ABSTRACT BODY:

Purpose: This study introduces a hybrid mathematical model of the human retina that combines a heterogeneous vascular network description of the arterioles with a compartmental representation of the capillaries and venules to predict retinal blood flow and tissue oxygenation.

Methods: A previous heterogeneous model of the retinal arterioles is adapted here into a hybrid model of the retinal vasculature in which every terminal arteriole is connected in series to compartments representing capillaries, small venules, and large venules (Figure 1A). An overall pressure drop of 16 mmHg is assumed across the arterioles, yielding a total flow of 36,670 nL/min to the retinal microcirculation. A Green's function method is used to model oxygen transport in the arterioles, and a Krogh cylinder model is used in the capillaries and venules (oxygen demand is $1 \text{ cm}^3 \text{ O}_2 / 100 \text{ cm}^3 / \text{min}$). A metabolic wall signal is calculated from blood and tissue PO_2 and is conducted upstream to communicate the metabolic status of the retina to the arterioles.

Results: The wall signal conducted upstream from the capillaries and venules is shown in Figure 1B. The signal generated by the hybrid model is compared with the signal generated by an entirely compartmental model to demonstrate the role of spatial heterogeneity in the system. A more than two-fold range of wall signal values is communicated upstream and depends on vascular path lengths (Figure 1B) and PO_2 (Figure 1C). A 25% reduction in blood PO_2 leads to a doubling of the signal in many pathways.

Conclusions: A hybrid vascular model is introduced that accounts for spatial heterogeneity and oxygen transport in the retina. The model predicts that a higher metabolic wall signal is generated in pathways with a lower PO_2 at the terminal arteriole. This model provides the geometric and hemodynamic framework necessary to predict blood flow regulation in the human retina and will ultimately be used for early detection and treatment of ischemic and metabolic disorders of the eye.

ABSTRACT BODY:

Purpose: Early detection of primary open-angle glaucoma (POAG), a leading cause of blindness, is essential for mitigating severe visual impairment. The World Health Organization has highlighted the importance of engaging with communities about vision care and early disease intervention. We established the All Eyes on Us (AEOU) study in collaboration with University Settlement in the Broadway-Slavic Village neighborhood of Cleveland, Ohio to assess community-based perceptions of vision care and barriers to seeking vision care.

Methods: In collaboration with University Settlement, a community resource center for over 90 years in the Broadway-Slavic Village community of Cleveland, Ohio, we established a Community Advisory Board (CAB) comprised of community members interested in learning more about vision care and health. The CAB helped design our interview guide, which we administered to Broadway-Slavic Village community members over age 40 as semi-structured interviews designed to illuminate perceptions of and obstacles to vision care. Interviews with 60 individuals (30 self-reported African American and 30 self-reported White) were 30-45 minutes in length and audio-recorded. Of these, we transcribed and coded 59 interviews for thematic elements using the NVivo 12 Plus qualitative software package. One interview was coded manually.

Results: While study interviews demonstrated a wide array of perspectives of vision care, there were several common themes. Some reasons people reported for not going to the eye doctor included cost, insurance issues, lack of transportation, and not knowing where to seek eye care. Several individuals mentioned that they did not have general knowledge about eye health and were unaware of the importance of seeking vision care. Interestingly, when asked about their frequency of eye doctor visits compared to what they would suggest for others, study participants commonly said that people should seek vision care annually but said that they personally go less frequently.

Conclusions: We obtained perspectives of 60 Cleveland, Ohio community members; interview topics ranged from how they value vision care for themselves and other members of their community to the reasons that they are unable to access vision care. This information will help illuminate the needs of the community and inspire research into interventions by which improved access to adequate eye care can be achieved.

ABSTRACT BODY:

Purpose: Juvenile open angle glaucoma (JOAG) can lead to irreversible blindness if not detected and treated at early stages of disease. Myocilin (MYOC) mutations are known to cause JOAG in individuals and families worldwide. We have identified a large Filipino family with JOAG due to a novel MYOC stop-loss mutation, c.1515A>G (p.*505Wext*42). Examining this family over 4 years has allowed for determining the natural history of disease related to this mutation, including information about the onset of intraocular pressure (IOP) elevation, timing of treatment and therapeutic outcomes.

Methods: Fifty-seven members of a 4-generation family were screened for the novel MYOC stop loss mutation. 26 family members carried the mutation and were recruited for the clinical study. Clinically unaffected mutation carriers were monitored over the course of 51 months including visual acuity (VA) assessment, slit-lamp exam, applanation tonometry, gonioscopy and fundus exam.

Results: Twenty six of the 57 family members were carriers of the novel stop loss mutation. 13 mutation carriers were affected by JOAG (mean age of diagnosis 28.6 years; SD=7.9; range 16-43). Despite treatment, 11 mutation carriers had no light perception in at least one eye. Five mutation carriers were newly diagnosed with JOAG as part of the family ascertainment.

Of the 26 mutation carriers, 8 subjects (mean age 7 years; SD=4.9; range 1-15) did not have clinical evidence of glaucoma. These 8 subjects were examined regularly over the course of 51 months. One subject developed IOP elevation at age 14. The average intraocular pressure was within the normal range for the remaining 7 subjects (range: 12-20 mmHg). There was no significant change in the VA and cup to disc ratio and no indication of an upward IOP trend in this subgroup.

Conclusions: This is the first stop-loss MYOC mutation that has been described. In this family, this mutation appears to exhibit variable age of onset with 100% penetrance by age 49. It does not seem to cause elevated IOP in the first decade of life. Similar to a common MYOC mutation (GLN368X), the variable age of onset could suggest that other factors, including POAG polygenic risk score can modify disease development. Evaluation of unaffected mutation carriers provides insight into the natural history of MYOC-associated JOAG. This information will be of critical importance as gene-based therapies become available in the future.

ABSTRACT BODY:

Purpose: This study sought to evaluate higher-order SD-OCT features, including ellipsoid zone integrity and drusen burden, as predictive imaging biomarkers for a machine learning (ML) prognostic model for the development of subfoveal geographic atrophy (sfGA) in non-neovascular age-related macular degeneration (NNVAMD) over 5 years.

Methods: This was a retrospective cohort study of eyes with NNVAMD without sfGA with a 5-year follow-up interval. Based on sfGA status at year five, eyes were categorized into two subgroups: non-converter and sfGA converter. The macular scans at baseline were evaluated using an automated machine learning-enhanced multi-layer segmentation platform with expert reader verification for assessment of retinal anatomy, including outer retinal integrity [e.g., ellipsoid zone (EZ)] and the sub-RPE compartment (e.g., drusen burden). The feature complexities were compared using multiple decision trees and random forest ML modeling for a prediction assessment. Model performance was evaluated with a 5-fold cross-validation.

Results: One hundred and thirty-seven were included in this assessment, including 116 non-converters and 21 sfGA converters. Multiple higher-order OCT features, including EZ integrity metrics and sub-RPE compartment metrics, that were associated with sfGA conversion were analyzed. Feature selection for model inclusion was based on univariate analysis significance. Utilizing 7 significant baseline imaging features, the predictive performance of the ML sfGA prediction model was evaluated and achieved an area under the receiver operating characteristic (ROC) curve (AUC) of 0.85. SD-OCT features were ranked on their predictive ability to identify the development of sfGA and demonstrated that the most important feature was associated with EZ integrity and drusen burden.

Conclusions: Utilizing a ML classifier, higher-order SD-OCT quantitative biomarkers (i.e., EZ integrity, sub-RPE compartment) appeared to provide a high-performance model for predicting the development of sfGA in NNVAMD within 5 years of baseline assessment.

ABSTRACT BODY:

Purpose: RP59 is due to mutations in the essential gene, dehydrodolichyl diphosphate synthase (DHDDS), which is ultimately required for protein N-glycosylation. A subset of DHDDS mutations cause non-syndromic RP. To identify genes and pathways that are affected by disruption of the Dhdds locus, we analyzed the retina RNA profiles of two RP59 mouse models, in comparison to controls.

Methods: Total RNA was isolated from the retinas (2/sample) of N=3 mice/genotype: Dhdds^{K42E/K42E} knock-in (KI, 4 wks.; an RP59 mutation); Dhdds^{flx/flx} Rho iCre (KO; rod-specific Dhdds knockout, 4 wks.); Dhdds^{flx/flx} without iCre littermates; and WT (C57Bl/6J) controls. RNA was analyzed using the NanoString platform by the UAB Nanostring Core Laboratory. Data from three panels were analyzed: Neuropathology (770 genes), Glial (770 genes), and a Custom Panel (479 genes) with retina- and glycosylation pathway-related genes. Data were combined and analyzed using NanoString software nSolver 4.0 and advanced analysis 2.0, setting a fold-change cutoff of 2.0. In Situ Hybridization (ISH) and cytokine array analysis were performed to validate transcript/protein level increases of selected target genes. Statistical analysis: Student's t-test; significance threshold, P<0.001.

Results: Excluding overlap among panels, 1466 unique genes were analyzed, resulting in 11 up- (range: 2- to 6-fold) and 31 down-regulated (range: -2 to -131-fold) transcripts identified in KI retinas and 89 up- (2- to 15-fold) and 28-down-regulated (range: -2 to -8-fold) transcripts found in KO retinas. Pathway analysis showed significant changes in the adaptive immune system, intracellular signaling by second messengers and cytokines, toll receptor cascades, extracellular matrix reorganization, and neutrophil degranulation genes. In KI retinas, significant changes were seen in neuronal systems, signaling by nuclear receptors and rho GTPases, and vesicle-mediated transport pathways genes. ISH analysis suggested upregulation of C1qb, an inflammatory marker, in activated microglia.

Conclusions: The results are consistent with the previously observed early degenerative changes, neuroinflammation and cytokine upregulation observed in rod-specific Dhdds KO retinas and the physiologic changes previously observed in DhddsK42E/K42E KI mice. Since several of the identified genes yield proteins that become glycosylated, they may be candidates for primary and secondary effects relevant to altered Dhdds function.

TITLE: Identifying Barriers to Follow-Up After Teleretinal Screening for Diabetic Retinopathy

SESSION TITLE: Diabetic Retinopathy Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Ali, Y.I. Chu, C.Y. Weng, Baylor College of Medicine, Houston, Texas, UNITED STATES|O. Ali, Y.I. Chu, C.Y. Weng, Ben Taub General Hospital, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Omar Ali: Commercial Relationship: Code N (No Commercial Relationship) | Yvonne Chu: Commercial Relationship: Code N (No Commercial Relationship) | Christina Weng: Commercial Relationship(s);Allergan/AbbVie:Code C (Consultant);Alimera Sciences:Code C (Consultant);Alcon:Code C (Consultant);Novartis:Code C (Consultant);Regeneron:Code C (Consultant);REGENXBIO:Code C (Consultant);Genentech:Code C (Consultant);DORC:Code C (Consultant)

ABSTRACT BODY:

Purpose: Diabetes mellitus and its primary ophthalmic complication, diabetic retinopathy (DR), continue to increase in prevalence worldwide. A large-scale teleretinal screening program has been utilized in the Harris County, the largest county in Texas, since 2013. While screening has improved DR screening compliance overall, a significant proportion of patients with sight-threatening diabetic eye disease (STDED) are lost to follow-up (FU). This study aims to identify barriers that may hinder patients from FU after a positive initial screening.

Methods: Retrospective cohort analysis of patients in the Harris Health System (HHS) who were screened via nonmydriatic fundus photography at 13 primary care clinics in 2018. Of the 11,622 screened patients, 891 patients were detected to have STDED on teleretinal screening, and 333 patients failed to FU for an in-clinic evaluation by a retina specialist within 1 year of initial screening. Of this final cohort, 103 patients responded to a telephone survey questionnaire designed to explore their perceived barriers to FU.

Results: The majority of survey respondents were English speakers (52.43%), and self-identified as Hispanic/Latino (61.17%). The most common reported barriers by nearly 47% of survey respondents were cost of the healthcare and lack of clarity in processes post-screening (Figure 1). Patients reported a mean commute time of 35.19 minutes (SD 25.52) to see a retina specialist and the average number of barriers reported by each patient was 2.46 (SD 1.58). No statistically significant relationship was found between language preference, screening location, commute time, or age/race/sex and the mean number of barriers reported.

Conclusions: The HHS teleretinal screening program has significantly increased access to DR screening, but compliance following positive screening for STDED remains a challenge. Among patients found to have STDED on teleretinal screening in 2018, approximately 37.4% were lost to FU. Our study identified several factors that may preclude patients from FU, including cost, employment demands, transportation issues, and lack of understanding in post-screening instructions. Future quality improvement interventions, such as a refined process in providing patient instructions, are being planned based on these findings.

TITLE: Estimates of Direction and Distance by People with Vision and Hearing Impairment

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. XIONG, G.E. Legge, Center for Applied and Translational Sensory Science, University of Minnesota, Minneapolis, Minnesota, UNITED STATES|G.E. Legge, Psychology, University of Minnesota, Minneapolis, Minnesota, UNITED STATES|Y. XIONG, D. Brunt, Envision Research Institute, Kansas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): YINGZI XIONG: Commercial Relationship: Code N (No Commercial Relationship) | Diamond Brunt: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Legge: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Accurate judgements of direction and distance are important for safe mobility. For people with vision or hearing impairment, it is important to optimally utilize their residual vision and hearing in such activities. Here we asked how people with various combinations of vision and hearing impairment integrate their residual vision and hearing in judging direction and distance.

Methods: There were three groups—vision impairment (VL, N = 9); dual sensory impairment with combined vision and hearing impairment (DSL, N = 6); and healthy controls (N = 6). Their mean acuities were 0.73, 0.42 and 0.0 logMAR; mean contrast sensitivities were 0.98, 1.35 and 2.0 logCS; and mean hearing thresholds were 9.1, 36.0 and 7.5 dB, respectively. Subjects were asked to walk to a briefly presented (5 s) target on the floor in a room under dark or normal lighting conditions. There were three types of targets—1) broadband auditory sound pulses, 2) visual LED flashes (8.4 cd/m²), and 3) both auditory pulses and visual flashes (audiovisual targets). In a direction trial, the target was presented from one of six directions on the horizontal plane ($\pm 6^\circ$, $\pm 13^\circ$ and $\pm 20^\circ$). In a distance trial, the target was presented at one of six distances from straight ahead (0.9m to 5.4m). Precision was calculated as the standard deviation of 6 trials for each subject response for each target modality.

Results: The lighting conditions did not significantly affect the subjects' distance or direction precision. For both distance and direction estimation, the three groups had similar precision in the visual condition, but the DSL group showed significantly lower precision in the auditory condition than the other groups. Within each group, the auditory condition always showed lower precision than the visual and audiovisual conditions, regardless of the lighting conditions. The audiovisual condition always had similar precision to the visual condition in all three groups, possibly indicating that subjects primarily relied on their vision while the auditory signal provided little additional benefit.

Conclusions: Our preliminary results showed that visual localization remains intact with vision impairment, but sound localization is susceptible to hearing impairment. In both direction and distance judgments, when localizing multimodal targets subjects primarily rely on their vision regardless of their vision and hearing status.

ABSTRACT BODY:

Purpose: DARC (Detection of Apoptosis Retinal Cells) consists of a fluorescently-labelled annexin A5 molecule (ANX776) which binds to externalised phosphatidylserine (PS) on retinal cells undergoing apoptosis and stress. However, recently, endothelial cell PS externalisation has been demonstrated as one of the earliest stages in neovascularization. Here we assess if DARC can be used as a biomarker of vascular leakage and angiogenesis in vivo.

Methods: Pilot experiments were performed on 3 New Zealand White (NZW) rabbits to evaluate the natural history of vessel leakage and neovascularisation using FFA. Following this, 6 NZW rabbits had intravitreal injections humanVEGF165 (1 ug, Sigma, UK) into the left eye only of each animal, with 3 being given ranibizumab treatment. Animals were assessed 2 and 4 days later, using intravenous ANX776 (0.2mg) and 1% sodium fluorescein after baseline autofluorescence.

Results: Although not present at 2 days, all control rabbit eyes treated with hVEGF had fluorescein leakage at 4 days compared to ranibizumab eyes. All left hVEGF eyes were found to have significantly ($p<0.05$) more DARC positive-staining compared to the untreated contralateral right eye 2 days after treatment; however, ranibizumab eyes had significantly less ($p<0.05$) than untreated hVEGF eyes.. Staining appeared as single spots localised to the vascular branches of the main stems of the retinal vessels.

Conclusions: This is the first time in vivo that DARC has been shown to identify phosphatidylserine in angiogenic processes, and illustrates its use as a biomarker for anti-angiogenic treatments. DARC can be therefore used in vivo to identify the earliest stages of leakage and angiogenesis in choroidal neovascularisation, diabetic eye disease and potentially any retinal disease in which pathological angiogenesis occurs.

TITLE: Novel Genetic Variants Identified in “Poor” Responders to Anti-VEGF Therapy in Patients with Diabetic Macular Edema—A Whole Exome Sequencing Approach

SESSION TITLE: Diabetic macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Cabrera, L. Marek, F. Monickaraj, A. Das, Ophthalmology and Visual Sciences, University of New Mexico School of Medicine, Albuquerque, New Mexico, UNITED STATES|S. Rangasamy, C. Legendre, Translational Genomics Research Institute, Phoenix, Arizona, UNITED STATES|A. Das, New Mexico VA Health Care System, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrea Cabrera: Commercial Relationship: Code N (No Commercial Relationship) | Sampathkumar Rangasamy: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Legendre: Commercial Relationship: Code N (No Commercial Relationship) | Lauren Marek: Commercial Relationship: Code N (No Commercial Relationship) | Finny Monickaraj: Commercial Relationship: Code N (No Commercial Relationship) | Arup Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: All major clinical trials have shown that only 27-40% of diabetic macular edema (DME) patients show vision improvement of >15 letters with intravitreal anti-VEGF injections. Thus, a substantial proportion of patients are “poor” responders to anti-VEGF therapy. Our goal was to identify genetic variants, if any, that may help determine “good” vs “poor” response to anti-VEGF therapy.

Methods: We conducted whole-exome sequencing (WES) on two cohorts, “Good” Responders (reduction of baseline central retinal thickness, CRT >25% after three monthly anti-VEGF injections; n=10) and “Poor” Responders (reduction of CRT <10% or increase in CRT after three monthly injections; n=10). DNA was isolated from white blood cells followed by quality evaluation and quantification. DNA libraries were constructed using HiFi Library Amplification Kit followed by exome region capturing by Agilent SureSelect XTLI and Human All Exon V7 capture. Exome sequencing was performed on the Illumina NovaSeq 6000 for 100X coverage. The sequenced data were processed and aligned to the reference genome (Hg19/GRCh38) using TGen pipeline and Constitutional variant calling with high functional impact performed with DeepVariant caller.

Results: After comprehensive exome variant analysis to identify coding variants with functional impact, we identified that “Poor” responders had increased burden of missense mutation. Further, gene enrichment analysis revealed enrichment of ultra-rare variants in Sphingomyelin Phosphodiesterase 4 (SMPD4), Golgi Associated, Gamma Adaptin Ear Containing, ARF Binding Protein 2 (GGA2), and Mucin 12 (MUC12) in the “poor” responder cohort. These genes have been shown to play an important role in signaling of cell proliferation, apoptosis, and cell adhesion.

Conclusions: Our data provides evidence for protein-coding genetic variants that may influence patient response to anti-VEGF therapy. A thorough understanding and functional validation of the mechanistic consequences of these variants using cell and animal model of diabetes will help in the identification of risk genes that play a role in the anti-VEGF response in DME patients and may help identify personalized treatment strategies.

SUBMITTER (NAME ONLY): Diamond Brunt

TITLE: Impacts of Vision and Hearing Impairment on Egocentric Straight-ahead

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Brunt, Y. XIONG, Envision Research Institute, Wichita, Kansas, UNITED STATES|G.E. Legge, Psychology, University of Minnesota, Minneapolis, Minnesota, UNITED STATES|Y. XIONG, G.E. Legge, Center for Applied and Translational Sensory Science, University of Minnesota, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Diamond Brunt: Commercial Relationship: Code N (No Commercial Relationship) | YINGZI XIONG: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Legge: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Egocentric perception of straight-ahead is an important internal reference for spatial orientation. For people with sensory impairment who receive reduced external sensory input, such internal reference may affect mobility and judgments of spatial layout. This study investigates the impacts of vision and hearing impairment on the perception of egocentric straight-ahead and the relationship to real-life tasks such as walking without veering.

Methods: Subjects with vision impairment (VL, N = 9), dual sensory impairment (DSL, combined vision and hearing impairment, N = 6), and healthy controls (N = 6) participated in this study. Across all subjects, the acuity ranged from -0.14 to 1.66 logMAR, the contrast sensitivity ranged from 0 to 2.25 logCS, and the hearing threshold ranged from -1.3 to 55 dB. The egocentric straight-ahead was measured in three modalities: proprioception, vision and audition. In measuring proprioception, subjects closed their eyes and pointed to their perceived straight-ahead. To measure vision and audition, subjects adjusted a LED light or clicking sound in the horizontal plane to their perceived straight-ahead. Each condition was tested with eight trials. The center point between the two eyes was measured as the reference for body center. Bias was calculated as the mean error in the angle between the reported straight-ahead and a straight-ahead line defined by body center. Precision was calculated as the standard deviation across the eight trials

Results: There was no significant group difference in bias in any of the three modalities. The biases were also not significantly related to hearing asymmetry, hearing threshold, binocular acuity or contrast sensitivity. When comparing the precision, only the auditory condition showed a significant group difference. Post-hoc analysis showed that the control group had significantly higher precision than both VL and DSL groups. Hearing threshold and binocular acuity were both significant predictors for the auditory precision, with higher hearing threshold and worse acuity related to reduced precision.

Conclusions: Our preliminary results showed that vision and hearing impairment did not significantly affect the perception of proprioceptive and visual straight-ahead, but both reduced the precision of auditory straight-ahead. The impacts of vision and hearing impairment on other real-life tasks such as walking without veering is currently under investigation.

ABSTRACT BODY:

Purpose: Abnormal angiogenesis underpins vision loss associated with several diseases including wet age-related macular degeneration (AMD), diabetic retinopathy, diabetic macular edema (DME), and macular edema following retinal vein occlusion. Anti-vascular endothelial growth factor (VEGF) therapies have shown consistent success in these pathologies. However, in addition to VEGF, the angiopoietin-Tie2 pathway has also been shown to play a role in angiogenesis. ABP-201, our tetravalent bispecific antibody, was engineered with the goal of inhibiting VEGF and angiopoietin-2 concomitantly. This is the first study assessing the activity of ABP-201 in the eye, using a rat laser-induced choroidal neovascularization (CNV) disease model.

Methods: Brown-Norway rats received a single 5 µL intravitreal injection of ABP-201 in three concentrations, vehicle, or aflibercept (EYLEA[®]) in the right eye. Four or five lesions were burned within two discs from the optic nerve using a laser. Fundus imaging and optical coherence tomography (OCT) verified the lesions immediately following challenge. On Days 7 and 15, fluorescein angiography and OCT assessed lesion leakage and volume. Data were expressed as means ± SEM and analyzed using one-way ANOVA.

Results: On Day 7, all three doses of ABP-201 induced a highly significant reduction in both lesion volume (27%, 27%, and 40%, respectively, for all $p < 0.01$) and in leakage (33%, 35%, and 37%, respectively, for all $p < 0.0002$) when compared to vehicle. On Day 15, the mid and high doses of ABP-201 induced a significant reduction in lesion volume (26% and 27%, respectively, for both $p < 0.05$) and all three doses induced a significant reduction in leakage (28%, 33%, and 36%, respectively, for all $p < 0.05$). For both lesion volume and leakage, the performance of ABP-201 was similar or better than aflibercept.

Conclusions: Our study demonstrated that ABP-201 was beneficial for reducing neovascular lesion formation and vascular leakage in rat model of laser-induced CNV. These results pave the way to begin to utilize this bispecific antibody, engineered to improve both efficacy and durability compared to current VEGF therapies, for the treatment of wet-AMD and DME, as well as other angiogenic eye diseases.

ABSTRACT BODY:

Purpose: To evaluate the sources of variation and accuracy of the tracking scanning laser ophthalmoscope (TSLO) as an eye-tracking measurement system

Methods: Gauge Repeatability and Reproducibility (Gauge R&R) was assessed on TSLO outputs to examine variability from apparatus, operator, signal input, and interaction between operator/signals. Twelve total pre-determined amplitude and frequency values of sinusoidal motion, representing the span of human fixation, were input into a custom-built steerable model eye. Three operators (AA,AB,AC) recorded three 10-second videos for each input on three separate days. The second frequency input at 30 Hz was discarded due to overlap with the device framerate. We completed a variance component analysis, and linearity and bias analyses to assess TSLO's precision and accuracy. Bias was measured as the difference between the true value and observed value.

Results: Variance component analysis showed that part-to-part variation was the main contributor to variance for both frequency (99.99%) and amplitude (99.93%) inputs. The repeatability and reproducibility variance components contributed minimally to variability, at 0.007% for frequency and 0.14% for amplitude. There was a positive correlation between frequency signal input value and bias for all operators ($\max p=1.7e^{-13}$), indicating the presence of linearity (i.e., higher frequencies have lower accuracy). For amplitude measurements, there was a tendency to underestimate large amplitudes, with linearity being present for operator 2 ($p=0.03$) and 3 ($p=8.7e^{-6}$). However, the maximum significant bias was 3.75 Hz at a frequency of 100Hz and -12 arcsecs at an amplitude of 360 arcsecs.

Conclusions: The TSLO can reliably distinguish between signals of different values, with very minimal contribution from apparatus error or operator bias. A large proportion of the TSLO variation stemmed from differences between signal inputs, 99.99% for amplitude and 99.3% for frequency. Gage R&R contribution fell well below 10%, at 0.007% for frequency and 0.14% for amplitude. Overall, TSLO showed excellent operator repeatability and apparatus reproducibility. Biases noted would be likely to be clinically insignificant.

TITLE: Optimization of Glaucoma Management During a Pandemic: Drive-Through IOP Checks

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Shah, A. Ooms, A.S. Khouri, M. Habel, Rutgers New Jersey Medical School
Department of Ophthalmology & Visual Science, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Khelly Shah: Commercial Relationship: Code N (No Commercial Relationship) | Ashley Ooms: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship: Code N (No Commercial Relationship) | Miriam Habel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In this pilot study, we compared the efficacy of drive-through intraocular pressure (IOP) checks in combination with E-health visits to E-health visits alone in the management of glaucoma patients during the COVID-19 pandemic.

Methods: We performed a retrospective chart review for visits from April 2020 – November 2020 to compare subjects that received E-health visits (Group 1) versus subjects that received E-health visits with a drive-through IOP check (Group 2). Drive-through visits consisted of temperature screening with a non-contact infrared thermometer, near visual acuity check, and IOP measurements using a Tono-Pen XL Tonometer (Reichert, Depew, NY) followed by a video E-health visit with a glaucoma specialist. Group 1 patients only attended a video visit. We compared the proportion of interventions done at the visit as well as changes in visual acuity (VA) and IOP after the tele-visits between the 2 groups. The 4 types of interventions were: change in drop type, change in drop frequency, change in number of drops, and recommending surgical or laser intervention.

Results: 28 subjects were included in our pilot study (mean age 74.9 +/- 3.8 years, 57.1% female). There was no significant difference in baseline characteristics between group 1 (n=15) and group 2 (n=13, Table 1). 6.7% of Group 1 patients had an intervention done compared to 38.5% of group 2 patients. Fisher exact probability testing showed a significant increase in the proportion of interventions done in group 2 subjects compared to group 1 subjects (p=.041), with the most common interventions being changing number of drops and drop frequency. There was no significant difference in changes in VA or IOP between the 2 groups (Table 1).

Conclusions: Drive-through IOP checks in combination with virtual visits resulted in more interventions than virtual visits alone in the care of glaucoma patients during the COVID-19 pandemic. This novel healthcare modality can address the mismatch between capacity and demand for glaucoma care both during a pandemic and can further expand access to sub-specialized care.

ABSTRACT BODY:

Purpose: Genome-wide association studies (GWAS) have identified common and rare variants in association with age-related macular degeneration (AMD). Despite the success of GWAS, the molecular mechanism underlying AMD gene-disease associations, however, is largely unknown. The human proteome plays direct role in biological processes and is major resource for druggable therapeutic targets. In this study, we systematically evaluated the causal influence of plasma proteins on AMD by cross-linking GWAS of plasma proteins with AMD.

Methods: We curated published GWAS of human plasma proteome which identified cis- and trans- protein quantitative trait loci (pQTLs) for approximately 2600 proteins. cis-pQTLs were defined as the SNPs residing within +/- 1Mb of the protein-coding genes, and the other pQTLs were trans. AMD GWAS studies included the International AMD Genomics Consortium (16,144 cases and 17,832 controls), the Boston-French-FINRISK study (4332 cases and 25,268 controls), and the UK Biobank (5860 cases and 126,726 controls). GWAS of proteins and AMD were conducted in independent populations. Two-sample Mendelian randomization (MR) and colocalization analysis were used to infer causal associations between proteins and AMD using pQTLs as instrument variables.

Results: We identified trans-pQTL hotspots across different chromosomes which harbored causal variants for AMD and multiple proteins, such as genetic loci near CFH (chr.1), C7 (chr.5), CTRB2 (chr.16), and APOE (chr.19). We proposed a remotely regulatory mechanism of AMD showing AMD risk loci regulated distant proteins (trans-proteins) by altering local genes or proteins, which in turn may affect the disease. Gene ontology enrichment analysis suggested that the trans-proteins were enriched for genes involved in response to nutrient ($P=0.005$) and retina homeostasis ($P=0.01$). MR and colocalization analysis identified putatively causal pathways for AMD. For example, the APOE loci drive the causal effects of APOE on AMD in cis ($\text{Beta}=-0.52$, $P_{\text{MR}}=1.5 \times 10^{-23}$), and may also through vertical pleiotropic effects on multiple trans-proteins including MAN2B2, NAPB, and LRRN1.

Conclusions: Our study not only identified novel proteins associated with AMD, but also defined network structures that shed light on the regulatory mechanism of AMD pathogenesis.

ABSTRACT BODY:

Purpose: Purpose: To assess potential relationships between dietary nitrate intake and risk of progression in age-related macular degeneration (AMD).

Methods: Methods: Post hoc analysis of 2 large prospective clinical trial cohorts: Age-Related Eye Diseases Study (AREDS) and AREDS2. Dietary nitrate intake was calculated for each participant by analysis of food frequency questionnaire. AMD progression was evaluated by reading center grading of annual fundus photographs. Cox proportional hazard analyses were performed for AMD progression, according to quartiles of dietary nitrate intake (quartile 1 as reference), with adjustment for age, gender, smoking status, and caloric intake.

Results: Results: In the combined AREDS/AREDS2 cohort (n=7788 eligible participants without late AMD in either eye at baseline), higher dietary nitrate intake was associated with decreased risk of late AMD (HR 0.80 for quartile 4, 95% CI 0.72-0.90). Risk of each late AMD subtype was also reduced, with both risk of geographic atrophy (GA; HR 0.78, 0.67-0.91) and neovascular AMD (NV-AMD; HR 0.61, 0.53-0.71) reduced. Similar associations were observed in each cohort, considered separately: HR 0.70 (0.59-0.83), 0.74 (0.60-0.90), and 0.73 (0.59-0.91), in AREDS, and 0.85 (0.74-0.97), 0.86 (0.70-1.06), and 0.88 (0.72-1.07), in AREDS2, respectively. In additional analyses of the AREDS cohort (n = 4288 eligible participants), adjustment was made also for dietary lutein/zeaxanthin intake (since this is correlated with nitrate intake); higher nitrate intake was still associated with decreased risk of late AMD (HR 0.68, 0.56-0.82), GA (0.67, 0.53-0.85), and CNV (0.73, 0.57-0.92). Also in the AREDS cohort, higher nitrate intake was also associated with decreased risk of progression to large drusen: HR 0.82 (0.68-0.99).

Conclusions: Conclusions: Higher dietary nitrate intake has protective associations against progression to late AMD. This is true for both subtypes of late AMD. Higher intake also appears associated with decreased risk of large drusen, so nitrate intake may be protective across the spectrum of AMD severity. The associations are independent of lutein/zeaxanthin intake, with which nitrates share some food group sources. These findings may justify further studies of nitrate supplementation, including randomized controlled trials.

TITLE: Systemic immunosuppression and risk of endophthalmitis after intravitreal anti-vascular endothelial growth factor injections

SESSION TITLE: Endophthalmitis/ trauma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.S. Kim, S.N. Patel, A. Obeid, J. Hsu, S.J. Garg, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|P.P. Storey, Austin Retina Associates, Austin, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Julie Kim: Commercial Relationship: Code N (No Commercial Relationship) | Samir Patel: Commercial Relationship: Code N (No Commercial Relationship) | Philip Storey: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Obeid: Commercial Relationship: Code N (No Commercial Relationship) | Jason Hsu: Commercial Relationship: Code N (No Commercial Relationship) | Sunir Garg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The impact of systemic immunosuppressive therapy on the rates and outcomes of endophthalmitis following intravitreal anti-vascular endothelial growth factor (VEGF) injections remains largely unexplored. The aim of this study was to examine whether systemic immunosuppressive therapy alters a patient's risk for developing endophthalmitis after anti-VEGF injections.

Methods: This is a retrospective, single-center cohort study examining all eyes that underwent intravitreal anti-VEGF injections (bevacizumab, ranibizumab, or aflibercept) from January 2016 to September 2019. Two cohorts (no immunosuppression vs immunosuppression) were created based on immunosuppressive status at time of intravitreal injection. The primary outcome was the occurrence of endophthalmitis rates, while visual acuity (VA) and culture-positive cases were secondary outcomes. Within both cohorts, patients who developed presumed post-injection endophthalmitis that underwent ocular tap with intravitreal antibiotics were identified and compared using Chi-Square or Mann-Whitney U. $P < 0.05$ was considered significant.

Results: Of 270,347 anti-VEGF injections administered to 23,252 patients, 1300 (0.48%) injections were administered to 412 patients who were on systemic immunosuppressive therapy. In this cohort of eyes, five developed endophthalmitis for a rate of 0.38% (1 in 260 injections) compared to 100 eyes not on systemic immunosuppressants for a rate of 0.037% (1 in 2690 injections) with an odds ratio (OR) of 9.86 (95% CI: 4.0-24.3, $P < 0.001$). Among the five eyes with presumed endophthalmitis, 3 had positive cultures (0.023%, 1 in 433 injections) compared to the 2 (0.012%, 1 in 8,407 injections) in the immunocompetent group for an OR of 19.4 [95% CI: 5.9-63.4, $P < 0.001$]. Symptom onset occurred 2.51 (95% CI: 0.15-4.87, $P = 0.040$) days earlier in the immunosuppressed patients; however, visual outcomes at 6 months were similar between the two groups.

Conclusions: Eyes receiving intravitreal anti-VEGF injections who are concurrently on systemic immunosuppressive therapy may be at an increased risk for developing PIE. However, final visual outcomes following post-injection endophthalmitis treatment is similar regardless of systemic immunosuppression status. Additional studies are indicated to further elucidate the role, if any, of immunosuppressive therapy in the management of PIE.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is the only treatable risk factor for primary open-angle glaucoma (POAG). Our previous pathway analysis of IOP-associated loci identified 2 networks focused on an unspecified estrogen receptor and estrogen receptor 1 (ESR1), respectively (Liu 2020). Here we seek to confirm the role of ESR1 signaling in the aqueous humor (AH) outflow pathway.

Methods: We examined which 17 IOP-associated genes in the estrogen receptor networks were specifically expressed in a single-cell RNA sequencing (scRNA-Seq) dataset of human outflow tissue (van Zyl 2020) as well as an RNA-Seq dataset of nonglaucomatous human TM (n=4) and Schlemms Canal (SC) (n=2) cells. To confirm ESR1 activity in the outflow pathway, we examined its protein expression in nonglaucomatous human (n=4) and mouse outflow tissues (n=2) by antibody-based immunofluorescence, using tissue from an *Esr1*^{-/-} mouse as a negative control (n=1). We also measured 17 β -estradiol (E2) concentration in glaucomatous (n=4) and nonglaucomatous (n=4) human AH using an ELISA kit (Enzo Life Sciences).

Results: Seven IOP genes from the estrogen receptor networks (i.e., CAV2, FBXO32, SIX3, FOXC1, SPTBN1, TCF7L2, and TNXB) were expressed in ≥ 1 cell clusters defined by scRNA-Seq, including cell clusters localized to the TM, SC, collector channels, ciliary muscle, Schwalbe's line, vascular endothelium, etc. As confirmation, in a separate RNA-Seq study of human TM and SC cells, 8 genes of interest (i.e., CAV2, ETS1, FBXO32, VEGFC, FOXC1, SPTBN1, TCF7L2, and TMEM119) were highly expressed (i.e., FPKM ≥ 10) in either TM or SC cells, with SPTBN1 having the highest expression (i.e., 85.85 FPKM and 85.83 FPKM). *Esr1* protein was expressed in the iridocorneal angle of female B6J wild-type, but not *Esr1*^{-/-} mice. Similarly, ESR1 protein was expressed in human TM/SC. E2 was present in both glaucomatous (34.46 ± 7.08 pg/mL) and nonglaucomatous human (37.90 ± 14.80 pg/mL) AH ($p > 0.05$).

Conclusions: Many IOP-associated genes within the estrogen receptor networks are highly expressed in the outflow pathway including in the TM, SC, ciliary muscle, and vascular endothelium. The confirmation of ESR1 protein expression in human and mouse outflow tissues and the presence of E2 in AH further supports a possible function of ESR1 signaling in IOP regulation through modulation of AH outflow.

ABSTRACT BODY:

Purpose: Microglia and macrophages play roles in AMD-relevant processes of immune surveillance, neurodegeneration, and neovascularization. We analyzed the distribution of cells expressing Iba1 and TMEM119, specific markers for microglia/ macrophage and brain microglia, respectively, in human donor eyes at different AMD stages.

Methods: Twelve µm-thick sections of maculae from 20 eyes of white donors were immuno-stained with Iba1 (Wako 019-19741) and TMEM119 (Abcam ab185333), using red-substrate enzymatic detection and scanned with a 40X objective. Immunoreactivity presence was assessed by one observer as 0 (none), 1 (a few cells), 2 (some cells) and 3 (all over or all cells). Positive controls were resident microglia cells in the inner retina, choroidal macrophages, and Kupffer cells in surgically excised human liver. Negative control experiments omitted primary antibody. RPE cells were phenotyped by published methods (PMID 25813989, 26024109).

Results: In all eyes (4 normal,16 AMD; 7 early-or-intermediate (e-i)AMD, 6 geographic atrophy (GA) AMD, 3 neovascular (nv)AMD), elongated and dendritic cells in inner retina and in choroid were Iba1+, and only in these locations, in normal eyes. Iba1+ cells appeared in outer retina in e-iAMD eyes. In advanced AMD, Iba1+ cells were amoeboid and found in GA areas and in fibrotic scar (nvAMD), where photoreceptors (PR) and RPE layer are absent (both stages) or scarred (nvAMD). Fewer Iba1+ cells were found in inner retina and choroid compared normal and e-iAMD eyes. A few RPE cells were stained (sloughed, intraretinal and subducted phenotypes); most were not. Like Iba1, TMEM119+ cells were found in inner retina and choroid in normal eyes and additionally in outer retina of AMD eyes. Unlike Iba1, TMEM119 signal was found in PR inner segment ellipsoids, ganglion cells, and Müller cells, as seen in mouse (PMID 31853425).

Conclusions: Iba1+ and TMEM119+ cells in outer retina of advanced AMD eyes are most likely activated microglia; we cannot exclude choroidal cells. Some RPE phenotypes that express immune markers in AMD (Cao ARVO 2020) were Iba1+ and TMEM119+ but most RPE cells were unlabeled. TMEM119 signal in PR ellipsoids possibly localizes to mitochondria. Results will assist interpretation of planned single-cell RNA sequencing studies.

ABSTRACT BODY:

Purpose: Negative electroretinogram (ERG) reflecting inner retinal dysfunction can be used as diagnostic tool to determine the anatomical abnormality location in eye disease. The aim of this study is to determine the frequency and etiology of negative ERG in an electrophysiology referral centre.

Methods: Retrospective review of ERGs performed at the Save Sight Institute from January 2011 to December 2020 . ERGs were performed according to ISCEV standard. The b:a ratio was analyzed in Dark Adapted (DA) 3.0 or 12.0. Data were then divided into 2 groups: Group A true negative ERGs (b:a wave ratio of ≤ 1.0) and group B mild negative ERG (b:a wave ratio between 1 and 1.5).

Results: 4,530 patients had ERGs performed, of which 178 (3.9%) had an electronegative ERG consisting of 112 male and 66 female. 142 (3.1%) patients were in Group A and 36 (0.8%) patients were in Group B indicating that 20.2% of the electronegative ERG diagnoses were mild type. The median age at referral time was 36 (2-91) years. Photoreceptor dystrophy was the largest causative etiology with 53 (45A+8B) patients (28%) followed by Congenital Stationary Night Blindness (CSNB) with 42 (33A+9B) (16.5%), retinoschisis with 18 (15A+3B) (7.1%), retinal ischemia with 16 (15A+1B)(6.3%) and Paraneoplastic Autoimmune Retinopathy (PAIR) and nonPAIR with 14 patients (11A+3B)(5.5%). Batten disease, inflammatory retinopathy, Melanoma Associated Retinopathy and retinal detachment each had 5 (4A+1B)(2%), 3 (3A)(1.2%), 2 (2A)(0.8%), 2 (1A+1B) (0.8%) patients respectively. Birdshot chorioretinopathy, vigabatrin toxicity and foveal hypoplasia were diagnosed in 3 patients (0.4%) and 20 patients had an unclassified diagnosis.

Conclusions: The incidence of true negative ERG and mild negative ERG in our referral center was 3.1% and 0.8% with photoreceptor dystrophy as the main etiology followed by CSNB, retinoschisis, ischemia, and PAIR and nonPAIR. Classic negative ERG diagnoses such as CSNB and retinoschisis both had patients with mild negative ERG (Group B) suggesting the conceivable need to reconsider the traditional negative ERG definition of ≤ 1 .

ABSTRACT BODY:

Purpose: Studies have shown that elevated TGF β 2 induces pathological changes in the trabecular meshwork (TM) leading to ocular hypertension (OHT) which are similar to the phenotypes observed in primary open-angle glaucoma. Our published studies suggest that elevated TGF β 2 may be due to promoter region hyperacetylation in the TM. dCAS9 is a mutated form of CAS9, the key enzyme in the CRISPR system. When fused with KRAB, a repression domain, and guided by sgRNA, dCAS9-KRAB can repress gene expression without altering genomic DNA (CRISPR interference). In this study, we showed that CRISPR interference is a useful tool in decreasing intraocular pressure (IOP) by repressing TGF β 2 in mouse eyes.

Methods: Lentiviral dCAS9-KRAB and sgRNA expression vectors were co-transduced into TM cells at an MOI value of 1 to 50. On the fifth day post-transduction, cell lysate and condition medium were extracted and the expression of TGF β 2 and dCAS9 were determined using western immunoblotting. Lentiviral CRISPR interference vectors or control vectors were injected into mouse eyes followed by a second injection of adenoviral vectors expression active TGF β 2.

Results: Our initial screening showed two guide RNAs from a pool of sgRNAs were able to decrease the expression of TGF β 2 compared to control sgRNA in GTM3 cells. We also found similar efficiency of the sgRNAs in the inhibition of TGF β 2 in primary TM cell strains. ChIP-qPCR showed enrichment of dCAS9-KRAB at the TGF β 2 promoter region. In addition to TM cells, we tested our system in a mouse model. We injected male (n=6) and female (n=6) mouse eyes with lentiviral vectors expressing dCAS9-KRAB together with sgRNA targeting the CMV promoter or non-targeting sgRNA as control. We then injected both eyes with Ad5-CMV- Δ hTGF β 2. We found that specific sgRNA expressing eyes did not develop OHT while control sgRNA expressing eyes developed OHT (p<0.05).

Conclusions: CRISPR interference can be used as an important tool in decreasing TGF β 2 and TGF β 2-induced OHT. It can be used as an alternative for siRNA.

ABSTRACT BODY:

Purpose: Biallelic mutations in LAMA1 (laminin subunit alpha 1) (OMIM #150320) cause Poretti-Boltshauser Syndrome (PBS), a rare non-progressive cerebellar dysplasia disorder with ophthalmic manifestations including oculomotor apraxia, high myopia and retinal dystrophy. Only 32 variants nearly all loss-of-function, have been previously reported in 29 patients from 23 families. Clinical presentation included consistent as well as unspecific and variable features such as intellectual disability. Here we report 3 affected siblings, homozygous for a novel frameshift mutation in LAMA1 and their detailed retinal manifestations.

Methods: Whole genome sequencing (Illumina 150bp paired-end reads, average x30 read-depth) was conducted on members of a consanguineous family with myopia and retinal dystrophy in three of five adult children. Filtering for rare variants in known retinal genes and genome-wide variants in shared homozygous regions in affected individuals was employed. Clinical evaluation included full ophthalmic examination, detailed colour, autofluorescence retinal imaging, retinal optical coherence tomography (OCT) and electroretinography.

Results: Genetic analysis revealed a novel homozygous LAMA1 frameshift variant, c.1492del p.(Arg498GlyfsTer25), in two male and one female affected siblings. Two had oculomotor apraxia in childhood; none had symptoms nor signs of neurological failure as adults. Corrected visual acuities ranged from 6/6 to 6/24. All three had myopia, and a qualitatively similar retinopathy of wide-ranging severity, involving pigmentary changes in the temporal retina in the two lesser affected siblings and in the posterior pole in the more severely affected sibling. Electrophysiology showed mild to severe cone rod dystrophy.

Conclusions: This report describes the detailed retinal structural and functional consequences of LAMA1 deficiency in three siblings and these exhibit much variability. Biallelic mutations should be considered in myopia and retinopathy, even in the absence of systemic signs.

ABSTRACT BODY:

Purpose: Uveal melanomas (UM) are the most common primary intraocular malignancy in the adult population. Based on gene expression profiles, UM can be categorized as Class 1 (low risk for metastasis) or Class 2 (high risk for metastasis). PRAME (PReferentially expressed Antigen in MELanoma) protein is a member of the cancer-testis antigen family and has been suggested as an independent UM prognostic biomarker. PRAME can be detected in UM tissue by either RT-PCR or IHC but concordance in techniques has not been determined.

Methods: We retrospectively identified UM patients who had PRAME detected on RT-PCR testing (Decision Dx UM PRAME, Castle Biosciences, TX) following globe enucleation. In house PRAME IHC was performed on these specimens with cutoff of 50% for positive detection after slide review. ICH results, based on clinical stage, were compared.

Results: 15 UM patients (11 males (73%), average age 60.7 years) were analyzed. AJCC 8th edition staging was varied (Stage 1 n=2), Stage 2 (n=6), Stage 3 (n=6), Stage 4 (n=1) and Class 1 in 9 eyes (60%) and Class 2 in 6 eyes (40%). 11/15 (73%) cases showed concordant PRAME detection results by both RT-PCR and IHC. In 4/15 (27%) discordant cases, ICH did not reach significance for PRAME positivity. Tumor grade for these cases included 1a, 2b, 3d and 4e and 3 cases were low risk Class 1. No patients with discordance developed metastatic disease with 13 months mean last follow up (range 0.1-17 months).

Conclusions: Our findings reveal that PRAME RT-PCR and IHC provide concordant results in 73% of enucleated UM eyes. The discordant results differed in tumor stage and may be due to a lack uniform standardization of IHC based nuclear PRAME detection or geospatial variations within each tumor. Further studies are required to determine the methodologic and prognostic implications.

ABSTRACT BODY:

Purpose: In autosomal recessive Stargardt disease (STGD1) and dry age-related macular degeneration (AMD), excessive accumulation of lipofuscin is associated with retinal pigment epithelium (RPE) cell death, photoreceptor cell damage, and vision loss. A2E and iso-A2E are prominent fluorophores of ocular lipofuscin that mediate phototoxicity and degeneration. Previous work from our lab in vitro, in quail eyes, and in human donor eyes have indicated that macular carotenoids (MC) can attenuate bisretinoid formation and phototoxicity, but mouse studies have been hampered by poor carotenoid uptake due to their very active carotenoid cleavage enzyme, Bco2. In this study, we have crossed Bco2 KO "macular pigment mice" with a mouse model of STGD1.

Methods: $Abca4^{-/-}/Bco2^{-/-}$ and $Abca4^{-/-}$ mice on C57BL6/J background were fed with lutein, zeaxanthin, or a placebo chow (~2.6 mg of carotenoid/mouse/day; DSM, Kaiseraugst, Switzerland; n=12/group) for 3 months, and their optokinetic response (OKR), electroretinography (ERG) and optical coherence tomography (OCT) were measured after 1-3 months of carotenoid supplementation. Mice were sacrificed after 3 months of supplementation, and their blood and tissues (eye, liver, and brain) were collected. A2E and iso-A2E levels from RPE/choroid and carotenoid levels from the retina were quantified by HPLC

Results: Lutein and zeaxanthin supplemented $Abca4^{-/-}/Bco2^{-/-}$ mice had 33-71% lower levels of RPE/choroid A2E and iso-A2E compared to control mice fed with placebo chow ($p<0.05$) and had improved visual performance. Carotenoid supplementation in $Abca4^{-/-}$ mice minimally raised retinal carotenoid levels and did not show much difference in bisretinoid levels or visual acuity compared to the control diet-fed group. There was a statistically significant inverse correlation between MC levels in the retina and A2E and iso-A2E levels in the RPE/choroid. Scotopic and photopic a and b-wave response and photoreceptor cell viability did not show any significant differences relative to WT mice of same age in either mouse line, irrespective of their supplementation status.

Conclusions: Supplementation with MC effectively reduces bisretinoid formation and improves visual acuity in a mouse model of STGD1 genetically enhanced to accumulate carotenoids in the retina. These results provide further impetus to pursue oral carotenoids as therapeutic interventions for STGD1 and AMD.

ABSTRACT BODY:

Purpose: Alzheimer's disease is a neurodegenerative disease, whose signs can appear decades before clinically detectable symptoms. In addition to age, genetic factors are one of the most important risk factors. One population at increased risk are first-degree relatives of AD patients, at a 2- to 3-fold increased risk for developing dementia. This probability increases if relatives are carriers of the apolipoprotein E (APOE) $\epsilon 4$ allele.

The aim of the present study was to analyze the possible changes that may occur in visual acuity (VA) and contrast sensitive test (CST) in first-degree relatives of Alzheimer's disease patients who are carriers of $\epsilon 4$ allele for the ApoE.

Methods: A complete eye examination was performed in all participants, who were free of ocular pathology. This case-control study was conducted in 28 subjects with family history of AD (FH+) , ApoE $\epsilon 4$ carriers and with a mean age of 53.39 years and 16 age-matched control subjects without a family history of AD (FH-), ApoE $\epsilon 4$ non-carriers and with a mean age of 53.94 years.

Results: In comparison with FH- ApoE $\epsilon 4$ non-carriers, in FH+ ApoE $\epsilon 4$ carriers we found statistical significant increase ($p < 0.05$) both in VA (1.04 ± 0.10 , FH+ vs 0.98 ± 0.04 , FH-) and in CS in the spatial frequency (SF) of 12 cycles/degree (1.68 ± 0.18 , FH+ vs 1.54 ± 0.17 , FH-).

Conclusions: The VA and CST registered changes in FH+ ApoE $\epsilon 4$ carriers compared to FH- ApoE $\epsilon 4$ non-carriers. In first-degree relatives of AD patients, an increase of VA and CS in the 12 cycles/degree SF could be the first functional changes to appear.

ABSTRACT BODY:

Purpose: X-linked retinitis pigmentosa (XLRP) is a severe phenotype of retinitis pigmentosa clinically characterized by onset of night blindness in childhood, followed by progressive vision loss that results in blindness for most individuals. BIIB112 (NSR-RPGR) is an AAV8 vector-based gene therapy that uses codon optimization to express the full-length, correctly sequenced retinitis pigmentosa GTPase regulator (RPGR) protein in the photoreceptors of individuals with XLRP caused by mutations in RPGR. Here, we present results from 2 ongoing trials in participants with XLRP: XIRIUS, a dose-expansion study of BIIB112, and XOLARIS, a natural disease progression study.

Methods: Part 1 of XIRIUS is a Phase 1, 3+3, six-dose-escalation study (NCT03116113) of BIIB112 in participants with XLRP aged ≥18 years. A subgroup of participants was identified from XOLARIS who met XIRIUS part 1 inclusion and exclusion criteria and completed 12 months of follow-up (N=69). Retinal sensitivity responder criterion was

defined as an achievement of ≥ 7 dB improvement from baseline at ≥ 5 loci.

Results: Overall, 18 participants were treated with BIIB112. Treatment with the 4 highest doses (n=12) resulted in early (Month 1 responders, 6/12 [50%]) and durable (Month 12 responders, 4/12 [33%]) improvements in central retinal sensitivity. No untreated participants in XOLARIS who met the inclusion criteria for XIRIUS achieved central retinal sensitivity response (improvement of ≥ 7 dB at ≥ 5 loci) at Month 12 (33% difference in response rate between groups). Improvements in low-luminance visual acuity (LLVA), assessed by a gain of ≥ 15 Early Treatment Diabetic Retinopathy Study (ETDRS) letters, were observed in treated eyes in XIRIUS as early as Month 1 and through 12 months of follow-up (Month 12 proportion of participants with gain of ≥ 15 ETDRS letters: treated eyes, 3/11 [27%]; untreated eyes, 0/11 [0%]; one participant was missing a baseline LLVA assessment score). Most adverse events were mild and resolved, and no dose-limiting toxicities occurred at any dose. Inflammation, mostly observed at the higher doses, was successfully treated with oral corticosteroids.

Conclusions: Treatment with BIIB112 was well tolerated and, in cohorts 3-6, led to early and durable improvements in 2 measures of visual function.

ABSTRACT BODY:

Purpose: The ability to manipulate accommodative response real-time during an experiment will be useful to study the properties of feedback-driven accommodation and its interaction with vergence and pupils. Usage of pinholes or low spatial frequency targets may render the blur-feedback open-loop, but they do not allow real-time manipulation of blur input. This feasibility study describes a technique for real-time manipulation of blur-driven accommodation using an electrically- tunable lens coupled with a dynamic, infrared (IR) photorefractor.

Methods: Real-time manipulation of an accommodative response was achieved by measuring the response of one eye dynamically at 50 fps using the Plusoptix PowerRef 3 photorefractor (PR) and synchronously feeding a low-pass filtered version of its output to a calibrated electrically-tunable lens (ETL, Optotune, EL-16-40-TC-VIS) placed along the visual axis of the participant. In Experiment 1, the PR output of the target fixing eye was added to the ETL placed in front of the fellow eye occluded using an IR filter. In Experiment 2, the ETL dynamically subtracted the PR output of the consensual accommodative response from the IR filter occluded eye from the direct response of the eye viewing an accommodative target. These experiments were performed on two young adults (26 and 34 yrs) viewing a broadband spatial frequency target located at 100 and 40 cm from the fixating eye.

Results: Low-pass filtering of the PR output by 50Hz resulted in the ETL smoothly altering its dynamic power, with a fixed delay of only 20 ms. In Experiment 1, the mean refraction of target fixing and the fellow eye was -0.69 ± 0.04 D and 1.00 ± 0.10 D in both subjects before initiation of manipulation. The fellow eye PR output decreased to 0.36 ± 0.19 D after initiation of manipulation, as predicted from the addition of optical power by the ETL. In Experiment 2, the mean consensual accommodative response was 1.03 ± 0.14 D before initiation of manipulation. The direct PR output decreased to 0.41 ± 0.06 D after manipulation, as may be predicted from the subtraction of optical power by the ETL.

Conclusions: These results indicate that the dynamic coupling between the PR and ETL allows real-time manipulation of blur-driven accommodation with negligible temporal delays. This set-up has the potential to be used in studies of the near-triad seeking dynamic manipulation of blur input.

ABSTRACT BODY:

Purpose: Since late glaucoma is the most damaging complication after acute corneal events such as surgery or trauma, our aim has been to develop effective prophylaxis. We have administered antibody against TNF- α for the purpose of protecting the retinal ganglion cell against apoptosis (the hallmark of glaucoma)—and to compare with the effect of corticosteroids.

Methods: Rabbits with normal corneas or with alkali-burned corneas were injected subconjunctivally with the biologics. They were evaluated clinically and with dark- and light-adapted ERG, OCT, and IOP manometrically. The tissues were stained ex vivo in 3 days experiments with TUNEL, DAPI, and H&E. The optic nerves was evaluated after 50 days with paraphenylenediamine staining.

Results: Subconjunctival administration of 0.4 mg or 4.0 mg of adalimumab, and 1.0 mg, 10.0 or 100 mg infliximab were all well tolerated. 40 mg adalimumab showed toxicity. 4.0 mg of adalimumab suppressed apoptosis the most. Local subconjunctival injection, compared to systemic infusion, resulted in substantially higher retinal bioavailability which should reduce systemic side effects. Analysis of the optic nerve axons confirmed the safety of 100 mg infliximab and the 4.0 mg adalimumab.

Conclusions: A subconjunctival injection of 4.0 mg adalimumab has excellent protective effect against retinal ganglion cell apoptosis and no observed toxicity. Corticosteroids, especially triamcinolone 20 – 40 mg sub-Tenon or subconjunctivally, are also having a suppressive effect against apoptosis, but limited applicability because of their side effects. A clinical study for anti-glaucoma prophylaxis after corneal surgery or trauma is proposed.

TITLE: Spatial properties of L- and M-cone driven incremental (on-) and decremental (off-) electroretinograms: normal subjects Vs. glaucoma patients

SESSION TITLE: Electrophysiology: Advances, disease and injury

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A.J. Aher, F. Horn, C.R. Huchzermeyer, R. Lämmer, J.J. Kremers, Department of Ophthalmology, University Hospital Erlangen, Erlangen, GERMANY|

Commercial Relationships Disclosure (Abstract): Avinash Aher: Commercial Relationship: Code N (No Commercial Relationship) | Folkert Horn: Commercial Relationship: Code N (No Commercial Relationship) | Cord Huchzermeyer: Commercial Relationship: Code N (No Commercial Relationship) | Robert Lämmer: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the electroretinographical (ERG) responses elicited by L- and M-cone isolating incremental (On) and decremental (Off) sawtooth stimuli in normal subjects and glaucoma patients.

Methods: Twenty-one normal subjects and 44 primary open angle glaucoma patients participated in the present study. L- and M-cone isolating rapid On- and Off-sawtooth (4Hz) stimuli were generated using the triple silent substitution technique. The cone contrast was 18% with a mean luminance of 284 cd/m^2 . ERGs were recorded with Full-Field (FF) and 70 deg diameter stimuli. The On- and Off-ERG responses were summed (called Ladd and Madd) to study the response asymmetries to increments and decrements. The steady state pattern ERG (PERG) was also recorded in a subpopulation of each group with 0.8 and 16 deg black and white checkerboard stimuli at the rate of 15 reversals/s. The initial positive (P) and subsequent late negative (LN) ERG components of Ladd and Madd were compared between the subject groups and correlated with retinal nerve fiber layer thickness (RNFLT) and PERG.

Results: The responses to L-On stimuli resembled those to M-Off stimuli and vice versa particularly with 70° stimuli. The P_{Ladd} amplitudes were not significantly different between the two subject groups. However, the P_{Ladd} with 70 deg stimuli was significantly ($P < 0.01$) smaller compared to those of FF stimuli. The amplitudes of the LN_{Ladd} in FF were similar in the two subject groups, whereas, for the 70 deg stimuli, the LN_{Ladd} amplitude was significantly ($P < 0.01$) smaller in the glaucoma patients. Both P_{Madd} and LN_{Madd} were not significantly different between the subject groups. The PERG amplitude in response to 0.8 deg check sizes and the ratio of the amplitude of responses to 0.8 deg over that to 16 deg checks (PERG Ratio) were significantly ($P < 0.05$) different between the subject groups. The LN_{Ladd} amplitude with 70 deg diameter stimuli and the PERG amplitude with 0.8 deg checks were significantly correlated with the retinal nerve fiber layer thickness.

Conclusions: The responses to cone isolating sawtooth stimuli elicited ERGs that strongly reflect (parvocellularity based) cone opponency. Compared to (magnocellular) luminance based responses (PERG), the cone opponent ERG responses have little diagnostic value, indicating that the magnocellular system is functionally more affected by glaucoma.

ABSTRACT BODY:

Purpose: To determine the role of FGFR2-mediated signaling in keratocytes during corneal development by phenotypic characterization of stromal specific FGFR2 knockout (KO) mouse

Methods: In vitro analysis of FGFR2 knockdown was performed in cultured normal corneal keratocytes using Silencer® Select FGFR2 siRNA and siCtr (control), based on manufacture's protocol. The cells were processed after 48 h post-transfection. The immunohistochemical analysis of FGFR2 knockdown in cells was determined by confocal microscopy. To determine the in vivo effect of FGFR2, a FGFR2 KO mouse model was generated. FGFR2 flox mice (Jackson Labs) were crossed with inducible keratocyte specific-Cre mice (Kera-rtTA/tet-O-Cre, Dr. Winston Kao, University of Cincinnati). The pregnant females were fed doxycycline chow (600 mg/kg) to induce tissue-specific FGFR2 KO pups. The flox-, Cre-, and wild-type (wt) mice were used as controls. Corneal thickness were determined using an ultrahigh resolution spectral domain optical coherence tomography instrument (SDOCT, Bioptigen).

Results: In vitro, FGFR2 gene silencing severely inhibited pluripotency of stromal keratocytes when cultured in the presence of FGF2 (FGFR2-ligand) compared to control siRNA. The FGFR2 gene silenced-cells also exhibited pluripotency in the presence of IGF, suggesting that FGFR2 was needed for the pluripotency maintenance of keratocytes. OCT-based analysis of the FGFR2 KO mice corneas showed relatively thinner cornea compared to control mice. Immunohistochemical analysis also showed thinner cornea in FGFR2 mice compared to the control mice. Collagen-1 immunostaining was significantly down-regulated in KO mice corneal stroma compared to control mice.

Conclusions: Our earlier results showed that FGFR2 was significantly downregulated in keratoconus corneal stroma. In vitro analysis showed FGFR2 knockdown affected the pluripotency of stromal keratocytes. The FGFR2 KO mice showed stromal thinning. Suggesting that the stromal-specific conditional FGFR2 KO mouse model will provide the functional understanding of FGFR2 in stromal keratocytes and also serve as a keratoconus animal model.

TITLE: Low temperature vacuum-dehydrated amnion membrane (Omnigen) - Case series for the treatment of ocular surface burn and related complications at a tertiary eye unit in the UK.

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Mehta, S. Pradhan, F. Figueiredo, Ophthalmology, Royal Victoria Infirmary, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|F. Figueiredo, Faculty of Medical Sciences, University of Newcastle upon Tyne, Biosciences Institute., Newcastle upon Tyne, Tyne and Wear, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Ankur Mehta: Commercial Relationship: Code N (No Commercial Relationship) | Sayali Pradhan: Commercial Relationship: Code N (No Commercial Relationship) | Francisco Figueiredo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cryopreserved amniotic membrane (AM) is widely used in the management of ocular surface burns (OSB). A novel low-temperature vacuum-dehydrated AM product called Omnigen (NuVision, Nottingham, UK-Licensed 2015) is available, but its clinical use is not broadly reported. Omnigen (OG) is delivered to the eye as a pre-mounted device using a special contact lens (OmniLenz -OL). This case series aims to document and describe the use of OG for the treatment of ocular surface burns and its complications.

Methods: A retrospective analysis of consecutive patients with acute OSB and related complications undergoing treatment with pre-mounted OG was identified from a registry between September 2019 to December 2020. Electronic medical records were reviewed and the following data extracted at 2 time points (OG insertion and last follow up): demographics, best corrected visual acuity (BCVA) in LogMAR; symptoms; epithelial defect (ED) recorded in largest axis. Successful treatment was defined as no loss of BCVA (or improvement) or resolution of ED (less than 0.5mm).

Results: A cohort of 11 patients had unilateral OSB as their primary diagnosis, 5 (45.5%) patients had repeat OG treatments giving a total of 17 OG treatments, consisting of 2 acute alkali OSB and 15 chronic OSB (14 alkali and 1 thermal). All OSB were classified as Roper Hall grade 4 at presentation. Mean age of 35.6 (SD 12.7), 9.1% of which were female. Of the total treatments, 12 were left eyes (70.6%).

Pain was the most common presenting symptoms (n=12; 70.6%), then foreign body sensation in 5 cases (29.4%). Mean presenting BCVA was +2.4 (SD 1.2). Mean BCVA at last review was +2.3 (SD 1.1) mainly due to deeper corneal stromal damage. Mean ED was recorded as 3.4 (SD 2.9 mm). Mean follow-up was 3.3 (SD 3.8) months. Successful treatment was achieved in terms of BCVA in 16 (94.1%) of eyes treated and in terms of ED, in 13 (76.5%) eyes treated. There were no documented complications.

Conclusions: This study demonstrates Omnigen to be a successful and safe treatment for OSB in both acute and chronic setting. This study reports small numbers and a mixture of acute and chronic OSB. Therefore, further studies are needed to demonstrate the overall long-term efficacy and safety of OG in a clinical setting of acute and chronic OSB.

ABSTRACT BODY:

Purpose: A single MMC treatment enhances reinnervation of the intraepithelial corneal nerves after debridement injury. RNAseq studies performed on mouse corneas revealed that MMC enhanced protease inhibitor expression in the epithelium. To confirm that the gene expression changes in mouse corneal epithelial cells was due to a direct impact of MMC on corneal epithelial cells, we performed RNAseq studies on transiently treated telomerase immortalized human corneal limbal epithelial (HCLEs) and primary human corneal epithelial (PHCLE) cells before and after MMC treatment.

Methods: HCLE and PHCLE cells were cultured in KSFM media to 70% confluence. Cells were treated with 0.0025% MMC for 3h followed by RNA extraction. For each variable, 4 replicate sets of RNA were isolated. mRNA expression profiling was performed in the NIAMS Genome Core Facility at the NIH. Single end, 50 base reads were mapped to the mouse genome mm10 using TopHat 2.1.0. For phagocytosis studies, fluorescent 1.0 mm latex beads were opsinized with BSA and added to cell cultures for 1 hr. Cells were washed, fixed and stained with phalloidin. The fluorescence intensity of the beads present per cell were corrected for difference in cell size.

Results: Comparing 5-fold up and down regulated genes, we determined genes that are altered in expression after MMC treatment in HCLE and PHCLE cells. There are 15 MMC signature genes with 11 upregulated and 4 down regulated. There are too few down regulated genes to determine shared gene ontology but the 11 up regulated genes show common gene ontology terms for cytokines with 4 of the genes falling into category [CXCL1, CXCL16, IL32, and ISG15]. In addition, MMC induced an increase in expression of autophagy and phagocytosis genes which was also shown by the phagocytosis studies.

Conclusions: MMC treatment impacts gene expression in the corneal epithelium both in vivo and in vitro in HCLE and PHCLE cells by inducing the up-regulation of numerous cytokines, autophagy and phagocytosis genes which lead to increased phagocytosis by corneal epithelial cells. The enhanced reinnervation seen in the mouse corneal epithelium after a single MMC treatment during debridement wounding may be due to its ability to alter immune cell recruitment via alterations in cytokine secretion and/or the improved ability to remove debris released by injured cells and severed axons.

TITLE: Red Blood Cell Velocity Variability in Small Retinal Vessels

SESSION TITLE: Adaptive optics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Warner, T. Gast, K. Sapoznik, A. Carmichael-Martins, S.A. Burns, Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Raymond Warner: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Gast: Commercial Relationship: Code N (No Commercial Relationship) | Kaitlyn Sapoznik: Commercial Relationship: Code N (No Commercial Relationship) | Alessandra Carmichael-Martins: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Burns: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To understand the temporal and spatial variability of red blood cell velocity in small retinal vessels using a dual-beam Adaptive Optics Scanning Laser Ophthalmoscope

Methods: Experiment 1 measures temporal blood velocity variability in a local vascular region consisting of an arteriole, capillary, and venule by measuring blood velocities in 3 young healthy subjects repeatedly over two days. Data consisted of 10 imaging periods separated into two sessions: 1) Five 6-minute image acquisition periods with 30-minute rest intervals and 2) Five 6-minute image acquisition periods with 10-minute rest intervals. Experiment 2 measures spatial distribution of velocity variability by imaging three capillary segments in 5 young healthy subjects during three 2-minute imaging conditions: 1) A baseline imaging condition, 2) A full-field flicker and 3) no flicker condition again.

Images were collected in 3-second 100-frame videos at 29 Hz and processed via MATLABTM software. Red blood cells travelling through the selected capillaries were detected based on a z-score algorithm for the first channel. Then regions of interest centered on detected cells were averaged across all cell detections for each channel. Five videos were used for analysis during each condition. Regions of interests were averaged over three consecutive frames and the displacement of the average RBCs between both channels (3.32 ms) determines the velocity (mm/s).

Results: Red blood cell velocities were measurable in all subjects. The coefficient of variation (C.V.) was used to determine the physiological variability of the selected vessels among all subjects relative to the average velocity for each condition. Average C.V. for both days in arterioles was 7% (± 2), in capillaries was 19% (± 6), and in venules was 8% (± 2). ANOVA and post-hoc t-test showed significant differences in RBC variability in capillaries compared to arteriole and venules in Experiment 1 [$F(2, 118) = 199.70, p < 0.001$]. In Experiment 2, individual capillaries varied in their blood flow response despite changes in metabolic demand. Average C.V. was 16% during baseline, 15% during flicker stimulation, and 18% after flicker stimulation.

Conclusions: Small retinal vessels in humans exhibit unique spatial and temporal characteristics that are involved in meeting metabolic demand. This inherent variation places limits on studying vascular regulation at the single capillary level.

ABSTRACT BODY:

Purpose: Retinal organoids show great promise as a transplantable treatment for retinal degeneration. Quantifying organoid anatomical features and visual function recovery in vivo after organoid transplantation involves spectral domain optical coherence tomography (SD-OCT) and superior colliculus recordings (SCR). Volumetric analysis of organoid structures and its role in visual recovery has not been investigated. We sought to correlate transplant imaging characteristics on SD-OCT with SCR functional recordings in a model of retinitis pigmentosa with rhodopsin mutation (S334ter-3).

Methods: Human embryonic stem cells (hESC) were induced into retinal organoids and differentiated in vitro for 30-70 days. Retinal organoids suitable for transplantation were chosen based on outer tissue transparency and morphological criteria. Organoids were then transplanted into the subretinal space of S334ter-3 rats. SD-OCT were completed at 2 weeks and 1 month after transplantation, then every 1-2 months. After overnight dark adaptation, extracellular recording was utilized in the superior colliculus of the rats and the data was analyzed using MATLAB according to established procedures. SD-OCT were analyzed for native retina and transplant volume, morphology, and transplant distance to the optic disc using 3D Slicer and ImageJ, both open-source image analysis software.

Results: Preliminary data demonstrated rats with positive SCR had greater final organoid volumes than rats with no SCR. Further analysis is ongoing.

Conclusions: Our data showed that lower organoid transplant volumes were linked to lower visual function recovery. This pilot study suggests that quantitative and volumetric analysis of retinal organoid transplants using SD-OCT may predict the quality of retinal transplantation.

Commercial Relationships Disclosure (Abstract): Alyssa Coleman: Commercial Relationship: Code N (No Commercial Relationship) | Sunny Patel: Commercial Relationship: Code N (No Commercial Relationship) | Rebecca Sarran: Commercial Relationship: Code N (No Commercial Relationship) | Mathew MacCumber: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent promising results in the use of gene therapy for inherited retinal disease (IRD) have prompted the implementation of genetic testing to evaluate for the presence of mutations in relevant genes. This study reports the findings following a retrospective review of genetic testing results in patients diagnosed with IRD. Subsequent analysis of data will provide insight into the relative frequency of pathogenic retina-associated gene mutations within Chicago, IL.

Methods: A query was made of the Illinois Retina Associates (IRA) and Rush University Eye Center Physicians (RUECP) databases to identify patients with diagnoses representing IRD as identified by the following ICD-10-CM codes: pigmentary retinal disorder (H35.52), unspecified hereditary retinal dystrophy (H35.50), and other dystrophies primary involving the sensory retina (H35.53). Eligibility was confirmed via chart review. Patients were included if a prior diagnosis of IRD was present and associated with pending or returned genetic testing results. After confirming eligibility, the following de-identified data was entered into the study database: medical record number, age, gender, race, clinical diagnosis, genetic testing service, genetic panel used, and results.

Results: 487 patients at IRA and 49 at RUECP were identified as having appropriate codes between 1/1/2014 and 12/31/2020. 68 patients have been tested for retinal specific gene mutations through commercial genetic laboratories to date. 67 patients have testing resulted. 0/67 (0%) patients were positive for RPE 65. 49/67 (73%) patients had positive results of heterozygosity in at least one implicated gene. 54/67 (80%) patients had positive results of variants of unknown significance. Pathogenic variants were identified in 27 different genes, the most frequent being ABCA4, USH2A, and NR2E3 in decreasing order.

Conclusions: ABCA4 and USH2A were identified as the two most frequent implicated genes, consistent with previously published data. In contrast to prior publications, we found the third most frequent pathogenic variant to be NR2E3, which was previously reported as a rare cause of IRD. These contrasting findings suggest that additional analyses of IRD genetic testing results from large populations are required to provide those researching novel gene therapies with the target that will provide the greatest impact.

ABSTRACT BODY:

Purpose: Corneal endothelial cells (CEnC) have minimal regenerative capacity, and insults to the endothelium may lead to significant corneal swelling. Studies have reported corneal nerve damage is associated with CEnC loss, suggesting nerves exert trophic effects on CEnC. Previously, we have demonstrated the cytoprotective function of the neuropeptide α -MSH against inflammatory and oxidative stress in CEnC ex vivo. Here, we investigate the efficacy of α -MSH in preventing corneal edema in a model of corneal endothelial injury.

Methods: Corneal injury was induced by transcorneal freezing in BALB/c mice (n=8/group) by placing a -196°C 2 mm-diameter steel rod on the center of the cornea for 10 seconds. Beginning immediately after injury, mice received subconjunctival injections of 10 μL of 10^{-4} M α -MSH or PBS (control) twice weekly for a total of 8 weeks. Corneal edema was evaluated by assessing corneal opacity on slit lamp biomicroscopy and central corneal thickness (CCT) via optical coherence tomography. CEnC density and variability in cell size (polymegathism) and shape (hexagonality) were evaluated by in vivo confocal microscopy.

Results: In the untreated control group, transcorneal freezing led to significant corneal edema on d1 post-injury (CCT:180 \pm 28 μm vs. baseline 101 \pm 2 μm , P=0.007) which remained elevated 8wk after injury (186 \pm 14 μm , P<0.001). There was a significant reduction in CEnC density (1821 \pm 42 cell/mm² vs. baseline 2954 \pm 67, P<0.001), an increase in polymegathism (CV: 41 \pm 3 vs. baseline 28 \pm 2, P=0.001) and a decline with a trend to significance in CEnC hexagonality (hexagonal cells%: 52 \pm 3 vs. baseline 59 \pm 4, P=0.079) at 8wk in the control group. In contrast, treatment with α -MSH restored normal (pre-injury) CCT (103 \pm 3 μm , P=0.60). Further, compared to untreated control, subconjunctival injections of α -MSH led to clearer corneas with a significant reduction in edema (117 \pm 12, P=0.004), improved CEnC density (2209 \pm 132, P<0.001) and reduced CEnC polymegathism (CV:34 \pm 2, P=0.001). Restoration of normal CEnC morphology occurred earlier in the α -MSH treatment group compared to the control group.

Conclusions: Our results demonstrate that following corneal injury, treatment with α -MSH reverses corneal endothelial function by reducing CEnC loss. Our findings suggest a therapeutic role for α -MSH in preventing/restoring endothelial function following corneal injuries.

ABSTRACT BODY:

Purpose: During development, the proper histoarchitecture of the retina is achieved through a delicate balance between proliferation, differentiation, and cell death. Retinal ganglion cells (RGCs) in particular increase in numbers during development except for two periods of sharp decline that appear conserved in vertebrates. The mechanisms responsible for these phenomena are incompletely understood. Notably, we observed that the first wave of RGC death is replicated within human stem-cell derived retinal organoids. Thus, we took advantage of this model to investigate the mechanisms of RGC death in the developing human retina.

Methods: Retinal organoids were differentiated from human induced pluripotent stem cells (hiPSCs) and collected weekly between weeks 6 and 10 of differentiation. The timeline of the first wave of RGC death was characterized by immunofluorescent staining of RGCs and further confirmed in organoids generated from a fluorescent reporter line. Potential microglia involvement was evaluated at the transcriptional and translational levels. TUNEL and activated caspase 3 immunostaining were performed to assess for apoptotic cell death, and Western blot was used to identify the intracellular pathways involved.

Results: Retinal ganglion cell numbers consistently decreased at week 8 of differentiation, as observed by different quantitative methods. Immunofluorescent staining for IBA1 and RT-PCR for microglia markers verified the absence of microglia in this model, while a spike in cell death coinciding with the trough in RGC numbers was observed by TUNEL staining and cleaved caspase 3 immunofluorescence. Interestingly, we observed a decrease in the BAX/BCL2 ratio and a marked increase in cleaved caspase 8, suggestive of the involvement of the extrinsic apoptotic pathway.

Conclusions: Human retinal organoids recapitulate the first wave of developmental ganglion cell death in vitro. The absence of microglia in this model and the evidence of caspase-dependent apoptosis revealed an additional contributor to regulating RGC numbers in human retinal development. The activation of caspase 3 and caspase 8 suggest the recruitment of the extrinsic apoptotic pathway. This knowledge can lead to new insights regarding congenital retinal abnormalities.

ABSTRACT BODY:

Purpose: We aimed to identify the incidence, risk factors, demographic and clinical profile for Dupilumab-induced ocular surface disease (DIOSD) in patients with atopic dermatitis (AD) and propose a standardised treatment protocol

Methods: Prospective case series including 40 eyes of 20 patients with AD developing ocular symptoms after commencing Dupilumab at the Royal Victoria Infirmary referred to the Corneal Service from dermatology department, between September 2018 to May 2019. Patients were evaluated using a standard history and examination protocol including subjective symptom severity grading and Ocular Surface Disease Index (OSDI) questionnaire on each visit. Patient demographics, onset and severity of ocular symptoms, BCVA and slit-lamp examination findings were evaluated. Standard treatment prescribed included topical dexamethasone 0.1% preservative free (PF) tapering dose, ketotifen 0.025% (PF), ciclosporin 0.1% PF, lubricants and hydrocortisone 0.5% ointment for lid margins.

Results: Thirty two (28.31%) Dupilumab treated AD patients out of 113 consecutive patients developed DIOSD, 20 (62.5 %) of which were evaluated in the Cornea Service. The median age was 38.0 years (SD 15.8; range 19 – 74). Equal male to female ratio. History of allergic conjunctivitis was reported in 50%. The average time to onset of ocular symptoms was 9.2 (SD 8.7) weeks. Symptoms included burning, itching, tearing, foreign body sensation, photosensitivity, and discharge. 90% of patients had bilateral conjunctival inflammation and blepharitis at presentation. Good response to treatment was noted with significant improvement in the subjective severity scale and the mean OSDI score (from 34.0 to 10.2). Median follow-up was 18 weeks (SD 9.4; range 10-44).

Conclusions: DIOSD is not uncommon. No difference in severity was noted in patients with a previous history of allergic conjunctivitis. Most cases responded well to topical anti-inflammatory treatment combined with anti-allergic eye drops. No patient discontinued Dupilumab. With timely referral and appropriate treatment better clinical outcomes and patient satisfaction can be achieved. Further prospective studies with longer follow-up with a focus on the efficacy of prophylactic topical treatment prior to starting Dupilumab and possible disease mechanisms are needed.

ABSTRACT BODY:

Purpose: Aldose reductase transgenic (AR-Tg) mice created to model diabetic eye disease showed an unexpected diabetes-independent phenotype involving cell swelling at the retinal nerve fiber layer and decreases in pattern ERG compared to controls. The purpose of our study was to identify the cell types and potential role of AR as a driver of this phenotype.

Methods: PCR genotyping ruled out the Rd8 mutation of the Crb1 gene in this model. Retinal morphology was routinely assessed by H&E staining. Immunofluorescence was used for detection and quantitation of Brn3a as a marker for RGCs, GFAP and CRALBP for Müller glia, and Iba-1 for microglia, and a species-specific antibody to human AR (AKR1B1) to map transgene expression. GraphPad Prism was used to measure differences in comparison groups according to either t-test or 1 way ANOVA followed by Tukey's Multiple Comparison Test.

Results: The human AR (hAR) transgene was designed using a hybrid lens crystallin gene promoter. As expected, strong immunostaining was observed in lens. Unexpectedly, we observed a significant ($p<0.01$) increase in the number of hAR-immunopositive cells in the RGC and inner nuclear layers compared to nontransgenic controls. By 18 weeks of age, and in the absence of experimentally-induced diabetes, AR-Tg mice developed a layer of swollen and vacuole-rich cells adjacent to the RGC layer ($p=0.003$). Treatment from birth with Sorbinil (0.25mg/ml in drinking water), a well characterized AR inhibitor, prevented these changes ($p=0.003$), suggesting that the change in cell morphology was associated with AR activity. Patterns of immunostaining with GFAP, CRALBP, and hAR species-specific antiserum suggest that the swollen cells are likely endfeet of Müller glia containing transgene-derived hAR. In addition, a proinflammatory phenotype characterized by increased numbers of activated retinal microglia was observed in AR-Tg retina compared to nontransgenic control ($p<0.001$) or after treatment with Sorbinil ($p<0.01$).

Conclusions: Elevated levels of AR gene expression typical of the diabetic retina induce a proinflammatory phenotype in mouse Müller glia and retinal microglia. Sorbinil substantially prevented these structural and functional changes, suggesting that suppression of retinal inflammation by AR inhibitors may represent a novel approach to prevention of diabetic retinopathy.

ABSTRACT BODY:

Purpose: To identify an association between the vascular properties of choroidal neovascularization obtained by optical coherence angiography (OCT-A) and the resulting amount of retinal fluid (RF) in neovascular age related macular degeneration (nAMD).

Methods: In this prospective observational study, 54 patients with type 1 and type 2 treatment naïve nAMD were included and treated according to a treat and extend regimen with intravitreal aflibercept.

At baseline and month 1 each patient underwent the following examinations:

A 97-line high resolution OCT volume scan using HR2 + OCT device (Spectralis, Heidelberg Engineering, Germany).

A deep learning algorithm was used to automatically detect, quantify and localize RF in OCT volume scans.

A 6x6mm volumetric flow scan was made using a swept-source OCTA device (PlexElite 9000, Zeiss). Angio Tool GUI was used to skeletonize MNV properties and quantify MNV area (VA), vessel density (VD), total number of endpoints (TNE), total number of junctions (TNJ), junction density (JD) and total vessel length (TVL). Subsequently linear regression models and mixed models were used to analyze.

Results: Fluid and MNV properties were not normally distributed, therefore logarithmization was performed to normalize data prior to linear regression.

The median amount of total RF was 173.7 nl (84.7; 614.5) at baseline, which consisted of 156.6 nl (60.3; 435.8) of subretinal fluid (SRF) and 2.3 nl (0.04; 22.3) of intraretinal fluid.

After the first anti-VEGF treatment the median amount of RF decreased to 5.0nl (0.96; 18).

RF at baseline was significantly associated with the numbers of TNE (coefficient= 0.50; $p=0.002$; $R^2=0.17$), SRF with TVL (coefficient= 0.33; $p=0.04$; $R^2=0.08$) and TNE (coefficient= 0.57; $p=0.000762$; $R^2=0.2$). IRF was significantly associated with VA (coefficient= 1.082; $p=0.04$; $R^2=0.08$).

None of the vessel parameters was significantly associated with the relative fluid decrease after the first anti-VEGF treatment.

Conclusions: In this study population the number of endpoints as well as the vessel length correlated with the volume of fluid at baseline, indicating that these vessel parameters were biomarkers for exudative activity. However, none of the vessel parameter had an influence on the treatment response.

TITLE: The Neuroprotective Action of p58IPK is Independent of Macrophage Regulation in Retinal Disease Models

SESSION TITLE: Retinal diseases: molecular and biochemical mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. McLaughlin, J. Wang, J.J. Wang, S.X. Zhang, Ophthalmology and Ross Eye Institute, University at Buffalo, Buffalo, New York, UNITED STATES|T. McLaughlin, J.J. Wang, S.X. Zhang, SUNY Eye Institute, State University of New York, University at Buffalo, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Todd McLaughlin: Commercial Relationship: Code N (No Commercial Relationship) | Jinli Wang: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Wang: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: p58IPK is a multifunctional ER chaperone and a regulator of cell stress response in a variety of cell types and tissues including the retina, pancreas, and immune cells. The goal of the present study is to evaluate the neuroprotective effect of p58IPK overexpression in mouse retina and elucidate the mechanism by which p58IPK acts as a neuroprotectant involving regulation of macrophage activation.

Methods: Conditional knockout (cKO) of p58IPK in macrophages was achieved by crossing p58IPK floxed mice with a myeloid-specific Cre line (LysM-Cre). We determined knockout efficiency by qPCR in cultured bone marrow derived macrophages (BMDMs). Overexpression of p58IPK in wild type (WT) retina was accomplished by intravitreal injection of adeno-associated virus (AAV). Neurodegeneration was assessed at 14 days post-induction in two disease models, a microbead induced increase in intraocular pressure (IOP) and an ischemia-reperfusion (IR) model. The loss of RGCs was examined by immunohistochemistry (IHC) for Brn3a. The structure and function of the cKO eyes were assessed by IHC for multiple retinal markers, morphological measurements, and electroretinogram (ERG).

Results: We find that BMDMs from p58IPK fl/fl; LysM-Cre (p58IPK cKO) mice have a 97% knockdown of p58IPK mRNA compared to BMDMs from p58IPK fl/fl (WT) mice, validating the loss of p58IPK from macrophages. p58IPK cKO retina has no substantial differences from WT retina in retinal structure or cellular composition, including the number of Brn3a+ RGCs. p58IPK cKO mice have a trend for reduced b wave amplitudes in both light- and dark-adapted ERGs compared to WT mice. Injection of AAV-p58IPK in WT mice with increased IOP results in greater Brn3a+ RGC survival compared to AAV-GFP overexpression. However, in p58IPK cKO mice, in which p58IPK is lost only in macrophages, we find no difference in Brn3+ RGC survival compared to WT using the same IOP model. Similarly, p58IPK cKO mice suffer identical loss of Brn3a+ RGCs in the IR model, compared to WT.

Conclusions: Though broad p58IPK overexpression in retina reduces RGC loss in disease models, the loss of p58IPK specifically in macrophages does not substantially ameliorate RGC loss in the same model or in a second disease model. These results suggest that the neuroprotective effect of p58IPK does not likely involve a regulation of macrophage activation.

ABSTRACT BODY:

Purpose: Oculocutaneous albinism type 3 (OCA3) is an autosomal recessive disorder caused by mutations in the TYRP1 gene. Tyrosinase-related protein 1 (Tyrp1) is involved in eumelanin synthesis, catalyzing the oxidation of dihydroxyindole carboxylic acid oxidase (DHICA) to indolequinone carboxylic acid (IQCA). Here, we used computational methods to assess molecular docking of DHICA and IQCA in Tyrp1 and associated OCA3 mutants.

