl methyl ether. Detection of sex hormones in the extracts was carried out by liquid chromatography-mass spectrometry on a Thermo QExactive Plus quadrupole-orbitrap MS. The extracts were examined for the presence of testosterone, dihydrotestosterone, estrone, estradiol, estriol, androstenedione, progesterone and DHEA. All experiments and analyses were run in duplicate.

Results: Testosterone, androstenedione and DHEA were detected in cell lysates of DHEA-treated cells cultured with and without PPAR γ -agonist (rosiglitazone) and in the culture supernatants, whereas progesterone was detected in cell lysates only. When cells were cultured without DHEA, testosterone, androstenedione, progesterone and DHEA were detected in the cell lysates only, but not the supernatant. Signal intensity (ion counts) indicated that the detected sex hormones were present in much greater abundance in the supernatant than in cell lysate. Dihydrotestosterone and estrogens were not detectable in any of the samples using our current methods.

Conclusions: iHMGEc synthesize the androgens testosterone and androstenedione from the precursor DHEA, followed by the release of these sex hormones from cells into the culture medium. The synthesis of dihydrotestosterone and the estrogens will be confirmed using a more sensitive MS approach.

TITLE: Characterizing Corneoscleral Permeability in Microgravity: A Novel Model for Testing Topical Ophthalmic Medication For Spaceflight

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Bigley, J. Ong, A. Chaudhry, M.V. Fedorchak, Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Daniel Bigley: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Ong: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Chaudhry: Commercial Relationship: Code N (No Commercial Relationship) | Morgan Fedorchak: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During spaceflight, astronauts may use topical ophthalmic medication for conditions such as inflammation and Spaceflight Associated Neuro-Ocular Syndrome (SANS). We sought to construct a microgravity-proof model for determining corneal permeability, which will be employed on a parabolic flight to test the hypothesis that corneoscleral permeability in microgravity differs from that of terrestrial gravity. The present study seeks to prove the corneoscleral permeability modeling capability of the novel microgravity-proof experimental set-up.

Methods: Corneas were dissected from freshly enucleated bovine eyes and tightly secured in Corning™ Costar™ Netwell™ Inserts (N=6) using rubber gaskets fit to the diameter of the inserts. 3 mL Milli-Q water was pipetted into wells to allow for interfacing with the cornea-insert system. 1 mL 10% fluorescein solution was applied to corneal surfaces and allowed to diffuse into well water. Samples were taken from individual wells at assigned time intervals. Diffusion was characterized by absorption spectroscopy (480 nm). Average sample absorptions were adjusted for absorption of Milli-Q control by subtracting the average control absorption.

Results: Average adjusted sample absorption (AU) and time (min) displayed a strong positive linear correlation ($r=0.90$, $r^2=0.82$, $p=0.013$). Interestingly, a lag in diffusion of fluorescein across the corneal membrane resulted in earlier time intervals (0.5 min to 2.5 min) having adjusted absorbances that were essentially 0 AU, causing large standard error (SEM=3377). Nevertheless, the data set highlights that the model can demonstrate relatively low and high concentrations of diffused molecules via absorbance values.

Conclusions: The novel set-up has the capacity to model corneoscleral permeability, demonstrating a successful proof of concept for investigation of permeability variation due to microgravity. Successful trialing with fluorescein indicates that "lag time," the time it takes before any significant absorbance is measured, must be considered when investigating permeability of ophthalmic medications and constructing time intervals for sampling.

TITLE: Characteristics of traumatic retinal detachments after open globe injury

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sangani, M.A. Zarbin, N. Bhagat, IOVS-New Jersey Med School, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Roshun Sangani: Commercial Relationship: Code N (No Commercial Relationship) | Marco Zarbin: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal detachments (RD) related to open globe injuries (OGIs) have poor visual and anatomic prognosis. This study attempts to determine the characteristics of open globes at-risk of recurrent RDs.

Methods: We retrospectively analyzed all cases of traumatic RDRs after OGI performed at a single tertiary care center over a 3-year duration. The eyes with recurrent RDs were labeled group 1 and the remaining eyes that underwent successful primary RD repair were labeled group 2. Variables recorded included age, gender, duration between OGI and primary RDR, duration between primary RDR and additional RDR, zone of injury, use of silicone oil, presence of choroidal detachment (CD), and presence of intraocular foreign body (IOFB).

Results: Of the 19 cases of traumatic RDR identified, 6 (32%) had recurrent RD and underwent further surgical repairs. The average follow-up duration of the study was 12 months. The average time between initial OGI and RDR in cases with and without recurrent RD (group 1 and 2) was 18 days and 8 days respectively. Furthermore, the average time of initial RDR and recurrent RDR repair (group 2) was 84 days. The average age of both groups was 41 years old. Males comprised 100% of group 1, and 92% of group 2. Moreover, the zones of OGI (Z1, Z2, Z3) was (33%, 50%, 17%) and 61%, 8%, 31% in Groups 1 and 2 respectively. Also, presence of proliferative vitreoretinopathy (PVR) was noted in 100% of eyes in group 1 and 38.5% of eyes in group 2. Silicone oil was used for tamponade in 100% of group 1 eyes and 70% of group 2 eyes. Half (50%) of the patients in group 1 had CDs, compared to 13% of patients in group 2. The presence of an IOFB was noted to be 50% and 46% of cases in groups 1 and 2 respectively.

Conclusions: Recurrent RDs were seen in 32% of OGIs in this study. Two-thirds of these eyes had Zone 2 or 3 injuries, and 50% cases had CDs with PVR diagnosed in all subjects. Interestingly both groups had a high incidence of IOFBs.

TITLE: Accuracy of electronic health records for systemic risk factors of ophthalmology patients

SESSION TITLE: Data science, machine learning, and artificial intelligence

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Chen, C. Yee, M. Hribar, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aiyin Chen: Commercial Relationship: Code N (No Commercial Relationship) | Claudine Yee: Commercial Relationship: Code N (No Commercial Relationship) | Michelle Hribar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Systemic conditions such as hypertension (HTN) is a risk factor for ocular diseases. Electronic health records (EHRs) contain extensive data on systemic conditions that can help identify risk factors for eye disease, but the quality of EHR data is unclear. This project assesses the readiness of EHRs for large scale ophthalmic epidemiology research by examining data accuracy in EHRs of an ophthalmology practice for providing a definitive diagnosis of HTN.

Methods: Retrospective chart review of randomly selected cataract surgery patients at Oregon Health & Science University (OHSU) was conducted in OHSU's EHR (Epic) and a combined EHR database outside our institution (Care Everywhere). Charts were reviewed for evidence of a primary care provider (PCP) at OHSU, while progress notes, problem lists, and medication lists were examined for evidence of a HTN diagnosis. Diagnosis of HTN was established when HTN was documented in any progress note or problem list, and anti-HTN medications appeared in medication list. The absence of HTN was established when there was no documentation of HTN and anti-HTN medications. Cases that did not fit into either category were deemed uncertain. Documentation in medication lists was compared for consistency between our institution's EHR and outside EHRs.

Results: Of 134 patients reviewed, 69 (51%) had a PCP at OHSU, and 65 (48%) did not. Further, 87 patients (65%) had a certain diagnosis of HTN, 37(28%) did not have HTN, and 10(7%) were uncertain. There was no difference in frequency of uncertain cases between patients who had PCPs at OHSU vs those at outside institutions ($P = 0.52$). Patients were more likely to have an accurate HTN diagnosis in the problem list if they had OHSU PCPs (81%) than those without (61%; $P = 0.01$). Discrepancies between anti-HTN medications listed in the OHSU EHR and outside EHRs were present in 32% of patients; of these, 56% had PCPs at OHSU and 44% had outside PCPs ($P = 0.25$).

Conclusions: EHRs provide a valid diagnosis of HTN in most cases. Accuracy of the HTN diagnosis, particularly in problem lists, increases when the patient's PCP is affiliated with the same institution. Inconsistencies exist in documentation of medications across different EHRs. Analysis of EHR data reliability is necessary before conducting large scale ophthalmic research.

ABSTRACT BODY:

Purpose: Intraocular pressure (IOP) is currently the only modifiable risk factor for glaucoma, yet glaucoma can continue to progress despite controlled IOP. Thus, development of glaucoma neurotherapeutics remains an unmet need. Scutellarin is a flavonoid that exhibits a number of neuroprotective effects on the brain and the eye. Here, we investigated the neurobehavioral effects of oral scutellarin treatment in a novel experimental model of chronic glaucoma.

Methods: Ten adult C57BL/6J mice (Group 1) were unilaterally injected with an optically clear hydrogel into the anterior chamber to obstruct aqueous outflow and induce chronic IOP elevation. Eight other mice (Group 2) received a unilateral intracameral injection of phosphate-buffered saline only. Another eight mice (Group 3) with hydrogel-induced unilateral chronic IOP elevation also received daily oral gavage of 300 mg/kg scutellarin from 1 week before to 2 weeks after hydrogel injection. Tonometry, optical coherence tomography, and optokinetic visuobehavioral testing were performed longitudinally to monitor the IOP, total retinal thickness, visual acuity, and contrast threshold of bilateral eyes in all three groups.

Results: Intracameral hydrogel injection resulted in unilateral chronic IOP elevation with no significant IOP difference between scutellarin treatment and untreated groups (Figure 1). With scutellarin treatment, the hydrogel-injected eyes showed less retinal thinning and reduced visual behavioral deficits when compared to the untreated, hydrogel-injected eyes (Figure 2). No significant difference in retinal thickness or optokinetic measures was found in the non-injected eyes over time or between all groups.

Conclusions: Oral scutellarin treatment appeared to preserve retinal structure and visual function in experimental glaucoma induced by chronic IOP elevation. Scutellarin may be a possible candidate as a novel neurotherapeutic agent for glaucoma treatment.

TITLE: Visual acuity outcomes following cataract surgery in Macular Telangiectasia Type 2 patients

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.S. Heng, Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|J.S. Heng, J.T. Handa, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jacob Heng: Commercial Relationship: Code N (No Commercial Relationship) | James Handa: Commercial Relationship(s);Bayer Pharmaceuticals:Code F (Financial Support);Clover Therapeutics:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To evaluate visual acuity outcomes following cataract surgery in eyes with Macular Telangiectasia (MacTel) Type 2.

Methods: Retrospective single-center cohort study of patients who underwent cataract surgery and were followed up at the same institution. Pre-operative evaluation included examination by a retinal specialist and macular optical coherence tomography (OCT). Primary outcome measure was post-operative change in best-corrected visual acuity (BCVA). Secondary study outcomes were achieving post-operative BCVA better than Snellen acuity of 20/40 and time to loss of visual acuity by 2 lines or more. Multivariate analyses were carried out using regression methods with generalized estimating equations.

Results: 20 eyes of 11 patients underwent cataract surgery and were followed for a median of 25.5 months (IQR 17.5 – 44.2 months). The median improvement in BCVA post cataract surgery was 10.5 letters (IQR 3.50 – 20.25). In a multivariate generalized linear model, only nuclear sclerosis grade ($p=0.00177$) was significantly associated with post-operative change in BCVA. The presence of foveal ellipsoid zone (EZ) breaks ($p < 0.001$) on OCT was inversely correlated with post-operative BCVA better than 20/40 in a multivariate logistic regression model. In addition, the presence of foveal EZ breaks ($p < 0.001$) and MacTel Type 2 disease stage ($p=0.027$) were independently associated with shorter time to vision loss of two lines or more in a multivariate Cox regression model.