Methods: The mutations for analysis, C30R, H215Y, D308N, and R326H, were selected from ClinVar and The Human Gene Mutation Database. The crystal structure of human Tyrp1 (5M8L) was minimized using molecular dynamics in water and subjected to global mutagenesis to ascertain the $\Delta\Delta G$ values of folding. In total, four known mutations of Tyrp1 and the wild type (chain A of 5M8L) were simulated for 100 ns in pH 5.5. Global mutagenesis was conducted to identify residues critical to protein folding, a Weighted Histogram Analysis Method (WHAM) was applied to compare free energy landscapes of the active site between the wild type and mutants, and Maestro software was used to dock DHICA and IQCA.

Results: C30R and H215Y exhibit greater instability according to experimental results, which is consistent with their unfolding parameters of 1, indicating protein misfolding. Global mutagenesis suggests that of the four mutants, D308N and R326H were the only ones that were not completely unfolded or misfolded, with unfolding parameters of 0.56 and 0.98, respectively. Free energy landscapes generated by WHAM indicate that the binding cleft (residues Y362, N378, and T391) of both of these mutants are larger and less well defined. The docking of DHICA in Tyrp1 highlights four interactions that remain constant between DHICA and the protein: three hydrogen bonds and one salt bridge. D212 and E216 are the most common recipients of these interactions.

Conclusions: Our observations are consistent with the results of biochemical analysis of recombinant Tyrp1 and four mutant variants from this study. The docking of DHICA, in the most stable protein conformations as determined by WHAM, indicate that the hydrogen bond and salt bridge interactions that stabilize DHICA remain similar among wild type Tyrp1, D308N, and R326H. However, the strength of these interactions and stability of the docked ligand may decrease proportionally to mutation severity due to the larger and less well-defined nature of the binding cleft in mutants.

ABSTRACT BODY:

Purpose: Identification of sclerotic vessels resulting from ischemia can be challenging with conventional color fundus photography (CFP). We aim to use this pilot study to evaluate the detection of retinal vessel whitening from branch retinal vein occlusion (BRVO) using CFP and newer confocal scanning laser Multicolor (MC) imaging.

Methods: This retrospective study identified patients with BRVO using the imaging database at the University of California San Diego. Whitening on CFP and MC was graded by retinal specialists compared to reference images. Graders were asked to choose their preferred MC channel (infrared, blue, or green) to identify whitening. Vessel whitening by MC was further correlated to the area of ischemia on FFA and analyzed longitudinally.

Results: MC images from 32 BRVO patients (n=33 eyes, 21 females, mean age 69.7 years) and 29 healthy controls (n=29 eyes, 20 females, 70.1 years) were analyzed. To test the difference in MC versus CFP for vessel sclerosis detection, 24 patients (n=24 eyes) with available images in both modalities were graded and compared, showing a significantly higher grade of vessel whitening by MC compared with CFP ($p < 0.05$). The green channel was preferred in 70% of MC images to best identify whitening in cases with whitening visible on CFP (n=30 eyes, 3 eyes were excluded due to poor image quality), followed by blue (30%) and 0% infrared. Longitudinal analysis with MC images (n=32 cases/194 eyes) found significantly higher grading scores, indicating more vessel whitening, as time progressed ($p < 0.001$). Finally, MC images matched with same-date fluorescein angiography (n=28 cases/eyes) had a moderate correlation between vessel whitening and the area of ischemia ($r=0.438$, $p=0.022$).

Conclusions: MC imaging appears to better identify retinal vessel whitening compared with CFP in BRVO patients, preferably with the green MC channel. A limiting factor in this study was that in some cases MC and CFP images were not taken on the same day. However, the MC module may be a quick, non-invasive tool to highlight vessel whitening in ischemic BRVO.

ABSTRACT BODY:

Purpose: Uveal melanoma is the most common primary intraocular tumor in adults and arises from the transformation of melanocytes. Despite the treatment of the eye tumor, the survival of patients is greatly reduced due to the development of metastases to the liver. Extracellular vesicles (EVs) are released by cancer cells, which allow oncoproteins or genetic material to be transferred to distant cells in order to modify their microenvironment and promote the spread of cancer. Our hypothesis is that EVs from the ocular tumor prepare the hepatic stroma for metastatic cell colonization via endothelial cells and by activating hepatic stellate cells. Our study aims to characterize the melanocytic and melanomic EVs and to study their impact on the hepatic microenvironment and their interactions with liver cells.

Methods: EVs were isolated from uveal melanoma cells and melanocytes by differential centrifugation. Their concentration/size were characterized by Western immunoblotting, high-sensitivity flow cytometry and cryogenic electron microscopy using exosomal or melanomic markers. The mechanisms of internalization of EVs in hepatic stellate cells and endothelial cells have been investigated by confocal microscopy using inhibitors of endocytosis pathways. The contractility of stellate cells on more or less rigid hydrogels and the tubular organization of endothelial cells on Matrigel post-exposure to melanomic EVs were determined by traction force microscopy or time-lapse. The selective biodistribution of EVs in organs was studied by fluorescence imaging in mice.

Results: The extravesicular fraction of uveal melanoma cells and melanocytes contained exosomes and microvesicles. The stellate cells that had internalized the melanomic EVs were more contractile, while the endothelial cells developed capillary-like tubular networks faster. Melanomic EVs were mainly accumulated in the liver and lungs of mice.

Conclusions: We have demonstrated that the extravesicular signaling from uveal melanoma cells activates hepatic stellate cells, which become more contractile. Melanomic EVs also have proangiogenic potential. The discovery of melanoma-specific proteins on the surface of the EVs of metastatic patients could lead to the development of new imaging modalities for micrometastases or drug vectors for targeted delivery to liver metastases.

ABSTRACT BODY:

Purpose: Granzyme B (GzmB) is a cytotoxic serine protease that advances aging/age-related diseases and chronic inflammation via pathological extracellular matrix (ECM) degradation and increased vascular permeability. Extracellular GzmB is increased in the aging outer retina and in the choroid of donor eyes with neovascular AMD (nAMD) and with choroidal neovascularization (CNV), but its role in CNV is not known. This study determines the effect of exogenous GzmB using an ex vivo model of microvascular angiogenesis.

Methods: Ex vivo choroid sprouting assay (CSA) using peripheral retinal pigment epithelium (RPE)/Bruch's membrane (BrM)/choroid/sclera tissue explants from 3-month-old C57BL/6 mice was established and cultured for 10 days. Explants were stimulated with either exogenous GzmB (50nM) or PBS on Days 4, 6, 8 and 10 of culture. Western blot was performed to assess the expression and cleavage of ECM proteins, decorin and fibronectin in the CSA supernatant. Images of CSA explants were captured, vascular sprouting was analysed and quantified by a standardized SWIFT-Choroid macro based on ImageJ software. CSA relative vascular sprouting area (mm²) and western blot relative band intensity data were statistically evaluated.

Results: Relative vascular sprouting area was significantly ($p < 0.05$; $n \geq 11$ per group) increased in choroid explants stimulated with exogenous GzmB compared with controls. Western blot also reveals significantly increased cleavage of fibronectin ($p = 0.001$; $n = 3$ per group) and expression of decorin ($p < 0.05$; $n = 4$ per group) in GzmB-stimulated choroid explants compared with controls. ECM remodelling induced by GzmB cleavage of important ECM proteins could diminish outer retinal barrier function, promote vascular leakage and inflammation, and dysregulated angiogenesis in CNV.

Conclusions: GzmB cleavage of ECM proteins including decorin and fibronectin may contribute to CNV development in nAMD via an ECM remodelling/pro-angiogenesis pathway. Further studies are needed to investigate the possibility that pharmacological inhibition of extracellular GzmB could mitigate CNV in nAMD.

TITLE: In-silico comparison of CB2 selectivity among endocannabinoid ω -6 and -3 epoxyethanolamides

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.J. Kim, G.W. McCollum, J.S. Penn, Ophthalmology and Visual Sciences, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Minjae Kim: Commercial Relationship: Code N (No Commercial Relationship) | Gary McCollum: Commercial Relationship: Code N (No Commercial Relationship) | John Penn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cannabinoid (CB) receptors are G-coupled protein receptors, and two CB receptors have been identified so far, CB1 and CB2. There is abundant data suggesting that epoxyeicosatrienoic ethanolamides (EET-EAs) and epoxydocosahexaenoic ethanolamides (EDP-EAs), which are derived from ω -6 and -3 fatty acids, respectively, may inhibit retinal inflammation through CB2 activation. In this study, we aim to provide a comprehensive in-silico comparison of the regioisomers of EET-EA and EDP-EA on their affinities to CB1 and CB2.

Methods: CB1 (PDB:5TGZ) and CB2 (PDB:5ZTY) have been used for molecular docking of 5,6-, 8,9-, 11,12-, and 14,15-EET-EA as well as 4,5-, 7,8-, 10,11-, 13,14-, 16,17-, and 19,20-EDP-EA. Additionally, arachidonoyl ethanolamide (AEA), docosahexaenoyl ethanolamide (DHA-EA), CB1-selective AM-6538 (PubChem CID: 46912833), and CB2-selective AM-10257 (PubChem CID: 137321161) have also been investigated. Docking was carried out with AutoDock Vina (Scripps Research, USA) and scored by their binding free energy, ΔG in kcal/mol. Their protein-ligand interactions were visualized with PyMOL (Schrödinger, Inc., USA).

Results: AM-6538 and AM-10257 displayed CB1- and CB2-selectivity, respectively, and their predicted binding modes were consistent with their crystallographies in the literature. AEA and DHA-EA displayed preference for CB2 over CB1, and their metabolites, EET-EA and EDP-EA, shared a similar pattern but showed more CB2-selectivity. This is consistent with the literature in that the epoxygenation step of AEA and DHA-EA serves as a "bioactivation" event, since the products exhibit enhanced selectivity for CB2. Among EET-EAs, 11,12-EET-EA had the highest affinity to CB2 (ΔG of -8.3 kcal/mol). Among EDP-EAs, 19,20-EDP-EA had the highest affinity to CB2 (ΔG of -9.0 kcal/mol). The PyMOL visualization predicted that the intracellular region of CB receptors most likely contains the binding site, where phenylalanine at position 183 in CB2 associates with hydrophobic tails of EET-EA and EDP-EA.

Conclusions: The results predict that EET-EA and EDP-EA bind to the intracellular region of cannabinoid receptors and are more CB2-selective than their parent compounds, AEA and DHA-EA. Considering the rising interest in CB2 agonism to inhibit retinal inflammation, these epoxygenated fatty acids, specifically 11,12-EET-EA and 19,20-EDP-EA, can be potentially useful in inhibiting inflammation in DR.

ABSTRACT BODY:

Purpose: The literature is limited on the visual acuity outcomes of patients with a poor presenting visual acuity (VA) who undergo bevacizumab treatment for neovascular age-related macular degeneration (nAMD), especially since the landmark bevacizumab trials excluded patients with VA < 20/320. We performed a retrospective, observational cohort study to investigate the annual visual acuity changes of patients who had a presenting VA worse than 20/320 and underwent bevacizumab therapy for nAMD.

Methods: Eyes with a presenting VA < 20/320 treated for nAMD with bevacizumab from January 1, 2012 to December 31, 2020 were included. Eyes with previous intravitreal anti-VEGF injections, previous non-cataract intraocular surgery, or < 12 months of treatment were excluded. Data on visual acuities, number of injections, and treatment regimen were collected annually. The primary outcome was the mean VA change from presentation at one year in Early Treatment Diabetic Retinopathy Study (ETDRS) letters. Secondary outcomes included the mean VA change at years 2-6 and the percentage of eyes that gained attained vision > 20/320 at one year.

Results: 120 eyes completed at least one year of treatment and qualified for the study. The mean VA change at 1 year was +20.5 letters (SD=26.0). 53 eyes (44.2%) achieved vision > 20/320 at one year. The mean VA change at 2 and 3 years was +16.0 letters (SD=23.8, N=89) and +17.8 letters (SD=27.5, N=59), respectively. The annual total number of injections and the VA change in subsequent years are summarized in Table 1.

Conclusions: Eyes with poor presenting vision treated for nAMD with bevacizumab can gain visual acuity in the first year of treatment and maintain some degree of improved vision in subsequent years.

ABSTRACT BODY:

Purpose: Coordination between eye and hand movements is essential for a child's interaction with the environment. We previously reported longer reach times in strabismic children, and in children with impaired binocularity, compared with controls (Kelly et al, ARVO, 2019, 2020). Anisometropia results in reduced binocularity, but to a lesser extent than strabismus. Thus, reaching in anisometropic children may not be disrupted. Here, we evaluate hand kinematics during visually-guided reaching in children with anisometropia.

Methods: Results from 21 children (age 7-12 years) diagnosed with anisometropia (visual acuity, 20/16–20/630; stereoacuity, 40"–nil) were compared to 20 age-similar controls. Hand movements were recorded using the LEAP motion device. Children reached and touched a small dot that appeared in 1 of 4 positions ($\pm 5^\circ$ or $\pm 10^\circ$ horizontally displaced from fixation). Kinematic measures were time-to-reach onset, reach duration, peak velocity, duration of acceleration, and duration of deceleration. Sensory factors were amblyopia (present n=15 vs not present n=5) and stereoacuity (nil n=6 vs measurable n=14).

Results: Anisometropic children did not differ on any hand kinematic measure compared with controls (time to reach onset, 333 ± 73 vs 334 ± 61 ms, $p=0.98$; reach duration, 516 ± 66 vs 526 ± 47 ms, $p=0.50$; peak velocity, 1.35 ± 0.24 vs 1.35 ± 0.16 m/sec, $p=0.91$; duration of acceleration 187 ± 26 vs 189 ± 24 ms, $p=0.85$; duration of deceleration 324 ± 48 vs 334 ± 37 ms, $p=0.43$). Hand kinematics did not differ with sensory factors (amblyopia, stereoacuity).

Conclusions: Despite decorrelated binocular experience during a critical period of visuomotor development, we found no significant impact of anisometropia on hand kinematics during visually-guided reaching in children. This finding may be due to better binocularity outcomes found in anisometropic children compared with strabismic children. Children, regardless of visual deficit, may increase their speed of reaching, but pay a price with precision. Children with normal vision may improve precision and accuracy with experience, but those with abnormal vision may compensate and adapt movements (increased duration of acceleration, reduced peak velocity) to reach normal levels of accuracy and precision, as seen in adults with anisometropic amblyopia (Niechwiej-Szwedo et al, 2011). However, spatial accuracy and precision cannot be measured reliably with the LEAP device.

ABSTRACT BODY:

Purpose: Gauge the impact of digital medicine and associated tools on glaucoma management and medication adherence during the COVID-19 pandemic.

Methods: The study was conducted at EyeCare Consultants of New Jersey's two locations in Woodland Park and Edison, NJ. Eye care professionals (ECPs) (two ophthalmologists & two optometrists) surveyed 100 glaucoma patients during the first several months of the COVID-19 pandemic (March - August 2020). All those surveyed received previous digital instruction with CheckedUp, a patient education digital platform utilizing auditory, visual, and touch elements to engage patients with eyecare education during prior in-person visits. All patients were randomized into two groups: Group 1 received traditional phone calls while Group 2 received video calls (video with ECP and screen share of CheckedUp) during the pandemic to ensure adherence with ocular medications and address acute issues during this time period. All patients in Group 2 were shown the same glaucoma educational videos in English using the CheckedUp platform. Both groups received follow-up with an in-person visit in August. Surveys elicited responses to gauge consistency of ocular medication use.

Results: Adherence was defined as daily compliance with the glaucoma medication throughout the five-month period. The survey results demonstrated a significant difference between Group 1 and Group 2. Adherence during months without in-person office visits were compared to self-reported adherence for the same five-month time period in the year prior to the COVID-19 pandemic. Group 1's overall adherence was 64% (32/50 patients) at the August in-person visit and revealed that several patients used their drops inconsistently or differently from their prescribed regimen. Group 2's overall adherence was 90% (45/50 patients) at the August in-person visit and patients demonstrated continued comprehension of glaucoma risk and the importance of consistent medication use. A majority of Group 2 patients also commented that the ECP video call with CheckedUp helped reinforce the importance of eye pressure control in glaucoma.

Conclusions: This study illustrates the ability of digital medicine platforms to supplement in-person office visits to manage glaucoma, even during a pandemic such as COVID-19. Compliance remains an important issue in the medical management of glaucoma and digital solutions like CheckedUp assist with optimizing patient care.

ABSTRACT BODY:

Purpose: Keratoconus (KC) is the most common corneal ectasia and a major cause of corneal transplantation worldwide. Recent studies have suggested the contribution of two missense mutations (N843S and S419A) in the phosphatase domain of PPIP5K2 to the etiology of KC. PPIP5K2 is a cell-signaling kinase/phosphatase highly expressed in human and mouse cornea tissues. We aimed to identify the potential target genes of PPIP5K2 using human cancer cell line HCT116, primary human corneal epithelial cells (HCEC), and human corneal stromal fibroblast (HCSF).

Methods: First, differentially expressed (DE) genes were identified using Total RNA-Seq in HCT116 cells with stable PPIP5K2-knockdown (n=8). Data were analyzed by Ingenuity Pathway Analysis and WebGestalt's gene ontology analysis. Second, we knocked down PPIP5K2 expression in HCEC (n=3) and HCSF (n=3) for 24 hours using Dicer-Substrate Short Interfering RNAs (DsiRNA) via electroporation. Third, we validated changes in expression of six DE genes (MGMT, NR2F1, BMP4, HIST1H2AI, CDK6 and FUT8) in HCEC and HCSF using droplet digital PCR (ddPCR).

Results: We identified 81 genes with DE in HCT116 cells (|fold change| > 1.5, p<0.05). Pathway analyses implicated the enrichment of genes involved in protein degradation/synthesis, connective tissue disorders, cellular assembly and organization. The pathways affected include TGF β -signaling and LPS/IL-1 mediated inhibition of RXR function, which have been suggested to be involved in KC pathogenesis. We successfully decreased the expression of PPIP5K2 in human HCEC and HCSF cells for more than 80%. Following the successful knockdown of PPIP5K2 expression in HCEC and HCSF, our ddPCR data confirmed that CDK6 and HIST1H2AI were downregulated in HCEC whereas MGMT, NR2F1 and FUT8 were upregulated in HCSF, similar to those discovered in HCT116 cells.

Conclusions: We identified several target genes of PPIP5K2 in HCT116 cells and validated five target genes in primary HCEC and HCSF cells. In addition, we will perform Total RNA-Seq in PPIP5K2-knockdown corneal cells to identify DE genes and their pathways which may be more specific to corneal cells and contributing to KC.

TITLE: Microstructural Finite Element Modeling of the Entire Lamina Cribrosa in the Human Optic Nerve Head

SESSION TITLE: Glaucoma: molecular, biochemical and biomechanical disease mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.C. Downs, C.A. Girkin, R.G. Grytz, A. Karimi, Ophthalmology and Visual Sciences, The University of Alabama at Birmingham School of Medicine, Birmingham, Alabama, UNITED STATES|S.M. Rahmati, School of Biological Sciences, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): J Crawford Downs: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Girkin: Commercial Relationship: Code N (No Commercial Relationship) | Seyed Rahmati: Commercial Relationship: Code N (No Commercial Relationship) | Rafael Grytz: Commercial Relationship: Code N (No Commercial Relationship) | Alireza Karimi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The microstructure of the lamina cribrosa (LC), including the size, volume fraction, and orientation of the LC beams likely play a crucial role in protecting the retinal ganglion cell axons passing through the scleral canal. Prior computational models have been limited to multiscale approaches, in which a small chunk of the LC microstructure is subjected to displacement boundary conditions predicted from a parent mesoscale model. This regional approach cannot calculate the stresses and strains across the entire LC, and is unable to accurately represent the relatively compliant neural tissues (NT).

Methods: A finite element (FE) model of posterior pole of the eye was developed, including the LC microstructure that is constructed directly from the binary images of the LC microstructure (Figure). Models of three human donor eye were used to estimate the stresses and strains in the LC and NT under acute IOP elevation, and compared with identical models in which the LC was represented as a single material with either mapped connective tissue volume fraction (CTVF) and anisotropic properties based on local LC beam direction, or homogeneous isotropic neo-Hookean properties. The models were subjected to an IOP elevation to 45 mmHg after pre-stressing from 0 to 10 mmHg, and solved in CalculiX. ONH and LC displacements were matched across the three modeling approaches within each eye, and stresses and strains were compared for the LC and NT combined (continuum material and microstructural), and the LC and NT separately.

Results: The regional volumetric average von Mises stress, and 1st, 2nd, and 3rd principal stresses and strains showed that the microstructural model with neo-Hookean properties yielded similar results to our prior approach using an LC continuum representation with mapped CTVF/anisotropy, but the microstructural modeling approach allows analysis of the stresses and strains in the LC and NT separately. In the microstructural models, the LC beams carried most of the IOP load but exhibited less strain, while the encapsulated NT exhibited lower stresses and much higher strains. Strain levels matched prior experimental studies.

Conclusions: Microstructural modeling will provide greater insight into the biomechanical factors driving damage to the axons (NT) and connective tissue remodeling of the LC that occur in glaucoma.

TITLE: Levels of systemic VEGF-A and ranibizumab in the infant of a nursing mother receiving intravitreal ranibizumab therapy followed by a 'pump and dump' strategy

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Juncal, R. Kohly, S.B. Marafon, N.A. Figueiredo, L. Hostovsky, Y. Diambomba, K. Koushan, R.H. Muni, University of Toronto, Toronto, Ontario, CANADA]

Commercial Relationships Disclosure (Abstract): Verena Juncal: Commercial Relationship: Code N (No Commercial Relationship) | Radha Kohly: Commercial Relationship: Code N (No Commercial Relationship) | Samara Marafon: Commercial Relationship: Code N (No Commercial Relationship) | Natalia Figueiredo: Commercial Relationship: Code N (No Commercial Relationship) | Liran Hostovsky: Commercial Relationship: Code N (No Commercial Relationship) | Yenge Diambomba: Commercial Relationship: Code N (No Commercial Relationship) | Keyvan Koushan: Commercial Relationship: Code N (No Commercial Relationship) | Rajeev Muni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the levels of ranibizumab and vascular endothelial growth factor (VEGF)-A in the breast milk of a nursing mother and in the bloodstream of her infant after intravitreal ranibizumab injections followed by a 3-day 'pump and dump' strategy.

Methods: This is a prospective, interventional clinical study that included both a 34-year-old nursing patient who required bilateral ranibizumab injections post-partum and her newborn child. The mother received an injection of ranibizumab 0.5mg in each eye with 1-week interval between eyes. The infant was regularly breastfed, except for 3 days following each injection, when a 'pump and dump' strategy was adopted, where the mother regularly pumped and discarded the breast milk while the infant was fed exclusively with formula. Breast milk samples were obtained at baseline and then daily for 14 days after the first injection. The infant's blood samples were obtained daily for 11 days starting on the day before breastfeeding was resumed. Plasma and serum samples were obtained for VEGF-A and ranibizumab analysis, respectively. In addition, blood samples of 3 control infants of similar gestational age as the index infant were obtained and analyzed for plasma VEGF-A levels

Results: Ranibizumab levels remained below the lower limit of quantitation (LLOQ) of the assay at all time points in the mother's breast milk and in the infant's serum. VEGF-A levels in the breast milk gradually reduced from 5266pg/ml at baseline to 1537pg/ml at day 11, and then increased to 3438pg/ml at day 14. Plasma VEGF-A levels in the infant remained below the LLOQ at all time points, except for days 9 (20.45pg/ml) and 11 (13.19pg/ml). Plasma VEGF-A levels in the control patients were also below the LLOQ.

Conclusions: Ranibizumab was not detected in the infant of a nursing mother who received intravitreal ranibizumab injection followed by a 3-day 'pump and dump' strategy and systemic VEGF-A levels did not seem to be affected. This suggests that a 3-day 'pump and dump' strategy could possibly be a safe option for nursing mothers who require intravitreal ranibizumab therapy but want to continue breastfeeding.

TITLE: α B-crystallin super chaperone for treating protein aggregation diseases

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. MAHALINGAM, S. Srivastava, P. Santhoshkumar, K. Sharma, Department of Ophthalmology, University of Missouri, Columbia, Missouri, UNITED STATES|K. Sharma, Department of Biochemistry, University of Missouri, Columbia, Missouri, UNITED STATES|

Commercial Relationships Disclosure (Abstract): SUNDARARAJAN MAHALINGAM: Commercial Relationship: Code N (No Commercial Relationship) | Swati Srivastava: Commercial Relationship: Code N (No Commercial Relationship) | Puttur Santhoshkumar: Commercial Relationship: Code N (No Commercial Relationship) | K Krishna Sharma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: α B-crystallin super chaperone (α B Δ 54-61) can be prepared by deleting 54-61 amino acid residues in α B-crystallin. The objective of this study was to evaluate the therapeutic potentials of α B Δ 54-61 super chaperone using cell culture systems and *C. elegans* model system. Additionally, whether heat- or urea-induced unfolding and refolding of α B Δ 54-61 and WT protein increases the proteins ability to protect cells from oxidative stress and apoptosis was also evaluated.

Methods: The therapeutic efficacy of the WT- and Δ 54-61- α B-crystallins was investigated a *C. elegans* model (CL4176) for Alzheimer's disease (AD). The α B-crystallin response to counter thermal and chemical-induced stress was studied using wild type (N2 strain) *C. elegans*. The chaperone-like activity of heat-/urea-activated wild-type and α B Δ 54-61 were measured using luciferase and lysozyme as client proteins. The structural and molecular changes in Δ 54-61- α B-crystallin after urea/heat activation were investigated using multi-angle light scattering analysis method. The cytoprotective effects of the native and heat/urea-activated α B-crystallins were evaluated in ARPE-19 cells using cell integrity assay and 2,7-dichlorofluorescein diacetate staining.

Results: The super chaperone protected *C. elegans* (N2 strain) from paraquat and juglone-induced oxidative stress to a greater extent than did by wild-type α B-crystallin. The mutant super chaperone also prevented A β -induced toxicity on ARPE-19 cells in a more effective manner when compared to the wild-type protein. The mutant α B-crystallin also delayed A β -induced paralysis in a *C. elegans* model for AD and showed 10% increase in lifespan of the worm. *C. elegans* pre-treated with mutant α B-crystallin and exposed to thermal stress (35°C) showed a 11% increase in survival. In contrast, the wild-type protein treated worms showed no significant increase in survival when compared to placebo. Heat- and urea-induced unfolding/refolding events showed two-fold increase in the chaperone-like function with a concomitant increase in surface hydrophobicity of the mutant protein, even though increased hydrophobicity didn't result in enhanced cytoprotective effects.

Conclusions: Our findings suggest that α B-crystallin super chaperone (α B Δ 54-61) has improved therapeutic potential in cell culture and *C. elegans* model system.

ABSTRACT BODY:

Purpose: Patients primary open-angle glaucoma (POAG) are required to take long-term treatments with topical medications to halt disease progression. Measuring patients' acceptance of the use of the eyedrops prescribed should help to better understand and predict their behavior toward treatment. This issue has not been studied in glaucoma patients, especially in low-middle income nations. This cross-sectional survey aimed to describe the level of acceptance of Brazilian patients toward the long-term treatment with eyedrops and to find potential predictors of high acceptance.

Methods: POAG patient were recruited from the Glaucoma Service - Santa Casa of São Paulo, São Paulo, Brazil. Clinical and demographic data were retrieved from participants electronic records. All patients answered the ACCEPT® questionnaire. This is a generic patient-reported outcome questionnaire specifically developed to assess patients' acceptance of long-term medications. The questionnaire comprises seven independent dimensions: one on general acceptance (Acceptance/General) and six treatment-attribute specific, covering all specific attributes of drug: Acceptance/Medication Inconvenience, Acceptance/Long-term Treatment, Acceptance/Regimen Constraints, Acceptance/Numerous Medications, Acceptance/ Side effects, and Acceptance/Effectiveness. Scores based on categorical/ordinal data are linearly transformed to range from 0 to 100 with a higher score indicating greater acceptance.

Results: The sample comprised 96 patients with POAG. The mean age was 63.2 ± 8.9 years; 48 were male and 48 female; 55 (57.3%) were white, 36 (37.5%) African-Brazilian, and 5 (5.2 %) were of mixed color; most patients (97.9%) had less than high school degree and all had a family income $<USD8,000$. The mean ACCEPT score was 79.5 ± 6.0 .

Conclusions:

In this cohort of Brazilian patients with glaucoma, acceptance of treatment was high. The adequate interpretation of this data can provide valuable insights about patient priorities and current unmet needs.

ABSTRACT BODY:

Purpose: We previously reported A β accumulation in lenses from patients Alzheimer's Disease (AD) (Goldstein et al., 2003) and Down syndrome (Moncaster et al., 2010), a common chromosomal disorder in which age-related A β brain pathology is an invariant feature. A β co-localized with α B-crystallin in these lenses. Here we investigate the molecular mechanisms underpinning α B-crystallin interactions with A β and implications for AD pathogenesis.

Methods: Immunohistofluorescence, Confocal Microscopy, Immunogold electron microscopy, SDS-page and immunoblotting, electron paramagnetic resonance spectroscopy (EPR), quasi-elastic light scattering (QLS) spectroscopy, cell and organotypic slice culture, LDH and Propidium iodide assays.

Results: Electron paramagnetic resonance spectroscopy revealed that α B-crystallin dynamically interacts with and binds to A β in vitro in concordance with previous findings. Quasi-elastic light scattering spectroscopy showed that α B-crystallin suppresses formation of high molecular weight A β aggregates by stabilizing soluble hetero-oligomeric complexes. However, whilst co-incubation of α B-crystallin and A β suppressed A β fibrillogenesis, α B-crystallin potentiated A β neurotoxicity in mouse primary neurons and organotypic rat hippocampus slice culture as detected by LDH and Propidium Iodide assays.

Conclusions: These results indicate that α B-crystallin potentiates A β neurotoxicity by stabilizing soluble hetero-oligomers.

ABSTRACT BODY:

Purpose: To evaluate a novel topical ointment AZR-MD-001 1%, containing selenium disulphide, on ocular signs and symptoms in symptomatic contact lens wearers in a 4 month prospective placebo controlled double masked randomised trial.

Methods: Symptomatic contact lens wearers (Contact Lens Dry Eye Questionnaire-8 [CLDEQ-8] score >12) with signs of Meibomian Gland Dysfunction (Meibomian Gland secretion score [MGS] ≤12) were enrolled. Participants were randomly assigned to receive either the test AZR-MD-001 1% or vehicle ointment to the lower eyelid margin twice per week (NCT03972501). MGS and number of Meibomian glands yielding liquid secretion (MGYLS) were measured at baseline, after 2, 4, 6 weeks and 2, 3 and 4 months of treatment. CLDEQ-8 was completed at baseline, 1 and 4 months. Differences between active and vehicle were analysed relative to baseline using ANCOVA.

Results: Fourteen subjects (5 males, 9 females, aged 30.8 ± 13.8 years) completed the study. Compared to baseline, change in MGS significantly improved in the active treatment group after 2 weeks (Mean 3.4 ± 6.1 , $p < 0.05$) and continued to improve to four months (19.5 ± 7.6 , $p < 0.0001$). In the vehicle group, change in MGS from baseline improved at month 4 (Mean 16 ± 10.1 , $p < 0.005$). Compared to baseline, the change in MGLYS was not significant in the active group after 2 and 4 weeks (Mean 0.7 ± 1.8 ; 2.1 ± 3.4 , respectively), but improved after 6 weeks (3.5 ± 3.4 , $p < 0.001$) and remained significantly improved by month 4 (3.4 ± 4.1 , $p < 0.001$). In the vehicle group, change in MGLYS from baseline was improved at 4 months only. The active reached statistical superiority over the vehicle in both change in MGS and MGLYS at 6 weeks onwards. Both active and control showed a significant improvement in CLDEQ-8 score at 1 and 4 months. At 4 months a larger proportion of subjects using the active (5/7) showed a clinical improvement in CLDEQ-8 score compared with placebo (2/7, $p = 0.11$).

Conclusions: Use of a topical ointment containing selenium disulphide, designed to treat hyperkeratinisation at the gland orifices, appears to improve Meibomian gland patency and secretion by more than 30% in symptomatic contact lens wearers after six weeks of twice weekly use compared to placebo. Improvements were maintained to 4 months of use. These early findings including improved symptoms warrant further exploration.

ABSTRACT BODY:

Purpose: RHODOPSIN (RHO) mutations accounts for ~25-30% of autosomal dominant retinitis pigmentosa (adRP). Structural instability of mutant rhodopsin (RHO) causes dominant negative effect leads to the death of rod photoreceptors and vision loss. We hypothesize to restore the RHO homeostasis and rescue rods from RHO-associated adRP using previously discovered non-retinoid chaperone of RHO. The goal of this study is to test this hypothesis in ex vivo culture of the Rho^{P23H/+} knock-in mouse retina.

Methods: We established retinal explant culture with RPE from the Rho^{P23H/+} and Rho^{+/+} mouse. Retinal morphology was analyzed by immunohistochemistry (IHC) of retinal explants at different days in vitro (DIV). To test the effect of small molecule chaperone on RHO homeostasis and retinal degeneration, Rho^{P23H/+} retinal explants were treated with the compound and DMSO for 10 DIV. Retinae were collected for IHC, immunoblots and RNA-seq. The safety of compound was examined by TUNEL assay using Rho^{+/+} retinal explants.

Results: IHC of RHO showed a gradual decrease of RHO level and outer segment (OS) length in both the Rho^{P23H/+} and Rho^{+/+} retinae along with time. The Rho^{P23H/+}, but not Rho^{+/+} retinal explants showed a time-dependent decrease of outer nuclear layer (ONL), confirming a progressive degeneration in dish as seen in vivo. Importantly, treated with the compound, the Rho^{P23H/+} retinae showed higher RHO level, improved RHO glycosylation, less ubiquitinated RHO, longer OS length, and thicker ONL, suggesting the compound indeed improved RHO homeostasis and supported photoreceptor survival. Interestingly, this small molecule increased the ratio of RHO in the OS/IS layer to that in the ONL of Rho^{P23H/P23H} retinal explants, consolidating its chaperone activity. The RNA-seq data suggests that the compound mitigated the primary immune response and reduced microglia activation. Additionally, protein homeostasis pathways were upregulated.

Conclusions: We showed that the non-retinoid chaperone improved RHO homeostasis and protected photoreceptors in the Rho^{P23H/+} knock-in mouse retinae in ex vivo culture. The efficacious dose of the compound showed no significant toxicity. Our results strongly support the notion that improving RHO homeostasis is sufficient to protect retina from RHO-associated adRP. Future development of a continuous ocular drug delivery system will allow us to test the efficacy of this compound in vivo.

ABSTRACT BODY:

Purpose: To assess the performance of machine learning algorithms in detecting keratoconus (KCN) from corneal parameters in a tomography dataset, such as elevation, topography, and pachymetry.

Methods: We developed numerous machine learning models to detect keratoconus from corneal parameters. Elevation, topography and pachymetry dataset were obtained from 5881 eyes of 2800 patients in Brazil using a high-resolution rotating Scheimpflug camera system for anterior segment analysis (Pentacam® HR – Oculus, Optikgeräte GmbH). The accuracy of models was computed using each dataset of elevation, topography and pachymetry parameters separately. 10-fold cross validation of the area under the receiver operating characteristic curve (AUC) was used to evaluate the accuracy of different models. Thus, 3 independent datasets were created. Each of them was evaluated, and performance evaluation related to KCN detection was observed.

Results: A total of 1726 eyes were normal, and 4155 eyes were diagnosed as KCN. Figure 1 presents the distribution of the anterior cornea curvature radius (ACCR) of the cornea parameter versus the mean radius of cornea curvature (MRCC) in the 7 to 9 mm area parameter of normal versus KCN eyes. The cubic support vector machine (SVM) outperformed all other machine learning classifiers with an AUC of 1 for detecting KCN using elevation parameters only (Figure 2, ROC on left and confusion matrix on the right panel). The highest accuracy of classifiers for detecting KCN using pachymetry only and topography only parameters were 96.6% and 95.2%, respectively.

Conclusions: The results suggest that the cubic support vector machine (SVM) using elevation parameters provide the highest accuracy in detecting normal from KCN cases. This algorithm might be of help for detecting KCN patients in ophthalmological clinical sets.

ABSTRACT BODY:

Purpose: While one might expect that universal masking would decrease the risk of oral flora contamination during the injection procedure, anecdotal reports of oral flora-related endophthalmitis during COVID-19 have emerged. We performed a prospective observational cohort study to determine the effect of taping the top of face masks on air particle counts directed toward the eye during simulated intravitreal injections.

Methods: Thirteen healthy N95 qualitative fit tested human subjects were recruited, three women and ten men, with an age range of [24, 35]. Each wore a cloth, surgical, or N95 mask in randomized order. The number of air particles were quantified using a particle counter suspended over the right eye while each subject breathed normally, deeply, or spoke using a standardized script. Particle counts were obtained with the top of each mask taped and untaped. The main outcome measurements were particle counts in the size classes of 0.3 mm, 0.5 mm, 1 mm, 3 mm, 5 mm, 10 mm, and total particle count. The Wilcoxon signed rank test was used to test for paired differences between taped and untaped particle counts for each combination of mask type and respiratory mode, at each particle size.

Results: Taping cloth masks while subjects were speaking significantly reduced particle counts for the size classes of 0.3 mm ($p=0.03$), 0.5 mm ($p=0.01$), 1 mm ($p=0.03$), and total particle counts ($p=0.008$) compared to no taping. Taping the top of cloth masks during normal or deep breathing did not significantly affect particle counts compared to no taping. Taping the top of surgical or N95 masks did not significantly alter particle counts for any breathing condition tested.

Conclusions: Taping the top of cloth masks prior to simulated intravitreal injections significantly reduced air particle counts directed toward the eye when subjects were speaking compared to no taping. This may have implications for decreasing air particles reaching the eye during intravitreal injections, including aerosolized droplets from a patient's mouth that may carry oral pathogens.

ABSTRACT BODY:

Purpose: We previously showed that microRNA-10b (miR-10b) is one of the most abundant limbal miRNAs, which is upregulated in the limbus vs. central cornea and may regulate corneal epithelial homeostasis and stem cell functions. Additionally, we showed its upregulation in diabetic (DM) vs. normal limbus, which may contribute to diabetic corneal disease. Our purpose was to investigate miR-10b target genes and regulated proteins using combined genomic and proteomic analyses to elucidate its role in the limbus.

Methods: Human autopsy normal corneas were procured from the National Disease Research Interchange in Optisol medium. In vitro experiments were performed with stem cell-enriched human primary limbal epithelial cells (LECs). LECs were transfected with either miR-10b mimic, inhibitor, or their corresponding controls using Lipofectamine RNAiMAX (Thermo Fisher) following the manufacturer's instructions. At day 3 post-transfection cells were harvested for total RNA isolation using Trizol for next generation mRNA sequencing. A matching set of transfected cells was collected and analyzed by global proteomic analysis.

Results: Proteomics and mRNA-seq elucidated changes in pathways regulating limbal epithelial stem cells (LESC) maintenance and differentiation as a result of miR-10b overexpression in LECs. Our previous findings indicated major transcription factors controlling eye development and maintenance of the cornea as potential targets of miR-10b. Our current study found that miR-10b mimic downregulates KLF4, RAP2A, and EPHB2 that regulate epithelial-mesenchymal transition. Pathway analysis indicated a role in cell cycle regulation because of changes in related predicted miR-10b targets — E2F7 and CDK6. Previous findings showed that miR-10b increased LEC proliferation. Transfection with miR-10b resulted in downregulation of DKK1, GSK3B, CEMIP, and NEDD4/L that regulate canonical Wnt signaling pathway. There was a good concordance between the two methods.

Conclusions: Our data revealed potential direct targets of miR-10b and unveiled the underlying pathways affecting human limbal epithelial cell maintenance, proliferation and self-renewal. Combined approach of proteomics and genomics profiling provides insight into the regulation by microRNAs of their targets on a genome/proteome-wide scale.

ABSTRACT BODY:

Purpose: The poor visual outcomes associated with fungal keratitis (FK) is attributable, in part, to the ineffectiveness of current antifungals. The development of novel therapy requires the identification of putative targets in the fungus, which we reasoned include pathways involved in the assimilation of corneal collagen (protein) as a nutrient source. The fungal unfolded protein response (UPR) is critical in this regard as it maintains the fidelity of the secretion pathway and, consequently, the release of collagenases into the cornea. Accordingly, we tested the hypothesis that the UPR is essential for corneal virulence in a predominant agent of FK, *Aspergillus fumigatus*.

Methods: The gene encoding HacA, a transcription factor essential for the UPR, was deleted in *A. fumigatus* using a CRISPR/Cas9 method, and the resulting mutant (hacA KO) was confirmed by PCR. Collagenase secretion was measured in culture supernatants using azocollagen hydrolysis (Millipore Sigma). Stress sensitivity assays were performed in rich (YPD) or minimal media as indicated. For the virulence studies, C57BL/6J mice were immunosuppressed with methylprednisolone (100mg/kg) on the days preceding and following infection. On the day of infection, corneas were abraded with an algerbrush and topically inoculated with germinated spores of the WT or hacA KO strains (n= 20/group). At 48 or 72 h post-inoculation, eyes were clinically scored and corneas were resected for histological analysis (PASH staining) or fungal burden assessment using colony-forming units (CFUs). WT and hacA KO data sets were compared by student's T-test.

Results: The *A. fumigatus* hacA KO mutant displayed hypersensitivity to stresses that induce protein misfolding, including increased temperature, DTT, and tunicamycin. The mutant was also deficient in secreted collagenase activity and could not grow on biological tissue ex vivo. Compared to mice infected with WT *A. fumigatus*, hacA KO-infected corneas displayed decreased clinical scores and fungal burden; this corresponded with the histopathology, which revealed reduced neutrophil infiltration and essentially no fungal invasion into the stroma.

Conclusions: Our results confirm our hypothesis that the UPR is essential for *A. fumigatus* nutrient acquisition on protein-rich substrates as well as virulence in a murine model of FK. These data suggest that the fungal UPR could serve as a target for antifungal intervention.

ABSTRACT BODY:

Purpose: Sensory innervation of the cornea is essential for the perception of stimuli critical for blinking, maintenance of hydration, and injury avoidance. Disease, infection and ophthalmic surgical procedures can all damage corneal central nerves, resulting in scarring and vision problems. Corneal nerves regenerate over several years, however, sub-basal nerve density never returns to normal. Despite the clinical need to promote corneal nerve regeneration, few specific therapeutic interventions are available. Cell therapy, specifically MSCs presents an attractive treatment option for enhancing nerve regeneration in this critical ocular structure. In this project, we studied the role of MSCs in corneal nerve regeneration.

Methods: Mouse TGs neurons were isolated from Thy1-YFP mice which have fluorescent corneal nerves. Human corneal MSCs (CO-MSCs) and bone marrow MSCs (BM-MSCs) were used. 2D and 3D co-culture system was developed to grow TGs in presence of each type of MSCs. The morphology of the TGs was monitored over 7 days. Cells were then fixed and immune-stained on day 7. Immunocytochemistry was performed to observe $\beta 3$ tubulin and CD90 expression marker for TGs and MSCs respectively. Confocal microscopy and Neurolucida software used to analyze the density and length of the neurites in different conditions.

Results: Morphology observations illustrated enhanced axonal growth and survival over time in presence of MSCs compared to TG-only conditions. After 5 days, TGs started to shrink and finally die after 8 to 10 days whereas TGs in presence of MSCs showed enhanced survival after 2 weeks in culture. Immunostaining data ($\beta 3$ tubulin/CD90) and then analysis using Neurolucida illustrated a significant increase in density and the complexity of the TGs in the co-culture system versus TGs alone. Finally, a significant increase in neuron branching was observed in 3D versus 2D.

Conclusions: These results demonstrate the distinct effect of MSCs in maintenance, growth, and elongation of neurites nerve regeneration over time. Further functional experiments will be performed to study the effect of MSCs in vivo and the mechanisms by which MSCs can promote corneal nerve regeneration after injury. These studies will enable us to develop highly novel therapeutics for the restoration of damaged corneal nerves and potentially, other ocular diseases.

ABSTRACT BODY:

Purpose: Complement factor H (CFH) regulates alternative complement pathway activation. The non-canonical functions of CFH in the eye are also of interest, as recombinant human CFH (rhCFH; GEM103) is in development for the treatment of geographic atrophy in a genetically-defined age-related macular degeneration population. The hypothesis that rhCFH has anti-angiogenic activity in the eye was tested in a laser induced choroidal neovascularization (CNV) mouse model. To better understand the CNV phenotype reported in mice locally treated with polyethylene glycol (PEG;PMID:25088354), we tested the hypothesis that PEG treatment increases vascular endothelial growth factor (VEGF) production in retinal pigment epithelial (RPE) cells.

Methods: In mice, CNV was induced using a 532nm laser. Three days post laser, both eyes of each animal were intravitreally (IVT) treated with either rhCFH, aflibercept (anti-VEGF; positive control) or vehicle. CNV severity was determined by fluorescein angiography (FA), optical coherence tomography (OCT) in live animals on days 12 & 15, and isolectin B4 (ISB4) staining intensity on day 15 retinal flatmounts. In the cell-based model, induced pluripotent stem cell derived (iPS) RPE were treated for 28 days with either of PEG or vehicle. Conditioned media and cell lysates were collected on days 0, 2, 14 and 28 for VEGF protein and mRNA assessment, respectively.

Results: FA grades in rhCFH treated animals were decreased compared to vehicle at days 12 and 15 ($P<0.0001$) and were comparable to aflibercept treated mice ($P>0.99$). OCT-defined CNV area was also reduced in the rhCFH cohort at d12 ($P<0.001$) and 15 ($P<0.05$). A decrease in ISB4 staining intensity was observed in retinal flat mounts from rhCFH- vs PBS- treated mice ($P=0.008$). In cultured iPS RPE, an increase in VEGF mRNA and protein was observed following 2 or 4 weeks of treatment with PEG compared to vehicle ($P<0.0001$).

Conclusions: CNV severity was significantly reduced in rhCFH-treated mice compared to PBS group while being similar to aflibercept-treated controls, as measured by FA grading, OCT area, and ISB4 staining. These results demonstrate that IVT administration of rhCFH can provide anti-angiogenic effects in the eye and would not pose an increased risk of CNV development. In contrast, treatment with PEGylated molecules, has a potential to enhance VEGF secretion from RPE cells.

ABSTRACT BODY:

Purpose: To assess the clinical value of optical coherence tomography angiography (OCTA) for monitoring proliferative diabetic retinopathy (PDR).

Methods: In this prospective cohort study, we enrolled PDR patients with neovascularization (NV) within the Early Treatment Diabetic Retinopathy Study fields 1 or 2. Clinicians treated the eyes per standard of care. Participants underwent high-definition (400x400) 6x6-mm OCTA scans centered on disc, fovea, and temporal retina consecutively with ~0.5mm overlap using a commercial spectral-domain OCTA system. A custom algorithm measured the NV vessel area and the central non-perfusion area (NPA) on en face OCTA. The OCTA images of baseline and 1-year follow-up visits were registered for comparison.

Results: We included 10 eyes of 9 PDR patients (6 male) with 13 NVs (2 NVs/eye in 3 eyes), including 1 NV at the disc and 12 NV elsewhere, detected on OCTA scans. The clinical characteristics of the study participants were summarized in table 1. From baseline to one-year follow-up visit, the macular NPA increased on average 8.6% ($P=0.25$); while the NV vessel area decreased on average 25.5% ($P=0.37$) (Figure 1). Four eyes did not receive any treatment during the follow-up, while 6 eyes were treated with multiple anti-VEGF injections. The NV vessel area in untreated eyes enlarged significantly more than that in treated eyes (increased 9.4% vs. decreased 48.7%, $P=0.017$). The NPA changes were similar in treated and untreated eyes (9.9% vs. 7.8%, $P=0.96$).

Conclusions: OCTA is useful for quantifying and monitoring NV in PDR. Anti-VEGF treatment reduces NV growth, but does not affect NPA enlargement.

Commercial Relationships Disclosure (Abstract): Tamara Voor: Commercial Relationship: Code N (No Commercial Relationship) | Hank Patrick: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Lee: Commercial Relationship: Code N (No Commercial Relationship) | Angeline Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the outcomes of patients undergoing pars plana vitrectomy (PPV) surgery for complications of proliferative diabetic retinopathy (PDR).

Methods: Retrospective, observational chart review of 291 eyes of 217 patients that underwent PPV for complications of PDR at a large county hospital in Dallas, Texas from 2014 to 2019. Outcome measures included retinal re-attachment success rate, best-corrected visual acuity, and need for repeat PPV. Patients were excluded if they had less than 6 months of follow-up.

Results: Patients were 55.8% male and 44.2% female with an average age of 51 years (standard deviation (SD) of ± 9.5). Patients were followed for an average of 27.6 months, with a range of 6 to 71 months. The average Hgb A1c at time of surgery was 8.1 (SD ± 2.0). 72.3% of patients had their insurance covered by charity and 18.2% were covered by Medicaid/Medicare. 202 (93.1%) patients had other vascular risk factors or complications from diabetes, including hypertension (88.0%), hyperlipidemia (54.8%), chronic kidney disease (43.3%), need for dialysis (12.4%), coronary artery disease (8.8%), peripheral neuropathy (7.8%), need for amputation (7.4%), myocardial infarction (6.9%), and stroke (6.5%).

PPV surgery was performed for non-clearing vitreous hemorrhage in 110 eyes (37.8%), tractional retinal detachment (TRD) involving the macula in 98 eyes (33.7%), TRD not involving the macula in 50 eyes (17.2%), combined TRD and rhegmatogenous retinal detachment in 19 eyes (6.4%), and vitreomacular interface abnormalities in 14 eyes (4.7%). 81 eyes (27.8%) required gas tamponade and 29 eyes (10.0%) required silicone oil.

Average logMAR visual acuity was 1.75 (SD ± 0.74) pre-operatively and 0.92 (SD ± 0.87) at 1 year post-op. Retinal re-attachment success rate for patients with TRDs was 77.6% at 6 mo, 62.1% at 1 year, and 88.8% at most recent follow up. Common post-op complications included VH within 6 mos and cataracts. As of the most recent follow-up, 79 eyes (27%) needed repeat PPV and 91 (31.2%) needed cataract extraction (CE).

Conclusions: This study shows that vitrectomy is an overall safe and effective procedure that improves vision and stabilizes the retina in those with complications from PDR.

TITLE: A glial point of view: investigating corneal Schwann cells in ex vivo murine organ and whole-eye cultures

SESSION TITLE: Corneal Stromal Repair and Corneal Biology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: G. Schultz, University of Connecticut School of Medicine, Farmington, Connecticut, UNITED STATES|P. Bargagna-Mohan, R. Mohan, Neuroscience, UConn Health, Farmington, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gwendolyn Schultz: Commercial Relationship: Code N (No Commercial Relationship) | Paola Bargagna-Mohan: Commercial Relationship: Code N (No Commercial Relationship) | Royce Mohan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the setting of human corneal transplants and refractive surgery, incomplete stromal reinnervation and/or axonal degeneration pose clinical concerns. Corneal Schwann cells (cSCs) are glial cells that ensheath and provide trophic support to stromal axons. To investigate cSCs during corneal tissue preservation, as well as to study how stromal injury impacts cSCs, we analyzed the expression of cSC markers using ex vivo mouse corneal and eye-globe models.

Methods: We used adult wild-type (WT) C57LB6 mice, and PLP-eGFP transgenic mice (Bargagna-Mohan et al., J. Neurosci. Res., 2020). For the organ culture model, WT (n= 6) and PLP-eGFP (n=4) corneas including limbal tissue were excised, and cultured at 37°C in Opti-minimal essential medium containing 4% Dextran, 8% fetal bovine serum, and a cocktail of antibiotic/antimycotic for 6 days (6d). For the whole-eye model, after eye enucleation, using a 1.5-mm diameter trephine a circular incision was made on WT corneas to injure the stroma. Control (uninjured, n= 5) and injured eye-globes (n= 10) were cultured for 6d, and after fixation, corneas were isolated. All corneas were then processed for whole mount immunohistochemical analysis using the axonal marker b-III tubulin and cSC markers PLP-1 and DKK. Stained tissues were examined by epifluorescence microscopy.

Results: In the organ culture model, 6d post-culture caused a loss of axonal density mostly in the central zone in both WT and PLP corneas. At the limbus/peripheral zone, b-III tubulin+ axons co-stained with PLP-1+ and DKK+ cSCs, whereas in the mid-central cornea b-III tubulin staining was fragmented, and showed some axons lacking PLP-1 and DKK staining. In the whole-eye model, axonal integrity was more evident at the proximal sites where viability of cSCs was higher. At the distal sites trephine injury caused b-III tubulin fragmentation and downregulation of PLP-1 and DKK expression, suggesting these severed axons are highly sensitive to cSC loss.

Conclusions: Our results suggest that cSCs in the central cornea lose expression of PLP-1 and DKK after 6d in culture. This loss of expression appears to be associated with a certain degree of axonal degeneration, which is possibly due to a loss of trophic support from cSCs. Further studies will explore methods of how to best support the cSCs, and thus, the neural network that is crucial for corneal function.

ABSTRACT BODY:

Purpose: This study determines how a novel cataract surgery grading system at a single U.S. teaching institution may predict intra-operative complications and post-operative outcomes.

Methods: This is a retrospective observational study on non-consecutive cataract surgical cases performed by residents at Columbia University Irving Medical Center/Edward S. Harkness Eye Institute. Risk scores (Table), preoperative best-corrected visual acuity (BCVA), intra-operative complications, post-operative day 1 (POD1) and month 1 (POM1) BCVA, and POM1 exam findings were tabulated. Risk scores were used to stratify cases among residents at different levels of training. The relationship between preoperative risk scores and POD1/POM1 BCVA was modeled using linear regression. The relationship between preoperative risk scores and rates of each type of complication was modeled using logistic regression. Logistic regression was used to model the rates of complications across different levels of training, and odds ratios were calculated before and after adjusting for case mix using risk scores.

Results: Data was collected on 530 cases from January 2017 to May 2020 and risk scores ranged from 0 to 8 (mean = 1.31). Mean POM1 visual acuity was 0.37 LogMAR, and 80% of cases had visual acuity equal to or better than 20/30 at POM1. Average POM1 visual acuity for cases that had posterior capsular rupture was 0.56. Risk scores did not have a significant association with posterior capsule rupture. Risk scores were predictive of corneal edema (OR = 1.36, p = 0.0032), having any POM1 complication (OR = 1.20, p = 0.034), and having any complication overall (OR = 1.21, p = 0.014). Risk scores were also predictive of POD1 (β = 0.13, p < 0.0001) and POM1 (β = 0.057, p = 0.00048) visual acuity. There was not a significant association between level of training and rates of intra-operative or post-operative complications, both before and after adjusting for case mix (p > 0.05).

Conclusions: Our pre-operative cataract surgical risk score was highly correlated with post-operative visual acuity and the presence of POM1 corneal edema. Risk scores were also predictive for any POM1 complication and any complication overall. Rates of complications were not correlated to the year of training, both before and after adjusting for the risk score.

ABSTRACT BODY:

Purpose: Glucagon-like peptide-1 receptor (GLP1R) agonists regulate blood glucose and are commonly used to treat type II diabetes. Recent work by our group showed that treatment with the novel GLP1R agonist NLY01 mitigated neuroinflammation and decreased glial activation to rescue retinal ganglion cells in an animal model of glaucoma (PMID 33147455). In this study, we used insurance claims data to examine whether GLP1R agonists impacted glaucoma risk.

Methods: A retrospective cohort of adult patients who initiated a new GLP1R agonist (i.e. exenatide, liraglutide, albiglutide, dulaglutide, semaglutide, or lixisenatide) was 1:3 age, gender, race, classes of active diabetes medication, and year of index date matched to a cohort of patients who initiated a different class of oral diabetic medication during their time in the database. Exclusion occurred for < 2 years in the database, < 18 years old, failure to visit an eyecare provider prior to the index date, a prior diagnosis of glaucoma, glaucoma suspect, or ocular hypertension, and prior glaucoma medication, procedure, or surgery. Primary outcome was a new diagnosis of primary open angle glaucoma, glaucoma suspect, or low tension glaucoma. Diabetes severity was assessed using hemoglobin A1c and the Diabetes Complications Severity Index (DCSI), a validated metric based on six categories of diabetic complications. Inverse probability of treatment weight (IPTW) was used within a multivariable Cox proportional hazard regression model to test the association between exposure to GLP1R agonists and the primary outcome. IPTW was derived from a propensity score model based on the DCSI, HbA1c, demographic factors, and other systemic health conditions.

Results: Cohorts were comprised of 1961 new users of GLP1R agonists matched to 4371 unexposed controls. After IPTW, age was the only imbalanced covariate between cohorts (SMD > 0.1). Ten new diagnoses of glaucoma (0.51%) were present in the GLP1R agonist cohort compared to 58 (1.33%) in the unexposed controls, conferring a reduced hazard of 0.54 (95%CI: 0.35-0.85, p=0.007) among GLP1R agonist initiators, suggesting that GLP1R agonists reduced the risk for glaucoma.

Conclusions: GLP1R agonists were associated with a statistically significant hazard reduction for a new glaucoma diagnosis. Our findings support further investigations into the use of GLP1R agonists in glaucoma prevention.

ABSTRACT BODY:

Purpose: Coronavirus disease 2019 (COVID-19) is a pandemic viral illness which may predispose to co-infections and whose ophthalmic manifestations are still not well understood. This study was performed to determine the rate of bacterial or fungal co-infection and associated endogenous endophthalmitis in inpatients with COVID-19.

Methods: This was a retrospective cohort study of inpatients with COVID-19-associated pneumonia at seven general hospitals in Louisville, Kentucky from March to May 2020. All patients were positive by polymerase chain reaction for SARS-CoV-2 and had clinical evidence of pneumonia necessitating hospital admission. Records were reviewed for demographic data, clinical evidence of systemic bacterial or fungal co-infection, culture results, and evidence of endophthalmitis.

Results: There were 632 patients in this study. Median age was 63 (IQR 48-74), and 53% were female. 65 of them (10.3%) had a systemic, culture-positive bacterial or fungal co-infection (60 bacterial, 5 fungal). Of these 65 patients, 11 developed bacteremia (16.9% of co-infected patients; 1.7% of all COVID inpatients). One patient with Streptococcal bacteremia and septic arthritis developed endogenous endophthalmitis in one eye (1/65 co-infected patients, 1.5%; 1/632 total COVID inpatients, 0.16%), which was successfully treated with intravitreal antibiotics. No patients with negative blood cultures developed endophthalmitis, although the sole endophthalmitis patient presented with intraocular infection prior to blood cultures being positive.

Conclusions: Bacterial or fungal co-infection is relatively common in inpatients with COVID-19. Endogenous bacterial endophthalmitis, while rare, is still a possible and potentially devastating complication of the disease. Consequently, visual complaints in COVID-19 inpatients should be assessed promptly.

ABSTRACT BODY:

Purpose: Phenotypic and genotypic associations in childhood and early-onset glaucoma have not been well described in large datasets due to disease rarity, inconsistent use of disease definitions and limited availability of genetic testing. We performed a retrospective clinical and molecular study to report the relative frequencies of childhood and early-onset glaucoma subtypes and their genetic findings in a large single cohort.

Methods: We reviewed the referrals of individuals with childhood glaucoma (diagnosed 0 to <18 years) and early-onset glaucoma (diagnosed 18 to <40 years) recruited to the Australian and New Zealand Registry of Advanced Glaucoma (ANZRAG) over a 13-year period (2007-2020). Subtypes of glaucoma were determined using the Childhood Glaucoma Research Network (CGRN) classifications. DNA extracted from blood or saliva samples underwent sequencing of genes associated with glaucoma.

Results: 290 individuals with childhood glaucoma and 370 individuals with early-onset glaucoma were referred to the ANZRAG. Primary glaucoma was most prevalent in both cohorts. In the childhood cohort, 57.6% of individuals (167/290) had primary congenital glaucoma and 19.3% (56/290) had juvenile open-angle glaucoma (JOAG). JOAG constituted 73.2% of the early-onset glaucoma cohort (271/370). Genetic testing in probands resulted in a diagnostic yield of 24.7% (125/506) and a reclassification of glaucoma subtype in 10.4% of probands (13/125). The highest molecular diagnostic rate was achieved in probands with glaucoma associated with non-acquired ocular anomalies (56.5%). Pathogenic variants in 18 genes associated with childhood and early-onset glaucoma were found. Biallelic variants in CYP1B1 (n=29; 5.7%) and heterozygous variants in MYOC (n=24; 4.7%) and FOXC1 (n=21; 4.2%) were most commonly reported amongst probands. Biallelic CYP1B1 variants were reported in twice as many females as

males (66.7% vs. 33.3%; $p=0.01$).

Conclusions: We report on one of the largest international childhood and early-onset glaucoma cohorts using the CGRN classifications. Primary glaucomas were more prevalent than secondary glaucomas. Genetic diagnoses ascertained in 24.7% of probands supported clinical diagnoses and genetic counselling. International collaborative efforts to characterise genetic associations in rare phenotypes will improve genetic diagnostic rates and management of childhood and early-onset glaucoma.

ABSTRACT BODY:

Purpose: Cumulative UV exposure is significant in skin melanoma, and implicated in primary iris melanoma. UV, absorbed by the cornea, iris, lens, and vitreous, does not reach the posterior eye however visible (white) light radiates the retina, underlying retinal pigmented epithelium (RPE), and choroid. The effects of visible light exposure on the choroidal microenvironment and potential roles in choroidal melanoma progression are unknown. This preliminary study investigated if acute light exposure affected viability and secretion of pro-inflammatory CCL2 and IL8 (involved in macrophage and neutrophil migration) in human choroidal melanoma cells.

Methods: Choroidal melanoma cells were grown in RPMI with FBS, L-glutamine and sodium pyruvate (MP38 and MP46: RPMI+20% FBS; 92.1: RPMI+10% FBS). ARPE19 cells (DMEM+10% FBS, L-glutamine, and +/- pyruvate) were used as controls; RPE cells in vivo normally absorb abundant visible light. Cells were grown in 96 well black plates (8000 cells/well) (n=5 per cell line; in triplicate) for 18hrs, then fresh medium (with 1% FBS) for 16 hours. Cells were then exposed to 32,000 lux light (LED, λ : 400-700nm) for 4 hours (37°C); unexposed control cells were grown in parallel conditions. Viability of light-exposed and control cells was measured with alamarBlue. Conditioned medium (light-exposed and control) was assessed with ELISA for pro-inflammatory cytokines, CCL2 and IL8.

Results: Viability was reduced 10% to 15% immediately after light exposure for 92.1 and MP46 cells ($p<0.05$; t-test) but not MP38 cells ($p>0.05$). Surprisingly, ARPE19 cells showed dramatic cell death (~100%) after light exposure, that was mitigated by sodium pyruvate (110mg/ml). Secretion of CCL2 and IL8 was not induced following light exposure for any cell lines (light and control: ~20-100 pg/ml).

Conclusions: Acute light exposure reduced viability of MP46 and 92.1 melanoma cells but not MP38 cells, possibly due to melanin levels (MP38>MP46 and 92.1). No increase in CCL2 and IL8 secretion was noted following light exposure for melanoma cells, however, cumulative effects of light exposure, resembling real-life, remain to be clarified. Incidental light-induced ARPE19 cell death, ameliorated with sodium pyruvate, indicates effects on metabolism and reduced oxidative stress, and will be studied further.

Commercial Relationships Disclosure (Abstract): Peng Yan: Commercial Relationship: Code N (No Commercial Relationship) | James Im: Commercial Relationship: Code N (No Commercial Relationship) | Ronald Chow: Commercial Relationship: Code N (No Commercial Relationship) | Yaping Jin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic macular edema (DME) is a leading cause of vision loss among people of working age with diabetes. It is a major public health issue. Optical coherence tomography (OCT) technology allows for accurate assessment of DME but systematic reviews on the prevalence of DME diagnosed based on OCT are lacking. A systematic review and meta-analysis was performed to assess the global prevalence of DME diagnosed with OCT.

Methods: Three electronic databases (EMBASE, CINAHL and PubMed) were searched on May 25, 2020 using key words such as “diabetic macular edema”, “prevalence” and “optical coherence tomography”. The quality of retrieved studies was evaluated using the Joanna Briggs Institute Checklist for Prevalence Studies. Pooled prevalence estimates and 95% confidence intervals (CI) were calculated using a random-effects model following the assessment of heterogeneity (I^2).

Results: The search found 1524 studies. After removing duplicates, 1245 studies remained. After abstract screening and full-text assessment based on pre-established criteria, six studies were included in the meta-analysis. The sample size of included studies ranged from 75 to 978 patients, with a mean age of 50.6-68.2 years. Four studies had more females (51.1%-61.5%). The other two studies had predominantly males (64.5% and 74.4%). Three studies were conducted in developed countries and three studies in developing countries. The prevalence of DME ranged from 4.0% to 48.7% among individual studies. The associated I^2 value was 98.9%, suggesting that the random effects model was appropriate to combine individual studies. The pooled prevalence of DME was 17.9% (95% CI: 5.4%-35.5%) overall, 18.6% (95% CI 7.7%-32.8%) in developed countries and 17.7% (95% CI: 1.0%-47.7%) in developing countries. In comparison, using fundus photography exams, a meta-analysis published in 2012 reported a pooled prevalence of DME of 6.81%.

Conclusions: The prevalence of DME diagnosed based on OCT was 18%, which was 2-3 times higher than the prevalence of DME diagnosed with fundus photography. Modern OCT technology allows for early detection of DME before significant vision loss. Given the global pandemic of diabetes mellitus and obesity, there is an increasing need to inform physicians and educate people with diabetes regarding early detection and treatment of DME based on OCT.

TITLE: The role of pH measurement at presentation in predicting outcomes from acute ocular surface chemical injury

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Spowart, S. Pradhan, C. Bruce, B. Salvador-Culla, G. Figueiredo, F.C. Figueiredo, Royal Victoria Infirmary, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|F.C. Figueiredo, Biosciences Institute, Newcastle University Faculty of Medical Sciences, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Emma Spowart: Commercial Relationship: Code N (No Commercial Relationship) | Sayali Pradhan: Commercial Relationship: Code N (No Commercial Relationship) | Charlotte Bruce: Commercial Relationship: Code N (No Commercial Relationship) | Borja Salvador-Culla: Commercial Relationship: Code N (No Commercial Relationship) | Gustavo Figueiredo: Commercial Relationship: Code N (No Commercial Relationship) | Francisco Figueiredo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In acute chemical ocular injuries, the role of pH measurement before irrigation is unclear. We performed a retrospective observational study to determine whether tear film pH measured at presentation in acute chemical eye injuries carries any prognostic value.

Methods: Data including demographics, pH values, nature of chemical, injury circumstances and severity, and clinical and visual outcomes were assessed from previously collated data from patients presenting to the emergency eye department in a UK tertiary hospital. All patients had pH measured before and after irrigation (irrespective of whether irrigation was started before attendance). Spearman rank correlation coefficient and univariate binary logistic regression analysis were used to assess associations between pH on arrival, injury severity, and clinical and visual outcomes.

Results: Pre-irrigation pH was recorded in 135 eyes (113 patients, 66.4% male, mean age 35.5 years [range 2 - 78; SD 15.4]; 15 acid, 108 alkali, 12 unknown). In patients presenting within 24 hours of injury (n = 108 eyes), pH positively correlated with injury severity at presentation ($r_s = 0.20$, $p = 0.02$). In patients with abnormal pH on presentation ($6.5 < \text{pH} < 7.5$; n = 26 eyes), pH correlated strongly with injury severity ($r_s = 0.72$, $p < 0.01$). There was no significant correlation with visual outcome ($r_s = 0.12$, $p = 0.11$). Presenting pH was a significant predictive factor for presence of limbal damage at follow up in patients presenting within 24 hours of injury and with follow up after the initial presentation (n = 70 eyes, 60 patients, follow up 1-3929 days, mean 579.4 days, SD 1206.0 days), ($p = 0.026$, Nagelkerke R^2 0.090)

Conclusions: In patients presenting within 24 hours of injury, pH at presentation positively correlated with injury severity and was a significant predictive factor for limbal damage at follow up. As well as guiding acute management, pH measurement is a useful test as a prognostic indicator to counsel patients.

TITLE:

Outcomes of bent ab interno needle goniotomy in primary open angle glaucoma

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Townsend, A. Badar, S. Dixon, P. Parekh, E. Martin, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jackson Townsend: Commercial Relationship: Code N (No Commercial Relationship) | Ayesha Badar: Commercial Relationship: Code N (No Commercial Relationship) | Stephan Dixon: Commercial Relationship: Code N (No Commercial Relationship) | Priyanka Parekh: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Martin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Bent ab interno needle goniotomy (BANG) is a novel minimally invasive glaucoma procedure that has been developed to increase trabecular outflow. We performed this study to evaluate the reduction in intraocular pressure (IOP) and IOP lowering medication in primary open angle glaucoma (POAG) after bent ab interno needle goniotomy.

Methods: We performed a retrospective chart review of 43 eyes of 33 patients who underwent the procedure with cataract surgery from 7/18/19 to 9/29/2020 in our outpatient surgical center. Mild, moderate, and severe glaucoma were included. 24 eyes were classified as POAG. Mean age was 70, 76% of patients Caucasian, and 42% of patients were male. Cataract extraction was performed prior to repositioning patient for direct gonioscopy. 25-gauge needle was bent at the tip to form a nearly 90 degree bend and attached to a viscoelastic cannula. A nasal goniotomy was created, which was then stripped for at least 30 degrees of trabecular meshwork. Reflex heme was noted. Irrigation/aspiration was used to remove reflex heme and viscoelastic prior to hydrating main wound and filling anterior chamber with adequate depth of pressure.

Results: Average IOP reduction for all glaucoma patients at post op month 3 was 20.80% ($P<0.0001$). Average drop reduction was 0.88 ($P=0.0009$). The percentage of patients reaching IOP reductions of greater than 20% was 55.81%. When classified by type of glaucoma, POAG identified statistically significant decrease in IOP by 17.69% ($P=0.0301$) and drop reduction of 0.708 ($P=0.0389$). The percentage of patients reaching IOP reduction greater than 20% was 37.5%. When further stratified by severity of primary open angle glaucoma, the percent reduction was 25.893% ($P=0.0118$), 9.523% ($P=0.5235$), and 23.585% ($P=0.1114$) for mild, moderate, and severe POAG, respectively. The percentage of patients reaching IOP reductions of greater than 20% was 66.67%, 16.67%, and 50% in mild, moderate, and severe POAG, respectively.

Conclusions: There is significant reduction across all severity of glaucoma, when classified by POAG, and further stratified by mild POAG. BANG procedure is an economical option, and when combined with cataract extraction, demonstrates greater than expected improvement in IOP. For phakic patients, cataract extraction/BANG may represent a viable first step instead of more conventional and invasive surgical intervention for glaucoma.

TITLE: ECM stiffness regulates the myofibroblastic differentiation of cultured primary keratocytes via subcellular changes in contractility and focal adhesion assembly.

SESSION TITLE: Corneal stromal wound repair and healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Maruri, D. Schmidtke, V. Varner, The Department of Bioengineering, The University of Texas at Dallas, Richardson, Texas, UNITED STATES|M. Miron-Mendoza, M. Petroll, The Department of Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Daniel Maruri: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Miron-Mendoza: Commercial Relationship: Code N (No Commercial Relationship) | David Schmidtke: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Petroll: Commercial Relationship: Code N (No Commercial Relationship) | Victor Varner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have suggested that focal adhesion size is correlated with the stiffness of ECM, but it remains unclear how signaling downstream of focal adhesion formation modulates changes in corneal keratocyte morphology and mechanical activation.

Methods: Polyacrylamide (PA) hydrogels of varying stiffness were fabricated on glass coverslips, functionalized with type I collagen, and used as substrata for two-dimensional (2D) cell culture. The gels were plated with primary corneal keratocytes (NRKs) in either serum-free media or media containing exogenous TGF- β 1. In some experiments focal adhesion kinase (FAK) inhibitor (PF-573228) was also added to the culture media. Afterward, NRKs were fixed and stained for F-actin, as well as markers for myofibroblastic activation (α -SMA), contractility (pMLC), or focal adhesions (vinculin). Focal adhesion size and traction stresses exerted by NRKs were also measured.

Results: Treatment with TGF- β 1 elicited distinct cellular phenotypes when NRKs were cultured on gels of varying stiffness. Cells cultured on either stiff (10 kPa) PA gels or collagen-coated glass coverslips formed abundant stress fibers, exhibited elevated levels of α -SMA immunofluorescence, and exerted large traction forces. These cells also formed abundant focal adhesions distributed across the entire cell body. NRKs cultured on soft (1 kPa) substrata, however, exhibited behaviors more indicative of a quiescent phenotype, even in the presence of TGF- β 1. They formed fewer stress fibers, retained a more elongated morphology, and exerted significantly lower traction forces, with small focal adhesions, localized primarily at the tips of cellular projections. pMLC immunofluorescence further revealed stiffness-dependent differences in subcellular contractility, with contractions localized in the tips of cellular projections in cells cultured on soft substrata. Traction force maps correlated strongly with these patterns of pMLC immunofluorescence. FAK inhibition blocked myofibroblast transformation and the associated phenotypic changes.

Conclusions: Taken together, these data suggest that mechanotransductive signaling downstream of FAK activation is required for TGF- β 1 induced myofibroblast transformation of corneal keratocytes.

ABSTRACT BODY:

Purpose: Visual field representation is preserved throughout the visual system. Inherited retinal dystrophies resulting in photoreceptor death cause characteristic patterns of visual field loss. Previous work has shown secondary remodelling in the inner retinal layers which raises the question of whether these changes are transmitted along the visual system to V1.

Methods: A cohort of patients with choroideremia (peripheral vision loss) and Stargardt disease (central vision loss), and age- and sex-matched control participants underwent visual field testing and T1 structural MRI scanning. Retinal thickness and visual field sensitivity were analysed in terms of degrees of visual space. Neuroimaging data was analysed using the free open cloud platform brainlife.io. An automated processing pipeline combining FreeSurfer and the approach developed by Benson and colleagues, was used to analyse V1-cortical thickness according to degrees of visual space represented. Repeated measures ANOVA with Huynh-Feldt adjustment were conducted for V1 thickness.

Results: In both patients groups, V1 thickness changed across eccentricities compared to controls ($P = 0.01$ in Stargardt patients and $P < 0.01$ in choroideremia). The key changes occurred across all eccentricities in choroideremia patients and between two and six degrees in the Stargardt patients. V1 thickness was not significantly correlated to microperimetry threshold ($p=0.08$, $P=0.56$) or octopus periphery score ($p=0.10$, $P=0.45$).

Conclusions: There is evidence of V1 thinning following retinal damage. A generalised effect of photoreceptor loss in the visual cortex due to retinal disease is not currently taken into account when planning retinal treatment. These effects along the visual pathway may require additional intervention to limit the impact of eye disease on brain tissue. We must consider the visual system as a whole rather than in terms of eye or brain.

TITLE: Comparative Surgical Approaches Following Failed Pneumatic Retinopexy

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.N. Omizo, K.S. Lum, J.C. Lai, Retina Consultants of Hawaii, Aiea, Hawaii, UNITED STATES|J.N. Omizo, Hawaii Macula and Retina Institute, Aiea, Hawaii, UNITED STATES|J.C. Lai, Surgery, University of Hawaii John A. Burns School of Medicine, Honolulu, Hawaii, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jase Omizo: Commercial Relationship: Code N (No Commercial Relationship) | Kelli-Ann Lum: Commercial Relationship: Code N (No Commercial Relationship) | James Lai: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Since its introduction in 1986, pneumatic retinopexy (PR) has been an effective procedure to repair select rhegmatogenous retinal detachments (RRD). However, in cases of re-detachment following PR, it is unclear which surgical option offers the best chance of reattachment. A retrospective observational clinical study was performed to examine the success rate of different surgical approaches to secondary RRD repair originally managed with PR.

Methods: A retrospective chart review was performed on patients presenting with RRD to four different doctors at the Retina Consultants of Hawaii from February 1, 2013 to December 31, 2019. Patients treated with PR for RRD repair who subsequently experienced a re-detachment were included in this study. Data collected included affected eye, date and type of procedures, and postoperative retina attachment status. A successful case was defined as an attached retina with no recurrence of retinal breaks or tears after one month following surgery. Cases where silicone oil remained in the post-operative eye or lacked a sufficient follow up time of three months after oil removal were excluded from the study. A Fisher's exact test was used to compare the success rate of different surgical approaches, a p value <0.05 was considered statistically significant.

Results: There were 15 eyes included in this study. Of these, 40% (6/15 eyes) were managed with pars plana vitrectomy (PPV) (3 with gas and 3 oil), 40% (6/15 eyes) were managed with a combination scleral buckle with PPV (5 with gas and 1 oil), and 20% (3/15 eyes) were managed with a repeat PR. The success rate was 50% for PPV, 83% for combination scleral buckle with PPV, and 0% for repeat PR. The success rate of reattachment with combination scleral buckle with PPV was significantly higher than with repeat PR ($p=0.048$). There was no significant difference in success rate between PPV vs. combination scleral buckle with PPV ($p=0.242$).

Conclusions: This study shows significantly better surgical outcomes when treating a failed PR RRD repair with combination scleral buckle with PPV rather than with a secondary PR. It raises the possibility that a scleral buckle is not necessary following a failed PR. Due to the small sample size and retrospective nature of the study, additional examination would be useful to further elucidate the best surgical approach following a failed PR.

ABSTRACT BODY:

Purpose: Photorefractive of young children is currently practiced nation-wide in Flanders, Belgium, at age one. Children with high refractive error are referred to an ophthalmologist and mostly prescribed glasses. Wearing of glasses has increased from 4.7% to 6.4% in four-year-olds in Flanders between 2012 and 2017 but it is unknown how many cases of amblyopia have been prevented from developing by the prescription of early glasses. In a randomized controlled trial (RCT), we will establish whether early glasses for high refractive error at age one reduce the development of amblyopia between age one and four. As a secondary outcome early literacy will be compared in groups with and without glasses.

Methods: In preparation of the RCT, Children's Healthcare Centers (CHCs), research-orthoptists and facilities for the examination of children were recruited. Youth healthcare physicians were contacted in most healthcare regions in the Netherlands, to engage clusters of CHCs in child-rich neighborhoods. Research-orthoptists were sought via orthoptic professional societies, meetings and announcements. Locations for examination of the children were sought among institutions for visually impaired, CHCs and hospitals.

Results: Five preventive healthcare organizations will participate with one cluster of CHCs in Utrecht: Neighborhood Leidsche Rijn, one cluster in Harderwijk, Ermelo and Putten, one cluster in Tiel, Geldermalsen and Culemborg, one cluster in Eindhoven-North, and one cluster in Venlo and Roermond. Study locations were ensured in two institutions for visually impaired, one in a CHC and one in a hospital. So far four study orthoptists have been engaged for retinoscopy in cycloplegia at age one, and randomization of children surpassing the AAPOS 2003 criteria and follow-up until age four.

Conclusions: Sufficient CHCs, youth healthcare physicians and nurses and research-orthoptists have committed themselves to this RCT. When the relation between the size and sort of refractive error at age one or two and the increased odds to develop amblyopia will have been established objectively, the use of practice-based referral criteria will no longer be necessary.

ABSTRACT BODY:

Purpose: This study aims to evaluate the intereye asymmetry of selected structural and functional parameters in glaucoma and normal eyes between groups divided by the degree of circumpapillary retinal nerve fiber layer (cRNFL) thickness asymmetry between eyes.

Methods: Subjects with glaucoma and normal controls were included. Patients underwent 24-2 perimetry and Spectral Domain Optical Coherence Tomography (SD-OCT). Parameters analyzed were: cRNFL, average circumpapillary choroidal thickness (cChoroid), the hypotenuse of the vertical optic nerve head cup (HVOC) and VF mean deviation (MD). cChoroid was calculated as the mean between the measurements at 0°, 90°, 180° and 270° of the circular B-scan. For calculating HVOC the length and depth of the optic nerve cup were used as the sides of a right triangle. The length was measured as the distance between the innermost portion of the descending RNFL tissue at the Bruch's membrane opening level plan. The depth was measured as distance between the former line and the maximum depth of the anterior prelaminar tissue. Patients were divided into 3 groups based on the degree of asymmetry of cRNFL between eyes. Statistical analysis was performed using general estimate equations (GEE), One-way ANOVA and Tukey HSD test.

Results: 110 eyes (55 subjects) qualified for the study. The mean (SD) age was 65 (13.38) years. The number of subjects was 49 in the glaucoma and 6 in the control group. Three groups were divided by the terciles of the cRNFL difference between eyes: 1: $\leq 4 \mu\text{m}$ (n=21, 4 controls); 2: 5-13 μm (n=18, 2 controls) and 3: $\geq 14 \mu\text{m}$ (n=16, no controls). The mean (SD) cRNFL asymmetry within the groups was: 2.71 (1.35) μm , 9.28 (2.90) μm and 25.31 (12.56) μm (p<0.001), respectively. The average of the parameters in each group are depicted in table 1 showing that MD, cRNFL and HVOC were worse in the group with more intereye asymmetry. The MD, cRNFL and HVOC average differences between eyes comparing the 3 groups were significant (p<0.001)(Table 2).

Conclusions: The ONH parameter HVOC and the VF MD demonstrated significant intereye differences between the groups based on the degree of intereye asymmetry of the cRNFL. Evaluating additional SD-OCT parameters asymmetry may provide additional biomarkers and strategies for the diagnosis and monitoring of glaucoma.

Commercial Relationships Disclosure (Abstract): Arthur DeCarlo: Commercial Relationship: Code N (No Commercial Relationship) | Brian Samuels: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of blindness in adults despite a variety of management strategies which help to slow its progression. In a quest to identify a new pharmacological approach for regulating intraocular pressure (IOP), a primary cause of glaucoma, this research focuses on the brain center that modulates most circadian rhythms, which potentially includes IOP variation. Our objective was to chemically stimulate the SCN directly by microinjection of either a glutamate receptor agonist, NMDA, or the GABA_A receptor antagonist, BMI, and determine the role of these two major signaling systems in the regulation of IOP within the SCN.

Methods: Male Sprague-Dawley rats (n=38) were placed under mild isoflurane anesthesia at midday. Using a stereotactic surgical approach, a 75 nL injectate of 0.4 mM BMI, or a dose range of NMDA 13-51 mM, or control 0.1M phosphate buffered saline, was delivered to the targeted area of the anterior hypothalamus after 10 minutes of stable baseline recordings of IOP, heart rate (HR), blood pressure (MAP), and intracranial pressure (ICP) were obtained. IOP, ICP and the cardiac responses were monitored for 60 minutes following injection.

Results: When injected directly into the SCN of anesthetized rats, both BMI (n=5) and saline (n=5) produced a rise in IOP (Fig. 1) that was 2.6 to 3.9-fold greater, respectively, than the NMDA response (n=5), which was near background level (saline-NMDA difference = 9.8 mm Hg, 3.9 fold +/- 1.5, n=10, AUC p=0.001; BMI-NMDA difference = 3.8 +/- 2.4 mm Hg, 2.7 fold +/- 1.5, n=10, AUC p=0.03). Alternatively, saline injected into either the ventricle (n=2) or the optic chiasma/supraoptic decussate region (och/sod) (n=5) did not stimulate a rise in IOP. BMI injected into the ventricle (n=3), however, led to a significant rise in IOP (3.6 +/- 1.0-fold relative to saline, p=0.03). Neither saline, BMI, nor NMDA injection into the SCN led to a significant rise in HR or MAP. ICP, however, was significantly increased by BMI microinjection into the SCN (3.1-fold rise relative to the saline response (p=0.03, n=9).

Conclusions: These data support the hypothesis that CNS regulation of IOP can be independent from HR, MAP, and ICP modulation, and suggest that IOP may be regulated through the SCN by both glutamatergic and GABAergic neuronal pathways.

ABSTRACT BODY:

Purpose: To assess night vision problems among drivers to aid in traffic safety. Night visual problems are risk factor in most of the high way fatalities hence measuring only visual acuity in our Driver and Vehicle Licensing Authority (DVLA) is not enough. There is inadequate information on the various visual disturbances and complaints of drivers on the roads at night in Ghana. This research seeks to assess the visual problems encountered during night time driving in the Kumasi Metropolis in the Ashanti Region.

Methods: Night driving difficulties were assessed cross- sectionally using questionnaire comprising of demographics and night driving behaviors and characteristics, night visual problems and a preexisting Night Driving Questionnaire (VND-Q) among 311 drivers in Kumasi metropolis. The participants' aged, 20 to 72 years. Cross tabulations were used for age and gender of the participants with vision and night driving questionnaire (VND-Q) items used in assessing various difficulty levels. The statistical significance between age and gender with vision and night driving questionnaire (VND-Q) items were also analyzed using Pearson's Chi-square.

Results: Participants were mean \pm SD age of 36.58 ± 10.67 with more males (87.5%). Glare (40.8%) was the most prevalent night vision problem recorded in the metropolis. Most of the night driving difficulties correlated positively and significantly with age. The relationship between gender of participants and the difficulty levels in reading street signs ($p = 0.850$), seeing the road because of oncoming headlight ($p = 0.599$) and seeing because of glare when driving at dawn or dusk ($p = 0.193$) were not statistically significant. Driving during poor weather and rainy condition (20.4%), causing a lot of difficulty when driving on the road. Most drivers (<50years) have no difficulty in seeing dark colored cars, reading street signs, seeing pedestrians and animals, judging distance between drivers, and other cars at night.

Conclusions: Glare is the most occurring night visual problem with the highest prevalence for both male and female drivers among other night vision problems on the roads in the Kumasi metropolis. Due to night driving difficulties, among gender, men are 0.92 (CI 0.20-0.43) times more likely to drive at night than women. For traffic safety, simple tests for contrast and glare sensitivity should be reinforced as regular requirements for driving license issuance in Ghana.

Commercial Relationships Disclosure (Abstract): Edward Xie: Commercial Relationship: Code N (No Commercial Relationship) | Urooba Nadeem: Commercial Relationship: Code N (No Commercial Relationship) | Bingqing Xie: Commercial Relationship: Code N (No Commercial Relationship) | Mark Souza: Commercial Relationship: Code N (No Commercial Relationship) | Hugo Barba: Commercial Relationship: Code N (No Commercial Relationship) | David Dao: Commercial Relationship: Code N (No Commercial Relationship) | Dinanath Sulakhe: Commercial Relationship: Code N (No Commercial Relationship) | Dimitra Skondra: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: By 2040, patients with age-related macular degeneration (AMD) are expected to reach 288 million; however, no cure or definite prevention exists to date. The purpose of this study is to use advanced bioinformatics tools to study drug-gene associations in order to identify drugs/compounds interacting with genes involved in AMD.

Methods: We queried PubMed Gene to compile a comprehensive list of genes described in AMD, wet AMD, dry AMD, intermediate AMD, and geographic atrophy (GA) to date. We also combined some of the sub-types to reflect the genes that play a role at distinct stages of the disease. Gene enrichment analysis was performed using ToppGene on AMD-related gene lists against the drug databases. This analysis estimates the statistical significance of overrepresented compounds from multiple drug-gene interaction databases to construct a Pharmacome. We selected compounds with adjusted p-value <0.05. Compounds with no clinical indications (e.g., paraquat and ethanol) were filtered out from the resulting drug lists.

Results: Among 77,146 candidate drugs/compounds in the database, our analysis revealed multiple drugs/compounds with significant interactions to genes involved in AMD. Amongst the top 20 most significant, drug classes such as anti-diabetics, antioxidants, statins, and flavonoids were identified. Metformin, the most common anti-diabetic medication, was identified as the drug with the strongest association to wet-AMD genes and was also in the top 20 for dry AMD subtypes. Curcumin, a flavonoid polyphenol, was identified as the drug with the strongest associations to all AMD-affiliated genes as well as to genes in the dry AMD subtype (both intermediate and GA). Other top compounds identified include statins and various antioxidants – glutathione, N-acetylcysteine, vitamins E & C – which were seen in the top 10 results of our AMD conditions.

Conclusions: This bioinformatics drug-gene interactions approach predicts drugs which can affect multiple genes involved in AMD. Multiple drugs with well-known pharmacodynamics and safety profiles like metformin and statin as well as antioxidants/nutrients like glutathione and curcumin are revealed by this analysis. Predicted bioinformatics studies require further validation from preclinical and clinical studies; however, this unbiased approach could identify potential candidates among existing drugs/compounds that could be repurposed for AMD.

TITLE: Axial length change with short-term exposure to visual stimuli with a limited range of spatial frequencies

SESSION TITLE: Effects of Light Intensity and Blur on Refractive Development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Teoh, M.J. Collins, S.A. Read, E. Pieterse, Queensland University of Technology School of Optometry and Vision Science, Kelvin Grove, Queensland, AUSTRALIA

Commercial Relationships Disclosure (Abstract): Swee Chai Teoh: Commercial Relationship: Code N (No Commercial Relationship) | Michael Collins: Commercial Relationship: Code N (No Commercial Relationship) | Scott Read: Commercial Relationship: Code N (No Commercial Relationship) | Emily Pieterse: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Animals reared in environments with limited spatial frequency information can show changes in eye growth. The human eye shows short-term changes in axial length (AxL) in response to defocus, which limits the spatial information available to the eye. This study investigated the change in AxL with 60-minute exposure to videos filtered to present differing ranges of spatial frequencies, including full spectrum (FS), lowpass (≤ 1.5 cpd, LSF), bandpass (3 – 6 cpd, MSF) and highpass (≥ 10 cpd, HSF) (Figure 1), all viewed in the distance with no blur present.

Methods: Thirteen participants were tested on four separate days. Each session involved a 20-min washout (watching the FS video) and then 60-min exposure to a spatially filtered video (randomized order). Participants watched all videos binocularly, with optimum distance refractive correction. AxL of the RE was measured with Lenstar LS 900 at baseline (after washout), and then at 30 and 60 min. A still image was used as a fixation target when measuring the AxL and to measure the accommodation response with a binocular autorefractor WAM-5500. The ON- and OFF-retinal response stimulated by the videos was also analysed using the “Realtime ON OFF analysis of the visual world” software.

Results: A two-way repeated measures ANOVA showed that AxL did not change significantly by viewing the spatially filtered videos ($F_{3,33} = 0.71$, $p = 0.56$). The AxL change with 60-min exposure to LSF ($+3 \pm 6 \mu\text{m}$), MSF ($+2 \pm 7 \mu\text{m}$) and HSF ($+4 \pm 6 \mu\text{m}$) and FS videos ($-0.5 \pm 4 \mu\text{m}$) were similar (Figure 2). The change in accommodation response (range: 0.03 D to 0.13 D) stimulated by the videos was minimal and not statistically significant ($P > 0.05$). All four videos were found to result in a bias towards an ON-retinal pathway stimulation.

Conclusions: The spatial frequency detail of the visual stimulus did not cause significant short-term changes in axial length, when the eye was optimally corrected. This result does not support the hypothesis that the spatial frequency content of the retinal image is the primary factor in short-term defocus mediated changes in axial length.

TITLE: Comparison of meibomian gland morphology in patients with evaporative dry eye versus healthy subjects.

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Garza Leon, R.R. Crespo Treviño, A.K. Salinas Sánchez, F. Amparo, Clinical Science, Universidad de Monterrey Division de Ciencias de la Salud, San Pedro Garza Garcia, Nuevo León, MEXICO|

Commercial Relationships Disclosure (Abstract): Manuel Garza Leon: Commercial Relationship(s);Alcon :Code C (Consultant);S4Oprik:Code F (Financial Support);SIFI:Code F (Financial Support) | Ricaurte Crespo Treviño: Commercial Relationship: Code N (No Commercial Relationship) | Anna Salinas Sánchez: Commercial Relationship: Code N (No Commercial Relationship) | Francisco Amparo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is no conclusive information regarding the impact of meibomian gland (MG) morphology in tear film physiology and disease. We present a retrospective and observational clinical study that investigated the prevalence of anatomical and morphological MG alterations between patients with evaporative dry eye disease and healthy controls, and the correlation between these alterations and common clinical parameters used during meibomian gland disease evaluation.

Methods: Retrospective chart review of patients with evaporative dry eye and healthy individuals. The inclusion criteria for healthy subjects included an OSDI (Ocular Surface Disease Index) score of <12 points, non-invasive tear film break-up time (NIKBUT) > 10 sec, and absence of ocular surface staining (any type of dry eye was excluded). Patients with evaporative dry eye were selected based on the International Workshop on Meibomian Gland Dysfunction criteria. Demographic data, OSDI questionnaire, meibomian gland characteristics, ocular surface staining, non-invasive tear film break-up time, and infrared meibography were analyzed. Descriptive statistics and linear and logistical regression were used to evaluate the correlation between the clinical parameters and MG morphology.

Results: 75 eyes of 75 subjects were studied with a mean age of 40.68±18.43 (56% women), 42 (56%) subjects presented dry eyes and 33 (44%) were healthy controls. 90.7% of the subjects presented a morphological alteration in the upper lid and only 44% in the lower lid. We did not find significant differences in MG alterations in the upper lid between healthy and dry-eye subjects. Patients with evaporative dry eye presented MG alterations in the lower lid more frequently than healthy subjects (54.8 vs 30.3%; p=0.03). However, the presence of shortened glands was the only MG alteration that was more prevalent in the lower lid in dry-eye patients than in healthy subjects (p <0.05).

Conclusions: In the studied population, subjects with evaporative dry eye presented more alterations in the lower lid than healthy subjects, and meibomian-gland shortening was the most common morphological alteration in patients with dry eye.

TITLE: Adaptive optics retinal imaging with deep learning cone segmentation enables area-based analysis in RHO-associated retinitis pigmentosa

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Giannini, J. Liu, T. Liu, N. Aguilera, L.A. Huryn, J. Tam, National Eye Institute, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): John Giannini: Commercial Relationship: Code N (No Commercial Relationship) | Jianfei Liu: Commercial Relationship: Code N (No Commercial Relationship) | Tao Liu: Commercial Relationship: Code N (No Commercial Relationship) | Nancy Aguilera: Commercial Relationship: Code N (No Commercial Relationship) | Laryssa Huryn: Commercial Relationship: Code N (No Commercial Relationship) | Johnny Tam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Adaptive optics (AO) retinal imaging with single-cell resolution has enabled the extraction of quantitative information about the human photoreceptor mosaic, but characterizing small changes remains challenging. In diseases such as RHO-associated retinitis pigmentosa (RP), where rod loss precedes cone loss, the structural integrity of the cone mosaic could be altered due to rod-dependent cone survival. In this study, we investigate area-based metrics enabled by cone segmentation and their utility in characterizing subtle disruptions in the cone mosaic of patients with RP.

Methods: Non-confocal split detection retinal images were acquired using a custom-built AO scanning light ophthalmoscope. Images from two patients with molecularly-confirmed RHO-associated RP were compared to images from two healthy volunteers at matched eccentricities (2-3 mm temporal from fovea). Cone boundaries were localized using deep learning segmentation (PMID: 31701095), and cone centers were derived from the extracted cone boundaries. Cone boundaries were used to generate area-based metrics such as cone size (area within each cone) and percentage of retinal area occupied by cones, and cone centers were used to generate point-based metrics such as cone density.

Results: Subtle disruptions to the cone mosaic were observed in patients with RHO-associated RP, including variable cone size and local inter-cone area (area enclosed by nearest neighbors). There was a 24.5% decrease in cone density in patients with RP (healthy: average \pm SD, 10747 \pm 947 cells/mm²; RP: 8631 \pm 656 cells/mm²; n=4,216 cones; p < 0.01, two-tailed t-test). The percentage of retinal area occupied by cones was similar across healthy (45.6 \pm 3.8%) and RP (46.0 \pm 3.2%), which could be explained by a 24.1% increase in the average size of cones (healthy: 42.4 \pm 8.1 μ m²; RP: 52.7 \pm 10.4 μ m²; n=4,216 cones; p < 0.01, two-tailed t-test). These metrics show how area-based cone metrics enrich the interpretation of changes in cone density and help characterize subtle structural changes to the cone mosaic.

Conclusions: Diseases involving progressive photoreceptor loss, such as RP, may benefit from the introduction of area-based metrics alongside existing point-based metrics for characterizing early changes to the cone photoreceptors secondary to rod degeneration.

ABSTRACT BODY:

Purpose: To investigate the demographics, clinical presentation, management, and visual outcomes in the Latinx population presenting with ophthalmic injuries at the Wilmer Eye Institute. A high proportion of workplace injuries, up to 20% in fiscal year 2020, in Latinx patients was noted at our institution, and no prior studies focused on the nature of injuries in this population.

Methods: Retrospective chart review of 73 patients who presented with ophthalmic injuries to the Wilmer Eye Institute, Johns Hopkins Hospital between January 1, 2006 and March 31, 2018. Injuries identified using ICD codes included orbital fracture, open globe, lid laceration, superficial injury of eye/adnexa, hyphema, traumatic cataract, retinal detachment, corneal foreign body, orbital foreign body, chemical splash, partial-thickness corneal laceration, and optic or oculomotor nerve injuries.

Results: Of 73 participants, 61 (83.6%) were male. Mean age (\pm SD) was 33.4 (\pm 14.3) years. Of 46 (63.0%) employed, 26 (56.5%) worked in construction. Forty-five (61.6%) had medical insurance and 24 (32.9%) did not. Of 79 eyes injured, 32 (40.5%) were work-related injuries, 26 (32.9%) assault injuries, and 21 (26.6%) by another cause. Thirty-three (41.8%) eyes were injured by blunt object, 19 (24.1%) by sharp object, 9 (11.4%) by a fall, 6 (7.6%) by a chemical, and 12 (15.2%) by unknown mechanism. In 23 instances where the use of eye protection was documented, 6 (26.1%) were protected using eye protection. Injuries included 29 (36.7%) orbital fractures, 17 (21.5%) open globes, 15 (19.0%) lid lacerations, and 14 (17.7%) superficial injuries. Forty-one (51.9%) eyes required surgery, including 17 (41.5%) open globe repairs, 10 (24.4%) vitrectomies, and 12 (15.2%) eyelid laceration repairs. Final visual acuity (VA) was 20/40 or better in 50 (63.3%) eyes, 20/50-20/200 in 11 (13.9%) eyes, 1/200-19/200 in 4 (5.1%) eyes, CF-NLP in 12 (15.2%) eyes, and unmeasured in 2 (2.5%) eyes.

Conclusions: In Latinx patients, ophthalmic trauma occurred most commonly in the workplace, highlighting the importance of improving education regarding eye protection in this setting. Injury occurred most often by blunt object. Most common injuries were orbital fractures and open globes, and most common surgeries performed were open globe repairs and vitrectomies. Final VA was worse than 20/200 in about 20% of eyes.

ABSTRACT BODY:

Purpose: OTX-TKI, an intravitreal, bioresorbable, hydrogel-based implant, is designed to deliver the small molecule tyrosine kinase inhibitor, axitinib, in a sustained-release formulation to the vitreous & can potentially address the need for a novel treatment approach for nAMD that provides a longer duration of action. Here we report the preliminary safety, tolerability & biological activity of OTX-TKI in subjects with nAMD.

Methods: Prospective, multi-center, open-label, dose escalation Phase 1 study is ongoing. Subjects with nAMD (treatment-naïve or with a history of anti-VEGF therapy) were eligible to receive intravitreal placement of OTX-TKI. Three cohorts were evaluated: Cohort 1: 200 µg (n=6); Cohort 2: 400 µg (n=7); Cohort 3 (enrolling): 3a) 600 µg (n=5/6) & 3b) 400 µg + anti-VEGF induction therapy (n=2/6). Assessments included: Spectral-domain optical coherence tomography (SD-OCT) imaging to assess central subfield thickness (CSFT), best-corrected visual acuity (BCVA), & adverse event collection. Assessments were performed at baseline, day 0 (injection), days 3, 7, 14, & continued monthly until implants were no longer visible.

Results: No ocular serious adverse events have been reported to date (200 µg: 9-10.5 months; 400 µg: 12+ months; 600 µg: 4.5 months; 400 µg + Anti-VEGF: 3 months ongoing follow-up). No changes in intraocular pressure were observed in any subject & no subject required steroids. CSFT was noted to remain mostly stable in the 200 µg group. In the 400 & 600 µg groups, many subjects showed a decrease in CSFT & demonstrated a clinically meaningful reduction in intraretinal &/or subretinal fluid by 2 months. Reduction was maintained for up to 13 months in one subject in the 400 µg group, while in the 600 µg group, up to 4.5 months (only subject to reach this time point so far). Implants exhibited little movement in the vitreous & were generally no longer visible after 9 - 10.5 months (200 µg).

Conclusions: OTX-TKI appears to be generally well-tolerated to date with a favorable safety profile. Preliminary signs of biological activity, as evidenced by a decrease in CSFT in the 400 µg & 600 µg groups by two months, has been observed in many subjects with durability up to 13 months. Minimal movement & consistent resorption of implants has been observed. Study is still enrolling, and additional follow-up of current dose groups is ongoing.

ABSTRACT BODY:

Purpose: In the retinal pigment epithelium (RPE), Cathepsin D (CatD) is the principal lysosomal protease responsible for breaking down internalized proteins. CatD activity and its maturation through the endolysosomes requires a low pH. Key pathological hallmark of Stargardt disease (STGD1) and its mouse model (*Abca4*^{-/-}) is the accumulation of autofluorescent lipofuscin in the RPE. Both STGD1 donor eye and *Abca4*^{-/-} RPE showed significant deposition of complement proteins on the RPE cells. These RPE lipofuscin granules contain A2E-bisretinoids, lipid and protein aggregates, including complement fragments. Notably, increased lysosomal pH in the RPE was previously evidenced in the *Abca4*^{-/-} mice. In this study, we investigated the specific role of CatD in the endolysosomes of STGD1 experimental models.

Methods: Age-matched wild-type (WT) and *Abca4*^{-/-} mice (n=3) were used to prepare RPE homogenates for immunoblotting analysis of mature CatD level. Pooled RPE sheets of 6-mo-old WT and *Abca4*^{-/-} mice (n=4) were used for proteomics analysis by liquid chromatography-mass spectrometry (LC-MS). Functional activity of CatD in RPE cells of WT and *Abca4*^{-/-} mice (n=3) were measured by fluorometric assay. Statistical significance was determined by paired t-test. CatD and α -synuclein, its physiological substrate, were evaluated by immunohistochemistry (IHC) in fixed mouse eyes (WT and *Abca4*^{-/-}) and induced pluripotent stem cell (iPSC) derived RPE cells from STGD1 patient vs control unaffected individuals.

Results: By LC-MS proteomics analysis, we found a ~1.6-fold (p<0.001) increase in level of total CatD (immature, intermediate, mature) forms in RPE cells of *Abca4*^{-/-} mice vs WT. Surprisingly, quantitative immunoblotting analysis showed a ~1.7-fold (p=0.042) decrease of mature CatD in the RPE of *Abca4*^{-/-} mice vs WT. Importantly, CatD functional activity was reduced in the RPE of *Abca4*^{-/-} mice by ~42% (p=0.024) compared to WT. By IHC, STGD1 iPSC-RPE cells but not normal controls showed significant accumulation of α -synuclein consistent with impaired CatD activity.

Conclusions: Our studies suggest that CatD is an integral component of maintaining the homeostasis of the RPE cells. In STGD1 RPE cells, decreased CatD functional activity and reduced protein maturation further exacerbate the endolysosomal dysfunction. Our findings introduce a molecular mechanism involving CatD in the pathophysiology of STGD1 with important therapeutic implications.

TITLE: The role of Optical Coherence Tomography Angiography in detecting and monitoring inflammatory choroidal neovascular membranes

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.J. Grasic, W. Kongwattananon, H. Lin, H. Sen, S. Kodati, ophthalmology, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): David Grasic: Commercial Relationship: Code N (No Commercial Relationship) | Wijk Kongwattananon: Commercial Relationship: Code N (No Commercial Relationship) | Henry Lin: Commercial Relationship: Code N (No Commercial Relationship) | H Nida Sen: Commercial Relationship: Code N (No Commercial Relationship) | Shilpa Kodati: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optical Coherence Tomography Angiography (OCT-A) has emerged as a valuable adjunctive imaging modality for the detection of choroidal neovascular membranes (CNVM). The goal of this study is to investigate the utility of OCT-A for the detection of inflammatory CNVM (i-CNVM) and monitoring their response to treatment.

Methods: A retrospective review of patients with a diagnosis of uveitis and associated i-CNVs based on clinical exam and OCT (CIRRUS, Carl Zeiss Meditec, Inc, Dublin, OH) was conducted. 6 × 6-mm SD-OCTA (CIRRUS AngioPlex, Carl Zeiss Meditec, Inc, Dublin, OH) or 6 × 6-mm swept-source OCTA (Plex Elite 9000; Carl Zeiss Meditec, Inc) images were acquired and the outer retina to choriocapillaris (ORCC) slab evaluated by two graders for the presence of i-CNVM. Follow up images were qualitatively assessed in order to determine if regression of i-CNVM occurred following treatment.

Results: Thirteen eyes (punctate inner choroidopathy (n=4), persistent placoid maculopathy (n=2), sarcoid uveitis (n=2), tuberculous choroiditis (n=1), birdshot chorioretinopathy (n=1), syphilitic uveitis (n=1), serpiginous choroiditis (n=1) and idiopathic panuveitis (n=1)) with i-CNVM and OCT-A images were identified. I-CNVM was detected on OCT-A in 11/13 eyes (84.6%). Treatment for i-CNVM included intravitreal bevacizumab (n=1), intravitreal ranibizumab (n=2), intravitreal aflibercept (n=8), subtenon triamcinolone acetonide (n=2) and intravitreal dexamethasone implant (n=2). Of these 11 eyes with detectable i-CNVM, 7 (63.6%) had a new diagnosis of i-CNVM. Mean best corrected visual acuity post-treatment improved from 0.68 (range 0.1-1.5) to 0.57 (-0.2-1.5) (p=0.08). Notably, 10 eyes (90.9%) demonstrated regression in i-CNVM area on OCT-A with treatment and of those 10 eyes, 4 (40.0%) showed complete regression in i-CNVM with treatment.

Conclusions: Our results show that OCT-A is an effective modality for detecting i-CNVM and that visible regression of the CNVM is apparent in the majority of cases following treatment.

ABSTRACT BODY:

Purpose: Fetal alcohol exposure is associated with a myriad of nervous system impacts. Retinal abnormalities and visual deficits also have been observed in fetal alcohol spectrum disorder (FASD). The purpose of this study was to characterize retinal manifestations of binge-like ethanol (EtOH) exposure in a zebrafish model of FASD and to investigate the role of EtOH-mediated proteostasis impairment for visual dysfunction.

Methods: We exposed zebrafish to 1% EtOH from 5-7 days post fertilization, within a developmental period following early establishment of working cone vision but before maturation of rods. Functional assays were carried out 2- and 3-days post-exposure. We employed a transgenic reporter for ubiquitin-system impairment in cone PRs (gnat2:Ub-G76V-YFP), determining the effect of EtOH on reporter accumulation via immunoblotting. The functional effects of EtOH were assessed by optomotor response (OMR) assays and electroretinogram (ERG) recordings in intact zebrafish larvae.

Results: Exposure to 1% EtOH produced a concentration in larvae of 16 ± 4 mM (SEM, $n=5$), which returned to baseline levels after one day following washout. OMR performance was significantly impaired at 2 and 3 days post-EtOH exposure, which was evident across different stimulus contrast levels and spatial frequencies. Cone-dependent ERG responses exhibited altered maximum amplitudes, sensitivity, and/or response thresholds for b-waves and isolated a-waves. After 2-days recovery, maximum b and a-wave amplitudes were reduced by 43 ± 10 and $34 \pm 23\%$ compared to controls, respectively ($p < 0.05$; $n=13-22$); response thresholds for b and a waves were increased by 1.0 ± 0.2 and 0.6 ± 0.1 log intensity units, respectively ($p < 0.05$, $n=7-12$). We also observed accumulation of unstable Ub-G76V-YFP following EtOH exposure in transgenic zebrafish, suggesting ubiquitin-system impairment within cones. Pre-treatment with $0.5 \mu\text{M}$ Torin1, an mTOR1/2 inhibitor previously shown to enhance both autophagy and proteasomal function (Zhao et al., 2015, PNAS), robustly protected against some damaging effects of EtOH on visual function, as revealed by OMR performance and rescue of multiple ERG parameters.

Conclusions: Together, these results show that binge-like EtOH exposure in immature zebrafish larvae produces visual dysfunction, including effects on cone PR neurons. Part of the damaging effects of EtOH on retinal neurons may involve disruption of proteostasis.

ABSTRACT BODY:

Purpose: To evaluate microaneurysm turnover (MAT) as a predictive biomarker for retinopathy progression and development of sight-threatening complications, diabetic macular edema (DME) or proliferative retinopathy (PDR), in patients with type 2 diabetes and mild nonproliferative retinopathy (NPDR) in a 5-year follow-up.

Methods: A 5-year prospective, longitudinal study was designed to follow 212 patients with type 2 diabetes (T2D) and mild NPDR (ETDRS grades 20 and 35). Ophthalmological examinations of the study eye including color fundus photography (CFP) and optical coherence tomography were performed at baseline, at the first 6-months visit and annually. Outcomes were DME and/or PDR development. MAT analysis included determination of MA formation and disappearance rates, automatically assessed using the RetMarkerDR at 12-month visits. Retinopathy severity progression was evaluated using step increase in ETDRS severity grades.

Results: Of the 212 individuals with T2D and mild NPDR, 162 completed the 5-year follow up period of the study or developed an endpoint (n=25). MAT calculated on the first year showed significant association with the development of any endpoint ($p = 0.0178$), in particularly MA disappearance rate ($p = 0.007$). MAT showed also significant association with ETDRS severity worsening in the 5-year period ($p = 0.0353$). There were variations between MAT values in the first year of follow-up (2.04 ± 3.18) and the 5-year (2.26 ± 3.06 ; $p = 0.060$), with a clear increase in the MA disappearance rate being observed in the last year of the study (1.50 ± 1.93) compared with the first-year of follow-up (1.05 ± 1.99 ; $p = 0.003$).

Conclusions: MAT in eyes with T2D and mild NPDR is associated with retinopathy severity progression and development of DME and/or PDR in a period of 5-years.

ABSTRACT BODY:

Purpose: Previously we have shown the regulatory roles of limbal stromal cell (LSC)-derived exosomes (Exos) in normal (N) and diabetic (DM) limbal epithelial cells (LEC) in vitro and ex vivo organ-cultured corneas. Our purpose was to evaluate the effects of N and DM LEC-derived Exos in N and DM LSC maintenance, proliferation and wound healing.

Methods: Human autopsy age-matched N and DM eyes were from the National Disease Research Interchange. LEC and LSC were isolated from dissected corneas using Dispase/Trypsin and collagenase type IV, respectively. Exosomes were prepared from N and DM LEC-conditioned media by ultracentrifugation. LEC-derived Exos were characterized by NanoSight for morphology and particle size, and by flow cytometry and western blot for their markers (CD63, CD81). Exos were labeled with PKH-67 dye to determine their uptake by LSCs and LECs using confocal microscopy. MTS proliferation assay and scratch wound assay were performed on Exo-treated LSC. Markers of mesenchymal stem cells (MSC) and differentiated keratocytes were assessed by western blot.

Results: Isolated Exos sizes ranged between 50-200 nm with the typical cup shape morphology. N and DM Exos were positive for CD63 and CD81 by both western blot and flow cytometry. The uptaken Exos were observed by confocal microscopy and confirmed by FACS analysis in PKH-67-labeled Exo treated LSC and LECs. FACS analysis showed significant five-fold higher LEC-derived Exo uptake by LSCs than LECs. N Exo treatment significantly stimulated LSC wound healing and proliferation, with the stronger effect than with DM Exo treatment. N Exo treatment increased, whereas DM Exo decreased the protein level of MSC marker, CD90, in N LSCs compared to untreated control by western blot. On the contrary, treatment of N LSCs with N Exo decreased keratocyte markers, ALDH3A1, lumican and keratocan, with a less pronounced effect after DM Exo treatment.

Conclusions: The increased uptake of LEC-derived Exos by LSCs than by LECs suggests the cross-talk between limbal epithelial and stromal cells. The greater effects of N Exos than DM Exos on cell proliferation, wound healing and marker expressions may be due to the differences in their cargos.

TITLE: The role of melanopsin phototransduction pathways in the injury-resistant ability of intrinsically photosensitive retinal ganglion cells

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Jiang, Y. Zhu, Ophthalmology, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zheng Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Yan Zhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glutamate toxicity mediated by NMDA receptors is involved in many retinal diseases, including retinal ischemia and optic nerve injury, which affect many types of retinal ganglion cells (RGCs). Interestingly, a subpopulation of retinal ganglion cells, named intrinsically photosensitive retinal ganglion cells (ipRGCs), are known to be more resistant than other RGCs to retinal injuries. However, the underlying mechanism of their injury-resistant ability is unknown. Distinct from other RGCs, ipRGCs are capable of detecting light without rod and cone photoreceptor cells, owing to their intrinsically expressed light-sensitive GPCR, melanopsin. The relationship between their intrinsic photosensitivity and injury-resistant ability also is not clear. In this work, we used NMDA-induced excitotoxicity model to study the role of melanopsin-mediated phototransduction pathways in the neuroprotective effect of melanopsin.

Methods: NMDA-mediated neurotoxicity was induced by intravitreally injecting 1 mM NMDA and measured by RGC density change based on immunolabelling with RPBMS, a RGC marker. AAV2-OPN4 virus was intravitreally injected to test the effects of ectopic melanopsin in conventional RGCs. ON- and OFF- α -RGCs were distinguished by immunolabelling with SMI32 antibody on Opn4-Cre;Rosa-tdTomato retina. Trpc6 and Trpc7 double knockout animals were used to examine the involvement of TRP-dependent phototransduction pathway.

Results: We found that virally expressing melanopsin in conventional RGCs increases their survival rate in NMDA-toxicity model, suggesting that melanopsin is sufficient to provide a neuroprotective effect in RGCs. In addition, M4-ipRGCs, also known as ON- α -RGC, have a higher survival rate than OFF- α -RGCs after NMDA treatment, suggesting that low expression of melanopsin is still capable of providing a neuroprotective effect. Interestingly, knocking out TRPC6 and TRPC7 does not reduce the survival rate of ipRGCs, suggesting that the TRP-dependent transduction pathway is not required for the NMDA-toxicity-resilient ability of ipRGCs.

Conclusions: Our data indicate that the NMDA-toxicity-resilient ability of ipRGCs does not require TRPC channels and that virally expressed melanopsin is sufficient to provide a neuroprotective effect in conventional RGCs.

ABSTRACT BODY:

Purpose: Eye injuries are found in 10-13% of all combat casualties and, more recently, among civilians with improvised explosive device (IED) injury. Bomb blast injuries exerts a shearing force on the air-tissue interfaces through the blast wave, invoking a significant acute IOP elevation. A sudden elevation in the IOP could significantly amplify the mechanical deformation and/or strain within the laminar region that result in neuronal cell death. This study is aimed to estimate the stresses and deformations in the ONH due to IED explosion using a set of two eye-specific fluid-structure interaction (FSI) ONH models.

Methods: Eye-specific FE models of the ONH, including the pia, optic nerve, LC, sclera, and retina were constructed based on the 3D delineation of anatomic surfaces of the posterior eye obtained from two human donors and then the generic anterior segment was added. An IED with the weights of 1 and 2 kg was placed within 2, 3, and 4 m of the victim's temporal (side) and frontal (front) while the ground was covered with a deformable soil to reflect the blast wave. Prior studies ignored the overpressure due to the blast reinforcement by the ground.

Results: Reflection of the bomb blast pressure from the ground reached to the eye prior to the bomb blast pressure itself, which suggests a crucial role for the ground in reinforcement of the blast pressure and ocular injury simulations. Results revealed an IOP elevation of ~ 6,000-48,000 mmHg, with the highest IOP for the IED weight of 2 kg/victim distance of 2 m (front blast) and the lowest for the IED weight of 1 kg/victim distance of 4m (side blast); this suggests the important role of the victim's position with respect to the blast wave in ocular injury analyses (Figure). IOP was elevated by ~2900 and ~2700 mmHg within 1.6 ms after the blast for the front and side blasts, respectively, matching values reported in the literature, but IOPs were much higher due to ground blast reinforcement after 1.6 ms. Stresses and strains were highest in the temporal quadrant of the eye.

Conclusions: The findings of this study have implications for not only understanding of the stresses and deformations in the ONH due to IED explosion, but also for providing information for the military experts to design a better visor (eye armor) to help break the stress of the wave pressure and protect against blast-induced injuries in the ocular-orbital region.

ABSTRACT BODY:

Purpose: We previously reported that binding of HSV-1 glycoprotein K (gK) to signal peptide peptidase (SPP) is required for virus infectivity. The goal of this study was to map the gK binding region to SPP and to determine if blocking gK binding to SPP using gK peptides reduces HSV-1 primary infection, latency-reactivation, and corneal scarring.

Methods: The gK domain binding to SPP was mapped using co-immunoprecipitation assays. Effect of this peptide, which we call gK4, on virus infectivity was determined by plaque assay, FACS and RT-PCR. The effect of ocular administration of gK4 on ocular HSV-1 replication was evaluated in BALB/c and C57BL/6 mice.

Results: Using a combination of gK fragments and gK peptides the binding domain of gK to SPP was mapped to 5 amino acids. HSV-1 replication in Vero cells was significantly inhibited by gK4 peptide treatment compared to control peptide. BALB/c mice treated with gK4 peptide as eye drops showed significantly less virus replication in the tear film and significantly fewer viral transcripts in the cornea and trigeminal ganglia during primary ocular infection with virulent HSV-1 strain McKrae. Survival in BALB/c mice was improved after treatment with gK4 peptide. Similar results were obtained following treatment of C57BL/6 mice with gK4 peptide.

Conclusions: Our results suggest that the gK4 peptide significantly reduced virus replication both in vitro and in vivo. Thus, gK4 peptide may have therapeutic potential to control ocular HSV-1 infections.

ABSTRACT BODY:

Purpose: Stem cell-derived retinal organoids are widely used to study complex developmental and disease mechanisms. Pluripotent cells can self-organize to form laminated retinal tissue in vitro, but it is unclear whether organoids follow the same histogenetic clock or molecular mechanisms as retinal progenitors in vivo. As a first step to improve organoid disease modeling and use in future therapy we charted the timing of retinal ganglion cell (RGC) neurogenesis in organoid cultures and tested the role of three late-progenitor micro RNAs (LP-miRNAs)—let-7, miR-9, and miR-125b—in retinal organoid differentiation in vitro.

Methods: We isolated induced Pluripotent Stem Cells (iPSCs) from Isl2-GFP BAC transgenic RGC reporter mouse embryonic fibroblasts by transduction with Nanog, Lin28, Sox2, and Oct4. To determine RGC birthdates, we added 5-ethynyl-2'-deoxyuridine (EdU) to organoid cultures during four different two-day windows, and we measured LP-miRNA levels over time by quantitative PCR. To inhibit LP-miRNAs, we stably targeted Isl2-GFP iPSCs with an inducible polysponge vector via CRISPR/Cas9 recombination.

Results: iPSC-derived RGCs expressing Isl2-GFP were born from differentiation days 7 to 15 with peak birthdates at day 10. These EdU labeling results suggest that LP-miRNAs may act to limit RGC genesis over time, as they do in vivo during normal retinal development. To directly test how LP-miRNAs affect organoid RGC production, we isolated Isl2-GFP iPSC clones that express a polymerized miRNA sponge under the control of a Tet-On system. The multivalent sponge targets all three LP-miRNAs, is incorporated into the 3' UTR of an RFP fluorescent reporter, and is strongly induced after doxycycline addition.

Conclusions: Retinal organoids possess great potential as therapeutic and disease model tools. The timing of RGC birthdates match in vitro and in vivo—and appear to be controlled by the same miRNA mechanisms, providing a basis to model disease and manipulate organoids to produce specific cell types or molecules.

ABSTRACT BODY:

Purpose: C1q and the classical complement cascade, key regulators of synaptic pruning in neuronal development, are aberrantly activated in neurodegenerative ophthalmic diseases, including geographic atrophy and glaucoma. ANX007 is a novel fragment antibody that specifically recognizes the substrate-binding head groups of C1q and functionally inhibits the classical complement cascade. Nonclinical studies were completed to assess ANX007 biodistribution and C1q target engagement in the eye and serum following intravitreal (IVT) administration in cynomolgus monkeys.

Methods: Three studies were completed. In a single dose study, animals received 1 or 5 mg/eye IVT (n=2/group/timepoint), and serum, vitreous, and non-perfused tissue samples were collected through Day 30 post-dose. In combined analyses of two repeat-dose studies, animals received two monthly IVT doses of 0, 1, 2.5, or 5 mg/eye on Days 1 and 29 (n=2-6/group/timepoint), and terminal serum, aqueous, and vitreous were collected on Day 44 or 59 in each study. In 0 and 5 mg/eye groups, animals were perfused, and retina, choroid and optic nerve samples were collected on Day 44 or 59. Free ANX007 and free C1q were measured using specific and sensitive ELISA-based assays.

Results: All doses were well-tolerated. Vitreous ANX007 levels were measurable up to 30 days following a single or repeat doses of ANX007 at all dose levels studied. The ANX007 half-life in the vitreous was 3 days. Aqueous and vitreous levels were highly correlated, and aqueous levels were 4-fold lower than in the vitreous. In perfused tissue following two monthly 5 mg/eye doses, ANX007 levels were measurable 30 days post-last dose in the retina and choroid, and through 15 days in the optic nerve samples, confirming the diffusion of drug to the back of the eye. Presence of free drug was associated with a complete reduction of free C1q in fluids and perfused tissues.

Conclusions: Following IVT administration, ANX007 distributes to relevant sites of neurodegenerative ophthalmic disease within the retina, with clear evidence of C1q target engagement. Engagement of C1q in the aqueous humor reflects inhibition in the vitreous and retinal tissue, and is hypothesized to be sufficient to mitigate classical complement activation in neurodegenerative ophthalmic disease. This data supports further clinical evaluation of ANX007 for the treatment of such diseases.

TITLE: Alterations in Gene Expression of Human Trabecular Meshwork Cells in Response to Hyperglycemic Conditions

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Singh, A. Soundararajan, D. Jusufbegovic, J. Lind, P.P. Pattabiraman, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chevy Singh: Commercial Relationship: Code N (No Commercial Relationship) | Avinash Soundararajan: Commercial Relationship: Code N (No Commercial Relationship) | Denis Jusufbegovic: Commercial Relationship: Code N (No Commercial Relationship) | John Lind: Commercial Relationship: Code N (No Commercial Relationship) | Padmanabhan Pattabiraman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetes mellitus (DM) and elevated Intraocular pressure are risk factors for glaucoma, however the mechanisms of this association has not been investigated. The purpose of this study is to understand the alteration in gene expression response in human trabecular meshwork (HTM) cells to hyperglycemic conditions.

Methods: Cultured HTM cells from three donor eyes were maintained in 1% fetal bovine serum (FBS) glucose-free Dulbecco's Modified Eagle Medium (DMEM) with glucose concentrations of 5.5 mM (physiologic serum glucose) or 30 mM (DM patients) for 5 days followed by RNA collection, cDNA conversion and qPCR. Statistical analysis was done via student's t-test where results were statistically significant if $p < 0.05$ for the sample size $n=3$. We particularly examined the gene expression involved in tissue fibrosis including extracellular matrix (ECM), endothelial mesenchymal transition (EndMT) and genes involved in lipid biosynthesis.

Results: Hyperglycemic conditions showed a significant decrease in the cholesterol biosynthetic enzymes 3-hydroxy-3-methyl-glutaryl-coenzyme A synthase (HMGCS) and reductase (HMGCR) ($p=0.04$) and its regulatory transcription factor Sterol regulatory element-binding protein - SREBP 1 and 2. Interestingly there was an increasing trend in - a) profibrotic genes - Collagen 1A, alpha smooth muscle actin, transforming growth factor beta 2 (TGFB2), and Serpin Family E Member 1 (SERPINE), b) extracellular matrix (ECM) components - Fibronectin (FN), Tenascin C (TNC), Collagen 4 alpha (COL4A), Collagen 6 alpha (COL6A), and Elastin (ELN), and c) transcription factors involved in EndMT associated with fibrosis - Snail family transcriptional repressor 1 (SNAIL), Snail family transcriptional repressor 2 (SLUG), and Twist-related protein 1 (TWIST1).

Conclusions: Our preliminary data reveals a negative relationship between cholesterol biosynthesis machinery and positive correlation to fibrotic phenotype in TM as a response to elevated glucose levels. Interestingly, increased ECM deposition in the TM outflow pathway is known to increase resistance to aqueous humor outflow and elevate IOP. Therefore we predict that EndMT resulting in TM fibrosis could be a potential mechanism of IOP elevation in DM subjects.

ABSTRACT BODY:

Purpose: To develop deep learning (DL) models for predicting age, sex, race, diabetes diagnosis, hypertension, cardiovascular disease, and axial length from Spectralis optical coherence tomography (OCT) retinal nerve fiber layer (RNFL) circle and radial scans.

Methods: Spectralis OCT circle and radial scans of the optic nerve head (ONH) acquired from healthy subjects, glaucoma suspects and glaucoma patients from the Diagnostic Imaging in Glaucoma Study (DIGS) and African

Descent and Glaucoma Evaluation Study (ADAGES) were randomly assigned to training (85%), validation (5%) and testing (10%) datasets by patient. DL models were trained on unsegmented circle and radial scans to predict age, sex, race, diabetes diagnosis, hypertension, cardiovascular disease (CVD), and axial length. The circle scan dataset included 52,552 individual B-scans from 1,772 patients. The radial dataset included 111,456 individual B-scans from 730 patients.

Results: The DL models of the best circle and radial scans predicted age with a mean absolute error (MAE (95% CI)) within 5.4 (4.9, 5.9) years and 5.1 (4.5, 5.8) years, respectively and a R^2 (95% CI) of 0.73 (0.67, 0.78) and 0.64 (0.49, 0.76), respectively. For Axial length, the circle scan model had a MAE of 0.7 (0.6, 0.9) mm and an R^2 of 0.3 (0.2, 0.4), and the radial scan model had a MAE of 0.8 (0.7, 1.0) mm and an R^2 of 0.4 (0.2, 0.5). Accuracies (AUROC (95% CI)) for predicting sex in the best circle and radial scans was 0.72 (0.65, 0.79) and 0.68 (0.59, 0.77), respectively. The AUROC for predicting race in the best circle and radial scans was excellent, both 0.96, with 95% CIs of (0.92, 0.98) and (0.91, 0.99), respectively. The AUROC for predicting diabetes diagnosis in the best circle and radial scans was 0.65 (0.52, 0.77) and 0.76 (0.64, 0.85), respectively. The AUROC for predicting hypertension in circle scans was 0.71 (0.59, 0.81) and in radial scans was 0.64 (0.54, 0.73). The AUROC for predicting CVD diagnosis in circle scans was 0.56 (0.47, 0.65) and in radial scans was 0.54 (0.48, 0.62).

Conclusions: These results suggest that there are indicators of demographic and clinical characteristics embedded within OCT images showing that DL can infer these characteristics from images of the ONH. With the exception of predictions of diabetes, the DL models of circle scans predicted clinical and demographic features as well or better than radial scans.

ABSTRACT BODY:

Purpose: Stargardt disease is an inherited, chronic, and progressive retinal dystrophy caused by mutations in the ABCA4 gene resulting in the most common form of juvenile macular degeneration, for which there are currently no therapeutic options. The ABCA4 coding sequence is 6,822 nucleotides in length and therefore exceeds the packaging capacity of a typical AAV capsid. To enable delivery of large genes, several dual AAV vector strategies have been employed, including homologous recombination, trans-splicing, and intein-mediated protein splicing, but each method has advantages and limitations. To overcome these hurdles, we have created a dual AAV approach that allows efficient recombination of N-terminal and C-terminal ABCA4 fragments by exploiting Cre recombinase.

Methods: The first AAV vector encodes the N-terminal region of the ABCA4 gene and also expresses Cre recombinase via a self-cleaving T2A peptide. The second AAV vector encodes the C-terminal region of the ABCA4 gene. Cre recombinase recognizes LoxP sites inserted into each ABCA4 construct and combines the N- and C-terminal fragments resulting in a full-size ABCA4 expression cassette that will exist episomally within the cell. During the same recombination process, the Cre recombinase gene loses its promoter and inactivates itself.

Results: We have demonstrated that infection in tissue culture with a 1:1 ratio of AAV.ABCA_N and AAV.ABCA_C vectors results in efficient ABCA4 coding sequence reconstitution and full-length ABCA4 protein production within 48 hours. Tissue culture cells infected with ABCA_N and ABCA_C vectors lacking Cre recombinase show no detectable full-length ABCA4 protein after up to 120 hours.

Conclusions: Full-length ABCA4 protein can be efficiently reconstituted from two independent AAV vectors by utilizing Cre recombinase. Future studies exploring Cre-mediated ABCA4 reconstitution in vivo and the ability of dual AAV-delivered ABCA4 to clear lipofuscin build-up will be essential milestones to move this early-stage program towards the clinic.

TITLE: The Sensitivity to Light Decrement Controls Rod Response to Flickering Light

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Guo, Y. Umino, E.C. Solessio, Ophthalmology, State University of New York Upstate Medical University, Syracuse, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ying Guo: Commercial Relationship: Code N (No Commercial Relationship) | Yumiko Umino: Commercial Relationship: Code N (No Commercial Relationship) | Eduardo Solessio: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The recovery kinetics of rod photoreceptor response controls rod response to sinusoidal flicker and consequently sets mouse behavioral flicker sensitivity (temporal contrast sensitivity, TCS) at mesopic lights (Umino Y et al., 2019). The purpose of this work is to study the mechanism underlying the control of rod flicker response by rod recovery kinetics. We hypothesize that faster rod recovery kinetics would enhance rod sensitivity to light decrement, leading to increased rod flicker response.

Methods: Rod flicker response was recorded by trans-retinal ERG in WT and a transgenic line (R9OE) over-expressing R9AP that has faster rod recovery kinetics due to increased G_{α^*} -E* inactivation. Retinas were perfused with Ames medium supplemented with DL-AP4 (50 μ M), CNQX (20 μ M) and BaCl₂ (100 μ M) to isolate photoreceptor response. Because the sinusoidal stimuli does not permit separation of response to light increments and decrements, we utilized square wave flicker of 75% contrast of 0.5 Hz at backgrounds 10–3200 R*/rod/s. All comparisons were done at equivalent suppression of circulating current to match the effect of calcium feedback on rod response.

Results: We used brief flashes of various intensities to measure the dim flash sensitivity and the EC₅₀ at different backgrounds to represent rod sensitivity to light increment. WT and R9OE mice display similar flash sensitivity and EC₅₀. We also found that WT and R9OE mice have similar ON responses to square flicker at all backgrounds. By contrast, WT and R9OE mice have similar OFF responses to square flicker which increase with background until 80 R*/rod/s, above which they diverge. WT mice response remains constant while, R9OE mice response keeps increasing, peaking at 800 R*/rod/s and then decreasing. Thus, R9OE mice exhibit larger OFF responses at 80-3200 R*/rod/s, consistent with behavioral flicker sensitivity. We also used 1.5-second steps of various negative contrasts to acquire the contrast gain to light decrement. WT and R9OE mice have similar contrast gain at <80 R*/rod/s. While, R9OE mice display higher contrast gain than WT mice at 80-3200 R*/rod/s.

Conclusions: At mesopic light, the rate of G_{α^*} -E* inactivation in rod phototransduction cascade sets rod sensitivity to light decrement. Thus, the rod sensitivity to light decrement, not increment, controls rod response and behavioral sensitivity to flicker.

ABSTRACT BODY:

Purpose: In recent years, optical coherence tomography angiography (OCTA) has improved our understanding of microvascular changes in myopic macular degeneration. We performed a prospective cross-sectional study using widefield swept-source OCTA (WF SS-OCTA) to assess retinal microvasculature and choroidal thickness in myopia.

Methods: Patients with high myopia (HM; Spherical Equivalent (SE) ≤ -6 D or axial length ≥ 26.5 mm), mild/moderate myopia (MM; $-6\text{D} < \text{SE} \leq -1\text{D}$), and age-matched healthy subjects were imaged with PLEX Elite 9000 (Zeiss) using 3x3mm, 6x6mm, and 12x12mm scans centered on the fovea. Foveal Avascular Zone (FAZ) perimeter, area, and circularity, as well as vessel skeleton density (VSD), vessel density (VD), and choroidal thickness (CT) of entire retina, superficial, and deep slabs were analyzed using the ARI Network (Zeiss Portal).

Results: 186 eyes were analyzed; these eyes were categorized as 75 with HM, 43 with MM, and 68 age-matched controls. HM was associated with increased FAZ perimeter in 6x6 and 12x12 scans ($P < .05$, Table) and decreased circularity in all scans ($P < .002$, Table). HM and MM were associated with decreased VSD and VD in all slabs ($P < .03$, Table). Furthermore, HM was associated with a decrease in every ETDRS subfield, with a larger decrease temporally in 12x12 scans ($\beta_{\text{VSD}} = -13.21$, $\beta_{\text{VD}} = -0.40$, $P < .001$). HM was associated with decreased CT in all scan sizes ($P < .03$, Table). Changes in CT were unevenly distributed, with thinning most evident in the region between central fovea and optic disc and superior nasal subfields ($P < .02$, Figure C).

Conclusions: We identified decreased vessel density associated with myopia using WF SS-OCTA in a large, comprehensive cohort at a single center. We also observed regional differences including a greater decrease in VSD and VD in the temporal quadrant and uneven reductions in CT. Further work may help identify risk factors for the progression of pathologic myopia and other vision threatening complications.

SUBMITTER (NAME ONLY): Julia Fallon

TITLE: Impact of Ophthalmic Infection on New York State Hospital Admission Length, Charges and Hospital Costs from 2010-2017

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Fallon, J. Lin, A. Barash, New York Eye and Ear Infirmary of Mount Sinai Ophthalmology, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Julia Fallon: Commercial Relationship: Code N (No Commercial Relationship) | Jun Lin: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Barash: Commercial Relationship(s);Allergan:Code C (Consultant)

ABSTRACT BODY:

Purpose: To determine if ophthalmic infection was associated with increase in cost or duration of stay in those admitted for ocular disease in New York (NY) state from 2010-2017

Methods: The NY Statewide Planning and Research Cooperative System (SPARCS) database was queried for discharges categorized by "Major Diseases and Disorders of the Eye" (Code 2, All Patient Refined Major Diagnostic Category). These were subcategorized into those admitted for infections and inflammation related to the eye versus those that were admitted for other reasons, using the Clinical Classifications Software (CCS) Diagnosis code, based on the ICD code associated with the hospital stay. We did a statistical analysis of length of stay, costs and charges between these groups utilizing an unpaired two-tailed t-test.

Results: 32,494 discharges were available for analysis. 4 discharges were excluded as they lacked CCS diagnosis information and 7 were excluded for lacking reliable length of stay or cost data. 32,483 unique discharges were analyzed. 48% were female. Ages were 18% 0 to 17 years old, 10% 18 to 29, 21% 30 to 49, 28% 50 to 69, and 23% 70 and older. The average length of stay was 3.6 days (standard deviation 4.84). The average total patient charges and hospital costs for each admission were \$27,900 and \$9,888, respectively. Medicare and Medicaid accounted for majority of the primary payment means, accounting for 31% and 32% of discharges each. There were 11,696 admissions associated with a CCS Diagnosis code related to infection or inflammation, accounting for over 1/3 of all discharges (36%). Infection was significantly associated with a longer duration of admission (4.2 days vs. 3.3 days, p-value <0.01). However, these stays were associated with lower charges to the patient and overall cost (\$26,211 vs. \$28,850, p-value <0.01; \$9,234 vs. \$10,256 p-value <0.01).

Conclusions: Across NY state hospital discharges for ophthalmic complaints from 2010-2017, eye infection and/or inflammation was associated with increased length of stay, but overall decreased charges to the patient and overall cost to the healthcare system. To our knowledge, this is the first analysis of ophthalmology patients utilizing the SPARCS database.

ABSTRACT BODY:

Purpose: Understanding disparities in healthcare utilization can identify barriers to access and motivate efforts to overcome them. We examine disparities in eyecare utilization by race and socioeconomic status (SES) among Medicare beneficiaries with glaucoma.

Methods: A nationally representative 5% sample of Medicare beneficiaries >65 years with glaucoma (≥ 1 ICD-9/10 code, and a Chronic Conditions Warehouse glaucoma diagnosis) was assembled. Low SES was defined as ≥ 2 low-income indicators (dual Medicare/Medicaid eligibility; Part D limited income subsidies; eligibility for Part A/B state buy-in). Eye care utilisation was measured using CPT codes for in/outpatient visits, visual field (VF) and retinal nerve fibre layer optic coherence tomography (RNFL OCT) testing, and laser/surgical intervention between 6/30/2014-12/31/2016. We estimated adjusted incidence rate ratios (IRR) for eyecare utilization comparing race and SES.

Results: 79,787 glaucoma beneficiaries were included. Compared to Whites, Black beneficiaries were less likely have outpatient visits (IRR [95% CI] 0.90 [0.89-0.91]), VF testing (0.92 [0.91-0.94]), and RNFL OCT testing (0.77 [0.75-0.79]); but more likely to undergo glaucoma surgery (1.17 [1.04-1.30]). Hispanic beneficiaries were less likely to undergo RNFL OCT testing (0.90 [0.86-0.93]). Asian beneficiaries were more likely to have outpatient visits (1.06 [1.04-1.09]) and VF testing (1.10 [1.07-1.14]).

Low SES beneficiaries were less likely vs high SES to have outpatient visits (0.92 [0.91-0.93]), VF testing (0.81 [0.80-0.83]), RNFL OCT testing (0.77 [0.76-0.79]) and glaucoma surgery (0.79 [0.70-0.90]). White beneficiaries of low SES were less likely vs high SES to undergo outpatient visits (0.86 [0.84-0.87]), VF testing (0.76 [0.74-0.78]), RNFL OCT testing (0.76 [0.74-0.79]), selective laser trabeculoplasty (SLT) (0.74 [0.64-0.85]), and trabeculoplasty (0.60 [0.44-0.82]), aqueous shunt (0.63 [0.42-0.96]) and minimally invasive glaucoma surgery (MIGS) (0.74 [0.59-0.92]). There was no difference in all eyecare utilization by SES among Black beneficiaries.

Conclusions: Black and Hispanic beneficiaries with glaucoma generally receive less eyecare than Whites. Even when adjusted, the association of low SES with eyecare utilization differed by race. Further research is needed to understand reasons for these disparities.

ABSTRACT BODY:

Purpose: Dry age-related macular degeneration (dAMD), the main blindness cause in the elderly, is characterized by retinal pigment epithelium (RPE) and photoreceptors (PR) atrophy circumscribed to the macular area. At the moment, there are no effective therapies to prevent or delay the vision loss affecting dAMD patients. We have developed a dAMD model induced by superior cervical ganglionectomy (SCGx) in C57BL/6J mice, which reproduces the disease hallmarks exclusively circumscribed to the RPE/outer retina temporal region. Environmental enrichment (EE) is a complex condition that boosts physical and social stimulation. Several reports show that EE provides a better recovery from different neuropathology and retinal alterations. In this context, our aim was analyzing the effect of EE on the alterations induced by experimental dAMD.

Methods: Adult male C57BL/6j mice were submitted to unilateral SCGx, where the contralateral side was submitted to a sham procedure. Animals were continuously exposed to SE or EE during different intervals. Visual function (electroretinography and visual behavior tests) was analyzed at 4, 6 and 10 weeks post-SCGx. Retinal histology and ultrastructure were analyzed at 10 weeks post-SCGx. RPE mitochondria and oxidative stress markers were assessed by Western blotting, specific probes, and immunofluorescence at 6 weeks post-SCGx.

Results: SCGx induced a reduction of the melanin content and RPE65 immunoreactivity at the temporal RPE, as well as a decrease in mitochondria mass, an increase in mitochondria superoxide and lipid peroxidation products. Moreover, SCGx induced ultrastructural alterations at the temporal RPE and PR. EE did not prevent SCGx-induced choroid alterations but significantly prevented the visual dysfunction, histology and ultrastructure alterations, mitochondria and oxidative stress. Moreover, EE reversed the functional and structural damage induced by SCGx when started at 4 weeks post-surgery.

Conclusions: Therefore, exposure to EE prevented, and reversed the damage induced by experimental dAMD, probably through RPE mitochondria protection and RPE oxidative damage prevention, thus becoming as a promising novel therapeutic strategy for dAMD.

ABSTRACT BODY:

Purpose: We designed the ARI Network Hub: an online platform to share and process swept-source (SS) OCT angiography data. Our goal was to bring together leading clinicians with scientists and developers to accelerate retinal research through collaboration. In this work we analyze the success of this cloud-based solution in the 4 years since origination.

Methods: We set up a platform where different sites can upload deidentified data directly from a PLEX® Elite 9000 (ZEISS, Dublin, CA) instrument into the ARI Network Hub, and share it in collaboration with other sites as well as execute prototype algorithms. The initial 4-year goal was to add up to 220 sites on board. Prototype algorithm development for innovation was shaped by the clinicians part of this collaborative effort. We tracked number of sites, collaborations started between them, data uploaded, prototype algorithms shared and algorithms executed within the system. We analyzed scalability needs in terms of data storage, processing power and bandwidth to further understand the optimal design of such a cloud-based solution.

Results: 195 sites joined within the 4 years, leading to more than 289 independent publications derived from this collaborative effort. Data uploads were minimal during year 1 but increased during year 2 at a stable rate of ~100 and ~0.7TB per year quarter (/y.qtr) in terms of independent OCT volume datasets and size, respectively. Growth increased ~150%/y.qtr in both number and size in the remaining 2 years (Figure 1). Data uploaded after 4 years was a total of 22000 datasets holding 17TB. 23 processing algorithms were shared across participating sites, with macular density quantification algorithms being of highest usage. Algorithm usage saw an increase with the number of algorithms made available and data shared within the system. There was high non-uniformity across sites in terms of data shared, as well as in algorithm use both across sites and over time, highlighting the need of quick scalability of the design both in storage and calculations.

Conclusions: The proposed cloud-based solution was adopted and proved to accelerate research, especially considering the streamlined collaboration between institutions and device manufacturers. The vast amount of data acquired and collected represents high potential for future collaborative research and algorithm development.

TITLE: Rising incidence of ocular chemical injury secondary to assault in the Northeast of England

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.C. Figueiredo, C. Bruce, C. Cartes, S. Pradhan, Ophthalmology, Royal Victoria Infirmary, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|F.C. Figueiredo, Biosciences Institute, Newcastle University Faculty of Medical Sciences, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Francisco Figueiredo: Commercial Relationship: Code N (No Commercial Relationship) | Charlotte Bruce: Commercial Relationship: Code N (No Commercial Relationship) | Cristian Cartes: Commercial Relationship: Code N (No Commercial Relationship) | Sayali Pradhan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the rising incidence of ocular chemical assaults and analyse the epidemiologic and clinical profile of these injuries at a tertiary eye centre in the Northeast (NE) of England. These acts of violence affect the victims physically, psychologically and impact their quality of life negatively. Hence, constitute a significant social concern

Methods: Retrospective review of all consecutive cases with ocular injuries secondary to chemical assault presenting to the Eye Emergency Department, Royal Victoria Infirmary, Newcastle upon Tyne, UK between November 2015 and October 2020. The incidence, patient demographics, nature of chemicals, severity, management and clinical outcomes were recorded

Results: During the study period, 126 eyes of 90 patients endured these injuries secondary to an assault. Number of chemical assaults was 7 (9 eyes), 22 (31 eyes), 23 (30 eyes), 15 (21 eyes) and 23 (35 eyes) in the 1st, 2nd, 3rd, 4th and 5th year respectively. The mean age was 32.3 years (SD 11.7; Range 13-78). Male (92.2%) preponderance was noted. The ocular injury was unilateral in 54 patients (60.0%) and bilateral in 36 (40.0%). Ammonia was the commonest chemical used (67.8 %). Roper Hall severity grading at presentation was grade 1 in 61.9% (n= 78), Grade 2 in 12.7% (n=16), grade 3 in 12.7% (n=16), grade 4 in 7.9% (n= 10) and undocumented in 4.8% (n=6). Out of the 90 eyes, 82 (91.1%) were acutely managed medically. Eight eyes (8.9 %) needed amniotic membrane transplant, 7 of which were Roper Hall Grade IV and 1 was Grade III. Five of these patients progressed to total limbal stem cell failure despite maximal medical and surgical management

Conclusions: A rise in incidence of eye injuries caused by chemical assault, also known as “acid attack”, has been observed in young adult men over the past 5 years in NE of England. This can be vision threatening and is a rather serious medical and social concern requiring further investigation to be able to increase public awareness, implement stricter regulations, better surveillance and means of prevention and provide adequate support to the victims

TITLE: The R345W-fibulin-3 mutation increases the sensitivity of the outer retina to damage caused by sodium iodate

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Geathers, J. Liao, S.L. Grillo, A.J. Barber, J. Sundstrom, Ophthalmology, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|W. Wang, The University of Texas at Austin, Austin, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jasmine Geathers: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Liao: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Grillo: Commercial Relationship: Code N (No Commercial Relationship) | Weiwei Wang: Commercial Relationship: Code N (No Commercial Relationship) | Alistair Barber: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Sundstrom: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Malattia Leventinese (ML), an autosomal dominant inherited degenerative eye disease, is caused by a point mutation (R345W) in the fibulin-3 (Fib3) gene (efemp1) that results in hyperreflective foci (detected by optical coherence tomography) in association with sub-retinal pigment epithelium (RPE) drusen and hyper-pigmentation. The purpose this study was to determine the extent of augmentation of hyperreflectivity caused by sodium iodate (SI)-induced retinal degeneration in mice carrying the R345W fib3 mutation.

Methods: Eighteen C57 three-month-old male and female mice were injected with SI dissolved in PBS at 15, 30, 45, or 60 mg/kg. Spectral-domain optic coherence topography (SD-OCT) images were acquired 7 days later (Bioptigen). Frozen vertical retinal cross-sections (10 µm thick) of eyes from wild-type (WT), heterozygous (Fib3^{+/-ki}), and homozygous (Fib3^{ki/ki}) mice were processed for H&E staining.

Results: Hyperreflective foci (HRF) were detected by SD-OCT in the retinas of WT mice given 45 and 60 mg/kg, but not in those given 15 and 30 mg/kg. H&E sections appeared normal in the control mice, and in the WT mice that received 15 and 30 mg/kg of SI. The retinas of WT mice receiving 45 and 60 mg/kg were thinner than the control (31.2% and 27.1%, p<0.001), due to the loss of tissue in the photoreceptor layer. Thinning of the ONL and disorganization of the RPE layer was also noted. Hyperreflective foci were evident in Fib3^{+/-ki} and Fib3^{ki/ki} mice given SI at 30, 45, and 60 mg/kg but were not apparent in mice given 15mg/kg. H&E images followed a similar trend, with the 15mg/kg dose looking similar to the controls, whereas sections from Fib3^{+/-ki} and Fib3^{ki/ki} mice treated with 30, 45, and 60mg/kg presented with pigmented lesions in the neural retina.

Conclusions: The results suggest that SI causes HRF and induces pigment migration into the neural retina in WT mice. Furthermore, presence of the fib3 mutation increases sensitivity to SI exposure, leading to more dramatic retinal degeneration and pigment migration. Our results suggest that the R345W mutation increases susceptibility of the outer retina and RPE to chemical or metabolic insult.

TITLE: Activation of p38-MAPK is Required for VEGFA165-induced Migration, but not Proliferation, of Primary Human Retinal Microvascular Endothelial Cells

SESSION TITLE: Retinal diseases: molecular and biochemical mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Putris, W.A. Dailey, B. Metcalf, M. Deshpande, K.P. Mitton, Eye Research Institute, Oakland University, Rochester, Michigan, UNITED STATES|N. Putris, B. Metcalf, Oakland University William Beaumont School of Medicine, Rochester, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nahrain Putris: Commercial Relationship: Code N (No Commercial Relationship) | Wendy Dailey: Commercial Relationship: Code N (No Commercial Relationship) | Brandon Metcalf: Commercial Relationship: Code N (No Commercial Relationship) | Mirinalini Deshpande: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Mitton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In addition to the well-known pathological consequences of elevated total VEGFA, reports of isoform switching of VEGFA165b to VEGFA165a in the vitreous of patients with proliferative eye diseases led us to ask whether this isoform shift is a significant contributor to the hyperactivation of primary human retinal microvascular endothelial cells (HRMECs). As part of this investigation, we compared the contributions of MAPK, AKT, and p38-MAPK to proliferation and migration in primary HRMECs using in situ immunofluorescence assays.

Methods: VEGFA165 isoforms were compared for their effects on cell proliferation, measured with infrared-fluorescence Cell-Tag assays. Cell migration was compared using a fluorescent transmembrane migration assay in the multiwell plate format. Relative contribution of the MAPK, AKT, and p38-MAPK pathway to cell proliferation and migration were assessed using pharmacological inhibition of MAPK, AKT, and p38-MAPK activation.

Results: At a saturating activation concentration (5,000pM), VEGFA165b was as good or slightly more potent than VEGFA165a as a stimulator of cell proliferation but was not significantly different between both isoforms. The p38-MAPK inhibitor SB203580 increased HRMEC proliferation but was also found to be a potent activator of MAPK, while blocking p38-MAPK activation. VEGFA165a stimulated cell migration more than 6-fold compared to VEGFA165b at 1000 pM. Inhibition of MAPK with U0126 (MEK inhibitor), did not inhibit VEGFA165-induced migration. Inhibition of AKT activation with MK2206 did not inhibit a VEGFA165-induced cell migration. Inhibition of p38-MAPK with BIRB796 completely blocked VEGFA165-induced cell migration.

Conclusions: VEGFA165b was a poor activator of HRMEC migration at lower, physiological, concentrations where VEGFA165a induced substantial cell migration. This was consistent with our dose-response analysis of their relative activation of intracellular signaling pathways (MAPK, AKT, and p38-MAPK). VEGFA165 driven cell migration was mostly mediated via activation of the p38-MAPK pathway. VEGFA165-induced proliferation of primary HRMECs did not require activation of p38-MAPK in addition to MAPK.

TITLE: Progressive loss of retinal arteriolar smooth muscle cells (SMCs) with aging and caveolin-1 (Cav1) depletion: Assessing the importance of endothelial cell (EC)-Cav1 in retinal SMC maintenance

SESSION TITLE: Pathophysiology of ocular aging and degeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Gurley, Ophthalmology, Dean McGee Eye Institute, Oklahoma City, Oklahoma, UNITED STATES|J. Gurley, E.A. Hargis, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|N. Standifer, The University of Oklahoma, Norman, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jami Gurley: Commercial Relationship: Code N (No Commercial Relationship) | Nick Standifer: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Hargis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal vascular disease accounts for the majority of vision loss, and aging and diabetes increase the risk for retinal vascular dysfunction and degeneration. Loss of retinal SMCs has been observed in diabetic humans, and in aged and global Cav1 knockout (KO) mouse retinas. However, the relationships among aging, diabetes, and Cav1 function as it relates to SMC maintenance is unclear. The purpose of this study was 1) to characterize SMC loss that occurs with murine aging, 2) to evaluate potential SMC loss in aged human retinas, and 3) to assess the importance of EC-Cav1 on SMC maintenance.

Methods: Micron IV imaging was used to monitor longitudinal in vivo SMC loss in wild type (WT) animals expressing SMC-GFP driven by the alpha-smooth muscle actin (α SMA) promoter. Aged human retinal punches were stained with α SMA and collagen IV antibodies in order to visualize SMC coverage by immunohistochemistry (IHC). Tie2- and Sm22-Cre recombination of the Cav1 floxed gene were used to generate EC- and SMC-Cav1 KO mice, respectively. SMC coverage area and gap numbers per area along retinal arterioles were determined by ImageJ analysis of confocal laser scanning microscopy images from murine retinal flat mounts stained with α SMA and CD31 (as per Reagan et al. 2018).

Results: Retinal SMC loss occurs in WT mice as early as 10 months of age. We also observed incomplete SMC coverage along aged human arterioles. Tie2-, but not Sm22-, Cav1 KOs exhibited reduced arteriolar SMC coverage compared to WT controls (WT: 0.994 ± 0.002 ; Tie2-KO: 0.979 ± 0.003 ; Sm22-KO: 0.997 ± 0.001 ; $p < 0.0001$ WT vs Tie2-KO). Likewise, Tie2-KO retinas showed increased arteriolar SMC gap numbers per area compared to WT and Sm22-KOs (WT: 0.023 ± 0.006 ; Tie2-KO: 0.129 ± 0.020 ; Sm22-KO: 0.025 ± 0.008 ; $p < 0.0001$ WT vs Tie2-KO).

Conclusions: Our data suggest that aging, as well as loss of EC-Cav1 function, results in reduced SMC coverage along retinal arterioles. Additionally, our data support that EC-, rather than SMC-specific Cav1, is important for arteriolar SMC maintenance in adult murine retinas. Future studies will investigate the importance of EC-Cav1 on SMC maintenance and retinal vascular disease through assessment of: 1) cellular and metabolic EC functions, 2) EC/SMC interactions, and 3) potential EC-Cav1 dysfunction in DR progression.

TITLE: Peptidyl Arginine Deiminase 4 (PAD4) inhibition does not prevent neutrophil extracellular traps (NETs) formation or significantly decrease ocular inflammation in two mouse models of uveitis

SESSION TITLE: Translational Immunology and Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Wilson, V. Wang, K. Pepple, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|R. Kuley, R. Moore, C. Lood, Rheumatology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Leslie Wilson: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Wang: Commercial Relationship: Code N (No Commercial Relationship) | Runa Kuley: Commercial Relationship: Code N (No Commercial Relationship) | Richard Moore: Commercial Relationship: Code N (No Commercial Relationship) | Christian Lood: Commercial Relationship: Code N (No Commercial Relationship) | Kathryn Pepple: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Determine if NETs form in eyes with experimental uveitis, and measure the impact of inhibiting NET formation on ocular inflammation in Primed Mycobacterial Uveitis (PMU) and Experimental Autoimmune Uveitis (EAU).

Methods: For chemical inhibition of NETs, uveitis was induced with either the PMU or IRBP immunization EAU protocol in C57BL6 mice. Mice were divided into groups treated with either PBS, dexamethasone (Dex), or chloride amidine (CI-Am) a PAD4 inhibitor that significantly reduced NET formation in a mouse model of ANCA vasculitis. For genetic inhibition of NETs, PMU or EAU was induced in C57BL6 and PAD4 deficient animals. Ocular inflammation was scored on the day of peak inflammation in PMU using optical coherence tomography (OCT) or by fundus score in EAU. To detect intraocular NETs, immunohistochemistry (IHC) was performed on ocular sections with antibodies to detect myeloperoxidase (MPO), citrullinated H3, and extracellular DNA. Additionally, intraocular NET concentration was determined using an ELISA that detects extracellular DNA complexed with MPO. Comparisons between treatment groups were made using Kruskal Wallis or unpaired t-test. Differences in NET concentration between right and left eyes in PMU animals were compared using paired t-test. Significant differences were determined as $p < 0.05$.

Results: NETs were detected in inflamed eyes by IHC (A) and ELISA (B). NETs concentrations were significantly elevated in inflamed (right eyes) of PMU animals compared to uninflamed fellow (left eyes) for all treatments. In PMU, no treatment significantly decreased NET concentration compared to PBS. In EAU, treatment with Dex and CI-Am decreased aqueous NET concentration compared to PBS, but not significantly. There was a mild, non-significant decrease in inflammation score in PMU animals treated with CI-Am (C). In EAU, CI-Am treatment also non-significantly decreased inflammation score compared to PBS (D). Only Dex significantly decreased fundus scores in EAU animals. PAD4 deficiency did not impact NET concentration or clinical score in PMU or EAU.

Conclusions: NETs are present in eyes with uveitis, but their formation is not PAD4 dependent. Treatment with CI-Am has a mild anti-inflammatory impact on uveitis, but this effect is likely mediated by inhibition of other protein deiminases and not PAD4

TITLE: VEGFR2 trafficking by KIF13B is a novel therapeutic target for wet AMD

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K. Yamada, C. Zhou, Pharmacology and Regenerative Medicine, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|K. Yamada, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kaori Yamada: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Zhou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor (VEGF) and its receptor VEGFR2 are promising therapeutic targets for wet AMD. As a topically applicable option, we developed the peptide KAI to selectively interfere with VEGFR2 trafficking to the cell surface where it receives VEGF. This study sought to determine the efficacy of KAI in the mouse model of choroidal neovascularization (CNV).

Methods: The specificity of KAI was tested by surface plasmon resonance (SPR). The drug delivery was analyzed by cryosection and the ELISA after treatment of KAI eyedrop to the mouse eyes. For the laser-induced CNV model, mice with laser-induced ruptures in Bruch's membrane received daily treatment of KAI eyedrop or control peptide. The other groups of mice received intravitreal injection of anti-VEGF or IgG control. After 2 weeks, CNV was quantified and compared.

Results: First, we showed the specificity and high affinity of KAI to VEGFR2. Next, biodistribution revealed successful delivery of KAI eyedrop to the back of the mouse eyes. KAI significantly reduced the disease progression in laser-induced CNV. The comparison with current therapy suggests that KAI eyedrop is as effective as current therapy to prevent CNV in wet AMD. Moreover, the genetic deletion of a kinesin KIF13B, which mediates VEGFR2 trafficking to the cell surface, confirmed the pivotal role of KIF13B in disease progression of wet AMD and neovascularization from choroidal vessels.

Conclusions: Taken together, pharmacological inhibition and genetic deletion complementarily suggest the therapeutic possibility of targeting VEGFR2 trafficking to inhibit pathological angiogenesis in wet AMD.

ABSTRACT BODY:

Purpose: Herpes Keratitis (HK) is a corneal infection causing the highest rate of infectious blindness in developed countries. The immune response to HK in human tissue has not been widely studied to date. This study aims to characterise the different subsets and locations of immune cells in human corneal tissue and compare them between herpetic and cadaver corneas.

Methods: Six corneas from cadavers were collected from NSW Tissue Banks and 1 HK sample was collected from Sydney Eye Hospital. $\frac{3}{4}$ segments of each cornea was incubated with Collagenase Type II for 4 hours to extract cells from the epithelium and stroma in a single suspension before staining with monoclonal anti-human antibodies and analysing them by high parameter flow cytometry. The 23 markers include CD14, CD11c, CD4, CD8 and CD56. Results are presented as mean (\pm SEM).

The remaining $\frac{1}{4}$ segments from each cornea were fixed in 4% paraformaldehyde for 24 hours prior to staining with fluorescently labelled DAPI, langerin, CD3 and CD56. Sections were imaged to assess the locations and morphologies of Langerhans cells, T cells and natural killer cells.

Results: Epithelia of the cadaver samples (time post-enucleation range 0-1 days) showed an increased presence of CD14⁺ macrophages (10.46 ± 2.23) and conventional type 2 dendritic cells (13.94 ± 7.43) compared to the HK corneal sample (1.56 ; 0.28 respectively). However, CD4 cells, CD8 T cells and natural killer cells were shown at higher proportions in the epithelium of the HK sample (21.4 ; 31.5 ; 16.1 respectively) compared to the cadaver control groups (19.74 ± 7.86 ; 26.97 ± 5.11 ; 2.97 ± 1.14). Similar trends were seen in the stroma however, there was no difference between natural killer cell populations.

Immunofluorescence microscopy of the HK cornea showed that there was an accumulation of T cells in the central region of the stroma (59) whereas human cadaver samples showed minimal T cells in this corresponding region (3.33 ± 1.67). Human cadaver samples showed Langerhans' cells, T cells and natural killer cells residing in the limbal epithelium and stroma as previously shown.

Conclusions: Human HK tissue exhibited a decrease in myeloid cells and increase in lymphocytes compared to cadaver samples, which were mainly located in the central stroma. Further investigation is required to better characterise the role of these cell types and the pathway of myeloid cells in human HK.

TITLE: Comparison of the quality of life between glaucoma and age-related macular degeneration patients living in a middle-income country.

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.M. Maccione, K.S. Tomishige, C.S. Germano, P.A. Ottaiano, N. Kasahara, Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo, SP, BRAZIL

Commercial Relationships Disclosure (Abstract): Renato Maccione: Commercial Relationship: Code N (No Commercial Relationship) | Kenzo Tomishige: Commercial Relationship: Code N (No Commercial Relationship) | Caroline Germano: Commercial Relationship: Code N (No Commercial Relationship) | Patrícia Ottaiano: Commercial Relationship: Code N (No Commercial Relationship) | Niro Kasahara: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Health-related quality of life (QoL) has emerged as an essential health outcome in population health, clinical trials, and clinical improvement. Both patients with glaucoma and age-related macular degeneration (AMD) have compromised QoL as compared to their age-matched counterparts with normal vision. This topic has not been extensively assessed in patients with eye diseases living in low-middle income countries. This cross-sectional, case-control study aimed to compare the QoL between primary open-angle glaucoma (POAG) and AMD Brazilian patients.

Methods: Patients with AMD, POAG, and normal controls underwent a complete eye examination including measurement of best-corrected visual acuity, biomicroscopy, tonometry, and eye fundus evaluation; all participants answered the Brazilian-Portuguese version of the Visual Function Questionnaire 25 (VFQ-25). The VFQ-25 consists of a base set of 25 vision-target questions representing 11 vision-related constructs and one additional single-item general health rating question. Each item was scored and an overall composite score was calculated and compared among groups with the ANOVA test.

Results: The sample comprised 48 patients with AMD, 56 with POAG, and 53 controls. All groups were matched for age, gender, ethnic distribution, and comorbidities. VFQ-25 total score was lower in both POAG (61.8 ± 20.4) and AMD (50.7 ± 20.9) as compared to controls (89.3 ± 9.1 , $P < 0.000$); AMD patients' score was lower than POAG patients ($P = 0.04$).

Conclusions: Brazilian patients with POAG and AMD presented significantly lower QoL highlighting the need to improve the care of patients in this middle-income country.

ABSTRACT BODY:

Purpose: To assess whether vision measures are predictive of disease progression to advanced AMD in people with intermediate (I) AMD.

Methods: 125 participants were tested monocularly (best correction) on a test battery described previously (Lott, et al, 2020)¹ and followed over time. All enrolled participants had high contrast acuity better than 20/40 (≤ 0.30 logMAR) at baseline (BL). AMD status was ascertained by dilated eye exam and fundus photos, and each eye was categorized as follows: Control (no drusen or small drusen only), Early (medium drusen), or I-AMD (large drusen and/or pigment abnormalities)². Progression to advanced AMD (neovascularization [NV] or geographic atrophy [GA]) was determined by dilated exam and OCT. General estimating equations (GEE) logistic regression analyses were used to assess the association between vision measures and progression to advanced AMD, taking into account the correlation between the two eyes.

Results: To date, 29 eyes (of 22 participants) progressed to advanced AMD (20 NV, 9 GA) an average of 1.82 +/- 1.05 years after vision data were collected (range 0.08 – 4.52 years). All eyes that progressed had I-AMD at BL vision testing, so age-matched I-AMD eyes that did not develop advanced AMD in either eye were the comparison group (39 eyes of 27 participants). In GEE logistic regression models including age, only shape discrimination hyperacuity (SDH)³ ($p < 0.05$) was a significant predictor of progression to NV. When AMD pigment status (PS; present/absent) was included with age and SDH in the NV model, neither PS nor SDH attained statistical significance due to high shared covariance; PS and SDH were significantly associated in I-AMD⁴. In separate models including age, significant functional predictors of GA were low contrast acuity at low luminance⁵ (LC_LL) ($p < 0.007$) or optotype contrast sensitivity (CS) ($p < 0.04$). When PS was included in the GA model with age and LC_LL, only LC_LL was statistically significant ($p < 0.01$). When PS was included in the model with age and CS, both PS and CS remained significant ($p < 0.05$ and $p < 0.03$, respectively).

Conclusions: Clinically feasible vision function tests may aid the prediction of progression to advanced AMD. Different vision measures predict NV (SDH) vs. GA (LC_LL or CS).

TITLE: Electronic clinical decision support tool for hydroxychloroquine dosing guideline adherence

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Chen, B. Kuo, A. Kalur, J. Muste, R.P. Singh, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|A. Kalur, J. Muste, R.P. Singh, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rebecca Chen: Commercial Relationship: Code N (No Commercial Relationship) | Blanche Kuo: Commercial Relationship: Code N (No Commercial Relationship) | Aneesha Kalur: Commercial Relationship: Code N (No Commercial Relationship) | Justin Muste: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To implement and assess the impact of an electronic clinical decision support tool (DST) on prescriber adherence to 2016 Academy of Ophthalmology (AAO) recommendations for a hydroxychloroquine maximum daily dose of 5 mg/kg actual body weight.

Methods: A DST was developed to trigger a pop-up alert within the electronic medical record when a prescriber orders hydroxychloroquine exceeding 5 mg/kg actual body weight or >400mg daily. The prescriber may choose to amend the prescription or override the alert. The tool was implemented on April 21, 2020. A chart review was performed of all hydroxychloroquine prescriptions in the 6-month post-intervention period (May – November 2020). Inclusion criteria were patient age ≥ 18 years; availability of dose and frequency; availability of actual body weight; and outpatient prescription status. Only the most recent prescription was used in cases of an individual patient having multiple prescriptions. Prevalence of excess hydroxychloroquine dosing ($>5\text{mg/kg/day}$) and mean daily dose in the post-intervention period was compared to previously collected, pre-intervention data from 2018 (under review for publication), using the chi-squared test and 2-sample t-test, respectively. The odds ratios of excessive dosing was assessed using multivariable logistic regression that included sex, race, weight, and prescriber specialty.

Results: There were 7915 patients with active hydroxychloroquine prescription, of which 7415 (94%) met inclusion criteria. There prevalence of excessive dosing decreased from 27.4% pre-DST to 21.1% post-DST ($P<0.001$). Mean daily dose decreased from 342 ± 94 mg (4.3 ± 1.4 mg/kg/day) pre-DST to 324 ± 93 mg (4.1 ± 1.3 mg/kg/day) post-DST ($P<0.001$). Only 0.2% prescriptions exceeded mean 400mg daily, and 0.1% prescriptions were indicated for COVID-19. In multivariable analysis, a rheumatologist prescriber (in comparison to all other specialties, OR 0.66 [99% CI 0.54-0.80]) and greater weight (OR 0.94 [99% CI 0.93-0.95], equivalent to -0.062 log odds per 1 kg increase in weight) were associated with reduced odds of excessive dosing.

Conclusions: Implementation of a DST significantly improved prescriber adherence with 2016 AAO ophthalmic safety recommendations for hydroxychloroquine dosing. As daily dosage is a strong predictor of retinopathy risk, an electronic DST demonstrates potential to reduce ophthalmic morbidity associated with chronic hydroxychloroquine use.

TITLE: Assessing open angle glaucoma as an independent risk factor for stroke

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Sadek, I.S. Shaikh, S.T. Elsamna, A.S. Khouri, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hadeel Sadek: Commercial Relationship: Code N (No Commercial Relationship) | Ibraheem Shaikh: Commercial Relationship: Code N (No Commercial Relationship) | Samer Elsamna: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of vision-threatening disease worldwide and its open-angle variant has previously been explored as a risk factor for stroke. Using a large sample population database, we investigated the possible impact of open-angle glaucoma (OAG) both with and without numerous other clinical and non-clinical factors on the risk of developing stroke.

Methods: Cases of OAG were obtained from the National Inpatient Sample (NIS) database between 2002 and 2013 using ICD-9 codes. Associated morbidities and procedures were assessed in a random sample of cases with a primary hospital admitting diagnosis of stroke, no prior history of stroke, and a history of OAG. Univariate and multivariate logistic regression analyses were carried out in glaucoma cases to determine risk factors for stroke. A second analysis was conducted after propensity matching (1:5 ratio) for other risk factors to determine if glaucoma was independently associated with increased risk of stroke. The Bonferroni correction method was applied.

Results: The random sample consisted of 395,724 cases which were grouped into stroke (n=4,614) and non-stroke (n=391,110) cohorts. History of OAG (n=4,187) was found to be strongly associated with stroke in univariate analysis (OR: 2.26, 95% CI: 2.07-2.46) but this association was found to be weaker (OR: 1.11, 95% CI: 1.04-1.18) in multivariate analysis (Figure 1). When propensity matching (Figure 2) was performed for clinical and non-clinical risk factors found to be significant for stroke (including age, sex, race, insurance status, hypertension, diabetes, alcohol use, congestive heart failure, and valve disease), glaucoma was no longer significantly associated with stroke (p=0.06).

Conclusions: A large patient population was utilized to determine whether OAG is independently associated with stroke. Our findings suggest that prior noted association with stroke is likely based on similar risk factors rather than an independent association. Study limitations include lack of evidence for causal relationships in a retrospective study and limitations in coding of historical diagnoses in patient records.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) scans are important for clinical evaluation of the retina, but manual evaluation of each B-scan is time consuming and requires significant expertise. To improve the workflow, a B-scan of interest tool (BSOI) was created using deep learning to indicate B-scans of interest as well as B-scans of poor image quality (IQ). The purpose of this study was to determine if the BSOI tool agreed with doctors' clinical judgement.

Methods: Macular cube 512x128 scans were acquired using CIRRUS™ 6000 (ZEISS, Dublin, CA) on 47 subjects with various pathologies including macular degeneration, diabetic eye disease, epiretinal membranes, macular hole and central serous retinopathy. The BSOI tool first runs an IQ algorithm which flags B-scans with poor IQ then further flags good IQ scans if it finds one of the retinal pathologies as referenced in [1]. The prototype tool was integrated into the macular thickness analysis report, flagging B-scans of interest with a red indicator and poor IQ scans with a yellow indicator.

5 independent expert graders (2 retina specialists (RS) and 3 optometrists (OD)) evaluated the tool results and used a feedback feature to indicate if they agreed (thumbs up) or disagreed (thumbs down) (Fig 1). Intraclass correlation coefficient (ICC) and pair-wise Cohen's kappa between graders were used to assess inter-grader consensus. Graders also answered a survey rating the clinical utility and loading time of the tool.

Results: Mean agreement of an individual grader with the tool was 79% and majority vote agreement between graders and the tool was 81%. Table 1 shows agreement (and 95% confidence interval) of each grader and survey answers. The ICC was 0.44 (0.32, 0.60) indicating poor reliability of agreement between all doctors. Kappas showed fair to moderate agreement between pairwise doctors.

Conclusions: This tool successfully flags B-scans that may have otherwise been missed by doctors. When evaluating agreement between graders on individual cases, differences in inter-clinician's grades were observed, even between retinal specialists. The mean agreement between the B-scan of interest algorithm and the graders were considered clinically acceptable. All graders agreed that the tool increases efficiency with appropriate loading time, can be useful for diagnoses and can be used by both technicians as well as clinicians.

ABSTRACT BODY:

Purpose: The significance of peripapillary retinal nerve fiber layer (RNFL) thickness variations in patients with retinitis pigmentosa (RP) is inconsistent. We performed a retrospective medical record review to investigate whether thickening or thinning of the RNFL in eyes of patients with RP correlated with indications of macular atrophy via spectral-domain optical coherence tomography (SD-OCT) and ocular examination.

Methods: The medical records of 30 eyes from 15 patients with retinitis pigmentosa who are currently enrolled in the University of Florida Health Eye Center database were reviewed. All patients had complete ocular evaluations combined with SD-OCT of both the optic nerve and macula. We analyzed changes to best corrected visual acuity (BCVA), central retinal thickness (CRT), total macular volume (TMV), ellipsoid zone (EZ), and peripapillary RNFL thickness. Data processing was completed using MS excel. The relationship between predictors and outcome variables were assessed using Pearson linear correlation on statistical software SAS.

Results: A total of 15 patients (11 females, 4 males) were included with mean age = 44.7 ± 16.4 years (range, 17-68 years). CRT was significantly correlated with RNFL thickness of the temporal quadrant ($r = -0.41686$, $p = 0.0219$) and EZ foveal sparing ($r = -0.47375$, $p = 0.0082$). Additionally, we found significant correlations between BCVA vs. EZ foveal sparing ($r = 0.56157$, $p = 0.0012$) and CME vs. ERM ($r = 0.43301$, $p = 0.0168$).

Conclusions: The results of our study suggested a possible association between peripapillary RNFL quadrant thickness and central retinal thickness in patients with retinitis pigmentosa. CRT is associated with foveal EZ and temporal thickness of peripapillary RNFL. The eyes with foveal EZ reserved had thicker CRT and thinner temporal peripapillary RNFL. The eyes with damaged EZ under fovea had thinner CRT and thicker temporal peripapillary RNFL due to possible glial cells proliferation. The thickness of temporal peripapillary RNFL can serve as a marker for progressive macular atrophy in patients with retinitis pigmentosa.

ABSTRACT BODY:

Purpose: The purposes were to 1) develop nanoconjugates for effective delivery of antisense oligonucleotides (AON) to human stem cell-enriched limbal epithelial cells (LEC) for gene therapy of diabetic keratopathy, and 2) to validate the effect of a novel nanoconjugate with AON to miR-203a suppressing Wnt5a (decreased in diabetes) and to compare it to nanoconjugate with AON to cathepsin F (CF) (increased in diabetes), and miR-409 targeting c-met proto-oncogene (decreased in diabetes), in human diabetic LEC and organ-cultured corneas.

Methods: Stem cell-enriched LEC cultures and corneal organ cultures were obtained from postmortem human donor eyes. Nanoconjugates based on polymalic acid scaffold (1) were synthesized and contained a cell-targeting antibody to LEC transferrin receptor, and morpholino AON to CF and to miR-409 that targets c-met, or to miR-203a (all AON at 10 or 20 μ M). Control nanoconjugate had a scrambled sequence AON (Gene Tools). Healing of scratch-induced (LEC) and heptanol-induced corneal epithelial wounds was monitored microscopically.

Results: Treatment with nanoconjugate bearing AON to miR409+CF caused an increase of its target c-met and a decrease of CF protein levels in diabetic LEC and in organ-cultured diabetic corneas. This treatment also upregulated corneal epithelial stem cell markers and accelerated wound healing of cultured LEC and organ-cultured diabetic corneas, indicating that non-toxic nanoconjugates provide a new tool for gene therapy for normalizing diabetic limbal epithelial cells and organ-cultured corneas. Recently, we found a significantly decreased expression of Wnt5a protein and upregulation of its suppressing miR-203a in diabetic LEC and corneal epithelium. Also, miR-203a antagomir inhibitor increased Wnt5a expression and promoted wound healing in diabetic LEC. We made a nanoconjugate with AON to miR-203a to restore (upregulate) Wnt5a expression and validated its ability to normalize wound healing by diabetic corneal epithelial cells. The data will be presented to support the validity of this approach and possible use for combined treatment with nanoconjugates carrying AON miR409+CF.

Conclusions: Cell-targeting nanoconjugates may be used as a new tool for gene therapy in normalizing diabetic limbal epithelial cells and diabetic corneal wound healing.