Conclusions: There was a modest but significant improvement in visual acuity after cataract surgery in eyes with MacTel Type 2. This improvement was correlated with the severity of the cataract. The presence of central foveal EZ breaks was associated with poorer post-operative visual acuity and subsequent vision loss from disease progression.

ABSTRACT BODY:

Purpose: There is a dearth of medical literature on the status of eyecare in Native American Populations. We performed a retrospective, observational clinical study to assess outcomes of ophthalmic surgical interventions among the Navajo Nation population in the Four Corners region of the United States.

Methods: We analyzed 8 years of longitudinal data from the Moran Eye Center Global Outreach Division database (2013-2020). Records from Navajo patients (n=147) who underwent cataract, glaucoma, and pterygium excision surgery as part of the Navajo Nation Eye Care Initiative were reviewed for surgical outcomes and complications. Intraoperative and postoperative complication rates were calculated, and the nature of complications were evaluated. Surgical techniques, medical comorbidities, and mitigating efforts were reviewed on a case-by-case basis.

Results: The vast majority of surgical interventions studied were cataract extraction with IOL implantation. Over the 8 years (n=200 surgeries, 147 patients), 12 patients (7.5%) experienced intraoperative or postoperative complications. Ten patients were noted to have complications of cataract surgery, including hyphema with permanent MVL in the setting of uncontrolled T2DM, Descemet's detachment, IOL dislocation, residual cortical material, and posterior capsule tears. There were also two cases of pterygium graft maladherence.

Conclusions: This is the first analysis of surgical outcomes in the Navajo tribe of the Intermountain West. In a population with known high rates of diagnosed T2DM and likely high rates of undiagnosed HTN, a rate of 92.5% uncomplicated surgeries is remarkable. Critically, this study speaks to the need for surgical capacitation and training of skilled ophthalmologists deployed in geographical proximity to Native American Indian territories. The results we describe help provide a justification for outreach surgeries and a framework for quality improvement in the delivery of eye care in the Navajo Nation.

SUBMITTER (NAME ONLY): Charles Dale

TITLE: Interrater agreement of meibomian gland loss quantified by IR meibography software within a multi-functional corneal topographer

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Dale, A. Ravikumar, E. Ritchey, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Charles Dale: Commercial Relationship: Code N (No Commercial Relationship) | Ayeswarya Ravikumar: Commercial Relationship: Code N (No Commercial Relationship) | Eric Ritchey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Meibomian gland loss is a significant predictor for dry eye disease. Non-contact infrared meibography is a popular imaging technique integrated into multi-functional corneal topographers, and can be used clinically to grade the degree of meibomian gland loss in patients. In this study, we examined the inter-observer reliability of the CSO Antares, a multi-functional corneal topographer and infrared meibographer with integrated analysis software, in quantifying meibomian gland loss in upper and lower eyelids.

Methods: Ninety-six images were taken of the meibomian glands for the upper and lower eyelids in both eyes for 24 subjects. Images were analyzed by two independent graders using the directions provided with the Antares integrated analysis software. Interrater reliability was compared for the calculated percent area loss using Bland-Altman limits of agreement, as well as categorically by a displayed 5-point Likert clinical grading scale (grade 0 as <10% loss; grade 1 as <25% loss; grade 2 as <50% loss; grade 3 as <75% loss; and grade 4 as $\geq 75\%$ loss) using a weighted Cohen's kappa statistic.

Results: Subjects ranged in age from 8-24 years old, with a mean age of 14.8 years old. When comparing the calculated percent area meibomian gland loss between graders, a mean difference of 0.856% (SD=4.117%) was observed for upper eyelids, and a mean difference of 21.41% (SD=12.56%) was observed for lower eyelids. Categorical meibomian gland loss scores using a 5-point Likert clinical grading scale displayed strong agreement between the 2 observers for grading meibomian gland loss for the upper eyelids ($\kappa = 0.722$, $p < .0005$), and fair agreement for grading meibomian gland loss for lower eyelids ($\kappa = 0.557$, $p < .0005$).

Conclusions: Inter-observer grading repeatability for meibomian gland loss with the integrated analysis software of CSO Antares topographer displayed stronger limits of agreement between observers for both the continuous percent area loss metric and the 5-point Likert clinical grading scale when examining upper eyelids. For lower eyelids, more inter-observer variability was observed in the analysis of meibomian gland loss for both metrics. These findings suggest that the grading approach with the integrated analysis software of the Antares is better suited for consistent evaluation of meibomian gland loss for upper eyelids between eye care practitioners.

TITLE: Comparing Clinic Cycle Time and Patient Follow Up with Same-Day Visual Field Visits versus Separate Day Visual Field Visits in Glaucoma Patients in a County Hospital System

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kalakuntla, E. Jung, B. Wong, Ophthalmology, Keck Hospital of USC, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tej Kalakuntla: Commercial Relationship: Code N (No Commercial Relationship) | Eric Jung: Commercial Relationship: Code N (No Commercial Relationship) | Brandon Wong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Automated Humphrey visual field (HVF) testing is critical in diagnosing and monitoring glaucoma, but obtaining testing is a time-intensive process that may lead to extended clinic visit times for patients. Visual field testing is often scheduled as stand-alone appointments separate from the date of provider examination, but it is not currently known whether this strategy improves clinic efficiency or patient compliance with visits.

Methods: Retrospective analysis was performed on LAC+USC ophthalmology patients with an ICD-10 coding (diagnosis of glaucoma) who were scheduled for HVF on the same day as the provider or on separate day from provider visit between 1/2/2019 and 7/28/2019. Clinic cycle time, appointment no-show rates, and patient demographics were calculated and compared for visits. An unpaired two-tailed t-test was used to compare cycle times between groups.

Results: There were 371 same-day HVF and provider visits and 409 HVF visits scheduled separately from the provider visits. Glaucoma patients attended 195 (52.3%) of the same-day HVF and provider visits and missed 173 (46.4%) of them in their entirety. In four visits (1.08%), patients attended their HVF visit but left prior to being seen by the provider. Of the separately scheduled HVF and provider appointments, only 9 patients (2.2%) successfully attended both visits. For 328 (80.2%) of the separate visits, patients missed both visits entirely. 69 separate day visit pairs (16.87%) resulted in patients attending their provider visit only and missing their HVF visit, while 3 different day visit pairs (0.73%) resulted in patients attending only their HVF visit and missing their provider visit. Mean cycle time for patients with same day HVF and provider appointment was 4.83 hours, while combined average time spent at the clinic when HVF was separately scheduled from a provider visit was 5.81 hours. There was no statistically significant difference in combined cycle time when scheduling a separate HVF appointment (p-value = 0.30).

Conclusions: Compared to same day HVF and provider visits, separate day HVF testing does not improve clinic cycle time and may lead to increased no-show rates in glaucoma patients in a county hospital setting.

ABSTRACT BODY:

Purpose: The emergence of COVID-19 has introduced new challenges to eye care practitioners, not the least of which is mask-related fog on slit lamps, condensing lenses, phoropters, and perimeters. In this case series, we examine the effect that phoropter lens condensation has on visual acuity and contrast sensitivity and evaluate the efficacy of an anti-fog device at preventing condensation on a phoropter lens.

Methods: Snellen visual acuity (VA) and contrast sensitivity (CS) measured across four spatial frequencies (3, 6, 12, 18 cycles/degree) with Vector Vision (Guardion Health Sciences, San Diego, CA) were examined. Both VA and CS were evaluated monocularly in healthy subjects wearing KN95 masks, first while viewing through a Lorgnette occluder as a control (no lens), then through a phoropter. When using the phoropter the +0.125 lens was deployed bilaterally to emulate lens presence during refraction while minimally affecting refractive error. During testing the right lens of the phoropter was room temperature (20°C) and the left lens was heated to 37-40°C using a flexible electric heating strip. Subjects were not masked to which side was heated.

Results: Ten eyes of 5 subjects (2 female, 3 Male, mean age 32.4yr) were evaluated. Baseline mean LogMAR VA (\pm SD) was 0.00 \pm 0.12 in the right eye (OD) and 0.04 \pm 0.16 in the left eye (OS). Mean CS area under the curve (AUC) was 6.7 \pm 0.4 OD, and 6.7 \pm 0.5 OS. There was no difference in baseline VA or CS between left and right eyes (both $P>0.3$). Eyes re-tested through the heated phoropter lens had mean LogMAR VA of 0.02 \pm 0.1 and CS AUC of 6.8 \pm 0.7 and were not different from baseline (both $P>0.2$). However, eyes re-tested through the unheated phoropter lens (control) showed mean LogMAR VA of 0.09 \pm 0.1, and CS AUC of 5.0 \pm 1, both of which were significantly worse than baseline (both $P<0.05$). All subjects reported various amounts of condensation on the room temperature lens and no condensation on the heated lens.

Conclusions: An electrically heated adhesive fabric eliminated mask-related fog on the phoropter lens and prevented fog-associated deficits in VA and CS. The utilization of lens heating devices on microscopes, perimeters, and phoropters will alleviate fogging introduced by measures intended to limit the spread of COVID-19.

ABSTRACT BODY:

Purpose: Telemedicine is an emerging technology in the health sector in Mexico. The success of any new technology depends on many factors including the knowledge and understanding of the concept and attitude towards technology and working environment by the potential users. The objective of this study was to assess the awareness, knowledge, and attitude toward telemedicine among adults living in Guadalajara western Mexico.

Methods: A cross-sectional survey was carried out among adults assisting to three commercial malls. A total of 143 non-health personnel were included in the study. A pre-validated self-administered questionnaire was used for the survey to assess the awareness, knowledge, and attitude toward concepts of telehealth, telemedicine and teleophthalmology. The questionnaires were administered by an interviewer in a face-to-face format. Completed questionnaires were analyzed as per the study objectives using descriptive statistics for the quantitative data and content analysis considering a p value equal or less than 0.05 as statistically significant.

Results: A total of 148 patients completed the survey (78 females and 70 male) with a mean age of 43.2 ± 15.5 years.. Overall, 78.4% of participants had used the Internet for a variety of reasons including some health-related issues and 74.3% had finished high school. The knowledge level of the respondents was found to be moderate (47.5%) regarding telemedicine and low (36.5%). To most of the respondents, self-care regarding health is relevant (84.4%), especially eye health care (91.9%). With regard to the attitude towards telemedicine 62% of the respondents possess high attitude, 21% possess moderate attitude and 17% possess low level of attitude toward telemedicine and telehealth programs.

Conclusions: The current results suggest that although the respondents' knowledge is very limited in telemedicine, a large proportion of them have positive attitude towards telemedicine and teleophthalmology. Education on new technology applied to health seems to be relevant to impulse lay-persons to use telemedicine facilities when they are available.

ABSTRACT BODY:

Purpose: Optical Coherence Tomography (OCT) is an important imaging technique in ophthalmology. Traditionally, clinical OCT requires an operator and patient cooperation to both align and correct for refractive errors. Automating the tasks of alignment and focusing can increase the accessibility of OCT and make it available outside of specialty clinics. In order to automate these tasks, we developed a robotically-aligned OCT scanner that automatically aligns and corrects defocus refractive error.

Methods: We built a 100kHz swept-source retinal OCT scanner designed for 16-degree field of view imaging. This scanner was mounted on a 7 degree-of-freedom robot (Fig. 1) along with 3 pupil cameras and 4 IR LEDs for eye tracking. The pupil cameras capture real-time images of the eye, which are then utilized to extract location—through linear triangulation—and orientation—through pupil-center and corneal-reflection segmentation analysis. Using the tracking information as input, the robotic arm is controlled in real-time to orient the scanner relative to the eye's optical axis as well as position it to correct for misalignment error. Once aligned, the system triggers automatic focusing to correct any refractive errors. Dynamically switching from regular dense volumes (160,000 AScans) to a sparse scan (400 AScans) in real-time allowed for faster focusing compared to traditional approaches. We demonstrated the automatic focusing of the system by imaging a retinal model eye (Rowe Tech. Design) through varying trial lenses to evaluate the time to regain focus and the dioptric correction range (Fig. 2).