ABSTRACT BODY:

Purpose: COVID-19 continues to disrupt the delivery of ophthalmic care in the third wave of the pandemic. Increased rates of anxiety has been reported in patient cohorts as COVID-19 impacts patients' hospital perceptions and has upended the patient experience. We sought to assess the impacts of COVID-19 on glaucoma patient self-perceived outcomes and experiences as assessed by the POEM questionnaire.

Methods: 126 consecutive patients attending a tertiary clinic over a 2-week period were surveyed with the Patient Reported Outcome and Experience measure (POEM). POEM is an 8-item questionnaire that addresses aspects of outcome (acceptability of treatment, fear of blindness, impact on daily life), and aspects of experience (safety, understanding, organization of care). The questionnaire was modified to determine if each item was more of a concern during the COVID pandemic. Assessments were performed in September 2020 and results were compared to pre-COVID survey results (n= 780). The questionnaires were conducted anonymously with no pairing to clinical data or demographics attempted.

Results: Survey results showed that the items showing the biggest reduction in agreement pertained to the understanding of how glaucoma is treated and patients' perception of their treatment team. There was a a 10-15% decrease in agreement for Q2 (I understand how my eye problem is managed), Q4 (I think my glaucoma is not getting worse), Q7 (I feel safe under the care of my glaucoma team) and Q8 (My glaucoma care is well organized) compared to pre COVID-19 questionnaire findings. Patients identified Q6 (I'm not worried about losing vision from glaucoma), Q7 (I feel safe under the care of my glaucoma team) and Q8 (My glaucoma care is well organized) as the most common aspects of their glaucoma care that COVID has increased concern over with 28.8%, 32.1% and 40.2% giving 'yes' responses respectively.

Conclusions: The COVID-19 pandemic has resulted in an increased uncertainty amongst patients about how their glaucoma is managed. Patients may not feel as safe about their glaucoma care and heightened anxiety about losing vision are issues which need to be addressed. Further studies investigating the patient experience and outcomes are required to fully elucidate the true psychological and physiological impacts of COVID-19.

TITLE: Flipping the opsin switch: Cis-regulatory elements required for thyroid hormone-mediated differential expression of the tandemly-replicated long wavelength-sensitive (lws) opsin genes of the zebrafish

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.L. Stenkamp, R. Mackin, Biological Sciences, University of Idaho, Moscow, Idaho, UNITED STATES|R. Ashino, S. Kawamura, Integrated Biosciences, University of Tokyo Graduate School of Frontier Sciences, Kashiwa, Chiba, JAPAN|

Commercial Relationships Disclosure (Abstract): Deborah Stenkamp: Commercial Relationship: Code N (No Commercial Relationship) | Robert Mackin: Commercial Relationship: Code N (No Commercial Relationship) | Ryuichi Ashino: Commercial Relationship: Code N (No Commercial Relationship) | Shoji Kawamura: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human trichromatic color vision requires that the tandemly-replicated LWS/MWS (long- and medium-wavelength sensitive) cone opsin genes are differentially expressed in subsets of cones. We recently reported that the nuclear signaling molecule thyroid hormone (TH) is endogenously involved in differential regulation of the tandemly-replicated lws1/lws2 cone opsin array in zebrafish (Mackin et al., 2019; PNAS). The goal of the current study is to identify cis-regulatory elements residing on the lws locus that are needed for the TH-induced switch from expression of lws2 to lws1.

Methods: We performed stable and transient transgenesis of lws1 and lws2 fluorescent reporter constructs, followed by TH treatment of larvae, confocal imaging of whole eyes, and quantification of cones expressing such reporters (n=9-15 larvae for each condition). Constructs for these assays harbored selected deletions of the lws locus.

Results: Analysis of fluorescent reporter expression within two stable transgenic lines revealed that the same 2.6kb region upstream of lws1 was needed for endogenous patterns of both lws1 and lws2 expression, and for the lws2 to lws1 switch in response to TH. Using transient transgenesis assays, we further dissected this region to identify two, separate ~25bp regions within 0.6kb immediately upstream of lws1. Each of these regions contains a predicted, palindromic TH response element (ppTRE). Deletion of the region containing ppTRE1 resulted in no increase of lws1 in response to TH (# cones expressing lws1 reporter, TH vs. control, p=1.0) and eliminated any expression of lws2. Deletion of the region containing ppTRE2 also resulted in no increase of lws1 in response to TH (p=0.60), and in addition there was no decrease of lws2 in response to TH (p=0.13).

Conclusions: These findings expand our understanding of the mechanisms by which TH differentially regulates the zebrafish lws1/lws2 array. This work contributes to filling in knowledge gaps of visual system development and may also provide insight into how TH regulates other gene arrays including the tandemly replicated LWS/MWS cone opsin array in humans.

ABSTRACT BODY:

Purpose: Confocal scanning laser ophthalmoscopy (cSLO) offers improvements over handheld fundus photography in telemedicine applications, such as screening for diabetic retinopathy. Here we report on a portable cSLO design that uses a novel scan pattern to reduce acquisition times over traditional cSLOs and allows widefield color imaging at reduced cost due to its chromatically multiplexed topology.

Methods: A handheld patient interface receives light from a green laser diode and NIR superluminescent diode, operating at 520 and 785nm, respectively. The light is collimated, scanned by galvanometers, and relayed into the patient's pupil using off-the-shelf optics and custom optomechanics. A tunable liquid lens compensates for patient refraction. The two light sources are temporally multiplexed so that only one is active at any time, allowing light collected from the patient eye to be detected on a single photomultiplier tube with no filtering. The optical design achieves diffraction-limited performance over a 50° FOV at a working distance of 16mm. Patient safety is ensured by limiting incident power on the subject eye to <200μW in NIR and <100μW in green, well below ANSI Z80.36-2016 limits. The galvanometers use a novel hybrid spiral scan pattern composed of concentric constant angular velocity (CAV) and constant linear velocity (CLV) portions. The spiral pattern provides a convenient fixation target, and its circular outline is a natural fit for ophthalmic imaging. The CAV/CLV hybridization offers performance advantages over a traditional raster, as well as scan fidelity improvements over CAV or CLV spirals alone. The scan operates at 5.6Hz with 30μm radial resolution. GPU-based algorithms produce contrast-enhanced frames in real time, which are then registered and colorized in post-processing.

Results: Feasibility of the prototype cSLO device in screening applications was demonstrated by imaging a healthy human volunteer under a protocol approved by the Duke University IRB.

Conclusions: We have presented an optimized portable confocal scanning laser ophthalmoscope that offers speed and cost improvements over current designs. Performance of the system was demonstrated by imaging a healthy human volunteer.

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the effect of spatial averaging on the multifocal electroretinography (mfERG) averaged ring peak times in patients screened for hydroxychloroquine (HCQ) toxicity.

Methods: This was a retrospective review of the records of patients screened for HCQ retinopathy at the USF Eye Institute (University of South Florida) during the period of 2015-2020. Only the records of patients referred internally were used. Patients were tested binocularly with Diagnosys mfERG system (Diagnosys LLC, Lowell, MA) using 61 hexagons grouped in 5 rings. The effects of the lowest level (level 1, or 4%) of spatial averaging on the mfERG N1, P1 and N2 peak times ring averaged values were evaluated.

Results: The records of 40 patients (4 males, 36 females) aged 54.4 ± 14.1 yrs. were selected for analysis. The use of spatial averaging had a differential effect on different rings and mfERG components. Thus, for N1 peak times, only a small, but statistically significant effect was detected for ring #1 (central element): -0.29 ± 0.57 ms right eyes (RE) and -0.54 ± 1.34 ms left eyes (LE) ($p < 0.01$), while the timing for the other rings was unaffected. In contrast, for the P1 component ring #2 peak time was affected (-0.18 ± 0.43 ms / -0.18 ± 0.47 ms RE/LE; $p < 0.05$) and additionally the timing for ring #1 in right eyes (-0.23 ± 0.51 ms; $p < 0.01$) and for ring #4 in left eyes -0.23 ± 0.48 ms; $p < 0.01$, one sample Wilcoxon test). No significant changes were observed for the N2 component timing as a group, although in individual cases the change in timing varied from -20.6 to +18.3 ms. The magnitude of change in timing was strongly correlated with the percent change in timing due to spatial averaging for N1 for rings #1 to #4 (R^2 0.20 to 0.33), while such a correlation was less pronounced for P1 (rings #1 to #3 RE, #1 & #4 LE; R^2 0.11 to 0.44) and for N2 (rings #1, #3, #4 RE, rings #2 & #3 LE; R^2 0.12 to 0.19).

Conclusions: The application of low-level spatial averaging during mfERG analysis can affect the peak times of mfERG components in various ways and given the generally narrow margin of normative values for mfERG peak times, can introduce bias in the results. Therefore, such approach should be strongly discouraged in HCQ toxicity screening mfERG analysis.

ABSTRACT BODY:

Purpose: Purpose: Determine whether the metastatic UM cell line OMM2.5 shows high STAT3 activation as compared to non-metastatic UM cell line MEL270 derived from the same UM patient. Does the OM2.5 cell line express more immunosuppressive chemokines/cytokines, and/or less inflammatory cytokines/chemokines.

Methods: Methods: The proliferation of OMM2.5 and MEL270 UM cell lines was determined by IncuCyte Live-Cell Analysis assays. The levels of STAT3 and tyrosine phosphorylated STAT3 in cell lysates was determined by immunoblotting. The expression of STAT3-depedent chemokines and cytokines was compared in MEL270 versus OMM2.5 cells by quantitative real time PCR.

Results: Results: The metastatic UM cell line OMM2.5 cell line showed increased cell proliferation compared to the primary MEL270 UM cells isolated from the same patient. In addition, STAT3 activation was markedly elevated as evidenced by its tyrosine phosphorylation in the metastatic OMM2.5 cell line relative to MEL270 UM cells. Moreover, the gene expression levels of multiple STAT3 regulated genes, such as STAT1, TXNIP, and LIF was significantly increased in metastatic OMM2.5 cells vs. non-metastatic MEL270 UM cells. LIF (leukemia inhibitory factor) is a cytokine that plays a key role in regulating the adaptive immune response. TXNIP (Thioredoxin-interacting protein) is a redox regulator that causes accumulation of reactive oxygen species, and has been associated with tumorigenesis in several cancer. STAT1 is a transcription factor that promotes oncogenesis in various cancer types.

Conclusions: Conclusions: Taken together, these data indicate that the STAT3 signaling pathway is activated in metastatic uveal melanoma cell lines. Thus, STAT3 may be an attractive pharmacological target to treat metastatic uveal melanoma.

TITLE: A Unique Ophthalmic Presentation Leading to a Diagnostic Dilemma in Wegener's Granulomatosis

SESSION TITLE: Translational Immunology and Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Arpaia, K. Hawthorne, Howerton Eye Clinic, Austin, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kaylin Arpaia: Commercial Relationship: Code N (No Commercial Relationship) | Kristen Hawthorne: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A 22-year-old female with a biopsy proven history of Wegener's granulomatosis (WG) maintained on prednisone 40mg daily, presented with a red, painful left eye of 3 weeks duration. She had been cared for in the prior 2 weeks by a referring ophthalmologist with reports of a slow growing, mass in the anterior chamber. Historical manifestations of her disease were sinus related as well as unilateral scleritis to the left eye. Her condition had been quiescent during her recent pregnancy which resulted in her second child three months prior. She had been on cyclophosphamide at the beginning of her diagnosis but after several years, she was taken off the alkylating agent and maintained on oral steroids alone.

Methods: On examination, her visual acuities were 20/70-1 right eye and LP left eye, with the majority of her vision in the left eye lost in 2018 to complications of anterior and posterior scleritis. Anterior segment examination of the left eye showed conjunctival hyperemia localized inferotemporally and a soft, ameboid, white mass in the anterior chamber measuring 7.5 x 5.5mm without corneal involvement. Concern for infectious or fungal etiology was high considering the patient was maintained chronically with 40mg prednisone daily. External photography of the white anterior segment mass was taken. (Figure 1, Figure 2) A preliminary diagnosis of infectious uveitis was made, and the patient was prescribed topical antibiotic and antifungal therapies with a plan for a biopsy/culture of the lesion with concurrent intracameral and subconjunctival antibiotic, antifungal and steroid therapy.

Results: Biopsy results showed that the mass was made entirely of inflammatory material, linking it to WG as opposed to the suspected infectious etiology.

Conclusions: This case shows a unique ophthalmic manifestation of WG in the anterior segment. While there are numerous reports detailing cases of episcleritis, anterior scleritis, ulcerative keratitis, and other inflammatory conditions of the eye associated with WG, to our knowledge there are no such reports of anterior segment masses. This case is interesting in that the inflammatory disease flared with the documented finding while on a high dose of oral steroids, leading to a diagnostic challenge. A review of current treatment recommendations and ophthalmic manifestations of WG accompany this case report as a guide for a challenging ophthalmic and systemic disease.

ABSTRACT BODY:

Purpose: It has previously been demonstrated that dry eye disease (DED) results in decreased corneal nerve density. The aim of the current study was to evaluate if DED results in alterations of neuropeptides (NPs) and neurotrophins in the cornea and trigeminal ganglia (TG).

Methods: Adult 6-8-week-old C57BL/6N female mice were injected with 0.5mg of scopolamine hydrobromide and kept in a controlled environment chamber for 14 days and compared to control mice. Clinical evaluations included slit-lamp microscopy, tear secretion, corneal esthesiometry and challenge with [5M] saline. Nerve density was assessed by immunohistochemistry of corneal whole-mounts for β III Tubulin and confocal microscopy. mRNA and proteins levels of 11 molecular targets of NPs and neurotrophins were assessed by qRT-PCR and ELISA for corneas and TG. A one-way ANOVA with Tukey's multiple comparison was used to compare effects between groups.

Results: DED mice demonstrated decreased tear secretion ($p \leq 0.0001$) and increased corneal fluorescein staining compared to controls ($p \leq 0.0001$). Decreased corneal nerve density was measured in DED ($78.2 \pm 2.8 \text{ mm/mm}^2$) compared to controls (142.5 ± 13.7 ; $p \leq 0.0001$). A significant increase in paw wipe response was observed with 10 μL of [5M] saline in DED compared to controls 38.6 vs. 17.2 ($p \leq 0.0001$). Corneal qRT-PCR revealed decreased neurotrophin expression in DED compared to controls, with 3.1-fold decrease in NGF, 2.4-fold decrease in BDNF and 2.9-fold decrease in NT3 (all $p < 0.0001$), which was confirmed at the protein level by ELISA (all $p < 0.0001$). In addition, there was an upregulation of corneal Substance P (3.4-fold) and CGRP (2.5-fold) in DED compared to controls ($p < 0.0001$ for both). Interestingly, there was downregulation of VIP (2.5-fold), PACAP (3.3-fold), Neurotensin (5.0-fold), Somatostatin (2.0-fold) and NPY (5.0-fold) (all $p < 0.01$). In contrast TG of DED mice demonstrated 4.5-fold upregulation of NGF and 6.3-fold increase in NT-4/5 vs controls ($p < 0.0001$). However, within the TG, only Substance P and Somatostatin were increased in DED by 1.7-fold and 2.2-fold respectively (both < 0.05).

Conclusions: This study provides evidence of imbalance in corneal and TG neurotrophins and NPs in DED. A deeper understanding of the neurochemistry, trophic factors and nervous system may lead to improved treatments for DED.

ABSTRACT BODY:

Purpose: To examine the inter-grader reproducibility of characterizing peak foveal cone density in normal subjects.

Methods: 300x300 μm foveal AOSLO images from the right eye of 44 normal volunteers were included. Semi-automated cone identification was performed by three observers, with resulting cone coordinates used to generate cone density maps. Two approaches were employed to estimate the location of peak cone density from these maps: 1) the point of absolute maximum density and 2) the center of an ellipse created by the 95th percentile isodensity contour. Cone density values at these locations were also compared. For each method, the repeatability and measurement error of peak cone density estimates were assessed. The variability in peak cone density location between observers was assessed by calculating confidence ellipses (CE) for each peak density location estimation method described above, and intraclass correlation coefficients (ICCs) were calculated to characterize interobserver variability in density estimates.

Results: The interobserver ICC of the maximum cone density value was 0.805 (95% CI = 0.718-0.893). The ICC using the isodensity contour method was slightly lower (0.748, 95% CI = 0.640-0.856). Accordingly, the measurement error for the maximum cone density method was 21,441 cones/ mm^2 (12.3%) whereas the measurement error for the isodensity contour method was 24,549 cones/ mm^2 (14.4%). Despite this, there was no significant difference between the average peak cone density value extracted using the two methods ($p=0.09$). The location of maximum density was significantly more reproducible between observers when using the isodensity contour method (mean \pm SD CE area = $231.93 \pm 775.15 \mu\text{m}^2$) compared to the maximum density method (mean \pm SD CE area = $905.62 \pm 1214.42 \mu\text{m}^2$, $p<0.0001$).

Conclusions: Peak foveal cone density is important, not only as a quantitative metric of cell packing, but also as an anchor for calculation of retinal eccentricities. Understanding measurement errors, both in peak cone density estimation and in its retinal location is critical, to inform the approach to its identification. The superior reproducibility of the retinal location with the isodensity contour method may best serve comparison of parafoveal metrics, while the maximum density technique could be used to give the best estimate of the highest cone density within the retina, despite variability in the resulting exact retinal location.

ABSTRACT BODY:

Purpose: Though topical ophthalmic steroids are effective in treating allergic conjunctivitis (AC), physicians report infrequent use due to side effects and/or risk of abuse associated with long term use demonstrating the need for a physician administered sustained release steroid with a favorable safety profile. DEXTENZA (dexamethasone ophthalmic insert) 0.4mg is a hydrogel-based intracanalicular insert designed to deliver preservative-free dexamethasone over 30 days. The objective of this study is to evaluate the safety of a steroid insert (DEX) for the treatment of signs and symptoms of chronic AC.

Methods: This was a pooled post-hoc analysis of four prospective, randomized, double-masked, vehicle-controlled, parallel-group studies using a modified Conjunctival Allergen Challenge (CAC) model. In all studies, subjects with a history of ocular allergies were randomized to receive DEX or placebo (PV) inserted into the canaliculus of both eyes on the same day. Safety assessments were performed in each of the four studies which included assessments of adverse events (AEs), visual acuity (VA), and intraocular pressure (IOP).

Results: The safety population from the four trials included 315 subjects (DEX N=154, PV N=161). Overall, 12.3% and 14.3% of DEX and PV subjects reported ocular adverse events, respectively, all of which were mild or moderate in severity. No ocular SAEs were reported and there was a single non-ocular SAE across the four trials (hospitalization due to depression in the DEX group) which was considered unrelated to study treatment. The most common adverse events (>1%) in DEX-treated subjects were increased IOP (3.2%), reduced VA (1.3%), lacrimation increased (1.3%), and eye discharge (1.3%). All AEs of increased IOP were resolved. VA assessments showed no consistent changes over time and all instances of worsening VA were transient. There were no patterns of AEs that would raise concern regarding the safety of DEX.

Conclusions: Overall, findings from the pooled post hoc analysis of four studies demonstrated DEX was generally safe and well tolerated for the treatment of allergic conjunctivitis. Rates of increased IOP following treatment with DEX were low. The physician-administered insert has the potential to be a non-abusable, hands-free, alternative to steroid eye drops.

TITLE: Low Vision Referral Patterns in Intermediate AMD

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Larochelle, J. Patnaik, A. Lynch, N. Mandava, K. Hanson, Dept. of Ophthalmology, University of Colorado, Denver, Colorado, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ryan Larochelle: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Patnaik: Commercial Relationship: Code N (No Commercial Relationship) | Anne Lynch: Commercial Relationship: Code N (No Commercial Relationship) | Naresh Mandava: Commercial Relationship: Code N (No Commercial Relationship) | Kara Hanson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Low vision (LV) services are underutilized, but sparse data exist regarding referral patterns. In this retrospective chart review, we examined our institution's intermediate age-related macular degeneration (iAMD) database to determine factors influencing referral.

Methods: We determined which patients in our iAMD registry had been referred to LV, excluding patients with neovascularization or geographic atrophy in either eye. Visual acuity (VA) was collected at the time of LV referral or the most recent visit for patients not referred. Visual Function Questionnaire (VFQ-25) scores (composite and 12 subscales) were collected at enrollment into the iAMD study. We compared patients referred to LV and patients not referred with Chi-square testing and the Wilcoxon rank sum test. Multivariable logistic regression analysis was used to examine each subscale of the VFQ-25 separately ($P < 0.05$).

Results: We found 36 (16%) of the 232 iAMD patients were referred to LV (Table 1). Referred patients were significantly more likely to be older, have worse VA in both eyes, and have lower VFQ-25 composite scores. Univariate analysis of VFQ-25 subscales demonstrated significantly worse scores for LV patients in general vision, near, distance, mental health, role limitations, dependency, and driving (Table 2). In the multivariable analysis, significant subscales included lower scores in general health, general vision, and driving.

Referred patients had a median VA of 20/40 in the better eye and a median VFQ-25 score of 84. We found 46 (48%) of the non-referred patients had VA of 20/40 or worse and/or VFQ-25 score of 84 or lower. Factors identified as reasons for not referring included cataract or posterior capsular opacification amenable to a procedure, fluctuating vision, and extensive comorbidities. However, two thirds of these patients had no documented or discernable reason for not receiving referral.

Conclusions: LV services help AMD patients maximize the function of their remaining vision. This study demonstrates that our institution refers patients with worse objective and functional vision, but that many more patients might benefit from LV services. This study was limited in that VA and VFQ-25 data were not obtained simultaneously. Future studies should aim to identify specific metrics that should prompt LV referral and apply this approach to other diseases.

ABSTRACT BODY:

Purpose: Until recently diagnostic ophthalmic ultrasonography has exclusively utilized piezo-electric transducer technology to visualize ophthalmic anatomy. The purpose of this study was to compare the quality of ultrasonic images from the recent FDA approved handheld Butterfly iQ (BiQ), an Ultrasound-on-a-Chip device, with a standard 10MHz piezo-electric ophthalmic ultrasound.

Methods: A cross-sectional blinded study of sonographic image quality was performed as a comparison between the BiQ portable ultrasound and the 10MHz Accutome B-Scan Pro. Study participants had ultrasound procedures performed on each eye during a typical ophthalmic visit per the standard of care. The BiQ was connected to an iPad for video capture and settings adjustment. Four imaging presets (MSK, MSK-Soft Tissue, Nerve, and Pediatric Lung) with the highest clarity were selected from the BiQ software library. One minute video clips were taken using each ultrasound probe. De-identified still images were cropped, randomized, and presented to three blinded ophthalmologist graders who rated images on a ten-point Likert scale based on four criteria: Resolution, Detail, Image Quality, and Diagnostic Confidence. Resolution was defined as “sharpness of the image and lack of haziness,” detail as “clarity of outlines, how well structures and boundaries are defined,” image quality as “overall image assessment (e.g., absence of noise, contrast between structures),” and diagnostic confidence as “confidence in making clinical decisions based on image.” An ANOVA with post hoc pairwise comparison was performed in SPSS.

Results: The ANOVA results (Table 1) illustrate that 2/3 evaluators reported no statistically significant differences between the BiQ and Accutome in all categories. With respect to image Detail, there was a statistically significant difference for 1/3 graders between the Accutome and two of the BiQ modalities (MSK and Nerve); however, the overall results of the study indicate that there were no statistically significant differences in function of the images generated by the Butterfly iQ ultrasound versus the 10MHz Accutome B-Scan Pro.

Conclusions: These results show promise for the future of portable ultrasound. The benefits of Butterfly iQ are cost-effective, pocket-sized, and versatile, highlighting its potential for clinical utility.

ABSTRACT BODY:

Purpose: The 4th generation quinolones are the treatment of choice for infectious bacterial keratitis, however, recent reports suggest an increase in resistance to these drugs, so it is important to recognize the sensitivity of other drugs and compare them with the gold standard

Methods: A cross-sectional study including a consecutive analysis of patients records with a diagnosis of bacterial keratitis with a positive culture and antibiogram report between January 2009 and December 2017 of the Cornea department of the Dr. Luis Sánchez Bulnes Hospital of the Association to Avoid Blindness in Mexico were included. Demographic data, Gram stain, bacterial profile and antimicrobial resistance were analyzed.

Results: In the studied period, a total of 794 (49.53%) cases with a positive culture were included. 27.1% of patients had polymicrobial infections so 1034 cultures were evaluated. 52.3% of the patients were male, the mean age was 48.28 ± 20.43 years (range 1 to 97 years). 81.33% (841) of the cultures were gram positive. The antibiotic with the highest sensitivity for gram positive was Netilmicin (93.23%), followed by Moxifloxacin (92.98%) and Gatifloxacin (92.39%). For gram negative cultures again Netilmicin had the highest sensitivity (88.08%), followed by Gatifloxacin (86.01%) and Moxifloxacin (84.45%).

Conclusions: Gram positive bacterias are the most common cause of infectious keratitis, Staphylococcus and Pseudomonas as the most common isolates. Netilmicine and 4th generation flouroquinolones had a very good sensibility for both types of bacteria.

TITLE: Elucidating the Role of AMP-activated protein kinase (AMPK) in Human Glaucomatous Lamina Cribrosa (LC) cells

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.K. Powell, M. Irnaten, A. Smyth, C.J. O'Brien, Clinical Research Centre, Mater Misericordiae University Hospital, University College Dublin, Dublin, IRELAND|S.K. Powell, A. Smyth, C.J. O'Brien, Department of Ophthalmology, Mater Misericordiae University Hospital, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Sarah Powell: Commercial Relationship: Code N (No Commercial Relationship) | Mustapha Irnaten: Commercial Relationship: Code N (No Commercial Relationship) | Aoife Smyth: Commercial Relationship: Code N (No Commercial Relationship) | Colm O'Brien: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Lamina Cribrosa (LC) region of the optic nerve is an important site of damage in glaucoma. AMP-activated protein kinase (AMPK) is the main sensor of cellular energy status in virtually all cells, and is highly conserved across all eukaryotic species. AMPK is upregulated in both cancer and fibrosis. AMPK is activated in response to energy stress by sensing increases in AMP: ATP and ADP: ATP ratios. Here, we investigate the expression of an isoform of AMPK in normal and glaucoma LC cells and examine the possible effect of AMPK on pro-fibrotic gene expression found in glaucoma LC cells.

Methods: LC cells were obtained and cultured from 2 normal non-glaucomatous and 2 confirmed glaucoma age matched eye donors. Expression of an AMPK isoform was measured in both normal and glaucoma LC cells using Quantitative Real Time Polymerase Chain Reaction (qPCR).

Results: The expression level of the AMPK isoform was found to be significantly enhanced in glaucoma LC cells compared to normal control LC cells (1.23 ± 0.083 in glaucoma LC cells versus 0.86 ± 0.067 in normal LC cells; $p < 0.05$; $n=2$). The relative expression of AMPK was calculated using $\Delta\Delta C_t$ method, after being normalized to the housekeeping ribosomal gene 18S.

Conclusions: The data shows that AMPK is significantly elevated in glaucoma LC cells versus normal LC cells. This suggests a role for AMPK as a key driver of underlying fibrotic changes in glaucomatous LC cells, leading to increased proliferation, reduced apoptosis and augmented metabolism. Blockade of AMPK appears to be critically associated with this process of metabolism. Halting the pro-fibrotic activity and metabolism of glaucoma LC cells by restoring AMPK expression and activity to normal levels may lead to a new therapeutic approach targeted at reducing fibrosis in glaucoma. We anticipate that this novel therapeutic approach could ameliorate the ongoing optic nerve cupping, thereby enhancing long-term patient outcomes and quality of life in glaucoma.

ABSTRACT BODY:

Purpose: Trabecular meshwork (TM) tissue is subjected to constant mechanical stretch due to ocular pulse created by the cardiac cycle. This triggers the modification of various intracellular signaling responses to counter mechanical insults. A loss of such response can lead to elevated intraocular pressure (IOP), a major risk factor for primary open-angle glaucoma. The purpose of this study was to understand the metabolic response of TM cells to mechanical stretch.

Methods: Normal primary human TM cells (n=3) in culture were subjected to 15% mechanical stretch, 1 cycle/second, for 8h and 24h using a computer-controlled Flexcell unit, and unstretched cells were controls. We profiled for mRNA changes in 8h samples using qPCR and protein changes using mass spectrometry-based quantitative proteomics on 24h samples. The data was statistically significant if the $p \leq 0.05$ for mRNA using paired Student's t-test and proteins were screened out using criteria, $p \leq 0.05$ and mean $\pm 2\sigma$ of log2 as confidence fold change limits.

Results: Cyclic mechanical stretch significantly increased 9 proteins and decreased 31 proteins including those involved in metabolism. Among those, were the proteins involved in cholesterol biogenesis, which showed significant changes (Fig 1)- levels of squalene synthase, a critical enzyme in the cholesterol biosynthetic pathway significantly increased ($p=0.04$) with an increasing trend in HMG CoA synthase (HMGCS), and HMG CoA reductase (HMGCR) and a significant decrease in Kelch-like ECH-associated protein 1 (KEAP1) ($p=0.04$), which is a negative regulator of nuclear factor-E2-related factor 2 (Nrf2) involved in sterol metabolism. Further examining the mRNA transcripts of genes involved in cholesterol biosynthesis machinery, there was a significant upregulation of sterol regulatory element-binding protein 2 (SREBP2) ($p=0.05$), a transcription factor and the master regulator of sterol pathway, as well as HMGCS ($p=0.03$), and HMGCR ($p=0.03$) genes.

Conclusions: This is a first-hand report on comparative analysis between changes in mRNA and proteins in response to mechanical stretch. We find that TM cells respond to the changes in biomechanical properties by orchestrating the transcriptional control of cholesterol biosynthesis and tightly regulating the enzymes in the sterol synthesis pathway.

ABSTRACT BODY:

Purpose: Although risk factors for DR and DME are well-established in adults with diabetes, they are not as clearly defined in pediatric populations. This study aimed to identify factors associated with DR and DME in a pediatric population with T1D.

Methods: Retrospective chart review was conducted of pediatric (≤ 21 years old) medical records from the Joslin's Beetham Eye Institute from 2005-2020. Data collected included demographic characteristics and DR and DME severity. Body mass index (BMI) and blood pressure (BP) were categorized according to CDC sex and age-adjusted growth curves (BMI: under/normal weight ($< 85^{\text{th}}$ %ile), overweight/obese ($\geq 85^{\text{th}}$ %ile); BP: normal ($< 90^{\text{th}}$ %ile), elevated/high ($\geq 90^{\text{th}}$ %ile). Analyses were adjusted for correlation between eyes of the same person.

Results: In total, 1735 youth (3454 eyes) were included with mean \pm SD age 15.4 \pm 4.6 yrs, T1D duration 7.1 \pm 5.3 yrs, T1D onset 8.3 \pm 5.4 yrs, and A1c 8.4 \pm 1.3%; 50.7% were female, 30.7% were overweight/obese, and 4.1% had elevated/high BP. DR was present in 8.5% and DME in 1.3% of the eyes. Unadjusted analyses found DR presence was associated with higher A1c ($p < .0001$), longer T1D duration ($p < .0001$), younger age of T1D onset ($p = 0.0002$), older attained age ($p < .0001$), female sex ($p = 0.001$), and elevated/high BP ($p < .0001$). After backwards elimination modeling, older age ($p < .0001$), longer T1D duration ($p = 0.002$), and higher A1c ($p = 0.01$) remained significantly associated with DR. In unadjusted analyses, DME was associated with higher A1c ($p = 0.0003$), longer T1D duration ($p < .0001$), younger age of T1D onset ($p = 0.02$), older age ($p < .0001$), female sex ($p = 0.03$), elevated/high BP ($p = 0.002$), and obese/overweight BMI ($p = 0.03$). When adjusting for A1c, T1D duration, age of T1D onset, age, and DR presence, obese/overweight BMI ($p = 0.04$) and elevated/high BP ($p = 0.04$) remained associated with DME.

Conclusions: In this pediatric group with T1D, DR with or without DME was present in 8.5% of eyes. In addition to non-modifiable factors, DR and DME were associated with modifiable systemic risk factors (A1c, BMI, BP). Efforts to optimize these factors in youth from an early age may help reduce adverse ocular outcomes. Future longitudinal studies can assess if early intervention to improve glycemic control, weight, and BP can reduce occurrence of DR and DME in youth with T1D.

SUBMITTER (NAME ONLY): Kyoung-Hee Kim

TITLE: Toward a Non-Invasive Solution of Wet AMD: Sunitinib, Pazopanib, and Axitinib Eyedrops versus Intraocular Injection of Aflibercept

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Kim, J. Oh, D. Cho, M.J. Kim, R&D Center, SCAI Therapeutics, Daejeon, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure (Abstract): Kyoung-Hee Kim: Commercial Relationship(s);SCAI Therapeutics:Code E (Employment) | Joo Young Oh: Commercial Relationship(s);SCAI Therapeutics:Code E (Employment) | Daegeun Cho: Commercial Relationship(s);SCAI Therapeutics:Code E (Employment) | Myungjo J. Kim: Commercial Relationship(s);SCAI Therapeutics:Code E (Employment)

ABSTRACT BODY:

Purpose: Wet AMD is a disastrous disease of vision loss where the only medicinal treatment currently available is an intraocular injection of aflibercept or ranibizumab. However, such an intravitreal injection often causes various side-effects and complication. Therefore, we prepared and evaluated eyedrops of three VEGFR tyrosine kinase inhibitors (TKIs) for a safer, non-invasive solution of wet AMD.

Methods: Three TKIs — sunitinib, pazopanib, and axitinib — are aqueously dispersed with our proprietary technology: D-SUT (0.05%), D-PZP (0.2%), and D-AXT (0.01%). C57BL/6 mice were used for a laser-induced choroidal neovascularization (CNV) model. A total of 30 mice were classified into six groups: G1 (PBS), G2 (aflibercept), G3 (SUT solution, 0.05%), G4(D-SUT), G5 (D-PZP), G6 (D-AXT). Aflibercept (1 uL/eye) was given as single intravitreal injection. Test samples and PBS (5 uL/eye each) were instilled twice a day for 10 days. Corrected total fluorescence and volume of CNV lesions were measured after 10 treatment days by FFA and OCT, respectively. The concentration of test samples at the retina was measured.

Results: D-SUT, D-PZP and D-AXT, given as eyedrops, showed statistically significant suppression of the CNV lesion volume by 49%, 26%, and 25%, respectively, compared to the PBS control ($p<0.0001$, $p<0.01$, and $p<0.05$, respectively), whereas SUT solution itself did not. The efficacy of D-SUT is statistically significant compared to that of SUT ($p<0.05$) as well. All three TKI dispersions showed comparable suppression of the area and volume of CNV lesion with the aflibercept injection. Given the concentrations of TKIs in the retina, sufficient amounts of TKIs were delivered to the retina.

Conclusions: We have demonstrated that the eyedrops of three TKI dispersions showed comparable efficacy with the intravitreal injection of aflibercept. Corresponding ocular pharmacokinetic study and tissue distribution analysis of TKI dispersion support the straightforward way of drug delivery through the cornea to the retina. Further efforts to develop the TKI eyedrops for patient-friendly wet AMD treatments are under way.

ABSTRACT BODY:

Purpose: To assess national and international internet search trends and public interest in refractive diseases and interventions during the COVID-19 pandemic compared to existing trends prior to the pandemic.

Methods: A Google Trends search for refractive terms was performed between the time periods of January 1, 2016 to November 1, 2020. Refractive terms were divided into two groups: disease terms and procedure/treatment terms. Relative search volume (RSV) indices for refractive terms were assessed in the United States (US) and worldwide from the initial 18-week COVID-19 pandemic period (March 1, 2020 to July 4, 2020) and the subsequent 18-week period. (July 5, 2020 to November 1, 2020) These results were compared to pooled data of overlapping weeks between 2016-2019. A t-test of two independent samples assuming unequal variances was utilized to compare the two groups.

Results: The relative public interest in refractive disease and procedure/treatment terms showed a sharp decline in the initial 18-weeks of the pandemic with a slow increase over the following 18-weeks compared to prior to the pandemic (Figure 1). There was a statistically significant decrease in mean RSV for multiple refractive disease terms (near far sighted/sightedness, keratoconus, hyperopia, cataract, astigmatism, myopia, near sighted/sightedness, blurry/blurred vision) and refractive procedure/treatment terms (intraocular lens, LASIK, cataract surgery/removal/extraction, LASEK, contact lens/lenses) both in the US and worldwide in 2020 compared to 2016-2019.

Conclusions: The onset of the COVID-19 pandemic correlates with declining relative popularity of searches related to refractive disease and elective refractive procedures/treatments. Declining interest in refractive diseases and treatments may lead to poorer health literacy, delay in care, and potentially worse outcomes for these conditions.

TITLE: Digital profiling and analysis of barriers to teleconsultations among ophthalmic patients in North West London (NWL)

SESSION TITLE: Healthcare Delivery during Covid Pandemic

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Mushtaq, A. Ghulakhszian, C. Dinah, Central Middlesex Hospital, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Jameel Mushtaq: Commercial Relationship: Code N (No Commercial Relationship) | Arevik Ghulakhszian: Commercial Relationship: Code N (No Commercial Relationship) | Christiana Dinah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent advances in technology have allowed remote diagnosis and consultation by medical professionals. The recent COVID-19 outbreak has accelerated this process into widespread adoption. In Ophthalmology, Teleconsultation allows communication between ophthalmic professionals and patients remotely, theoretically increasing efficiency, accessibility and safety of consultations. It is unclear what groups of patients are unable to access this mode of healthcare delivery, putting them at risk of worse outcomes both presently and in the future. Through creation of patient digital profiles, barriers to teleconsultations can be understood, allowing development of tailored interventions at a regional and national level.

Methods: A 28 item survey was administered to patients attending the Macula clinic in NWL involving demographics, current technological access and views towards teleophthalmology.

Results: 106 patients were included (mean age:75.2+/-13.3). The most common device owned was a smartphone (66%), with the most common operating system being Android (55% of smartphone owners). Twenty-one percent of patients did not have access to a suitable device and 25% of patients did not have access to the internet. Those without access to any device were older (82.1vs73.5; $P=0.007$) and those without access to the internet were older (80.8 vs 73.3; $p=0.01$) and less educated ($p=0.04$ [PB1]). Patients without access to help at home had lower confidence (4.1 vs 2.0; $p<0.001$) and perceived usefulness (3.8 vs 2.2; $p<0.001$) of teleconsultations. Number of devices owned correlated with confidence ($r=0.46$; $p<0.001$) and perceived usefulness ($r=0.20$; $p=0.043$).

Conclusions: A significant proportion of ophthalmic patients in NWL are unable to access healthcare via video teleconsultations. These may be older and/or more isolated patients which will require targeted interventions. Digital profiling should be considered to maximise inclusivity of digital health interventions.

ABSTRACT BODY:

Purpose: Intravitreal gene therapy has the potential to significantly reduce treatment burden and improve vision outcomes in patients with neovascular AMD (nAMD). OPTIC is a phase 1 study designed to assess the safety, tolerability and efficacy of a single intravitreal injection of ADVIM-022 (AAV.7m8-afibercept gene therapy) in patients with nAMD.

Methods: Open-label, multicenter, dose-ranging study in treatment-experienced patients with a previous confirmed response to anti-VEGF therapy. Patients were administered a single intravitreal injection of ADVIM-022 at 6×10^{11} vg/eye (Cohort 1: n=6, Cohort 4: n=9) or at 2×10^{11} vg/eye (Cohort 2: n=6, Cohort 3: n=9). Incidence and severity of adverse events, change in visual acuity (BCVA), change in central retinal thickness (CST), need for and number of supplemental aflibercept injections were evaluated.

Results: As of October 15, 2020, median follow-up was 86 weeks (Cohort 1), 64 weeks (Cohort 2), 48 weeks (Cohort 3) and 16 weeks (Cohort 4). Patients in all 4 cohorts previously received frequent anti-VEGF injections (mean 7.1–9.2 injections in the prior 12 months) to maintain relatively good baseline BCVA (mean 65.0–65.9 ETDRS letters) prior to receiving ADVIM-022. ADVIM-022 continues to be well tolerated with a favorable safety profile. All ADVIM-022-related ocular adverse events were mild (78%) to moderate (22%). Ocular inflammation predominantly affecting the anterior segment, when observed, has been responsive to steroid eye drops. No cases of retinal involvement or vasculitis were reported. A significant reduction in anti-VEGF injection burden was observed with both doses; 14/15 patients receiving high dose and 10/15 patients receiving low dose remained supplemental anti-VEGF injection free while mean annualized anti-VEGF injection frequency was reduced by 99% (high dose) and 85% (low dose) after ADVIM-022. For Cohorts 1–3, data pending for cohort 4, BCVA was maintained with a mean change of -2.5 to +0.2 ETDRS letters, and CST improved with a mean change of -19.7 to -132.7 μ m.

Conclusions: ADVIM-022 is designed to provide continuous expression of aflibercept following a single intravitreal injection. Over 80% of patients with nAMD treated with a single injection of ADVIM-022 in OPTIC have not needed any supplemental anti-VEGF injections up to 92 weeks follow-up. ADVIM-022 has the potential to reduce treatment burden and improve patient vision outcomes.

TITLE: Comparison of Virtual Reality Visual Field Testing to Humphrey Visual Field Testing in an Academic Ophthalmology Practice

SESSION TITLE: Visual Fields and Psychophysics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N.B. Nanti, J. Lenoci, Stony Brook University Hospital, Stony Brook, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nehali Nanti: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Lenoci: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Humphrey visual field testing is considered the gold standard. Yet, the machine is expensive and large and the test is time consuming and difficult for patients. Virtual visual field testing is convenient, cost effective and may offer an alternative to Humphrey testing. This study compares a commercially available virtual reality visual field to the Humphrey automated perimetry in a comprehensive academic practice.

Methods: During the COVID-19 pandemic, virtual reality visual field testing was implemented in the Department of Ophthalmology at Stony Brook University. This study retrospectively reviewed patients who underwent virtual visual field testing (VVF) using the BOLT strategy from Virtual Field.io from July 2020 through December 2020. Of these patients, those who had a prior Humphrey 24-2 SITA standard visual field (HVF) performed within 12 months were included. All ocular diagnoses were included. Primary outcome data collected included mean deviation, pattern standard deviation, visual field index, fixation losses, test duration, and false positives and negatives.

Results: A total of 76 patients underwent VVF testing. Of these, 50 eyes of 48 patients had a HVF performed in the prior 12 months and were included in the final analysis (M: 43.75%, F: 56.25%, mean age 55.28). VVF demonstrated no difference in ratio of fixation losses (mean difference -0.08, $p=0.45$) or number of false negatives (mean difference 2.07%, $p=0.05$) but had significantly less false positives (mean difference 5.13%, $p=0.05$). There was no statically significant difference in the mean deviation of the VVF compared to the HVF (mean difference 4.11, $p=0.45$). The VVF had a lower pattern deviation (mean difference -0.23, $p=0.05$) and visual field index (mean difference -2.87, $p=0.05$) compared to the HVF. Test duration was shorter with the VVF by 2.4 minutes (mean difference 2.43, $p=0.05$). Pearson's correlation coefficients for mean deviation, pattern deviation and virtual field index were 0.74 ($p<0.01$), 0.65 ($p<0.01$), and 0.71 ($p<0.01$).

Conclusions: Virtual visual field testing using the BOLT strategy was similar to the Zeiss Humphrey SITA-Standard 24-2. VVF testing provides advantages over HVF in terms of cost effectiveness, portability and efficiency. However, prospective studies are needed to assess virtual field reproducibility and progression analysis.

ABSTRACT BODY:

Purpose: The risk of dry eye disease (DED) increases with age in both men and women. Although sex hormones are known to be important for maintaining the ocular surface health, their role in the etiology of DED is still undefined. In this study, age-related changes were investigated in the ocular surface tissues of aromatase (Aro) and estrogen receptor (ER) KO mice.

Methods: The pathology of ocular surface tissues in the aromatase (an estrogen synthase) and estrogen receptor isoform, ER α and ER β , knockout (KO) mice was investigated. The age-related changes in the KO mice were compared to their age- and sex-matched wild type (WT) control mice.

Results: In 6-month old male Aro-KO mice, estrogen deficiency resulted in multiple defects in the lacrimal glands, which can be best characterized as accelerated aging, those including severe acinar atrophy, appearance of Harderian gland-like structures, increase of gland ducts and morphologic dysplasia (cytomegaly, karyomegaly, and cell and nuclear polymorphism) across the gland. Interestingly, the similar phenotype was also seen in the male ER α KO mice as young as 4-month old, suggesting that estrogen's anti-aging effect in the lacrimal gland of male mice is likely mediated through ER α pathway. Deletion of aromatase significantly increased the size and weight of the lacrimal glands in female KO mice. Increase of immune cell infiltration was found in the lacrimal glands of female Aro-KO mice when compared to the age-matched female WT mice. No apparent histopathology was noticed in the meibomian glands and goblet cells between the Aro-KO and WT mice. No significant difference was found in the corneal fluorescein staining score between the one-year old Aro-KO mice and their age- and sex-matched WT control mice.

Conclusions: Estrogen deficiency results in different responses in the lacrimal glands of male and female mice. Our study suggests that estrogen can play an anti-aging role, mediated through ER α , in the lacrimal glands of male mice. The anti-inflammatory function mediated via the estrogen-ER β pathway in female lacrimal glands is under further investigation.

ABSTRACT BODY:

Purpose: Inherited retinal diseases are an important cause of blindness, and due to the recent advancement of gene-directed trials it is increasingly important to understand the molecular basis of these disorders. The aim of this study was to examine the mutation spectrum of the 5 most common genes involved in inherited retinal disease in a large molecularly characterized cohort from the United Kingdom.

Methods: We performed a retrospective study of electronic patient records of the Genetics Service of Moorfields Eye Hospital. The 5 most common genes, by persons affected, causing inherited retinal disease in this cohort have previously been reported (Pontikos et al., 2020) as ABCA4, USH2A, RPGR, PRPH2, and BEST1. The electronic records database was interrogated, and all patients with a molecular diagnosis due to one of the above 5 genes were analyzed. A total of 1870 patients from 1720 families were included. For autosomal recessive disorders where 2 or more likely pathogenic or pathogenic changes were reported, all mutant alleles were included.

Results: The most common pathogenic or likely pathogenic mutations in our cohort for ABCA4 were c.5882G>A (p.Gly1961Glu) and c.5461-10T>C (212 and 119 of 2024 mutant ABCA4-alleles, respectively). The five most frequent mutant alleles (c.5882G>A (p.Gly1961Glu), c.5461-10T>C, c.2588G>C (p.Gly863Ala), c.4139C>T (p.Pro1380Leu), c.5714+5G>A) account for more than 25% of disease-associated variants in ABCA4. In USH2A the c.2299del (p.Glu767Serfs*21) mutation was most commonly involved (130/749 mutant USH2A-alleles), c.2405_2406del (p.Glu802Glyfs*32) and c.2426_2427del (p.Glu809Glyfs*25) were most prevalent in RPGR (23 and 21/239 mutant RPGR-alleles, respectively), while c.514C>T (p.Arg172Trp) was the most common in PRPH2 (40/194 mutant PRPH2-alleles). In BEST1 the most commonly observed mutations were c.728C>T (p.Ala243Val) and c.652C>T (p.Arg218Cys) (11 and 10 of 201 mutant BEST1-alleles, respectively).

Conclusions: Our findings provide meaningful population-based data of the mutation spectrum of ABCA4, USH2A, RPGR, PRPH2, and BEST1 from a large cohort of patients with a molecular diagnosis from the United Kingdom.

TITLE: Quantitative calibration of sensor strip ERG electrodes – Update.

SESSION TITLE: Electrophysiology: Advances, disease and injury

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Chen, S.E. Brodie, Ophthalmology, NYU Langone Health, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Dinah Chen: Commercial Relationship: Code N (No Commercial Relationship) | Scott Brodie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: ERGs are traditionally recorded using corneal electrodes, which can be difficult for some patients to tolerate. In the last several years, adhesive skin electrodes have gained in acceptance. We have previously reported on the clinical usefulness of qualitative interpretation of ERG recordings using skin electrodes for a wide spectrum of retinal disorders, as well as a preliminary estimate of the quantitative comparison of simultaneous ERG recordings using contact lens (CL) and adhesive skin electrodes to compare differences in signal strength. In the present report, we update our quantitative findings.

Methods: The study was Institutional Review Board approved. 89 subjects were drawn from the practice of one of the authors who were referred for full-field ERG testing for multiple clinical indications. Informed consent was obtained from patients or accompanying parents. ERGs (obtained according to ISCEV standards) were recorded simultaneously from both eyes with ERG-jet corneal CL electrodes and LKC Technologies Sensor Strip adhesive skin electrodes using multi-channel instrumentation (Diagnosys LLC, Espion3). A- and b-wave amplitudes and implicit times were compared between the two electrode types.

Results: Waveform morphologies were similar for both electrodes. Regression coefficients (conversion factors) for a- and b-wave amplitudes under photopic and scotopic conditions were tightly clustered: DA 0.01 b-wave: 0.368; DA 3 a-wave: 0.343; DA 3 b-wave: 0.360; LA 3 a-wave: 0.256; LA 3 b-wave: 0.325; 30-Hz flicker peak-to-peak: 0.384. Regression coefficients for implicit times were nearly equal to 1.0, indicating comparable latencies for skin and CL electrode recordings: DA 0.01 b-wave: 0.971; DA 3 a-wave: 0.926; DA 3 b-wave: 0.996; LA 3 a-wave: 0.967; LA 3 b-wave: 0.964. The regression coefficient for the entire amplitude data set was 0.336, with an overall correlation between skin and CL electrode amplitudes of 0.799. The regression coefficient for the entire implicit time data set was 0.980, with an overall correlation of 0.96.

Conclusions: Our best estimate for the conversion factor between ERG amplitudes recorded with adhesive skin electrodes and CL electrodes is 0.336 – skin electrode amplitudes are about 1/3 the amplitudes recorded simultaneously using CL electrodes - with a high correlation between skin and CL electrode amplitudes. Implicit times are nearly identical for the two electrode types.

ABSTRACT BODY:

Purpose: Over the past 20 years, the mainstay of treatment for retinopathy of prematurity (ROP) has changed from laser photocoagulation therapy to intravitreal injection of anti-vascular endothelial growth factor (antiVEGF). Despite the change in therapy, little is known about the long term outcomes associated with anti-VEGF agents. We performed a retrospective, observational study to determine if there is a difference in the long-term visual and neurodevelopmental outcomes of patients who were treated with laser photocoagulation versus patients treated with an anti-VEGF injection.

Methods: Out of 105 patients who were treated for ROP at Rush University, 24 patients met the inclusion criteria of having at least 1 follow up appointment. 14 were treated using laser photocoagulation, and 10 were treated with an anti-VEGF agent (bevacizumab or ranibizumab). We analyzed visual acuity, ocular alignment, refractive errors, presence of amblyopia, presence of a diagnosed neurodevelopmental disorder, and other notable ocular abnormalities. A student's t-test and a Chi square test were used for statistical analysis.

Results: Analysis of our results showed that patients treated with laser therapy were more likely to be amblyopic than those treated with an anti-VEGF agent (50% versus 10%, $p=0.04$). Additionally, there was a statistically significant difference in the sphere of patients, with laser treatment patients being more myopic (-8 D versus -2.06 D, $p=0.01$). However, the average age at last eye visit has been identified as a possible confounding variable, with the average age being 12 years for patients treated with laser therapy (SD = 2.59) and 2 years for those treated with anti-VEGF (SD = 1.20). Visual acuity could not be analyzed since only one patient in the anti-VEGF group was able to read the eye chart. Analysis of all other categories analyzed revealed no statistically significant differences.

Conclusions: Our results showed a statistically significant difference for two of the outcomes analyzed. Patients treated with laser therapy were more likely to be amblyopic and were more myopic than those treated with an anti-VEGF agent. Further research would include an age-matched, larger sample size. If our results are confirmed, this would suggest a benefit of administering anti-VEGF injections over laser photocoagulation.

TITLE: MicroPulse Transscleral Laser Therapy - Fluence as Predictor of IOP Reduction

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Grippo, Grippo Glaucoma & Cataract Center, City of Buenos Aires, Buenos Aires, ARGENTINA|T. Grippo, Ophthalmology, Hospital Aleman, City of Buenos Aires, Buenos Aires, ARGENTINA|F.G. Sanchez, Glaucoma research, Legacy Devers Eye Institute at Legacy Good Samaritan Medical Center, Portland, Oregon, UNITED STATES|F.G. Sanchez, Legacy Research Institute, Portland, Oregon, UNITED STATES|J. Stauffer, G. Marcellino, IRIDEX Corp, Mountain View, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tomas Grippo: Commercial Relationship(s);Iridex Corp., Mountain View, CA:Code C (Consultant) | Facundo Sanchez: Commercial Relationship(s);Iridex Corp.,Mountain View, CA:Code C (Consultant) | Joan Stauffer: Commercial Relationship(s);Iridex Corp.,Mountain View, CA:Code E (Employment) | George Marcellino: Commercial Relationship(s);Iridex Corp.,Mountain View, CA:Code E (Employment)

ABSTRACT BODY:

Purpose: To determine whether Fluence (F) is a better indicator than Total Energy (TE) in predicting IOP reduction with MicroPulse® Transscleral Laser Therapy (MP-TLT, Iridex Corp., Mountain View, CA) in patients with glaucoma.

Methods: F and TE were calculated from data obtained from published literature. The F formula was adjusted to account for sweep velocity. $F = (\text{power (Watts)} \times \text{duty cycle} \times \text{dwell time (s)}) / \text{fiber area}$. Dwell time is exposure time divided by velocity of the sweep. $TE = \text{power} \times \text{duty cycle} \times \text{exposure time (s)}$. Studies without a description of the treatment parameters (power, exposure time, number of sweeps per procedure) or less than 6 months follow-up were excluded. Boxplots were created to compare the distribution of F and TE, and its relationship with IOP reduction by separating the cohorts into Group A: "equal or lower than the median fluence", and Group B: "above the median fluence"; and mixed effects models were used to compare the parameters between groups. All analyses were performed using R (version 4.0.0, R Foundation for Statistical Computing, Vienna, Austria).

Results: Four of 30 (13.3%) publications included the number of sweeps used to allow for F calculation, yet personal communication with the authors allowed the inclusion of 6 more papers, which yielded a total of 656 eyes from 15 cohorts for analysis (some of the studies included more than one cohort).

Table 1 compares F, TE, baseline IOP, and IOP reduction between group A and group B. Figure 1 shows the distribution of these variables within the groups. Group B had a statistically higher IOP reduction than group A ($p < .001$), and there was no overlap in IOP reduction between the groups (Figure 1, top). TE was not statistically different between group A and group B ($p = .447$), and overlapped in the boxplot (Figure 1, bottom); suggesting that this variable may have less impact on IOP outcomes compared to F. Baseline IOP was not statistically different between the groups ($p = .518$).

Conclusions: Most authors do not report the number of sweeps performed. This fails to account for the impact of sweep velocity on outcomes. In contrary to TE, F combines all the laser parameters including sweep velocity into a single number expressed in Joules/cm². IOP reduction was statistically higher in the high F group (group B), suggesting that F may be a better light-dose metric and a more reliable indicator of IOP reduction than TE.

TITLE: Iris Suturing for Posterior Chamber Intraocular Lens Dislocation:

A comparison of In-the-bag versus Out-of-the-bag Dislocations and Development of Uveitis Glaucoma Hyphema Syndrome

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Pandit, V. Paranjpe, H.A. Parikh, K. Wald, Ophthalmology, NYU Langone Health, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Saagar Pandit: Commercial Relationship: Code N (No Commercial Relationship) | Vikram Paranjpe: Commercial Relationship: Code N (No Commercial Relationship) | Hardik Parikh: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Wald: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine cases of new onset uveitis-glaucoma-hyphema (UGH) syndrome after posterior chamber intraocular lens (PCIOL) repositioning with iris-sutured IOL, differentiating between in-the-bag versus out-of-the-bag dislocations.

Methods: Retrospective chart review was performed on 99 patients with a posteriorly dislocated IOL operated upon by a single surgeon from 2018-2020. Patients with previously diagnosed UGH, retained lens fragment, early dislocation, or lost-to-follow-up after one month were excluded. Variables of interest included 1-piece versus 3-piece IOL, in-the-bag versus out-of-the bag dislocation, and history of pxeudoexfoliation. UGH was defined as having at least one of the following: elevated intraocular pressure >25 mmHg, anterior uveitis, hyphema, or post-operative cystoid macular edema (CME).

Results: 24 patients were eligible for the study. 18 patients were noted to have in-the-bag dislocations (75%). A total of 12 patients developed UGH (50%). Two of the 12 patients (16.67%) exhibited uveitis, glaucoma, and CME. No patients had hyphema. Among patients with UGH, mean age was 73 years old. 7 of 12 cases were in-the-bag dislocations (58.3%), and 6 of 12 cases (50%) had pre-existing pxeudoexfoliation (PXE). Among in-the-bag dislocations with UGH, 5 out of 7 patients had 1-piece IOLs (71%); whereas among the 5 cases of out-of-the-bag dislocations with UGH, all had 3-piece IOLs. Moreover, none of the patients with out-of-the-bag dislocation had pre-existing PXE. A final logMAR VA of 0.314 for in-the-bag dislocations with UGH ($p = 0.832$) was not found to be statistically significant compared to out-of-the bag UGH patients. Mean follow-up time was 4.5 months. Patients were treated with topical steroids (9 out of 12, 75%), topical nonsteroidal anti-inflammatory (8 out of 12, 67%), and pressure lowering drops (9 out of 12, 75%).

Conclusions: UGH is a notable complication of iris sutured PCIOL repositioning. Pre-existing PXE may be a predisposing factor for in-the-bag dislocations. There was a tendency toward UGH with single-piece in-the-bag dislocations, and three-piece out-of-the-bag dislocations. Moreover, both in-the-bag and out of-the-bag dislocations appear to have similar visual outcomes. However, a larger sample size with longer follow-up time is necessary to draw more definitive conclusions.

ABSTRACT BODY:

Purpose: Keratoconus (KC), a bilateral, asymmetric corneal degeneration, leads to high myopia, irregular astigmatism, and corneal scarring. In a 4-generation KC family, we identified a rare variant rs373951075 (G>A) in a PCSK1 intron co-segregating with KC in an autosomal dominant pattern. Here, we evaluated the genetic contribution of PCSK1 to KC pathogenesis.

Methods: We used two mouse models of human PCSK1 deficiency: ENU-induced Pcsk1^{N222D} & targeted mutation Pcsk1^{tm1Dfs} mice. We examined the thickness and curvature of mouse corneas using anterior segment optical coherence tomography (OCT) with a Bioptigen Envisu R2200 system at 3 & 6 months. We performed histological analysis at 6 months. In addition, we checked the expression of PCSK1 in a RNA-Seq dataset of human corneas. We performed bioinformatics analysis with rs373951075 using the UCSC Human Genome Browser and Ingenuity Pathway Analysis (IPA) to identify its potential function and target genes.

Results: We evaluated 70 (37 male, 33 female, 32 WT, 33 heterozygous, 5 homozygous) Pcsk1^{N222D} & Pcsk1^{tm1Dfs} mice. The average corneal thickness measured by OCT was 110±11µm for WT mice, which did not differ significantly from the mutant mice. No curvature abnormalities were detected in either mutant group. Histologic analyses did not reveal morphologic alterations related to KC in corneas of either mutants at 6 months. The expression of PCSK1 mRNA was limited to background/barely detectable levels in human corneas with RNA-Seq. Bioinformatics analysis indicated that rs373951075 is located in a consensus sequence (TGATGTCAT) binding to JUND, an AP1 transcription factor subunit. This region is predicted to be a distal enhancer to neighboring genes based on ENCODE data. Using IPA Pathway Building, we found that JUND, FOS and estradiol can regulate expression of only 1 of 10 neighboring genes: CAST, which is associated with KC. CAST is also highly expressed in human corneas. Our network analysis connects JUND/CAST/Estradiol with many KC-associated genes, including LOX, IL1B, TGFB1, MMP9, SMAD3, COL5A1, RXRA, COL6A1, FNDC3B, WNT10A, WNT7B, LUM, FBN1, LTBP1, FOXO1, CSNK1E, THBS2, and DCN.

Conclusions: Data from the Pcsk1 mice suggest that Pcsk1 may not contribute to development of KC. Further analyses suggest that the KC-segregating intronic variant rs373951075 in the PCSK1 region may serve as an enhancer for CAST. Future functional experiments will test the role of CAST in KC.

ABSTRACT BODY:

Purpose: The Cngb1 gene encodes the β -subunit of the rod photoreceptor cyclic nucleotide-gated (CNG) cation channel. GARP2, a splice variant of the Cngb1 gene, is exclusively expressed in rods and suggested to function as a structural protein, a calcium-binding protein, and a modulator of the basal activity of cGMP phosphodiesterase (PDE). We set out to further assess the structural and functional role of GARP2 within the retina.

Methods: GARP2 knockout mice were generated using ZFN-mediated gene editing. Morphological features were assessed by optical coherence tomography and immunohistochemistry techniques at P180. Functional properties were then assessed by in-vivo electroretinogram (ERG) and whole-cell patch-clamp recordings from retinal slices.

Results: The retina in KO mice exhibited no major alterations, except for occasional longer and bent rod outer segments. The maximum amplitude of the ERG a-waves ($460 \pm 150 \mu\text{V}$ vs. $306 \pm 70 \mu\text{V}$) and b-waves ($1108 \pm 333 \mu\text{V}$ vs. $589 \pm 103 \mu\text{V}$) were reduced in KO mice, with KO mice showing lower than predicted b-wave amplitudes for the measured a-wave. However, single-cell recordings showed no significant differences in the physiological properties of rods and RBCs between the genotypes. Surprisingly, KO rod photoreceptors showed a significant decrease in dark noise levels compared to WT ($0.57 \pm 0.07 \Delta\text{pA}^2/\text{Hz}$ vs. $0.3 \pm 0.04 \Delta\text{pA}^2/\text{Hz}$), $p < 0.01$).

Conclusions: Our morphological analysis suggests that the retina in KO mice develops correctly, with a possible minor role for GARP2 in the structural stability in rod photoreceptors. Importantly, we were able to confirm the modulatory role of GARP2 on the basal activity of PDE, its important role in controlling dark noise levels and implications for regulating visual phototransduction and single-photon sensitivity.

TITLE: Functional Physiology of the Regenerated Zebrafish Retina

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Morey, D.M. Mitchell, D.L. Stenkamp, Biological Sciences, University of Idaho, Moscow, Idaho, UNITED STATES|P.C. Meighan, M.D. Varnum, Integrative Physiology and Neuroscience, Washington State University, Pullman, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lindsey Morey: Commercial Relationship: Code N (No Commercial Relationship) | Diana Mitchell: Commercial Relationship: Code N (No Commercial Relationship) | Peter Meighan: Commercial Relationship: Code N (No Commercial Relationship) | Michael Varnum: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Stenkamp: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Zebrafish regenerate their retinas following damage, resulting in restoration of visual function (McGinn et al., 2018 J Neurosci). Behavioral measures of visual function are restored more rapidly following a lesion that destroys only neurons of the inner retina and spares photoreceptors (PR) and glia (=selective lesion), than following a lesion that destroys all retinal neurons and spares only glia (=extensive lesion) (Sherpa et al., 2014 Dev Neurobiol). Here we further evaluate the recovery of visual function through characterization of the electroretinogram (ERG) over time following these two types of retinal damage.

Methods: Right eyes of zebrafish (6mo–1.5yrs, both sexes) were lesioned with intravitreal injection of either 10 μ M (extensive) or 2 μ M (selective) ouabain. Left eyes served as unlesioned controls. Retinal neuronal communication was analyzed at selected recovery times using ERG recordings in intact zebrafish (extensive, n=4-13 per timepoint; selective, n=3-12 per timepoint). Eyes were then harvested and cryosectioned, permitting subsequent histological analysis of bipolar cells (BP), which is currently underway.

Results: A qualitative study of the ERG waveforms focused on the “post-photoreceptor response” (PPR), which in a healthy retina is dominated by the “b-wave” or ON BP response, to assess BP function and connectivity to PRs during regeneration. There was a rapid reduction in the amplitude of the PPR after both extensive and selective lesions, though the reduction was greater for extensively-lesioned fish. During early stages of functional recovery after both types of lesions, we observed a deviated waveform, which was consistent with emergence of a d-wave (OFF BP response) elicited at light termination. After 45 days post-injury (DPI) for extensive and 21 DPI for selective lesions, the PPR waveform amplitude increased and peaked sooner after the light stimulus compared to earlier DPIs, suggesting emergence of the b-wave (ON BP response). By 90 DPI for extensive and 30 DPI for selective lesion, the PPR waveform became more typical of a healthy retina, but did not return to pre-lesion amplitudes.

Conclusions: Consistent with published behavioral results, PPR recovery following an extensive lesion occurred more slowly than PPR recovery following a selective lesion. Interestingly, the ERG waveform topography suggests that PR-OFF BP connectivity may functionally recover before PR-ON BP connectivity.

TITLE: Retinal vascular changes compared with cone distribution in diabetic subjects

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.E. Elsner, T. Gast, B. Walker, R. Gilbert, S.A. Burns, Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ann Elsner: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Gast: Commercial Relationship: Code N (No Commercial Relationship) | Brittany Walker: Commercial Relationship: Code N (No Commercial Relationship) | Robert Gilbert: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Burns: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We compared microvascular changes of diabetic subjects in several modes of a custom adaptive optics scanning laser ophthalmoscope (AOSLO) to cone distribution models. We analyzed vascular features that show increasing stages of response to ischemia: 1) microaneurysms of sufficient size to include a build-up of epithelial cells; 2) capillary bends or loops that indicate vessel tubule formation and initial elongation, and 3) doubled or collateral vessels or complex tangles that indicate extensive elongation and alteration of direction of growth.

Methods: Cone density and retinal vessels were imaged for 10 diabetic subjects (29-79 yr, 54.5 +/- 12.7 yr. All subjects were consented and tested in a manner approved by the Indiana University Institutional Review Board, which adhered to the Declaration of Helsinki. We performed OCT and OCTA (Heidelberg Spectralis II), then imaged cones and then retinal microcirculation with AOSLO in about 1.5 hr. We simultaneously acquired confocal and multiply scattered light images, using a roughly 100 micron diameter confocal aperture and 3 offset apertures of about 500 microns diameter and offset by 300 microns that differed in direction or wavelength. We used both reflectance mode and motion (variance) mapping for vessels, montaging images for the 6 x 6 deg central retina and temporal retina to 7 deg. To assess the response to retinal ischemia for stages 1-3, we graded all AOSLO imaging modes. Cone density modelling used a 2 parameter exponential model: $\ln(\text{cone density}) = a * \text{microns eccentricity} + b$ and the deviation from our published norms.

Results: This sample of diabetic subjects had a widely varying response to ischemia. A minimal ischemic response was 1) few microaneurysms, no 2) no capillary bends or 3) doubled vessels. Some eyes with a strong ischemic response had significantly low cone density parameter ($b=10.3$ or 10.4 vs. $10.8 \pm .222$) and 1) many microaneurysms, some overlapping; 2) capillary bends, loops and vessels of varying diameter; and 3) doubled/collateral vessels, some a tangled mass. Vascular lesions differed for imaging modes, e.g. fine gauge tangles better seen in reflectance mode, but some microaneurysms better with motion mapping while others in a reflectance image.

Conclusions: Diabetic subjects have numerous lesions detectably small with clinical means that can be associated with low cone density decrease, which may imply neural damage.

ABSTRACT BODY:

Purpose: Viral vector-mediated Gene therapy is at the forefront of the treatment for inherited and acquired retinal disorders. The eye provides a tight blood-brain barrier, low antigenicity to the viruses, and ease of surgical access. Retinal Pigment epithelium (RPE) cells are one of the primary targets for gene therapy. A combination of the cell-specific promoter and lentiviruses, adeno-associated virus (AAV)5, or AAV7m8 successfully transduces RPE cells in vivo. We sought to evaluate RPE cells' immune response after viral gene delivery by subretinal injections.

Methods: 6 weeks old C57Bl6 wild type mice were injected with Lentivirus, AAV5, or AAV7m8 carrying GFP reporter gene driven by CMV promoter via subretinal injection. After 7 or 14 days of injection, the mice were sacrificed, and the eyes were enucleated. The RPE florets were imaged for GFP fluorescence expression using the confocal microscope to confirm the transduction. RPE cells were later dissociated, mRNA was isolated and converted to cDNA. These were subjected to qPCR using the primers for IFN γ , IL-1 α , IL-1 β , IL-6, CD-8, and Iba-1 immunogenic markers.

Results: IFN γ , an activator of macrophages, and IL-1 α , an inflammatory cytokine, were not detected in RPE cells after the viral gene delivery. The expression of IL-6, another pro-inflammatory cytokine, was negligible at week 1, being marginally higher in the lentiviral injected eye relative to both AAV7m8 and AAV5. The expression of IL-6 subsequently decreased at week 2. Expression of IL1 β cytokine was profound in the week 1 sample. Its expression in the lentiviral injected eye was 2-fold higher than AAV7m8, or AAV5, which was abolished entirely at week 2. CD-8 transcripts were 2.7-fold higher for lentiviral and 5.2 fold higher for AAV7m8 compared to AAV5 mediated gene delivery. Its expression persisted at week 2. The expression of Iba-1, a microglia marker, was significantly higher with a 2-fold higher presence for AAVs compared to lentivirus. Its upregulation continued in the AAV7m8 injected eye at week 2. We did not detect any of the above cytokines in the PBS injected control eyes.

Conclusions: Our results indicate that transduced RPE cells by subretinal delivery of viruses elicited inflammatory cytokines. The extent of cellular toxicity in the RPE was greater for AAVs compared to lentivirus. It might be beneficial to consider adjunct immune suppressor therapy for the viral-mediated delivery or use non-viral modalities.

ABSTRACT BODY:

Purpose: Nonadherence to glaucoma drop therapy continues to be an issue in 30-80% of patients and can lead to fluctuations in intraocular pressure (IOP). There remains an unmet need for a therapy with a consistent and durable IOP lowering profile that improves patient compliance. OTX-TIC, an intracameral, bioresorbable, hydrogel-based implant, is designed to deliver travoprost at therapeutic levels in the anterior chamber and can potentially address issues with chronic drop therapy. This study evaluates the safety, tolerability and efficacy of OTX-TIC in subjects with glaucoma.

Methods: Prospective, multicenter, open-label, Phase 1 study in adult subjects with primary open angle glaucoma (POAG) or ocular hypertension (OHT). After washout, subjects were enrolled into 4 cohorts (Cohort 1, 15µg; Cohort 2, 26µg; Cohort 3, fast-degrading hydrogel 15µg; Cohort 4, fast-degrading hydrogel 5µg) and received a single OTX-TIC implant (TIC) in the study eye and topical travoprost (Travatan Z; TZ) in the fellow eye. Diurnal IOP (8am, 10am, 4pm) was assessed at baseline, Days 14, 42, 85, and Months 4, 6, and 4-week follow-up after (8am only). Safety measures include adverse event (AE) collection, endothelial cell count (ECC), and pachymetry.

Results: All cohorts have completed enrollment: Cohort 1 (n=5), Cohort 2 (n=4), Cohort 3 (n=5) and Cohort 4 (n=5). TIC lowered mean IOP levels up to 22, 9, 6 and 6 months in Cohorts 1, 2, 3, and 4, respectively. Eyes treated with TIC had a baseline mean IOP of 21-27 mmHg and all four cohorts showed IOP lowering of 7-11 mmHg which was comparable to TZ-treated eyes. Cohort 2 showed the most consistent and durable response with all subjects going to Month 6 without need for rescue medication in 50% of subjects to Month 9. TIC biodegraded consistently in 5-7 months for Cohorts 1 & 2 and 3-5 months for Cohorts 3 & 4. In all cohorts, no clinically meaningful changes in ECC or corneal thickness were observed. The most common AEs reported were low grade inflammation (all cohorts) and peripheral anterior synechiae (Cohort 1 only).

Conclusions: OTX-TIC showed similar IOP control compared to topical travoprost therapy in subjects with POAG or OHT which was sustained for at least 6 months in many subjects. OTX-TIC was generally well tolerated with a favorable safety profile. Durability of IOP lowering effect was longest and most consistent in Cohort 2.

ABSTRACT BODY:

Purpose: During corneal wound healing, keratocytes within the corneal stroma are activated into a repair phenotype when soluble growth factors, such as transforming growth factor-beta 1 (TGF- β 1) and platelet-derived growth factor-BB (PDGF-BB), are released into the stromal space. This process is often accompanied by changes in tissue stiffness, and previous work has shown that the TGF- β 1-mediated myofibroblastic activation of these cells is stiffness-dependent. Still, it is unclear if stiffness can also regulate keratocyte behavior in response to other growth factors, such as PDGF-BB. Here, we used a polyacrylamide (PA) gel system to determine whether changes in substratum stiffness can modulate the proliferation and motility of primary corneal keratocytes treated with PDGF-BB.

Methods: Functionalized PA substrata with an elastic modulus of either 1 kPa (soft) or 10 kPa (stiff) were fabricated to mimic the mechanical properties of either normal or fibrotic corneal tissue. The substrates were then plated with primary rabbit corneal keratocytes (NRKs) and cultured in defined serum-free media in either the presence or absence of PDGF-BB. Fixed cells were then stained with either F-actin, to visualize cell morphology, or EdU incorporation, to quantify proliferation. In other experiments, a circular freeze injury was introduced to mimic wound healing, and time-lapse phase-contrast images were captured to quantify keratocyte motility.

Results: In the presence of PDGF-BB, NRKs plated on stiffer substrates exhibited a more elongated morphology, an increased cell area, and a higher rate of proliferation than their counterparts cultured on soft PA gels. To assay changes in keratocyte motility, we also quantified NRK migration into decellularized wounds created on both soft and stiff PA substrata. On all substrata, the NRKs migrated from the densely populated region surrounding the wound into the decellularized area. Keratocytes treated with PDGF-BB traveled further into the wound and exhibited faster migration speeds than cells maintained in serum-free conditions, but we did not observe any stiffness-dependent differences in the PDGF-BB-driven motility of these cells.

Conclusions: Taken together, these results suggest that changes in ECM stiffness can modulate the proliferation and morphology of corneal keratocytes, but not their motility, in response to PDGF-BB.

ABSTRACT BODY:

Purpose: To examine the relative ranking of perceived vision loss impacts and its association with eye examination recommendation compliance.

Methods: Data were from the Ocular SOL ancillary study to the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) which evaluated ocular health, knowledge, risk factors, and health care use with 1235 HCHS/SOL participants (age ≥ 40 yrs) at the Miami, FL study site. Participants were asked how various conditions would impact their day-to-day life (i.e. loss of memory, hearing, eyesight, speech or an arm or a leg). Each response was rated on a scale of 1 to 10 with 1 having the least impact and 10 having the greatest impact on daily life. Mean responses and corresponding 95% confidence intervals were calculated and compared by paired t-tests. ANOVA was conducted to examine the difference among gender, education, Hispanic heritage, as well as the association with preventive eye care compliance (reported eye examination by an eye care professional in the past 24 months) in the study population and in the subgroup who had diabetes based on American Diabetes Association criteria. All analyses were adjusted for the complex survey design.

Results: Losing eyesight was ranked as #1 condition impacting daily life at 9.74, 95% CI [9.68, 9.80] (paired t-test, $P < .05$), above losing memory (9.61, [9.52, 9.71]), losing hearing (9.14 [9.01, 9.26]), losing speech (9.10 [8.98, 9.22]), or losing an arm or a leg (8.71 [8.56, 8.86]); means not independent. Relative rankings were consistent across gender, education, and Hispanic ethnicity. Females perceived a higher impact of losing eyesight than males (9.81 vs. 9.66, $P < 0.01$). There were no meaningful differences in the perceived impact of losing vision by preventive eye care compliance status (yes vs. no: 9.76 vs. 9.72, $P = 0.5$). However, among the 264 participants who had diabetes, those who had an eye examination within the past 24 months, reported a greater perceived impact of losing vision (9.81 vs. 9.47, $P = 0.04$).

Conclusions: Among Hispanics/Latinos the perceived impact of losing eyesight is consistently ranked #1 among select conditions that would impact daily life. This concern, however, did not appear to result in better preventive ocular care compliance, except possibly for those living with diabetes. Educational campaigns designed to promote better eye care compliance in Hispanics need to be developed and tested.

ABSTRACT BODY:

Purpose: The optimal approach to utilizing anti-vascular endothelial growth factor (anti-VEGF) pharmacotherapy for the management of diabetic retinopathy (DR) is incompletely defined. Objective metrics such as DR severity scale (DRSS) or panretinal leakage index (PLI) may be able to help guide retreatment among these patients in routine clinical practice. The prospective, randomized PRIME trial compared as needed (PRN) intravitreal aflibercept injections (IAI) guided by real-time DRSS level or PLI for patients with DR.

Methods: Forty eyes with DR (DRSS 47 to 71) without diabetic macular edema (DME) received monthly IAI until ≥ 2 -step DRSS improvement was achieved. Eyes were randomized (1:1): eyes in Arm 1 were retreated according to DRSS level changes and eyes in Arm 2 were retreated according to PLI changes, as graded in real-time by a central reading center (CRC). Main outcome measures included changes in DRSS level and PLI compared to baseline.

Results: Through week 52 (W52), 95% of eyes achieved a ≥ 2 -step DRSS improvement. Following DRSS improvement, 97% of eyes required at least one PRN IAI to maintain anatomic improvements. In eyes requiring PRN IAI and completing W52, 100% and 59% of eyes in Arm 1 and Arm 2 experienced DRSS worsening ($p=0.01$), respectively. Through W52, mean PLI decreased 18.2% ($p=0.49$) and 54.6% ($p<0.0001$) in Arms 1 and 2 respectively. Eyes with NPDR and PDR at baseline achieved the ≥ 2 -step DRSS improvement after a mean 4.9 and 3.6 IAI ($p=0.03$). Two eyes developed a PDR event at W52 following a 5-month quiescent period and a 4- to 5-step DRSS worsening over the preceding one month.

Conclusions: The prospective, randomized PRIME trial utilized CRC-determined criteria to guide retreatment with IAI for DR without DME; most patients required ongoing re-treatment every 3-4 months and recurrence of ultra-widefield fluorescein angiography-determined leakage appeared to precede DRSS level worsening, suggesting PLI as a

potential biomarker for retreatment needs. This data reaffirms that close clinical follow-up is important even among eyes that achieve substantive DRSS-improvements with apparently quiescent disease for months.

TITLE: Osteopontin drives retinal ganglion cell resiliency in glaucomatous neuropathy

SESSION TITLE: Neuroprotection

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Kinde, M. Zhao, K. Toma, Y. Han, X. Duan, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|L. Li, Y. Hu, Ophthalmology, Stanford University, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Benyam Kinde: Commercial Relationship: Code N (No Commercial Relationship) | Mengya Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Kenichi Toma: Commercial Relationship: Code N (No Commercial Relationship) | Liang Li: Commercial Relationship: Code N (No Commercial Relationship) | Yang Hu: Commercial Relationship: Code N (No Commercial Relationship) | Ying Han: Commercial Relationship: Code N (No Commercial Relationship) | Xin Duan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) injury and loss in the context of increased intraocular (IOP) are hallmark features of glaucomatous neuropathy. Understanding how different RGC subtypes respond to chronic injury may provide insight into key players involved in neuroprotection and highlight novel therapeutic targets for the treatment of glaucoma.

Methods: Chronic IOP elevation was achieved using the silicone oil (SO)-induced ocular hypertension under-detected (SOHU) model. SO was injected into the anterior chamber of mice 8–10 weeks of age and a saline control into the contralateral eye. IOP was measured using the TonoLab tonometer weekly for up to 6 weeks. AAV-mediated OPN knockdown (KD) or overexpression (OE) in RGCs occurred at 8 weeks of age. Mice were sacrificed at 1 week and 4 weeks post-SOHU surgery for RGC subtype-specific immunohistochemistry (IHC) analysis. OPN expression was also assessed by IHC in post-mortem human retina, as well as an enzyme-linked immunosorbent assay (ELISA) to quantify OPN in the aqueous humor (AH) from patients with glaucoma.

Results: α RGCs and intrinsic photosensitive-RGCs (ipRGCs and M1-RGCs) were found to be uniquely resilient in the setting of chronically-elevated IOP. This increased resiliency was associated with high expression of OPN, a widely-expressed constituent of the central nervous system extracellular matrix, and shown to promote optic nerve regrowth in combination with growth factors in our previous work. KD of OPN in α RGCs in the SOHU model led to a marked decrease in α RGC survival, while OE of OPN in otherwise susceptible RGCs (Foxp2-RGCs) resulted in a dramatic boost in survival after 4 weeks of elevated IOP. In post-mortem human retina, we found that OPN is expressed in large, α -like RGCs and OPN quantification by ELISA from AH of patients with glaucoma demonstrated that the degree of OPN expression is correlated with disease severity.

Conclusions: OPN is thought to play a role tissue repair in response to neuronal injury. Work by others has implicated a neuroprotective role of OPN in ischemic stroke, spinal cord injury, and Alzheimer's disease, and our findings suggest a novel role for OPN in promoting RGC resiliency in mouse models of glaucomatous neuropathy. Our preliminary work with post-mortem human retina, as well as analysis of AH of patients with glaucoma indicate that OPN may be a target for slowing glaucomatous neuropathy in humans.

TITLE: ATF4 is required for both the maintenance of the lens epithelium and late lens fiber cell differentiation

SESSION TITLE: Lens Development and Differentiation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Xiang, A. Faranda, Y. Wang, S.G. Novo, M.K. Duncan, Biological Sciences, University of Delaware, Newark, Delaware, UNITED STATES|J. Xiang, D.W. Li, Sun Yat-Sen University Zhongshan Ophthalmic Center, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure (Abstract): Jiawen Xiang: Commercial Relationship: Code N (No Commercial Relationship) | Adam Faranda: Commercial Relationship: Code N (No Commercial Relationship) | Yan Wang: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Novo: Commercial Relationship: Code N (No Commercial Relationship) | David Li: Commercial Relationship: Code N (No Commercial Relationship) | Melinda Duncan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: ATF4 is a key transcription factor implicated in diverse biological processes -including the unfolded protein response and regulation of amino acid homeostasis. It was reported over two decades ago that ATF4 null mice have defects in lens development, although there is controversy about whether the primary defect manifested in the lens fiber or epithelial cell. While several reports have found that ATF4 levels upregulate in the lens when the secretory pathway is overloaded with unfolded protein, the function of ATF4 in the healthy lens is largely unknown. Here, we take an unbiased approach to elucidate ATF4 function in the developing lens.

Methods: RNA-seq was performed on E16.5 embryonic lenses obtained from ATF4 knock out homozygous (ATF4^{-/-}) and WT embryos, followed by iPathwayGuide bioinformatics analysis. E16.5 ATF4^{-/-} and WT embryonic lens phenotype was detected by hematoxylin and eosin staining.

Results: The central lens epithelium of E16.5 ATF4^{-/-} mice is disorganized while vacuoles are seen throughout the lens fibers (Figure 1.A). RNAseq revealed that 562 genes were differentially expressed (DEGs) in E16.5 ATF4^{-/-} lenses, with 173 upregulated and 389 downregulated. The downregulated genes included lens epithelium markers like Foxe3 and E-Cadherin (Cdh1) as well as late lens fiber differentiation markers like Crybb2, Birc7 and Dnase2b. Pathway analysis of these DEGs revealed that genes regulating several different metabolic pathways were downregulated, including at least 17 genes known to regulate amino acid synthesis and transport (including Aldoc, Pycr1 and Phgdh) and at least 7 genes known to be involved with glucagon signaling and insulin secretion including Gcg, Pygl, Camk2a and Abcc8(Figure 1.B). Immunostaining has confirmed that E-cadherin downregulates in while α-SMA (Acta2) upregulates in the ATF4^{-/-} lens at the protein level.

Conclusions: Our data demonstrate that ATF4 is required for both lens epithelial cell maintenance and the terminal differentiation of lens fiber cells during late embryonic development. As the downregulated genes are highly enriched in those encoding proteins important for cellular metabolism, we are hypothesizing that ATF4 is required to establish the unique metabolic requirements of the lens.

TITLE: Preoperative versus intraoperative bevacizumab injection in diabetic patients with vitreous hemorrhage

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Pfannenstiel, H. Yu, M. Champion, R. Ajlan, Department of Ophthalmology, University of Kansas School of Medicine, Kansas City, Kansas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Matthew Pfannenstiel: Commercial Relationship: Code N (No Commercial Relationship) | Harrison Yu: Commercial Relationship: Code N (No Commercial Relationship) | Mary Champion: Commercial Relationship: Code N (No Commercial Relationship) | Radwan Ajlan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify vitreous hemorrhage (VH) recurrence rate in diabetic patients during the one-month postoperative visit after pars plana vitrectomy (PPV) with bevacizumab injection either before or during surgery.

Methods: Retrospective chart review was performed for 104 patients that underwent PPV for diabetic VH at the University of Kansas Medical Center during the past three years. Patients who received bevacizumab injection intraoperatively or within 30 days before surgery were included. Patients who were not compliant with postoperative follow-up were excluded. Data collection included LogMAR visual acuity, age, gender, type of diabetes, bevacizumab injection status, vitreous status, and postoperative course. This study was approved by the Institutional Review Board of the University of Kansas School of Medicine.

Results: Forty-eight patients met the study inclusion criteria (27 females, 21 males), with an average age of 52 ± 12.87 years old. The preoperative bevacizumab injection group had 18 patients (53.7 ± 15.43 years old) (9 females, 9 males), including eight patients with tractional retinal detachment (TRD). After one month, four patients (22.2%) had recurrent VH, including one (5.6%) who needed repeat surgery for blood removal. The intraoperative bevacizumab injection group had 30 patients (51 ± 11.22 years old) (18 females, 12 males), including 12 patients with concurrent TRD. After one month, five patients (16.7%) had recurrent VH, including three patients (10%) who needed repeat surgery for blood removal. There was no statistically significant difference between groups regarding size ($p=0.11$), age ($p=0.52$), gender ($p=0.71$), VH recurrence rate at one month ($p=0.92$), or need for repeat surgery ($p=1$).

Conclusions: Early postoperative VH recurrence impacts patients' outcomes and expectations. Our study did not detect a significant difference in VH recurrence at one month after surgery when bevacizumab was injected intraoperatively or within 30 days before surgery. Intraoperative bevacizumab injection may be useful in diabetic patients with VH when bevacizumab cannot be administered preoperatively. Larger prospective trials are needed to further clarify the long-term outcome in similar patients.

TITLE: Comparing Butterfly IQ vs Conventional Ophthalmic Ultrasonic Imaging

SESSION TITLE: Multidisciplinary imaging technologies and applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.K. To, A.N. Vu, A. Browne, Gavin Herbert Eye Institute, Department of Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|D. Horton, E. Dzihic, University of California Irvine School of Medicine, Irvine, California, UNITED STATES|A. Browne, Institute of Clinical and Translational Science, Department of Biomedical Engineering, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): David Horton: Commercial Relationship: Code N (No Commercial Relationship) | Ermin Dzihic: Commercial Relationship: Code N (No Commercial Relationship) | Josiah To: Commercial Relationship: Code N (No Commercial Relationship) | Anderson Vu: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Browne: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Limited reports systematically characterize portable ultrasound devices, such as the Butterfly IQ (BiQ), in ocular imaging. In this study we compare the image resolution of the BiQ portable ultrasound with a conventional piezo-based ophthalmic ultrasound when scanning a phantom model. We hypothesize that the BiQ will perform as well as the conventional B-Scan ophthalmic ultrasound.