Results: Focusing was obtained in <3s over a Diopter range of -12D to 12D. Gaze tracking tests demonstrate 0.337° accuracy and 0.236° precision within a 28° range. Pupil tracking tests demonstrate 19.5µm lateral and 34.2µm axial accuracy along with 5.9µm lateral and 6.1µm axial precision within a 300mm lateral and 150mm axial range. Freestanding human imaging without a fixation target demonstrated successful automatic alignment.

Conclusions: We demonstrate an autonomous system that can image freestanding subjects as well as quickly correct for ocular defocus.

TITLE: Investigating the role of neuronal Nrf2 in glaucoma

SESSION TITLE: Neuroprotection

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Naguib, T.S. Rex, M. Gil, Neuroscience, Vanderbilt University, Nashville, Tennessee, UNITED STATES|T.S. Rex, J.R. Backstrom, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sarah Naguib: Commercial Relationship: Code N (No Commercial Relationship) | Tonia Rex: Commercial Relationship: Code N (No Commercial Relationship) | Melanie Gil: Commercial Relationship: Code N (No Commercial Relationship) | Jon Backstrom: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our goal is to study the role of neuronal Nrf2 in early glaucomatous pathogenesis by removing and/or overexpressing Nrf2 in the neurons of the ganglion cell layer in ocular hypertensive and control mice.

Methods: We intravitreally injected AAV2/2.CMV.Nrf2 or AAV2/2.CMV.eGFP into 2-3 month old male and female C57Bl/6 or Nrf2 KO mice. After 2 weeks, we bilaterally injected polystyrene beads into the anterior chamber of both C57Bl/6 mice or Nrf2 KO mice to induce ocular hypertension. We quantified superoxide levels in vivo using dihydroethidium. We measured visual function using flash ERG, VEP and the photopic negative response (PhNR).

Results: In AAV2/2.CMV.eGFP injected C57 mice, there was a 3-fold increase in DHE fluorescence in the microbead group in comparison to the saline-injected controls. This increase was absent in microbead injected C57 mice injected with AAV.Nrf2 ($p=0.27$). The PhNR was decreased in microbead injected C57 mice injected with AAV2/2.CMV.eGFP at $26.91\text{mV} \pm 5.10$ as compared to controls at $41.98\text{mV} \pm 3.56$; $p=0.0043$. This decrease was prevented by overexpression of Nrf2, with a PhNR of $40.6\text{ mV} \pm 5.37$. DHE fluorescence was further increased in ocular hypertensive Nrf2 KO as compared to C57 mice. Treating the Nrf2 KO mice with AAV.Nrf2 prevented the increase in DHE fluorescence. The average amplitude of the PhNR in Nrf2 KO mice (saline and microbead) was significantly reduced in comparison to C57 controls. Treatment with AAV.Nrf2-treated Nrf2 KO groups preserved the mean amplitude of the PhNR as compared to Nrf2 KO mice that received AAV.eGFP.

Conclusions: Overexpression of Nrf2 in ganglion cell layer neurons via intravitreal injection of AAV2/2.CMV.Nrf2 reduced ROS levels and preserved the PhNR after microbead occlusion and in the Nrf2 KO mouse. This suggests that much of the oxidative stress and susceptibility in the Nrf2 KO derives from the retinal ganglion cells. This data also suggests that AAV2/2.CMV.Nrf2 may be an effective gene therapy for the treatment of glaucoma and should be explored further.

ABSTRACT BODY:

Purpose: To address the scarcity of high quality adjudicated labels for training supervised deep learning models. We used an automated sans-coding approach, developing a teacher model from a small high quality labeled dataset to subsequently assign diabetic retinopathy (DR) referral pseudolabels to a large unlabeled dataset. A student model was then trained from the combined dataset.

Methods: We utilized two publicly available fundus photo DR datasets. High quality adjudicated DR severity labels were applied to the first dataset of fundus photos (n=1744). Google Cloud Automated Machine Learning (AutoML) was next used to train a deep learning image classification model sans-coding, termed the teacher model for referable and nonreferable DR. The resulting algorithm was deployed in Google Cloud platform and made available for inference. The teacher model was used to generate DR referral predictions for an unlabeled public fundus photo dataset (n=58,689). The resulting image-label pairs were combined with the high quality teacher model's training dataset, and a student deep learning model was trained.

Results: The teacher model area under the precision-recall curve (AUPRC), accuracy, sensitivity, specificity was 0.964, 92.0%, 73.9, 98.4 respectively, while the student model metrics improved to 0.976, 92.5%, 87.0%, 94.5% on the internal validation dataset. Teacher model external validation accuracy, sensitivity and specificity was 93.3%, 94.4%, 75.0%, while student model external validation metrics improved to 97.6%, 99.5%, 66.7% respectively.

Conclusions:

We demonstrate a sans-coding framework, which utilizes AutoML to address label scarcity for deep learning in DR. We show that self-training is an effective method to increase performance and decrease overfitting, which may simultaneously save time on expensive yet high-quality expert labeling. While the student model external validation dataset had 1 more false positive than the teacher model, clinically costly false negatives decreased by 10 as compared to the teacher model. As the tools for machine learning continue to be democratized, our methodology has potential to address the remaining disparity of expensive clinical labeling which bottlenecks small scale clinicians and researchers.

TITLE: Real-life in situ measurement of blinking using a wearable device: establishing a gold standard for spontaneous blinking

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Chen, N.C. Chidi-Egboka, I. Jalbert, P. Wagner, B. Golebiowski, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Jiaying Chen: Commercial Relationship: Code N (No Commercial Relationship) | Ngozi Chidi-Egboka: Commercial Relationship: Code N (No Commercial Relationship) | Isabelle Jalbert: Commercial Relationship: Code N (No Commercial Relationship) | Peter Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Blanka Golebiowski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The study of blinking has been hampered in part by the lack of a gold standard condition for measurement. This study measured blinking in situ in a real-life setting during various reading and non-reading tasks and also examined repeatability.

Methods: Ten healthy adults (30.7 ± 3.6 years; 4M:6F) completed a randomised cross-over intervention study. Participants wore an eye-tracking headset (Pupil Labs GmbH) during 8 tasks (15 min each): A) conversation, B) reading from printed text, C) laptop screen, D) smart TV at 6 m, E) smartphone, F) smartphone at 50% brightness, G) smartphone (more complex text), H) walking indoors. To determine repeatability, task E was completed twice. Symptoms (Instant Ocular Symptom Survey) were measured before and after each task. Spontaneous blink rate and interblink interval were recorded using the headset. Blink parameters were compared between tasks using repeated measures ANOVA and post hoc comparisons with Bonferroni correction. Ocular symptoms pre- and post-task were compared using the Paired t-test. Repeatability was examined using the Bland & Altman method (Coefficient of Repeatability, CoR).

Results: Blink rate was reduced during all reading tasks (B to G) compared to conversation ($p \leq 0.003$) and walking ($p \leq 0.04$). There was no significant difference in blink rate between conversation and walking, nor between any of the reading tasks. There were no significant differences in interblink interval between tasks. Ocular symptoms worsened after reading from a smartphone at reduced brightness ($p = 0.02$), more complex text ($p = 0.04$) and from a distant TV screen ($p = 0.01$). CoR was ± 14.5 blinks/min for blink rate and ± 22.4 s for interblink interval while reading from a smartphone.

Conclusions: The wearable eye tracker can reliably measure blink rate and interblink interval in situ. In a real-life setting, blink rate was reduced during reading compared to conversation or walking, irrespective of reading task complexity, working distance or device used.

TITLE: Intravitreal Carboplatin as Salvage Treatment for Progressive Vitreous Disease in Retinoblastoma: a Phase I Clinical Trial

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. King, M.W. Wilson, R. Brennan, Surgery, St. Jude Children's Research Hospital, Memphis, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Benjamin King: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Wilson: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Brennan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intravitreal chemotherapy is an increasingly popular treatment modality for vitreous seeding in intraocular retinoblastoma. The most commonly used agent – melphalan – is associated with multiple reports of retinal toxicity. Other chemotherapeutic agents may offer similar efficacy with a more favorable safety profile

Methods: The iRET protocol was a prospectively enrolled phase I clinical trial testing the safety and efficacy of intravitreal carboplatin in the treatment of progressive vitreous disease in intraocular retinoblastoma. Children who developed new vitreous seeds after completing primary treatment were eligible to receive an intravitreal injection of 0.3 mg carboplatin every 2 weeks. A serious adverse event prompted dose reduction to 3 µg.

Results: Four patients were enrolled at an initial dose of 0.3 mg. Complete regression of vitreous seeds was noted in all patients following 5, 2, 2 and 1 injections. Two patients developed recurrent vitreous disease at 3 months and 25 months after complete regression. All four patients are long term survivors, but those with recurrence ultimately required enucleation. A serious adverse event occurred in one patient who developed acute vision loss with extinguished electroretinography response 72 hours after the second injection. The protocol was temporarily suspended pending dose recalculation. Two additional adverse events were noted including cataract (previously therapy included subconjunctival carboplatin exposure) and grade 3 neutropenia. Three patients were enrolled at an injection dose of 3 µg and treated with a total of 5, 2 and 1 injections respectively, with close monitoring of ERG in all cases. Complete regression of vitreous disease was not achieved in any patient at the 3 µg dose, as well as no change in ERG, but all three showed immediate clinical response to intravitreal melphalan (ocular salvage x / 3). Therefore the protocol was terminated due to lack of efficacy rather than pursue dose escalation.

Conclusions: Intravitreal carboplatin may be effective in treating progressive vitreous seeding at higher doses. Given the occurrence of permanent retinal toxicity however, its overall therapeutic ratio appears to be unacceptably low. Other alternative agents should be investigated.

ABSTRACT BODY:

Purpose: To evaluate perioperative management and outcomes of after-hours urgent ophthalmic surgery performed at inpatient versus outpatient hospital-based operating venues at a single institution in an effort to minimize insufficiencies, waste, and patient-centered complications.

Methods: A retrospective chart review was performed for all patients who underwent urgent or emergent ophthalmic surgery outside of normal operative block times between January 2018 -April 2020. Primary outcomes measures included length of time to first incision, duration of surgery, improvement in visual acuity, and post-operative complications. Comparisons of each outcome measure were made based on the location where the surgery was performed which were designated as main in-patient operating room (MOR) or a hospital-based outpatient surgical center (OSC) where most routine outpatient ophthalmic surgery is performed.

Results: 73 patients were included. 24 patients (32.9%) involved open globe injuries while the remainder underwent urgent surgical intervention for other peri-ocular or orbital reasons that were not associated with a penetrating or perforating globe injuries. There were two locations designated as MOR and two locations denoted as OSC. 32 surgeries were performed at the MORs and 41 cases were performed at the OSCs. Average duration from admission to surgery was 5.29 ± 2.64 hours for open globes versus 17.64 ± 30.46 for non-open globes ($p=0.01$). The average length of surgery was 2.16 ± 1.19 hours for open-globe procedures versus 1.78 ± 0.84 for non-globe cases ($p>0.05$). Duration between admission and surgery was 24.1 ± 35.95 hours for the MORs versus 5.4 ± 4.34 prior to surgery at the OSCs ($p=0.01$). Average length of surgery was 2.14 ± 0.94 hours for MOR versus 1.72 ± 0.98 for OSC ($p=0.06$). OSCs were 11 times more likely to have cases start within 12 hours of admission ($p<0.001$). 11 patients (34.4%) who underwent surgery at the MOR locations experienced post-operative complications compared to 15 patients (36.6%) at OSCs ($p=0.85$).

Conclusions: This study did not find that improvement in visual acuity or complications rates were significantly impacted by the surgery location; however, less ideal peri-surgical circumstances were encountered with utilization of the MOR including longer hospitalizations and greater intra-operative duration.

TITLE: Perceptual learning with attention tasks improves contrast sensitivity in V1 of human adults with amblyopia

SESSION TITLE: Amblyopia: Translational Studies and Trials

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Hou, G. Acevedo Munares, The Smith-Kettlewell Eye Research Institute, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chuan Hou: Commercial Relationship: Code N (No Commercial Relationship) | Gabriela Acevedo Munares: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The neural correlates of perceptual learning in amblyopia remain unclear. The specificity of task orientation in behavioral studies is commonly interpreted as evidence that perceptual learning reflects plasticity in the primary visual cortex (V1). However, physiological evidence for this assumption is modest or controversial. To reveal neural correlates of perceptual learning, we measured contrast sensitivity in V1 of human adults with amblyopia using fMRI-informed EEG source imaging before and after perceptual learning.

Methods: A group of adults with amblyopia was trained using dichoptic attention tasks for about 2 visits/week for 2 months. The training task was to quickly search for and count the number of Targets presented in the trained eye while simultaneously being presented with Distractors in the untrained eye through a mirror stereoscope. We arranged 90% of trials with Targets in the amblyopic eye and only 10% of trials with Targets in the non-amblyopic fellow eye in each training session. We expected to improve attentional deployment considerably in the amblyopic eye. Contrast response function in each eye was measured by 128-channel swept parameter visual evoked potential (sVEP) before and after training. Contrast threshold was defined by using the regression to zero amplitude approach. V1 was defined by structure and fMRI in a separate session from EEG recordings. Contrast sensitivity ($1/\text{threshold}$) in V1 was compared in each participant pre and post training.

Results: Contrast sensitivity in V1 improved for both the amblyopic and the fellow eye of adults with amblyopia after perceptual learning with attention tasks. The improvement was greater in the amblyopic eye than that in the fellow eye. We did not find significant difference in improvement between anisometropic and strabismic subgroups. Contrast sensitivity improvement in V1 indicates learning effect by enhancing attentional deployment in the amblyopic brain.

Conclusions: Perceptual learning with attention tasks improves contrast sensitivity in V1 of human adults with amblyopia. Our results suggest that top-down mechanisms play an important role in perceptual learning-induced plasticity in early visual cortex.

Commercial Relationships Disclosure (Abstract): Shruti Singh Kakan: Commercial Relationship: Code N (No Commercial Relationship) | Maria Edman: Commercial Relationship: Code N (No Commercial Relationship) | Brooke Hjelm: Commercial Relationship: Code N (No Commercial Relationship) | Curtis Okamoto: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Hamm-Alvarez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sjögren's Syndrome (SS) is an autoimmune disease exhibiting inflammation and loss of function of exocrine glands including lacrimal gland (LG). Diagnosis of SS is lengthy and cumbersome. The male NOD mouse exhibits many symptoms of the autoimmune-mediated dry eye seen in SS patients. To identify tear biomarkers that might aid in diagnosis of SS-associated dry eye, we investigated the miRNA composition of tears from male NOD mice. miRNAs are 19-26 nucleotide long, highly-conserved, RNAs that regulate mRNA transcription and are altered in disease. Relative to proteins, miRNAs have less sequence heterogeneity and inter-individual variance, and have shown high sensitivity as biomarkers.

Methods: Tears were collected with topical stimulation of LG with carbachol from male NOD (disease model), BALB/c (healthy control) and female NOD mice (strain control lacking LG inflammation) aged 12-14 weeks. Tear RNA was isolated from pools of 5 mice per sample with 5 samples of male NOD and BALB/c mice and 3 samples of female NOD. RNA quality was determined using Tapestation, then a small-RNA library was prepared using the Illumina TruSeq Small RNA library prep kit and sequenced on an Illumina HiSeq system. Following bioinformatics data analysis, miRNA hits were identified and validated using qRT-PCR. Hits were considered significant if they were up or downregulated in NOD tears with a \log_2 FC of ± 0.5 in the same direction when compared to both male BALB/c and female NOD, and had a p value < 0.05 (DESeq2).

Results: In comparison to both male BALB/c and female NOD mice, 8 tear miRNAs (miR-107-3p, miR-181a-5p, miR-181b-5p, miR-3572-3p, miR-3572-5p, miR-3963, miR-3076-3p) were upregulated whereas another 8 (miR-322-3p, miR-322-5p, miR-146b-5p, miR-146a-5p, miR-147-3p, miR-421-3p, miR-542-3p, miR-503-5p) were downregulated in male NOD. miRNAs 146a/b-5p which was significantly downregulated in male NOD mouse tears, and miR-155-5p, which was slightly but not significantly upregulated in male NOD mouse tears, have been implicated in autoimmune inflammation. The remaining miRNAs represent novel hits with their functional relevance under investigation.

Conclusions: We have identified a panel of differentially expressed miRNA in male NOD mouse tears that may serve as novel biomarkers for early detection of SS.

ABSTRACT BODY:

Purpose: To explore the diagnostic value of quantitative limbal palisades of Vogt complex (PVC) parameters by en face optical coherence tomography (OCT) for limbal stem cell deficiency (LSCD).

Methods: Retrospective analysis of limbal en face OCT images of 11 eyes of 11 patients with LSCD and 10 eyes of 10 healthy controls. PVC was defined as the hyporeflective tissue within the anatomical limbus, including the palisades of Vogt and the surrounding limbal epithelium. Three-dimensional en face scans through the PVC, of 9µm depth each, were assessed to determine the anterior and superficial borders (end of Bowman's layer) and the posterior and deep borders (transition of hyper-hyporeflective sclera-limbus). The area and volume of each scan were measured manually with ImageJ. Minimum and maximum depth were determined as the first and last appearance of the PVC on the OCT device, respectively. Statistical models were performed to account for different limbal scans of the same eye and age. Slit-lamp grading (0: no loss, 1: <50% loss and 2: ≥50% loss of palisades of Vogt) were correlated to en face OCT parameters.

Results: Mean age was 54.1±19.9 and 39.5±13.6 years in the LSCD and control groups, respectively (p>0.05). There was no statistically significant difference between gender and limbus location (nasal, temporal, superior, inferior) within groups (p=0.61 and p=0.11, respectively). Compared to controls, the LSCD group showed an overall decreased PVC area (0.41±0.04 and 0.86±0.05 mm², p=0.001), maximum area (1.27±0.29 and 2.27±0.19 mm², p=0.013) and volume (0.06±0.01 and 0.09±0.01 mm³, p=0.001) on en face OCT. The comparison for each limbal location is shown in Figure 1. PVC area, maximum area and volume showed a strong inverse correlation with slit-lamp grading (r=-0.586, r=-0.519 and r=-0.586, respectively; p<0.001).

Conclusions: PVC parameters were significantly decreased in LSCD patients compared to healthy controls. All limbal locations with LSCD showed significant PVC changes compared to their respective control regions. En face OCT is a promising non-invasive and quantitative tool for the diagnosis of LSCD.

TITLE: Pleiotropic Loci Exist for Advanced AMD and Celiac Disease

SESSION TITLE: Genetics of corneal dystrophy, glaucoma, lens and AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.E. Cohen, D.L. Geiser, J. SanGiovanni, The University of Arizona BIO5 Institute, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jorey Cohen: Commercial Relationship: Code N (No Commercial Relationship) | Dawn Geiser: Commercial Relationship: Code N (No Commercial Relationship) | John Paul SanGiovanni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Nutrient-based interventions are used for tertiary prevention of advanced AMD. Pleiotropic loci exist for AMD and health conditions characterized by altered nutrient absorption.

Methods: We examined advanced AMD (AAMD)-associated missense DNA variants from the IAMDC|GWAS Catalog|PheWeb for pleiotropy with Celiac Disease (CD), a condition characterized by malabsorption of zinc (a key constituent of the AREDS formulation) and other minerals linked to diet-associated reductions in likelihood of having or progressing to AAMD. The genetic architecture of co-inherited SNPs in people of western-European ancestry ($r^2 > 0.80$, LDLink-NCI and HaploReg 4.1) was also analyzed.

Results: Analysis of IAMDC, GWAS Catalog and PheWeb data showed that 13 genes containing AAMD-related ($P < 1.0E-7$) exonic SNPs also carry CD-associated DNA variants. Analysis of all concordant genes (those containing any form of genome-wide AAMD- and CD-related variation) yielded a CD enrichment Q-value of $2.3E-18$. We filtered IAMDC results for AAMD by genome-wide CD-associated loci ($P < 1.0E-7$) that were identified in a fine-mapping study on $> 24,000$ people (PMID: 22057235). Within the 6p21 locus, 58 SNPs in 25 LD-independent ($r^2 < 0.60$) loci were both associated with AAMD and CD. These loci include SNPs in complete LD ($r^2 > 1.0$) with 6 missense DNA sequence variants (in CCHCR1, MSH5, C2, CFB, TNXB, PSMB9).

Conclusions: Our findings provide a reasonable basis for investigating the possibility of a common underlying biology and therapeutic options for AAMD and Celiac Disease through processes driven by proteins encoded by genes in the 6p21 locus.

TITLE: Telegenetics for Inherited Retinal Diseases during the COVID-19 pandemic

SESSION TITLE: Genetics of Retinal dystrophies and Functional Genomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Kumar, A. Al Moujahed, T. Chemudupati, V.B. Mahajan, Molecular Surgery Program, Department of Ophthalmology, Stanford University, Stanford, California, UNITED STATES|S. Tsang, Columbia University, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aarushi Kumar: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Al Moujahed: Commercial Relationship: Code N (No Commercial Relationship) | Teja Chemudupati: Commercial Relationship: Code N (No Commercial Relationship) | Stephen H. Tsang: Commercial Relationship: Code N (No Commercial Relationship) | Vinit Mahajan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Inherited Retinal Diseases (IRDs) are a group of rare genetic disorders that require a detailed approach and workflow for diagnosis. To facilitate optimal patient care while minimizing the hazard of direct person-to-person exposure during the COVID-19 pandemic, we developed a telehealth management protocol, or telegenetics, for complete or hybrid virtual visits.

Methods: Our telegenetics protocol comprised of three key components: (1) Digitization of diagnostic imaging and electrophysiological testing for review by physicians remotely; (2) Telemedicine video visits performed using MyHealth, a Health Insurance Portability and Accountability Act (HIPAA) compliant platform. (3) Complete shift to remote genetic testing using IRB-approved e-consents (electronic consent forms) and remote genetic testing saliva kits.