Methods: Five BiQ imaging presets (MSK, MSK-Soft Tissue(MSK-ST), Nerve(N), Pediatric Lung(PL), and Ophthalmic(Ophtho)) were chosen and compared against the 10 MHz B-Scan probe on the Ellex Eye Cubed v3 ultrasound unit. Knox gelatin mixed with a gelatin:water ratio of 5:1 cast in a 5cm x 5cm x 2.5cm silicone mold was used as a phantom. Models contained a total of 6 paper stacks made of 3 paper sheets (1mm x 1mm x 0.1mm) with double-sided Scotch tape between layers to increase gap thickness in set increments as in Fig 1 (A, D). The BiQ was held parallel to the ground and scanned in a vertical pattern as in Fig 1 (B, E). The B-scan gain was set to 50 dB and the BiQ gain was set to 0 for MSK, 0 for MSK-ST, 0 for N, 20 for PL, and 0 for Ophtho. Calculated gap length was compared to image-based measurements, which were determined using ImageJ. Resolution was measured in ImageJ using the 1D brightness vs depth plot profile function as in Fig 1 (C, F). The derivative of the plot profile was used to create a slope function in order to determine the local minima, which corresponds to the position of peak brightness. The 1D linear distances were then measured between calculated slope minima of each peak.

Results: The BiQ was less accurate than the Eye Cubed at measuring distances less than 200 microns. The Eye Cubed measured 0.19 +/- 0.00 mm while the butterfly had measurements of 0.39 +/- 0.06 mm(MSK), 0.30 +/- 0.04 mm(MSK-ST), 0.26 +/- 0.39 mm(PL), 0.39 +/- 0.04 mm(N), 0.26 +/- 0.07 mm(Ophtho) for the 1-layer molds. At distances greater than 200 microns (>2 layers of double-sided tape) the BiQ and Eye Cubed performed similarly.

Conclusions: The BiQ demonstrates promising potential as a portable and less costly alternative to conventional piezo-based ophthalmic ultrasound machines in the evaluation of ophthalmic pathologies.

ABSTRACT BODY:

Purpose: To assess the value of automated central macular fluid volume (CMFV) as treatment indication for diabetic macular edema (DME).

Methods: In this retrospective observational study, we consecutively enrolled adult diabetic patients who underwent comprehensive clinical examinations, 6x6-mm horizontal 19-line macular structural optical coherence tomography (OCT) raster scans (Spectralis, Heidelberg), and 6x6-mm macular OCT angiography (OCTA) volumetric scans (Avanti, OptoVue) at the baseline enrollment visit. Two retinal specialists reviewed the baseline raster OCT scans independently and diagnosed center-involved DME if intraretinal or subretinal fluid was detected with 1-mm of the foveal center. A third retinal specialist arbitrated any discrepancy. Mean central macular thickness (CMT) within the 1-mm circle was measured on Spectralis OCT scans using the embedded software. A deep-learning algorithm automatically quantified fluid volumes within the central 1-mm circles (CMFV) on the OCTA scans. All patients with DME were treated per standard of care.

Results: We enrolled one eye for each of 215 diabetic patients (98 men) with a mean age of 60 years. Center-involved DME was diagnosed in 93 eyes. The area under the receiver operating characteristic curve (AROC) of CMFV for diagnosis of center-involved DME was 0.907 with a sensitivity of 78.5% at the specificity of 95%. Forty-eight eyes with center-involved DME underwent anti-VEGF injections at the enrollment visit, among whom 34 (71%) eyes fulfilled the DRCR.net treatment criteria (CMT $\geq 320\mu\text{m}$ in male or CMT $\geq 305\mu\text{m}$ in female). Among the 14 treated eyes who were missed according to DRCR.net criteria, 6 (43%) of them would have been diagnosed as center-involved DME, and indicated a treatment, according to the CMFV. Four of these six eyes underwent focal laser treatment previously. Both CMFV and CMT were significantly correlated with best-corrected visual acuity ($r=-0.303$, $P<0.001$, and $r=-0.339$, $P<0.001$, respectively).

Conclusions: CMFV may be a useful biomarker for DME treatment decisions, particularly for those eyes previously treated with focal laser. A cohort study is indicated to assess the treatment response of CMFV.

ABSTRACT BODY:

Purpose: The electroretinogram (ERG) response to bright flashes delivered in the dark is driven largely by rod photoreceptors. It has been suggested that the time taken for the a-wave to rise from 10% to 90% of the peak amplitude (termed here the 10-90% rise-time, RT10-90) yields a quantitative measure of rod sensitivity. We investigated associations of this parameter with age and explored heritability in a twin study.

Methods: Healthy adult volunteers from the TwinsUK cohort based at St Thomas' Hospital in London underwent dark-adapted and light-adapted ERG recordings using conductive fibre electrodes following mydriasis. As part of the protocol, white xenon flashes ($67 \text{ photopic cd m}^{-2} \text{ s}$) were delivered in the dark and then later in the presence of a rod-saturating blue background ($1.0 \text{ photopic and } 30 \text{ scotopic cd m}^{-2}$). Subtraction of the latter responses (derived from the cone system) from the former responses (derived from the rod and cone system) yielded the estimated dark-adapted rod system response. RT10-90 measurements were extracted made from these derived responses. We quantified coefficients of intra-pair correlation for monozygotic (MZ) and dizygotic (DZ) twin pairs, and estimated heritability using structural equation modelling. The correlation with age was calculated also.

Results: Recordings were obtained from 208 participants (59 MZ and 45 DZ pairs). Mean (SD) age was 62.8 (10.8) years for the whole cohort. 93% were female. Mean (SD) RT10-90 for the derived rod responses was 3.8 (0.5) ms, with a median of 3.7 ms. The parameter was correlated positively with age (correlation coefficient 0.46). Coefficients of intra-pair correlation were 0.49 and 0.19 for MZ and DZ pairs respectively. Age-adjusted heritability was estimated to be 0.48 (95% CI 0.23-0.66).

Conclusions: The 10-90% rise-time parameter showed a moderate positive correlation with age, indicating that rod system sensitivity declines with age. This might reflect pre-retinal optical factors as well as potential changes at the level of the photoreceptors. The intra-pair correlation was higher for MZ than DZ twins, indicating that genetic factors contribute to the variance of this parameter, and our point estimate of heritability was 48%.

ABSTRACT BODY:

Purpose: To investigate the association of serum cholesterol with baseline and longitudinal glaucomatous disease progression.

Methods:

A Prospective longitudinal cohort study of 2056 eyes from 1026 pre-perimetric and perimetric glaucoma cases drawn from the Progression Risk of Glaucoma: Relevant SNPs with Significant Association (PROGRESSA) study.

Lipid profiles were measured on serum samples obtained at study enrolment. Mixed effects multivariable linear regression compared lipid parameters to baseline and longitudinal SD-OCT peripapillary retinal nerve fibre layer (pRNFL) and macular ganglion cell-inner plexiform layer (mGCIPL) thickness data, and with longitudinal Humphrey Visual Field data.

Results: After accounting for age, sex, IOP and lipid lowering therapy, a higher serum total cholesterol was associated with a thinner average mGCIPL thickness (Beta: -0.98 [-1.59, -0.37] $P < 0.001$), thinner worst mGCIPL hemisphere (Beta: -1.11 $\mu\text{m}/\text{SD}$ [-1.86, -0.36] $P = 0.004$), and thinner worst pRNFL quadrant thickness (Beta: -1.92 $\mu\text{m}/\text{SD}$ [-3.41, -0.44] $P = 0.011$) at study enrolment. A higher serum LDL-cholesterol concentration was associated with a thinner average mGCIPL thickness (Beta: -0.81 $\mu\text{m}/\text{SD}$ [-1.4, -0.22] $P = 0.007$), a thinner worst mGCIPL hemisphere (Beta: -1.02 $\mu\text{m}/\text{SD}$ [-1.8, -0.29] $P = 0.006$), and a thinner worst pRNFL quadrant (Beta: -1.81 $\mu\text{m}/\text{SD}$ [-3.25, -0.36] $P = 0.014$).

Review of longitudinal progression data (mean follow up: 6.6 ± 1.8 years) showed that a higher total cholesterol was associated with a greater risk of visual field progression (HR: 1.13/SD, [1.02, 1.26] $P = 0.023$). A higher LDL cholesterol was associated with a faster rate of average mGCIPL thinning (Beta: -0.06 $\mu\text{m}/\text{year}/\text{SD}$ [-0.11, -0.001] $P = 0.045$), a faster rate of mGCIPL thinning in the faster progressing hemisphere (Beta: -0.073 $\mu\text{m}/\text{year}/\text{SD}$ [-0.14, -0.001] $P = 0.046$), a faster rate of average pRNFL progression (Beta: -0.06 $\mu\text{m}/\text{year}/\text{SD}$ [-0.12, -0.01] $P = 0.018$), and a faster rate of pRNFL thinning in the faster progressing quadrant (Beta: -0.11 $\mu\text{m}/\text{year}/\text{SD}$ [-0.21, -0.002] $P = 0.045$). Further evaluation identified that a higher genetic risk score for LDL-cholesterol was associated with a thinner average mGCIPL thickness (Beta: -0.95 $\mu\text{m}/\text{SD}$ [-1.75, -0.15] $P = 0.020$), and a thinner worst affected pRNFL quadrant (Beta: -1.87 $\mu\text{m}/\text{SD}$ [-0.02, -3.72] $P = 0.049$).

Conclusions: Hyperlipidaemia is an important risk factor for disease progression in glaucoma.

ABSTRACT BODY:

Purpose: Poor adherence to glaucoma medication regimens may be associated with subsequent optic nerve damage and irreversible visual loss. Specific barriers to effective patient adherence in low-middle income countries are not fully recognized and new disease-specific instruments to assess adherence have been developed. The purpose of this cross-sectional study was to evaluate adherence of glaucoma patients to treatment and to determine possible associations between medical, demographic/socioeconomic (and other factors) and adherence to topical ocular hypotensive therapy.

Methods: POAG patient were recruited from the Glaucoma Service - ISCMSP, São Paulo, Brazil. Clinical and demographic data were retrieved from participants electronic records. All patients answered the Glaucoma Treatment Compliance Assessment Tool (GTCAT). This questionnaire was designed to evaluate multiple behavioral factors associated with glaucoma medication adherence. It includes 47 statements with a 5-interval Likert-type scale response with anchoring definitions (from 1 = strongly disagree to 5 = strongly agree). The scores were correlated with clinical and sociodemographic parameters.

Results: The sample comprised 96 patients with POAG. The mean age was 63.2 ±8.9 years; 48 were male and 48 female; 55 (57.3%) were white, 36 (37.5%) African-Brazilian, and 5 (5.2 %) were of mixed color; most patients (97.9%) had less than high school degree and all had a family income <USD8,000. The GTCAT identified 69 (71.8%) patients who “sometimes forget to use drops”, 68 (70.8%) patients who “sometimes fall asleep before dosing time”, and 60 (62.5%) patients “whose drops aren’t with them at the time to take them”; 82 (85.4%) patients referred “to use reminders to take medications”; 82 (85.4%) patients agreed that “doctor answers my questions”, and 77 (80.5%) said “they are happy with their eye doctor”.

Conclusions: The GTCAT identified a number of mostly unintentional factors associated with adherence in this cohort of Brazilian patients. The data may impact on how to understand and improve adherence to ocular hypotensive treatment in the Brazilian population and alike.

TITLE: The potential role of DKK3 in the pathogenesis of posterior capsular opacification

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H.L. Angle, A. Faranda, S.G. Novo, A. Krishnan, M.K. Duncan, Biology, University of Delaware, Newark, Delaware, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hunter Angle: Commercial Relationship: Code N (No Commercial Relationship) | Adam Faranda: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Novo: Commercial Relationship: Code N (No Commercial Relationship) | Aarthi Krishnan: Commercial Relationship: Code N (No Commercial Relationship) | Melinda Duncan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Posterior capsular opacification (PCO) is the leading complication of cataract surgery (PCS) While it is established that canonical TGF β /pSMAD3 signaling is a major driver of PCO, we have previously reported that canonical Wnt signaling also upregulates in lens epithelial cells (LECs) PCS. As TGF β and canonical Wnt signaling can synergize to drive fibrosis in other systems, we sought to understand the mechanisms by which Wnt signaling upregulates in LECs PCS.

Methods: The transcriptome of adult mouse LECs was profiled by RNAseq either immediately after lens fiber cell removal or 6, 24, 48, or 120 hours later. The corneal transcriptome of adult mice was also investigated via RNAseq. Mice lacking the DKK3 gene were obtained from the Riken mouse resource, and bred to mice harboring a transgenic canonical Wnt signaling reporter (WntR) whose read out is nuclear localized Green fluorescent protein (GFP). Adult eyes were isolated from mice heterozygous for WntR and either wildtype (WT) or homozygous for the DKK3 null allele. The activity of WntR was assessed by confocal immunofluorescent staining for GFP, which was quantitated using Fiji ImageJ.

Results: The mRNA levels of DKK3, a known Pax6 target gene, are high in naïve LECs and downregulate by 6hrs PCS and remain low in these cells through 120 hours PCS. However, while DKK3 was first described as an inhibitor of canonical Wnt signaling, LECs lacking DKK3 do not upregulate canonical Wnt signaling suggesting that Dkk3 downregulation in LECs PCS is not responsible for the upregulation of canonical Wnt signaling we have previously found to occur in LECs PCS. Notably, DKK3 mRNA levels are also very high in the adult mouse cornea, and DKK3 null mice exhibited a 50% reduction in canonical Wnt reporter activity compared to wildtype (p=0.03) suggesting that DKK3 activates canonical Wnt reporter signaling in the cornea as has been reported in other cell types.

Conclusions: While DKK3 is not essential to keep canonical Wnt signaling low in the lens epithelium, it still may regulate normal lens biology and/or PCO as its high levels in the healthy lens rapidly decrease after cataract surgery and this protein has been reported to modulate both TGF β and NF κ B signaling in other systems. This hypothesis is actively being tested by transcriptome profiling of the DKK3 null lens.

ABSTRACT BODY:

Purpose: Dry Eye (DE) is a prevalent disease in the US and considerably impacts quality of life. Given its heterogeneous nature, biomarkers are needed in DE that can identify underlying contributors to disease. One potential biomarker is the presence of activated dendritic cells (aDCs) in the central cornea, which can be quantified using In-Vivo Confocal Microscopy (IVCM). The purpose of this study was to examine whether aDCs could serve as a biomarker for DE that is associated with a systemic immune disorder.

Methods: Retrospective chart review of 128 individuals with DE symptoms (DE Questionnaire-5 \geq 6) who underwent IVCM between October 2018- July 2020 at the Miami Veterans Administration Medical Center. Exclusion criteria included corneal scarring and history of previous ocular infections. All individuals underwent a standardized ocular surface examination. IVCM images were analyzed with ACCmetrics software, aDCs were manually quantified based on presence of ≥ 3 dendrites that were of the same size or longer than the body of the cell. A receiver operating curve (ROC) analysis was used to examine relationships between aDCs number and systemic immune disease. Based on this analysis, individuals were grouped into categories by aDCs number (≥ 2 versus < 2) and demographic and DE parameters were examined.

Results: The mean age of the study population was 57.1 ± 15.0 years; 71.1% were male, 53.1% self-identified as white and 24.2% as Hispanic. The mean number of aDCs in the cornea was 1.28 ± 2.16 cells/mm². ROC analysis found that the presence ≥ 2 aDCs in the central cornea had a sensitivity of 60% and specificity of 77% for the diagnosis of a systemic immune disorder. Individuals were thus grouped by aDCs number (≥ 2 versus < 2); those with $\text{aDC} \geq 2$ were more likely to be black, have Secondary Sjogren's, use autologous serum tears, have a higher nerve fiber area, higher nerve fractal dimension, and lower nasal and middle conjunctivochalasis scores.

Conclusions: The presence of ≥ 2 aDC in the central cornea suggests a systemic immune disorder in individuals with DE symptoms. Further longitudinal research is needed to evaluate our finding in more diverse populations and to evaluate if changes in aDC number correlate with changes in clinical symptoms and signs of disease.

ABSTRACT BODY:

Purpose: An association between childhood diagnosis of strabismus and increased risk of diagnosis of several mental health disorders by early adulthood has been demonstrated in previously published literature, however the number and demographics of such studies are limited. To further examine these potential associations, we performed a large, retrospective cohort study using data from multiple large health organizations in the United States.

Methods: Patients 0 to 15 years old with a strabismus diagnosis were identified in TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising multiple large health organizations in the United States. Relative risk of being diagnosed with any one of several mental health disorders between a patient with a strabismus diagnosis versus one without was calculated using logistic regression to control for primary demographic factors and propensity score matching using a greedy nearest-neighbor matching algorithm.

Results: A total of 131,413 patients with strabismus diagnosed at an average age of 3.7 years old were identified. Patients with a history of strabismus were more likely to be diagnosed with several mental health disorders including generalized anxiety disorder (RR 1.73, 95% CI 1.55-1.93], major depressive disorder (RR 1.22, 95% CI 1.10-1.35), attention deficit hyperactive disorder (RR 1.57, 95% CI 1.51-1.64), substance use disorder (RR 1.60, 95% CI 1.15-2.23), adjustment disorder (RR 1.78, 95% CI 1.63-1.95), obsessive-compulsive disorder (RR 1.63, 95% CI 1.33-1.99), post-traumatic stress disorder (RR 1.21, 95% CI 1.01-1.46), anorexia (RR 1.92, 95% CI 1.73-2.12), conduct disorders (RR 1.75, 95% CI 1.64-1.86), and Tourette's disorder (RR 1.34, 95% CI 1.02-1.77).

Conclusions: In the age group studied (0-15 years old), an association exists between previous diagnosis of strabismus and subsequent diagnosis of several mental health disorders. More research is needed to further elucidate these relationships.

ABSTRACT BODY:

Purpose: To explore the retinal proteome profile at times after localized optic nerve injury and compare the protein expressions at the regions characterized by primary and secondary retinal ganglion cell (RGC) degeneration

Methods: Unilateral partial optic nerve transection (pONT) was performed on the temporal side of the optic nerve in adult Wistar rats. The RGC density from 1 to 8 weeks after pONT was topographically quantified with Rbpms antibody. Temporal and nasal retinal samples were collected separately from the eyes after pONT and soluble proteins (n=4; 3 technical replicates) were subjected to profiling with a high resolution hybrid quadrupole time-of-flight MS running on label-free SWATHTM acquisition (SCIEX). An information dependent acquisition ion library was generated from all individual biological replicates for SWATHTM peptides quantification. MS spectra were searched for protein identification with ProteinPilot 5.0 (SCIEX) using the Paragon algorithm. Cellular localization of significantly regulated proteins ($P < 0.05$; FC > 1.4 or < 0.7) using immunohistochemistry was performed.

Results: There was $78.9 \pm 5.8\%$ and $27.7 \pm 6.0\%$ of RGC survival in the temporal quadrant at 1 and 8 weeks respectively indicating primary RGC degeneration. No change in RGC density was observed in the nasal quadrant at 1 week after pONT (n=8) but the percentage loss increased to $43.6 \pm 7.7\%$ at 8 weeks (n=15; $P = 0.0001$) demonstrating secondary RGC degeneration. A total of 3641 proteins ($> 25,000$ peptides) with $FDR < 1\%$ were identified in the rat retinas as an ion library. Compared to nasal retina, 6, 12 and 65 differentially expressed proteins were detected in the temporal retina at 1, 4, and 8 weeks respectively. Approximately 6, 4 and 3 folds upregulation of aldehyde dehydrogenase 1A1 (ALDH1A1) was noted in the temporal retina at 1, 4 and 8 weeks respectively. Immunohistochemistry showed that increased immunoreactivity of ALDH1A1 was predominately localized to Muller cells at the temporal retina at 1 week but not nasal retina, and the upregulation was diminished at 4 and 8 weeks.

Conclusions: The finding demonstrated differential protein expression between primary and secondary RGC degeneration. The temporal change of ALDH1A1 suggests that Muller cells respond to localized injury and may play a role in detoxification during progressive RGC degeneration.

ABSTRACT BODY:

Purpose: Superficial keratectomy with topical disodium ethylenediaminetetraacetic acid (Na₂-EDTA) is an established treatment for band keratopathy (BK). Use of the dipotassium form (K₂-EDTA) acquired from easily available blood collection vacutainer tubes as an alternative to the commercially available Na₂-EDTA was only recently reported in 2018. We report our experience of using K₂-EDTA to treat band keratopathy.

Methods: Retrospective case series of 20 eyes (19 patients) undergoing superficial keratectomy with K₂-EDTA chelation from July 2018 to September 2019. Symptomatic BK patients with visual impairment or discomfort from ocular surface instability were included. 12.3% K₂-EDTA solution was applied topically after superficial keratectomy and chelation was achieved. Followed by placing a bandage contact lens to facilitate epithelial healing/comfort. Outcomes measured were BCVA, resolution of symptoms, time to re-epithelialisation, recurrence, complications, and need for any further treatment.

Results: Mean age was 67.4 years (SD 19.2; range: 24 - 88) and 55% were Males. The indications for the procedure included discomfort 12 eyes (60%), impaired vision in 7 (35%) and improve cosmetic appearance in 1 (5%). The mean operation time was 22 minutes (SD 8) timed from application of the drape and including superficial keratectomy. Effective clearance of the BK was accomplished in all patients. No major complications reported. Post op BCVA improved in 4 but remained the same in 3 eyes undergoing the procedure for visual improvement due to associated corneal scarring (n=2) and age-related macular degeneration (n=1). Corneal surface healing was achieved in all patients except one who developed a persistent epithelial defect due to underlying neurotrophic cornea secondary to past acanthamoeba keratitis resolving with temporary lateral tarsorrhaphy. Recurrence of BSK was noted in none of the patients on mean 150 days (SD 121) follow up time.

Conclusions: Superficial keratectomy with topical 12.3 % K₂-EDTA chelation serves as an efficient and safe surgical technique for band shaped keratopathy clearance and is cheaper as compared to the traditional Na₂-EDTA solution.

ABSTRACT BODY:

Purpose: Non-infectious uveitis (NIU) is a significant cause of blindness. It is an immune mediated disease however the exact pathogenesis remains elusive. Considerable evidence exists on the immunomodulatory effects of EVs in various diseases; although very little is known regarding EVs in uveitis patients. We have previously shown that cytokine stimulated ARPE19 cells, release Extracellular Vesicles (EVs); these EVs are capable of inhibiting T cell proliferation, inducing pro-inflammatory cytokines from monocytes as well as inducing monocyte cell death, in PBMCs from NIU patients. The purpose of this study is to establish a reliable protocol to isolate EVs from uveitis patients and to determine their immune-modulatory potential in-vitro.

Methods: EVs were isolated from the serum of NIU patients using Size Exclusion Chromatography (SEC), in 500ul fractions. Appropriate fractions were then pooled and concentrated via filtration. Various markers on the surface of isolated EVs were analyzed using the MACSPlex Exosome kit. The EVs were set up in culture with PBMCs or ARPE19 cells; after stimulation the cells were stained to determine cell activation and cytokine production.

Results: The first six SEC fractions contained EVs of appropriate size with very low protein content along with the presence of exosome associated markers CD9, CD63 and CD81. A higher number of EVs were isolated from the sera of patients, as compared to healthy controls. Additionally, EVs from patients expressed increased levels of CD8, CD29, CD44, and importantly HLA-DR/DP/DQ, indicating their potential to activate cells in-vivo. An upregulation of CD69 and CD25 on T cells was observed when the cells were cultured with EVs from patients. Culturing PBMCs, with EVs from patients lead to an increase in IFN γ production from CD4 $^{+}$ T cells as compared to those cultured with EVs from healthy controls. Additionally, incubating ARPE19 cells with the EVs from patients, increased the expression of MCP1 and IL8 in ARPE19 cells.

Conclusions: We observed that SEC, along with filtration, is a reliable and fast method for isolating EVs from low volume samples. Preliminary data indicates that EVs isolated from uveitis patients can induce a robust activation of various cells in-vitro. Future experiments are designed to understand the pro-inflammatory nature of the EVs isolated from NIU patients as well as to further substantiate these results.

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Tamakuwala, C. Piacentino, University of the Incarnate Word Rosenberg School of Optometry, San Antonio, Texas, UNITED STATES|M. Montelongo, Sponsel Foundation, San Antonio, Texas, UNITED STATES|R. Trevino, ODStudy Associates, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Karan Tamakuwala: Commercial Relationship: Code N (No Commercial Relationship) | Craig Piacentino: Commercial Relationship: Code N (No Commercial Relationship) | Mario Montelongo: Commercial Relationship: Code N (No Commercial Relationship) | Rick Trevino: Commercial Relationship(s);Revenio Group:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To compare peak diurnal intraocular pressure (IOP) assessed by serial home tonometry using the iCare HOME tonometer by the water drinking test (WDT).

Methods: Healthy adults 20-40yrs old with normal ocular health were eligible for inclusion. One eye selected at random was enrolled in the study. All study IOP measurements are the mean of 3 sequential recordings of "Excellent" or "Good" reliability obtained via self-tonometry using an iCare HOME device in an upright seated posture. The WDT was performed after a training session and demonstrated proficiency using the tonometer. Baseline IOP was established, then 1 liter of bottled drinking water was consumed within 5 min. Self-tonometry was performed at 15, 30 and 45 min. The tonometer was then dispensed to the patient for serial home tonometry performed every 2 hrs over a 24 hr period commencing >12 hrs following the WDT. Finally, the subject completed an opinion survey regarding the two procedures.

Results: 11 subjects (5M, 6F; 5 OD, 6 OS; mean \pm SD age: 24.6 \pm 1.8yr) completed the study. Peak IOP achieved during the WDT was significantly correlated with the peak obtain by serial home tonometry ($r = 0.81$, $p = 0.003$). Mean (\pm SD) difference in peak IOP between the two procedures was 0.2 \pm 2.2 mmHg, with \pm 4.3 mmHg 95% CI. Reliability of home tonometry assessed via agreement of the 3 sequential IOP measurements was excellent ($ICC_{(2,1)}: 0.86$; 95%CI: 0.58-0.94). There was no indication that nocturnal measurements (00:00-06:00 hours) were less reliable than those obtained during waking hours (NIGHT $ICC_{(2,1)}: 0.87$; 95%CI: 0.57-0.95, DAY $ICC_{(2,1)}: 0.86$; 95%CI: 0.57-0.94). Survey responses indicated that a majority of subjects (73%-82%) had no difficulty performing either procedure; however, a majority expressed preference for the WDT (64% vs 36%).

Conclusions: There is good agreement between serial home tonometry performed using the iCare HOME tonometer and the WDT in estimating peak diurnal IOP of healthy young adults. These results suggest that both procedures may be useful in the assessment of peak diurnal IOP. Further research in glaucoma patients is warranted.

ABSTRACT BODY:

Purpose: To investigate predictors for macular neovascularization (MNV) associated with central serous chorioretinopathy (CSCR) based on multimodal imaging

Methods: Retrospective multi-center chart review study of 134 eyes of 128 consecutive patients with CSCR. Eyes were classified per the multimodal imaging-based classification of CSCR at baseline into i) simple/ complex CSCR & ii) primary episode/ recurrent/ resolved CSCR. Baseline characteristics of MNV and predictors were evaluated with ANOVA.

Results: Of the 134 eyes with CSCR, MNV was present in 32.8% (n=44). Based on severity, those with MNV primarily consisted of complex (72.7%, n=32), followed by simple (22.7%, n=10), and atypical (4.5%, n=2) types. Those without MNV, in contrast, were more commonly simple (55.6%, n=50) than complex (44.4%, n=40). Compared with complex CSCR with MNV cohort, simple CSCR with MNV had a better baseline decimal visual acuity (0.72 vs 0.49, p=0.03) without differences in age (mean 59 vs 59 years, p=0.76), subfoveal choroidal thickness (SFCT 393 vs 390 μ m, p=0.997), and reported duration of symptoms (median 6 vs 18 weeks, p=0.38).

Based on presentation, those with MNV were as likely to be primary (45.5%, n=20) as recurrent (45.5%, n=20), with the rest as resolved cases (9.1%, n=4). No differences between primary, recurrent vs resolved cohorts were found in age (mean 58, 61 vs 52, p=0.27), visual acuity (mean 0.56, 0.50 vs 0.65, p=0.66), SFCT (414, 383 vs 329 μ m, p=0.55), and duration (median 7, 7 vs 30, p=0.42). However, primary CSCR with MNV were older (58 vs 47, p=0.0003), worse visual acuity (0.56 vs 0.75, p=0.01), and of longer duration (median 7 vs 1, p=0.0002) than those without MNV. Similarly, recurrent CSCR with MNV were older (61 vs 52, p=0.004), without differences in visual acuity (0.50 vs 0.61, p=0.31), SFCT (383 vs 424 μ m, p=0.21), and duration (median 7 vs 2, p=0.32) than those without MNV. Further analysis of MNV characteristics in each subgroup and predictive modeling is underway.

Conclusions: Prevalence of MNV associated with CSCR was 32.8% and more likely in complex CSCR and older age. Complex CSCR with MNV also had worse baseline visual acuity than simple CSCR with MNV and complex CSCR without MNV. Primary and recurrent presentations were similarly accounted for nearly half of MNV cases. Multimodal imaging-based classification of CSCR supports detailed analysis of associated MNV.

TITLE: Utilization and insurance payments for tele-ophthalmology in the United States over 10 years

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.C. Lee, S. Alber, N. Mehta, P. Emami-Naeini, G. Yiu, Ophthalmology, University of California Davis, Sacramento, California, UNITED STATES|G. Yiu, OptumLabs Visiting Fellow, Optum Inc, Eden Prairie, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sophie Lee: Commercial Relationship: Code N (No Commercial Relationship) | Susan Alber: Commercial Relationship: Code N (No Commercial Relationship) | Neesurg Mehta: Commercial Relationship: Code N (No Commercial Relationship) | Parisa Emami-Naeini: Commercial Relationship: Code N (No Commercial Relationship) | Glenn Yiu: Commercial Relationship(s);Allergan:Code C (Consultant);Carl Zeiss Meditec:Code C (Consultant);Intergalactic Therapeutics:Code C (Consultant);Iridex:Code C (Consultant);Regeneron:Code C (Consultant);Topcon:Code C (Consultant);Verily:Code C (Consultant);Clearside Biomedical:Code C (Consultant);Genentech:Code C (Consultant)

ABSTRACT BODY:

Purpose: Remote eye screening using tele-ophthalmology has the potential to reduce cost and improve rates of retinopathy screening in patients with diabetes. However, lower insurance reimbursements have limited the financial sustainability of many tele-ophthalmology programs. Here, we performed a retrospective claims-based analysis of tele-ophthalmology utilization and insurance payments using the OptumLabs[®] Data Warehouse (OLDW) – a comprehensive database of de-identified administrative claims for commercial enrollees in the U.S.

Methods: We analyzed all healthcare claims in OLDW database from 2010-2019 for tele-ophthalmology using Current Procedural Terminology (CPT) codes for tele-ophthalmology 92227 and 92228 for any providers, as well as fundus photography 92250 by non-eyecare providers. We evaluated the number of administrative claims for tele-ophthalmology codes, rates of insurance claim payments or denials, provider specialty and practice setting, as well as age, sex, race/ethnicity, household income, education level, and rural-urban commuting area (RUCA) codes.

Results: Utilization of tele-ophthalmology increased rapidly over the past 10 years, from 51 claims per 100,000 person-years in 2011 when tele-ophthalmology CPT codes were introduced, to 153 claims per 100,000 person-years in 2019. A majority of administrative claims for tele-ophthalmology include at least one diagnostic code for type 1 or 2 diabetes (59%). The rest include a diagnosis of diabetic eye disease (8%) or any eye condition (41%). However, insurance payments for tele-ophthalmology decreased over the 10-year period, from 88% of claims paid in 2011 to 65% in 2019.

Conclusions: Utilization of tele-ophthalmology has increased rapidly over the past 10 years, but insurance payments have declined. Given the potential cost-savings and reduction of in-person eye screening for diabetic patients, insurance providers should be encouraged to improve coverage for tele-retinal services.

TITLE: Types of identified errors of Endothelium Cells segmentation from Corneal Specular Microscopy using a U-Net Network

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.S. Abib, A.D. Britto Jr, Pontificia Universidade Catolica do Parana, Curitiba, PR, BRAZIL|F.C. Abib, Anatomy, Universidade Federal do Parana, Curitiba, PR, BRAZIL|F.C. Abib, Cornea, Prof. Fernando Abib Eye Clinic, Curitiba, PR, BRAZIL|

Commercial Relationships Disclosure (Abstract): Fernanda Abib: Commercial Relationship: Code N (No Commercial Relationship) | Fernando Abib: Commercial Relationship: Code N (No Commercial Relationship) | Alceu Britto Jr: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The traditional segmentation methods for Endothelial Cells in Non-Contact Corneal Specular Microscopy do not identify perfectly these cells, presenting distorted morphometric results, as demonstrated in ARVO 2016 by Ursulino, Hida, Holzchuh & Abib. The purpose of this cross-sectional study is to know the errors in determining the contours of Endothelial Cells (EC) generated by a U-Net network.

Methods: Images from two different contexts were used to train the U-Net: 1) 30 images from the ISBI Challenge: Segmentation of neuronal structures in EM stacks had their labels preprocessed 2) 78 Corneal Specular Microscopy images obtained automatically by Specular Microscopy Tomey EM-4000 in Prof Fernando Abib Eye Clinic, Brazil. A Data Augmentation algorithm using Keras library was used to increase the number of images to train the network. The EC training images were cropped to fit the size of 256x256 pixels, and their respective labels were binarized. The training labels from the ISBI Challenge were pre-processed. The images used to train the network were different from the ones used to test. The metric used to evaluate the training was the binary accuracy. With the endothelial images (30) of the tests performed by the U-Net, the tracing errors were classified as recommended by Ursulino, Hida, Holzchuh & Abib (ARVO 2016):

(Figure 1)

Type I - Non-counted cells;

Type II - Cell cluster;

Type III - Split cell.

Results: During the training phase, the binary accuracy obtained was of 93.14%. Type of Errors by U-Net identifying Endothelial Cells:

(Figure 2)

Type I - No case (0%) of cells not considered in the identified cells area;

Type II - 27 images (90%) didn't have clusters, but the contours in some part of the images were determined in light gray and rarely partially traced; 3 images (10%) had clusters defined only with two cells;

Type III - 4 images (13.3%) presented only one split cell, the other 26 images (86,6%) did not present it;

In all 30 images (100%), in some part of the reticulum, the outline of the cells was in light gray.

Conclusions: The U-Net network showed a small number of errors in determining the contours of the endothelial cells. This technology is promising for clinical use requiring a very high number of images for the network training.

ABSTRACT BODY:

Purpose: Biometric evaluations of the iris using Heidelberg Spectralis imaging technology.

Background: Infrared (IR) iris scans are used for biometric recognition in airports. However, eyeMDs have not embraced the latest IR technology to evaluate the iris, affected in diabetes, glaucoma, and inherited anterior segment diseases. In 2018, Postalache et al used IR imaging to detect features of the iris not seen in standard light photography. IR imaging could be used to identify crypts, collarettes, ciliary regions, pupillary regions, nevi, contraction furrows, and other features of the iris. Here we describe a novel use of IR imaging for the evaluation of the iris. This work could add to future imaging techniques for new tools for eyeMDs.

Methods: Eyes were imaged using Heidelberg Spectralis, 1081 λ (Heidelberg Engineering HRA + OCT : Heidelberg GE). Crypts were counted and collarettes were measured in each subject. Adobe Photoshop was used to identify and measure crypts and collarettes.

Results: Figure 1.1 - IR image iris in a WM. a) nevi, b) contraction furrows, c) pupillary region, d) ciliary region, e) collarette, f) pupillary boundary

Figure 1.2 - 90° sector IR image iris in WM. a) contraction furrow, b) crypt, c) ridge

Figure 2.1 - IR image iris in a South Asian. a) crypt, b) collarette, c) pupillary region, d) ciliary region, e) pupillary boundary

Figure 2.2 - 90° sector IR image iris in a South Asian. a) five crypts in the iris, b) ridge.

Figure 3.1: IR image iris in a Asian. Collarette outlined in white, arrows point to five crypts

Figure 3.2: 90° sector IR image iris in a Asian. Arrows point to five crypts in the iris

Figure 4.1: IR image iris in a East Asian subject. Collarette is outlined in white, arrows point to five crypts in the iris.

Figure 4.2: 90° sector IR image iris in a East Asian. Arrows point to six crypts in the iris.

Figure 5.1: IR image iris in a East Asian. Collarette is outlined in white.

Figure 5.2: 90° sector IR image iris in a Filipino. Arrows point to six crypts in the iris.

Table 1: total number of crypts identified in a 90° sector IR image and collarette measurements for each subject. There are ethnic differences in the number of crypts in the iris. Collarette measurements differ across ethnic lines as well.

Conclusions: This small pilot study shows that IR photography can document small changes in the iris. We hope other researchers will join us to explore the latest software tools to evaluate the iris.

TITLE: Risk Factors for the Development of Horseshoe Retinal Tears in Fellow Eyes

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Peng, BioSciences, Rice University, Houston, Texas, UNITED STATES|S. Laswell, H. Yu, C.C. Wykoff, Retina Consultants of Texas, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Enoch Peng: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Laswell: Commercial Relationship: Code N (No Commercial Relationship) | Hannah Yu: Commercial Relationship: Code N (No Commercial Relationship) | Charles Wykoff: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Horseshoe retinal tears (HRT) can progress to retinal detachments (RD) if untreated. While there are known risk factors for HRT development, there is little data related to risk factors for HRT development in the fellow eye (FE) after HRT development in one eye. The purpose of this study was to investigate risk factors associated with HRT development in the FE of patients with HRT in one eye.

Methods: Medical records were reviewed for patients with initial HRT between October 1, 2015 and December 31, 2017 at a large, urban, retina practice. Eyes were excluded if they had prior HRT or RD treatment, a concurrent RD at initial visit, or only 1 visit; eyes with localized RD were included if treatment consisted of cryotherapy or laser demarcation. Vitreous attachment status was graded using presenting macula optical coherence tomography (OCT) images with a four-stage method: 0=fully attached, 1=extra foveally attached, 2=foveally attached, 3=fully detached in view, 4=fully detached out of view. Logistic regression was used to assess factors associated with FE HRT including FE and study eye (SE) posterior vitreous detachment (PVD) status, SE subsequent breaks, SE vitreous hemorrhage (VH), and SE lattice degeneration.

Results: 246 patients presented with an HRT in the SE during the inclusion period with a mean follow up of 68.8 months (median 30.2; IQR 8.0-125.9). Among patients who had an intervention (244, 99.2%), the majority received laser demarcation (239, 98.0). 40 (16.3%) patients developed a FE HRT, and experienced floaters (22, 55%), flashes (8, 20%), blurred vision (5, 12.5%), eye pain (1, 2.5%), light sensitivity (1, 2.5%), and shadow (1, 2.5%), while 7 (17.5%) patients were asymptomatic. Mean time between SE HRT and FE HRT was 6.2 months (median 1, range 0-46). Logistic regression demonstrated an association between occurrence of FE HRT and a stage 3 PVD at the time of initial SE HRT ($p=0.0283$). There was also an association between FE HRT and the development of subsequent breaks in the SE ($p=0.00124$). There were no associations between FE HRT and SE VH ($p=0.86$), SE PVD ($p=0.7719$), or SE lattice degeneration ($p=0.0874$).

Conclusions: The current study found statistically significant associations between development of FE HRT and (1) stage 3 PVD in the FE at the time of SE HRT presentation and (2) subsequent HRT in the SE. These factors may be important to consider in the clinical management of patients with HRT.

TITLE: Anti-VEGF drugs clearly decrease phagocytic ability of retinal microglia.

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Heiduschka, Y. Zhang, T. Plagemann, N. Eter, Ophthalmology, Westfälische Wilhelms-Universität Münster Fachbereich 05 Medizinische Fakultät, Münster, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Peter Heiduschka: Commercial Relationship: Code N (No Commercial Relationship) | Yahan Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Tanja Plagemann: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Eter: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While anti-VEGF drugs show high efficacy in the treatment of neovascular AMD, many patients develop geographic atrophy after a longer treatment. We performed an experimental in vitro study to evaluate influence of anti-VEGF drugs on cultivated microglial cells, which are the intrinsic immune cells of the retina and may play a key role in degenerative processes in the retina.

Methods: Microglial cells were isolated and cultivated from pig eyes. Identity of the cells was confirmed by staining against the typical microglial markers Iba1, CD11b and CD68. Microglial cells were exposed to the anti-VEGF drugs aflibercept and bevacizumab of different concentrations ranging from 0.33 to 5.71 mg/ml and ranibizumab at 5 mg/ml. Proliferation was checked by the Click-iT Edu assay, cell viability by ATP viability luciferase assay and phagocytic ability by measuring of the uptake of fluorescent micro beads. Moreover, we looked at the morphology of the cells and investigated influence of simultaneous presence of LPS or microglial inhibitors dexamethasone, minocycline and tripeptide TKP on phagocytosis.

Results: Extent of proliferation was not changed by anti-VEGF drugs. At the highest concentration of the drugs, cells treated with bevacizumab and ranibizumab showed a reduced size, loss of processes and a “foam”-like appearance. Cells treated with aflibercept showed only mild changes of morphology. Cell viability was reduced down to about 70±5% at the highest drug concentrations. Ability to phagocytose decreased clearly already at 0.33 mg/ml bevacizumab (61.0±2.7%) and at 0.66 mg/ml aflibercept (61.4±4.9%). At the highest concentrations of the drugs, ability to phagocytose diminished almost completely (bevacizumab 2.4±0.5%, aflibercept 5.6±0.8%, ranibizumab 5.2±0.8%). LPS or the microglia inhibitors did not change the phenomenon that the drugs reduced phagocytosis, nevertheless, extent of that reduction was smaller depending on the inhibitor and the anti-VEGF drug. When anti-VEGF drug was exchanged by clean medium, ability to phagocytose recovered quickly depending on time and drug concentration.

Conclusions: Anti-VEGF drugs reduce viability moderately and do not show effect on proliferation of microglial cells. In contrast, their ability to phagocytose is reduced dramatically. It may be speculated that reduced microglial phagocytosis allows enhanced accumulation of cellular debris, which in turn may promote progression of dry AMD.

ABSTRACT BODY:

Purpose: Heparan-alpha-glucosaminide N-acetyltransferase (HGSNAT) is a lysosomal membrane enzyme that has been historically associated with mucopolysaccharidosis type IIIC (MPS IIIC) or Sanfilippo C syndrome. The variant c.1843G>A (p.Ala615Thr) in HGSNAT has been recently associated with late-onset nonsyndromic pericentral retinitis pigmentosa (RP). The aim of this study is to expand the phenotypic and genotypic spectrum of HGSNAT-related retinopathy.

Methods: This retrospective study from the Casey Eye Institute and the Instituto de Genética Ocular found nine patients with variants in HGSNAT and who presented pericentral retinopathy. We reviewed ophthalmologic data extracted from medical records, color fundus photos, fundus autofluorescence (FAF), and optical coherence tomography (OCT).

Results: Of the nine patients, seven were female, and the median age was 55 (range: 24-77) years. The age of ophthalmologic symptoms onset varied from 15 to 70 (mean 48; median 50) years. The visual acuity varied from 20/20 to 20/80 (mean 20/25; median 20/20), and the plurality of the eyes were 20/20. Color fundus photos varied from normal to the presence of bone spicules in the mid-periphery. FAF showed a pericentral pattern of hypoautofluorescent changes, and two patients presented with hypoautofluorescent spots in the nasal periphery. OCT revealed cystoid macular edema in three patients and outer retinal atrophy surrounding the fovea area in all patients. Genetic testing found four homozygous patients with p.Ala615Thr variant. The remaining patients were compound heterozygous and had the following variants: c.1843G>A (p.Ala615Thr), c.32_46del (p.Leu11_Ser16delinsPro); c.1843G>A (p.Ala615Thr), c.715del (p.Arg239Alafs*37); c.1843G>A (p.Ala615Thr), c.1297A>G (p.Asn433Asp); c.1218G>T (p.Leu406Phe), c.1220C>T (p.Thr407Ile); and c.1726G>T (p.Gly576*), c.525dupT (p.Val176Cysfs*16), c.118G>A (p.Asp40Asn).

Conclusions: There were differences in age of onset between patients; however, all presented with late-onset retinopathy. FAF was more sensitive at demonstrating retinal changes than color fundus photographs. These findings suggest mutations in HGSNAT may cause retinal dystrophy with a late-onset and pericentral pattern.

ABSTRACT BODY:

Purpose: To assess the intraocular pressure-lowering effect of the Multi-Pressure Dial (MPD) system on retinal vessel diameter measured by spectral domain optical coherence tomography (SD-OCT, Spectralis, Heidelberg).

Methods: Prospective, randomized, controlled, pilot study. 15 healthy subjects and 15 subjects with open-angle glaucoma were randomized to receive application of 10 mmHg negative pressure to one eye (study eye) with the MPD. Following a baseline evaluation, both the study and control eye of each subject were imaged with OCT at baseline prior to negative pressure and then during the application of negative pressure at the 2, 10 and 30-minute time points. OCT imaging was repeated at 2 and 10 minutes after cessation of negative pressure. The primary outcome measures were retinal vessel parameters. For each patient, the en face OCT image, which is generated from a series of repeated image acquisitions, was used to evaluate the retinal vasculature. In each image, the inferotemporal branch artery and branch vein were utilized for measurement prior to any branching near the peripapillary reference zone.

Results: At baseline, venous diameter (VD) was statistically significantly less in glaucomatous subjects ($121 \pm 15 \mu\text{m}$) compared to healthy subjects ($133 \pm 15 \mu\text{m}$, $P < 0.05$). Arterial diameter (AD) was also less in glaucomatous subjects ($91 \pm 17 \mu\text{m}$) compared to healthy subjects (100 ± 17), but the difference was not statistically significant ($P = 0.20$). In subjects with glaucoma, with negative pressure application, there was a statistically significant increase in both AD and VD compared to baseline at 2 minutes, (A: $99 \pm 16 \mu\text{m}$, V: $127 \pm 16 \mu\text{m}$), 10 minutes (A: $101 \pm 17 \mu\text{m}$, V: $128 \pm 17 \mu\text{m}$), and 30 minutes (A: $103 \pm 17 \mu\text{m}$, V: $128 \pm 17 \mu\text{m}$). There was no statistically significant difference in AD or VD in healthy subjects at any of the time points during negative pressure application in comparison to baseline.

Conclusions: Glaucomatous subjects have diminished venous and arterial diameter compared to healthy subjects. IOP reduction via the MPD has a vasodilatory effect on the retinal vasculature in eyes with a history of glaucoma, suggesting an increase in blood flow occurs during application of negative pressure. Further research will be valuable for assessing the impact of transient IOP reduction on changes in ocular blood flow.

ABSTRACT BODY:

Purpose: To report the incidence and clinical features of infectious endophthalmitis after intravitreal (IV) injection of vascular endothelial growth factor inhibitors (anti-VEGF) from 2018-2020 and compare the findings to characteristics of endophthalmitis after anti-VEGF injection from prior years.

Methods: Retrospective case series of patients treated at a tertiary referral center between 01/01/2018 – 12/31/2020 with clinically diagnosed endophthalmitis occurring < 4 weeks after IV anti-VEGF injection.

Results: Between 2018-2020, the rate of clinically diagnosed endophthalmitis was 0.013% (9/71,779) and of culture positive endophthalmitis was 0.008% (6/71,779). The endophthalmitis rates per injection were: aflibercept 0.020% (8/40,302); ranibizumab 0.019% (1/5,242); bevacizumab 0% (0/25,548); and brolucizumab 0% (0/687).

The overall rates of endophthalmitis among all injections from 2018-2020 are similar to previously published data of endophthalmitis after IV anti-VEGF from 2005-2017 (0.013% vs 0.013% [p=0.91]). The incidences of endophthalmitis after aflibercept and ranibizumab from 2018-2020 were slightly increased from 2005-2017, though these differences were not significant (aflibercept: 0.020% vs 0.014% [p=0.51]; ranibizumab: 0.019% vs. 0.016% [p=0.87]).

From 2018-2020, a total of 6 eyes had culture positive endophthalmitis. Associations included aflibercept (5/6) and ranibizumab (1/6). All cases of endophthalmitis occurred < 5 days after IV injection. The causative organisms were coagulase negative Staphylococcus (3/6), Streptococcus (2/6), and Abiotrophia defectiva, a nutritionally variant streptococci, (1/6). At final follow up, two eyes had achieved a visual acuity (VA) better than or equal to 20/200 and the two eyes infected with Streptococcus species required enucleation. The 3 eyes with negative cultures had received aflibercept injections and 2/3 achieved their pre-injection VA.

Conclusions: Endophthalmitis rates after IV anti-VEGF remain low. Poor VA outcomes continue being associated with Streptococcus species. Nutritionally variant streptococci may be a rare cause of endophthalmitis after IV anti-VEGF injection.

ABSTRACT BODY:

Purpose: Neovascular age-related macular degeneration (nAMD) clinical trial data suggest better visual outcomes for patients receiving more intensive aflibercept intravitreal injections (IVIs). Real-world data in nAMD have described more modest outcomes; so it is unclear if there is pragmatic benefit in pursuing greater treatment intensity for individuals, when clinical resources are already limited. This retrospective, observational study aims to describe the effect of IVI frequency on visual outcomes for nAMD patients at different stages of treatment.

Methods: Patients, initiated on treatment for nAMD with 3 years of follow up, were identified through our patients' database. The visual acuity (VA) in early treatment of diabetic retinopathy (ETDRS) letters and IVIs frequency were recorded over a period of 3 years. Age, gender, macula fluid, lens status were recorded. Descriptive and comparative statistics were performed with SPSS v.24.

Results: 175 eyes (89 left, 87 pseudophakic) from 175 patients (109 female, mean age 79.1 years) with 3 years of continuous treatment were identified. Each eye received a mean (95% confidence interval) of 7.6(7.4,7.7), 5.2(4.9,5.5) and 5.4(5.1,5.7) IVIs to achieve mean VAs of 63.7(61.9,65.5), 61.4(59.4,63.5) and 60.6(58.2,62.9) ETDRS letters over their first, second and third years of treatment respectively. 137 eyes (78.3%) received 3 loading IVIs within 9 weeks to gain a mean 5.6(1.1,13.3) ETDRS letters over their first year of treatment. This was statistically equivocal ($p=0.55$) to the 4.2(2.2,13.6) ETDRS letters gained by eyes experiencing loading delays. Univariate logistic regression found that completing loading within 9 weeks had no statistically significant power to predict the absence of retinal fluid 1 year after treatment started($p=0.46$). Univariate linear regression found that annual IVI frequency had statistically significant power to predict VA gain over the first (unstandardised $B=3.8$ (0.2,7.4), $p=0.036$) and second years of treatment (unstandardised $B=0.7$ (0.0-1.3), $p=0.038$), but not the third ($p=0.31$).

Conclusions: A significant increase in visual gain was noted in the first year of treatment for eyes receiving more IVIs in our data. The visual outcomes of second and third years of treatment appear less sensitive to treatment frequency. In a resource limited environment, patients in their first year of treatment should be prioritised.

ABSTRACT BODY:

Purpose: Understanding the ocular manifestation of Neuronal Ceroid Lipofuscin (NCL) (Batten disease) is crucial to initiate investigation of the diagnosis as visual decline is often the presenting feature in NCL. This study reports the electrophysiological and multimodal imaging that provides clues to suspect NCL and urgent neurologic and genetic referral.

Methods: Retrospective review of six Batten patients. Visual acuity (VA), electroretinogram (ERG), ultra wide-field (UWF) fundus photography and autofluorescence (FAF), and ocular coherence tomography (OCT) were analyzed.

Results: Six unrelated children, 4 female and 2 male ranging from 4.6 to 11.7 years old with 5 CLN3 mutation and CLN5 mutation. The patients from the cohort had previous diagnosis of speech delay, autism, attention deficit and hyperactivity disorder prior to their first Ophthalmic review. Estimated interval between eye complaint and genetic result was 22.9 ± 14.9 months. VAs ranged from 0.18 to 1.00 logMAR with follow up (FU) obtainable from 3 patients. Two CLN3 patients and 1 CLN5 patient had 0.81 ± 0.35 logMAR and 0.36 ± 0.02 logMAR loss per year during 2.35 and 4.87 years FU respectively.

Electronegative ERGs were identified in each patient. Bull's eye maculopathies were common with hyperAF ring surrounding hypoAF fovea on FAF. Macular OCT findings were schitic changes (1 patients) and ellipsoid zone (EZ) loss at the fovea (4 patients).

Conclusions: While VAs were variable, macular disruption and electronegative ERG were consistent across the NCL cohort. These macular OCT and ERG findings provide strong evidence to initiate further investigations including genetic testing for NCL.

ABSTRACT BODY:

Purpose: Increases in oxidative stress is well documented in ischemic retinopathy. The $\alpha 1$ Na/K-ATPase (NKA) has an enzyme independent receptor function through its interaction with signaling proteins such as Src and caveolin-1. Moreover, the $\alpha 1$ NKA/Src receptor complex serves as a reactive oxygen species (ROS) amplifier. In this study, we investigated how the disruption of $\alpha 1$ NKA signaling secondary to a loss of caveolin binding motif (CBM) affects ischemic retinopathy in the mouse model.

Methods: Mice expressing the mutated CBM (mCBM) $\alpha 1$ NKA were obtained by knocking-in of F97A and F100A substitution in $\alpha 1$ NKA. The homozygous mCBM genotype was embryonic lethal, but heterozygous (Het) mice were viable. Oxygen induced retinopathy (OIR) was triggered in mCBM Het neonatal mice and wild-type (Wt) littermates by exposure to 75% oxygen from postnatal day (P) 7 to 12. Eyes were collected and fixed at P12 and P17. Retinas were isolated, stained with lectin, flat-mounted and imaged using fluorescence microscopy. Retinal vascular obliteration and neovascularization (NV) were quantified using SWIFT_NV macro and Image J. Marker genes for angiogenesis, inflammation and the Nrf2 pathway were determined by quantitative RT-PCR. Results were expressed as mean \pm SEM. Data were analyzed using unpaired t-test or one-way ANOVA followed by Tukey's correction for multiple comparisons.

Results: At P12, there was no significant difference of avascular area (AV) between mCBM Het and Wt litter mates. However, at P17, mCBM Het mice had significantly reduced AV and NV compared to the Wt. Consistently, the expression of gene markers for angiogenesis (Vegf, Angpt2 and Epo), inflammation (Tnfa and Cxcl10) was significantly lower in mCBM Het mice. In room air environment, the basal levels of Nrf2-targeted gene markers were increased in mCBM Het mice at P17 compared to Wt. Under OIR conditions, this increase was augmented significantly in mCBM Het mice.

Conclusions: $\alpha 1$ NKA signaling is involved in the mouse model of OIR. The loss of CBM in $\alpha 1$ NKA protects mice from OIR and is associated with increased levels of Nrf2-targeted genes.

ABSTRACT BODY:

Purpose: To examine fetal hemoglobin levels on systemic oxygenation and development of retinopathy of prematurity (ROP) in preterm infants.

Methods: A prospective study of preterm infants (born < 31 weeks gestational age or <1500 g) with HbF measured at birth (cord blood), 31-, 34-, and 37-weeks post-menstrual age (PMA), complete blood gas and SpO₂ recorded up to 42-weeks PMA, and at least one ROP exam.

Results: From September 1, 2017 through December 31, 2018, 64 preterm infants were enrolled; 3 patients were excluded due to incomplete hemoglobin studies and 1 patient was withdrawn by their parent from the study prior to the first blood sample. Higher HbF was associated with significantly higher SpO₂, lower PCO₂, lower FiO₂ from birth to 31 weeks PMA and 31 to 34 weeks PMA ($r_s=0.51$, $r_s=-0.62$, and $r_s=-0.63$; $p<0.0001$ and $r_s=0.71$, $r_s=-0.58$, and $r_s=-0.79$; $p<0.0001$, respectively). To maintain oxygen saturation goals set by the neonatal intensive care unit, higher median FiO₂ was required for HbF in the lowest tercile from birth compared to HbF in the highest tercile to 31 weeks and 31 to 34 weeks PMA; FiO₂=35 (21-100) vs 21 (21-30) $p<0.006$ and FiO₂=30 (28-100) vs 21 (21-30); $p<0.001$, respectively. Preterm infants with ROP had poorer indices of systemic oxygenation, as measured by median levels of SpO₂ and PCO₂, and lower levels of HbF ($p<0.039$ and $p<0.0001$, respectively) up to 34 weeks PMA).

Conclusions: Low HbF levels correlated with poor oxygenation indices in the preterm infant and were associated with an increased risk for developing ROP. These results show that HbF levels influence systemic oxygenation. Thus, oxygen therapy may need titration that is based on HbF levels to reduce the risk of ROP development.

TITLE: Epidermal Growth Factor Enhances Exosome-mediated Anti-angiogenic Signals between M1 Macrophages and Human Corneal Endothelial Cells

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Kim, Department of Ophthalmology, Chung-Ang University College of Medicine, Seoul, KOREA (THE REPUBLIC OF)|S. Lee, K. Kim, CORIA (Chung-Ang Ocular Surface Rehabilitation via Immune-inflammation Alleviation) Laboratory, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure (Abstract): Soojin Lee: Commercial Relationship: Code N (No Commercial Relationship) | Kyoung Woo Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Epidermal growth factor (EGF) has been known to alleviate inflammation in atopic dermatitis, but in the field of ophthalmology, its role is limited to the regeneration of corneal epithelial cells and corneal sensory nerves. Antigen-presenting cells such as dendritic cells and macrophages are known to exist in cornea, and in particular, macrophages are located in the deep stromal layer near the corneal endothelial layer. We investigated whether EGF mediates anti-angiogenic signals by the alleviation of inflammation between M1 macrophages and corneal endothelial cells.

Methods: Monocytes (THP-1 cell line) were treated with lipopolysaccharide (LPS) to be transformed into M1 macrophages. EGF protein was treated in M1 macrophages and the changes in the mRNA level of interleukin 1beta (IL-1 β) and IL-6 were analyzed. Then, exosomes were isolated from EGF-treated M1 macrophages and the exosomes were treated in human corneal endothelial cells to evaluate the mRNA expression of vascular cell adhesion molecule 1 (VCAM-1), intercellular adhesion molecule 1 (ICAM-1), vascular endothelial growth factor (VEGF), matrix metalloproteinase 2 (MMP-2), MMP-9, and platelet-derived growth factor (PDGF).

Results: Upon EGF treatment, the expressions of IL-1 β and IL-6 in M1 macrophages significantly decreased compared to before administration. When the exosomes isolated from EGF-treated macrophage cells were treated in cultured human corneal endothelial cells, all of VCAM-1, ICAM-1, VEGF, MMP-2, MMP-9, and PDGF were downregulated in mRNA level.

Conclusions: EGF inhibits IL-1 β and IL-6 in M1 macrophages, and may further mediate the anti-angiogenic signals in human corneal endothelial cells via exosomes
Conflicts of Interest: The authors declare that they have no conflict of interest.

ABSTRACT BODY:

Purpose: Previous studies have shown that intravitreal injection of healthy human CD34+ bone marrow stem cells (BMSCs) can result in regenerative or protective effects on the retina in eyes with retinal degeneration or diabetic retinopathy (DR). This study compared the gene expression changes in the retina resulting from intravitreal injection of human CD 34+ BMSCs in eyes with retinal degeneration versus DR to test the hypothesis that CD34+ BMSCs can have regenerative or protective effects on the retina via differing molecular mechanisms depending on retinal pathology.

Methods: Mice with retinal degeneration (rd1 mice) or diabetic retinopathy (streptozotocin-induced diabetic mice) had chronic systemic immunosuppression maintained to avoid rejection of human cells via placement of an Alzet subcutaneous pump to deliver tacrolimus and rapamycin. The right eye received intravitreal injection PBS (control) or healthy human CD34+ BMSC (50k cells) harvested via magnetic beads from bone marrow. These animals were euthanized at week 1, retinas were harvested, total RNA isolated and microarray analysis was performed on RNA samples. Gene expression changes (Fold Change ≤ -1.5 or $\geq +1.5$, ANOVA $P < 0.05$) between CD34+ BMSC injected and PBS injected control eyes were identified and compared between the two different murine models. Ingenuity pathway analysis was then performed on these overlaying genes to identify the pathways involved.

Results: Microarray analysis of the murine retina revealed changes in gene expression of 5275 and 331 genes in eyes with retinal degenerative and DR, respectively, compared to control eyes. Only 38 of these genes were altered in both rd1 and DR murine retina. These common genes include genes involved in pathways regulating photo-transduction, ocular angiogenesis, vascular endothelial growth factor signaling and inflammatory response. The genes uniquely altered in rd1 murine retina included those regulating cell cycle and growth, gene expression and repair, and immune response. The genes uniquely altered in DR murine retina included genes regulating ocular angiogenesis and cell cycle.

Conclusions: The protective effects of human CD34+ BMSCs following intravitreal injection appear to be via multiple molecular pathways that may be common and unique depending on the retinal pathology.

ABSTRACT BODY:

Purpose: Clinicians integrate a wealth of information when assessing the rate of glaucomatous functional progression and they use instrument-derived visual field printouts and global indices to assist this task. We sought to determine the global indices that best correlate with the subjective assessment of the rate of visual field progression by glaucoma experts.

Methods: Expert glaucoma specialists (n=11) reviewed a series of visual field printouts for 5 biannual visits from 100 glaucoma or glaucoma suspect eyes of 51 participants enrolled in the ongoing Portland Progression Project. Each clinician independently scored each series from 1 (improvement) to 7 (very rapid progression). They also scored 20 of those eyes twice to assess intra-clinician repeatability. Generalized estimating equation models were used to predict the average score among the clinicians from the rates of change of each of the available global indices; Mean Deviation (MD), Pattern Standard Deviation (PSD) and Visual Field Index (VFI).

Results: The average MD of study eyes was -2.4dB (range -16.8 to +2.8dB); 18% had average MD < -6dB. When assessing intra-clinician repeatability, 94% of individual clinician scores varied by ≤ 1 point. The mean inter-clinician score was also highly repeatable, with an intraclass correlation coefficient of 0.95. This score was more strongly correlated with the rate of change of VFI ($r=-0.85$) than either MD ($r=-0.80$) or PSD ($r=0.64$); see Figure 1. In bivariable regression models using two global indices, the rate of VFI change was the sole significant predictor. However, among eyes with average VFI>99% (n=25) for which VFI is near its maximum possible value, these correlations were $r=-0.40$ for MD, $r=-0.53$ for VFI, and $r=0.59$ for PSD (Figure 2); and the rate of PSD was the strongest predictor in regression models.

Conclusions: Overall, the mean assessment of functional change from a group of highly experienced glaucoma clinicians correlated better with rates of change of VFI than MD or PSD. However, in early glaucoma or glaucoma suspect eyes, clinician judgment correlated slightly better with changes in PSD, than MD or VFI. This may be related to clinicians identifying localized changes at the earliest stages of the disease. Future studies can use this information to better monitor the rate of progression, and use this data to develop improved quantifications of the rate of functional progression.

ABSTRACT BODY:

Purpose: The 44 channel (44Ch) suprachoroidal retinal prosthesis is a second-generation bionic eye implant that follows on from a proof of concept study conducted between 2012 and 2014. The 44Ch implant is designed to provide artificial vision (phosphenes) to recipients with end-stage retinitis pigmentosa (RP). We aimed to compare the performance of visual function and functional vision tasks at pre-implantation and post device activation.

Methods: The 44Ch suprachoroidal retinal prosthesis was unilaterally implanted in 4 participants with advanced RP, age range 39 to 66 years, between February and August 2018. After a 16-week period of vision rehabilitation training, participants were assessed on three laboratory-based visual function tasks: moving bar (MB), square localisation (SL) and grating acuity (GA), followed by three functional vision tasks: table-top search (TTS), doorway detection (DWD) and obstacle avoidance (OA). Assessment time points were pre-implantation and from post-device activation at weeks 17 (W17), W20, W32, W44, W56 and W68. Data was pooled across all 4 participants and performance was compared between device on and off.

Results: With device on, three of the four participants could discriminate MB speeds ranging from 7 to 30 degrees per second. Average pointing error for all four participants, across all visits on SL, was $10.3 \pm 3.3^\circ$ (device on) versus $27.7 \pm 8.7^\circ$ (device off), $p < 0.001$. Two of the four participants had measurable GA of 0.033 cycles-per-degree. On average, the device improved participants' ability to locate objects on the TTS, detect and touch the doorway on DWD task and detect and avoid more obstacles during OA, at all-time points post-activation ($p < 0.04$), compared to device off.

Conclusions: The 44Ch second generation suprachoroidal implant improved overall performance on both laboratory-based visual function and functional vision tasks, compared to device off. The device shows the capability to provide visual sensory information, to aid detection of obstacles and improve accuracy when reaching for an object, for people with profound vision loss due to RP.

TITLE: Analysis of progression of retinal microvascular ischemia in patients with sickle cell disease using optical coherence tomography angiography

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Freeman, K. Sioufi, E.A. Say, J. Blice, G. Magrath, Medical University of South Carolina, Charleston, South Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Dylan Freeman: Commercial Relationship: Code N (No Commercial Relationship) | Kareem Sioufi: Commercial Relationship: Code N (No Commercial Relationship) | Emil Say: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Blice: Commercial Relationship: Code N (No Commercial Relationship) | George Magrath: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate rate of progression and factors affecting retinal microvascular ischemia in patients with sickle cell disease.

Methods: Retrospective review of 40 eyes in 25 patients diagnosed with sickle cell disease and scanned using Zeiss Cirrus-HD. We evaluated 3x3mm optical coherence tomography-angiography (OCT-A) scans at two sequential visits about 1 year apart. Vascular density (VD) was measured at the superficial (sVD) and deep (dVD) plexuses using post capture image processing platform on ImageJ (National Institute of Health). All statistical analyses were performed using SPSS, Version 27 (SPSS, Inc, Chicago, Illinois, USA).

Results: Sickle cell status was sickle cell trait in 1, SS in 14, SC in 6, and Sb in 4 patients. Mean follow-up interval duration was 13.7 months (range: 6-25). Mean logMAR was 0.75 and 0.062 at the first and second visit, respectively. By OCT-A, the mean sVD was 51.33% (range: 41.2-57.3%) and 47.41% (range: 29.31-54.60%) while mean dVD was 46.41% (range: 37.3-53.7) and 46.43% (range: 36.61-53.18) at the first and second visit, respectively. Mean difference in VD between visits was -3.87% for sVD and +0.01% for dVD. There was a statistically significant decrease in sVD ($p<0.001$) but no statistically significant change in dVD ($p=0.984$) or VA. Subgroup analysis showed no significant difference in mean sVD reduction based on sickle cell status, history of prior stroke, and history of avascular necrosis.

Conclusions: Over a follow-up period of 1-year, patients with sickle cell disease demonstrated progression of retinal microvascular ischemia by OCT-A. This reduction in VD appears to affect the superficial plexus more so than the deep plexus.

ABSTRACT BODY:

Purpose: Factor I (FI) is a serine protease inhibitor of the alternative pathway of the complement system. This regulation of the complement system is achieved by cleavage of C3b (known as cofactor activity). Heterozygous rare genetic variants in CFI are associated with AAMD. The clinical impact of these variants is unknown since a majority have not been functionally characterized and are classified based on predictive models as 'variants of uncertain significance' (VUS). This study assessed the functional significance of VUS in CFI.

Methods:

Our previous cross-sectional study demonstrated that heterozygous CFI variants in AAMD can be categorized into three major types [Java et al. Trans Vis Sci Tech 2020; 9(9):37]. Type 1 variants caused a quantitative deficiency of FI (decreased FI level with a proportional decrease in function). Type 2 variants demonstrated a qualitative deficiency (normal FI level but decreased function). However, Type 3 variants consisted of VUS that were less dysfunctional than Types 1 and 2 but were not as biologically active as wild-type. In this study we present an in-depth functional assessment of the Type 3 variants. We utilized serum FI antigenic levels, site-directed mutagenesis followed by expression of the recombinant variant and a comprehensive set of functional assays to characterize nine Type 3 variants identified in 34 individuals (R202I, Q217H, S221Y, G263V, G362A, K441R, Q462H, I492L and N536K).

Results: Our study established that the expression of the recombinant protein compared to wild-type by 293T cells was reduced for Q217H, S221Y and G263V. Further, R202I and G362A had significantly reduced cofactor activity. These results led to recategorization of Q217H, S221Y and G263V as Type 1 variants and to reclassification of R202I and G362A as Type 2. The remaining Type 3 variants (K441R, Q462H, I492L and N536K) are best classified as being benign at this time. This study highlights the utility of an in-depth functional analysis in defining the pathologic and clinical implications of complement variants in AAMD and provides further insights relative to the pathogenic mechanisms underlying AMD.

Conclusions: This approach will be a useful model system for guiding more appropriate therapeutic decisions relative to an individualized treatment plan for patients and thereby pave the way for precision medicine in AMD.

TITLE: DNA testing for inherited retinal disease (IRD): Initial experience with the SPARK/Invitae 'ID your IRD' genetic testing panel

SESSION TITLE: Genetics of Retinal dystrophies and Functional Genomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Lidder, Y. Modi, V.S. Dedania, S.E. Brodie, Department of Ophthalmology, NYU Langone Health, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alcina Lidder: Commercial Relationship: Code N (No Commercial Relationship) | Yasha Modi: Commercial Relationship: Code N (No Commercial Relationship) | Vaidehi Dedania: Commercial Relationship: Code N (No Commercial Relationship) | Scott Brodie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the diagnostic yield and clinical impact of the SPARK/Invitae gene panel in patients with known or suspected inherited degenerative retinal disease, in comparison with traditional clinical assessments.

Methods: Patients of the authors' clinical practices obtained genetic screening at no charge via the SPARK/Invitae "ID your IRD" genetic testing panel, which ranged from 248 genes to 293 genes. Over 16 months, tests were submitted for 87 patients and results were available for 70 patients. Clinical diagnoses prior to submitting the gene panel included retinitis pigmentosa; Stargardt disease; Best vitelliform dystrophy; Leber congenital amaurosis; choroideremia; achromatopsia; cone-rod dystrophy; congenital stationary night blindness; occult macular dystrophy; and familial dominant drusen in addition to patients with normal clinical findings and unclear diagnoses.

Results: Of 70 patients, SPARK/Invitae considered the results "Positive" or "Potentially Positive" in 24 cases (34.3%), "Carrier" in 16 cases (22.9%) and "Uncertain" in 30 cases (42.9%). "Uncertain" results comprised patients with only "Variants of Uncertain Significance." Patients categorized as a "Carrier" by SPARK/Invitae but who demonstrated pathogenic genetic changes correlating to the clinical diagnosis were considered to be in agreement with the clinical impression. The genetic diagnosis agreed with the clinical diagnosis in 30/70 (42.9%) total patients. Test results were consistent with the clinical impression in 13/26 (50.0%) retinitis pigmentosa cases, 6/8 (75.0%) Stargardt patients, 3/7 (42.9%) cone-rod dystrophy cases, and 2/4 (50.0%) Best vitelliform dystrophy patients. Gene testing helped elucidate diagnoses in two patients with unclear clinical impressions: one panel showed autosomal recessive achromatopsia and the other showed a carrier state for autosomal recessive retinitis pigmentosa. Of four patients with normal clinical exams, none had diagnostic results: all showed "Uncertain" findings.

Conclusions: The SPARK/Invitae gene panel provided a genetic diagnosis consistent with the clinical impression in about 40 percent of patients. Retinitis pigmentosa and Stargardt disease were the most common clinical diagnoses and the diagnoses most often confirmed by testing. Genetic screening also assisted in clarifying unknown diagnoses for two patients.

ABSTRACT BODY:

Purpose: To determine the relationship of various systemic and ocular characteristics with macular vessel density in the African American Eye Disease Study.

Methods: Participants consisted of African Americans 40 years of age and older residing in Inglewood, CA. They underwent 6x6-mm macula eye scans using spectral-domain optical coherence tomography angiography (OCTA; CIRRUS 5000 HD-OCT with AngioPlex; ZEISS, Dublin, CA, USA), a clinical examination, and a clinical questionnaire. Participants with glaucoma, severe non-proliferative diabetic retinopathy, proliferative diabetic retinopathy, and macular edema were excluded. A custom MATLAB based software was used to quantify vessel area density (VAD), vessel skeleton density (VSD), and flux in the superficial retinal layer (SRL) of the macula. Inter-eye correlation was controlled for using generalized estimating equations (GEE). Using SAS, a multivariate regression analysis was performed to determine systemic and ocular determinants of macular vessel metrics using stepwise selection. Candidate variables included: age, gender, body mass index, history of smoking, history of diabetes, diabetes duration, history of stroke or brain hemorrhage (SB), systolic blood pressure (BP), diastolic blood pressure (DBP), pulse pressure (PP), mean arterial pressure (MAP), central subfield thickness (CSFT), visual field mean deviation (MD), intraocular pressure (IOP), axial length (AL), mean ocular perfusion pressure (MOPP), and signal strength (SS). **Results:** A total of 2221 OCTA imaged eyes from 1472 participants remained after excluding eyes for either poor image quality or the presence of an ocular disease. As demonstrated in the table, after controlling for signal strength and age, longer axial length and reduced central subfield thickness were independently associated with reduced VAD, VSD and Flux. Male gender and decreased diastolic blood pressure were also independently associated with reduced flux.

Conclusions: When assessing OCTA images in a clinical setting, it is important to consider the effect axial length, central subfield thickness, gender, and diastolic blood pressure may have on the macular microcirculation.

TITLE: Differentially expressed microRNAs within extracellular vesicles of a functionally active subpopulation of endothelial colony forming cells demonstrate neurovasculotrophic effects

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.V. Marra, School of Medicine, University of California San Diego, La Jolla, California, UNITED STATES|K.V. Marra, E. Aguilar, A. Ouchi, G. Wei, M. Friedlander, Molecular Medicine, Scripps Research Institute, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kyle Marra: Commercial Relationship: Code N (No Commercial Relationship) | Edith Aguilar: Commercial Relationship: Code N (No Commercial Relationship) | Ayumi Ouchi: Commercial Relationship: Code N (No Commercial Relationship) | Guoqin Wei: Commercial Relationship: Code N (No Commercial Relationship) | Martin Friedlander: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Endothelial colony forming cells (ECFCs) are endothelial progenitor cells with neurovasculotrophic effects achieved via paracrine action. ECFCs, however, are not functionally homogenous. ECFCs with high expression of CD44 hyaluronan receptor (CD44^{hi}) rescue the oxygen-induced retinopathy (OIR) model of ischemic retinopathy as well as rd10 mice with retinal neurodegeneration; ECFCs with low expression of CD44 (CD44^{lo}) do not. Extracellular vesicles from CD44^{hi} ECFCs (EVs^{hi}) recapitulate this effect while vesicles from CD44^{lo} ECFCs (EVs^{lo}) are ineffective. Here, we investigate the role of EVs^{hi} in mediating the paracrine rescue effects of CD44^{hi} ECFCs and compare their intravesicular small RNA cargo of EVs^{hi} and EVs^{lo} using an -omics based approach to identify microRNA (miR) mediators of their trophic effects.

Methods: Sorted CD44^{hi} ECFCs treated with neutral sphingomyelinase inhibitor GW4869, used to inhibit exosome biogenesis/release, were intravitreally injected into OIR mice. DICER1 knockdown ECFCs (ECFCs-shDICER1) and a control scramble RNA cell line (ECFCs-scrRNA) were generated using lentiviral transfection. Sorted CD44^{hi} ECFCs-shDICER1 and CD44^{hi} ECFCs-scrRNA and their EVs were intravitreally injected into OIR mice. Small RNA of EVs^{hi} and EVs^{lo} were sequenced with Next Generation Sequencing to identify differentially expressed intravesicular miRs. miRs that validated well on RT-qPCR and control scramble miR were injected into OIR.

Results: CD44^{hi} ECFCs rescued OIR and these effects were attenuated after GW4869 treatment. CD44^{hi} ECFCs-shDICER1 and their EVs were significantly less effective in rescuing OIR than CD44^{hi} ECFCs-scrRNA and their EVs, respectively. Small RNA sequencing of EVs^{hi} identified 9 upregulated and 10 downregulated miRs in comparison to EVs^{lo}. On RT-qPCR, 7 of the 9 upregulated miRs validated well. All miRs were functionally tested in OIR and 3 candidate miRs fully rescued the model.

Conclusions: CD44^{hi} ECFCs shed vesicles containing neurovasculotrophic miRs that may contribute to the efficacy of EVs^{hi} treatment in mouse models of ischemic/neurodegenerative retinopathy.

Coussa, Department of Ophthalmology, The University of Iowa Hospitals and Clinics, Iowa City, Iowa, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Fares Antaki: Commercial Relationship: Code N (No Commercial Relationship) | Razek Georges Coussa: Commercial Relationship: Code N (No Commercial Relationship) | Karim Hammamji: Commercial Relationship: Code N (No Commercial Relationship) | Mikael Sebag: Commercial Relationship: Code N (No Commercial Relationship) | Renaud Duval: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Automated machine learning (AutoML) is a new area in artificial intelligence that automates important components in the machine learning design pipeline. It has not been broadly used for retinal disease detection from fundus images. This study aimed to assess the discriminative performance of AutoML in classifying retinal pathologies from ultra-widefield (UWF) fundus pseudocolor images.

Methods: Using Google Cloud AutoML Vision, we developed a deep learning classification model to detect normal fundi, retinal vein occlusion (RVO), retinitis pigmentosa (RP), and retinal detachment (RD) from UWF pseudocolor images. We selected those diseases for the presence of retinal hemorrhage in RVO, retinal pigment epithelial changes in RP, and retinal elevation in RD. We used an open-access dataset provided by the Tsukazaki Optos Public Project (13,047 images) to curate a smaller dataset of training and validation images. Two ophthalmologists (raters) independently graded the images according to consensus criteria. Selected images were then uploaded to the online platform for testing and training through the graphical interface and without any coding. Cohen's kappa coefficient (κ) was used to assess the inter-rater agreement during data labeling. The performance of the AutoML model is reported using the area under the precision-recall curve (AuPRC), precision, and recall.

Results: A total of 2,311 images were relabeled. There was almost perfect agreement between the two raters for normal ($\kappa = 0.82$), RVO ($\kappa = 0.85$) and RD ($\kappa = 0.82$) images, and substantial agreement for RP images ($\kappa = 0.75$). The final dataset included 1,355 images (472 normal, 311 RVO, 187 RP, and 385 RD). The overall AuPRC was 0.95, and the precision and recall were both 91.85%. The per-label precision and recall were as follows: normal (88.46% and 97.87%), RVO (96.43% and 87.1%), RP (100% and 78.95%) and RD (90% and 94.74%).

Conclusions: We demonstrate the feasibility of using AutoML by ophthalmologists without coding experience to create a deep learning disease classification model from UWF images. The model can detect RVO, RP, and RD (three retinal diseases with distinctive clinical features) with excellent precision and recall. With that being established, further research aimed at developing more challenging classification tasks is being carried out by our group (e.g. disease types and stages).

TITLE: Prevalence of Gunn's Dots and Associated Systematic Factors in an Adult Population

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Xue, L. Gao, Y. Wang, Beijing Tongren Hospital, Beijing, Beijing, CHINA|C. Xue, Peking University Third Hospital, Beijing, CHINA|J. Jonas, Ruprecht Karls Universitat Heidelberg, GERMANY|

Commercial Relationships Disclosure (Abstract): Cancan Xue: Commercial Relationship: Code N (No Commercial Relationship) | Liqin Gao: Commercial Relationship: Code N (No Commercial Relationship) | Ya Xing Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jost Jonas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the prevalence of Gunn's dots and associated systemic factors in adult Chinese in a community-based study.

Methods: The Tongren Health Care Study included individuals aged 45+ years and who regularly underwent detailed medical and ophthalmic examinations. Based on the color fundus photographs, Gunn's dots were evaluated by an experienced ophthalmologist. Individuals with eye diseases including age-related macular degeneration, retinal vein occlusion, diabetic retinopathy, myopic retinopathy, glaucoma or non-glaucomatous optic neuropathy, were excluded from the analysis.

Results: Out of 5845 individuals (male: 2461/42.1%), 1670 (27.5%) individuals were excluded due to ocular diseases and 120 (2.1%) individuals were excluded due to unreadable fundus photographs, so that the study eventually included 4118 participants (mean age: 58.3±9.9 years; range: 45-100 years; male: 1699/41.3%). Gunn's dots were found in 931 participants (729/78.3% bilateral and 202/21.7% unilateral), with a prevalence of 22.6±0.07% (95% confidence interval (CI): 21.4 to 23.9%). The prevalence of Gunn's dots decreased from 34.9±1.6 % in participants aged 45-49 years, to 26.0±1.6 % in those aged 55-59 years, and to 2.1±0.6 % in those aged 70+ years. Gunn's dots were more commonly seen in eyes with higher estimated glomerular filtration rate (eGFR), with the presence of 0.0%, 10.7±1.7%, 22.5±1.1 %, and 48.6±8.6 % in those participants with an eGFR of less than 30ml/min/1.73m², 60-74ml/min/1.73m², 90-99 ml/min/1.73m² and higher than 115ml/min/1.73m², respectively. In multivariable analysis, the prevalence of Gunn's dots decreased with older age (odds ratio (OR): 0.92; 95%CI: 0.91 to 0.93; P<0.001), and increased with a higher eGFR (OR: 1.01; 95%CI: 1.001 to 1.02; P=0.02) and higher serum concentration of triglycerides (OR:1.10; 95%CI:1.03 to 1.17; P=0.008). It was not significantly associated with gender (P=0.13).

Conclusions: The prevalence of Gunn's dots decreased with older age, lower eGFR and lower serum triglyceride concentrations. These findings may be of help to elucidate the etiology of Gunn's dots and their clinical meaning.

TITLE: Precursors to Geographic Atrophy in Age-Related Macular Degeneration (AMD)

SESSION TITLE: AMD imaging - GA

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K. Taylor, S. Cleland, J.W. Pak, M. Banghart, B. Blodi, A. Domalpally, Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kenneth Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Spencer Cleland: Commercial Relationship: Code N (No Commercial Relationship) | Jeong Pak: Commercial Relationship: Code N (No Commercial Relationship) | Mark Banghart: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Blodi: Commercial Relationship: Code N (No Commercial Relationship) | Amitha Domalpally: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Incomplete and complete Retinal Pigment Epithelial (RPE) Outer Retinal Atrophy (iRORA and cRORA) are consensus terms published by the Classification of Atrophy Meeting (CAM) group to describe OCT based retinal changes associated with development of atrophy in eyes with Age Related Macular Degeneration (AMD). This is a retrospective cohort study to identify the prevalence of iRORA and the risk of progression to late AMD, particularly cRORA.

Methods: Participants enrolled in the Age-Related Eye Disease Study 2 (AREDS2) at Year 5 and Year 10 study visits from a single center, the University of Wisconsin were included. SDOCT scans (97 B scans each) of 102 eyes of 65 patients with AMD were evaluated by two graders. Disagreements were adjudicated by a senior grader. Year 5 SDOCT scans and color photographs were evaluated to exclude eyes with late AMD (cRORA and neovascular AMD). cRORA was defined using the CAM criteria as follows: choroidal hypertransmission > 250 μ m, attenuation or disruption of RPE, and photoreceptor degeneration, that is, subsidence of the inner nuclear layer (INL) and outer plexiform layer (OPL), presence of a hyporeflective wedge in the Henle fiber layer (HFL), thinning of the outer nuclear layer (ONL), disruption of the external limiting membrane (ELM) or disintegrity of the ellipsoid zone (EZ), and when these criteria do not meet the definition of cRORA or RPE tear. 76 eyes of 48 subjects with intermediate AMD which remained were evaluated for iRORA, which was identified if all three above criteria for cRORA were met but the size was < 250 μ m. Also, the type of photoreceptor degeneration, when present, was documented. Subsequently, 10-year scans were graded and eyes with late AMD were identified.

Results: At year 5, iRORA was present in 11 eyes (14.5%). Absence of the ELM was the most commonly seen feature of photoreceptor disruption (100%). 20 eyes (26.3%) at year 10 follow up had cRORA. Of the eyes with iRORA at year 5, 5 (45.5%) developed cRORA at year 10. For eyes with iRORA, the odds ratio for developing cRORA was 2.17 (95% CI 0.52, 9.08; p=0.28).

Conclusions: iRORA represents a stage before development of irreversible endpoints such as geographic atrophy (GA). Long term studies with larger sample size are required to understand this important new step in AMD classification. It remains to be studied if some OCT related features of iRORA may be more predictive of progression than others.

ABSTRACT BODY:

Purpose: Several lines of evidence implicate the involvement of endoplasmic reticulum stress (ER stress) and its transducers in neurodegenerative diseases such as retinitis pigmentosa. ER stress triggers an intracellular signaling pathway called the Unfolded Protein Response (UPR). IRE1 α is an ER resident protein that plays a major role in orchestrating the UPR. Here we aim to assess the contribution of IRE1 α to photoreceptor homeostasis and retinal degeneration.

Methods: We selectively deleted IRE1 α in rod photoreceptors of mice and investigated the physiological consequences in photoreceptor homeostasis and function. We also crossed these animals with the rhodopsin Rho P23H mouse model of retinitis pigmentosa in order to evaluate the consequences of IRE1 α loss in an in vivo setting of retinal degenerative disease. We assessed retinal thickness longitudinally using Optical Coherence Topography (OCT) and evaluated the retinal function by electroretinography (ERG) as animals aged.

Results: OCT imaging and histological analysis of IRE1 α deficient mouse retinas did not reveal any abnormalities during early time points (1 and 3 months old). At 6 months and older however, the IRE1 α deficient mice showed a progressive thinning of their outer nuclear layer (ONL) in the retina compared to the controls. ERG recordings during these later time points also showed decreased scotopic responses while photopic responses were unchanged. Analysis performed on IRE1 α deficient mice on the rhodopsin Rho^{P23H} background revealed an exacerbated retinal degeneration in the absence of IRE1 α .

Conclusions: These results suggest that IRE1 α is dispensable for retinal development but important for maintaining photoreceptor homeostasis in aging retinas and for protecting against ER stress-related photoreceptor degeneration. Future work will establish whether there are compensatory changes in the other UPR pathways that could explain the lack of retinal phenotype observed during development.

TITLE: Objective and Subjective Behavioral Measures in Myopic and Non-Myopic Children during the COVID-19 Pandemic

SESSION TITLE: Impacts of Covid on patients and practice

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Piña, H. Mirhajianmoghadam, L.A. Ostrin, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amanda Piña: Commercial Relationship: Code N (No Commercial Relationship) | Hanieh Mirhajianmoghadam: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Ostrin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has dramatically affected children's lifestyle, requiring a shift to electronic device use for education and entertainment, which may ultimately impact eye growth and myopia. Our goal was to assess sleep, time outdoors, physical activity, near work, and electronic device use during the summer COVID-19 pandemic in myopic and non-myopic children. Additionally, behaviors were compared with a typical summer before the pandemic.

Methods: Healthy children (ages 8.3 ± 2.4 years, $n=53$) in Houston, Texas participated. Children wore an Actiwatch for 10 days while quarantine measures were in place for objective measures of light exposure, time outdoors, activity, and sleep. Additionally, parents completed a questionnaire regarding children's demographics, ocular history, and visual activity, including electronic device use, during the COVID-19 pandemic and also for a typical summer before COVID-19. Data were analyzed with repeated measures ANOVA for session (COVID-19 vs pre-COVID-19), day of the week (weekday vs weekend), and refractive error group (myopic vs non-myopic).

Results: Objective measures showed that during the COVID-19 pandemic, myopic children had significantly lower daily light exposure ($P=.04$) and less physical activity ($P=.04$) than non-myopic children, with no significant differences in sleep duration or time outdoors between groups ($P>.05$ for all). Subjective measures showed that children demonstrated increased electronic device use during COVID-19 compared to pre-COVID-19 on weekdays (7.3 ± 0.6 vs 4.9 ± 0.5 hours per day, respectively, $P<0.001$) and weekends (7.9 ± 0.6 vs 6.1 ± 0.5 hours per day, respectively, $P<0.001$). Time spent doing near work was not significantly different during COVID-19, between days of the week, or by refractive error group ($P>.05$ for all).

Conclusions: Children's behaviors during the COVID-19 pandemic varied between myopes and non-myopes. Objective measures showed that during the pandemic, myopic children exhibited lower daily light exposure and physical activity than non-myopes. Additionally, based on parents' report, children's electronic device use increased, and physical activity and time outdoors decreased during the pandemic. Long term follow up is needed to understand if these behavioral changes as a result of the COVID-19 pandemic contribute to increased myopia progression.

ABSTRACT BODY:

Purpose: To describe the longitudinal outcomes of a safety-net patient population with neovascular glaucoma (NVG) treated with glaucoma drainage implants (GDIs).

Methods: We performed a retrospective observational study including eyes that received GDIs for NVG at LAC+USC Medical Center from 2008-2018. Exclusion criteria were an uncertain diagnosis of NVG, history of prior GDI in the study eye, or follow-up of less than one year. Patients were stratified into Ahmed (AGV) and Baerveldt (BGI) groups. The primary outcome was surgical success defined as the preservation of light perception, intraocular pressure (IOP) below 22 mmHg, and no additional glaucoma intervention. Secondary outcomes included visual acuity (VA), intraocular pressure (IOP), and medications prescribed at 1-, 2-, and 3-year intervals postoperatively. Data were compared between groups using Student's t-test for continuous variables and Fisher's exact test for categorical variables.

Results: 162 eyes from 151 patients met inclusion criteria and, of these eyes, all were reported at 1 year, 107 at 2 years, and 66 at 3 years. Mean age was 53.2 and 88% were Hispanic. Age and ethnicity did not vary between groups ($p = 0.49$ and 0.60). Preoperative IOP was 39.4 mmHg in AGVs and 32.7 mmHg in BGIs ($p = 0.0003$), but there was no significant difference in preoperative VA ($p = 0.28$). No significant differences were found in success rate between the groups at 1, 2 and 3 years postoperatively with AGVs reporting success in 75%, 60% and 59% respectively, and BGIs in 82%, 76% and 64%. In the subgroup of successful GDIs, there was not a statistically significant difference in the number of classes of drops used at each follow-up interval, though there was a trend toward a lower drop burden in the BGI group ($p = 0.14, 0.15, 0.41$ at 1, 2 and 3 years); VA and IOP did not vary significantly.

Conclusions: There were no significant differences found in longitudinal outcomes of AGVs and BGIs in the context of NVG.

ABSTRACT BODY:

Purpose: Developing a robust handheld OCT system, with ultrahigh speed, widefield, and real-time in vivo OCT/OCTA visualization for clinical imaging of pediatric retina.

Methods: We optimized the optical design for the handheld OCT/OCTA system that achieved a 55-degree field of view and a 1.3 mm beam size on the entrance pupil with low system optical aberrations (Fig. 1). A 11-element lens group was used to relay the imaging beam, and the fast and slow axis of the galvanometer scanner were separated and both conjugated to the pupil plane to reduce the vignetting artifacts. We used a 1060 nm, 400-kHz VCSEL (Thorlabs, Inc.) swept source laser with 100 nm bandwidth that provides an imaging depth of 6 mm and an axial resolution of 4.96 μm in air. A 4-coupler interferometer with an optimum coupling ratio delivered 1.8-mw incident power on the cornea. A motorized reference arm and an electrically tunable lens were rapidly adjusted during the imaging session to match the imaging subject's axial eye length and fine tune focus. Our GPU accelerated OCT acquisition software displayed en face and cross-sectional view of the retina on the imaging probe which enabled direct real-time feedback and facilitated alignment process and navigation. A high-speed alignment mode (10Hz volume rate) and a high-resolution OCTA scanning mode (500 \times 1500 A-scans, 3 B-scans per BM-scan, 5ms interscan time, and 1.875 seconds) were available for the operator to toggle between them.

Results: 3 healthy adult volunteers, 16 awake neonates in neonatal intensive care unit and 7 pediatric patients under general anesthesia in operating room prior to retinal surgery were successfully imaged, all the imaging sessions were completed within 5 minutes. Representative retinal OCT/OCTA images from a patient with X-linked retinoschisis and a patient with retinopathy of prematurity were shown in Fig 2. Vascular network and pathologies were clearly visualized in these images without pronounced motion artifacts.

Conclusions: We have demonstrated a 400-kHz and 55-degree field of view handheld OCT/OCTA system that has overcome many technical challenges in ultrahigh speed OCTA imaging as well as in pediatric retinal imaging in general. The advantages of the system have the potential to improve the diagnosis of retinal diseases and clinical validation.

ABSTRACT BODY:

Purpose: Primary open angle glaucoma (POAG) is a leading cause of blindness, characterised by optic nerve head excavation and retinal ganglion cell degeneration. Recent studies have shown that inactivation of the serine protease inhibitor neuroserpin (SERPINI1) is associated with plasmin-proteolytic excitotoxicity within the retina, and the protective effects of SERPINI1 overexpression have been previously reported in various neurodegenerative diseases. Here, we examined the protective effects of exogenous intravitreal SERPINI1 administration on inner retinal function and structure in a mouse model of experimental glaucoma.

Methods: Wild-type C57BL/6J mice (n=32) were subject to weekly intracameral microbead injections for eight weeks, to induce a chronic increase in intraocular pressure (glaucoma, n=8). Human recombinant SERPINI1 was injected intravitreally in healthy (SERPINI1, n=8) and experimental glaucoma mice (glaucoma+SERPINI1, n=8; weekly). PBS was administered as a vehicle control (PBS, n=8). Functional changes were assessed using positive scotopic threshold response (pSTR) amplitude measurements. Retinal structural changes were investigated using hematoxylin and eosin staining of tissue sections and quantified by light microscopy.

Results: Exogenous SERPINI1 administration in experimental glaucoma mice demonstrated significant preservation of pSTR amplitudes when compared to glaucoma mice alone ($p<0.02$). Healthy control mice treated with the SERPINI1 protein showed no significant changes in pSTR amplitudes, when compared to untreated and PBS treated mice ($p=0.19$). Histological quantification further revealed no significant changes to GCL density in untreated, PBS and SERPINI1 alone treated groups ($p=0.37$). However, there was significant rescue of the GCL population in glaucoma mice that were administered SERPINI1 protein intravitreally, when compared to the glaucoma control mice ($p<0.01$).

Conclusions: This study establishes a protective effect of exogenous SERPINI1 administration on the retina in chronic glaucoma conditions. The molecule may impart protection by suppressing the excitotoxicity associated with plasmin proteolytic actions. The exact molecular mechanisms of SERPINI1 effects and consequences of its loss however remain undefined. Future proteomics investigations will establish the SERPINI1 signalling networks that are involved in retinal neuroprotection in glaucoma.

ABSTRACT BODY:

Purpose: Orientation and Mobility (O&M) programs aim to equip individuals with vision disability with the skills and techniques that optimize their ability for safe, independent travel, and hence foster their social, economic and educational participation. The purpose of this study was to conduct a cost-benefit analysis from three perspectives: the general public, the experienced user and the potential users of O&M programs in Australia.

Methods: Willingness-to-pay, was collected via contingent valuation survey using a double-bound dichotomous choice approach. The survey had three arms: Arm 1, the general public via stratified random sampling, Arm 2, experienced users of O&M programs, and Arm 3, potential users of O&M programs, were drawn from a major O&M service provider's database and two eye clinics via convenience sampling. Willingness-to-pay was estimated using interval regression analyses, accounting for study arm, sex, occupation, income and self-rated health. The cost data, including labour, travel and occupancy costs, were estimated from a service provider's perspective. The Net Present Value, variation if delivered by tele-O&M programs and priority for resource allocation was investigated.

Results: Arm 1 (the general public) included 471 participants (60.7% female) with a mean age of 64.6 years (range 18 - 100); Arm 2 (the experienced user) included 96 participants (59.4% female) with a mean age of 61.9 years (range 19 - 97); and Arm 3 (the potential user) included 137 participants (59.9% female) with a mean age of 74.2 years (range 21 - 97). Overall, the adjusted mean Net Present Value of O&M programs was \$3857 (95%CI: \$3760 - \$3954) per client, with a highest NPV from the general public (\$4289, 95% CI: \$ 4185 - \$4392), followed by the experienced users (\$ 3158, 95% CI: \$ 2897 - \$3419) and the potential users (\$ 2867, 95% CI: \$ 2680 - \$3054). The NPV reached break-even for tele-O&M programs. Priorities for resource allocation were similar between O&M programs, low vision services and care worker assistance.

Conclusions: There was strong community support for investment into O&M programs, including tele-programs. The results of this survey indicated that investment into these programs generates substantial benefits for clients over and above the cost of providing the services.

TITLE: Reliability of home-based acuity assessment in children with amblyopia: a trial study

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Orge, B. Can, A. Peiffer, M. Kohen, E. Leonard, UH Cleveland Medical Center, Cleveland, Ohio, UNITED STATES|T. Le, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Faruk Orge: Commercial Relationship: Code N (No Commercial Relationship) | Tinh Le: Commercial Relationship: Code N (No Commercial Relationship) | Basak Can: Commercial Relationship: Code N (No Commercial Relationship) | Adam Peiffer: Commercial Relationship: Code N (No Commercial Relationship) | Maryo Kohen: Commercial Relationship: Code N (No Commercial Relationship) | Elaine Leonard: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The growing role of telehealth in ophthalmology has only been accelerated by the COVID 19 pandemic. Research has been performed assessing the reliability and utility of remote, web-based visual acuity (VA) measurements, but not to our knowledge in children with amblyopia. We assessed the reliability of parent-obtained, remote visual acuity measurements compared to clinic-obtained values.

Methods: InsideOutMedicine (Seattle, WA) is an online, HIPAA-compliant platform that enhances tracking of amblyopia patient treatment. The platform allows parents to create a virtual "log" in which they record daily treatment and other required values (i.e.VA) for providers to review.

We enrolled eligible patients by creating an account on the platform. Parents were instructed to measure their child's VA within 14 days of the clinic visit at which their child was enrolled. Parents measured their child's VA using the Eyehandbook app (Cloud Nine Development LLC, Overland Park, KS). They then entered the obtained visual acuity values in the platform.

We recorded baseline characteristics of included patients and compared parent-obtained visual acuity measurements to corresponding clinic-obtained measurements, utilizing intraclass correlation (ICC) to assess for correlation.

Results: 14 total patients received 15 parent-obtained VA measurements within 14 days of a clinic visit, for a total of 56 individual VA measurements. The study cohort had an average age of 6.14 years (std = 2.21) and contained 50% females. 8 of the patients had moderate amblyopia, while 5 had mild and 1 had severe amblyopia.

We decided to remove a single set of extreme outlier measurements (20/400 vs 20/50), as no other set of measurements differed by more than 3 lines, with an average difference of .59 lines.

Intraclass correlation coefficient (ICC) comparing clinic-obtained and parent-obtained visual acuity measurements was 0.889 ($p < 0.001$) for amblyopic eyes, .477 ($p = .044$) for healthy eyes, and was .888 ($p < .001$) for the entire sample.

Conclusions: In this small sample size trial, home-based, parent-obtained VA measurements in children with amblyopia correlated significantly with clinic-obtained values in both normal and amblyopic eyes. This small sample size study suggests that home-based visual acuity testing could have utility in this population, especially for tracking changes over time between clinic visits.

ABSTRACT BODY:

Purpose: Wide biologic variability and inconclusive Optical Coherence Tomography (OCT) detection of disc margin limit accurate representation of optic nerve head (ONH) disc area (DA). This cross-sectional study assesses the relationship between Pattern Electroretinogram (PERG) and OCT derived ONH measurements after controlling for DA.

Methods: Sixteen pre-perimetric glaucoma (PPG) subjects (thirty eyes) with normal Humphrey 24-2 visual field tests and suspicious ONH were consecutively recruited at Manhattan Eye Ear and Throat Hospital. Participants underwent Diopsys NOVA PERG and Cirrus and Spectralis OCT tests. Partial correlation analysis was conducted between PERG (Magnitude [Mag], MagnitudeD [MagD] and Magnitude D/Magnitude ratio [MagD/Mag ratio]) and ONH measurements (Rim Area and Bruch's Membrane Opening-Minimum Rim Width [MRW]), after controlling for DA. Hierarchical multiple regression analysis was used to determine the ability of PERG to predict variance in rim area and MRW global measurement after controlling for DA.

Results: After controlling for DA, partial correlation analysis showed a significant correlation between Mag, MagD and rim area, ($r>0.503$, $p<0.005$). Similarly, Mag, MagD and MagD/Mag ratio were significantly correlated with MRW temporal superior (MRW-TS) ($r>0.400$, $p<0.039$), and with MRW nasal inferior (MRW-NI) ($r>0.431$, $p<0.025$) sectors. MagD and MagD/Mag ratio significantly correlated with MRW global ($r>0.407$, $p<0.035$).

In two separate hierarchal linear regression models, in the prediction of rim area, after controlling for DA (step 1), Mag then MagD (step 2) explained an additional 26.8% and 25.2 % of variance in rim area ($B=0.174$ [95% CI: 0.065, 0.283], $P<0.005$) and ($B= 0.160$ [95% CI: 0.056, 0.265], $P<0.005$), respectively.

In prediction of MRW global, after controlling for DA (step 1), MagD then MagD/Mag ratio (step 2) explained an additional 13.4% and 12.8% of the variance in MRW global, ($B= 38.921$ [95% CI: 3.872,73.970], $P<0.05$) and ($B=129.024$ [95% CI: 9.589, 248.460], $P<0.05$), respectively.

Conclusions: PERG can predict variance not only in rim area and global MRW, but also in MRW-TS and MRW-NI sectors, after controlling for DA. This highlights the benefit of using PERG in addition to OCT ONH morphology measurements to increase diagnostic accuracy for early glaucoma diagnosis.

TITLE: Modelling Age Effects of Myopia Progression for the MiSight 1 day Clinical Trial

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Arumugam, A. Bradley, D. Hammond, P. Chamberlain, Coopervision Inc, Pleasanton, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Baskar Arumugam: Commercial Relationship(s);CooperVision Inc.:Code E (Employment) | Arthur Bradley: Commercial Relationship(s);CooperVision Inc.:Code E (Employment) | David Hammond: Commercial Relationship(s);CooperVision Inc.:Code E (Employment) | Paul Chamberlain: Commercial Relationship(s);CooperVision inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Age has a dominant impact on myopia progression rates within a population (Chua et al 2016). Controlled clinical interventions are, however, routinely constrained by a limited age range of subjects and retaining control cohorts for long study durations is difficult. This study aims to derive estimated annualized elongation (EAnE) models for both Proclear 1 day (omafilcon A, single vision, Coopervision, Inc.; P1d) and MiSight 1 day (omafilcon A, dual focus, CooperVision, Inc.; M1d) soft contact lens wearers over a 10 year age span from a 6-year randomized controlled clinical trial dataset.

Methods: Arumugam et al. (AAO, 2020) found that age also significantly affected axial progression rate in treated eyes, and after accounting for age, number of years in treatment had an insignificant effect, validating cross sectional analysis by age of the clinical trial data. Annualized measured axial elongations (AMAE) were calculated across the full age range (8–18 years) irrespective of treatment years in the study using a cross sectional age analysis. Control group (P1d) AMAE allowed optimization of equation coefficients for the exponential decay function as previously reported by Brennan et al. (AAO, 2018), using an iterative least squared error method. The AMAE rates for subjects treated with the M1d lenses were also plotted by age and the EAnE model was derived based on best fits.

Results: The P1d and M1d datasets consisted of 350 and 888 annualized changes in axial length, respectively. The following univariant (age in years) P1d and M1d EAnE models were derived:

P1d EAnE: $([-0.08135 * e^{-0.1(\text{age})}] / -0.1) - 0.06295$ $R^2: 0.97$

M1d EAnE: $-0.149 \ln(\text{age}) + 0.4659$ $R^2: 0.96$

The P1d EAnE function exhibits a concordant correlation coefficient to the Brennan 'white' ethnicity equation (EAnE = $0.268 * e^{-0.144 * [\text{age} - 9.02]}$ $R^2: 0.97$). A natural logarithm equation was found to be the best fit the M1d dataset. Using these EAnE models, the calculated cumulative axial elongation from 8 to 18 years of age for subjects wearing P1d and M1d lenses are predicted to be 1.84mm and 0.97mm respectively.

Conclusions: EAnE models predict, that if a myope commences M1d lens wear at 8 years of age and continues full time wear until 18, an average myopia control treatment effect of 0.87mm (>2D) would ensue. The findings further support evidence that the greatest impact on eye growth will occur when treatment is started early and sustained longer.

ABSTRACT BODY:

Purpose: Prorenin has been viewed as an ideal target molecule in preventing diabetes mellitus (DM)-related microangiopathies. However, none of drugs can specifically inhibit prorenin activation. Here we employed peptide vaccine technique and tested the effect of prorenin peptide vaccine (V_P) in murine models of type 2 diabetes mellitus (DM)

Methods: V_P was prepared by conjugating selected antigen from prorenin prosegment to keyhole limpet hemocyanin (KLH). C57BL/6J underwent 2× injection of KLH only (as control vaccine), peptide E1-conjugated with KLH (E1-KLH), E2-KLH or E3-KLH to optimize V_P . Then, mice underwent 3× vaccination. For three groups; db/db+KLH, db/db+ V_P and db/m+KLH, electroretinogram (ERG) and histological analyses were performed to assess the effect of V_P .

Results: E2-KLH was determined as V_P in subsequent experiments between three candidate vaccines. Specific immunoreactivity of anti-sera from V_P -immunized C57BL/6 mice against prorenin and BSA-conjugated E2, but not renin. Subcutaneous injection of 20 μ g V_P prevented the prolongation of implicit time of b-wave in db/db mice ($p < 0.05$). V_P significantly reduced the number of iba-1 positive activated microglia in the retina of db/db mice compared to db/db+KLH ($p < 0.05$). Furthermore, histological analysis demonstrated that V_P mitigated glomerular and tubular expansion in the kidney and fatty liver. V_P did not affect body weight, glucose levels and blood pressure.

Conclusions: Vaccination against prorenin is effective and safe in protecting the retina from insults due to type 2 DM.

ABSTRACT BODY:

Purpose: One of the key challenges remaining in the field of retinal prosthetics would be a lack of comprehensive understanding of electrically-evoked responses of various types of retinal ganglion cells (RGCs). For example, directionally selective (DS) RGCs are known to encode motion information from the visual world; interestingly however, no study has been reported regarding characteristics of network-mediated responses arising in those RGCs. In the present work, for the first time, we have explored the electrically-elicited network-mediated responses of ON-OFF DS RGCs in rabbit and mouse retinas.

Methods: Cell-attached patch-clamp technique was used to record spikes from DS RGCs in retinal explants from rabbits (n = 8) and mice (n = 6), both widely-studied species in retinal researches. ON-OFF DS RGCs were identified by their robust spiking at both onsets and offsets of stationary spot flashes and white bars moving in twelve different directions. Their direction selectivity index (DSI) was computed from moving bar responses. A monophasic half-sinusoidal pulse (4 ms duration, -100 μ A amplitude) was delivered from the epiretinal side. The stimulus was repeated at least 5 times.

Results: Unlike network-mediated responses of non-DS RGCs in our previous works, electric pulse evoked remarkably heterogeneous spiking patterns across DS RGCs in each species. Also, Fano Factors (FFs) of their spike counts were quite high in both species (0.84 ± 0.50 and 0.72 ± 0.40 for rabbits and mice), indicating unreliable responses across repeats of electric pulses. Intriguingly, the two species showed a contrasting difference in the relationship between electrically- and light-evoked responses: the peak firing rates of the rabbit DS RGCs were in a strong inverse correlation with their DSIs ($r = -0.839$). On the contrary, the peak firing rates of the mouse DS RGCs appeared to have a weaker correlation with their DSIs ($r = 0.161$).

Conclusions: Given the critical role in the dynamic visual perception, the natural responses of DS RGCs may be crucial for improved artificial vision. However, the heterogeneous and inconsistent network-mediated responses (i.e. high FFs) suggest it may be difficult. Also, the different correlations with light-evoked responses suggest the species-specific DS circuits should be better understood.

TITLE: Uncovering the Properties of Lens Resident Immune Cells

SESSION TITLE: Lens Cell Biology and Regulation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Menko, Pathology, Anatomy and Cell Biology, Thomas Jefferson University, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): A Sue Menko: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our previous studies provided the first evidence that despite the fact that the lens is avascular, it contains a subpopulation of tissue resident immune cells, a typical feature of most other tissues. As the properties of resident immune cells can include many tissue-protective functions, our purpose is to provide a deeper understanding of the properties specific of this unique lens cell population in order to begin to elucidate how they function in the lens.

Methods: This study uses both human and chick embryo post-cataract surgery injury explant cultures. Properties of resident immune cells associated with the lens epithelium on their endogenous basement membrane capsule and after these cells migrate of the capsule and onto the rigid tissue culture plastic surrounding the explant are examined by confocal microscopy imaging following immunofluorescence labeling.

Results: Resident immune cells that we have previously shown populate the lens during development were found to travel to the lens along the ciliary zonules in the absence of a vasculature. These cells were identified based on their expression of a monocyte/macrophage molecule. In the human post-cataract surgery explants CD45+ immune cells interspersed among the cells of the lens epithelium often extend dendritic processes consistent with the morphology of antigen presenting cells. These CD45+ cells migrate to the wound edge of the explant, where the transmembrane glycoprotein CD44, a hyaluronic acid receptor expressed by immune cells, is induced. With the chick post-cataract surgery explants we show that the CD44+ resident immune cells activated to migrate to the wound edge are vimentin-rich cells that express the TLR4 co-receptor CD14, identifying them as monocytes/macrophages and/or dendritic cells. Within 6 days after placing the human post-cataract surgery explants in culture, the CD45+ immune cells present remaining associated with the basement membrane capsule among the lens epithelial cells and those that had migrated onto the rigid substrate surrounding the explant, have acquired a myofibroblast phenotype.

Conclusions: Resident immune cells of the lens function as immediate responders to injury with properties consistent with their function as the liaisons between the innate and adaptive immune response and with the potential to acquire a myofibroblast phenotype, the agents of fibrosis.

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) is associated with mechanical changes in the trabecular meshwork, leading to increased aqueous humor (AH) outflow resistance. The role of Notch signaling, an evolutionarily conserved pathway implicated in mechanotransduction, has not been investigated in glaucoma pathogenesis. Here, we determine the expression of Notch pathway molecules in TM cells subjected to cyclical strain or when grown on hydrogels of varying rigidity.

Methods: Primary human total TM (hTM) cells were isolated and validated from donor corneal rings. hTM cells (3-7 passages) were plated on collagen coated 3 kPa or 80 kPa hydrogels for 72hrs with 10% FBS containing Ham's F12 medium. In cyclical strain experiments, hTM cells were cultured on collagen coated PDMS stretch chambers and subjected to uniaxial 20% strain for 24 h at 1Hz. mRNA and protein levels of Notch receptors, ligands, and effectors in the hTM cells was determined by RT-qPCR or western blot.

Results: On stiffer hydrogels, expression of Notch receptors 1(0.6-fold), 2(0.8-fold) 3(0.8-fold) or 4(0.3-fold) was significantly decreased. While expression of Notch ligand Jagged1 was similar on both substrates, expression of Jagged2 (0.4-fold), DLL1 (0.8-fold), 3 (0.8-fold) and 4 (0.3-fold) were all down-regulated. Correspondingly, downstream targets of Notch pathway, Hes3, 5 (0.3, 0.3-fold) or Hey1, 2 (0.4, 0.4-fold) were decreased. In cyclic stretch, expression of Notch receptors 1(0.8-fold), 3(0.9-fold) decreased, whereas Notch2(1.17-fold) increased. While expression of Notch ligands Jagged1 (0.9-fold), Jagged2 (0.8-fold), DLL1 (0.8-fold), 4 (0.8-fold) was down regulated. DLL3 (1.2-fold) was upregulated. Congruently, effectors of Notch pathway, Hes3 (1.2-fold) and 5 (1.2-fold) increased, and Hey1 (0.8-fold) was decreased, compared to non-stretched strains.

Conclusions: Our data demonstrates that Notch signaling in hTM cells differs by mechanical insult. Notably, where substratum stiffness elicited maximal intrinsic differences, cyclical strain did not. These results imply: (i) The different Notch components may have distinct mechanotransduction roles to maintain tissue homeostasis. (ii) Notch signaling may be temporal in cell fate determination. Overall, these findings warrant further studies on the exact role of Notch signal in human trabecular meshwork in health and disease.

Commercial Relationships Disclosure (Abstract): Paulo Bispo: Commercial Relationship: Code N (No Commercial Relationship) | Lawson Ung: Commercial Relationship: Code N (No Commercial Relationship) | James Chodosh: Commercial Relationship: Code N (No Commercial Relationship) | Lucia Sobrin: Commercial Relationship: Code N (No Commercial Relationship) | Michael Gilmore: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Eye infections are among the most common causes of blindness worldwide. The sooner effective therapy can be started, the more vision can be saved. However, current diagnostic modalities are time-consuming, lack sensitivity and inclusiveness, and may result in patients being treated with the wrong drug for long periods. We present a newly developed comprehensive ocular panel designed to improve diagnostic yields and provide a tool for rapid pathogen identification, with potential to improve treatment choices and at earlier stages of the disease

Methods: Using epidemiological information on the etiologies of ocular infections seen at our hospital and in combination with a literature review, we identified 46 pathogens and 2 resistance/virulence markers that are most commonly detected (>90% of cases). Genomic targets were scrutinized for stretches predicted to be specific for a particular species while being conserved across different strains from the same species. Regions of 150 to 300bp in length were selected and a set of primers for pre-enrichment, and two 50mer NanoString compatible probes were designed per target. DNA-DNA hybrids were detected and quantified using the NanoString nCounter SPRINT Profiler

Results: Analytical studies demonstrated highly sensitive detection of a broad spectrum of infectious agents, including bacteria, fungi, viruses and parasites, with limits of detection being as low as 25 femtograms per reaction. We also challenged the diagnostic panel in a pilot clinical study testing samples from infectious keratitis (n=6) and uveitis (n=6) for which the etiologies were confirmed by culture or real-time PCR, and included Gram-positive and -negative bacteria and herpesviruses. The NanoString-based panel correctly identified the causative agent from all clinical specimens. Detection was robust, with probe counts for the targeted pathogen ranging from 5×10^3 to 4×10^5 . For corneal ulcers, higher probe counts seem to correlate with the severity of presentation

Conclusions: This highly multiplexed panel for detection of ocular pathogens offers a sensitive, comprehensive, and uniform assay run directly on ocular specimens, that could significantly improve diagnostics of sight-threatening infections

ABSTRACT BODY:

Purpose: An image quality (IQ) algorithm is important in assisting medical assistants with little to no experience in ophthalmology to judge whether an image is of sufficient quality for clinical diagnosis.

In this study, we developed a binary IQ classification for providing real-time feedback in a remote care or primary care settings.

Methods: Data:

5173 images acquired using VELARA™ 200 (Zeiss, Dublin, CA) camera from a retrospective study were graded by 2 graders and adjudicated by an optometrist). The images were acquired from normal and diseased subjects with various retinal pathologies were graded for quality of readable clinical information in a 1-5 scale (1-very poor and 5-excellent). The ground truth (GT) is determined by converting the gradings to binary: 0- Insufficient if IQ is ≤ 2 (65.6% of 5173 images) and 1-Sufficient if IQ is > 2 (34.4%). Small pupils, incorrect fixation, out of focus and other artifacts were the main causes of insufficient IQ.

Algorithm:

The dataset is split into three: i) training- 3646, ii) validation- 928 and iii) hold-out test – 599. The training set is augmented using flip and brightness adjustments. The deep learning architectures used to train the IQ classification are shown in figure 1. ImageNet weights were preloaded, sigmoid activation with binary cross entropy loss were used. The data was resampled and reweighted to account for the class imbalance. For hyperparameter tuning, all the networks were trained using Adam with cyclic learning rate scheduler and Stochastic Gradient Descent (SGD) with Nesterov momentum. SGD with Nesterov is chosen for the final model as it performed better. Sensitivity, specificity and the execution time were compared to select the final IQ model.

Results: The performance of all networks in hold-out test set is shown in Figure 1. VGG-16 provided high sensitivity, specificity with lower execution time is selected as the final model. It achieved 99% sensitivity, 91% specificity and 220ms execution time in i5-10400H CPU. Figure 2 shows some of the examples results from IQ algorithm.

Conclusions: We developed an image quality algorithm with 99% sensitivity with an execution time to provide real-time feedback to the operator on whether to retake the fundus images.

TITLE: The Curvature and Collagen Network of the Human Lamina Cribrosa in Glaucoma and Control Eyes

SESSION TITLE: Glaucoma: molecular, biochemical and biomechanical disease mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Czerpak, Y. Ling, T.D. Nguyen, Mechanical Engineering, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|J.L. Jefferys, H.A. Quigley, Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Cameron Czerpak: Commercial Relationship: Code N (No Commercial Relationship) | Yik Tung Tracy Ling: Commercial Relationship: Code N (No Commercial Relationship) | Joan Jefferys: Commercial Relationship: Code N (No Commercial Relationship) | Harry Quigley: Commercial Relationship: Code N (No Commercial Relationship) | Thao Nguyen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To measure the curvature and features of the collagen beam-network structure of the lamina cribrosa (LC) of post-mortem human glaucoma eyes and analyze for differences between diagnosed glaucoma and age-matched normal eyes.

Methods: The posterior scleral cups of 10 normal eyes and 16 diagnosed glaucoma eyes (Midgett et al. 2020) with axon loss ranging from <10% to >50% were subjected to inflation testing with second harmonic generation (SHG) imaging, and analysis by digital volume correlation (DVC). SHG image Z stacks were analyzed by a custom algorithm (Ling et al. 2019) for ten structural features of the LC beams (Fig 1). The LC curvature was estimated by fitting a 5th order polynomial to the anterior surface of the imaged LC volume (Fig 1d). The structural and strain outcomes were averaged overall and regionally for each specimen. Results will be verified using generalized estimating equation models and linear mixed models.

Results: Preliminary results using unpaired t-tests show mean curvature, Gaussian curvature, and tortuosity averaged over the LC, the central region, and the peripheral region were significantly greater in the LC of diagnosed glaucoma eyes compared to age-matched normal eyes (all $p \leq 0.03$) (Fig 2). The specimen-averaged pore size, and beam aspect ratio (length/width) was significantly smaller in glaucoma eyes than normal eyes ($p \leq 0.04$) (Fig 2).

Conclusions: The smaller average pore size and beam aspect ratio may contribute to a stiffer pressure-induced strain response of the LC. In contrast, the greater curvature and beam tortuosity should produce a more compliant strain response. Computational modeling is needed to estimate the effects of the curvature and LC network structure on the strain response.

ABSTRACT BODY:

Purpose: Conjunctival ultraviolet autofluorescence (CUVAF) area has been associated with ocular ultraviolet (UV) radiation exposure and time spent outside. CUVAF area is also associated with greater risk of pterygium on cross-sectional studies; however, longitudinal data is lacking. We investigated the relationship between CUVAF area measured at 20 years of age and incident pterygium over a 7- to 8-year follow-up period.

Methods: Data from the 20-year (age range 19-22 years), 27-year (age range 25-28 years) and 28-year (age range 27-30 years) follow-ups of the Raine Study generation 2 birth cohort were used for this study. CUVAF images were taken at the 20-year follow-up and CUVAF area measured by a single grader using a custom-built software. Pterygium was defined as a wing-shaped fibrovascular growth crossing the limbus and was assessed by a single grader from colour photographs captured at the 20-, 27- and 28-year follow-ups. Participants without CUVAF images taken at the 20-year follow-up or who had a pterygium at the 20-year follow-up were excluded from the analysis. The primary outcome was incident pterygium in either eye. Cox regression was used for statistical analysis.

Results: Of the 1344 participants of the 20-year follow-up, 1313 (97.7%) had CUVAF data and 1298 (96.6%) did not have a pterygium. Of these, 970 (74.7%) had colour photos taken at either the 27- (n=907) or 28-year (n=712) follow-ups and incident pterygia in either eye were present in 13 (1.4%) participants. Of 159 (15%) of participants who reported smoking cigarettes at the 20-year follow-up, none had an incident pterygium. On Cox regression, total CUVAF area (of both eyes) was strongly associated with risk of incident pterygium (per 10mm² increase, hazard ratio [HR]=1.38, 95% confidence interval [CI]: 1.21, 1.57) and remained strongly associated with incident pterygium after adjusting for sex and self-reported time spent outside in summer (HR=1.45, 95% CI: 1.21, 1.73). The area under the ROC curve for total CUVAF area alone was 0.81. Sex, axial length, 25-hydroxyvitamin D concentration and self-reported family history of pterygium were not associated with risk of incident pterygium.

Conclusions: CUVAF area at 20 years was a strong predictor of subsequent development of pterygium and may be useful in identifying patients at high risk of pterygium.

TITLE: The Tsh transcription factor and the transcriptional co-regulator CtBP interact in *Drosophila melanogaster* eye development

SESSION TITLE: Gene editing and ocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Helms, J. Curtiss, Biology, New Mexico State University, Las Cruces, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kyle Helms: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Curtiss: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cell fate determination and proliferation need to be coordinated during development of multicellular organisms, and this requires tissue-specific gene transcription. Transcriptional co-regulators mediate between sequence-specific transcription factors and the transcriptional machinery to promote tissue-specific gene transcription. Current evidence suggests that the sequence-specific transcription factor, Teashirt (Tsh), and the transcriptional co-regulator, C-Terminal Binding Protein (CtBP), have roles in coordinating cell fate determination and proliferation during eye development in the fruit fly, *Drosophila melanogaster*. Whether these proteins interact physically during eye development has yet to be determined.

Methods: We have used genetic and molecular tools to address this question. Over-expressing tsh in proliferating eye precursors results in loss of eye tissue, and loss-of-function mutations in CtBP suppress the effects of over-expressing tsh, suggesting that tsh and CtBP function in the same process during eye development. Furthermore, in vitro Glutathione-S-Transferase (GST)-pulldowns detect direct physical interactions between Tsh and CtBP, and co-immunoprecipitations from lysates of proliferating eye precursors confirm the interaction in vivo.

Results: These results suggest that Tsh and CtBP interact physically during eye development and that their interaction is important for proper eye development.

Conclusions: Future experiments using this GFP-tagged tsh and mass spectrometry will help to identify any proteins complexed with Tsh/CtBP and provide further insight into to how this complex regulates proliferation during the development of the eye.

ABSTRACT BODY:

Purpose: Retinopathy is increasingly associated with traumatic brain injury. However, the mechanism(s) behind its often insidious pathology are not understood. Although animal models can provide a means to study this complex process, off target injury can complicate the disease picture. Here, we develop a rat model that provides a reproducible system reminiscent of the coup and counter coup/Commotio Retinae pathology.

Methods: A compressed air driven shock tube delivered 26 psi blast waves from a 3 mm diameter stainless steel nozzle held stereotaxically 2 mm over the cornea of 20 anesthetized age matched adult Sprague-Dawley rats. Body temperature was maintained at 37°C, and heart and breathing rate were monitored. One eye received the blast; sham animals received no blast. After 4 wks under cyclic light: ERGs, electron microscopy, sagittal FFPE sections carefully oriented through the optic nerve and pupil were stained with H&E and PAS. Cell counts of the outer-, inner-nuclear, and ganglion cell layer cell at 400 μ intervals were made from digitized scans with QuPath software.

Results: The animals tolerated the blast without physiological signs of stress, or external evidence of injury to the globe or ocular adnexa. In three animals, hemorrhage over the optic nerve head was noted. Flash intensity plots showed a reduction in ERG a and b wave amplitudes. Cellular morphometrics showed two patterns of degeneration. Pattern 1, Inner Nuclear layer degeneration, or ganglion cell loss with optic nerve degeneration; Pattern 2, Outer Nuclear Layer degeneration with RPE dropout often involving the mid-peripheral retina. EM showed disruption and breaking of rod outer segments, and separation of outer segments from the inner segment compared to controls.

Conclusions: In vivo focused blast injury to a single eye can be accomplished without external trauma or physiological stress, while also avoiding subjecting the body to the blast wave. Coup injury (posterior retinal hemorrhage and optic nerve trauma), and indirect (countercoup) injury (outer segment disruption and outer-inner segment separation, mid-peripheral outer nuclear layer cell degeneration with RPE loss) were readily produced. The focal single-eye blast model provides a valuable system recapitulating human ocular traumatic injury including Coup and Commotio Retinae, and other countercoup pathology.

SUBMITTER (NAME ONLY): Andrea Vincent

TITLE: Harboyan Syndrome with biallelic SLC4A11 pathogenic variants misdiagnosed as congenital CMV infection

SESSION TITLE: Genetics of corneal dystrophy, glaucoma, lens and AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.L. Vincent, G. Kiray, S. Hull, Eye Department, Auckland City Hospital, Auckland, Auckland, NEW ZEALAND|A.L. Vincent, G. Kiray, S. Hull, Ophthalmology, The University of Auckland Faculty of Medical and Health Sciences, Auckland, Auckland, NEW ZEALAND|

Commercial Relationships Disclosure (Abstract): Andrea Vincent: Commercial Relationship: Code N (No Commercial Relationship) | Gulunay Kiray: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Hull: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Harboyan syndrome is a rare autosomal recessive disorder characterised by congenital hereditary corneal endothelial dystrophy (CHED) with a later onset of sensorineural hearing loss (SNHL) due to pathogenic variants in the SLC4A11 gene. Congenital cytomegalovirus infection (CMV) may manifest with SNHL and visual impairment. We present a case of a 4 year old girl, diagnosed at birth with congenital CMV infection, but careful phenotyping and genetic testing permitted a definitive diagnosis.

Methods: Case report, clinical ocular and auditory phenotyping, next generation sequencing of corneal genes (Asper Ophthalmics), and parental segregation of variants

Results: A 4 year old female presented with bilateral corneal clouding, and BCVA of 6/19 OD and 6/15 OS. At pregnancy her mother had a 2nd trimester febrile illness and converted from CMV negative to positive, with CMV detected in an umbilical blood sample. Age 2 months a faint corneal haze was noted and normal audiology at 2 months (auditory brain response), and 8 months (otoacoustic emissions). At 18 months of age she developed a right esotropia, and was recorded as having clear corneas. A hypermetropic correction and patching was prescribed. Review at age 3.5 years showed bilateral moderate central corneal oedema, no evidence of bullae, central corneal thicknesses of 980 microns, and a clear periphery, with normal retina and optic nerves. Thought to be consistent with CHED, audiology was repeated demonstrating slight SNHL from 500-2000 Hz, sloping down to moderate SNHL at 8000Hz bilaterally. Genetic testing identified a previously reported pathogenic variant in SLC4A11 c.2609T>C, p.(Leu870Pro) and a second variant c.1318G>C, p.(Gly440Arg) with an allele frequency of 6.57e-6 in gnomAD , and damaging by multiple in silico tools. Parental segregation of these variants was confirmed.

Conclusions: Congenital CMV infection affects 1% of all births although only 15-20% have sequelae. Although progressive SNHL may be a feature, corneal clouding is not described, with the most common ocular features being strabismus, optic atrophy, cortical visual impairment and chorioretinitis. Biallelic mutations in SLC4A11 are more commonly causative of isolated CHED2, but also described in the rarer Harboyan syndrome. The combination of corneal opacification and progressive SNHL should alert the clinicians to alternate diagnoses.

TITLE: Prospective Analysis of Patient Satisfaction with Inherited Retinal Disease Clinic Visits Conducted via a Hybrid Telemedicine-based Approach

SESSION TITLE: Genetics of Retinal dystrophies and Functional Genomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Rali, J. Yan, N. Jain, Emory Eye Center, Atlanta, Georgia, UNITED STATES|S. Partin, Emory University, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aditya Rali: Commercial Relationship: Code N (No Commercial Relationship) | Stacy Partin: Commercial Relationship: Code N (No Commercial Relationship) | Jiong Yan: Commercial Relationship: Code N (No Commercial Relationship) | Nieraj Jain: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic adversely impacted patient access to in-person healthcare, bringing telemedicine to the forefront. The Emory Ophthalmic Genetics Service (EOGS) adopted a hybrid model of care, allowing patients to meet the physician via a video telehealth encounter and separately obtain ancillary in-person diagnostic testing. The goal of this study is to evaluate patient satisfaction and completion rate of diagnostic genetic testing with this novel care model for patients with inherited retinal diseases (IRDs).

Methods: Patients age 18 and older who were new to the EOGS and participated in a telemedicine-based IRD clinic appointment after October 1st, 2020, were eligible for this study. After obtaining informed consent, a trained interviewer administered a 14-question survey over the telephone. Each survey item contained 5 Likert-scale response options, assigned a value from 1 to 5. The survey was designed to address two main factors—information exchange and patient comfort. A mean “favorability index” for patient satisfaction was calculated for each item with a score of 5 being most favorable. Completion rate of diagnostic genetic testing was also evaluated. Diagnostic accuracy was determined by comparing the clinical diagnosis to the genetic diagnosis, where available, and results compared to a control group of in-person encounters from July 2019 to December 2019.

Results: Sixteen of 21 eligible patients completed the survey (Figure 1). Of these, 7 (44%) were female, with median age 56.5 (range, 25 to 73 years). Patients lived a median of 29.5 miles (range, 5 to 147 miles) from the Emory Eye Center. Six (37.5%), 6 (37.5%), and 14 (87.5%) patients underwent ancillary in-person testing with electroretinography, perimetry, and fundus imaging, respectively. The median (range) favorability index was 5 (4-5) and 4 (3-5) for information exchange and patient comfort, respectively. Responses were favorable (>3) for telemedicine for all survey items except one. Diagnostic genetic testing was recommended for 12 (75%) patients, and completed in 10 (83%) of those.

Conclusions: Our results suggest high patient satisfaction with a hybrid telemedicine-based approach for care delivery to patients with IRDs. Further study in a larger sample is warranted.

ABSTRACT BODY:

Purpose: Recent studies have implicated mitochondrial dysfunction in the pathophysiology of glaucoma, with in vivo characterization at the macula by Geyman et al. Evaluation of these mitochondrial alterations has been enabled measurement of flavoprotein fluorescence (FPF) through a non-invasive imaging platform. The current study is the first to evaluate FPF at the optic disc rim in primary open-angle glaucoma (POAG) patients compared to healthy controls.

Methods: 50 eyes of 30 POAG patients and 36 eyes of 20 healthy controls were imaged using the OcuMet Beacon (OcuSciences, Ann Arbor, MI; Investigational Device). Infrared and FPF measurements were obtained at the optic nerve head (ONH). Built-in software algorithms identified the optic disc margins on the infrared image and demarcated an elliptical annulus around the ONH rim. FPF was subsequently measured within the annulus boundaries. Averaged FPF of the entire area within the annulus and within anatomical sectors (temporal, superior, nasal, and inferior) were determined for each subject. Distinctions in FPF between POAG and control eyes were evaluated through mixed-effects logistic regression, adjusted for age and interocular pressure. Correlation between FPF and clinical characteristics for glaucoma were also characterized using linear mixed-effects models.

Results: The mean \pm SD of global FPF was significantly higher in POAG eyes compared to control eyes (46.4 \pm 27.9 vs. 28.0 \pm 11.7, $P<0.001$). Differences in FPF between POAG and controls eyes were also present for temporal ($P=0.001$), superior ($P<0.001$), nasal ($P=0.002$), and inferior ($P=0.001$) sectors. FPF exhibited significant correlation to Humphrey 24-2 visual field mean deviation ($P=0.001$). Significant correlation was also present between global FPF and global circumpapillary retinal nerve fiber thickness ($P<0.001$) and at the superior ($P=0.02$), inferior ($P=0.02$), and nasal ($P=0.003$) quadrants.

Conclusions: Measurement of FPF suggests increased mitochondrial dysfunction at the optic disc rim in POAG eyes. FPF may prove useful for evaluation of glaucomatous damage and may permit further exploration of pathophysiology. Future studies on stage-stratified POAG eyes will aim to assess the potential roles for FPF assessment in the detection of early glaucomatous pathology.

ABSTRACT BODY:

Purpose: To evaluate the efficacy of different designs of orthokeratology (OK) soft multifocal lenses (SMCL) and low-dose atropine (LAD) to control myopia evolution. The primary outcome relates to axial length (AL) progression during 24 months.

Methods: This is a retrospective study based on data that are extracted from the file of each patient who: (1) consulted EOUM between Jan 2017 and Dec 2018 and (2) were kept under the same MCS (same design/concentration).

Clinical population is composed of 104 SMCL, 140 OK and 42 LDA participants. Elements analyzed include baseline age, gender, ethnicity, spherical equivalent refractive error (SEQ), photopic pupil size, flat and steep K readings. AL was also evaluated at baseline and after 6, 12 and 24 months. To assess whether intervention had a statistically significant effect, a complex statistical model was built. It was developed by first consider all collected parameters. Then, statistically insignificant predictor terms were removed using backward stepwise elimination. In the final model, 5 predictors were retained (month, SEQ, gender, age and age-month interaction).

Results: For OD only, considering SMCL, 4 designs are compared. AL variation at 12/24 months was: 0.14 +/- 0.18 (N=43) and 0.29 +/- 0.29 (N=22) for senofilcon A; 0.07 +/- 0.29 (N=16) and 0.33 +/- 0.66 (N=10) for comfilcon A, 0.18 +/- 0.15 (N=18) and 0.33 +/- 0.25 (N=9) for Omafilcon Toric, 0.13 +/- 0.1 (N=8) and 0.2 +/- 0.06 (N=5) for etafilcon A. About OK lenses, AL results are: 0.18 +/- 0.19 (N=40) and 0.35 +/- 0.27 (N=36) for HDS 5 curves, 0.05 +/- 0.19 (N=44) and 0.17 +/- 0.29 (N=19) for custom 7 curves design; 0.13 +/- 0.17 (N=16) and 0.23 +/- 0.19 (N=11) for custom double-reservoir design, 0.03 +/- 0.18 (N=13) and 0.21 +/- 0.33 (N=15) for a 4 zones VST design. LDA results are 0.21 +/- 0.16 (N=34) and 0.37 +/- 0.25 (N=19). There was no statistical difference between SMCL or OK lenses, within the same category. However, OK led to significant better control after 1 year, which was no longer true after 24 months (see part 1)

Conclusions: When correctly selected at baseline, there is no long term difference between contact lens modalities used to control myopia evolution. OK lenses seem to give better results at the beginning but SMCL becomes as efficient with time. Atropine seems to lead to increased evolution at any time point.

ABSTRACT BODY:

Purpose: Age-related changes in the optical and biomechanical properties of the lens cause presbyopia. However, the molecular origins of these changes remain unknown. In this study, experimental and computational approaches were combined to offer a mechanistic theory of age-related changes in lens material properties.

Methods: Fresh porcine lenses were characterized intact using digital photography and lens compression to determine their macroscopic optical and biomechanical properties. Lenses were then homogenized and fractionated, allowing further characterization using Raman spectroscopy (RS), dynamic light scattering (DLS), and dynamic shear rheometry (DSR). Experiments were conducted at 50°C to simulate “biochemical aging.” The resulting data were used to calibrate a biochemical computational model of lens aging. This model simulated the kinetics of biochemical changes in the lens while predicting changes in optical and mechanical properties.

Results: RS indicated the thermal stability of lens proteins up to ~57°C, suggesting that incubation at 50°C may be a reasonable model for acceleration of biochemical kinetics in the lens. RS, DLS, and DSR measurements suggest that protein structural modifications precede aggregation, which in turn precedes changes in viscoelastic properties of lens protein solutions. At the macroscopic level, lens stiffening occurred at timescales very similar to those found using DSR. Changes to lens transparency occurred later in the process. Multi-scale modeling of these changes demonstrate the feasibility of protein unfolding leading to aggregation, then binding to the lens’ cytoskeleton. This could effectively reinforce the cytoskeleton by decreasing the mobility of its proteins.

Conclusions: While it is unknown whether thermosetting pig lenses recapitulates physiological aging mechanisms, this study offers the first mechanistic theory linking biochemical events to biomechanical and optical changes in lens material properties. Similarities between the ultimate material properties of intact lenses, homogenized lenses, and fractionated homogenates suggest that the simple experimental and theoretical models may capture the key aspects of age-related changes in lens material properties. Future work will require experiments using human donor lenses to ascertain the utility of both the experimental and theoretical models in understanding aging in the human lens.

ABSTRACT BODY:

Purpose: Protein S-nitrosylation (SNO) is the means by which nitric oxide (NO) bioactivity is conveyed throughout the body to regulate all manners of cellular function. Our previous work has suggested that addition of one or more SNO agents to preservation solutions can extend storage duration and improve the functional status of transplantable organs. This report characterizes the effect of SNO therapy on the corneal endothelial cells (CECs) during hypothermic storage, a key element in keratoplasty success.

Methods: Paired post-mortem human corneas (n=8) from research-consented donors were incubated in the hypothermic corneal storage solution (Life4⁰C, Numedis, Inc.) with SNO agent or without SNO agent. CEC density and corneal thickness were measured at day 0, 7 and 14 using Konan CellChek D+ and OptoVue OCT machine, respectively. Total RNA from CEC layer was isolated using Qiagen MiniKit on day 14 and subjected to RNA-Seq to analyze differential gene expression pattern.

Results: Under normal circumstances during hypothermic storage, CEC density tends to decrease and corneal thickness tends to increase. CEC density was decreased by 8.2% for SNO without donors control group, while it remain unaltered for SNO group between day 7 and day 14. Corneal thickness was increased by 15% in the control group compared to only 8.6% increase in the SNO group between day 7 and 14. RNA-Seq analysis revealed more than 70 genes (transcripts) that were differentially expressed in the SNO group compared to the control group ($P \leq 0.05$, $|\text{Log}_2 \text{Fold Change}| \geq 0.5$).

Conclusions: S-Nitrosylation therapy of hypothermic corneal storage might be beneficial to improve the quality of donated human corneas that are used for keratoplasty. With the significant alteration of transcriptome of the CEC with SNO therapy, these changes might contribute towards programming of the CECs to regulate long-term graft survival.

ABSTRACT BODY:

Purpose: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has already been detected in ocular samples. However, the role of the eye in Coronavirus disease 2019 (COVID-19) is still unclear. We investigated the presence of SARS-CoV-2 in conjunctival swabs from patients with confirmed severe form of COVID-19 searching for differences in the presentation and assay positivity.

Methods: This cross-sectional study included 50 conjunctival swab samples (one eye per patient) collected from 50 patients with confirmed COVID-19 in Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil. Samples were collected within 24 hours from the naso/oropharyngeal swab. Inclusion criteria was severe/critical disease and indication for hospitalization according to the Institutional Guideline, which was the presence of Severe Acute Respiratory Syndrome. Conjunctival swab was collected from the inferior fornix, without anesthesia, using a nylon flocked swab. Real-time reverse transcription polymerase chain reaction (rRT-PCR) was performed with primers and probes described in CDC protocol. The study was approved by the Institutional Ethics Committee and informed consent was obtained prior to procedures.

Results: Twenty-four patients were male and twenty-six were female. Median age was 57.38 years (SD 15.23). Mean duration of symptoms before ocular sampling was 7.6 days (SD 3.52). Naso/oropharyngeal swab RT-PCR (within 24 hours from the conjunctival swab) was positive in 34 (68%) patients, negative in 14 (28%) and inconclusive in 2 (4%) patients. All the patients with negative or inconclusive RT-PCR had COVID-19 diagnosis confirmed by another naso/oropharyngeal swab or serology. Five (10%) conjunctival swabs resulted in positive rRT-PCR analysis and two (4%) had inconclusive results. Among the positive patients, 2 patients had a negative naso/oropharyngeal swab and 1 patient had an inconclusive result. None of the patients had ocular symptoms.

Conclusions: The positivity rate of conjunctival swab for SARS-CoV-2 was higher when compared to previous studies and similar to those that evaluated moderate to severe forms of COVID-19, and was not associated with ocular symptoms. This suggests that a greater viral load may be present in the tear film of patients with severe form of COVID-19 and may not be associated with conjunctivitis. Special concern should be taken to healthcare workers.

ABSTRACT BODY:

Purpose: To evaluate the clinical outcomes of intravitreal methotrexate (MTX) therapy for the treatment of vitreoretinal lymphoma (VRL)

Methods: Single-center retrospective case series of patients with a diagnosis of VRL and treated with intravitreal MTX at Emory University. Patient records were reviewed for demographic information, ocular exam findings, disease course, and treatment regimens including number of MTX injections. Clinical outcomes recorded included final visual acuity (VA), time to partial (PR) or complete response (CR), disease-free survival, time to relapse, number of relapses, and any non-ocular CNS progression.

Results: Ten eyes of 7 patients (4 male, 6 female) were reviewed. The mean age was 70±years (range, 56-85). Five patients had a diagnosis of primary CNS lymphoma with a history of systemic chemotherapy. Three eyes (30%) exhibited vitreous involvement, four (40%) had subretinal lesions, and three (30%) presented with both. Mean initial logMAR VA was 0.38±0.52 (Snellen visual equivalent 20/50), while mean final logMAR VA was 0.34±0.27 (20/40) with a mean follow-up time of 26 months (range, 3-49 months).

Patients received an average of 6 intravitreal MTX injections (range, 1-10) over the course of treatment. Two patients were receiving systemic chemotherapy at the time of injection. Mean time to either PR or CR was 57±37 days, and 6 eyes (60%) exhibited regression with no relapse after local treatment. For the 4 eyes that relapsed, time to first relapse was 193±155 days, and one eye experienced a second relapse. VA remained stable overall between initial treatment and 1, 3, 6, and 12-month follow-up ($P>0.05$ for paired comparisons); however, the largest VA improvement occurred at 3-months, with an average ~2-line improvement to 20/30. One patient with PVRL developed non-ocular CNS lymphoma.

Conclusions: Intravitreal MTX was well-tolerated and led to disease response in the majority of patients at approximately 2 months after initiation of treatment of intraocular lymphoma. Further studies on the efficacy of intravitreal treatment alone versus combined systemic and intravitreal treatment are warranted.

Commercial Relationships Disclosure (Abstract): Vivek Srinivasan: Commercial Relationship(s);Optovue Inc.:Code P (Patent) | Tingwei Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Kho: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Employing visible light OCT, we report a stereotyped reflectivity pattern of the inner plexiform layer (IPL) that parallels IPL stratification. We characterize this pattern non-invasively in adult human subjects without ocular pathology.

Methods: Subjects were imaged by a visible light OCT prototype instrument at UC Davis with 1 micron axial resolution. A total of 15 eyes of 15 subjects were analyzed. The inner retinal layer boundaries were demarcated. At each transverse position, the IPL intensity was interpolated onto an IPL thickness percentage abscissa axis. Images were partitioned into transverse segments of 450 microns (1.5 degrees) and IPL intensities were averaged across each segment (Figure 1A-B). To detect salient features of intensity profiles, a 14th order polynomial fit was performed on the intensity profile within the IPL (Figure 1C). The polynomial fit provided access to features such as stratum location and intensity (Figure 1D).

Results: Figure 2A shows subject-by-subject fitting of stratum S5 intensity versus IPL thickness with mixed effects and fixed effects models. The fixed slopes are all greater than zero, pointing to an increase in S5 prominence with IPL thickness (Figure 2B).

Conclusions: The proposed method reveals IPL organization in living human subjects, potentially enabling studies of stratification during development and in diseases.

ABSTRACT BODY:

Purpose: To determine the ophthalmic complications in pediatric Ebola virus disease (EVD) survivors and EVD close-contacts, and the impact on quality of life and mental health within Sierra Leone.

Methods: Cross-sectional study. Pediatric EVD survivors and first-degree close contact controls were identified through the Sierra Leone Association of Ebola Survivors and Ministry of Health. EVD survivor status was confirmed by Ebola serum IgG testing. Patients enrolled in this study underwent a medical questionnaire and, ocular examination, and Quality of Life was evaluated with the Pediatric Quality of Life Inventory Version 4.0 (PedsQL). PedsQL assessed holistic quality of life over 4 domains. 1) Physical Functioning 2) Emotional Functioning 3) Social Functioning 4) School function.

Results: A total of 86 Ebola affected pediatric patients were examined which included twenty-three EVD survivors and 63 close contacts. Of EVD survivors, 39.1% were female and mean age was 11.5 years. Among close contacts, 46% were female and mean age was 9.5 years. Higher prevalence of uveitis was observed in the EVD survivor (13.0%) cohort compared to close contacts (1.7%) ($p=0.032$). Overall, 56.5% and 42.9% of EVD survivor eyes and close contact eyes presented with an ocular diagnosis that impaired vision, there was no statistically significant difference. The PedsQL total score showed low overall quality life in both patient populations (60.6 vs 67.0, $p=0.250$). The emotional functioning domain parent report was significantly lower among parents of EVD survivors compared to close contacts (57.4 vs 70.0, $p=0.035$). The main driver was a greater number of parents of EVD survivors affirming the question: "I feel Sad or Blue" (48.21 vs 65.71, $p=0.035$)

Conclusions: We observed a high burden of ocular and psychosocial sequelae in pediatric Ebola survivors in Sierra Leone. While uveitis was observed with a higher prevalence in this cohort of pediatric EVD survivors, non-uveitis eye disease also led to substantial visual acuity impairment in both groups. Psychosocial health burden was also observed within this pediatric population, irrespective of EVD infection. Future studies that examine the relationship between eye health and mental health in pediatric EVD survivors could better define these important relationships, particularly given the current pandemic.

ABSTRACT BODY:

Purpose: We previously reported that a visual field (VF) measurement algorithm, which was named “smart Strategy”, using the Variational Bayes Linear Regression with KOWA AP-7000 (Kowa Company, Ltd., Japan) was useful for saving measurement duration while maintaining the same accuracy as the Swedish Interactive Thresholding Algorithm Standard with Humphrey Field Analyzer (Carl Zeiss Meditec, Dublin, USA) (Br J Ophthalmol in press). We developed a new time-saving algorithm “smart Strategy Alpha”, which was modified the thresholding algorithm from smart Strategy, and assessed its usefulness by comparing with a conventional algorithm “Quick 1” in healthy subjects.

Methods: 22 eyes of 12 healthy subjects were included in the current study. VF measurements were performed using smart Strategy Alpha and the conventional Quick 1 with KOWA AP-7000. The 24-2 tests were conducted in the VF measurements. Measurement duration and visual sensitivities were compared between these algorithms using the linear mixed model where the subjects were treated as random effects.

Results: smart Strategy Alpha measurement duration was significantly 55 % shorter than Quick 1 on average. Mean (standard deviation) measurement duration were 114 (28) seconds for smart Strategy Alpha, and 251 (29) seconds for Quick 1 ($p<0.001$). On the other hand, mean deviation (MD) values were no significant differences between these algorithms. Mean (standard deviation) MD values were 0.03 (0.92) dB for smart Strategy Alpha, and -0.18 (1.09) dB for Quick 1 ($p=0.19$).

Conclusions: smart Strategy Alpha saved measurement duration while maintaining the same accuracy as Quick 1 in healthy subjects.

ABSTRACT BODY:

Purpose: Visual perception of object-motion and self-motion is critical for safe mobility. However, the risks of accidents and falls during mobility increase with age, presumably due to functional vision loss. We used head-mounted display (HMD) virtual reality (VR) as a tool to understand how the visual perception of self-motion and presence (the feeling of being “there”) varies with age.

Methods: Eighty-six (86) healthy participants aged 18 to 77 (37 females) with normal or corrected to normal visual acuities and normal visual fields were recruited for this study. We measured illusory self-motion perception (vection) and presence when participants viewed radially expanding patterns of optic flow. Optic flow was generated using a HMD VR (Oculus Rift CV1) to simulated different speeds of self-motion. Viewing was performed with the head stationary (passive condition) or with lateral-sway head movements (active conditions).

Results: Presence increased with age ($F_{2,83} = 5.44$, $p < 0.01$). Vection did not significantly change with age ($F_{2,83} = 1.82$, $p = 0.17$). However, head movements had a significant impact on perceived vection ($F_{2,166} = 19.84$, $p < 0.001$). A significant interaction was also found between age and viewing condition ($F_{4,166} = 3.60$, $p < 0.01$). Main effects of simulated speed on perceived vection ($F_{3,249} = 367.89$, $p < 0.001$) and presence ($F_{3,249} = 112.64$, $p < 0.001$) were also found. These results show vection increases with the speed of simulated self-motion, but generally decreases with increasing age (Figure 1).

Conclusions: This study shows there are age-related changes in the perception of self-motion and spatial presence in HMD VR. Our findings suggest that the experience of self-motion perception decreases with age, particularly at slow speeds consistent with normal walking. This may provide further clues to why the elderly have increased risk of accidents and falls.

TITLE: Monocyte-derived macrophages take up residence in the retina following widespread photoreceptor degeneration

SESSION TITLE: Microglia and other Macrophages in Health and Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K. Ronning, M. Burns, Center for Neuroscience, University of California Davis, Davis, California, UNITED STATES|S.J. Karlen, M. Burns, Cell Biology and Human Anatomy, University of California Davis, Davis, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kaitryn Ronning: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Karlen: Commercial Relationship: Code N (No Commercial Relationship) | Marie Burns: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During retinal degeneration, microglia undergo dramatic changes in gene expression and morphology to clear debris and dying cells. Additionally, monocytes from the periphery can infiltrate the retina to join the microglia in the immune response to degeneration. After cell loss is complete a population of resident macrophages re-tile the retina but it remains unclear (1) whether these cells return to a normal “resting” microglial state and (2) whether monocyte-derived macrophages that had infiltrated remain in the retina as part of this population.

Methods: We used in vivo retinal imaging, immunohistochemistry (IHC), flow cytometry, and single-cell mRNA sequencing (scRNAseq) to investigate retinal macrophages before, immediately after, and several weeks after cell loss in a light-inducible model of photoreceptor degeneration ($Arr1^{-/-}$ mice, 0 through 20 days of light exposure). All mice were handled according to ARVO, NIH, and UC Davis IACUC guidelines.

Results: In vivo retinal imaging and IHC revealed that ramified macrophages re-tile the inner retina following the completion of photoreceptor loss. Many macrophages exhibited a normal “resting” microglial morphology, although the degree of complexity varied more than that of cells in the healthy retina. ScRNAseq showed that the population of CD45+CD11b+ cells remained transcriptionally heterogeneous, even as homeostasis was re-established. To clearly distinguish between microglial and monocyte-derived macrophage subpopulations, we used a fluorescent lineage tracing paradigm ($Arr1^{-/-}$ Ai9^{KI/KI} Cx3cr1^{+YFP-CreER}). These fate mapping experiments confirmed that monocyte-derived macrophages take up long-term residence, assume a ramified microglia-like morphology, and comprise approximately half of the population of immune cells in the retina after degeneration.

Conclusions: After photoreceptor degeneration is complete, the remaining inner retina contains a heterogeneous population of ramified macrophages that includes both microglia and monocyte-derived macrophages. These monocyte-derived macrophages adopt a microglia-like phenotype, including gene expression similar to mildly activated microglia and a ramified morphology, persisting for several weeks after recovery and accounting for a substantial portion of the re-established, long-lived resident macrophage population in the retina.

ABSTRACT BODY:

Purpose: Blue cone monochromacy (BCM) is a debilitating, rare X-linked retinal disease resulting from the congenital absence of both L- and M-opsins, that causes severely impaired color discrimination, low vision, nystagmus, and photophobia. We developed ADVN-062, a vector optimized for intravitreal (IVT) delivery aimed at restoring the cone-specific expression of human L-opsin (hL-Opsin). This vector utilizes AAV.7m8 capsid that has been demonstrated to provide efficient transduction of foveal cones in primate retina when delivered intravitreally and uses the opsin LCR and a minimal M-opsin promoter to express human L-opsin in cones. The present study evaluated the dose dependent safety as well as levels and localization of hL-Opsin expression to establish the tolerability and potential efficacy of IVT-delivered ADVN-062 in nonhuman primates (NHPs).

Methods: Cynomolgus monkeys were treated with 5E9, 5E10, or 5E11 vg/eye ADVN-062 or vehicle via bilateral IVT injection, and monitored for ocular and systemic tolerability for 8wk without any steroid treatment. Retinal levels of hL-Opsin in the presence of endogenous NHP opsins were measured using liquid chromatography-tandem mass spectrometry (LC-MS/MS) at 8wk post-treatment. Retinal localization was evaluated by immunofluorescence (IF) analysis by using another AAV.7m8-based vector made to express myc-tagged hLOpsin IVT delivered at the same doses as ADVN-062. Transduction efficiency was determined as a percentage of hL-Opsin.myc-positive foveal cones in a series of histological retinal sections.

Results: IVT administration of ADVN-062 was well tolerated up to the highest dose of 5E11vg/eye and resulted in dose-dependent hL-Opsin expression. Cone specificity was confirmed by colocalization of cone cell markers in IF analyses of retinas expressing myc-tagged hL-opsin. ADVN-062 at lowest dose of 5E9 vg/eye resulted in variable transduction of foveal cones from 4.8% to 49.8%, and doses at 5E10 and 5E11 vg/eye resulted in transduction of foveal cones from 17.7% to 85.3% in the individual animals.

Conclusions: Based on published studies of minimal foveal cone density sufficient to maintain good visual acuity in humans with retinal degenerative diseases or dichromatic vision, our data suggest that IVT ADVN-062 at well tolerated doses may effectively transduce sufficient numbers of foveal cones to potentially achieve clinical efficacy.

TITLE: Post hoc Analysis of Clinical Suprachoroidal Injection Experience for Non-infectious Uveitis

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Shah, Ophthalmology, Midwest Eye Institute, Indianapolis, Indiana, UNITED STATES|C. Wan, B. Kapik, T.A. Ciulla, Clearside Biomedical Inc, Alpharetta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Milan Shah: Commercial Relationship(s);Clearside Biomedical, Inc:Code F (Financial Support) | Cherry Wan: Commercial Relationship(s);Clearside Biomedical, Inc:Code E (Employment);Clearside Biomedical, Inc:Code I (Personal Financial Interest) | Barry Kapik: Commercial Relationship(s);Clearside Biomedical, Inc:Code E (Employment);Clearside Biomedical, Inc:Code I (Personal Financial Interest) | Thomas Ciulla: Commercial Relationship(s);Clearside Biomedical, Inc:Code E (Employment);Clearside Biomedical, Inc:Code I (Personal Financial Interest);Clearside Biomedical, Inc:Code S (Non-remunerative)

ABSTRACT BODY:

Purpose: To analyze procedural characteristics of suprachoroidal injections (SCIs) using the SCS Microinjector[®] in two uveitis trials. The SCS Microinjector reliably delivers drug to the suprachoroidal space (SCS), an alternative administration route for chorioretinal diseases. SCIs are first attempted with a 900µm length needle and switched to 1100µm length if required. Correlations between needle length, baseline patient characteristics, and physician device experience, via survey, are presented.

Methods: Post hoc analyses were performed to assess the relationship between needle length for baseline SCI and patient characteristics. Univariate analysis was conducted with Pearson chi-square analysis for categorical variables and the biserial correlation for continuous variables. Multivariate logistical regression was run to confirm univariate findings. Furthermore, a user experience survey was completed to evaluate real-world SCI experience.

Results: Of the 133 total baseline SCIs, 74% were completed with the 900µm needle; the remaining with the 1100µm needle. Univariate analysis revealed no relationship between needle length used and gender, lens status, uveitis sub-type, disease course or onset. Disease duration was statistically correlated with needle length: 91% of injections were completed with the 900µm needle for Limited (≤3 months) and 70% for Persistent (>3 months). Age was moderately inversely correlated with needle length. SCI quadrant was statistically related: 82% of supratemporal injections were completed with the 900µm needle compared to 45% of injections administered superonasally. Multivariate logistical regression verified univariate analysis demonstrating the potential impact of age, disease duration and SCI quadrant on needle length. In the user experience survey, over 80% of the physicians responded that SCIs presented no new challenges compared to other types of injections.

Conclusions: While these analyses are retrospective with a small sample size, few patient characteristics were found to correlate with needle length, indicating the procedure can be completed for the majority of patients with the 900µm needle and using a 1100µm needle in remaining patients. This suggests that SCIs with the SCS Microinjector has potential to reliably and repeatably deliver drugs for chorioretinal diseases in an in-office setting.

ABSTRACT BODY:

Purpose: Collagen, an abundantly distributed extracellular matrix protein, is known to maintain the structural integrity of organs and tissues in mammals, and it not only plays a physical function as a structural protein, but also has various biological functions that regulate cell adhesion, migration, and differentiation. In this study, we investigated the migration activity of cells in the human Müller cell line MIO-M1 with certain amino acid sequences displayed on the collagen triple helices, which can control cell adhesion, proliferation, and survival by arbitrarily incorporating collagen-derived functional amino-acid sequences.

Methods: The wells of 48-well plates were coated with a peptide polymer containing four kinds of functional amino-acid sequences (GFOGER, GLOGEN, GVXGFO, and KGHRGF) at the concentrations of 1, 3, 10, 30, and 100%, and 3mm RTV silicones were placed in the center of each well. MIO-M1 cell-line cells (5×10^4 cells/well) were then seeded in the periphery, and the silicones were removed when the cells reached 80% confluence. Photographs were taken immediately after removal and 72 hours later, the cell migration area was measured with ImageJ software, and the migration activity was then compared and evaluated to see if the migration area of the control (0%) was 1. Migration measurements were performed ($n=5$), and the mean value was calculated.

Results: In the GFOGER group, the migration activity was higher in the concentration of 10, 30, and 100% compared to the control, respectively ($p<0.001$, unpaired t test), as well as in the concentration of 3% ($p<0.01$, unpaired t test). In the GLOGEN and KGHRGF groups, the migration activity was higher in the concentration of 30% and 100% compared to the control ($p<0.01$, unpaired t test). In the GVXGFO group, the migration activity was higher in the concentration of 100% compared to the control ($p<0.01$, unpaired t test).

Conclusions: The findings in this study showed that collagen-derived functional amino-acid sequences improved the migration activity of MIO-M1 cell-line cells.

ABSTRACT BODY:

Purpose: Myopia has become a major public health concern, particularly across much of Asia. It has been shown in multiple studies that outdoor activity has a protective effect on myopia. It is also known that short-wavelength visible violet light is the component of sunlight that appears to play an important role in preventing myopia progression in the chick and in humans. The mechanism underlying this effect has not been understood.

Methods: Lens defocus-induced myopia (LIM) in mice was performed by attaching 0 diopter (D) lenses on the left eyes and -30 D lenses on the right eyes with a frame on their skull. Combined with 50 lux of white background fluorescent lamp light from 08:00 to 20:00 every day, $400 \mu\text{W}/\text{cm}^2$ (360 nm ~ 400 nm) of violet light was added either 3 hours pre-dawn (05:00~08:00), all daytime exposure (08:00~20:00), continuous violet light, 3 hours of evening (17:00~20:00), or 3 hours of post-dusk (20:00~23:00) for three weeks of the LIM period. The violet light sensitive atypical opsin neuropsin (OPN5) is specifically deleted in the retina by crossing Chx10-Cre⁺ mice with Opn5^{flx/flx} mice (OPN5 cKO).

Results: 3 hours of evening violet light combined with white light significantly suppressed both the refractive shift ($p=0.006$) and axial lengthening ($p=0.045$) compared to white light only in control mice. By contrast, OPN5 cKO mice with violet light showed a refractive shift and an axial length change indistinguishable from the normal white light condition.

Conclusions: These findings identify OPN5 expressing retinal cells as crucial for emmetropization in mice and further suggest a strategy for myopia prevention in humans.

SUBMITTER (NAME ONLY): Kelleigh Hogan

TITLE: Exposure to bright ambient lighting is not protective if started after induction of experimental myopia in mice

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Hogan, P. Mohanty, D. Brown, M. Pardue, Biomedical Engineering, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|M. Pardue, Atlanta VA Medical Center, Decatur, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kelleigh Hogan: Commercial Relationship: Code N (No Commercial Relationship) | Pooja Mohanty: Commercial Relationship: Code N (No Commercial Relationship) | Dillon Brown: Commercial Relationship: Code N (No Commercial Relationship) | Machel Pardue: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Increased exposure to bright outdoor lighting protects against myopic development in both animal and human studies. However, the typical experimental paradigm for animal studies starts the bright light exposure prior to or at the time of myopic induction. The objective of this study was to evaluate whether the protective effect of bright light was maintained when exposure occurred after the start of lens-induced myopia (LIM) in C57 mice.

Methods: C57BL/6J mice were housed in bright ambient lighting (10,000 lux, 12:12 cycle) starting on post-natal day 23 (P23, pre-LIM, n = 9) or P30 (post-LIM, n = 7), and compared to mice housed in mesopic lighting (50 lux, 12:12 cycle) for the entirety of the experiment (mesopic, n = 7). On P28, LIM was induced by placing a -10D lens over the right eye (OD) in a subset of animals in each lighting group. Measurements of refractive error using photorefractometry, corneal curvature using keratometry, and ocular axial measurements from SD-OCT were taken at baseline, 1 week, and 2 weeks post-LIM. Three-way repeated measures ANOVA analysis was used to compare the effects of lighting, treatment, and age on each measurement taken.

Results: Mice with lens defocus had significant myopic shifts (OD-OS) compared to naïve controls ($p < 0.05$). The magnitude of the myopic shift was dependent on light exposure group. Mice exposed to bright light pre-LIM had significantly smaller myopia shifts (-3.63 ± 0.50 D) compared to the mesopic group (-4.89 ± 0.80 D, $p < 0.05$). However, this protective effect was not maintained when exposure occurred post-LIM (-4.35 ± 0.80 D, $p > 0.05$). No significant differences were found between groups for corneal curvature or axial ocular parameters.

Conclusions: Pre-LIM exposure to bright ambient lighting resulted in the expected reduction in myopic severity, but post-LIM exposure did not offer any protection against myopia. These results suggest that protective light may be most effective as a prophylactic treatment rather than a therapeutic treatment to slow further myopic development. Future research will focus on the mechanism(s) for the protective effect of photopic lighting and how its effectiveness changes with myopic induction.

SUBMITTER (NAME ONLY): Eugenia Custo Greig

TITLE: Demographic Characteristics and Clinic No Shows in Patients with Chronic Eye Disease

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Custo Greig, R. Gonzalez-Colaso, K.H. Nwanyanwu, Ophthalmology, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eugenia Custo Greig: Commercial Relationship: Code N (No Commercial Relationship) | Rosana Gonzalez-Colaso: Commercial Relationship: Code N (No Commercial Relationship) | Kristen Nwanyanwu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patient no shows reduce ophthalmologic clinic efficiency and effective resource allocation. We performed a retrospective cohort study to determine the effect of demographic characteristics on appointment no shows among patients with chronic eye disease.

Methods: A chart abstraction was performed for encounters of patients 18 and older with a diagnosis of glaucoma, diabetic retinopathy (DR), or age-related macular degeneration (AMD) seen in the Yale Ophthalmology Department between January 2013 and December 2018. Only encounters with comprehensive ophthalmologists, retina specialists, and glaucoma specialists were considered in this analysis. Demographic characteristics recorded for each encounter included age, gender, race, ethnicity, language preference, and zip code. Zip code information was utilized to determine median household income according to 2010 census data. Medical diagnostic information included history of diabetes mellitus, hypertension, and history of mental illness. No show encounters were defined as all encounters where the patient failed to cancel their visit and did not sign-in to their scheduled appointment. A multivariate mixed logistic regression model—which clusters data to account for random effects driven by intra-patient correlation—was utilized to determine demographic factors affecting odds of visit no show.

Results: The current study analyzed 90,698 visits for 6,167 unique patients. Demographic characteristics that increased the odds of no show included: Hispanic ethnicity (OR 1.58/ $p < 0.0001$), Black race (OR 1.87/ $p < 0.0001$), and preferred language other than English (OR 1.31/ $p = 0.0004$). Financial factors that increased the odds of no show included Medicare (OR 1.19/ $p = 0.0006$) or Medicaid (OR 1.66/ $p < 0.0001$) as primary insurance and residing in a zip code with reduced median household income (OR 1.68/ $p < 0.0001$). Medical characteristics that increased the odds of no show included a diagnosis of mental illness (OR 1.44/ $p < 0.0001$) or DR (OR 1.21/ $p = 0.01$). Results are displayed in Table 1.

Conclusions: Our results highlight the influence of demographic, ethnic, and racial disparities on proper health care utilization among patients with sight threatening disease. Future interventions aimed at reducing appointment no shows could channel resources to the at risk-populations identified in this analysis, improving access to care and clinic efficiency.

TITLE: Clinical Presentation and Outcomes for Gunshot Wounds to the Orbit

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Meer, B.J. Nguyen, S. Bautista, B. McGeehan, C.A. Briceño, Department of Ophthalmology, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elana Meer: Commercial Relationship: Code N (No Commercial Relationship) | Brian Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Sana Bautista: Commercial Relationship: Code N (No Commercial Relationship) | Brendan McGeehan: Commercial Relationship: Code N (No Commercial Relationship) | César Briceño: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To characterize the clinical presentation, surgical management, long-term complications and outcomes of gunshot wounds to the orbit.

Methods: A retrospective chart review was conducted of all cases of gunshot wounds involving the orbit at an academic institution with a level 1 trauma center. Data included patient demographics, clinical presentation and exam over time, surgical intervention, and long-term outcomes. Descriptive statistics were calculated using mean and standard deviation for continuous measures and frequency and percentage for categorical measures. Tests of associations included Fishers exact tests for categorical data, Kruskal-Wallis rank sum tests, ANOVA, and in the case of repeated measures, generalized estimating equations.

Results: 88 patients with a history of gunshot wound involving the orbit were included with average age of 32.6 years old. Patient were 85.2% male, 75% African-American, 25% Caucasian, and 5.7% Hispanic. Mean follow up was 8.25 years. While injury varied, 53.4% presented with intracranial injury, 21.6% presented with open globe rupture, 80.7% with orbital fracture, 89.8% with lid laceration, 88.6% with vision loss, 92% with pain, and 76.1% with bullet fragments in the orbit on imaging. Surgery occurred for 59.1% of patients, of which 26.9% underwent primary enucleation, 11.5% evisceration, 44.2% fracture repair, and 17.3% another procedure (craniotomy, complex laceration repair, etc). Long-term complications included abnormal lid or globe position in 26.1% of patients, reduced visual acuity in 55.2%, and persistent pain in 50.6%. Predictors on initial presentation for persistent pain included intracranial injury ($p=.003$), pain ($p=.006$), presence of radiographic intraorbital foreign body (bullet/ bullet fragments) ($p=.002$), abnormal CNV2 sensation ($p=.041$), and corneal abrasion ($p=.031$) on clinical exam. Visual acuity improvement over time in individuals who did not receive enucleation or evisceration on presentation was not significant ($p = .09$). Worsening visual acuity was significantly associated with hyphema, vision loss, and presence of intraorbital foreign body on presentation ($p<.05$)

Conclusions: To our knowledge, this represents the first, largest clinical epidemiologic study that serves to provide insight into the clinical presentation, surgical intervention, and long-term outcomes of gunshot wounds to the orbit, which will guide both ophthalmologists and trauma physicians

TITLE: Prevalence of psychiatric comorbidities in patients with scleritis

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Kombo, Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|A. Abdel-Aty, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ninani Kombo: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Abdel-Aty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We performed a retrospective, observational clinical study to identify the prevalence of psychiatric comorbidities among patients with acute scleritis.

Methods: The records of 256 patients with scleritis who presented to the Yale New Haven Health System between January 1, 2013 to January 1, 2018 were retrospectively reviewed. Data was collected on patient comorbidities. The study was approved by the Institutional Review Board (IRB).

Results: We identified 256 patients with a diagnosis of scleritis, 232 (90.6%) had diffuse anterior scleritis, 10 (3.9%) had nodular anterior scleritis, 5 (2%) had necrotizing scleritis, and 9 (3.5%) had posterior scleritis. At least one psychiatric comorbidity was present in 61 patients (23.8%), and 38 patients (14.8%) had at least two psychiatric comorbidities. The most common was major depression (16.8%) followed by an anxiety disorder (12.5%). 14 patients (5.6%) had a substance use disorder. The prevalence of psychiatric comorbidities in our sample was significantly higher than population averages as reported by the National Institutes of Mental Health (23.8% compared to 18.9%, $p < 0.05$).

Conclusions: A high percentage of scleritis patients have a comorbid mental health disorder. Similar to other chronic illnesses, scleritis may be a significant psychosocial stressor for these patients. Mental health disorders may affect treatment compliance and patient outcomes. Future prospective studies will further elucidate the relationship between scleritis and mental health.

Commercial Relationships Disclosure (Abstract): Ying Li: Commercial Relationship: Code N (No Commercial Relationship) | Nan Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Xian Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Micah Chrenek: Commercial Relationship: Code N (No Commercial Relationship) | Jiaying Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jana Sellers: Commercial Relationship: Code N (No Commercial Relationship) | Brenner Charles: Commercial Relationship: Code N (No Commercial Relationship) | Eldon Geisert: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Boatright: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose: To test whether oral administration of nicotinamide riboside (NR), a nicotinamide adenine dinucleotide (NAD⁺) precursor, protects retina ganglion cells (RGCs) from neurodegeneration in the DBA/2J (D2) mouse model of age-related inherited glaucoma.

Methods: Method: NR administration in drinking water (4000mg/kg of body weight per day) started when DBA/2J mice were 9 months old. NR was dissolved in drinking water and changed twice per week, continuing to 13 months old. Control cohort identically received water with no added NR. Intraocular pressure (IOP) was measured every month until experiment completion. Pattern electroretinography (PERG) using a Celeris system (Diagnosys LLC, MA) was recorded before euthanizing mice at 12-13 months old. Retinas were harvested for whole mount immunofluorescence staining with RGC marker Brn3a and imaged by fluorescent confocal microscopy. Retinal NAD⁺ levels were enzymatically assayed (Abcam, CA).

Results: Results: 13-month-old D2 retinas showed diminished NAD⁺ concentration compared to 4 months old ones. Our data showed that aged D2 mouse retinal NAD⁺ level with NR oral supplementary treatment was significantly higher than which from vehicle treatment group. (9.69 ± 1.72 pmol/ul vs 4.24 ± 1.06 pmol/ul, $p < 0.05$, $n = 6$, Mann-Whitney-U test). The amplitude of PERG in NR treatment group (5.05 ± 0.33 uV, $n = 44$) was also significantly higher than in vehicle group (3.22 ± 0.27 uV, $n = 34$) ($p < 0.05$, t-test). Retinal immunofluorescent Brn3a⁺ cell counts were significantly higher in NR treatment group than age matched vehicle group (27016.50 ± 3721.17 vs 15114.92 ± 4387.32 , $n = 24$, $p < 0.05$, t-test). There was no significant difference in IOP between NR-treated and non-treated eyes at all observation time points from 9 months old up to 12 months old.

Conclusions: Conclusion: NR oral supplementation aids more RGC survival in aged DBA/2J mice, and potentially preserves retinal function via preventing age-dependent NAD⁺ level decline. The effect of rendering RGCs more resilient to glaucomatous damage in a glaucoma model suggests that NR is worth exploring as a therapeutic candidate in treatment of glaucoma.

ABSTRACT BODY:

Purpose: A prognostic 15-gene expression profiling (GEP) test is widely used for risk stratification in patients with uveal melanoma (UM). The goal of this cross-sectional survey study was to understand patient experiences following 15-GEP testing compared to alternative or no prognostic testing.

Methods: An online questionnaire was distributed by the Melanoma Research Foundation's CURE OM initiative that captured anonymous information regarding patient-reported experiences. Patients were asked validated series of questions regarding the decision to undergo prognostic testing and the extent to which they felt decision regret.

Results: Of the 177 survey participants, 159 (90%) reported wanting prognostic information at diagnosis, but only 124 (70%) remembered the doctor discussing prognostic testing with them. Of all respondents, 91 (51%) had 15-GEP testing, 33 (19%) had alternative prognostic tests, 48 (27%) did not have any prognostic testing, and 19 (11%) did not know (10% of respondents reported having multiple tests). Interestingly, 15-GEP patients reported feeling more involved in their health care decisions regarding testing than those receiving alternative testing only (WilcoxRS, n=85 and 21 respondents, respectively; p=0.0006). Of 15-GEP-tested patients, the vast majority (80/81 respondents, 99%) reported gaining value from their test result, including increased knowledge and understanding, more personalized treatment options, information relevant to life planning, and a sense of relief from uncertainty about the future. Patients who received prognostic testing experienced lower levels of decision regret than those who opted out of testing, independent of which prognostic tests were used (K-W, p=0.001; WilcoxRS post-hoc, n=85, 16 and 5 for GEP, other tests and no GEP; GEP vs. other tests: p=0.89, GEP vs. no GEP: p=0.0002, other test vs. no GEP: p=0.003). Importantly, decision regret levels did not differ depending on 15-GEP Class result (K-W; n=28, 23, 30 for 1A, 1B, 2; p=0.13).

Conclusions: The majority of newly diagnosed UM patients desired prognostic information, though testing options were not always introduced by the doctor. Prognostic testing with 15-GEP had considerable value to UM patients, independent of Class result, and having this test offered at the time of diagnosis was associated with an increased sense of shared decision making.

TITLE: L-Arginine inhibits myopia in the mammalian eye

SESSION TITLE: Molecular and Structural

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.A. McFadden, School of Psychology and HMRI, College of Engineering, Science and Environment, The University of Newcastle, Callaghan, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Sally McFadden: Commercial Relationship(s);University of Newcastle:Code P (Patent);ALCON:Code C (Consultant);Dopavision:Code C (Consultant)

ABSTRACT BODY:

Purpose: Ocular growth is regulated by the sign of imposed defocus and likely involves amacrine cells. We have previously reported that one particular class of amacrine cell changes its expression of nNOS in a bidirectional manner, being upregulated in myopic eyes, and down regulated in hyperopic eyes in the guinea pig retina. We manipulated the expression of nNOS by administering L-arginine and show here that myopia was also inhibited.

Methods: Two groups of guinea pigs (n=20) were raised with a -6D lens on one eye from 5-12 days of age and twice daily were administered eye drops containing either 0.9% Saline or 1.7% L-Arginine (LA). Drops were given 1 hr after lights on and 6 hrs later in the middle of their day cycle. Lenses were removed during the drop administration which occurred under dim red light or in darkness. At 12 days of age, animals were cyclopleged and refractive error measured. Eye length was subsequently measured in anaesthetised animals using high frequency ultrasound.

Results: At the end of lens wear period, the mean refractive error in untreated eyes did not differ between the two groups (LA: $+5.2 \pm 0.5$ D; Saline: $+5.1 \pm 0.8$ D, $p = .88$). Significant relative myopia developed in 10/10 animals given saline eye drops sufficient to compensate for the -6D of imposed defocus (Saline: -6.7 ± 0.5 D, $p = 0.000$). In contrast, 7/10 animals administered LA eye drops did not develop myopia in the lens-wearing eye and the relative myopia in these 7 animals (LA: -2.5 ± 0.7 D) or the mean across all 10 animals (LA: -3.6 ± 0.8 D) was significantly less than that in the saline treated animals ($p = .000$ and $p = .007$ respectively). The myopia induced by -6D lens wear was caused by a longer eye. Control eyes given saline eye grew by 115 ± 18 μm ; while in animals given LA, the mean growth in ocular length was only 42 ± 17 μm . This reduction in ocular growth caused by LA was highly significant ($p = .01$), and no relative growth occurred in the 70% of animals which failed to develop myopia.