Results: Telegenetic care was provided for 113 patients, including 3 international patients (age range: 5-99 years). During the first eight months of this program, 25 return and 28 new patient evaluations were completed virtually. Sixty patients were seen in a hybrid manner (45 new and 15 return), where an in-person clinic visit was performed followed by remote consenting, and saliva collection, genetic testing, and genetic counseling. A spectrum of retinal dystrophies were diagnosed and pathogenic mutations were detected in several genes, including genes approved or under-investigation for gene therapy like RPE65, CHM, and RPGR. Four patients with cystoid macular edema were successfully treated with topical dorzolamide, and 26 were referred for low-vision rehabilitation

Conclusions: Telegenetic services have proved to be a useful tool during the COVID pandemic. They provide a safer alternative by limiting the exposure of patients and staff to the virus while maintaining the same high quality of care that was provided to patients before the pandemic. With the added efficiency and convenience of virtual patient care, we expect that telegenetics will continue and expand into other medical genetic conditions long after the pandemic.

TITLE: Single Cell RNA-Sequencing Points to an Inter-relationship between Corneal Macrophages and Dendritic Cells

SESSION TITLE: Corneal Immunology and T cell Responses

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Littleton, D.R. Saban, Immunology, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|S. Littleton, C. Yu, R. Mathew, J. Kalnitsky, D.R. Saban, Ophthalmology, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sejiro Littleton: Commercial Relationship: Code N (No Commercial Relationship) | Chen Yu: Commercial Relationship: Code N (No Commercial Relationship) | Rose Mathew: Commercial Relationship: Code N (No Commercial Relationship) | Joan Kalnitsky: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Saban: Commercial Relationship(s);Roche:Code C (Consultant);Novartis:Code F (Financial Support);Aeri:Code C (Consultant);Dompe:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Macrophages (MF) and dendritic cells (DC) are categorized as two separate cell types with distinct roles in innate immunity, but also can have overlapping functions given their highly complex and plastic nature. In the cornea, current classifications for these two population of mononuclear phagocytes are still limited to only several markers or genes. Thus, a better accounting of the full range and dynamics of their cell states is needed to more completely understand the distinct roles of these cells and how they fulfill their functions. We addressed this knowledge gap here at the transcriptome level, by applying single cell RNA-seq of mononuclear phagocytes from the cornea and their precursors from the blood in normal adult mice.

Methods: Corneas from n=25 male and n=25 female eight-week-old C57BL/6 mice were harvested, prepared as single cell suspensions, and FACS sorted for live CD45+ populations. Additionally, the peripheral blood of n=5 male and n=5 female mice were FACS sorted for live CD45+, CD11b+, CD115+, Ly6G- cells to enrich for circulating monocytes and precursor DCs. FACS sorted cornea and blood were pooled by sex before sequencing.

Results: Our dataset included n=3,237 viable cells and n=15,831 genes. Unbiased cluster analysis at a resolution of 1.5 via Seurat resulted in n=25 clusters. To understand the potential relationships between these clusters we conducted a pseudotime analysis. Any clusters with lymphoid or granulocyte signatures were excluded. Langerhan's cells were also excluded given their fetal origins. Our results revealed two main trajectory branches. One branch transitioned through a DC-like state, while the other did not. Interestingly, both branches converged into several closely related clusters dominated primarily by a MF gene signature, with genes related to DC function.

Conclusions: Collectively, our results suggest that corneal mononuclear phagocytes derived from adult blood precursors represent MFs of which had either transitioned through a DC-like state or did not, yet retained DC features. Hence, rather than a two-cell type model for DCs and MFs, our findings suggest that they exist in a continuum of cell states and expressed gene programs in the cornea. These implications may better explain how mononuclear phagocytes maintain such a diverse functional repertoire with efficient on-demand responses involved in corneal homeostasis and disease.

Commercial Relationships Disclosure (Abstract): YOSUKE TAKI: Commercial Relationship: Code N (No Commercial Relationship) | Yasuki Ito: Commercial Relationship: Code N (No Commercial Relationship) | JUN TAKEUCHI: Commercial Relationship: Code N (No Commercial Relationship) | YUYAKO NAKANO: Commercial Relationship: Code N (No Commercial Relationship) | ETSUYO HORIGUCHI: Commercial Relationship: Code N (No Commercial Relationship) | OHTA HIKARU: Commercial Relationship: Code N (No Commercial Relationship) | Hiroki Kaneko: Commercial Relationship: Code N (No Commercial Relationship) | Shinji Ueno: Commercial Relationship: Code N (No Commercial Relationship) | Hiroko Terasaki: Commercial Relationship: Code N (No Commercial Relationship) | keiko kataoka: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We investigated the changes in foveal avascular zone (FAZ) area after vitrectomy with internal limiting membrane (ILM) peeling for epiretinal membrane (ERM).

Methods: This retrospective observational case series included 21 eyes of 21 patients (age: 68.4 ± 6.5 years) who underwent vitrectomy with ILM peeling for ERM. Pre- and post-operative FAZ areas were measured using 3×3 mm superficial optical coherence tomography (OCT) angiography, and the relationship was investigated. In addition, the displacement distance of the centroid of FAZ was measured in OCT angiography images, and the association of the changes in FAZ area with pre-operative FAZ area, pre-operative foveal thickness, axial length, and the displacement distance of the centroid of FAZ were also investigated.

Results: Pre- and post-operative FAZ areas correlated significantly ($p < 0.001$). Preoperative FAZ areas larger than 0.10 mm^2 , were reduced after surgery and vice versa. The multivariate analysis showed that the changes in FAZ area were only associated with pre-operative FAZ area ($p = 0.001$), and were not associated with other factors (all $p > 0.05$).

Conclusions: Postoperative changes in FAZ area after ILM peeling only depended on baseline FAZ area. Because FAZ area of 0.10 mm^2 is much smaller than normal FAZ area, ILM may have centrifugal tractional forces on the fovea, and the FAZ area without the centrifugal tractional force of the ILM may be about 0.10 mm^2 .

TITLE: High-risk Histopathologic Features of Primarily Enucleated Retinoblastoma

SESSION TITLE: Recent Advances in Retinoblastomas, Intra and Extra Ocular Pathologies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Xu, X. Zhang, F. Gao, Z. Zhang, Beijing Institute of Ophthalmology, Beijing Tongren Hospital, CHINA|

Commercial Relationships Disclosure (Abstract): Xiaolin Xu: Commercial Relationship: Code N (No Commercial Relationship) | Xu Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Fei Gao: Commercial Relationship: Code N (No Commercial Relationship) | Zhibao Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the high-risk histopathologic features (HRFs) of retinoblastoma (RB) eyes enucleated as the primary treatment strategy.

Methods: A retrospective histopathological analysis of HRFs was performed. A total of 950 primarily enucleated RB eyes from Beijing Tongren Hospital were analyzed.

Results: Of the 950 primarily enucleated RB eyes, 362(38.1%) were classified as HRFs, of which 287 (30.2%) had post lamina cribrosa optic nerve invasion (including 32 (3.4%) with optic nerve transection invasion), 133 (14.0%) with massive choroidal invasion, 58 (6.1%) with anterior segment invasion, and 12(1.3%) with extraocular invasion. NVI was identified in 508 patients (53.5%) and was significantly correlated with HRFs. The proportion of HRFs was significantly higher in the NVI-positive group (50.6%) compared to the NVI-negative group (23.8%) ($P < 0.001$). The proportion of post lamina cribrosa optic nerve invasion was significantly higher in the NVI-positive group (44.1%) compared to the NVI-negative group (14.3%) ($P < 0.001$). The proportion of massive choroidal invasion was significantly higher in the NVI-positive group (18.9%) compared to the NVI-negative group (10.6%) ($P < 0.001$).

Conclusions: HRFs occurred in slightly more than one-third of RB cases, which was similar to HRFs incidence in developing countries and higher than that in developed countries. To a certain degree NVI is a predictor of HRFs. When considering primary treatment, especially intra-artery chemotherapy (IAC), the facts that more than one-third of RB eyes have HRFs and a little more than half of NVI-positive RB eyes have HRFs should be carefully thought out.

TITLE: Artificial Intelligence to detect glaucoma through OCT Angiography– a pilot study

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. MIGUEL, B. Silva, Ophthalmology, Polyclinique de la Baie, Saint-Martin-des-Champs, FRANCE|

Commercial Relationships Disclosure (Abstract): Ana MIGUEL: Commercial Relationship: Code N (No Commercial Relationship) | Bruno Silva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Artificial intelligence (AI) has been used successfully to diagnose several eye conditions, including glaucoma. OCT-Angiography (OCTA) is a non-invasive technology useful for glaucoma diagnosis and follow-up. To our knowledge, no study has applied AI in OCTA scans to increase the diagnostic capacity in glaucoma. Our purpose was to develop an AI tool to assist in glaucoma diagnosis using OCTA scans. We also intended to measure its performance using the area under the curve (AUROC), as done for diagnostic studies.

Methods: We performed an observational retrospective study from 2020 to 2015. We had local Ethics Committee approval and followed the tenets of the Helsinki declaration. Patients with retinographies, OCT, OCTA, visual fields, intraocular pressure (IOP) measurement, and complete ophthalmology records were included. A glaucoma expert reviewed the medical records to classify patients with glaucoma and those without glaucoma. Patients with systemic or other ophthalmologic pathologies and glaucoma-suspects were excluded, as well as incomplete records. Low-quality OCTA images were excluded (with strength signal index ≤ 50 , media opacities, or fixation artifacts). We built a deep-learning software using the OCTA scans, using 90% of them to train its neural network to distinguish the images between glaucoma and non-glaucoma. The remaining ten percent were used for validation. We used the TensorFlow (v.1.15.2) encoder library, followed by several layers of mathematical operations and the RMSProp optimizer, and a learning rate of 0.001.

Results: We included 262 patients, from which 40 were healthy controls, and 222 were glaucomatous patients. The AI system successfully discriminated glaucoma from healthy eyes from OCTA scans, with a sensitivity of 99.55%, a specificity of 92.5%, and an AUROC of 85%.

Conclusions: Despite a small database, the AI discriminating results were promising in this pilot study. Associating OCTA scans to AI may be an effective strategy to help ophthalmologists diagnose glaucoma. More extensive multi-centric studies are needed to improve deep learning algorithms and detect glaucoma better.

TITLE: Long-term follow-up of Glaucoma Drainage Implants (Tubes) in Paediatric Glaucoma Patients

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.A. Puertas, S. Koenig, Glaucoma Department, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Renata Puertas: Commercial Relationship: Code N (No Commercial Relationship) | Susanna Koenig: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the long-term outcomes and safety profile of tube implants in primary and secondary paediatric glaucoma patients (≤ 16 years of age) at a tertiary centre.

Methods: Between January 2005 and August 2020, 361 paediatric glaucoma patients had a tube implant. Of these, 121 were analysed and 83 eyes were included as a first tube implant with sufficient follow-up of at least 12 ± 2 months. This is a retrospective data collection. Failure was defined as loss of light perception (PL) vision, tube explantation, need for oral Acetazolamide or further glaucoma surgery. Eyes that did not fail by the above criteria, but were on supplemental topical medical therapy were considered qualified successes. Eyes that did not fail and were not on any medical therapy were considered complete successes.

Results: The mean age at surgery was 8.1 ± 5.3 years (55.4% female). The average intraocular pressure (IOP) at listing was 28.1 ± 7.2 mmHg, on 3.1 ± 0.9 medications with 27 (32.5%) patients taking oral Acetazolamide. The mean follow-up time was 3.4 ± 2.0 years. One year after tube implant [7 Ahmed valves (8.4%), 1 Molteno tube (1.2%), 75 Baerveldt tubes (90.4%) $n=79$], the IOP decreased to 14.8 ± 4.2 mmHg on 2.6 ± 1.0 medications. The average IOP was 15.7 ± 4.7 mmHg on 2.4 ± 0.8 medications after 3 years ($n = 46$) and 15.1 ± 5.5 mmHg on 2.6 ± 0.7 agents after 5 years ($n = 26$).