Conclusions: LA eye drops protect the eye from developing myopia in 70% of animals, where the mean myopia was 37% of that in control animals, and completely eliminated the excessive growth normally associated with myopia.

ABSTRACT BODY:

Purpose: Dysfunction of corneal sensory nerves can manifest in a wide range of sensory alterations, spanning from insufficient sensation as found in neurotrophic keratopathy to dysesthesia observed in Dry Eye Disease, an ocular surface disorder estimated to affect 5% of the global population. Changes in corneal sensory nerve function after recovery from injury are not well understood. This study tested the hypothesis that corneal sensory nerves regenerated from ocular surface injury display alterations in their activity profiles.

Methods: The impact of regeneration from injury on corneal nerve properties was tested using two models of nerve injury—Corneal Epithelial Debridement (CED) and Benzalkonium chloride (BAK) chemical injury, in adult Sprague Dawley rats of both sexes. CED is one of the most common corneal injury models and was induced using a rotary burr tool, with the entire corneal epithelium removed while sparing the corneal limbus. BAK injury was administered as a prolonged (30min+) ocular instillation with 0.01% Benzalkonium chloride, a common preservative found in eye drops that can damage corneal epithelium and nerves. At 14 and 28 days post injury, corneal nerve functional profiles were assessed in anesthetized rats using in vivo electrophysiological recordings of the trigeminal ganglion, which houses the cell bodies of corneal nerves, while the cornea was exposed to a range of stimuli that activate ion channels responsible for corneal nerve sensation.

Results: Our preliminary data indicate that the two injury models lead to differential response profiles of regenerated nerves that can be observed at both 14 and 28 days post injury. Compared to injury-naïve rats (n=25), CED animals (n=10) showed signs of decreased responsiveness, with blunted responses to stimuli like ocular dryness, hyperosmolar stress, and temperature decreases of the ocular surface. Conversely, BAK-treated animals (n=13) displayed activity shifts toward increased responsiveness compared to injury-naïve animals, with augmented responsiveness to cooling and heating of the ocular surface.

Conclusions: Our findings suggest that corneal sensory nerves that regenerate from injury show long-lasting and differential alterations in their functional activity profiles that are dependent on the model used for ocular surface injury.

ABSTRACT BODY:

Purpose: To report the incidence and investigate risk factors for the development of keratoconus in a young adult cohort with consecutive Scheimpflug imaging over an 8-year period.

Methods: Participants of the Raine Study generation 2 (Gen2) birth cohort underwent an eye examination at the 20-year (age range 19-22 years) and 28-year follow-ups. Scheimpflug imaging (Pentacam, Oculus, Wetzlar, Germany) was performed at each follow-up. Keratoconus was defined as a Belin/Ambrósio Enhanced Ectasia Display D (BAD-D) score >2.6 in either eye. Data from the worst eye was used for analysis, except for conjunctival ultraviolet autofluorescence (CUVAF, a marker of ocular sun exposure) data where the sum area of both eyes was used. Participants were excluded if they had keratoconus at the 20-year follow-up, had a history of significant eye trauma, wore orthokeratology lenses or did not have Scheimpflug imaging at both follow-ups. Logistic regression was used to investigate potential risk factors for keratoconus incidence over 8 years of follow-up.

Results: Of the 1295 participants who had Scheimpflug imaging at the 20-year follow-up, 685 (53%) had Scheimpflug imaging at the 28-year follow-up and 677 (52%) were eligible for analysis (52% female). There were 20 (3.0%) new cases of keratoconus. The mean (range) worst eye BAD-D score in the incident keratoconus group was 1.70 (0.20 to 2.57) and 3.45 (2.63 to 6.15) at the 20- and 28-year follow-ups, respectively. Keratoconus incidence was not associated with spherical refraction, visual acuity or self-reported history of asthma, eczema or asthma ($p>0.05$) on univariable analysis. Greater astigmatism, steeper corneal curvature and a thinner central cornea at the 20-year follow-up were associated with higher risk of keratoconus, but we focused on the BAD-D score as a derivative of these variables. In a multivariable model including sex, CUVAF area and BAD-D score at the 20-year follow-up, male sex (odds ratio [OR]=3.84, 95% confidence interval [95%CI]: 1.30, 11.29) and higher BAD-D score (OR=14.7, 95%CI: 5.93, 36.6), but not CUVAF area (OR=0.98, 95%CI: 0.96, 1.00), were significantly associated with higher risk of keratoconus.

Conclusions: The incidence of keratoconus was 3% over 8 years in this, predominantly Caucasian, young adult cohort in Perth, Australia. Sex and BAD-D score at the 20-year follow-up were significantly associated with greater risk of keratoconus.

ABSTRACT BODY:

Purpose: To evaluate differences in retinal and choroidal vasculature and structure in cognitively healthy individuals with at least one APOE e4 allele (who are at a greater risk for Alzheimer's disease than those without an APOE e4 allele) compared to those without an APOE e4 allele using retinal and choroidal quantitative parameters as well as a convolutional neural network (CNN).

Methods: In this cross-sectional study, 188 eyes of 98 cognitively healthy individuals with at least one APOE e4 allele and 225 eyes of 117 individuals without an APOE e4 allele were imaged. Of these, 150 eyes of 84 APOE e4 participants and 169 eyes of 98 participants without APOE e4 were used to develop a CNN. Zeiss Cirrus HD-5000 with AngioPlex (Carl Zeiss Meditec, Dublin, CA) was utilized to acquire OCT and OCTA images; enhanced depth imaging foveal OCT scans were acquired and underwent image binarization to determine choroidal area and vascularity index. Generalized estimating equations (GEE) adjusted for age and sex were used to compare parameters between groups.

Results: The two groups were matched with regards to age, sex, and Mini-Mental State Examination score (all $p > 0.05$). After adjustment for covariates in a multivariable GEE model, the two groups did not significantly differ in superficial capillary plexus vessel density or perfusion density, foveal avascular zone area, ganglion cell layer thickness, retinal nerve fiber layer thickness, central subfield thickness, subfoveal choroidal thickness, total choroidal area, choroid luminal area, or choroidal vascularity index (all $p > 0.05$). A CNN was unable to discriminate between the two groups (area under the receiver operating characteristic value = 0.526).

Conclusions: Retinal thickness, retinal microvasculature, and choroidal vasculature in cognitively healthy individuals with APOE e4-based predisposition to Alzheimer's disease do not significantly differ from cognitively healthy individuals without an APOE e4 allele. Longitudinal study may help better identify the onset of retinal microvascular abnormalities in relation to the onset of cognitive impairment.

ABSTRACT BODY:

Purpose: Previously, we showed that drusen contain microscopic calcium phosphate mineral deposits such as hydroxyapatite (HAP), and proposed that they could initiate the growth of such sub-RPE deposits (PMID: 25605911). Further, we found that larger mineral deposits called nodules are strongly associated with progression to advanced AMD within one year (odds ratio 6.4), suggesting that early detection of mineral deposits might serve as a useful early screen for AMD (PMID: 30404862). While such mineral deposits are readily detectable in vitro with stains such as OsteoSense and BoneTag, these stains have unknown human toxicity, pharmacokinetics, and metabolism and aren't administered orally. By comparison, the tetracycline family of legacy antibiotics have been used safely in humans for decades, are mostly administered orally, and were known as fluorescent mineral stains. We found that chlortetracycline and doxycycline selectively stained retinal HAP with increased quantum yield and lifetime, such that chlortetracycline-stained drusen were readily resolved from the short fluorescence lifetime of the remainder of the retina (PMID 32319262). However, some of their other optical properties are suboptimal, so in this study we tested other tetracyclines and related compounds as fluorescence stains for retinal minerals for suitability in in vivo studies.

Methods: We measured the fluorescence spectra and lifetimes of legacy tetracyclines free in solution and bound to HAP and other minerals, and as stains for unfixed flat-mounted aging human donor retinas by fluorescence lifetime microscopy (FLIM). Of particular interest were stains spectrally compatible with existing fluorescence (lifetime) ophthalmoscopes used for fluorescein angiography and FLIO.

Results: Multiple tetracyclines exhibit useful changes fluorescence upon HAP binding. For example, free anhydrochlortetracycline excites at 473 nm, has peak emission at 587 nm, and exhibits a principal lifetime component (two-component fit) of 0.184 ± 0.006 nsec, fractional intensity 84%. However, when bound to HAP the principal component increases more than 7-fold to 1.42 ± 0.05 nsec, fraction 70%.

Conclusions: These data indicate retinal HAP stained with anhydrochlortetracycline or others will exhibit fluorescence resolved spectrally and in lifetime from the known background of the retina.

ABSTRACT BODY:

Purpose: Defocus in the periphery of the retinal image field maybe a factor in refractive development. Peripheral defocus is generally attributed to changes in globe shape or axial length. However, age-related changes in crystalline lens shape and optics may also be a factor. The goal is to quantify the lens contribution to the shape of the retinal image field and its changes with age.

Methods: Data were acquired on 70 isolated human lenses obtained from the Ramayamma International Eye-Bank, Hyderabad, India (age: newborn to 56 years, post-mortem time: 0.3 to 4.4 days). The lenses were placed in a combined Laser-Ray Tracing (LRT) and Optical Coherence Tomography (OCT) system (Ruggeri et al, Biomed Opt Exp, 2018). The LRT measures the slopes of on- and off-axis rays refracted through the lens. OCT images are used to reconstruct the 3D lens shape (Martinez-Enriquez et al, IOVS, 2020). Slopes of 49 rays from a 3 mm x 3 mm raster scan with 0.5 mm spacing were used to find the focus position (axial position that minimizes RMS spot size relative to centroid) for incidence angles ranging from -30° to +30° in 5° increment. The curvature of the measured image field was calculated from the variation of the focus position with the incidence angle. In addition, the radii of curvature of the tangential, sagittal, least confusion and Petzval surfaces were calculated from a model of the lens reconstructed using the lens anterior and posterior radii of curvature, thickness and calculated equivalent refractive index. The age-dependence of the field curvature obtained from the measurements and from the lens model constructed from the OCT images was quantified.

Results: The measured image field and calculated Petzval surface of the lens are concave and progressively flatten with age (shift towards less myopic peripheral defocus) (Figure 1). The measured field curvature is steeper than the curvature predicted using a uniform equivalent index, suggesting that the lens gradient contributes to field curvature.

Conclusions: Lens growth produces changes in the retinal image field curvature, which contribute to age-dependent changes in ocular peripheral defocus that may be a factor in refractive development.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has been disruptive to daily life, including those living with low vision (LV). We conducted a retrospective chart review to understand how chief complaints(CC) of those presenting for low vision services have changed.

Methods: A random subset of 121 charts from NECO Center for Eye Care LV Clinic between 2019 (group 1, pre-COVID-19, n=61) and 2020 (group 2, during COVID-19, n=60) were reviewed. Eligible charts included: those over 18 years, English-speaking, and without cognitive impairment. Group 1 patients were 19-96 years (mean 65, SD±23) with mean best-corrected visual acuity (BCVA) of 0.95 logMAR (SD±0.73, Snellen equivalent 20/178), and mean contrast sensitivity (CS) of 1.03 logCS (SD±0.48). Group 2 patients were 18-98 years (mean 64, SD±21) with mean BCVA of 0.77 logMAR(SD±0.63, Snellen equivalent 20/117) and mean CS of 1.08 logCS (SD±0.48). CCs were categorized as: reading, driving, technology, general LV exam (i.e no specific complaint), mobility, and watching television. Employment status, onset of LV, prior technology use, and home support were also noted.

Results: We found a significant difference between proportions of CCs reported in 2019 vs. 2020 (Cramer's V=0.32, p=0.028). For group 1, top three CCs were reading(52%), general LV exam(34%), technology(15%). For group 2, the top three CCs were reading(43%), technology(27%), general LV exam(12%). There was no significant difference in age, BCVA, CS between groups.

The proportions of CCs were significantly different for those with prior technology use (Cramer's V=0.42, p=0.001). Patients with prior technology use reported difficulties using technology at a greater frequency.

Employment status also influenced reported CCs (Cramer's V=0.29, p=0.006). Reading was the top CC amongst retirees(64%) and technology amongst the employed(30%).

Logistic regression was performed to further explore predictors of technology CCs. Prior technology use was a significant predictor (OR=6.2; 95% CI, 2.0-19.2). Onset of LV, BCVA, home support, and gender were not significant predictors. There was a trend, with more technology related complaints in Group 2 (Cramer's V=0.15, p=0.11).

Conclusions: When exploring chief complaints in 2019 and 2020, we find that there may be a shift in LV patient needs. We note a trend of increasing technology related complaints in 2020, of which prior technology use was a significant predictor.

ABSTRACT BODY:

Purpose: To evaluate the global structure-relationship with optical coherence tomography (OCT) structural measures and OCT angiography (OCTA) vascular measures in subjects with primary open angle glaucoma (POAG).

Methods: 147 eyes from 101 Chinese subjects with POAG underwent OCT and OCTA scans centered on the optic nerve head, and 24-2 visual field testing using standard automated perimetry. A customized algorithm was applied to remove major vessels from the OCTA scans. For each eye, the mean circumpapillary retinal nerve fiber layer thickness from OCT (MRNFL) and mean binarized capillary density from OCTA (MCD) were calculated. Multi-variate regression analysis was performed with the visual field mean deviation (MD) as the dependent variable, and MRNFL and MCD as the predictor variables. Likelihood ratio testing was used to assess the fit of the model with MRNFL and MCD against univariate models trained using either measures separately.

Results: Mean age of the subjects was 63.48 ± 1.05 years and mean visual field severity was -3.74 ± 0.25 dB. Coefficients of MRNFL and MCD from the multi-variate regression analysis were both significant ($P < .001$). Likelihood ratio testing showed that the multi-variate model was significantly better ($P < .001$) than the univariate models using MCD or MRNFL. Predicted mean deviation from the multi-variate model achieved a Pearson correlation coefficient of 0.48 with MD, compared to 0.40 with MCD and 0.37 with MRNFL.

Conclusions: Structure-function modelling using both structural and vascular measures was better than univariate models using either structural or vascular measures, suggesting that combining both can provide complementary information to improve the structure-function relationship.

ABSTRACT BODY:

Purpose: To evaluate the accuracy of using unsegmented radial and circle OCT scans of the optic nerve head (ONH) in deep learning (DL) models to detect glaucoma and estimate visual field (VF) mean deviation (MD).

Methods: Spectralis ONH radial circle (ONHRC) scans from 192 healthy subjects (330 eyes) and 441 glaucoma patients [DMC1] (712 eyes) provided 2,601 OCTs with 62,424 radial and 7,803 circular B-scans for analysis. The ONH-centered OCTs consisted of 24 equally-spaced radial B-scans and 3 circular B-scans at diameters of 3.5mm, 4.1mm, 4.7mm. VF data consisted of 24-2 testing collected within 180 days of imaging. Subjects were randomly divided into independent training (85%), validation (5%), and test (10%) sets. Individual DL models were trained to

distinguish healthy vs. glaucoma eyes and predict VF MD based on unsegmented (1) radial and (2) circular B-scans using Resnet50 models. Diagnostic accuracy was evaluated using area under the receiver operating characteristic curve (AUC) and examined as a function of B-scan type (radial vs. circle), diameter, position, and glaucoma severity. VF estimation was evaluated using R^2 and mean absolute error (MAE).

Results: DL models using radial B-scans detected any glaucoma with an AUC (95% CI) of 0.77 (0.63 – 0.87), mild glaucoma (MD \geq -6.0 dB) with 0.69 (0.47 – 0.82), and moderate-to-severe glaucoma (MD $<$ -6.0 dB) with 0.86 (0.72 – 0.94). DL models using circular B-scans detected glaucoma with an AUC (95% CI) of 0.84 (0.76 – 0.89), mild glaucoma with 0.75 (0.66 – 0.83), and moderate-to-severe glaucoma with 0.97 (0.94 – 0.98). In detecting glaucoma, circular B-scan diameter had relatively little impact on performance, while radial B-scan position had a larger impact on performance (Figure 1). For predicting VF MD, DL models using circle scans performed better ($R^2 = 0.83$, MAE = 1.8 dB) than models using radial scans ($R^2 = 0.77$, MAE = 1.8 dB).

Conclusions: Circular B-scans outperformed radial in detecting glaucoma and performed comparably in estimating VF damage. However, radial orientation had a substantial impact on glaucoma detection accuracy. DL models that better exploit positional information could help increase accuracy.

ABSTRACT BODY:

Purpose: The purpose of this study is to investigate changes in epithelial thickness (ET) and total corneal thickness (TCT) one year after crosslinking surgery combined with photorefractive keratectomy (CXL+PRK) and whether these changes are related to post-operative visual and refractive outcomes.

Methods: 10 eyes with keratoconus from 10 subjects were imaged with a Scheimpflug topographer and a research grade swept-source optical coherence tomographer (SS-OCT) no more than one month prior to receiving CXL+PRK surgery and again one year later. The pre-operative thicknesses of the cornea and epithelial layer at the point of minimum total corneal thickness were acquired from the SS-OCT images using custom processing software. Regression analysis was used to explore associations with corneal thickness changes and visual and refractive outcomes one year after surgery.

Results: The mean pre-operative corneal ET ($54.5 \pm 3.4\mu\text{m}$) was not significantly different than the ET at the one year follow-up ($54.3 \pm 5.0\mu\text{m}$; $p=0.46$). The average pre-operative TCT ($478.0 \pm 33.2\mu\text{m}$) was significantly greater than the same measurement one year later ($438.5 \pm 15.4\mu\text{m}$; $p=0.00065$). Individual data demonstrated both increases and decreases in ET and TCT measurements, with changes up to 17% for some participants. Changes in ET were significantly associated with changes in best corrected spectacle acuity ($R^2=0.42$; $p=0.043$) and coma ($R^2=0.75$; $p=0.0012$), but not changes in refractive error ($p>0.05$). Changes in TCT were not significantly associated with changes in VA, coma or refractive error ($p>0.05$ for all).

Conclusions: Mean central TCT measurements were significantly less at the one year follow up but ET did not show a significant change. Both increases and decreases in individual thickness data were observed. Only changes in ET were significantly correlated with changes in VA and coma such that thickness changes were inversely proportional to VA changes and directly proportional to changes in coma.

TITLE: Systemic factors associated with diabetic macular edema in a New Mexico population

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.A. Marek, R.N. Mankad, G. Acosta, A. Cabrera, F. Monickaraj, A. Das, University of New Mexico School of Medicine, Albuquerque, New Mexico, UNITED STATES|A. Das, New Mexico VA Health Care System, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lauren Marek: Commercial Relationship: Code N (No Commercial Relationship) | Rushi Mankad: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Acosta: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Cabrera: Commercial Relationship: Code N (No Commercial Relationship) | Finny Monickaraj: Commercial Relationship: Code N (No Commercial Relationship) | Arup Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The diagnosis of diabetic macular edema (DME) in Type I and Type II diabetics has been associated with various risk factors that correlate with progression of disease. In order to further understand the multi-factorial nature of this disease, we performed a retrospective cohort study to further examine the role of potential systemic factors associated with the development of center-involving DME among a patient population in New Mexico.

Methods: Data on 24 systemic factors was collected from 121 patients seen between February 1, 2018 and February 1, 2020 with either Type I or Type II diabetes and a known diagnosis of center-involving DME (based on OCT). These patients were then compared to a control of 69 patients with mild non-proliferative diabetic retinopathy (NPDR). Each continuous variable was statistically analyzed with chi-squared or Fisher exact test.

Results: Our analysis revealed a statistically significant difference between DME patients and the control for the following risk factors: elevated systolic blood pressure ($p < 0.016$), insulin use ($p < 0.001$), and macroalbuminuria ($p < 0.001$). There was no correlation to the levels of HbA1c, cholesterol, LDL, HDL, triglycerides, and GFR. The majority of American Indians in our cohort did not have any center-involving DME.

Conclusions: Our results show that there was no correlation between HbA1c level and development of center-involving DME. Similarly, there was lack of correlation between lipid levels and DME. The strongest associations with DME were elevated systolic blood pressure, insulin use, and macroalbuminuria. American Indians in this population appear to be protected from center-involving DME. Our ongoing genomics study using whole exome sequencing will identify the possible genetic factors related to development of DME.

TITLE: Intense Light Stress Activated Necrosomes in Wild-Type but not RPE65-Null rd12 Mouse Retina

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Jin, C. Lu, S. Li, Neuroscience Center of Excellence, LSU Health New Orleans, New Orleans, Louisiana, UNITED STATES|M. Jin, Department of Ophthalmology, School of Medicine, LSU Health New Orleans, New Orleans, Louisiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Minghao Jin: Commercial Relationship: Code N (No Commercial Relationship) | Chunfeng Lu: Commercial Relationship: Code N (No Commercial Relationship) | Songhua Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Photoreceptors in wild-type, but not in RPE65-deficient, mouse degenerate in response to intense light damage. The mechanisms resulting in photoreceptor death or survival in these different genotype mice remain largely unknown. The purpose of this study was to know whether necrosome activation contributes to determination of the different fates of photoreceptors in wild-type and rd12 mice exposed to intense light.

Methods: Wild-type 129S2/Sv mice and rd12 mice treated with 9-cis-retinal (a functional iso-chromophore) or vehicle were exposed to 15000 lux light for different times. Photoreceptor degeneration was evaluated by peanut agglutinin (PNA)-staining, immunohistochemistry and immunoblot analysis of opsins. Expression of receptor interacting protein kinase 1 (RIPK1), RIPK3, and mixed lineage kinase domain-like protein (MLKL) in the retinas was analyzed by immunohistochemistry and immunoblot analysis. Activation of MLKL was assessed by detecting its phosphorylation. Correlation between photoreceptor degeneration and RIPK1 expression was determined by Spearman's correlation analysis. Interaction of the necrosome proteins (RIPK1, RIPK3, and MLKL) was analyzed by double-immunostaining and immunoprecipitation.

Results: Intense light induced a time-dependent rod and cone degeneration as well as gradual upregulation of RIPK1 expression in wild-type mice. Spearman's correlation analysis showed a negative correlation between photoreceptor degeneration and RIPK1 expression levels in the light exposed wild-type retinas. Intense light stress induced upregulation of RIPK1 in the retinas of rd12 mice treated with 9-cis-retinal, but not treated with vehicle. Expression of RIPK3 was markedly increased in the wild-type but not rd12 mouse retinas exposed to intense light. Retinal photodamage promoted colocalization and interaction of RIPK1 and RIPK3 in the photoreceptors of wild-type mice. Phosphorylation of MLKL was significantly increased in the wild-type retinas, but not in rd12 retinas, under the same light conditions.

Conclusions: Our results indicate 1. activation of the necrosomes contributed to light-induced photoreceptor degeneration and 2. functional visual pigments are required to activate the necrosomes in the photoreceptors under intense light stress.

ABSTRACT BODY:

Purpose: To clarify the mechanism of dysregulation in ATP-binding cassette transporter A1 (ABCA1) for the pathogenesis of glaucoma.

Methods: Experiments were performed using DBA/1J (wild type, WT) and ABCA1 deficient (KO) mice. Gfap-Cre::flox/flox ABCA1 and Gfap-Cre mice were used as astrocyte-specific ABCA1KO (Astro-cKO) and control mice, respectively. Intraocular pressure (IOP) was measured using a rebound tonometer. The number of retinal ganglion cells (RGCs) in the whole-mount retina was estimated by labeling them with an anti-Brn3a antibody. TdT-mediated dUTP nick end labeling (TUNEL) was performed to detect apoptotic cells. To investigate the complexity of RGC dendrites, the mice were crossed with Thy1-GFP mice to visualize their morphologies. For a detailed analysis of the optic nerve, we used serial block-face scanning electron microscopy (SBF-SEM). The ocular function was evaluated using a multifocal electroretinogram (mfERG).

Results: ABCA1KO mice showed no IOP elevation, reduction in RGC number, and an increase in apoptotic cells at 12 months old but not at 3 months old. ABCA1 signals were localized at the nerve fiber layer and co-localized with GFAP but not with vimentin signals, indicating predominant expression in astrocytes. Astro-cKO mice showed age-associated RGC degeneration without IOP elevation, atrophy of dendritic arbor of RGCs, thinning of retinal layers, axonal swelling, and impaired ocular function.

Conclusions: These data suggest that loss of function of ABCA1 is essential for glaucoma, especially astrocytic ABCA1 is important and triggers normal-tension glaucoma-like phenotype in mice.

TITLE: Real World Safety Profile of Fluocinolone Acetonide 0.18mg Injectable intravitreal Implant (FAi) in Chronic Uveitis

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Andrews, S. Hamdan, S. Gangaputra, S.J. Kim, Ophthalmology, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hans Andrews: Commercial Relationship: Code N (No Commercial Relationship) | Saif Hamdan: Commercial Relationship: Code N (No Commercial Relationship) | Sapna Gangaputra: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: FAi is a novel therapeutic agent, and little is known about its safety profile in the real-world setting. A retrospective chart review was performed to assess the safety of long-acting FAi in the management of chronic noninfectious uveitis.

Methods: A retrospective review of 103 eyes that received FAi was completed. Outcome variables included immediate and long-term complications such as intraocular pressure (IOP) events, visual acuity (VA) decrease, and cataract surgery events.

Results: Results are reported as the proportion of eyes with available data at each follow up visit. There were no recorded immediate complications of the injection procedure. Anterior chamber implant migration occurred twice among all 103 eyes during the study period. Median IOP at baseline was 16 (IQR 14-19). 2% of study eyes experienced a 10 mmHg or greater increase in IOP 1 month from baseline (n=2/84), 7% at 3 months (n=5/74), and 4% at 6 months (n=3/61). IOP lowering therapy was necessary for 19% of eyes by 6 months (13/61) with two eyes requiring surgical intervention. A 2-line visual acuity decrease was reported in 6% of eyes at 1 month (5/84), 9% at 3 months (7/74) and 9% of eyes at 6 months (6/61). 4 of the 14 phakic eyes at baseline required cataract surgery by 6 months.

Conclusions: In this series, FAi for chronic uveitis had lower rates of steroid-induced increase in IOP as compared to conventional intravitreal steroids and incidence of cataract surgery consistent with those published in the literature.

Commercial Relationships Disclosure (Abstract): Michael Singer: Commercial Relationship(s);Allergan:Code F (Financial Support);Genentech:Code F (Financial Support);Regeneraon:Code F (Financial Support);Alimera:Code F (Financial Support);Optos:Code F (Financial Support);oxurion:Code F (Financial Support);Eyepoint:Code C (Consultant);aerie:Code F (Financial Support);Novartis:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To better understand the timing of IOP >25 mmHg in the PALADIN Study

Methods: The PALADIN study is a 3-year observational US based prospective trial designed to explore safety signals with FAc when used in a real-world observational setting. A subset of patients' eyes with IOP > 25 mmHg were further analyzed from the PALADIN 24-month completer readout.

Results: Among 115 eyes reported, 37 events of an IOP >25 mmHg were reported. Among this group, there were 9 reported events of IOP > 30 mmHg. The majority of the eyes who experienced an IOP >25mmHg had received additional DME therapies during the follow-up period; they also had a baseline IOP > 15mmHg (76.9%). A small number of eyes with IOP > 25 mmHg were reported at all visits through month 24 with more occurring in year 1 vs year 2. 27% of events of IOP>25 mmHg occurred by 3 months. 49% occurred by 6 months, 62% by 9 months, and 72% occurred by month 12. Through 24 months, there were 9 events of IOP >30mmHg. Of the 9 events of IOP >30mm Hg, 78% were reported within the first 12 months of treatment, with the earliest being reported at month 2.

Conclusions: : A rise in IOP above 25mmHg is reported in a minority of eyes. 70% of eyes who experienced this event had it in year 1. Patients should have their IOP monitored at regular intervals to ensure timely detection of any IOP rise.

ABSTRACT BODY:

Purpose: Though considerable work has been performed studying the retinal microvasculature in patients with uveal melanoma (UM) after plaque brachytherapy, the effects of proton beam therapy (PBT) on this microvasculature are not as well understood. We performed a cross-sectional study of patients with uveal melanoma who underwent proton beam therapy in order to assess retinal vascular changes at the macula and the peripapillary region using optical coherence tomography angiography (OCTA).

Methods: We analyzed OCTA data from 17 adult patients with UM treated with PBT more than one year ago who returned for follow-up. OCT and OCTA data from the treated eye, including parafoveal capillary density from both superficial and deep plexuses, radial peripapillary capillary (RPC) density, and choriocapillaris flow ratio, were compared to the fellow untreated eye using Student's t-test.

This study was approved by the University of California, Davis Institutional Review Board.

Results: Several OCTA features demonstrated statistically significant differences between the two study groups. Peripapillary retinal nerve fiber layer (RNFL) thickness was decreased in the treated eyes as compared to the fellow eyes (88 μ m vs 102 μ m, $p = 0.01$). RPC density was also decreased in the same manner (42% vs 49%, $p = 0.02$). As previously described, the foveal avascular zone (FAZ) perimeter was increased in treated eyes.

Conclusions: The microvasculature of the macula and notably radial peripapillary capillary density are negatively impacted in eyes which have undergone PBT for UM, even in eyes without clinical signs of radiation maculopathy or papillopathy. This is consistent with existing data showing similar changes with plaque brachytherapy. The susceptibility of this plexus to radiation damage is not fully understood but may be further elucidated with additional study of larger patient populations.

TITLE: Examining the relationship between injector lumen diameter and exposed endothelial surface area and tissue conformation of DMEK tissue scrolls

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Schmidt, M.A. Greiner, J. Ling, C. Sales, Iowa Lions Eye Bank, Iowa City, Iowa, UNITED STATES|Y. Kam, M.A. Greiner, J. Ling, C. Sales, Ophthalmology and Visual Sciences, The University of Iowa Hospitals and Clinics, Iowa City, Iowa, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yong Kam: Commercial Relationship: Code N (No Commercial Relationship) | Gregory Schmidt: Commercial Relationship: Code N (No Commercial Relationship) | Mark Greiner: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Ling: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Sales: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The relationship between Descemet membrane endothelial keratoplasty (DMEK) tissue and injector devices is important to understand, particularly as options for tissue insertion expand. We hypothesize that the outer endothelial surface area of a DMEK scroll, which is exposed to trauma during tissue injection, is reduced when the internal diameter (ID) of the distal tube is narrowed.

Methods: DMEK tissues not suitable for transplantation (n=2, 8.0mm diameter) were loaded into either a Straiko or LEITR modified Jones tube (Gunther Weiss). Tissues were ejected from the proximal to the distal end of each tube, and images were captured using optical coherence tomography (OCT, Optovue RTVue) with the tissue positioned at the distal tube. The ID at the narrowest distal tube, as well as the DMEK scroll diameter as it passed through this point, were measured using ImageJ software. Using the measured diameter of the DMEK scrolls, we calculated the outer scroll surface area assuming that DMEK tissue forms a uniform cylinder.

Results: The narrowest ID measured at the distal end of the Straiko and LEITR tubes was 1,200µm (mean, 1,237µm±35; n=3) and 860µm (mean, 905µm±45; n=3), respectively. The diameter of the DMEK scroll at the narrowest ID of the Straiko and LEITR tubes was 1,122µm (mean, 1,174µm±83; n=3) and 795µm (mean, 884µm±80; n=3), respectively. The calculated DMEK outer scroll surface area was 27.3mm² for the Straiko and 19.7mm² for the LEITR tube, which represents a 27.8% decrease in exposed endothelial surface area for the LEITR compared to the Straiko tube. Qualitatively, DMEK tissues do not always form a uniform cylindrical conformation in either injector and sometimes form irregular corrugations (Figure 1).

Conclusions: In this series, DMEK tissue scroll diameter decreased in order to conform to the smallest luminal diameter of the injector. Reducing the injector's distal lumen size may result in a significant decrease in endothelial cells potentially exposed to trauma from the injector. However, tissue scroll conformation may be increasingly altered as the lumen narrows. Further studies are needed to assess the impact of lumen diameter on scroll conformation and endothelial cell loss.

TITLE: Quantification of Localised Wedge-Shaped Vessel Defects in Glaucoma

SESSION TITLE: Imaging in Glaucoma II: Basic and Clinical Studies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Saks, A. Schulz, S.L. Graham, Faculty of Medicine, Health and Human Sciences, Macquarie University, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Danit Saks: Commercial Relationship: Code N (No Commercial Relationship) | Angela Schulz: Commercial Relationship: Code N (No Commercial Relationship) | Stuart Graham: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Since vascular factors may be involved in the pathogenesis of glaucoma, the distribution and pattern of vascular dropout may reflect particular phenotypes. Previous optical coherence tomography angiography (OCTA) case reports have described a wedge-shaped vessel defect that projects from the optic nerve head (ONH) around the fovea in an arcuate manner, similar to retinal nerve fibre layer (RNFL) defects. This study investigates the prevalence and quantification of this vessel loss and its relationship to other parameters.

Methods: Spectral domain OCT and OCTA images from 299 subjects with suspect, early or moderate primary open angle glaucoma were reviewed (age: 67.5 ± 10.65 years; mean deviation (MD): $+2.38$ to -11.45 DB, mean = -1.63). Good quality OCTA images from 545 eyes were exported to ImageJ for analysis and to identify defects. Area and vessel density within the defect were quantified at the superficial vascular complex (SVC) level. Focal RNFL thinning was determined as a wedge-shaped defect of multiple confluent points below the 95% confidence interval.

Results: Vessel wedge defects were present in 10.8% of OCTA images (59/545 eyes; 68.9 ± 10.31 years; MD: $+2.11$ to -11.45 DB, mean = -3.27 , $p < 0.001$ compared to total cohort). Of these, 83% were located inferotemporally, including 6 eyes with both superior and inferior involvement. 47 wedge defects were able to be fully quantified due to location of the wedge relative to scanned area. Vessel density within the wedge defect averaged $16.45 \pm 6.08\%$, which was 81% of the global macular SVC density. Wedge area was on average $5.51 \pm 4.54 \text{ mm}^2$, with a width of $0.36 \pm 0.16 \text{ mm}$ at the ONH. In all eyes with wedge vessel loss, wedge-shaped RNFL thinning was identified in the corresponding region of the OCT scan. Those with vessel wedge defects also had, on average, $5 \mu\text{m}$ thinner peripapillary RNFL when compared to the total cohort ($p = 0.001$). However, analysis between global vascular and structural parameters showed only weak or no correlations.

Conclusions: This study quantified wedge-shaped vessel loss in a cross section of glaucoma patients and showed that approximately 11% of subjects have defects, predominantly inferiorly, that correlate with RNFL loss. The association between localised vessel loss and RNFL loss suggests there may be a common physiological cause, yet the temporal relationship between these factors is still to be defined and should be explored in a future longitudinal study.

TITLE: Perimeter bowl disinfection during the COVID-19 pandemic

SESSION TITLE: Healthcare Delivery during Covid Pandemic

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Romero, R. Bourque, T. Callan, K.G. Foote, E. Larson, R. Sprowl, A. Tamhakar, B. Gilbertson, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kique Romero: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Robert Bourque: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Thomas Callan: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Katharina Foote: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Eric Larson: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Robert Sprowl: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Ashwini Tamhakar: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Brad Gilbertson: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Automated bowl perimeters present unique challenges for disinfection between patients during the SARS-CoV-2 (COVID-19) pandemic. International public health guidelines recommend the use of 70% isopropyl alcohol (IPA) or Ultraviolet-C light (UV-C) for disinfection. In this study we evaluated the effect of repeated exposure on the visual field stimulus in Humphrey Field Analyzers.

Methods: We subjected perimeter bowls (HFA3 Model 860, ZEISS, Dublin, CA and HFATM II-i, ZEISS, Dublin, CA) to highly accelerated life tests (HALT) for exposure to IPA or UV-C. For IPA, the device was sanitized with an IPA atomizing spray 15 times, followed by an 84hr IPA deep soak of components integral to the stimulus. For UV-C (Figure 1), materials of concern were irradiated with a 254nm light for a cumulative lifetime exposure of 22.8 kJ/cm². This represents an excess of 75,000 disinfection cycles at above the 1-Log Reduction (D_{90}) dose for COVID-19. The effect on the visual field stimulus (combination of projected stimulus and background illumination) was evaluated either by auto verifying that the correct luminance values were recorded at calibrated positions on the instrument or by manually measuring the chromaticity and luminance of the bowl.

Results: Automatic verification tests on an HFA3 after exposure, showed that the instrument was within tolerance with a reading error spread less than 1dB for an attenuation range of 0-34dB (Table 1). UV-C exposure to the HFA II-i bowl itself resulted in a shift of less than 0.002 in chromaticity and 18fL in luminance. Other plastics (chin rest, cover, and baffle) were visibly affected by UV-C and exhibited a shift in chromaticity (> 0.02) and luminance (> 114fL) but this did not affect the visual field stimulus.

Conclusions: There was no effect on the visual field stimulus in an HFA3 or an HFA II-i after repeated exposure to 70% IPA or UV-C at 254nm for the lifetime of the instrument. There was visible solarization on some plastics, however these did not affect the test performance; they were either outside the bowl or were compensated by the stimulus intensity.

ABSTRACT BODY:

Purpose: To investigate the effect of Defocus Incorporated Multiple Segments (DIMS) lenses on choroidal thickness in schoolchildren

Methods: 183 myopic Chinese schoolchildren aged from 8-13 years were recruited in a 2-year double-masked and randomised clinical trial. They were either treated with DIMS lenses (n=93) or single vision (SV) lenses (n=90) in a random allocation for 2 years. Baseline measurements including cycloplegic refraction, axial length and subfoveal choroidal thickness (SFChT) were collected before the lens wear. SFChT were obtained from Ocular Coherence Tomography (OCT) images acquired by Heidelberg Spectral Domain OCT. SFChT were measured at 1 week, 1, 3, 6 months post lens wear. Cycloplegic refraction, axial length and SFChT were monitored in a 6-month interval afterwards.

Results: SFChT significantly increased after 1 week of DIMS lens wear compared to those wearing SV lenses (mean change relative to baseline \pm SD at 1 week; DIMS vs. SV; $6.57 \pm 13.54 \mu\text{m}$ vs. $-3.01 \pm 10.70 \mu\text{m}$; $p < 0.001$, repeated measure two-way ANOVA). The magnitude of the thickening increased in the first 6 months of DIMS lens wear. The choroidal thickening sustained during the 2-year lens wear (mean change relative to baseline \pm SD at 24 months; DIMS vs. SV; $13.45 \pm 26.06 \mu\text{m}$ vs. $-9.54 \pm 23.15 \mu\text{m}$). The changes in SFChT at 1 week showed a significant negative correlation with the changes in axial length at 24 months (Pearson $r = -0.2822$, $p < 0.001$).

Conclusions: Schoolchildren with DIMS lens had a significant thicker choroid at subfoveal region after 1 week of lens wear. The magnitude of choroidal thickening maintained throughout the DIMS lens wear for 2 years. Our results demonstrated that the myopic control effect by incorporating defocus produced a long-term and sustained choroidal thickening.

ABSTRACT BODY:

Purpose: Myopia (short-sightedness) is caused by excessive ocular growth. Hyperopic defocus can experimentally induce myopia, however the underlying mechanisms are not fully understood. Dopamine, retinoic acid and nitric oxide are intrinsic to eye growth and each helps regulate retinal gap-junction conductance. As such, cell-cell coupling may play an important role in the propagation of ocular growth signals in the retina. We investigated whether coupling between A-type horizontal cells (HC) is altered in myopic guinea pig retina.

Methods: Myopia was induced in guinea pigs from p6 using -6 diopter lenses covering one eye for 14 days. Coupling was assessed using cut-loading. Briefly; whole retinas were sustained in Ames solution (37°C, bubbled with 95% O₂ 5% CO₂) and a cut made with a scalpel blade coated in neurobiotin (3% wt/v in Ames media). Retinas were incubated for 25 minutes to allow dye to transfer, fixed (4% PFA 30 minutes), reacted with streptavidin (1:100 in PBS) and imaged using a confocal microscopy. Dye-transfer through HCs was modelled by measuring the decline in cell fluorescence per distance from the cut. For lighting experiments, animals were either dark or light-adapted for one hour prior to euthanasia and retinas were sustained in these lighting conditions for all subsequent stages.

Results: Lens-wearing Guinea pigs developed -4.95D of relative myopia in the lens-wearing eye compared with the contralateral control (W=-2.521, p=0.012). Across both eyes, A-type HCs were more extensively coupled in the superior retina than the inferior (F=7.684, p=0.024). The lens-wearing eye displayed significantly increased A-type HC coupling within both the superior and inferior retina under dark-adapted conditions relative to the contralateral control (F=6.556, p=0.034).

A-type HC coupling was dependant on the lighting environment, with light-adapted retinas displaying reduced coupling compared to dark-adapted retinas (F=17.587, p=0.001).

Conclusions: A-type HC-coupling is locally higher in superior retina which is naturally more myopic. Myopia development enhances coupling further and is possibly involved in propagating ocular growth signals in response to ocular defocus. Since coupling in A-type HCs is also enhanced by dark adaption, and conversely reduced by the light, it is possible that light stimulation may be used to counteract myopia development.

TITLE: Psychosocial Impact of Demodex Blepharitis

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Yeu, Virginia Eye Consultants, Virginia, UNITED STATES|M.J. Holdbrook, S.N. Baba, Tarsus Pharmaceuticals, Inc., California, UNITED STATES|P.J. Gomes, Ora Inc, Andover, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elizabeth Yeu: Commercial Relationship(s);Tarsus Pharmaceuticals, Inc:Code C (Consultant) | Mark Holdbrook: Commercial Relationship(s);Tarsus Pharmaceuticals, Inc:Code E (Employment) | Stephanie Baba: Commercial Relationship(s);Tarsus Pharmaceuticals, Inc:Code E (Employment) | Paul Gomes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Blepharitis affects approximately 20 million Americans, of whom about 45% have an associated Demodex mite infestation, but the psychosocial effects of Demodex blepharitis are poorly characterized. We retrospectively analyzed a large data set of patients with confirmed Demodex blepharitis to better understand the impact of this condition on quality of life and visual function.

Methods: Adult patients (age ≥ 18) with Demodex blepharitis were examined clinically and asked questions about their daily activities and quality of life. These 311 patients had objective signs of Demodex blepharitis, including the presence of Demodex mites, presence of collarettes (cylindrical dandruff) on the lashes, and lid margin erythema. Questionnaire responses from these 311 patients with confirmed Demodex blepharitis were analyzed.

Results: Among these Demodex blepharitis patients, the majority (80%) said the condition had negatively affected daily life. Women (84%) were more likely than men (72%) to experience a negative impact in one or more areas of daily life. Half of all respondents (47%) said they had difficulty driving at night because of their blepharitis. Nearly one-third (30%) said it added time to their daily hygiene routine. Some patients said that blepharitis had caused them to reduce contact lens wear (8%) or avoid ocular surgery (5%). Patients were emotionally affected, with 47% saying they were conscious of their eyes all day; 23% constantly worrying about their eyes; and 6% saying the condition affected their mental state. Demodex blepharitis also affected respondents' appearance, with about one-quarter saying it gave their eyes or eyelids a negative appearance to others (23%) and made it difficult for women to wear makeup (34%). A smaller percentage of women (5%) noted discomfort when wearing artificial lashes.

Conclusions: Demodex blepharitis has important functional and psychosocial effects on patients. Effective treatments for this condition may have a positive impact on patients' quality of life.

TITLE: Long-Term Ophthalmologic Outcome of Young Adults Born Extremely Preterm

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.T. Zhou, P. Hamel, C.X. Qian, Ophthalmology, Universite de Montreal, Montreal, Quebec, CANADA|P. Kassis, S. Chemtob, A. Nuyt, T. Luu, Pediatrics, Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Ellen Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Pierre-Olivier Kassis: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Hamel: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Qian: Commercial Relationship: Code N (No Commercial Relationship) | Sylvain Chemtob: Commercial Relationship: Code N (No Commercial Relationship) | Anne-Monique Nuyt: Commercial Relationship: Code N (No Commercial Relationship) | Thuy Mai Luu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) remains the dominant cause of severe visual impairment in childhood in North America and Europe. With the salient improvement in neonatal care since the 1980s, more and more very/extreme premature infants survived, whom now reach their adulthood. This study aimed to describe the visual function in a cohort of young adults who were born prematurely.

Methods: This cross-sectional observational study compared visual function of young adults (18-29 years old) born prematurely (< 30 weeks of gestational age [GA]) versus full-term controls. Participants were categorized into three groups: preterm without ROP, preterm with ROP and term. Comprehensive ophthalmologic examination was performed with blinding to preterm and ROP status. Best corrected visual acuity (BCVA) was assessed with a standardized linear Snellen chart and contrast sensitivity (CS) with the Vistech system. When analyzing BCVA, refractive errors and contrast sensitivities, we further grouped data based on the strong eyes (better BCVA) and the weak eyes (worse BCVA). Area-under-the-curve (AUC) analysis was performed to gauge the overall CS. Group comparisons were done using ANOVA.

Results: In this study, 88 individuals born prematurely and 86 individuals born full-term were recruited. Among the strong eyes of the 3 groups, there was no significant difference for BCVA or refractive errors (see image). Among the weak eyes, the preterm with ROP group had the worst BCVA and refractive outcomes compared to the preterm without ROP and term groups. In the strong eyes, the CS AUC of the preterm with ROP group (16.22 ± 2.69 ; $p < 0.0001$) was significantly lower than both the preterm without ROP (18.13 ± 2.01) and term (19.55 ± 2.48) groups. In the weak eyes, the AUC of the 3 groups showed a significant and progressive decline from the term group (18.9 ± 2.84) to the preterm without ROP group (18.29 ± 2.14), then to the preterm with ROP group (15.24 ± 2.21).

Conclusions: In our cohort of young adults born preterm, prematurity alone did not affect their BCVA and refractive errors. However, ROP was independently associated with a lower BCVA, higher refractive errors and a reduced contrast sensitivity. Our data have shown, that prematurity and ROP have independent effects on contrast sensitivity. This study highlights the necessity of long-term ophthalmologic follow-ups for adults who were born prematurely.

TITLE: A 12-week, Randomized, Double-blind, Placebo-controlled Study Assessing the Efficacy of EGHB010, a Standardized Extract of Paeoniae radix and Glycyrrhizae radix, in Patients with Early Age-related Macular Degeneration

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Kim, M. Kim, R. Kim, W. Park, Y. Park, Ophthalmology, Seoul St. Mary's Hospital, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure (Abstract): Joo Young Kim: Commercial Relationship: Code N (No Commercial Relationship) | Mirinae Kim: Commercial Relationship: Code N (No Commercial Relationship) | Rae Young Kim: Commercial Relationship: Code N (No Commercial Relationship) | Wookyoung Park: Commercial Relationship: Code N (No Commercial Relationship) | Young-Hoon Park: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: EGHB010, a standardized extract of Paeoniae radix and Glycyrrhizae radix, inhibits choroidal neovascularization (CNV). The aim of this study is to evaluate the efficacy and safety of EGHB010 on early age-related macular degeneration (AMD) progression inhibition.

Methods: The study was designed as a randomized, double-blind, single-center, placebo-controlled study. Subjects were 50 years of age or older, and early AMD satisfied the criteria of more than 15 small ($<63\ \mu\text{m}$) drusen, less than 20 intermediate ($\geq 63, <125\ \mu\text{m}$) drusen, or pigment abnormalities. For 12 weeks, the treatment group took EGHB010 and the control took the placebo. The main outcomes were the changes in macular pigment optical density (MPOD), central macular thickness (CMT), and central choroidal thickness (CCT). Subgroup analysis was performed on subjects with MPOD <0.75 at baseline.

Results: Forty-eight subjects out of 94 were assigned to the treatment group, and 46 to the control group. At 12 weeks, mean MPOD of the treatment group increased by 0.04 ± 0.27 (p-value = 0.2730), and that of the control group decreased by 0.03 ± 0.21 (p-value = 0.7240), but there was no significant difference between the two groups (p-value = 0.1234). There were no significant differences between the two groups in mean CMT and CCT (p-value = 0.6718 and 0.6608, respectively). In subgroup analysis, there were 39 subjects with MPOD <0.75 in the treatment group and 36 in the control. Mean MPOD of the treatment group significantly increased by 0.09 ± 0.25 (p-value = 0.0218), and there was a significant difference in mean MPOD at 12 weeks between the two groups (p-value = 0.0248). Adverse reactions were similar in both groups, and no subjects had serious adverse events.

Conclusions: EGHB010 is expected to increase MPOD when administered to subjects with MPOD <0.75 . EGHB010 is worth considering as a substance that inhibits the progression of early AMD.

Fortin, Department of Mining, Metallurgy and Materials Engineering, Université Laval, Quebec City, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Philippe Gros-Louis: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Lemay: Commercial Relationship: Code N (No Commercial Relationship) | Théophraste Lescot: Commercial Relationship: Code N (No Commercial Relationship) | Léo Piquet: Commercial Relationship: Code N (No Commercial Relationship) | Claudine Bellerive: Commercial Relationship: Code N (No Commercial Relationship) | Marc-André Fortin: Commercial Relationship: Code N (No Commercial Relationship) | Solange Landreville: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The radiation received by patients with uveal melanoma (UM) treated with brachytherapy is often poorly distributed for cases of non-spherical tumors. The manufacture of personalized brachytherapy implants (PBI) would improve patient comfort during treatment and reduce post-irradiation ocular complications. Our objective is to develop an in vitro experimental model reproducing the anatomy of the eye with a choroidal tumor in order to test the efficacy and functionality of PBI.

Methods: Our printed model will include the main elements of the extracellular matrix of the choroid and sclera, as well as choroidal fibroblasts (CF), choroidal melanocytes (CM) and UM cells (92.1, M μ 2 and Mel270). Cell death ratio (CDR) was quantified by fluorescence (LIVE/DEADTM Viability/Cytotoxicity Kit) to observe the response of choroidal and UM cell lines when embedded in a hydrogel for 0, 4 or 7 days (T0, T4 and T7). Surgical evaluation of PBI (N = 5) on freshly enucleated human eyes was done and scored (out of 35) based on mechanical properties and surgical precision (MPSP) for each prototype in order to compare them between each other and to standard brachytherapy implants (SBI).

Results: The cell line with the highest CDR was CF (T0= 23.86 \pm 2.53%) and the UM cell line with the lower CDR was Mel270 (T7= 0.79 \pm 0.42%). The CDR of the three other cell lines varied between 13.75 \pm 1.56% and 0.83 \pm 0.28%. Compared to the SBI MPSP score of 21, the two prototypes with flexible eyelets scored higher with a combined MPSP score of 27 and the resin prototype scored the highest of all prototypes with a MPSP score of 29. Both prototypes (with flexible eyelets or in resin) had higher score mainly in mechanical properties, while both the prototype with rigid eyelets and the prototype with full outline had lower scores in surgical precision, with the same MPSP score of 19.

Conclusions: Our results showed a low CDR with all 5 cell lines embedded in our model of hydrogel and identified two potential prototypes of PBI. However, bioprinting the dome and its irradiation will make it possible to better characterize the cellular structural changes post-irradiation, and to further optimize the prototypes of PBI. This would allow the development of an in vitro 3D model of choroidal melanoma for the validation of new forms of implants personalized according to the geometry of the tumor.

ABSTRACT BODY:

Purpose: *Toxoplasma gondii*, a globally distributed neurotropic parasite, is a leading cause of posterior uveitis and encephalitis. We investigated (i) whether *T. gondii* cysts preferentially localise in different regions of the retina and brain in a mouse model, and (ii) whether resident microglia are activated in a region-dependent manner during acute infection.

Methods: C57Bl/6J mice were intraperitoneally inoculated with *T. gondii* Pru-tdTomato tachyzoites (low-dose [5×10^3] n=5; high-dose [1×10^4] n=5) or PBS (n=5). In vivo multimodal fundus imaging was performed every 7 days to monitor clinical disease and initial retinal parasite invasion. Eyes and brains were collected at day 28 post-infection (or earlier if mice exhibited signs of severe infection); retinal wholemounts and brain sections were then processed for immunostaining (using Tmem119 and MHC class II antibodies) and confocal microscopy. *T. gondii* cyst burden and microglia density, field area and MHC class II expression were quantified using FIJI.

Results: Clinical disease (retinal lesions and perivascular cuffing) and tdTomato+ *T. gondii* parasites were observed in infected mice from day 14 using in vivo fundus imaging. Examination of fixed tissues revealed that cysts were detected only in mice infected with high-dose *T. gondii*. In the retina, *T. gondii* cysts were exclusively localised in the ganglion cell layer (GCL) and inner plexiform layer (IPL); whereas in the brain a predilection for cyst formation in the cortex occurred. Despite the regional specificity of *T. gondii* cysts, Tmem119+ microglia activation occurred throughout the retina and brain, evidenced by MHC class II upregulation and reduced microglia field area in all examined CNS regions (retina: GCL, IPL, and outer plexiform layer; brain: cortex, olfactory bulbs, hippocampus, cerebellum) compared to controls ($p < 0.05$). *T. gondii* infection was also associated with a large increase in Tmem119-MHC class II+ cells in the retinal GCL, and upregulation of MHC class II on brain vasculature.

Conclusions: *T. gondii* preferentially forms cysts in the innermost layers of the neural retina and the cerebral cortex; however, microglia activation is not restricted to these regions. Understanding the role of innate immunity in control of *T. gondii* replication in the CNS may lead to novel immunotherapeutic targets for toxoplasmosis.

ABSTRACT BODY:

Purpose: This study identified and sought to validate the association between a novel gelsolin (GSN) variant and the phenotype of Familial Amyloidosis of the Finnish type (FAF) in three first degree relatives harbouring a previously undocumented variant, and manifesting multiple clinical and ophthalmic features consistent with systemic gelsolin (GSN) amyloidosis.

Methods: Three first degree relatives presenting to a single tertiary ophthalmic outpatient clinic exhibiting clinical features consistent with FAF including cutis laxa and vision-affecting corneal stromal changes were enrolled in a genetic study of corneal disease. DNA extracted from whole blood samples collected from two individuals was subjected to exome sequencing. Genes associated with corneal disease were assessed for rare and potentially deleterious variants. Histopathological and immunohistochemical studies of proband corneal tissue collected at the time of corneal graft surgery were performed to investigate for the presence of GSN within corneal deposits.

Results: A previously undocumented GSN:c.1477T>C variant resulting in a predicted p.(Trp493Arg) missense variant was identified in the two individuals who underwent exome sequencing. This variant was subsequently confirmed in all three affected individuals through Sanger sequencing. This rare variant which was absent from the Genome Aggregation Database (gnomAD), a large population-based database of 125,748 exomes and 15,708 genomes, was predicted to be damaging by in silico tools (Phred scaled CADD score: 20.8). Histopathological studies performed on the proband cornea demonstrated irregular stromal inclusions which manifested classic amyloid features when subjected to Congo red staining, and intense GSN labelling in immunohistochemical studies.

Conclusions: This study is the first to describe an association between the GSN:c.1477T>C,p.(Trp493Arg) variant and FAF. This novel variant which affects a GSN region distant from the classic p.Asp214Asn variant and the gelsolin 2 (G2) domain, may lead to insights into the amyloidogenic mechanisms of FAF-associated GSN variants.

ABSTRACT BODY:

Purpose: Bardet-Biedl syndrome (BBS), a syndromic form of retinitis pigmentosa, is a rare autosomal recessive ciliopathy linked to mutations in over 20 BBS genes. It is characterized by rod-cone degeneration in conjunction with renal dysfunction, polydactyly, obesity, hypogonadism and/or intellectual disability. We recently identified and characterized a pedigree of rhesus monkeys with a spontaneous mutation in BBS7. Three affected homozygotes showed severe degeneration of the macular retina by 3-4 years of age, and one developed kidney failure by 6 years of age (Peterson et al., Exp Eye Res 189, 2019, 1078252). We are now beginning to define the development of the retinal degeneration phenotype from birth.

Methods: Ova and sperm were collected from BBS7 carriers to produce embryos by intracytoplasmic sperm injection. Trophectoderm biopsies were sequenced to select BBS7^{-/-} embryos, which were transferred to surrogate dams. A live infant was confirmed to be homozygous for the BBS7 mutation and was assessed by multimodal retinal imaging at 4, 8, 16 and 24 weeks of age, by electroretinography (ERG) at 6, 12 and 24 weeks, and by preferential looking measures of visual acuity at 2, 4, 8, 12 and 16 weeks.

Results: At the first retinal imaging session at 4 weeks of age, the EZ line was severely attenuated. Segmentation of OCT images from 4 - 24 weeks of age showed that thicknesses of the total retina and outer segment layers were well below the normal range as determined in 8 age-matched normal rhesus monkey infants, while the inner retinal layers were within or close to the normal range. At 6 - 24 weeks, photopic and scotopic electroretinograms were substantially reduced in amplitude and delayed. Visual acuity was half of normal values at all ages, compared with longitudinal values for 22 normal infants.

Conclusions: The first examination of an infant rhesus monkey with BBS7 showed evidence of retinal thinning and dysfunction as early as 4 weeks of age. The rapid onset of degenerative changes in this model will make it particularly valuable for preclinical studies of therapies for vision preservation or restoration. This is the first nonhuman primate model of retinitis pigmentosa with a known genetic cause, and its propagation will provide the foundation for future studies of cell replacement approaches to treatment for this family of blinding disorders.

ABSTRACT BODY:

Purpose: To explore the real-world clinical outcomes in patients with a history of glaucoma treated with sustained-release dexamethasone intraocular suspension 9% for inflammation control following cataract surgery.

Methods: Retrospective data were collected from records of patients at multiple surgical sites who received dexamethasone intraocular suspension at the end of cataract surgery between Mar 12 and Dec 15, 2019. Anterior chamber cell (ACC) and intraocular pressure (IOP) at postop days 1, 8, 14, and 30 were summarized, along with minimally invasive glaucoma surgery (MIGS) procedures and number of concomitant IOP-lowering medications.

Results: 641 eyes of 527 patients treated with dexamethasone intraocular suspension were included in the study; glaucoma history was reported for 80 eyes of 66 patients. 15 of these eyes had a MIGS procedure; mean (SD) IOP-lowering medications per eye was 1.4 (0.53). For those with a record at each visit, mean (SD) IOP was 18.5 (8.50), 14.3 (4.34), 15.3 (3.31), and 14.4 (3.51) mmHg at postop days 1, 8, 14, and 30; ACC clearing at these timepoints was present in 52%, 68%, 82%, and 90% of eyes. In the full study population, IOP at the same timepoints was 18.6 (6.69), 15.2 (4.51), 15.1 (3.86), and 14.1 (3.84) mmHg; and 40%, 65%, 85%, and 90% of eyes had no ACC.

Conclusions: Results in this subset of eyes provide real-world insight into the use of a sustained release intraocular corticosteroid in patients with glaucoma undergoing cataract surgery; antiinflammatory efficacy and safety with regard to IOP elevation were similar to the full study population.

ABSTRACT BODY:

Purpose: The purpose of the COOG2 study was to conduct a large, multicenter study to prospectively evaluate and optimize the established biomarker gene expression profile (GEP), along with emerging biomarkers PRAME and prognostic driver mutations BAP1, SF3B1 and EIF1AX using a novel next generation sequencing (NGS) panel.

Methods: Institutional Review Board (IRB)/Ethics Committee approval was prospectively obtained. Subjects who met the following inclusion criteria were enrolled prospectively: 18 years and older; diagnosed with a uveal melanoma; undergoing a fine needle aspiration biopsy with treatment of enucleation, I-125 plaque therapy, proton beam therapy, or close observation; able to consent to baseline/ongoing metastatic screening; no previous treatment for UM.

Results: 1756 patients were enrolled from 26 sites across the U.S. and Canada. Mean age at time of enrollment was 62 years. 793 patients were women and 963 were men. 1434 patients identified as non-Hispanic white, 57 self-identified as Hispanic, and the remainder declined to answer. 824 eyes enrolled in the study were right and 932 were left. 587 eyes were identified as blue/green, 240 as brown, and the remainder as mixed/intermediate. 98 (6%), 1356 (83%), 302 (17%), and tumors involved the iris, choroid, and ciliary body primarily, respectively. 83 (5%) had associated congenital ocular melanocytosis. The largest base dimension of the tumors in the study ranged from 1.9 mm to 34 mm (mean, 11.8 mm). The thickness of the tumors ranged from 0.5 to 18 mm (mean, 4.9 mm).

171 (10%) were treated with enucleation, and 1296 (74%) with radioactive plaque therapy with biopsy, 120 (7%) with proton beam therapy with biopsy, and 169 (10%) with biopsy then observation. GEP/Prame status was: 1A/Prame- for 577 (33%), 1A/Prame+ for 157 (9%), 1B/Prame- in 302 (17%), 1B/Prame+ in 104 (6%), 2/Prame- in 287 (16%), and 2/Prame+ in 234 (13%). The remaining 6% had a pending GEP analysis from recent enrollment. NGS results are in process.

Conclusions: The COOG network has prospectively collected clinical, molecular, and outcomes data in a 26-center study resulting in the largest database of information ever collected for this cancer. Forthcoming analyses will define a new, more accurate classification system for metastatic prognostication as well as the gold standard synthetic control arm for future adjuvant therapeutic trials.

TITLE:

Cataract Surgery Outcomes in Uveitis Patients: Experience at a Single
Tertiary Referral Center

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Samson, C.M. Samson, C.I. Samson, Ophthalmology, Manhattan Eye Ear and Throat Institute, New York, New York, UNITED STATES|J.M. Samson, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): James Samson: Commercial Relationship: Code N (No Commercial Relationship) | C Samson: Commercial Relationship: Code N (No Commercial Relationship) | C Samson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

To describe the cataract surgery outcomes of a cohort of patients with uveitis at a single tertiary care center

Methods:

Charts of patients seen on the Uveitis Service at the Manhattan Eye, Ear, and Throat Hospital with a diagnosis of uveitis who underwent cataract surgery between 2017 - 2020 were reviewed.

Results:

A total of 104 patient charts were reviewed with 121 eyes undergoing cataract surgery. The most common type of uveitis was anterior (66.9%). The most common etiologies were idiopathic (54.8%), sarcoidosis (5.77%), and birdshot (5.77%). 57.0% of patients had uveitis severe enough to warrant systemic immunomodulatory therapy. The complication rate, when including 'significant postoperative inflammation,' was 17.8%; without it, the rate was 5.0%. Intraoperative complication rate was 0.8%. 71.2% of patients had 20/40 or better vision at 1 year. Only 6.6% eyes had 20/200 or worse vision, all due to structural damage to the optic nerve or retina unrelated to the surgery.

Conclusions:

Uveitis patients undergoing cataract surgery have a high incidence of postoperative complications, despite a low intraoperative complication rate. Long-term outcomes depended more on the uveitis severity and control than incidents of operative or peri-operative complications.

TITLE: Volumetric Choroidal Segmentation with a Novel Deep Learning Approach fusing Spatial Information

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Cahyo, L. Schmetterer, Ocular Imaging, Singapore Eye Research Institute, Singapore, SINGAPORE|A. Yow, D. Wong, Nanyang Technological University, Singapore, Singapore, SINGAPORE|S. Saw, Singapore Eye Research Institute, Singapore, SINGAPORE|

Commercial Relationships Disclosure (Abstract): Dheo Cahyo: Commercial Relationship: Code N (No Commercial Relationship) | Ai Ping Yow: Commercial Relationship: Code N (No Commercial Relationship) | Seang Mei Saw: Commercial Relationship: Code N (No Commercial Relationship) | Leopold Schmetterer: Commercial Relationship: Code N (No Commercial Relationship) | Damon Wong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the performance of a novel deep learning-based volumetric choroidal segmentation approach incorporating spatial information on swept source optical coherence tomography (SS-OCT) images in eyes with myopia.

Methods: 126 myopia eyes were acquired using a commercial swept-source OCT (SS-OCT) system, DRI OCT Triton (Topcon Corp., Japan) at a 1050 nm wavelength, scanning speed of 100,000 A-scans/sec and 7 mm × 7 mm scanning protocol, centered at the macula. Each volumetric image contained 256 cross-sectional B-scans with dimensions of 256×128 pixels. Manual annotations of the choroid were used as the ground truth. We implemented a novel multi-task deep convolutional neural network architecture, which we named as SA-Net, that reconstructs and segments a target B-scan with the incorporation of spatial context from neighbouring B-scans. Intersection over Union (IoU) of the volumetric segmentation and Structural Similarity Index (SSIM) of the enface choroidal thickness map were used to assess the accuracy of the detected volume. Results were also compared with choroidal segmentation using U-Net.

Results: For the myopia eyes (spherical equivalent = 5.44 ± 2.11 D), the measured choroidal thickness was 0.204 ± 0.046 mm. SA-Net required a processing time of 1.08s for each volumetric choroidal segmentation, and achieved an average cross-validation segmentation IoU of 0.942 (95% CI: 0.937 to 0.946) compared to an IoU of 0.929 (95% CI: 0.923 to 0.934) with U-Net. The mean absolute difference between the ground truth choroidal volume and volumetric segmentation for SA-Net was 0.191 mm^3 (95% CI: 0.164 mm^3 to 0.218 mm^3) with a mean absolute sub-foveal choroidal thickness difference of 0.010 mm (95% CI: 0.008 mm to 0.012 mm) between the ground truth and segmented. For the choroidal thickness map we obtained SSIM of 0.700 (95% CI: 0.688 to 0.711) compared to the ground truth thickness map.

Conclusions: The novel SA-Net approach showed a high accuracy in detecting the choroid from volumetric OCT cube scans in eyes with myopia. This indicates that spatial information can provide useful context for volumetric segmentation. The results are promising for the automated detection of the choroid for further analysis in myopia and other ocular diseases.

ABSTRACT BODY:

Purpose: CRISPR-Cas9 genome editing has great potential for the treatment of numerous inherited retinal diseases, but its clinical application has been hampered by low precision and substantial indel formation. Cytosine and adenine base editors (CBEs and ABEs) enable conversion of a point mutation in a predictable manner independent of Cas9-induced double-stranded DNA breaks and homology-directed repair. We hypothesized that base editors can be used to target the mutations associated with inherited retinal diseases. To test our hypothesis, we delivered ABE to the rd12 mouse model, which harbors a de novo mutation in the Rpe65 gene, and evaluated the therapeutic efficacy of ABE.

Methods: We first screened for a sgRNA enabling mutation correction using an rd12 mutation-harboring stable cell line. Next, we packaged the selected sgRNA and ABE into a lentivirus, and subretinally delivered to the rd12 mice at 4 weeks old. After 5 weeks, we assessed the DNA correction and RPE65 rescue by deep targeted amplicon sequencing, off-target analysis, immunoblot and retinoid analysis. Furthermore, we evaluated visual function in treated mice with electroretinography, optomotor response assay and visual cortex recordings. Cone density was examined with retinal wholemount stained with cone opsin-specific antibodies.

Results: A subretinal injection of a lentivirus expressing the ABE and a sgRNA corrected a pathogenic mutation in the Rpe65 gene up to 29% with minimal indel and off-target mutations despite the absence of a canonical "NGG" protospacer-adjacent motif (PAM) sequence. The ABE-treated mice show restored RPE65 expression, retinoid isomerase activity, and retinal and visual function at near-normal levels. Treated mice also revealed a higher cone density on retinal flatmounts compared to untreated mice.

Conclusions: In this proof-of-concept study, we provide evidence of the clinical potential of base editors for the correction of mutations causing inherited retinal diseases and for restoring visual function. Base editing technology can provide an alternative treatment model of gene augmentation therapy to permanently rescue the function of a key vision-related protein disabled by mutations.

ABSTRACT BODY:

Purpose: Uncorrected myopic refractive error affects the lives and wellbeing of more than 500 million persons worldwide, most residing in low/middle-income countries. One of the obstacles to addressing the issue of uncorrected refractive error in rural communities in low/middle-income countries is the implementation of refraction measurement. In 2019, a pilot study was conducted in a remote rural community in India, testing an easy-to-use low-cost Refraction Kit (RK) for measurement of refraction error which can be performed by lay persons.

Methods: The easy-to-use RK was developed in 2019 by two vision science researchers; the RK consists of 16 pages of Tumbling E letter chart and a tape measure. The RK determines refraction error based on viewing distance in lieu of trial lenses; it was first tested in the lab on 8 myopic eyes for proof-of-concept. The RK was then pilot tested by a layperson in the rural village of Venkatapuram in Telangana, India, where there is no access to eye-care professionals. The layperson who conducted the tests was the local postmaster who trained by watching a 10 min tutorial video. The postmaster conducted the test on 30 primary school students (age: 8 -9; 13 girls and 17 boys). The duration of the test for each person was less than 10 minutes.

Results: In the laboratory proof-of-concept test, refraction error measured by RK ($M = 3.94$, $SD = 1.66$) was not significantly different from the eye prescriptions of the patients ($M = 3.56$, $SD = 1.69$) using paired t-test[1] ($t(7) = -1.58$, $p = 0.156$). In the on-site pilot study in India, it was found that 20% of students were nearsighted (2 girls and 4 boys) ranging from -1 to -3 diopters.

Conclusions: There is a dire need for providing low-cost and easy-to-use solutions for measuring refraction error in many remote areas around the world. The new low-cost RK could be potentially used to address this issue because of its low cost, relative accuracy, and ease of use by laypersons.

Commercial Relationships Disclosure (Abstract): Amee Azad: Commercial Relationship: Code N (No Commercial Relationship) | Evan Chen: Commercial Relationship: Code N (No Commercial Relationship) | Ravi Parikh: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Erickson: Commercial Relationship: Code N (No Commercial Relationship) | Prithvi Mruthyunjaya: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To characterize emergency department (ED) revisit rates related to ophthalmologic conditions, variation by diagnosis, and costs.

Methods: We identified 3- and 30-day ED revisit rates by diagnosis, diagnosis categories and demographic groups. Costs associated with revisits were described as a percentage of index visits and adjusted to 2016 US dollars using the Consumer Price Index. We utilized logistic multivariable regression analysis to identify factors significantly associated with revisits.

Results: Among a total of 828,125 index ED encounters from 2007-2016 with an ophthalmic condition as a primary diagnosis, the 3- and 30-day revisit for the overall cohort was 2.5% and 4.1% respectively. Conditions of the cornea and external disease comprised the majority of index diagnoses (65.2%) but were associated with low rates of 30-day revisit (3.1%). Thirty-day revisits rates were highest for conditions related to cataract and lens disorders (28.3%) as well as glaucoma (15.9%). Nearly all (99%) patients revisiting the ED with cataract and lens disorders had a cataract-related procedure within 30 days of the index encounter. In multivariable analysis, younger adults, those with insurance plans lacking out-of-network coverage and cases involving an ophthalmologist were associated with a significantly higher likelihood of a revisit within 3-days of an index visit. Conversely, patients with higher out-of-pocket costs during an index visit were significantly less likely to revisit in the same period.

Conclusions: Revisit rates for ocular conditions overall are low but varied by diagnosis category. Cataract and lens disorders had the highest 30-day revisit rate (with the vast majority within the 30-day postoperative period) followed by glaucomatous disorders. Younger patients, those with insurance lacking out-of-network coverage, those with lower OOP costs on an index visit and patients with an ophthalmologist participating in their ED care all had higher revisit rates. ED revisits for ocular conditions may be preventable with timely follow-up care, particularly for patients presenting in the acute post-operative period following cataract surgery.

ABSTRACT BODY:

Purpose: To evaluate the use of generative adversarial networks for the synthesis of high-resolution circumpapillary optical coherence tomography (OCT) images.

Methods: Cross-sectional circumpapillary OCT images of 1590 Chinese, 1040 Malay, and 1327 Indian healthy eyes from the Singapore Epidemiology of Eye Diseases (SEED) study were obtained from a commercial high resolution OCT system (Cirrus HD-OCT, Carl Zeiss Meditec) using an optic nerve head centered imaging protocol. These images were used to train ethnicity-specific Progressively Growing Generative Adversarial Network (PGGAN) models for the generation of synthetic images. In addition, another PGGAN model was trained using the images from all the three ethnicity datasets (a total of 3957 images). An evaluation dataset was constructed for each model using 25 generated synthetic images and an equal number of actual images from the corresponding training data. Two clinicians were asked to review the authenticity of the images in each dataset and were not provided with prior knowledge of the distributions.

Results: Examples of the generated images are shown in Figure 1. Each clinician reviewed the datasets independently. Between the two clinicians, the average accuracy was 49% for the Chinese evaluation dataset (Precision=49%, Recall=48%), 37% for the Malay evaluation dataset (Precision=31%, Recall=28%), 43% for the Indian evaluation dataset (Precision=28%, Recall =33%), and 37% for the combined evaluation dataset of all three ethnicities (Precision=27%, Recall=26%). There were differing opinions on 52% of the synthetic images generated from the Chinese, Malay, and Indian PGGAN models and 40% of the synthetic images from the combined ethnicity-based PGGAN model. Only 24%, 20%, 32%, and 28% of the images generated from the Chinese, Malay, Indian, and combined PGGAN models respectively, were correctly identified as synthetic images by both the clinicians.

Conclusions: Synthetic circumpapillary OCT images generated using PGGAN approach were difficult to discern from actual images. The results suggest a potential use of deep learning-based generative models for data generation and augmentation.

Commercial Relationships Disclosure (Abstract): Sandra Hammer: Commercial Relationship: Code N (No Commercial Relationship) | Delaney McFarland: Commercial Relationship: Code N (No Commercial Relationship) | George Abela: Commercial Relationship: Code N (No Commercial Relationship) | Sergio Li Calzi: Commercial Relationship: Code N (No Commercial Relationship) | Maria Grant: Commercial Relationship: Code N (No Commercial Relationship) | Julia Busik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous work highlights the detrimental effect elevated retinal cholesterol levels have on diabetic retinopathy (DR) progression. We have shown that downregulation of LXR α /SIRT1 results in dysregulated cholesterol metabolism and increased retinal cholesterol levels. In turn, elevated cholesterol levels lead to the formation of retinal cholesterol crystals (CC), exacerbating the pro-inflammatory and apoptotic milieu present in the diabetic retina. The focus of this study was to investigate the therapeutic potential of cholesterol lowering drugs in preventing CC-induced retinal damage in endothelial cells and in a type 2 diabetic mouse model.

Methods: Human retinal endothelial cells (HREC) were treated with CC (2mg/ml) and/or CC pretreated with Atorvastatin (10mM), Rosuvastatin (10mM), or α cyclodextrin (10mM) for 24hrs. Inflammation was measured via IL6 and IL8 levels by qRT-PCR. Cell survival was determined via trypan blue exclusion assay. Type 2 diabetes was modeled in vivo via the db/db mouse model. Alpha cyclodextrin was administered three times a week for 2 weeks via subcutaneous injections (4g/kg). Cholesterol crystals were visualized using SEM and quantified using ImageJ software analysis.

Results: Pretreatment of CC with Atorvastatin, Rosuvastatin, or α cyclodextrin reduced the amount of crystals when compared to non-treated controls ex vivo. In culture, administration of CC significantly upregulated IL6 and IL8 expression ($p < 0.0001$; $n = 3$) in retinal endothelial cells. Treatment with Atorvastatin ($p < 0.05$), Rosuvastatin ($p < 0.001$), or α cyclodextrin ($p < 0.0001$) significantly prevented CC-induced IL6 and IL8 upregulation ($n = 3$). CC significantly increased cell death ($p < 0.01$) after 24hrs while pretreatment with Atorvastatin, Rosuvastatin, or α cyclodextrin prevented CC-induced cell death ($n = 3$). Lastly, long term type 2 diabetes (6 months) significantly increased the amount of retinal CC ($p < 0.05$; $n = 5$) while treatment with α cyclodextrin significantly reduced crystal formation in diabetic mice ($p < 0.01$; $n = 3$).

Conclusions: Increased retinal cholesterol levels, resulting from long term diabetes, leads to the formation of pro-inflammatory CC formation. Treatment with cholesterol lowering and/or dissolving therapeutics is an effective strategy to reduce retinal inflammation and cell death by preventing CC induced retinal damage.

TITLE: Effect of lutein in olive oil in the mouse oxygen-induced retinopathy model

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Tsang, A.C. Lo, Department of Ophthalmology, The University of Hong Kong, Hong Kong, HONG KONG|A.M. Joussen, Ophthalmology, Charité – University Medicine Berlin, Berlin, GERMANY|

Commercial Relationships Disclosure (Abstract): Kwan Wun Tsang: Commercial Relationship: Code N (No Commercial Relationship) | Antonia Joussen: Commercial Relationship: Code N (No Commercial Relationship) | Amy Lo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP), a proliferative retinopathy in preterm babies, is an oxidative stress associated disease. Lutein as anti-oxidative agent is a potential therapeutic agent for ROP. To improve the bioavailability of lutein, olive oil was used to dissolve lutein. To investigating the effect of lutein in olive oil in ROP progression, retinal vasculature and function were examined in mouse oxygen-induced retinopathy (OIR) model.

Methods: C57Bl/6J mother and their pups were placed into 75% oxygen chamber from postnatal day (P) 7 to P12. DMSO, olive oil alone, lutein in DMSO or lutein in olive oil (0.2mg/kg) were intraperitoneally injected into the pups starting from P12 daily. Retinal vasculature was examined in isolectin-stained retinal flat mounts at P14 and P17. Retinal function was assessed at P17 using scotopic electroretinography (ERG).

Results: Olive oil alone, lutein in DMSO and lutein in olive oil did not affect the body weight under normal room air (RA) condition or after OIR at P14 and 17. Under normal RA, the pups receiving lutein in DMSO have higher a-wave and b-wave amplitudes at P17 without affecting the normal retinal vascular development when compared with DMSO, olive oil alone or lutein in olive oil treated group. After OIR, olive oil or lutein in olive oil treated groups have a larger avascular area (DMSO: 26.4±2.9%; olive oil: 32.3±2.6%; lutein in DMSO: 26.2±2.7%; lutein in olive oil: 32.4±3.4%). At P17, although no significant difference was observed in the size of neovascularization, olive oil alone, lutein in DMSO and lutein in olive oil treated pups have a larger avascular area (DMSO: 13.5± 2.8%; olive oil: 17.3±7.2%; lutein in DMSO: 18.1±1.6%; lutein in olive oil: 16.6±5.0%). Most importantly, lutein in olive oil treated pups have higher a-wave and b-wave amplitudes with shorter implicit times.

Conclusions: Lutein in olive oil treated pups displayed an improvement of retinal function including the function of photoreceptors, bipolar cells and Müller cells after OIR, suggesting that lutein in olive oil may preserve retinal function after OIR despite limited effects in vascular protection.

ABSTRACT BODY:

Purpose: Case reports and series describe post-selective laser trabeculoplasty (SLT) central corneal edema, with subsequent thinning and hyperopic shift, which can permanently affect vision. This study tested the hypothesis that the incidences of these findings post-SLT are low in the United States.

Methods: This is a 16-year retrospective population-based study of glaucoma patients >18 years using a de-identified database of administrative health claims for patients of a large national managed care company affiliated with Optum, the Clinformatics[®] Data Mart (CDM). Included for analysis were patients' first SLT with one year of continuous enrollment pre-SLT without prior corneal pathology including edema, ectasia, keratomalacia, recurrent erosions, endothelial dystrophy, herpes simplex and varicella zoster viral keratitis, corneal transplant and complications, corneal scars and other disorders of cornea. The primary outcome was corneal edema in at least one eye within 30 days post-SLT and secondary outcomes were keratomalacia, ectasia or other specified disorders of cornea in at least one eye within 120 days post-SLT.

Results: From the CDM's medical claims and medical procedures tables, 86,634 patients had undergone SLT in at least one eye. After exclusion of prior corneal pathology, 83,253 remained. The baseline characteristics of this cohort revealed 9,472(11%) had myopia, 3,718(4%) hyperopia, 1,518(2%) irregular astigmatism, 55,002(66%) primary open angle glaucoma, 10,765(13%) ocular hypertension, 5,010(6%) normal tension glaucoma, 2,452(3%) pseudoexfoliative glaucoma, 1,790(2%) pseudoexfoliation syndrome, 1,775(2%) pigmentary glaucoma, 1,409(2%) pigment dispersion syndrome, 1,755(2%) chronic angle closure glaucoma, 498(<1%) steroid response, and 310(<1%) uveitic glaucoma. 36 were found to have corneal edema within 30 days post-SLT, and 21 with keratomalacia, ectasia or other specified disorders of cornea within 120 days post-SLT. None overlapped. The overall incidence of both primary and secondary outcomes in patients without previous corneal pathology was 0.07%.

Conclusions: New corneal edema, keratomalacia, ectasia was found post-SLT at a low rate in a cohort with diverse glaucoma diagnoses. Laterality cannot be determined within the dataset, thus the rate may be even lower. Future studies may reveal risk factors among the baseline characteristics.

ABSTRACT BODY:

Purpose: Suprachoroidal space (SCS) injection of adeno-associated virus (AAV) provides widespread transgene expression in rat and monkeys (Ding et al. 2019). Here, we developed a technique to perform SCS injections in mice and tested various AAVs to determine whether similar results could be achieved in mice.

Methods: Adult C57BL/6 mice were injected with 3 uL of AAV9 (n=12 eyes) or AAV8 (n=14) CAG-GFP (1E13 vg/mL). For SCS injections, a 30-gauge needle was used to create a shallow incision in the sclera. A 33-gauge needle with 20-degree bevel attached to a 10 uL Hamilton syringe was advanced under the sclera. Correct localization into the SCS was confirmed by evaluating the bevel, which is observable under the transparent sclera but not the pigmented choroid. Once the bevel was within the SCS, the solution was slowly injected. Two weeks post-injection, fundus autofluorescence (FAF) imaging was performed, mice were sacrificed, and eyes were fixed and prepared for flatmounts (RPE/sclera, retina, cornea) or cryosections. Sections and flatmounts were stained with anti-GFP antibody. HALO software was used to quantify the total area of anti-GFP signal in RPE and retinal flatmounts.

Results: FAF imaging showed widespread GFP signal in the eye with AAV8 & AAV9 injection. Similarly, RPE and retinal flatmounts showed extensive GFP expression with both viral vectors. Cryosections showed that GFP signal in the retina was mostly found in the photoreceptor cell layer. Quantification of the total area of anti-GFP signal in RPE flatmounts revealed the greatest coverage in AAV9 group (59% \pm 25%), followed closely by AAV8 (49% \pm 18%). In the retina, AAV8 & AAV9 provided equal area of GFP expression (55% \pm 27% and 56% \pm 28% coverage, respectively). Lastly, GFP signal was also found in flatmounts of sclera and cornea (stromal layer and endothelial cells) with both vectors.

Conclusions: SCS injection of AAV8 and AAV9 provided widespread transgene expression. Several ocular tissues were transduced, including the sclera, RPE, retina, and cornea. The ability to perform SCS injections in mice allows for the exploration of this delivery method in relevant mouse models of ocular disease.

TITLE: Customized Color Settings of Digitally Assisted Vitreoretinal Surgery Enable a 3-Fold Decrease of Indocyanine Green Stain Concentration

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Park, S. Park, J. Do, Department of Ophthalmology, Kyungpook National University, Daegu, Daegu, KOREA (THE REPUBLIC OF)

Commercial Relationships Disclosure (Abstract): Dong Ho Park: Commercial Relationship: Code N (No Commercial Relationship) | Su Jin Park: Commercial Relationship: Code N (No Commercial Relationship) | Jae Rock Do: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the color contrast ratio (CCR) of the internal limiting membrane (ILM) using different color settings of digitally assisted vitreoretinal surgery (DAVS) with different indocyanine green (ICG) concentrations.

Methods: Consecutive patients were enrolled that underwent 25G vitrectomy and ILM peeling using a standard operating microscope (SOM) (25 eyes), DAVS Ver. 1.1 (12 eyes), and DAVS Ver. 1.3 (13 eyes). The SOM and DAVS Ver. 1.1 groups used 0.075% ICG, and DAVS Ver. 1.3 used 0.025% ICG. In DAVS Ver. 1.1, macular CCR was compared between four different presets in the red, green, and blue channels. In DAVS Ver.1.3, macular CCR was evaluated using two different customized settings mainly modifying the hue and saturation. ILM peeling time was compared.

Results: In DAVS Ver. 1.1, macular CCR was the highest in Preset 3 ($P < 0.01$). The CCR of customized Setting 2 of DAVS Ver. 1.3 with 0.025% ICG did not differ from that of Preset 3 of DAVS Ver. 1.1 with 0.075% ICG. ILM peeling time did not differ between the SOM with 0.075% ICG and DAVS Ver. 1.3 groups with 0.025% ICG.

Conclusions: Customized DAVS settings enable surgeons to use a 3-fold lower ICG concentration in ILM peeling.

ABSTRACT BODY:

Purpose: The development of anti-vascular endothelial growth factor (anti-VEGF) therapies has revolutionized the treatment of pediatric retinal disease including retinopathy of prematurity (ROP), however clinical data of long-term visual outcomes surrounding its use in these patients is incomplete. Here, we investigate long-term visual outcomes of infants screened for ROP in the anti-VEGF era.

Methods: We reviewed Stein Eye clinic charts of subjects born at UCLA Medical Centers and screened for ROP as neonates. Data collected included parameters at birth (e.g., gestational age (GA), birth weight (BW)), treatment modalities (e.g., laser, anti-VEGF), and visual outcomes (e.g., visual acuity, refraction, amblyopia, strabismus, poor structural outcomes). The most recent eye exam was used for each age group. Generalized estimating equations were used for analysis to account for inter-eye correlations. A final multivariate model was used, incorporating covariates significant at the univariate stage.

Results: 137 patients were included in the analysis, with average GA 28.03 ± 2.71 weeks and BW 1064.4 ± 368.9 g; 66 (48.1%) were inborn, and 76 (55.45%) were male. 76 (55.45%) did not develop ROP, 39 (28.4%) had Type 2 ROP, and 22 (16.1%) had Type 1 ROP; 23 patients received primary laser treatment, while an additional 4 received primary anti-VEGF followed by delayed laser treatment. Strabismus was associated positively with poor structural outcomes (OR = 1.36, $p=.023$) and negatively to GA (OR=0.97, $p=.017$); primary laser compared to primary anti-VEGF followed by delayed laser was positively associated with amblyopia (OR=1.33, $p=.002$) while controlling for GA. Subgroup analysis for visual acuity was performed on 51 patients who were 4+ years old, with average age at last follow-up 6.04 ± 1.3 years and average refraction -0.08 ± 3.7 D. Primary laser as compared to primary anti-VEGF followed by delayed laser was independently associated with worse visual acuity (OR=1.75, $p<.0001$). No treatment vs. primary anti-VEGF followed by delayed laser was also independently associated with worse VA (OR=1.34, $p=0.009$).

Conclusions: Primary anti-VEGF followed by delayed laser led to better visual outcomes than primary laser, independent of GA, BW, or underlying poor structural outcomes. This supports the concept that anti-VEGF treatment improves visual development in preterm neonates.

TITLE: Rod- and Cone-specific Phosphorylation of Retinal GRKs in Mice and Zebrafish

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.D. Chrispell, Y. Xiong, E.R. Weiss, Cell Biology & Physiology, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jared Chrispell: Commercial Relationship: Code N (No Commercial Relationship) | Yubin Xiong: Commercial Relationship: Code N (No Commercial Relationship) | Ellen Weiss: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the vertebrate retina, phosphorylation of photoactivated visual pigments in rods and cones by G protein-coupled receptor kinases is essential for sustained visual function. GRK1 and GRK7 are phosphorylated in a cAMP-dependent manner in vivo in the retinas of dark-adapted vertebrates. We have shown that a phosphomimetic of GRK1 affects the rate of dark adaptation in mouse rods but not in cones, suggesting a role in the disparate dark adaptation rates in these two cell types. The present work evaluates phosphorylation of GRKs in rods and cones of mice and zebrafish.