The average visual acuity (VA) was 0.6 ± 0.51 logMAR at listing. At one year follow up, VA was 0.6 ± 0.6 logMAR; at three years VA was 0.6 ± 0.6 logMAR and at 5 years, VA was 0.7 ± 0.5 logMAR ($p > .05$).

Altogether, one patient lost PL (1.2%) four years post-op, one tube was explanted and replaced with another tube due to poor IOP control (1.2%) and further eight (10%) patients needed additional glaucoma surgery.

Conclusions: Despite the inherent risk in the paediatric population, tube implants appear to be an effective procedure driving drastic reduction in pressure ($p < .00001$ at all times) as well as in use of medication in long-term ($p < .00001$ at all times). This study provides information about the safety profile of tube implants in a paediatric glaucoma population of a single hospital. New evidence of tube implant in glaucoma has changed adult glaucoma management in the last decade. We hope our study can show tube implants as a safe procedure and one more option for children who will need follow up and treatment for a lifetime.

TITLE: The Effect of Market Competition on the Price of Topical Eye Drops

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Watane, M. Kalavar, J. Reyes, N.A. Yannuzzi, J. Sridhar, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Arjun Watane: Commercial Relationship: Code N (No Commercial Relationship) | Meghana Kalavar: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Reyes: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Yannuzzi: Commercial Relationship: Code N (No Commercial Relationship) | Jayanth Sridhar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the relationship between the number of Federal Drug Administration (FDA)-approved manufacturers and the price change of generic and branded topical eye drops.

Methods: Retrospective analysis of topical eye drop medications with formulations listed in the Federal Drug Administration's (FDA) Orange Book and the National Average Drug Acquisition Cost database from 2013 to 2017.

Results: The most frequently prescribed generic topical drugs were glaucoma medications (34%), antimicrobials (32%), anti-inflammatories (24%), mydriatics (5%), and anesthetics (5%). The most frequently prescribed branded topical drugs were anti-inflammatories (45%), glaucoma medications (32%), antimicrobials (21%) and dry eye medications (3%). From 2013 to 2017, generic eye drops had a median price decrease of 20% (IQR 32%) while branded eye drops had a median price increase of 44% (IQR 28%) ($P < .001$). A significant inverse association was identified between the price change of generic eye drops and the total number of all manufacturers ($r = -.41$, $P = .010$), generic drug manufacturers ($r = -.32$, $P = .0496$), and alternative branded drug manufacturers ($r = -.57$, $P = .002$). There was no significant association between the price change of branded eye drops and number of manufacturers. Glaucoma ($r = -.58$, $P = .039$) and anti-inflammatory ($r = -.69$, $P = .047$) eye drops also had significant inverse associations with the number of generic manufacturers.

Conclusions: From 2013 to 2017, the price of generic eye drops decreased whereas the price of branded eye drops increased. Market competition was significantly inversely associated with price changes of generic eye drops but not branded eye drops.

TITLE: Lacrimal stenting with Nunchaku versus Crawford tubes for Congenital or Partial Acquired Nasolacrimal Duct System Obstruction

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Pratte, J. Cho, R. Short, E. Mellencamp, School of Medicine, University of Missouri System, Columbia, Missouri, UNITED STATES|C. Petris, Department of Ophthalmology, University of Missouri System, Columbia, Missouri, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eli Pratte: Commercial Relationship: Code N (No Commercial Relationship) | Junsang Cho: Commercial Relationship: Code N (No Commercial Relationship) | Riley Short: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Mellencamp: Commercial Relationship: Code N (No Commercial Relationship) | Carisa Petris: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare Nunchaku or Crawford stent placement during probing for the treatment of congenital or acquired nasolacrimal duct obstruction.

Methods: A retrospective chart analysis was undertaken for patients that underwent lacrimal stenting with Nunchaku-style tubes (19 patients, 27 eyes) and Crawford tube placement (37 patients, 40 eyes) at the same institution from 2017-2018 by one of two oculoplastic surgeons. With the exception of lacrimal balloon dilation, cases performed in conjunction with other surgical procedures, such as ectropion repair or dacryocystorhinostomy (DCR), were excluded. The primary outcome measure was resolution of daily epiphora.

Results: Outcomes were recorded in the early (<1 month) or late (1-3 months) post-operative period or long-term (>3 months) follow-up (Table 1). In the early post-operative period, the Nunchaku cohort 15 eyes (57.7%) had resolution of epiphora (9 ± 5.2 days) compared to 21 eyes (75.0%) of those that received a Crawford stent reported achieving success at 17.2 ± 7.6 days ($p=0.18$). In the late post-operative period, average time of follow-up for the Nunchaku cohort was 46.5 ± 10.5 days with 14 eyes (87.5%) reporting success compared to 61.3 ± 19.3 days with 3 eyes (75%) achieving success ($p=0.51$). In long-term follow-up, average duration was 118.4 ± 18.4 days with 5 eyes (100%) achieving success compared to average duration of 336.9 ± 241.2 days with 14 eyes (87.5%) reporting success ($p=0.99$).

We also analyzed success rates for patients receiving stents for congenital and acquired NLDO (Table 2). Average age of patients receiving Nunchaku stent for congenital NLDO was 3.5 ± 3.2 years compared to 70.6 ± 11.8 for acquired NLDO. For the Crawford stents, average age for congenital NLDO 2.1 ± 1 years and 53.7 ± 12.3 years for acquired NLDO. Success rates at every post-operative interval for both congenital and acquired NLDO was comparable between Nunchaku and Crawford stents.

Conclusions: The short and long-term follow-up visits demonstrated comparable rates of improvement in epiphora for both the Crawford and Nunchaku style lacrimal stents. The Nunchaku lacrimal stent is a "push-style" stent that does not require intranasal retrieval or tying/securing of the distal ends of the tubes. In instances where the Nunchaku style stent is appropriately utilized, there may be benefits of improved surgical efficiency.

ABSTRACT BODY:

Purpose: We have previously applied methods in genomics, structural chemistry, ophthalmic epidemiology and clinical trials to demonstrate associations of L-DOPA, dopamine (DA) and monoaminergic receptors with advanced AMD. In this work we report findings on human retinal transcriptomes to extend our investigations.

Methods: We used QC-validated and normalized RNA-seq data collected with Illumina HiSeq 2500 from a public-access NCBI GEO database (GSE115828) of retinal specimens in order to identify differential gene expression profiles in seven people with neovascular AMD (NV AMD), relative to twelve age-matched AMD-free peers. We conducted gene ontology and pathway analysis with Gene Set Enrichment Analysis (GSEA) software.

Results: RNA levels of DBH-like monooxygenase protein 1 (MOXD1), an enzyme implicated in dopamine catabolism, were 3.3-fold higher in retinal specimens of people with NV AMD ($P < 9.91E-5$; FDR Q = 0.095) – these findings were concordant with a published work reporting a 2.8-fold increase in MOXD1 expression within macular specimens of people with NV AMD (PMID: 22364233). Gene Ontology Enrichment Analysis on the full set of 17910 transcripts yielded strongest relationships for down regulation of chemical synaptic transmission (GO: 0007268; FDR Q = 6.3E-13) in the NV AMD cohort – subsequent Pathway Enrichment Analysis showed significant NV AMD-associated retinal down regulation of 14 genes in the KEGG Dopamine Synapse Pathway (hsa04728; FDR Q = 1.4E-4) and 4 genes in the WikiPathways Nicotine Effect on Dopaminergic Neurons Pathway (WP1602; FDR = 0.048). Gene sets from the Reactome Dopamine Release Cycle (FDR Q = 0.14) and Gene Ontology Regulation of Dopamine Secretion (FDR Q = 0.17) also showed significantly lower expression values in people with NV AMD.

Conclusions: Our findings strengthen inferences on AMD-associated alterations in function of monoaminergic signaling pathways.

TITLE: The Use of a Combination of Ozurdex (dexamethasone intravitreal implant) and Eylea (afibercept) versus Eylea Monotherapy for Diabetic Macular Edema: Preliminary Data from a Prospective, Comparative Trial (COED Trial)

SESSION TITLE: Diabetic macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Abbey, Texas Retina Associates, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ashkan Abbey: Commercial Relationship(s);Allergan:Code F (Financial Support);Allergan:Code C (Consultant);Allergan:Code R (Recipient);Regeneron:Code C (Consultant);Regeneron:Code R (Recipient);Genentech:Code C (Consultant);Genentech:Code R (Recipient);Alimera Sciences:Code C (Consultant);Alimera Sciences:Code R (Recipient);Spark Therapeutics:Code R (Recipient);Novartis:Code C (Consultant);Novartis:Code R (Recipient)

ABSTRACT BODY:

Purpose: This study evaluated the safety, efficacy, and durability advantages of Ozurdex (OZ) in conjunction with intravitreal aflibercept (AF) compared with AF monotherapy for treatment of diabetic macular edema (DME). We expect reduced time to resolution of DME on OCT and fewer total injections with the use of combination therapy.

Methods: COED is a prospective, randomized, open-label, multicenter collaborative study. Patients were randomized 1:1 to OZ and AF (active) or AF monotherapy (control), and assessed over 48 weeks. Treatment-naïve eyes with DME (or eyes previously treated with anti-VEGF after a 3-month washout period) with best-corrected visual acuity (BCVA) of 25 to 73 letters and central subfield retinal thickness (CST) of more than 300 µm were included. Patients that have completed 24 weeks of the trial were included in this preliminary analysis. The active group (AG) (n = 13) received OZ and AF at baseline. They would then receive monthly injections of AF, and treatment with OZ would be performed every 3 months PRN. Patients in the control group (CG) (n = 10) received AF at baseline. These patients would subsequently receive monthly injections of aflibercept PRN. At each visit, the following criteria were assessed to determine whether to treat:

- Macular Edema, defined as intraretinal or subretinal fluid (new or persistent), in conjunction with a CST \geq 300 µm as measured by SD-OCT.
- A decrease in BCVA of 6 letters or greater between the current visit and the BCVA reading from the previous visit with an increase in CST of $>$ 50 µm from the previous visit, associated with new fluid.
- A decrease in BCVA of 10 letters or greater from the best measurement (during the study) with an increase in CST of $>$ 50 µm from the previous visit, associated with new fluid.

Results: At week 24, the difference in mean BCVA (AG – CG) was -4.59 ± 5.33 (p = 0.40). The difference in mean CST was -37.88 ± 73.87 (p = 0.61). Eyes in AG received fewer treatments (mean 4.23 vs. 5.4).

Conclusions: OZ administered in conjunction with intravitreal AF for treatment of DME provides similar visual benefit at 24 weeks' follow-up compared with AF monotherapy and shows anatomic benefit with potential to reduce treatment burden.

TITLE: Gut microbiota from Sjögren Syndrome patients causes decreased T regulatory cells in the lymphoid organs and ocular barrier disruption in mice.

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Schaefer, R. Britton, Molecular Virology and Microbiology, Baylor College of Medicine, Houston, Texas, UNITED STATES|C. Trujillo-Vargas, S.C. Pflugfelder, C.S. De Paiva, Ophthalmology, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Laura Schaefer: Commercial Relationship: Code N (No Commercial Relationship) | Claudia Trujillo-Vargas: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Pflugfelder: Commercial Relationship: Code N (No Commercial Relationship) | Robert Britton: Commercial Relationship: Code N (No Commercial Relationship) | Cintia De Paiva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We are investigating the effects of the gut microbiota on immune homeostasis at the ocular surface and on ocular pathophysiology in Sjogren Syndrome.

Methods: 4-week-old female germ-free C57BL/6 mice were individually humanized with stools from either healthy donors or SS patients (n = 5 donors per group). Flow cytometry analysis investigated the frequency of CD4⁺FoxP3⁺ cells in ocular draining nodes, spleens, intestinal lamina propria and mesenteric lymph nodes 4 weeks post-humanization. A separate group of germ-free mice after humanization with SS and healthy donors were mated to established humanized colonies. Humanized mice (n = 3 different donors per group) were subjected to the standard desiccating stress for 5 days. Uptake of Oregon-Green-Dextran (OGD) dye was used to evaluate corneal barrier function after desiccating stress. Data analysis was performed after combining the results from individual subjects.

Results: We observed a consistent decrease in the percentages of CD4⁺FoxP3⁺ lymphocytes in the eye draining lymph nodes in the SS humanized mice compared to healthy donors (11.6±5 vs 15.8±4.6% of the total leukocytes, n=19 mice/group, p=0.01 unpaired t test). This finding was recapitulated in the offspring of the humanized colonies, in which we also observed the same phenomenon in the spleen and mediastinal lymph nodes, indicating that this effect has vertical transmission. Following exposure to desiccating stress for 5 days, we observed significant disruption of corneal barrier function in SS-humanized mice compared to healthy donors.

Conclusions: These findings suggest that the gut microbiota influences the proper development of T regulatory cells in draining lymph nodes of mucosal surfaces, such as the eye. They also suggest that the bacterial communities from Sjogren Syndrome patients are less protective of the ocular surface against desiccating environmental stress, as SS-humanized mice had worse corneal barrier function.

ABSTRACT BODY:

Purpose: Electroretinography is a quantitative and functional indicator of visual function and is an important tool for the diagnosis and management of retinal function in ocular disease. Dry age-related macular degeneration (AMD) demonstrates underlying mitochondrial dysfunction. The Valeda multi-wavelength photobiomodulation (PBM) device, and the Diopsys NOVA ERG device were used to investigate the effects on multiple parameters of visual function in the ELECTROLIGHT dry AMD study.

Methods: A total of 23 eyes from 15 subjects with intermediate Dry AMD were enrolled into the prospective clinical study and treated with one series of PBM treatment using the Valeda (3x per week for 3 weeks). PBM therapy consists of low-level light exposure to selected tissues resulting in positive effects on mitochondrial Cytochrome C Oxidase output and improvement in metabolic activity. Subjects were assessed for clinical and safety outcomes (i.e., visual acuity, contrast sensitivity, color vision, amsler grid test, perimetry, and ERG). Independent OCT outcomes at 3- and 6-months post-treatment were analyzed by a masked imaging center. An interim analysis was performed following the month 1 study visit.

Results: Subjects showed approximately 12.6 ± 1.25 letter improvement in BCVA at Month 1 compared to BL scores. Mars Contrast Sensitivity (CS) also showed improvement from BL to 1 month at 40 cm ($0.165 \log + 0.25$), 80 cm ($0.134 \log + 0.20$) and 120 cm ($0.22 \log + 0.37$). A positive correlation between multiluminance ERG and BCVA was seen and strong positive correlations between multiluminance ERG and fixed luminance ($R = 0.852$) and Chromatic ERG outcomes. Reductions in drusen were seen in select patients. Multiluminance ERG Magnitude AUC improved by 14.4% from baseline to the fourth test after completion of the 1-month treatment, and this difference was determined to be significant ($p = 0.001$).

Conclusions: Valeda provided statistically significant improvements in BCVA, CS and multiluminance ERG function from baseline at the 1-month time point following 9 PBM treatments. PBM therapy represents a novel approach to treat patients with dry AMD. Diopsys multiluminance ERG may be used as an early and sensitive measure of visual dysfunction in dry AMD patients.

TITLE: Utilization and success rates of various lacrimal surgeries with a Nunchaku-style lacrimal stent

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Mellencamp, J. Cho, R. Short, E. Pratte, School of Medicine, University of Missouri, Columbia, Missouri, UNITED STATES|C. Petris, Ophthalmology, University of Missouri, Columbia, Missouri, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elizabeth Mellencamp: Commercial Relationship: Code N (No Commercial Relationship) | Junsang Cho: Commercial Relationship: Code N (No Commercial Relationship) | Riley Short: Commercial Relationship: Code N (No Commercial Relationship) | Eli Pratte: Commercial Relationship: Code N (No Commercial Relationship) | Carisa Petris: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the utility of a Nunchaku-style stents in various lacrimal surgeries.

Methods: Charts were reviewed for patients who underwent placement of the Nunchaku (FCI Ophthalmics, Pembroke, MA) stent placement between (2017-2018) an oculoplastic surgeon at a single institution. The primary outcome measures were recorded as the rate of resolution of daily epiphora or absence of daily tearing symptoms at the early (<30 days) and late post-operative visits (>30 days). Patient demographics, type of surgery, use of a lacrimal balloon dacryoplasty or canaliculoplasty, concomitant procedures, level of obstruction, size of tube and post-operative complications were recorded.

Results: 40 patients (51 eyes) were included. 27 underwent probing for congenital or acquired NLDO, 18 had dacryocystorhinostomy (DCR), 4 had canalicular laceration repair, and 2 had canalicular reconstruction following Mohs surgery. Rates of epiphora were evaluated at early (10.8 ± 8.13 days) and late (57.7 ± 50.41 days) post-operative timepoints. At early post-op follow-up 15 eyes (54.9%) of patients undergoing probing with silicone intubation had resolution compared to 17 eyes (94.4%) who underwent endoDCR. At late follow-up 24 eyes (88.9%) who underwent probing with silicone intubation had resolution compared to 17 eyes (94.4%) who underwent endoDCR. Eyes who received stents for canalicular reconstruction after Mohs or canalicular laceration repair didn't exhibit occurrence of epiphora at any time points after surgery (table 1).

Conclusions: Traditionally Crawford style stents have been used in oculoplastic lacrimal surgery. The Nunchaku lacrimal stent - a self-retaining, push-style stent - circumvents the need for intranasal retrieval, securing, and is easier to remove. Overall, our results show that Nunchaku stenting with probing and endoDCR had high rates of success in the late post-operative period. In addition, low rates of new-onset epiphora after canalicular lacerations or canalicular repair after Mohs defects were seen. Higher rates of epiphora in the early post-operative period had improved at the later timepoints, which is likely attributable to post-operative swelling. This study provides further evidence that Nunchaku stents should be used with high confidence in treatment for patients with various lacrimal pathologies. Further studies directly comparing Nunchaku-style and Crawford tubes may be beneficial.

ABSTRACT BODY:

Purpose: The prevalence of blindness due to retinal injury has inspired widespread efforts to develop new treatments. Despite significant advances made in retinal cell transplantation, achieving proper repair of existing retinal tissue remains a significant obstacle. A new and exciting alternative strategy involves the stimulation of retinal regeneration from a patient's own stem-like cells. Müller glia are the only retinal cell type to express the orphan nuclear receptor TLX, a master regulator of neuronal stemness. Due to its enriched expression in Müller glia and the potential for pharmacologic manipulation, we hypothesize that TLX may serve as an ideal therapeutic target for stimulating repair and regeneration in the mammalian retina.

Methods: A transgenic mouse model was developed wherein Müller glia express a YFP reporter transgene, allowing us to effectively track Müller glia through 8 key stages of retinal development that coincide with available single cell RNA-sequencing (scRNA) datasets. Freshly enucleated eye cups were harvested from wild type and transgenic mice at each key developmental stage. All eyecups were fixed with 4% paraformaldehyde, washed with PBS and stored in 30% sucrose/PBS solution. Eyecups were cryopreserved and 12 um cryosections obtained for immunofluorescence detecting TLX and markers of Müller glia and other retinal cell types. Imaging was performed via confocal microscopy.

Results: TLX is highly expressed in the embryonic retinal progenitor cells during mouse retinal development via scRNA sequencing data. Müller glia start expressing TLX mRNA and protein at postnatal day 5 (P5) in mouse retina. By P8, TLX mRNA and protein are solely expressed by Müller glial cells in the retina.

Conclusions: Overall, we have temporospatially mapped the expression of TLX from embryonic retinal progenitor cells to fully differentiated retinal cell types of the adult retina. We find that TLX expression becomes restricted to Muller glia over the course of mouse retinal development. Collectively, these studies provide a foundation of understanding for the potential molecular mechanisms implicated in the retinal regenerative capacity of mammalian Müller glia and provide further basis for the study of TLX as a candidate target for retinal regeneration.

ABSTRACT BODY:

Purpose: To explore the capability of en face optical coherence tomography (OCT) in measuring the dimensions of the limbal palisades of Vogt complex (PVC) and describe the regional differences in healthy subjects.

Methods: Retrospective analysis of limbal en face OCT images from 10 eyes of 10 healthy individuals. The best quality image from all available regions (nasal, temporal, superior, inferior) were selected for each subject. PVC was defined as the hyporeflective tissue within the anatomical limbus, including the palisades of Vogt and the surrounding limbal epithelium. Three-dimensional en face scans through the PVC, of 9µm depth each, were assessed to determine the anterior and superficial borders (end of Bowman's layer) and the posterior and deep borders (transition of hyper-hyporeflective sclera-limbus). The area and volume of each scan were measured manually with ImageJ (Figure 1). Minimum and maximum depth were determined as the first and last appearance of the PVC on the OCT device, respectively. Statistical models were performed to account for different scans of the same eye and age.

Results: A total of 10 nasal, 10 temporal, 5 superior and 5 inferior en face OCTs regions were assessed. Mean age was 39.5±13.6 years [26-77] with equal male-to-female ratio. En face OCT PVC was detected in all regions. PVC area, volume, maximum area, maximum depth and thickness were greater in the superior and inferior limbus compared to the nasal and temporal (1.18 ± 0.10 and $0.68\pm0.05\text{mm}^2$, $p=0.003$; 3.15 ± 0.24 and $1.90\pm0.19\text{mm}^2$, $p<0.001$; 0.17 ± 0.02 and $0.06\pm0.01\text{mm}^3$, $p<0.001$; 129.4 ± 5.0 and $107.7\pm3.4\mu\text{m}$, $p=0.002$; and 63.4 ± 3.8 and $44.7\pm4.2\mu\text{m}$, $p<0.001$; respectively). PVC minimum depth was not statistically significant between the regions (62.5 ± 3.1 and $69.0\pm12.2\mu\text{m}$, $p=0.116$; respectively). Age was not a significant covariate in this study.

Conclusions: Superior and inferior PVC area, maximum area, volume, maximum depth and thickness were greater than nasal and temporal PVC, in accordance to previous histopathological reports on regional stem cell density. En face OCT can provide novel and potentially clinical useful quantitative measurements to assess PVC health.

ABSTRACT BODY:

Purpose: SARS-CoV-2 virus can remain stable on surfaces for several days. This cross-sectional analysis sought to determine the presence of SARS-CoV-2 virus on various surfaces that trainees and faculty of an academic eye clinic routinely came into contact with during the pandemic in New York City.

Methods: Samples were collected by faculty and trainees from surfaces encountered during daily life. On 4 different days, teams collected at least two samples using sterile swabs (Puritan HydraFlock). Prior to collection, nasal swabs were obtained from all individuals to check for SARS-CoV-2. Collection sites were grouped into four zones depending on proximity and the amount of the time personnel spent there. Zones included: (1) Work microenvironment: Slit lamp; door handles; computers; waiting room; reception; bathrooms (2) Work macroenvironment: ICU, ED, inpatient units; elevators, bathrooms; cafeteria (3) Living microenvironment: Home doorknob; kitchen; car; sitting area (4) Living macroenvironment: Subway station; subway cars; car services; restaurants; bike stations; grocery stores. Samples were transported to the lab in transport medium and RNA extraction was conducted using the QIAamp DSP Viral RNA Mini Kit. Presence of viral RNA was investigated using Luna Universal Probe One-step RT-qPCR.

Results: A total of 816 swabs were submitted. Only 2 (0.25%) samples were positive. The first was a sample from a patient bathroom sink handle in the main emergency room and the second was a nasal swab from a staff member who had been assigned to collect samples. Prior to this positive swab result, this staff member had tested positive for COVID-19, quarantined for two weeks, and had then received one prior negative test.

Conclusions: Though COVID-19 is currently widespread in the United States, this study shows that the healthcare personnel working in New York City at Edward S. Harkness Eye Institute at the Columbia University Irving Medical Center have a low chance of encountering viral RNA on surfaces they are in close contact with during their daily life. Considering the 1.77-2.39% citywide test positivity during the time this study was conducted, the likelihood of faculty and trainees getting infected from contaminated surfaces is 100 times less likely than acquiring COVID-19 from an infected individual. This result may be a reflection of the efficacy of disinfection protocols or the limited viability of the virus on inorganic surfaces.

ABSTRACT BODY:

Purpose: Uveal Melanoma (UM) is the most common primary intraocular malignancy in adults. It is characterized by developing early gain-of-function mutations (~98%) within GPCR components such as GNAQ and GNA11. Cysteinyl leukotriene receptor 1 (CYSLTR1) is another component in the structure of the G-protein coupled receptor (GPCR), which activates GNAQ/GNA11 and induces the MAPK/MEK/ERK signaling pathway. We previously identified CYSLTR1 expression in three primary and one metastatic UM cell lines as well as in the majority of UM enucleated specimens. Here, we investigated the biological effects of MK571, an inverse agonist of CYSLTR1, on UM cancer cells in an in vitro model.

Methods: In this study we used normal uveal melanocytes, CYSLTR1 negative, and four UM cell lines (MP41, MP46, MEL270, OMM2.5), CYSLTR1 positive. We determined the expression of CYSLTR1 receptor by immunocytochemistry. Cells were then treated with increasing concentrations of MK571 (25, 50, 75, 87.5µM) and our control were untreated cells. Afterwards, cell apoptosis was assessed using Annexin V/PI staining and flow cytometry. Statistical analysis was determined using two-way ANOVA; P<0.05 was considered significant.

Results: We found that inverse agonist, MK571, significantly increased the percentage of apoptotic cells (Annexin V positive cells) in a dose-dependent manner, including early and late apoptotic cell populations in all four cell lines treated ($p < 0.05$). Additionally, we found that after 48 hours of MK571 treatment, cells had ruptured, fragmented and nuclei shrinkage could be widely observed, furthermore, suggesting that this treatment could be responsible for inducing an apoptotic cell death in UM cells.

Conclusions: Inverse agonist, MK571, was proven to be effective as a single agent in inducing the apoptosis of four UM cell lines. It markedly reduced cell proliferation via induction of apoptosis. As such, it may serve as a novel therapeutic agent for uveal melanoma.

ABSTRACT BODY:

Purpose: To evaluate the outcomes of use of the fluticasone acetate implant in eyes with macular edema from retinal vein occlusion.

Methods: We retrospectively reviewed 13 eyes with macular edema from retinal vein occlusion who received an injection with the fluticasone implant. We evaluated visual acuity and central retinal thickness outcomes and documented complications including cataract progression and increased intraocular pressure (IOP).

Results: Visual acuity improved following injection with the fluticasone implant at final follow up (0.39 vs 0.26, $p=0.02$). In addition, central retinal thickness improved by 6 months, but then increased by final follow up (412mm, 302mm $p=0.01$, 345mm $p=0.3$). In all phakic patients, cataract progression was seen and required phacoemulsification surgery. Seven (53%) patients required IOP lowering medications and two (15%) required glaucoma filtration surgery.

Conclusions: Our study found the use of the fluticasone implant to be safe and effective for the management of macular edema from retinal vein occlusion. Further larger, randomized controlled studies are required to further evaluate their efficacy.

ABSTRACT BODY:

Purpose: It is important that randomized control trials (RCTs) represent real world patient populations. The purpose of this study was to compare the distribution of race in retinal vein occlusion (RVO) RCTs to the United States population.

Methods: We performed a cross-sectional study of the racial demographics of 8 RCTs for RVO and compared them to the United States 2019 census data. The number and percent of White, Black, Hispanic, Asian, American Indian/Alaska Native, Native Hawaiian/Pacific Islander participants was recorded. Chi-square test and one-sample z-test were used. Over- or underrepresentation of each race in every RCT was denoted.

Results: In the 8 RVO RCTs the white patient cohort was overrepresented in 5 RCTs. The difference was not statistically significant in 3. Of note, one study described the study participants only as white and non-white. The black patient cohort was underrepresented in 5, and not statistically different in 2. The Hispanic patient cohort was underrepresented in 6 and not statistically different in 1. The Asian patient cohort was overrepresented in 2 RCT, underrepresented in 1, and not statistically different in 4. The American Indian/Alaska Native and Hawaiian/Pacific Islander patient cohort was underrepresented in 6 RCT and not statistically different in 1.

Conclusions: The current study finds that that racial demographic data of subjects in majority of randomized control trials for treatment of retinal vein occlusion does not reflect that of the United States population, according to the 2019 US Census. Subjects identified as white tend to be overrepresented in randomized control trials. More efforts should be made to recruit underrepresented minorities to improve trial external validity and better serve these subpopulations.

ABSTRACT BODY:

Purpose: Decorrelation-based OCT is of interest for cornea biomechanics because it can provide spatially-resolved mechanical contrast based on the microstructural dynamics of the corneal tissue in a wholly non-perturbing manner. Previously, it was found that there was no significant relationship between intraocular pressure (IOP) within normal limits and decorrelation coefficient of the cornea averaged in depth. However, it was suspected that there may be a depth-dependent effect wherein the anterior half of the cornea experiences negative strain and the posterior half of the cornea experiences positive strain, and exhibits, respectively, a relative increase and decrease in decorrelation coefficient.

Methods: Whole porcine globes, obtained fresh from the abattoir, were used in this study with externally-controlled intraocular pressure. IOP was varied from 15 to 25 mmHg while the corneas were imaged with a spectral domain OCT system with a central wavelength of 1310nm. Scans were acquired using an M-B scan pattern with 2ms M-scans. Decorrelation coefficients were calculated using custom MATLAB software, pixelwise with a maximum of 0.06ms of lag.

Results:

It was found that there was a depth-dependent change in decorrelation coefficient as a function of IOP. (Figure 1). It is hypothesized that the change in decorrelation coefficient is due to changing internal stresses in the cornea as a result of IOP. This corresponds well with recently published literature regarding the distribution of strain within the cornea with increasing IOP.

Conclusions: As decorrelation-based OCT is used to study the depth-dependent mechanical properties of the cornea, for instance, in disease detection and treatment monitoring, the possible depth-dependent effect of IOP should be considered.

ABSTRACT BODY:

Purpose: To establish the degree of repeatability for numerous tomographic and aberrometric parameters for the Pentacam AXL and AXL Wave.

Methods: Retrospective study with three consecutive measurements per eye, all with good quality scores of the respective parameters. Tomography was measured by the Pentacam AXL and AXL Wave, aberrometry data originated exclusively from the AXL Wave (hence, was a subgroup of the entire measurements).

The following tomographic parameters were analysed: Chord μ , Chord α , HWTW, B/F Ratio; Pachymetry (apex, thinnest and their difference), anterior chamber depth (ext and int), corneal optical densitometry and pupil dia. (photopic).

The following aberrometric parameters (total eye) were analysed: RMS HOA, Spherical Aberration, Coma and pupil dia. (mesopic). Repeatability was assessed with the standard deviation and the coefficient of variation (CV [%])

Results: The study includes 97 patients (96 OD and 92 OS) with a mean age of $37 \pm 13,8$ years (the subgroup comprises 59 OD and 56 OS). The examined eyes were all phakic and without any known ocular pathologies. Tomographic parameters. Chord μ : mean=0,22 μ m, SD=0,02, CV=11,2; Chord α : mean=0,45 μ m, SD=0,04, CV=8,2; HWTW: mean=12,1mm, SD=0,05, CV=0,4; B/F Ratio: mean=82%, SD=0,31, CV=0,4; Pachy_{apex}: mean=540 μ m, SD=1,8, CV=0,3; Pachy_{thinnest}: mean=535 μ m, SD=2,1, CV=0,4; Pachy_{Diff}: mean=4,9 μ m, SD=1,2, CV=24,4; ACD_{ext}: mean=3,50mm, SD=0,02, CV=0,6; ACD_{int}: mean=2,97mm, SD=0,02, CV=0,7; COD: mean=13,2%, SD=0,65, CV=4,9; pupil dia_{photopic}: mean=2,7mm, SD=0,13, CV=4,9.

Aberrometric parameters. RMS HOA mean=0,126 μ m, SD=0,023, CV=18,3; spherical aberration: mean=0,046 μ m, SD=0,014, CV=30,1; coma: mean=0,066 μ m, SD=0,023, CV=34,2; pupil dia_{mesopic}: mean=5,1mm, SD=0,4, CV=7,0.

Conclusions: The analysis showed very good repeatability for all tomographic parameters. Standard deviations confirmed values clearly below clinical relevant deviations. CVs were excellent for six parameters and still good for further four. The standard deviations of the aberrometric parameters also revealed good repeatability. The slightly higher values for the coefficient of variations can be explained with the low mean value of the aberrations. The comparison of the repeatability for the mesopic and photopic pupil diameters showed a better repeatability under photopic conditions.

ABSTRACT BODY:

Purpose: To develop an automated algorithm for detection of genetic relatedness from color fundus photographs (FPs)

Methods: The degree of shared ancestry among pairs of UK Biobank participants (identity by descent, IBD) was estimated genome-wide using PLINK software. Pairs with $IBD > 0.1875$ (halfway between the expected IBD for third- and second-degree relatives) but < 0.98 (presumed duplicates) were considered related, while those with non-calculable IBD were considered unrelated. Unrelated FP pairs were generated using a combination of FPs from the related pairs and FPs randomly sampled from the rest of the data. FP pairs were divided into training and testing sets in an 80:20 ratio. A convolutional Siamese neural network-based algorithm composed of two Densenet-121 networks each pretrained on imageNet was trained to output a measure of genetic relatedness using 5620 pairs (2810 related and 2810 unrelated) of fundus images.

Results: Among the 1380 pairs of FPs in our test set, the model trained assigned each pair of images a Euclidean distance (ED), a measure of genetic relatedness. The average ED was 19.78 ± 10.06 among related pairs and 36.36 ± 12.29 among unrelated pairs, Fig 1. After normalization of EDs and using an optimal threshold for $ED=27.95$ (Youden's Y point), the sensitivity and specificity of our model were 78.7% and 74.7% respectively. When the computed EDs were used to determine probability of relatedness, the area under receiver operating curve for identifying related vs unrelated FP pairs reached 0.843. The ROC curve along with the associated confusion matrix using the computed threshold is shown in Fig 2.

Conclusions: A Siamese neural network based Euclidean distance obtained from pairs of FPs is able to accurately predict genetic relatedness.