Methods: Phosphorylation was analyzed by western blot analysis of retinal tissue (mice and adult zebrafish) and isolated eyes (larval zebrafish) using anti-phosphoGrk antibodies. Grk1a was targeted for knockout in zebrafish using CRISPR gene editing. Recovery of the cone photoresponse in zebrafish was evaluated by ERG using a white light dual flash with increasing interstimulus intervals. To evaluate the effect of elevated cAMP on the rate of cone recovery in vivo, zebrafish larvae were incubated with forskolin.

Results: GRK1 was not observed to be phosphorylated in dark-adapted *Nrl*^{-/-} mice, which only have cones. Phosphorylation of Grk1 is detected in dark-adapted *grk1b*^{-/-} zebrafish lacking the cone-specific paralog, suggesting that phosphorylated Grk1 is Grk1a in rods and that cone Grk1b is not phosphorylated. To evaluate this hypothesis, fish lacking the *grk1a* paralog are being generated. F0 mosaic larvae exhibit significant deletion of Grk1a and an absence of Grk1 phosphorylation in the dark. Wildtype larvae treated with forskolin display a significant decrease in the rate of cone recovery compared to vehicle. This decrease is also observed in *grk1b*^{-/-} larvae, which express only *grk7a* in cones. In contrast, forskolin has no effect on the rate of cone recovery in *grk7a*^{-/-} larvae, consistent with our observation that only Grk7 is phosphorylated in zebrafish cones.

Conclusions: These data are consistent with our report of a GRK1 phosphomimetic in mice suggesting a role for GRK1 phosphorylation in rod adaptation. Grk7, but not Grk1, phosphorylation seems to be important in cone adaptation in zebrafish. Further experiments using complete Grk1a knockouts and dark adaptation analyses will be used to determine the roles of GRK phosphorylation in vertebrates that, like humans, express both GRKs in cones.

TITLE: Defining multiplicity of plasmid electroporation in the retina for high-throughput genetic screening

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Woodworth, S. Wang, J.L. Goldberg, L.C. Greig, Ophthalmology, Stanford University, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mollie Woodworth: Commercial Relationship: Code N (No Commercial Relationship) | Sui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goldberg: Commercial Relationship: Code N (No Commercial Relationship) | Luciano Greig: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Electroporation of plasmid DNA into mouse retinal progenitor cells (RPCs) has been extensively used to investigate gene function during retinal development. To perform high-throughput genetic screens, it is important to know how many plasmid copies are delivered to individual electroporated RPCs and their progeny. Here we investigate multiplicity of electroporation in the retina based on fluorescent protein expression and high-throughput sequencing of barcoded plasmids.

Methods: CD1 mouse pups were electroporated on postnatal day 1 (P1) with plasmids containing a CMV-beta-actin (CAG) promoter driving expression of one of three fluorescent proteins, EGFP, tdTomato, or mKate. The plasmids were mixed in equimolar concentrations totaling 10, 100, or 1000 ng/ul. DNA was injected subretinally and electroporated using five 80V pulses. Mice were euthanized at postnatal day 21 (P21), and fixed retinas were cryosectioned and imaged on a Zeiss confocal microscope. In separate experiments, pups were electroporated with a library of plasmids containing BFP tagged with random 18-nucleotide barcodes. Individual electroporated cells were FACS-purified, and barcodes were PCR-amplified to perform high-throughput DNA sequencing.

Results:

All plasmid concentrations resulted in most transfected cells being labeled with all three fluorescent proteins, with random variation in expression levels resulting in a rainbow-like range of hues. Modeling suggests that most cells receive at least 6-10 plasmid copies at the lowest concentration and as many as 1000 copies at high concentrations. Experiments in which barcodes were recovered from individual cells by high-throughput sequencing allowed us to more directly estimate multiplicity of electroporation across a range of plasmid concentrations, further supporting our prior estimates.

Conclusions: Our results suggest that gene delivery by plasmid electroporation in the retina results in high plasmid copy numbers in each cell. These data support the premise of using high-throughput screening by electroporating libraries of plasmids, but highlights the importance of titrating the concentration of such libraries in order to avoid simultaneously manipulating thousands of genes in each cell.

TITLE: Comparison of microaneurysms (MA) number between early versus late phase fluorescein angiography (FA) and optical coherence tomography angiography (OCTA)

SESSION TITLE: OCT Angiography - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Adhikari, Roski Eye Institute, University of Southern California, Los Angeles, California, UNITED STATES|A.H. Kashani, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Suman Adhikari: Commercial Relationship: Code N (No Commercial Relationship) | Amir Kashani: Commercial Relationship(s); Carl Zeiss Meditec: Code F (Financial Support); Carl Zeiss Meditec: Code R (Recipient)

ABSTRACT BODY:

Purpose: To compare the number of MA in early versus late phase FA with counts from SS-OCTA images in subjects with diabetic retinopathy (DR).

Methods: This was a retrospective, observational study. Subjects were selected based on the availability of the images and the quality of the available images. The FA images were obtained from Spectralis® OCT (Heidelberg Engineering, Germany) and OCTA images were obtained from SS-OCTA (PlexElite™, Carl Zeiss Meditec, Dublin, CA). Early and late phase FA were defined as 30 seconds (range: 30-35 seconds) and 3 minutes (range: 2.71-3.46 minutes) during the transit respectively. MA counts from 6×6 mm OCTA scans were compared with counts from the corresponding area of early and late phase FA images. Statistical analysis was performed using ANOVA and a paired student t-test.

Results: Four eyes of 4 subjects were included in the study. The mean (\pm SD) age of the subjects was 56.5 (\pm 8.4) years. One of the subjects had proliferative DR and three had severe non-proliferative DR. The MA count in each eye on OCTA was 23, 11, 30 and 95 (Mean \pm SD = 39.8 \pm 32.6). The MA count during early and late phase FA for the same eyes was 41, 21, 52 and 140 (Mean \pm SD = 63.5 \pm 45.5) and 46, 27, 54 and 153 (Mean \pm SD = 70 \pm 48.9), respectively. There were significantly more MA detected in late phase FA than in OCTA ($P=0.04$). The difference in MA detected in early phase FA and OCTA did not reach significance ($P=0.49$).

Conclusions: The number of MAs counted on OCTA images is significantly less than on any stage of FA but closer to MA counts in the early phase of the FA. This suggests that patent MA with active blood flow are best represented on OCTA.

ABSTRACT BODY:

Purpose: To describe and evaluate a portable visual field (VF) quantification tool for determining monocular and simultaneous binocular VF measurements.

Methods: We used a virtual reality head mounted display (HMD) to quantify VF defects in the central 80 degrees diameter of two groups of patients by applying a fast thresholding strategy with an inverted static stimuli pattern. The first group included 20 patients (30 eyes) with known glaucomatous monocular VF defects. We compared the HMD VF monocular test results with the known full static standard automated perimetric (SAP) values as a reference measurement. In the second group, 20 patients (40 eyes) with binocular neurological and glaucomatous related VF defects, we validated HMD binocular measurements (testing both eyes simultaneously) by comparing the results with the integrated/combined monocular SAP VF tests for both eyes, as a reference test. We determined reproducibility by repeated testing of ten measurements in each group.

Results: The HMD VF measurements were comparable to their corresponding references in each group based on a point by point comparison. Testing points responses in discord with the corresponding SAP thresholds were counted to calculate VF measurement mismatches. These mismatches were 7.08% and 7.38% in the two groups, respectively, calculated as the ratio between the number of mismatched points to the total number of common test points. The HMD VF reliably quantified defects with an intraclass correlation coefficient (ICC) of 0.83 for the first test group and 0.73 for the second binocular test group.

Conclusions: Monocular and binocular HMD VF and SAP VF measurements were comparable in this pilot study.

TITLE: Impact of Fornix Based Micro-Trabeculectomy Technique on Astigmatism in Pseudophakic Patients

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Zhou, The University of Texas Medical Branch at Galveston, Galveston, Texas, UNITED STATES|A. Mazharuddin, B. Hong, G. Vizzeri, Ophthalmology and Visual Sciences, The University of Texas Medical Branch at Galveston, Galveston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): You Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Anam Mazharuddin: Commercial Relationship: Code N (No Commercial Relationship) | Bennett Hong: Commercial Relationship: Code N (No Commercial Relationship) | Gianmarco Vizzeri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Fornix-based micro trabeculectomy with adjunctive mitomycin C is a novel minimally invasive procedure that was first introduced at ARVO 2019 (poster #B0083). This study seeks to assess whether this modified technique induces significant astigmatism in pseudophakic patients.

Methods: This is a retrospective single surgeon case series. Pseudophakic patients who underwent micro trabeculectomy between 1/1/2013 and 1/1/2019 were included. Patients who did not have manifest refraction or demonstrated visual acuity of count fingers or less were excluded. Outcomes included were a change in significant astigmatism, which is defined as 1.0D or more, change in visual acuity (0.2 LogMAR), and shift in axis of astigmatism in the operative eye. Analysis was performed using the Student's T-Test.

Results: 31 patients had refraction before and after procedure available for comparison, and 21 had a second refraction after at least 1 year. Baseline demographics and primary outcomes for included patients are provided in Tables 1 and 2. The patients included were on average 74.9 years old and 42% male and 58% female. On average micro trabeculectomy was performed 4.3 years after cataract surgery. Average baseline astigmatism prior to surgery was 1.36D while post-procedure average astigmatism was 1.23D. 1 eye experienced an increase in astigmatism postoperatively that resolved after 1 year on repeat refraction. 2 eyes experienced a clinically significant decrease that remained stable after 1 year. 2 eyes that did not have astigmatism prior to the procedure developed astigmatism, however this was not significant ($\leq 1D$). 9 eyes experienced no change in astigmatism postoperatively. Analysis showed that there was no statistically significant difference between pre-trab and post-trab astigmatism outcomes (0.620, $p > 0.05$). Similarly, there was no statistically significant difference between baseline astigmatism and astigmatism measured at least one year post-operatively (0.524, $p > 0.05$). Visual acuity remained stable after procedure (0.827, $p > 0.05$). 3 eyes shifted from oblique or no cylindrical astigmatism (sphere only) to against the rule (ATR) astigmatism.

Conclusions: Incisional surgery can induce astigmatism and affect visual acuity. This study demonstrates that the novel micro trabeculectomy technique does not induce significant astigmatism in pseudophakic patients.

TITLE: “En face” Imaging of ILM Flap Following Macular Hole Surgery

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Tabandeh, A. Morozov, D.S. Boyer, Retina-Vitreous Associates Medical Group, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Homayoun Tabandeh: Commercial Relationship: Code N (No Commercial Relationship) | Andy Morozov: Commercial Relationship: Code N (No Commercial Relationship) | David Boyer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To visualize and evaluate the internal limiting membrane (ILM) flap following macular hole (MH) surgery.

Methods: Retrospective case series including eyes that underwent pars plana vitrectomy (PPV) and ILM flap for MH. Postoperatively, ICG fluorescence images were obtained using a confocal laser scanning system (Spectralis, Heidelberg Engineering Inc., Heidelberg, Germany) with the 795 nm ICG filter. Optical coherence tomography (OCT) was used to evaluate the status of the MH.

Results: Twenty eyes of 20 patients, mean age 67.2 years, with mean follow-up of 11.1 months were included in the study. Five (25%) eyes were highly myopic, 8 (40%) eyes had chronic MH, and 3 (18%) eyes had history of prior MH surgery and ILM removal. The MH closed in 19 (95%) eyes. Typically the ICG fluorescence imaging showed a well defined area of hypofluorescence corresponding to the harvest site and removed ILM, an area of hyperfluorescence corresponding to the ILM flap and the residual ILM, and an area of increased hyperfluorescence corresponding to the overlap area of ILM flap with the residual ILM. Hyperfluorescence over the MH site, and speckled hyperfluorescence over the macular region were present in most eyes. ICG fluorescence imaging demonstrated coverage of the MH by the ILM flap in 17 (85%) eyes, partial coverage in 1 (5%) eye, and no coverage in 2 (10%) eyes. Folding of the ILM flap was present in 5 (25%) eyes. OCT demonstrated bridging of the fovea by the ILM flap in 4 (20%) eyes.

Conclusions: ICG fluorescence imaging is a non-invasive imaging modality that provides an “en face” image of the ILM flap following MH surgery, allowing study of ILM flap techniques.

TITLE: The Use of Encircling versus Segmental Buckling as Primary Surgery for Retinal Detachment Repair

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Hwang, Rutgers Robert Wood Johnson Medical School, New Brunswick, New Jersey, UNITED STATES | K. Astafurov, D. Roth, Ophthalmology, Rutgers Robert Wood Johnson Medical School, New Brunswick, New Jersey, UNITED STATES |

Commercial Relationships Disclosure (Abstract): Chaewon Hwang: Commercial Relationship: Code N (No Commercial Relationship) | Konstantin Astafurov: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Roth: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary scleral buckling (SB) is a common technique employed to repair rhegmatogenous retinal detachment. This is most commonly accomplished using either encircling or segmental SB approach. However, currently, there is a lack of data comparing these two techniques. Here we present and compare features and outcomes of segmental primary SB versus encircling SB surgical approaches.

Methods: A retrospective chart review of 100 consecutive patients who underwent primary SB surgery between March 2019 and January 2020 for a rhegmatogenous retinal detachment at a single retina practice was performed. Data were collected on patients with greater than 3-month follow up after surgery.

Results: Out of the 100 surgical eyes, 95 were included in the final analysis: 55 of those eyes had encircling and 40 had segmental SB procedure, respectively. The average follow-up time was comparable between the two groups: 10.7 months and 10.6 months for segmental and encircling SB respectively ($P = 0.48$, t-test). The average pre-operative best corrected visual acuity (BCVA) was 20/110 for segmental and 20/68 for encircling SB, respectively. There was no significant difference in the average BCVA at the final follow up which was 20/35 for segmental and 20/38 for encircling SB, respectively ($P = 0.25$, t-test).

There were no significant differences in the lens status (phakic in 85% and 93% for segmental and encircling SB respectively, $P = 0.23$, Chi-square), fovea-on status (60% and 58% for segmental and encircling respectively, $P = 0.86$, Chi-square), and the extent of the retinal detachment (4.4 clock hours and 4.7 clock hours for segmental and encircling respectively, $P = 0.22$, t-test) between the patients in the two groups. Two patients in encircling SB group had recurrent retinal detachment requiring reoperation, while in the segmental SB group, none required reoperation at the final follow up.

Conclusions: Our results suggest that segmental SB technique is not inferior to the encircling SB technique in cases of primary buckling procedure for retinal detachment repair in regard to the anatomical success of single surgery and final visual outcome. Given that segmental scleral buckling technique is associated with less morbidity, it should be considered, when indicated, for the repair of retinal detachments amenable to surgery with primary SB.

ABSTRACT BODY:

Purpose: Keratoconus (KC) represents one of the leading causes for corneal transplantation. Early detection of KC is important due to its early age of onset and impact on quality of life of the patients. The aim of the study was to develop a simple, automatic machine learning model to detect subclinical KC from control (non-KC) using key parameters obtained from the entire Pentacam parameter set.

Methods: Complete Pentacam output (1692 parameters) and clinical data of 145 subclinical KC and 122 control eyes were collected and analysed. A random forest method was applied to these data to build models using different parameter combinations, and a best performing parameter set was identified. A final model was built using the key Pentacam parameter set, along with other clinical data, and validated using a separate test data.

Results: 3 novel Pentacam parameters were identified, consisting of eccentricity value at an angle of 30 degrees of the front cornea, eccentricity in the 9 mm diameter zone of the cornea and inferior versus superior corneal asymmetry, that were widely available in other commonly used imaging systems to achieve an accuracy of 94%, sensitivity of 97% and specificity of 91% that was comparable with previously reported models built using more parameters. The utility of this combination was further enhanced with the inclusion of clinical parameters (i.e. vision and refraction) to reach an accuracy of 97%, a sensitivity of 99%, and a specificity of 96% in detecting subclinical KC.

Conclusions: The use of the identified key Pentacam parameters along with important clinical parameters, achieved a high level of differentiation between subclinical KC and control eyes. The compact model proposed in this study could be incorporated into the diagnosis of subclinical keratoconus.

ABSTRACT BODY:

Purpose: Reports from populations of different geographic backgrounds show that about 90% percent of individuals with Leber hereditary optic neuropathy (LHON) harbour one of the three (primary) mitochondrial DNA (mtDNA) point mutations: m.3460G>A (MT-ND1), m.11778G>A (MT-ND4) or m.14484T>C (MT-ND6). The purpose of this study was to screen the whole mitochondrial genome of LHON patients negative for these three common mtDNA mutations to investigate the role of other mtDNA variants in the pathogenesis of this blinding optic neuropathy.

Methods: Forty-one individuals who were clinically suspected to have LHON were recruited from the Neuro-Ophthalmology Clinic (Medical Research Foundation, Sankara Nethralaya, Chennai, Tamil Nadu, India). A comprehensive neuro-ophthalmic examination, including slit lamp examination, indirect ophthalmoscopy and visual field perimetry was performed. Targeted re-sequencing using next-generation sequencing (NGS) on the HiSeqX Ten platform (Illumina, San Diego, California) was performed using a 2×150bp paired-end setting. The reads were aligned to the human mitochondrial genome sequence (hg19). The variants were filtered using VARIMAT tool (v.2.3.9) and haplogroup analysis was performed using haplogrep 2 tool (v2.0).

Results: Whole mitochondrial genome sequencing of 41 clinically suspected cases of LHON revealed a total of 1,594 variants of which 869 variants were present in the coding region, and 582 were synonymous and 287 were non-synonymous variants. We have identified secondary mtDNA variants reported in mitomap in 12 individuals (12/41, 29%) with variants in MTND1 being the most common (7/41, 17%). Control screening for the m.4216T>C and m.9966G>A variants was conducted on 25 unrelated healthy individuals. The majority of individuals belonged to haplogroup M (n= 23). None of the controls were positive for m.9966G>A, but m.4216 T>C was identified in 2 controls. We plan to screen additional controls in order to further investigate the pathogenic status of the m.4216T>C and m.9966G>A variants.

Conclusions: Our study of a well-characterized Indian LHON cohort negative for the three primary mtDNA mutations has revealed a number of secondary mtDNA variants that should be considered in the evaluation of optic atrophy cases. The MTND1 subunit gene could be a mutational hotspot for LHON in the Indian population.

TITLE: Intracamerally transplanted stem cells changed the segmental outflow pattern and reduced intraocular pressure in a mouse glaucoma model

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Du, Ophthalmology, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yiqin Du: Commercial Relationship(s);University of Pittsburgh:Code P (Patent)

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma is associated with pathological changes of the trabecular meshwork (TM). TM stem cells (TMSCs) preferentially home to the injured TM tissue for regeneration (Yun et al. Communi Biol. 2018; 1: 216). The hypothesis of this study was that intracamerally transplanted TMSCs can change the segmental outflow pattern for IOP regulation in a glaucoma mouse model.

Methods: Human TMSCs were labeled with Vybrant dye DiO and 5×10^4 cells were intracamerally transplanted into a primary open-angle glaucoma model of mice with transgenic myocilin (Myoc) Y437H mutation (Tg-MyocY437H, a kind gift from Dr. Gulab Zode, UNTHSC) as well as wildtype mice as controls. Human corneal fibroblasts were injected as a control. Mouse IOP was measured before cell injection and at 3 weeks after injection. At 3 weeks, anterior segment optical coherence tomography (OCT) was performed to evaluate central corneal thickness (CCT) and the anterior chamber angle. Then microbead perfusion was performed and mice were sacrificed. Wholemount staining on the TM was evaluated on a confocal microscope for quantifying the high-flow, low-flow, and no-flow region. Statistical analysis was done by one-way ANOVA followed by the Tukey posttest to assess the significance.

Results: TMSC injected mice showed similar CCT and anterior angle to the control groups (both $p > 0.05$), which indicates there was no effect on the CCT and the angle of TMSC injection, and the IOP measurement was not affected by CCT. With TMSC transplantation, Tg-MyocY437H mice had reduced IOP, increased high-flow length, and lowered no-flow length than controls (no injection, sham injection, and fibroblast inject) (all $p < 0.05$). The same change was observed in wildtype mice and there was no statistical difference between Tg-MyocY437H and wildtype mice. TMSCs distributed to the TM high-flow, low-flow, and no-flow regions.

Conclusions: TMSC intracameral transplantation can upregulate aqueous humor outflow and reduce IOP which is partially by increasing the high-flow region and reducing the no-flow region in mice

Giorgi-Sandoval, Research and Development, Asistencia e Investigación en Glaucoma, Guadalajara, Jalisco, MEXICO|

Commercial Relationships Disclosure (Abstract): Miriam Ramos-Hernández: Commercial Relationship: Code N (No Commercial Relationship) | Jose Paczka: Commercial Relationship: Code N (No Commercial Relationship) | Michelle Guzmán Ornelas: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Ibañez Sandoval: Commercial Relationship: Code N (No Commercial Relationship) | Luz Giorgi-Sandoval: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: End-stage glaucoma is a challenging clinical situation that required very low IOP to control it. Diverse non-dependent IOP factors are involved in visual function stability and neuroprotective compounds have been proposed as potentially helpful. Nootropic supplements such as Neuro Optimizer (Jarrow Formulas) have been purportedly used due to their neuroprotective effects. The objective of this study is to evaluate the benefit of orally administered Neuro Optimizer in patients with end-stage glaucoma in a real-world setting.

Methods: A retrospective assessment of data from 132 consecutive patients with end-stage glaucoma under oral treatment with Neuro Optimizer was performed. Clinical data including BCVA, IOP, number of glaucoma medications, visual field indexes evaluated by applanation tonometry, cup-to-disc (CD) ratio, peripapillary retinal nerve fiber layer (RNFL) and perimacular ganglion cell complex (GCC) thickness by OCT. Tolerability and safety issues were also assessed.

Results: One hundred and thirty-two patients were under oral Neuro Optimizer treatment, from which 31 were excluded. Therefore, 197 eyes of 101 patients (61 females, 40 males; mean age of 64.8 ± 17.6 years) were included. This population showed a greater proportion of POAG (59.4%), and usage of ≥ 2 glaucoma medications (81.1%). Mean time of Neuro Optimizer administration was 9.4 ± 3.3 months. Baseline IOP was 14.5 ± 5.8 mmHg (RE) and 14.7 ± 5.2 mmHg ($P=0.79$) and no difference was noted with the last visit values (RE, 14.8 ± 6.0 mmHg; LE, 14.4 ± 5.7 mmHg; $P=0.63$). BCVA, MD, DSM, CD ratio, CFNR and GCC were not statistically different when the two moments were compared ($p>0.05$). Mean pre-treatment VFI in both eyes (RE, 43.7 ± 32.4 %; LE, 39.8 ± 33.6 %) was higher as compared to the post-treatment period (RE, 37.5 ± 31.8 mmHg; $p=0.001$; LE, 34.1 ± 29.2 mmHg; $p=0.02$). Heartburn (9.9%), minor headache (7.9%) and a transient cutaneous rash (1.9%) were the side-effects recorded. Two patients (1.9%) interrupted supplement administration because of persistent headache. Eighteen patients (17.8%) claimed to have a subjective improvement in their vision.

Conclusions: The current results of this retrospective "real world" study of end-stage glaucoma patients showed no improvement but a reduced VFI when Neuro Optimizer was orally administered during a short-term period. No relevant safety/tolerability issues were relevant. Subjective perception of improvement was infrequent.

TITLE: Effect of Vitrectomy Surgery with Internal Limiting Membrane Peeling on Macular Morphology and Perfusion: Optical Coherence Tomography Analysis. A Retrospective Study

SESSION TITLE: OCT Angiography - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Mehta, G. Yiu, A. Morshiri, S.S. Park, Ophthalmology, University of California Davis, Sacramento, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Neesurg Mehta: Commercial Relationship: Code N (No Commercial Relationship) | Glenn Yiu: Commercial Relationship: Code N (No Commercial Relationship) | Ala Morshiri: Commercial Relationship: Code N (No Commercial Relationship) | Susanna Park: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Internal limiting membrane peeling (ILMP) is a common part of vitrectomy surgery for epiretinal membrane (ERM) or macular hole (MH). However, safety concerns remain since changes in macular thickness and vascular flow have been reported following ILMP. This retrospective study compared the macular morphology and flow following surgical ILMP when compared to the contralateral normal eye.

Methods: We identified 62 patients who had undergone ERM or MH surgery in one eye with normal contralateral eye and follow-up of at six months postoperatively. Optical coherence tomography (OCT) was used to measure central subfield thickness (CST), mean cube thickness (MCT) and macular volume (MV) in both eyes at pre and post-operative visits. In a subset of eyes with OCT angiography (OCTA) performed postoperatively, vascular density (VD) in the 3x3mm foveal and parafoveal regions of the superficial, deep and full vascular slabs was obtained from the most recent image. Paired Student t test was used to compare means (p-value<0.05 statistically significant).

Results: Among 62 patients, 44 had ERM surgery (35 with ILMP) and 18 had MH surgery (all with ILMP). Mean follow-up was 106.7 weeks (range 46.8-266.4 weeks). All operated eyes had significant reduction in CST, MCT and MV postoperatively. Among eyes that had ERM surgery with ILMP, mean CST, MCT and MV were 355um, 305um, and 9.6 mm³ respectively, while that for the contralateral eyes were 267um, 252um, and 9.0mm³ respectively (p value=2.33E-9, 1.82E-4, 0.01 respectively) at last postoperative visit. Among MH eyes, the operated eyes had mean CST, MCT and MV of 312um, 274um, and MV 9.05 mm³ respectively, while that for the contralateral eyes were 236um, 252um, and 9.1mm³, respectively (p value=0.01E-1, 0.03, 0.43 respectively). Postoperative OCTA was available in 10 eyes that had ILMP. No statistically significant difference was noted in the VD between the operated and contralateral eyes in the superficial, deep and full vascular slabs at the parafoveal and foveal regions.

Conclusions: Although eyes with ERM and MH had reduction in macular thickness and volume following vitrectomy, ILMP was not associated with reduction in macular thickness, volume or perfusion when compared to the contralateral normal eye in this limited retrospective study.

TITLE: α A-Crystallin modulates neuroinflammation in retina via stress specific inflammatory pathways

SESSION TITLE: Retinal physiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Nath, Y. Shan, A.M. Myers, P.E. Fort, Kellogg Eye Centre, University of Michigan Michigan Medicine, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Madhu Nath: Commercial Relationship: Code N (No Commercial Relationship) | Yang Shan: Commercial Relationship: Code N (No Commercial Relationship) | Angela Myers: Commercial Relationship: Code N (No Commercial Relationship) | Patrice Fort: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The α -crystallins molecular chaperones are involved in the pathophysiology of diabetic retinopathy (DR), however, the role and regulation of these proteins remained unclear. We recently demonstrated that the α A-crystallin exerts its intrinsic neuroprotective role during diabetes, by its phosphorylation on residue 148. We also reported that α A-crystallin is highly expressed by glial cells. Because of the growing interest of the potential causative role of low-grade inflammation in the DR pathophysiology, this study was carried out to delineate the regulatory function of α A-crystallin in the inflammatory response associated with metabolic stresses.

Methods: Primary Müller glial cells (MGCs) isolated from Ko- α A-crystallin mice were transfected with plasmids encoding either wild-type (WT), phosphomimetic (T148D), or non phosphorylatable mutants (T148A) of α A-crystallin. The cells were then exposed to multiple metabolic stress including serum starvation (SS) or high glucose with TNF- α (HG+T) before being evaluated for the expression of inflammatory markers by qPCR and protein expression of NF κ B1 & NLRP3 components by western blot.

Results: Elevated levels of inflammatory markers in SS were diminished in MGCs overexpressing WT (IL-6-97%; IL-1 β - 88%; MCP-1-89%; IL-18-72%) and further in T148D (IL-6-87%; IL-1 β - 86%; MCP-1-28%; IL-18-64%) as compared to EV. The HG+T induced increase in IL-6, IL-1 β , MCP-1 & IL-18 were dampened by WT (55%, 36%, 85% & 93% respectively) and even more significantly by T148D (IL-6- 92%; IL-1 β -54%; MCP-1-98%; IL-18-55%) overexpression, whereas T148A was ineffective in either stress. Further, overexpression of WT or the T148D, also lead to a significant reduction of Nlrp3 (85%), Asc (61%) and caspase-1 (68%) expression in serum deprived MGCs and nearly abolished the NF- κ B induction (α A-WT-97%; α A-T148D-95%) in HG+T stress. The protein levels of NLRP3 components and NF- κ B were consistent with the transcriptomic data in a metabolic stress specific manner.

Conclusions: The data gathered in this study demonstrate the central regulatory role of α A-crystallin and its modulation by phosphorylation on T148 in retinal MGC. This study demonstrates that α A-crystallin can dampen sustained expression of pro-inflammatory cytokines through modulation of multiple key inflammatory pathways, therefore, suggesting its potential as therapeutic target for modulation of chronic neuroinflammation.

ABSTRACT BODY:

Purpose: Give Kids Sight Day is an annual free outreach program in Philadelphia region, targeting low-income and underinsured communities. In 2020, a novel virtual screening program was conducted to face the challenges presented by the COVID19 pandemic. Continual innovation in vision screening methods is necessary to help reduce rates of blindness and visual impairment in children and adolescents. We performed a retrospective chart review to describe the outcomes of this new program.

Methods: Families to be screened were sent a packet with an eye chart and a 5-foot string, as well as instructions. On GKSD, screeners called the families and instructed the adults through screening the children over the phone. Results were collected and children who failed screening were sent to Wills Eye Hospital for an in-person appointment for re-screening and evaluation. After the Wills Eye Hospital Institutional Review Board approved this study, registration forms and clinical charts of all patients who attended GKSD 2020 were reviewed retrospectively. Demographic characteristics and ophthalmic findings were analyzed. Visual acuity on virtual screening was compared with in-person vision testing using Pearson correlation coefficient. Further subgroup analysis is being conducted at the time of abstract submission.

Results: Four hundred and seventy five children registered for virtual vision screening. Consequently, 151 children (43% female; 27% speaking languages other than English) with median age 11 years (age range 5-17 years) who failed screening received in-person evaluation. Out of these, 19% children underwent an eye exam for the first time. Refractive errors correctable with glasses were seen in 88%; 30 children with other diagnoses were referred to pediatric ophthalmology for further evaluation and management. There was a moderate correlation between screening and in-person visual acuity without refractive correction ($R=0.66$ OD, 0.58 OS); and a strong correlation between screening and in-person visual acuity with refractive correction ($R=0.76$ OD, 0.91 OS).

Conclusions: The GKSD virtual visual acuity testing demonstrated good correlation with in-person visual acuity testing, supporting the virtual screening approach as a useful tool for future applications in vision outreach programs.

ABSTRACT BODY:

Purpose: Recently, we found targeted BMP7+HGF dual gene therapy applied to stroma via PEI2-GNP effectively treated preformed corneal scar and restored transparency in vivo in rabbit with minimal acute toxicity (Invest Ophthalmol Vis Sci. 2018;59:1045-57). The goal of this study was to evaluate long-term in vivo tolerability of this BMP7+HGF therapy using a rabbit model.

Methods: Eighteen New Zealand White rabbits were used and divided into three groups. One eye of rabbit received BSS (n=6), naked-vector (n=6) or BMP7+HGF genes (n=6) via PEI2-GNP nanoparticles using published method (Invest Ophthalmol Vis Sci. 2018;59:1045-57). Rabbits were treated following ARVO guidelines under approved ACUC protocol. Clinical eye exams and diagnostic tools (Slit lamp, HRT3-RCM, Spectralis, and Specular microscopes; and pachymetry, tonometry, Schirmer, fluorescein and MacDonald-Shadduck tests) were employed in live rabbits in a time-dependent manner for 7 months for safety profiling. Thereafter, rabbits were humanely euthanized, corneal tissues were collected, and used for histological, immunofluorescence, and qRT-PCR analyses.

Results: Clinical eye exams detected no signs of chemosis, erythema, blepharospasm, or epiphora in all 3 groups until 7-month. HRT3-RCM, Spectralis and Specular biomicroscopy noted healthy corneal epithelium, stroma, and endothelium; and normal stromal and endothelial cell counts in all groups. No significant changes in intraocular pressure and MacDonald-Shadduck parameters in BMP7+HGF-delivered versus control eyes were observed ($p=0.9989$, $p=0.9876$). Histology and molecular investigations revealed no significant differences in cellular phenotype and levels of tested proinflammatory and fibrotic markers in BMP7+HGF-delivered versus control eyes ($p=0.9992$, $p=0.9619$; $p=0.9646$ $p=0.98379$).

Conclusions: Nanoparticle-mediated BMP7+HGF nanomedicine modality appears tolerable to the eye long-term in vivo.

ABSTRACT BODY:

Purpose: To develop a deep learning model to appraise fundus photograph image quality, and to determine how the quality of photography influences the predictive value of separate glaucomatous optic neuropathy (GON) detection deep learning (DL) models.

Methods: A training dataset of 2,815 optics disc photographs acquired from healthy and GON patients as part of the Diagnostic Innovations in Glaucoma Study (DIGS) and African Descent and Glaucoma Evaluation Study (ADAGES) was used to develop a DL model to quantify the quality of photographs (0=good, 1=poor). Image quality ground truth was determined by two reviewers, with high quality images defined as sufficient to detect GON. The DL quality model was then applied to an independent test dataset of 11,350 photographs from the Ocular Hypertension Treatment Study (OHTS). A previously published DL model to detect GON in fundus photos was also applied to the OHTS data. To determine the impact of DL predicted quality on automated review of fundus photos, area under the receiver operating characteristic curve (AUC) was calculated for both good quality OHTS photographs (score 0.0-0.1) and poorer quality photographs (score > 0.1).

Results: All OHTS photographs were considered good quality by the OHTS graders. In this dataset, 68 eyes reached OHTS primary open angle glaucoma (POAG) endpoint based on the development of visual field (41 eyes) or optic disc changes (55 eyes). The diagnostic accuracy of the DL model for POAG detection performed better in good quality compared to poorer quality photographs (AUROC: (95% CI)) of 0.86 (0.79, 0.91) and 0.81 (0.73, 0.88), respectively, though the differences did not reach statistical significance. Sensitivity at 90% specificity was also higher in the good quality (0.67) compared to poorer quality (0.44) photographs. Similar trends were found when the quality score was used to evaluate the DL glaucoma detection model separately on eyes that reached a visual field endpoint or an optic disc endpoint.

Conclusions: In the OHTS data, DL models for GON detection performed better in photos with DL predicted good quality, suggesting that DL based photograph quality assessment can be used to automatically identify low quality photos for removal. Incorporating quality assessment into automated review of fundus photos may thus improve GON detection model performance

ABSTRACT BODY:

Purpose: Limbal epithelial stem cells (LSCs) are vital for maintaining corneal epithelium homeostasis and for resurfacing the cornea after injury. The LSC niche is composed of a specialized hyaluronan (HA) matrix that is necessary for maintaining viable LSCs. In the cornea, HA has been shown to be almost exclusively expressed in the limbal region. Our preliminary data show HA rich clusters also exist in the peripheral cornea. Herein we characterize these HA clusters.

Methods: The distribution of LSCs, corneal epithelial progenitor cells (CEPCs), transient amplifying cells (TACs), and HA were analyzed in whole mounted corneas of wt (n=3) and HAS2^{Δ/ΔCorEpi} mice (n=3) using label-retaining techniques. For label retaining, mice were pulsed with 5-ethynyl-2'-deoxyuridine (EdU) via daily intraperitoneal injections from P7-P14 and thereafter chased for 8-weeks. LRCs were detected using Click-iT™ EdU Alexa Fluor™ 488 Imaging Kit. 1.0 mm central debridement wounds were used to trigger the influx of TACs into the peripheral cornea 24 or 48 hours prior to euthanasia. Corneas were stained for HA using biotinylated HA binding protein and analyzed under the LSM 800 confocal microscope (Carl Zeiss Microscopy LLC).

Results: After 8w chase, LRCs were mainly located in the limbal region, however, a small population LRCs were found within the corneal epithelium of all mice. HAS2^{Δ/ΔCorEpi} mice, which have previously been shown to be LSC deficient, presented limited LRCs in the limbal region, and, significantly fewer LRCs in the cornea when compared to wt mice. Wt mice present a rich HA network throughout the limbal epithelium and HA clusters within the peripheral cornea. In contrast, HAS2^{Δ/ΔCorEpi} mice presented limited HA expression within the limbal epithelium and few HA clusters within the peripheral cornea. A positive relationship was found between LRCs and HA clusters in naïve and wounded wt corneas 24h after wounding.

Conclusions: A positive relationship was found between HA clusters and LRCs (including TACs), within the wt limbal and peripheral corneal epithelium in vivo. Thus, our preliminary data indicate TACs could exist in the peripheral cornea within HA clusters.

TITLE: Development of a Meibomian Gland Dysfunction Model in the Rabbit

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Gallois-Bernos, C. Blackie, Johnson & Johnson Vision Care Research & Development, Johnson and Johnson Medical Devices, Jacksonville, Florida, UNITED STATES|S. Vasanth, L. Zhong, Toxikon Corp, Bedford, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Annabelle Gallois-Bernos: Commercial Relationship: Code N (No Commercial Relationship) | Shivakumar Vasanth: Commercial Relationship: Code N (No Commercial Relationship) | Lichun Zhong: Commercial Relationship: Code N (No Commercial Relationship) | Caroline Blackie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Create a model of evaporative dry eye or meibomian gland dysfunction in the rabbit via closure of meibomian glands, building on the Gilbard et al.'s previous work.

Methods: Six (6) New Zealand White rabbits were divided into two equal groups. Meibomian gland closure was achieved by cauterization of either alternating (Group 1) or all (Group 2) meibomian glands orifices in upper and lower eyelid of right eyes (OD), while left eyes (OS) were left untreated. Two (2) animals served as a control (no cauterization in either eye). Tear break-up time (TBUT) and tear production were measured on Day -2 and Day -1 (baseline), and slit lamp evaluations were performed prior to cauterization. Animals were followed for five weeks, with daily clinical observations (Draize score), weekly measurements of TBUT, tear production, and slit lamp evaluation prior to termination at Day 35.

Results: Clinical observations revealed eschar formation and swelling of the eyelids post cauterization that completely resolved at three weeks. Fluorescein staining did not reveal any corneal epithelial defect. There were no consistent differences in tear production between eyes or between time points in either group during the study. Cauterization of all meibomian gland orifices (Group 2) resulted in a consistent decrease in TBUT relative to baseline or untreated eye (Baseline Day -1 TBUT: 10.3 ± 1.5 sec in OD and 12.7 ± 2.1 sec in OS), which was significant at Day 14 (TBUT: 8.7 ± 1.5 sec in OD and 16.3 ± 2.1 sec in OS), Day 21 (TBUT: 7.7 ± 1.5 sec in OD and 15.7 ± 1.5 sec in OS) and Day 28 (TBUT: 8.7 ± 4.2 sec in OD and 16.7 ± 0.6 sec in OS), $p = 0.039$. Histopathological evaluation of eyes (sacrificed at Day 35) including eyelids, lacrimal, harderian, and meibomian glands did not reveal any significant findings.

Conclusions: Cauterization of all meibomian glands of rabbits yielded a significant reduction in tear film stability after 2 weeks and through 28 days. This model may be further optimized to serve as a tool to screen formulations for their ability to restore tear film stability and alleviate evaporative dry eye condition.

TITLE: Does Ocular Biometry in Adults Change Over Time?

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.K. Chan, R. Gulati, S. Basti, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nicholas Chan: Commercial Relationship: Code N (No Commercial Relationship) | Reeti Gulati: Commercial Relationship: Code N (No Commercial Relationship) | Surendra Basti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is standard practice to repeat biometry every 1-2 years prior to cataract surgery. The goal of this study was to assess if axial length (AL) and average keratometry (KER) (vital in lens calculation) change over time and question the clinical necessity of regularly repeating biometry.

Methods: Retrospective study of biometry data collected via IOL Master 700 (Zeiss, Germany) at Northwestern Memorial Hospital from January 1, 2016 through September 15, 2020. Inclusion criteria were patients over 35 years old, with two biometry measurements over 6 months apart. Patients were excluded if they had any other intraocular surgery, other than cataract. This analysis focused on AL and KER variables. To compare AL measurements among timepoints, a paired t-test was used. P-values were adjusted using the Bonferroni correction. Data was also stratified into four groups by axial length: hyperopia (<22mm), average (22 – 24.5mm), mild myopia (24.5 – 26.0mm), and high myopia (>26.0mm).

Results: A total of 201 patients (402 eyes) were included (average age 73.3, 59.3% female). Average time between biometry measurements was 21.5 months, average AL was 24.08 mm, and average KER was 43.73 D. The mean change in AL was 0.04 mm (95% CI: 0.03 to 0.05). The mean change in KER was 0.10 D (95% CI: -0.10 to 0.30, p=0.33). At the 6mo to 1 year interval (n=73), mean change in AL was 0.04 mm. Mean change in AL did not increase at the 1 to 2 year interval (n=204, Δ AL=0.05), the 2 to 3 year interval (n=87, Δ AL=0.03) or the 3 to 4 year interval (n=38, Δ AL=0.04). Using a linear regression model, there was no correlation between time and change in AL (p=0.06), nor between time and KER (p=0.15).

Eyes with high myopia showed a Δ AL of 0.07 (n=23; 95% CI: 0 to 0.15, p=0.06). This subgroup had the highest mean change in AL; compared to hyperopia (Δ AL = 0.04), average length eyes (Δ AL = 0.04) and moderate myopia (Δ AL of 0.03).

Conclusions: AL and KER change minimally over time between biometry readings. The mean change in AL was 0.04 mm (95% CI: 0.03 to 0.05). Change in AL did not increase with longer intervals of time between measurements. High myopes had a larger change in AL compared to shorter eyes, however, Δ AL was still low at 0.07 mm. These results suggest repeating biometry at a 1 to 2-year interval during surgical workup may not be a necessity, rather can be used selectively – for example, in high myopes.

ABSTRACT BODY:

Purpose: To compare sensitivity and specificity for the detection of reticular pseudodrusen (RPD) associated with age-related macular degeneration using multiple imaging modalities.

<gdiv></gdiv><gdiv></gdiv>

Methods: A post-hoc analysis was performed on images collected from a family-based prospective cohort study of 1320 elderly Amish subjects (age range 50–99 years) (2,640 eyes) who had a family history of at least 1 individual with AMD. All subjects underwent complete ophthalmic examination, spectral domain optical coherence tomography (SDOCT; 6x6mm ~ 20°), blue-light fundus autofluorescence (FAF), infrared reflectance (IR), and flash color fundus photography (CFP). Both eyes were included in this analysis. Individual imaging modalities were assessed separately in a masked fashion by expert human graders for the presence of RPD, also termed subretinal drusenoid deposits (SDD). To be deemed to be present, a minimum of three discrete lesions were required. Ground truth was established based on the presence of RPD on at least two modalities. Sensitivity and specificity were computed for each individual modality against the ground truth. As SDOCT images covered a smaller region (20° vs 30°) compared to other imaging analyses, SDOCT sensitivity and specificity was recomputed after cropping the other modalities to a similar region of interest.

<gdiv></gdiv><gdiv></gdiv>

Results: RPD were noted to be present on at least one modality in 140 (6.3%) of the 2640 eyes, and in 132 eyes (of 66 subjects; 5%) they were noted in at least two modalities (ground truth or reference determination). Overall, RPD were observed in 133 (5 %), 126 (4.8%), 115 (4.4%), 35 (1.3 %) eyes by IR, FAF, SDOCT and CFP respectively. Sensitivity and specificity for identification of RPD for each imaging modality is shown in Table 1. IR demonstrated the highest sensitivity, and CFP showed the lowest sensitivity. When cropping to a similar region, sensitivity and specificity of SDOCT improved to 93% and 95%, respectively.

<gdiv></gdiv><gdiv></gdiv>

Conclusions: IR imaging appears to be the most sensitive modality for detection of RPD, with a high specificity. SDOCT imaging can also show high sensitivity but may require the scan field to be enlarged beyond the dimensions commonly acquired in clinical practice.

ABSTRACT BODY:

Purpose: To determine if VEGF can be safely and effectively be obtained and detected in adequate quantities in the tears of premature infants to serve as a potential adjunct biomarker to indirect ophthalmoscopy for ROP disease screening, as well as to monitor disease progression and response to treatment.

Methods: Tear and saliva samples were collected from 20 infants born <28 weeks gestation or with a birth weight <900 g. Tear samples were collected using Schirmer strips placed in both eyes for 5 minutes. Saliva samples, acting as a surrogate for systemic VEGF, were collected using salivette cotton swabs placed in the infant's mouth for 3 minutes. Samples were diluted and analyzed using microfluidic platform detection antibodies directed against VEGF.

Results: Infants with ROP requiring treatment (n=4) and ROP not requiring treatment (n=5) were younger and smaller than infants without ROP (n=9). An increase tear to saliva ratio between 31-33 and 37-39 weeks gestation was found in infants without ROP and with ROP not requiring treatment but was persistently low in infants with ROP requiring treatment.

Conclusions: Adequate tear and saliva samples can be safely obtained from premature infants for analysis of VEGF. Infants with ROP requiring treatment have no increase in tear to saliva VEGF levels except following laser treatment. VEGF analysis may be an effective adjunct to ophthalmologic examination or may serve as a surrogate for ophthalmologic examination in resource-poor areas.

ABSTRACT BODY:

Purpose: The morphology of SC is believed to be closely related to glaucoma and accurate assessment on the dimension of Schlemm's Canal (SC) is vital. Optical coherence tomography (OCT) enables high-resolution, three-dimensional (3D) imaging of SC in living humans. This study quantitatively compares the performance of three commercial OCT systems in SC imaging and analyzes the impact factors that may affect the image quality as well as the morphological analysis of SC therefrom. Our study provides a guideline to choose an optimized OCT system for better visualization of SC.

Methods: Ten healthy subjects were imaged using three OCT machines: ZEISS Cirrus 5000 (840nm, spectral-domain (SD)-OCT), ZEISS Plex Elite 9000 (1060nm, swept-source (SS)-OCT) and Tomey Casia (1310nm, SS-OCT). For each subject, both eyes underwent two cubic scans by each machine, one on the nasal quadrant and the other temporal. The B-scan showing the largest SC was chosen and processed to obtain SC dimensional metrics. The SC contrast was investigated by quantitative comparison. Four morphological metrics, including the cross-sectional area (CSA), the perimeter, the longest, and shortest diameters of SC, were extracted via manual segmentation. The difference between the three OCT systems were analyzed.

Results: The CSAs were significantly different between different machines (Cirrus - Casia: $\Delta=1763.89\mu\text{m}^2$, $p < 0.001$; Plex - Casia: $\Delta=1026.21\mu\text{m}^2$, $p < 0.001$; Cirrus - Plex: $\Delta=737.68\mu\text{m}^2$, $p=0.003$), as well as the longest diameters (Cirrus - Casia: $\Delta=56.50\mu\text{m}$, $p < 0.001$; Plex - Casia: $\Delta=39.29\mu\text{m}$, $p < 0.001$; Cirrus - Plex: $\Delta=17.21\mu\text{m}$, $p=0.031$). The SC perimeter measured from Casia was significantly different compared to that from Cirrus or Plex (Cirrus - Casia: $\Delta=100.90\mu\text{m}$, $p < 0.001$; Plex - Casia: $\Delta=39.29\mu\text{m}$, $p < 0.001$). The shortest diameter measured from Cirrus and Casia was significantly different ($\Delta=-3.9\mu\text{m}$, $p=0.039$). The Michelson contrast was seen highest in Cirrus (0.63 ± 0.05), mediocre in Plex (0.57 ± 0.06), while lowest in Casia (0.40 ± 0.07). Based on visual assessment, the 1060nm system showed a good balance in angle delineation and SC visualization. Conversely, the 840nm system displayed good performance in SC visualization while the 1310nm system excelled in angle delineation.

Conclusions: The wavelength and resolution of the anterior segment OCT system may affect the visualization as well as the quantitative assessment of SC morphology.

TITLE: Miniaturization of Usher Syndrome Type 2A gene for AAV mediated gene therapy

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Wang, L.H. Vandenberghe, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts, UNITED STATES|W. Wang, L.H. Vandenberghe, Department of Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Weiwei Wang: Commercial Relationship: Code N (No Commercial Relationship) | Luk Vandenberghe: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Usher Syndrome (USH), an inherited disorder, is the leading cause of deaf-blindness. USH2A, one of the genes that causes Usher syndrome, encodes protein Usherin with an open reading frame of 15.6kb. Our goal is to engineer minigenes with reduced size and yet sufficient function, to meet the AAV volumetric constraints (<~5kb) for gene augmentation to rescue vision.

Methods: Full length Usherin consists of many motif repeats. We hypothesize that some of the repeats are redundant and aim to miniaturize USH2A through rational design of several exploratory minigenes and then high-throughput screening of combinatorial libraries with variant minigenes. We chose Oc-k1 cell line as our in vitro model as it displays the characteristic periciliary localization of Usherin and is originated from mouse organ of Corti. Our immunocytochemistry data showed that upon transfection, full length human USH2A expressed and localized at the periciliary region of Oc-k1 cell line (USH2A -/-). We observed that wild type Oc-k1 cells proliferate significantly faster than USH2A -/- cells, and full length USH2A can rescue cell proliferation. This yet to be explained feature is currently used as our in vitro screening platform.

Results: We designed 7 minigenes to interrogate the motif repeats and screened them by proliferation rate. Three minigenes achieved >60% rescue effect of the full USH2A, two displayed >30% increase and two had no effect compared to control group (vehicle vector). Four of the positive minigenes also demonstrated periciliary localization. Our result showed that deletion among the FN3 repeats affects cell proliferation less than the other motifs. Based on above results, we designed 3 independent libraries: Lib614 targets FN3 repeats #6~14, Lib1625 for #16~25, Lib2734 for #27~34. Each variant contains a unique barcode for batched screening through NGS. We have completed the assembly of Lib614, with Lib2734 assembly in progress. These libraries will be subject to cell proliferation assay and NGS for functionality screening.

Conclusions: We conclude that the FN3 repeats region, occupying almost 2/3 of the entire USH2A gene, bears redundant motifs that may be deleted for USH2A miniaturization. The proliferation assay with Oc-k1 cells revealed potential physiological role of USH2A, though it calls for further investigation on the mechanism to justify the correlation between in vitro proliferation and in vivo photoreceptor rescue.

ABSTRACT BODY:

Purpose: To investigate the relationship between genetic polymorphisms in Japanese patients with age-related macular choroidal neovascularization (CNV) and complement activation products in the aqueous humor.

Methods: We enrolled 248 eyes of 248 patients; 60 patients with neovascular age-related macular degeneration (nAMD), 62 patients with Pachychoroid neovasculopathy (PNV), 57 patients with polypoid choroidal angiopathy (PCV), 25 patients with retinal hemangiomatous proliferation (RAP), and 52 patients with cataract who received surgery as controls. Genotyping of ARMS2 A69S and CFH I62V, which was reported as the major susceptibility genes in Japanese nAMD patients, was performed by the TaqMan method. Aqueous humor was collected immediately before the first vitreous injection of anti-VEGF therapy or before cataract surgery. Complement activation products (C3a, C4a) concentrations were measured using a bead array system (Cytometric Bead Array, The BD-TM).

Results: In the patients with CNV, the allele frequency of ARMS2 A69S was TT: TG: GG = 4.1: 4.0: 1.9, and the C3a concentration (median, ng / mL) was 3.02: 3.00: 2.27, respectively. The C3a concentrations in the patients with TT (P = 0.001) and TG (P = 0.002) were significantly higher than those with GG. The allele frequency of CFH I62V was GG: GA: AA = 5.1: 4.0: 0.9, and the C3a concentration was 3.00: 2.93: 2.69, respectively. There were no significant relations between the CFH I62V allele and C3a concentration. The C4a concentration in the aqueous humor showed allele-specific changes in neither ARMS2 A69S nor CFH I62V genotypes. Neither ARMS 2 A69S nor CFH I62V was associated with C3a and C4a concentrations in the control group.

Conclusions: ARMS2 A69S may activate the intraocular complement system in association with the alternative pathway.

TITLE: Teprotumumab for the Treatment of Thyroid Eye Disease: Clinical Experience from Expanded Access Program (EAP)

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Wang, T. Mester, R. Douglas, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|S. Ugradar, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yao Wang: Commercial Relationship: Code N (No Commercial Relationship) | Tunde Mester: Commercial Relationship: Code N (No Commercial Relationship) | Shoaib Ugradar: Commercial Relationship: Code N (No Commercial Relationship) | Raymond Douglas: Commercial Relationship(s);Horizon Therapeutics :Code C (Consultant);Osmotica Pharmaceuticals :Code C (Consultant)

ABSTRACT BODY:

Purpose: Teprotumumab was approved in January of 2020 for the treatment of thyroid eye disease (TED). The purpose of this study was to evaluate additional efficacy parameters in patients receiving teprotumumab in the EAP (NCT04040894), which was initiated prior to the drug's approval by the US. Food and Drug Administration.

Methods: This was a retrospective cohort study of patients who received teprotumumab at one study center. Eligible patients included those who were at least 18 years old with a clinical diagnosis of active, moderate-to-severe TED with a clinical activity score (CAS) equal to/greater than 4 with onset of TED within 12 months. Patients were provided 8 infusions (10 mg/kg first infusion, 20 mg/kg thereafter) every 3 weeks over course of 21 weeks. End points included changes in proptosis, intraocular pressure (IOP), extraocular motility deficit, CAS, photophobia score (visual light sensitivity questionnaire-8 [VLSQ-8]), basic secretion test, volumetric analysis of facial compartments (Canfield Vectra H2 camera). Paired t-tests were used to evaluate statistical significance from baseline. Results are presented for the more severe (study) eye.

Results: 13 patients (4 males, 9 females) were included in the analysis. 10/13 patients were Caucasian. Average age was 46.5 ± 15.9 years with a mean TED duration of 7.1 ± 3.0 months. 10/13 (77%) received the complete set of 8 infusions (3 discontinued due to COVID-19, personal choice, and hyperglycemia). At week 21, the change from baseline (CFB) was -4.6 ± 2.1 mm (n=11) for proptosis and -4.0 ± 1.6 (n=11) for CAS (both $p < 0.001$), -9.1 ± 5.0 (n=11; $p < 0.001$) for light sensitivity, and -3.6 ± 3.4 mmHg (n=9; $p < 0.05$) for IOP. 6 patients (n=12) had abnormal wetting test at eligibility visit, compared to 3 at week 21 (n=10). 6 patients had manifest strabismus, 5 of who had complete data. Out of the 5 patients, all but one patient had improvements in either extraocular motility or strabismus measurements. Facial volumetric analysis demonstrated reductions in both upper (CFB: -1.4 ± 0.7 cc; n=4; $p = 0.03$) and lower lid volume (CFB: -2.2 ± 1.3 cc; n=4; $p = 0.04$).

Conclusions: These results support previously reported teprotumumab improvements in proptosis and CAS. Data from this cohort of patients suggest that teprotumumab may also be effective in improving light sensitivity, IOP, motility deficit, dry eyes, and periorbital edema.

ABSTRACT BODY:

Purpose: Primary congenital glaucoma (PCG) is a rare genetic disorder and accounts for 5% of childhood blindness worldwide. Increased intraocular pressure (IOP) leads to corneal clouding, globe size expansion, and optic nerve damage. Genetic studies to date only explain approximately 60% of the mutation etiology. We sought to find the causal mutation in a collection of PCG families prescreened and determined to be negative for mutations in known PCG genes CYP1B1, MYOC, and TEK.

Methods: After consent was obtained, medical histories and blood samples for DNA extraction were acquired from available members of 4 non-consanguineous families (African and European descent) with non-syndromic PCG. Exome sequencing was performed on the 4 affected probands utilizing either a Sure Select Human All Exon capture kit or a Roche/Nimblegen SeqCap EZ v2.0 capture kit, and an Illumina HiSeq platform. Golden Helix SVS software was used to remove variants that were outside of coding/splice site regions, synonymous, or with an allele frequency greater than 0.002 (gnomAD global data). Sanger sequencing validated the candidate variants and the genotypes of additional family members. Gene expression in ocular tissues was interrogated using the Iowa Ocular Tissue Database.

Results: Exome sequencing identified 4 rare heterozygous missense variants within either the extracellular LDL-receptor class A repeat domain (p.Gln1025His), B repeat domain (p.Arg2276His and p.Arg2577His) or linker region (p.Asp2101Gly) of the low density lipoprotein receptor 2 gene LRP2. Global and ethnically matched population allele counts were low for all variants (gnomAD database). FATHMM, SIFT, Polyphen2, and CADD algorithms predicted variants to be functionally detrimental. Vertebrate protein sequence alignments showed strong conservation of the reference residues at all 4 missense variant locations. LRP2 ocular gene expression was identified as high in the optic nerve, retina, and ciliary body.

Conclusions: We provide evidence for autosomal dominant PCG with reduced penetrance caused by heterozygous missense mutations in LRP2. Human LRP2 mutations residing in the same protein domains as our variants have been associated with high myopia with normal IOP. Our findings suggest that LRP2 may also play a role in early-onset glaucoma. Increased suspicion for glaucoma is advised with clinical inspection of individuals with high myopia.

TITLE: Rod bipolar cell contributions to changes in response sensitivity during light adaptation

SESSION TITLE: Inner retinal function

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Griffis, A.P. Sampath, Ophthalmology, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|C. Griffis, MC&IP, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Christopher Griffis: Commercial Relationship: Code N (No Commercial Relationship) | Alapakkam Sampath: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mammalian rod bipolar cells desensitize with increases in mean luminance. This process of light adaptation reflects the sum of presynaptic gain changes in rods and postsynaptic changes in the mGluR6 signaling cascade. Here we dissect these contributions and study their underlying mechanism by measuring the properties of light-evoked signals in both rods and rod bipolar cells using patch electrodes.

Methods: Whole-cell voltage clamp recordings were made from rod photoreceptors and rod bipolar cells in dark-adapted mouse retinal slices. Light-evoked responses were recorded for a series of flashes in darkness and during the presentation of background light up to 400 Rh^* (activated rhodopsins) $\text{rod}^{-1} \text{ sec}^{-1}$. A Hill equation with three free parameters was fit to the rod bipolar cell response-intensity relationship - including the maximum photocurrent (R_{max}), the half-maximal flash strength (k), and the extent of nonlinearity in response amplitude as a function of flash strength (n).

Results: Rod photoreceptors exhibited a 2-fold loss of sensitivity at light intensities that cause $\sim 50 \text{ Rh}^* \text{ sec}^{-1}$. Downstream rod bipolar cells exhibit a more complicated sensitivity change. In dim backgrounds, n was reduced from a value of 1.6 in darkness to 1.0 by approximately $10 \text{ Rh}^* \text{ rod}^{-1} \text{ sec}^{-1}$. At brighter light intensities, k began to shift, reflecting the decline in rod sensitivity. R_{max} was also reduced by up to 60% at the brightest backgrounds tested. Dialysis of 10mM BAPTA during recordings, or holding the membrane potential at +50mV, reduced this modulation. Nonstationary noise analysis of the falling phase of light-evoked responses elicited in darkness and in background light reveal that the reduction in R_{max} does not arise from a reduced TRPM1 single-channel current. Instead, it must result from a reduction in the coupling between the mGluR6 receptors and TRPM1 channels.

Conclusions: Measurements in mouse rod bipolar cells reveal that the loss in sensitivity as a function of background light is a combination of the loss in sensitivity due to rod phototransduction, along with mechanisms intrinsic to the rod bipolar cell dendrites. These collectively allow rod bipolar cells to respond robustly to single photon absorptions in a minority of the rods, while continuing the signal at brighter lights that also cause rod adaptation.

Commercial Relationships Disclosure (Abstract): Zelun Wang: Commercial Relationship: Code N (No Commercial Relationship) | Philip Williams: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) death underlies vision loss during glaucoma. RGCs exhibit differential resilience to glaucomatous neurodegeneration, but it is unclear what cellular characteristics underlie this heterogeneous survival. Since survival in degenerative conditions likely requires high energy expenditure, we set out to test whether metabolic fitness influences survival of resilient RGC subsets.

Methods: We measured cellular ATP by 2-photon in vivo imaging of the FRET biosensor ATeam1.03 expressed specifically in RGCs. This method allows us to assess variance in ATP levels across the RGC population at the resolution of individual cells. We examined ATP dynamics in RGCs following pharmacologic challenge, correlating their differential response to survival following axon injury by optic nerve crush.

Results: At baseline, mouse RGCs maintain normally distributed cellular ATP levels. Intravitreal injection of sodium azide (NaN_3), a mitochondrial respiration inhibitor, revealed three RGC populations with distinct energetic behavior: a population resistant to ATP decline; a susceptible population with early decline and prolonged ATP depletion; and an intermediate population exhibiting delayed onset of ATP decrease followed quickly by recovery. Individual ATP responses in RGCs were reproducible across repeat NaN_3 challenge injections. Further, NaN_3 was not toxic as no RGC loss was observed up to 8 weeks after injection, allowing correlation of ATP dynamics with survival after optic nerve injury. Preliminary analysis suggests that the ATP-stable population have increased survival 14 days after optic nerve crush (32% survival) compared to RGCs that exhibited transient or prolonged ATP decline (17% survival).

Conclusions: We can directly examine energetic characteristics of individual RGCs in vivo and match energetic signatures with survival potential. We have found three cohorts of RGCs differentiated by their susceptibility to mitochondrial inhibition. Our preliminary data suggest that this heterogeneity in the ability to sustain cellular ATP may influence RGC survival after axotomy. Future experiments will examine other energetic pathways using appropriate pharmacologic inhibitors, in addition to more relevant glaucoma models.

TITLE: Ophthalmological care during COVID-19 times. Perspectives from a Mexican eye healthcare system

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: I.A. Domínguez Varela, G. Ortiz-Morales, D. Gomez-Elizondo, A. Bustamante Arias, J.A. Nava García, J. Valdez-Garcia, Ophthalmology, Instituto Tecnológico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, MEXICO]

Commercial Relationships Disclosure (Abstract): Irving Domínguez Varela: Commercial Relationship: Code N (No Commercial Relationship) | Gustavo Ortiz-Morales: Commercial Relationship: Code N (No Commercial Relationship) | Daniela Gomez-Elizondo: Commercial Relationship: Code N (No Commercial Relationship) | Andres Bustamante Arias: Commercial Relationship: Code N (No Commercial Relationship) | José Nava García: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Eugenio Valdez-Garcia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the ophthalmological care management of cataract patients during the COVID-19 pandemic in an eye healthcare system in Mexico.

Methods: A retrospective observational study was designed to review the surgical management of cataract patients from March 1st to December 31, 2020, compared to the same period from 2019. We classified surgical management in three categories: urgent, emergent, and elective procedures, based on the the Mexican Society of Ophthalmology (SMO) and our Epidemiological Surveillance Unit (UVEH). Three eyecare centers participated in this study. The main outcome measure was the rate of reduction in urgent and elective surgeries performed. Priority was given to patients with retinal disease, glaucoma, brunescant cataracts, pediatric patients, and patients with visual acuity ($\leq 20/200$). Routine preoperative RT-PCR testing for SARS-COV-2 was required for all patients.

Results: 240 cataract surgeries were performed in the 2020 period compared to the 643 surgeries performed in the same period of the previous year (-62.7% in 2020 compared to 2019, $p < 0.0001$). (Fig. 1) The mean age of operated patients was 66.5 ± 11.81 years in 2019 and 66.2 ± 12.06 y in 2020. During the studied period, thirteen cataract surgeries (5.4%) were suspended in our healthcare system due to positive preoperative results for SARS-CoV-2 by nasopharyngeal PCR.

Conclusions: The implementation of strict protocols in our non-COVID-19 units allowed for surgical management of cataract patients. As expected, a significant reduction in the amount of cataract surgeries was recorded during the SARS-COV-2 outbreak. Preoperative PCR testing for all patients who undergo cataract surgery in conjunction with strict hospital protocols might allow for safe surgical management of cataracts.

From our healthcare university system, a tertiary referral hospital was converted into a COVID-19 unit in order to tackle the challenges of the pandemic. A second tertiary hospital increased its capacity to attend to the needs of all surgical and clinical necessities of non-COVID-19 patients. Lastly, the specialized ophthalmological unit (CAM) reopened in August, with restricted capacity, restructuration of areas, staff rotation, COVID-19 testing of staff and strict sanitary precautions.

TITLE: 5-Year Results of a Home Monitoring Device in Study Participants at High Risk for Neovascular Age-related Macular Degeneration

SESSION TITLE: AMD: clinical research - new therapies and technologies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M.T. Altman, M. Thomas, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|V. Chaikitmongkol, Department of Ophthalmology, Chiang Mai University, Suthep, Chiang Mai, THAILAND|N.M. Bressler, Department of Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Marcus Altman: Commercial Relationship: Code N (No Commercial Relationship) | Merina Thomas: Commercial Relationship: Code N (No Commercial Relationship) | Voraporn Chaikitmongkol: Commercial Relationship: Code N (No Commercial Relationship) | Neil Bressler: Commercial Relationship(s);Notal Vision Inc.:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) with choroidal neovascularization (CNV) is a leading cause of blindness, necessitating early treatment before significant vision loss occurs. The ForeseeHomeTM Preferential Hyperacuity Perimeter (PHP) is FDA-approved to aid in home monitoring for CNV related to AMD. A prospective cohort study evaluated how often home monitoring detects conversion to CNV in patients with intermediate AMD over a relatively long follow-up.

Methods: Patients were ≥55 years-old and had intermediate AMD with visual acuity ≥20/63 in the study eye. A previous study determined that an in-office qualifying test could identify patients most likely to use the PHP device successfully. Patients who qualified were then required to establish a baseline score at home with the device. If successful, the patient proceeded with daily home use. Patients were monitored for 5 years and could trigger an in-office visit by either a device alert or by reporting a visual symptom. If no CNV was detected at the visit, the patient could then re-establish a baseline with the device to continue home testing.

Results: 91 patients qualified for device use, with mean age of 73.1 years and visual acuity of 20/28. Of these, 132 study eyes established a baseline to begin home testing, with 54 eyes (41%, 95% CI 32%-50%) having at least one alert (by symptom and/or device) over 5 years of testing. Among 90 device-triggered visits, 83 (92%) were false positive, while 7 (8%, 95% CI 3%-15%) resulted in detection of CNV at mean 2.1 years following enrollment. Two eyes that developed CNV were diagnosed by symptom only without a device alert (2 of 9 total CNV cases; 22% false negatives, 95% CI 3%-60%). Mean visual acuity at time of CNV detection was ~20/32. 23 eyes that had a false-positive alert withdrew from the study due to a failure to re-establish baseline—of these, 6 (26%) developed CNV on average 2.7 years later. Mean monthly device usage was 15 times per month and was higher in the first year of an eye's enrollment versus the fifth year (18.5 vs 12.8 uses per month, difference = 5.7, 95% CI: 3.5-7.9; P<.001).

Conclusions: These data over 5 years suggest a large proportion of incident neovascular AMD cases were detected by home monitoring, and eyes monitored by the device had good visual acuity at time of CNV detection. In this study, the device showed a 22% false negative rate.

TITLE: Fibroblast growth factor (FGF) potentiates transforming growth factor-beta (TGF- β)-induced EMT of lens epithelial cells in a spatially dependent manner

SESSION TITLE: Lens Cell Biology and Regulation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Flokis, F.J. Lovicu, The University of Sydney School of Medical Sciences, Sydney, New South Wales, AUSTRALIA|F.J. Lovicu, The University of Sydney Save Sight Institute, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Mary Flokis: Commercial Relationship: Code N (No Commercial Relationship) | Frank Lovicu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Epithelial-to-mesenchymal transition (EMT) of lens epithelial cells is involved in the development of fibrotic cataract. Ocular growth factors and cytokines such as fibroblast growth factor (FGF) and transforming growth factor-beta (TGF- β) have been shown to regulate and/or dysregulate lens epithelial cell (LEC) regulatory processes, including proliferation, fibre differentiation and EMT. Here we tested the hypothesis that FGF-2 differentially potentiates lens epithelial TGF- β -induced EMT in the rodent lens.

Methods: Postnatal 21-day-old rat LEC explants treated with TGF- β 2 (50 pg/ml) to induce EMT, and/or co-treated with FGF-2 (150 ng/ml), were monitored over a 5-day culture period, comparing central and peripheral regions. Changes in levels of EMT marker α -SMA and fibre differentiation/elongation markers including β -crystallin were examined using immunolabeling, as well as canonical TGF- β signaling (Smads 2/3) at 2 hours. Western blotting was also used to compare LEC protein expression levels.

Results: Compared to LECs treated with only TGF- β 2, we show that the addition of a high fibre differentiating dose of FGF-2 differentially impacted TGF- β 2-treated LECs after 5 days of culture; with central LECs undergoing TGF- β 2-induced EMT, whereas peripheral LECs primarily undergoing lens fibre-cell elongation in place of EMT. This co-treatment with FGF-2 and TGF- β 2 retained labelling for α -SMA in central LECs with little to no β -crystallin; however, β -crystallin was most prominent in peripheral LECs. Interestingly, FGF did not potentiate nuclear translocation of Smad2/3 in TGF- β -treated LECs by 2 hours of culture.

Conclusions: The current study showed an important role for FGF-2 in potentiating EMT in TGF- β 2-treated LECs, in a spatially dependent manner. This provides a new perspective for the role of FGF-2 in lens, in particular its role in the modulation of TGF- β 2-induced EMT leading to cataract.

TITLE: Comparing the Speed of Glaucoma Progression at Various Stages as Measured by Function, Structure, and Perfusion

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Liu, E. Ing, J. WANG, A. Chen, B. Edmunds, O. Tan, P. Wei, Y. Jia, D. Huang, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Liang Liu: Commercial Relationship: Code N (No Commercial Relationship) | Eliesa Ing: Commercial Relationship: Code N (No Commercial Relationship) | JIE WANG: Commercial Relationship: Code N (No Commercial Relationship) | Aiyin Chen: Commercial Relationship: Code N (No Commercial Relationship) | Beth Edmunds: Commercial Relationship: Code N (No Commercial Relationship) | Ou Tan: Commercial Relationship(s);Optovue, Inc:Code P (Patent) | Ping Wei: Commercial Relationship: Code N (No Commercial Relationship) | Yali Jia: Commercial Relationship(s);Optovue, Inc:Code F (Financial Support);Optovue, Inc:Code P (Patent) | David Huang: Commercial Relationship(s);Optovue, Inc:Code F (Financial Support);Optovue, Inc:Code I (Personal Financial Interest);Optovue, Inc:Code P (Patent);Optovue, Inc:Code R (Recipient)

ABSTRACT BODY:

Purpose: To compare the speed of glaucoma progression as measured by visual field (VF), optical coherence tomography (OCT), and OCT angiography (OCTA).

Methods: This is a prospective, observational study. Pre-perimetric glaucoma (PPG) and perimetric glaucoma (PG) patients are followed up every 6 months for at least 18 months (average: 30.4 ± 11.0 months). One eye of each participant was scanned using 4.5x4.5-mm OCTA centered on the disc with the AngioVue system (Optovue). The nerve fiber layer plexus capillary density (NFLP CD) was defined as the percentage area occupied by flow pixels excluding large vessels. The nerve fiber layer (NFL) thickness was measured from ONH scan. The NFLP mean deviation (NFLP MD) and NFL MD were visual field (VF)-equivalent dB-scale quantities based on sectorwise nonlinear regression of NFLP CD and NFL thickness with VF deviation. The speed of glaucoma progression was measured by linear regression trend slope over time. A linear mixed model was used to calculate the P values of the slopes.

Results: Forty-one patients were analyzed. Twelve had PPG (average VF MD -0.55 dB), 29 had PG (average VF MD -5.13 dB; range -0.84 ~ -18.35 dB). Reproducibility, on dB scale, was best for NFL MD, followed by NFLP MD and VF MD (Table 1). The trend slope in VF MD was not significantly different from zero in either group. In the PPG group, progression as measured by NFL MD was significantly ($P < 0.007$, Wilcoxon test) faster compared to NFLP MD and VF MD. In the PG group, NFLP MD progression was significantly ($P < 0.001$) faster than NFL MD and VF MD. NFLP CD and NFLP MD had significant decrease only in the PG stage, not the PPG stage. While NFL thickness loss was twice faster ($P < 0.001$, Mann-Whitney test) in the PPG stage compared to the PG stage.

Conclusions: VF MD is not suitable for measuring progression over such a short follow-up period due to the high measurement variability of this functional parameter. NFL thickness and its derivative NFL MD may be useful in monitoring progression in PPG patients as these structural parameters decreased faster in this early stage. NFLP CD and its derivative NFLP MD may be useful in monitoring PG patients as these perfusion parameters decreased faster in this later stage.

ABSTRACT BODY:

Purpose: To compare the efficacy of intravitreal triamcinolone acetonide (Triesence®, IVT) and intravitreal dexamethasone implants (Ozurdex®, OZD) for cases of non-infectious posterior uveitis.

Methods: A clinical database was queried to identify all eyes treated with IVT or OZD from 2018 through 2020 at the University of California, Davis Health System. Clinical and imaging data, including visual acuity (VA), intraocular pressure (IOP), use of systemic immunomodulatory therapy (IMT), and central macular thickness (CMT) on optical coherence tomography were analyzed before and after their most recent IVT or OZD treatment. Eyes were excluded if there was a concurrent diagnosis of other fundus pathology (e.g. diabetic retinopathy, retinal vein occlusion), a lack of follow-up after treatment, or no light perception VA.

Results: 22 eyes from 16 patients (4 men, 12 women) were identified that met inclusion criteria. The average age at time of treatment was 67.3 years (range 37.7-98.4). The distribution of non-infectious uveitis amongst the eyes were: 15 idiopathic, 4 sarcoid, 2 tubulointerstitial nephritis and uveitis syndrome, and 1 Vogt-Koyanagi-Harada. 12 eyes received IVT (54.5%) and 10 eyes received OZD (45.5%). Only four eyes (three patients) were on systemic IMT at the time of injection. The patients were followed for a mean of 145.5+/-31.7 days for IVT and 160.5+/-34.7 days for OZD. Overall, there was a statistically significant improvement in LogMAR VA (-0.17, p=0.03), and reduction in CMT (-70.1 microns, p=0.01) after treatment, while there was no difference in IOP compared to baseline (p=0.26). The change in LogMAR VA after IVT treatment was -0.105+/-0.06 and after OZD treatment was -0.245+/-0.14, which was not statistically significant between groups (p=0.37). The change in CMT was -81.33 microns after IVT treatment, and -56.6 microns after OZD treatment, which was not significantly different between groups (p=0.6370).

Conclusions: The use of intravitreal steroid resulted in a significant improvement in VA, and CMT on OCT without significantly affecting IOP in eyes with non-infectious uveitis. No significant difference was noted in visual acuity and CMT change in following OZD when compared to IVT in this small retrospective study. While there was a trend towards better visual and imaging outcomes in eyes treated with OZD, it was not statistically significant.

ABSTRACT BODY:

Purpose: Studies have shown that artificial intelligence (AI) algorithms can help screen for treatment-requiring retinopathy of prematurity (ROP), though it is unknown how cost-effective this is versus standard methods. This study evaluated the cost-effectiveness of autonomous and assistive AI-based ROP screening compared to telemedicine and ophthalmoscopic screening over a range of probabilities, costs, and outcomes.

Methods: Decision trees created and analyzed in TreeAge Pro modeled outcomes and costs of four possible ROP screening strategies: ophthalmoscopy, telemedicine, assistive AI with telemedicine review, and autonomous AI with only positive screens reviewed. We assumed similar sensitivity for detection of severe ROP with a wide sensitivity analysis, but a higher specificity for ophthalmoscopy. Screening and treatment costs were based on Current Procedural Terminology codes, and opportunity costs to physicians were modeled. AI cost was assumed to be \$30. Outcomes were based on the Early Treatment of ROP study, defined as timely treatment, late treatment, or correctly untreated. Incremental cost-effectiveness ratios were calculated at a willingness-to-pay threshold of \$100,000. One- and two-way sensitivity analyses were performed comparing AI strategies to telemedicine and ophthalmoscopy, as was a probabilistic sensitivity analysis.

Results: Autonomous AI was as effective and less costly than each other screening modality (Table 1). Cost of AI evaluation was the most important factor in the sensitivity analysis. AI-based ROP screening was cost-effective up to \$17 for assistive and \$43 for autonomous screening compared to telemedicine, and \$51 and \$73 compared to ophthalmoscopy. In the probabilistic sensitivity analysis, both AI screening modalities were cost-effective in over half of trials in all but one comparison (Figure 1).

Conclusions: We demonstrate that AI-based screening strategies may be more cost-effective than traditional screening modalities across a range of parameters, and cost-effectiveness depends significantly on what cost is assigned to AI.

TITLE: The Effects of Donor-Recipient Age and Sex Compatibility in the Outcomes of Anterior Lamellar Keratoplasties

SESSION TITLE: Corneal transplantation and surgery

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Htoon, Singapore Eye Research Institute, Singapore, SINGAPORE|N. Chiam, Singapore National Eye Centre, Singapore, Singapore, SINGAPORE|H. Ong, A. Arundhati, J.S. Mehta, Corneal and External Diseases, Singapore National Eye Centre, Singapore, Singapore, SINGAPORE|H. Ong, J.S. Mehta, Tissue Engineering and Cell Therapy, Singapore Eye Research Institute, Singapore, SINGAPORE|

Commercial Relationships Disclosure (Abstract): Hon Shing Ong: Commercial Relationship: Code N (No Commercial Relationship) | Nathalie Chiam: Commercial Relationship: Code N (No Commercial Relationship) | Hla Myint Htoon: Commercial Relationship: Code N (No Commercial Relationship) | Anshu Arundhati: Commercial Relationship: Code N (No Commercial Relationship) | Jodhbir Mehta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal transplantations are the commonest allogenic transplant surgeries performed worldwide. Transplantable grade donor cornea is a finite resource. There is thus an impetus for eye banks to optimise the use of each harvested cornea, and clinicians to minimise risks of graft rejection and failure.

Studies on donor-recipient (D-R) age or sex compatibility have mainly been focused on penetrating keratoplasty (PK) and endothelial keratoplasty (EK) procedures. Although studies have reported beneficial effects of sex or H-Y matching in lowering risks of PK or EK rejection and failure, current evidence is still equivocal.

With better survival and lower rejection rates, anterior lamellar keratoplasty (ALK) has gained popularity as an alternative to PK, to treat corneal stromal diseases. We evaluated the effects of D-R age- and sex-matching on the outcomes of eyes that had undergone ALK surgeries.

Methods: ALK surgeries performed in an ophthalmic hospital over an 11-year period were identified (graft registry data). To analyse the effects of sex-matching, transplants were classified as 'presumed H-Y incompatible' (male donor to female recipient) or 'presumed H-Y compatible' (all other D-R sex combinations). For age-matching, differences in donor and recipient ages were calculated. Cox proportional hazards regressions were used to assess the influence of D-R sex- and age-matching on graft failure and rejection.

Results: 359 eyes (322 patients) were included. 246 (68.5%) grafts were presumed H-Y compatible. 14 (3.9%) grafts failed and 8 (2.2%) rejected. There were trends of lower hazard ratios (HRs) in graft failure and rejection in the presumed H-Y compatible group (0.59[95% CI 0.20-1.77] and 0.93[95% CI 0.22-3.89], respectively). Median difference in age between recipients and donors was 14.9 years (IQR 2.8-33.2). HRs of graft failure and rejection were not influenced by D-R age (HRs per 1-year increase in age difference: 1.00[95% CI 0.98-1.02] and 1.01[95% CI 0.99-1.03], respectively).

Conclusions: Sex- or age-matching had no significant effect on ALK rejection and failure. Although trends of fewer graft rejection and failure in presumed H-Y compatible grafts were observed, over 500,000 ALK surgeries would be required to achieve adequate power to show significant effects of matching, if any. Routine sex- and age-matching during graft allocation for ALK surgeries thus cannot be recommended.

ABSTRACT BODY:

Purpose: Posterior segment involvement in patients with HLA-B27 associated uveitis is a relatively uncommon condition, with a prevalence of 17.4 to 23.1%. This retrospective cohort study investigated the prevalence and characterized the posterior segment involvement in eyes with HLA-B27 associated uveitis. We also aimed to assess the patient characteristics which are associated with posterior segment involvement.

Methods: Medical records of 65 patients (130 eyes) with HLA-B27 associated uveitis, from two university uveitis clinics (United States and Turkey) were reviewed. Posterior segment findings were identified based on medical records and optical imaging including color fundus photography, fluorescein angiography and optical coherence tomography. Findings identified were vitreous haze, vasculitis, optic disc leakage and macular edema. Clinical course of anterior uveitis was described as acute, recurrent, or chronic according to the standardization of uveitis nomenclature (SUN) classification. Recurrent uveitis was defined as repeated episodes separated by periods of inactivity without treatment ≥ 3 months in duration, and chronic uveitis was persistence or relapse of symptoms within 3 months after discontinuation of treatment. Patients who had significant systemic and ocular comorbidities were excluded from the study.

Data was collected using REDCap and analyzed using Stata ver. 16.1.

Results: Forty-four patients were included from US while 21 patients were included from Turkey. The mean age at presentation was 41 ± 15.1 years with a majority being male [42 (65%)] and non-Hispanic Caucasian [34 (53%)]. Overall, 26 patients (36 eyes) demonstrated posterior segment findings; 15 (34%) belonged to US while 11 (52.4%) patients belonged to Turkey. Among eyes with posterior segment involvement, most common findings were peripheral vasculitis and vitreous haze [13 (36.11%) each] followed by macular edema and disc leakage [6 (16.67%) each]. Patients with chronic uveitis (5/7) presented with more posterior segment involvement in US while patients with recurrent uveitis (5/6) presented with more posterior segment findings in Turkish cohort.

Conclusions: Posterior ocular findings can be seen in up to 40% of patients with HLA-B27-associated uveitis. Patients with chronic or recurrent uveitis are more likely to have posterior segment involvement and therefore should warrant more comprehensive evaluation for posterior disease.

ABSTRACT BODY:

Purpose: While robust methods exist for suprachoroidal space (SCS) delivery in larger animals (e.g. rabbits, primates), reliable SCS injection in rodents has yet to be achieved given their substantially smaller eye size. We hypothesize that liquid formulations can be successfully deposited in the SCS when 1) a microneedle injector is properly scaled to ascertain the complete and precise penetration of the needle length across the extremely thin rodents' sclera, and 2) the eye is stabilized while injecting to reduce the probability of failure due to stochastic movements.

Methods: Glass microneedles were fabricated out of glass pipettes, tapering to a tip diameter of 110 μm . 3D-printing was utilized to fabricate different injector designs, and each design was tested to find the optimal configuration. Wistar rats (N=12) and guinea pigs (N=6) were each injected suprachoroidally in one eye with nanoparticle suspensions, while the contralateral eye remained naïve. A custom-made 3D-printed probe was constructed and used to secure the eye firmly in position while injecting. Fundoscopy, slit lamp examination and post-mortem analysis including histological and immunohistochemical staining were performed on all eyes post-procedure.

Results: An optimum injector was achieved with design features fit for miniscule dimensions of rodents' eyes and was used henceforth. Fundoscopy together with confocal imaging of the histology sections confirmed the targeted delivery of nanoparticles to the SCS in all eyes. The optimum microneedle length was found to be $160 \pm 10 \mu\text{m}$ and $260 \pm 10 \mu\text{m}$ for rats and guinea pigs, respectively. Immunohistochemistry and histopathological analysis further revealed no evidence of retinal/RPE abnormalities or choroidal complications in the injected eyes compared to the control eyes.

Conclusions: The ability to reliably deliver to the SCS of rodents facilitates pre-clinical testing of a variety of novel therapeutics and accelerates the development of new ocular therapies. Rodents are an ideal model for pre-clinical investigations given their low cost and availability of various ocular disease models. Here, we highlight the ability of a robust microneedle delivery technique for SCS injection in rodents. The proposed method accomplished SCS delivery with 100% success rate in a simple, minimally-invasive procedure that takes less than one minute for each injection and requires no surgical microscope.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) screening is critical to prevent vision loss, but how screening is conducted and documented in the real-world primary care setting has not been reported. We performed a retrospective, observational study to determine the practice patterns for preventative eye care for patients with diabetes seen in a large single-institution primary care network.

Methods: All adult patients with diabetes mellitus who were seen at least once at one of the practices within a large primary care network in the year of 2019 were identified (n=7449). A subset of patients was randomly selected for chart review (n=171), and all primary care encounters for diabetes care or general wellness within the year were reviewed for each patient. Within each encounter, we examined whether the primary care provider (PCP) documented: 1) a direct ophthalmoscope examination; and 2) if the patient's screening eye exam was up to date. The ophthalmology visit closest in date to each primary care encounter, if within 2 years of the encounter, was also reviewed for diagnoses and examination findings, and findings were compared to the PCP's direct ophthalmoscopy results. Statistics were calculated in R.

Results: 414 primary care encounters from 171 patients were reviewed, 38% (159) for an annual physical examination and 62% (255) for diabetes care. PCPs documented a direct ophthalmoscope examination in 14% (24) of the patients; all results were documented as normal (Table 1). PCPs also documented whether the ophthalmology exam was up to date for 79% (165) of patients; 42% (71) were up to date, and 37% (64) were not up to date. There was no documentation of ophthalmology exam status for the remaining 21% (36) of patients. 50% (85) of patients had an ophthalmology visit within 2 years. For the encounters where both direct ophthalmoscopy results and ophthalmology clinical diagnosis were available (n=18), the rate of agreement was 33% (13%, 59%); sensitivity of direct ophthalmoscopy for detecting posterior eye pathology was 0% (0%, 27%).

Conclusions: This study is one of the first to document the real-world practice patterns for DR screening in primary care, demonstrating the challenges associated with DR screening in that setting. Systems-level approaches are needed to improve preventative eye care for patients with diabetes.

ABSTRACT BODY:

Purpose: Although numerous numbers of accurately annotated data as grand truth is necessary for deep learning, the preparation of grand truth can create a bottleneck. In this study, we prepared a small number of annotated corneal endothelial images in a early-stage Fuchs endothelial corneal dystrophy (FECD) model mouse, and tested the feasibility of semi-supervised learning to widen the indication of AI to late-stage FECD.

Methods: Corneal endothelial images were obtained from FECD mouse-model eyes via contact specular microscopy. A trained model (AI 1) was created via the use of 28 manually annotated images (ground truth) of early-stage FECD mouse eyes. Supervised data 1 (n=250) of late-stage FECD was generated via AI 1, and AI 2 was generated via the use of supervised data 1. Then, supervised data 2 was generated by AI 2, and AI 3 was generated by using supervised data 2. Subsequently, those learning processes were repeated up to AI 12. Finally, AI was used to analyze the 25 test data images of late-stage FECD.

Results: AI 1 was generated via the 28 annotated image data of early-stage FECD. The guttae area detected by AI 1 was strongly associated with ground truth in early-stage FECD ($r=0.97$, $p=3.83 \times 10^{-27}$), however, AI 1 underestimated the guttae area by a mean systematic error (i.e., between the guttae area detected by AI and ground truth) of $-2.2 \pm 1.3\%$ ($r=0.86$, $p=2.83 \times 10^{-8}$) in late-stage FECD. After semi-supervised learning, systematic error tended to decrease throughout AI 2-9, though it increased slightly due to overestimation in AI 10-12. The mean systematic error of AI 9 was $-0.1 \pm 0.9\%$, and the guttae area detected by AI 9 was strongly associated with the manually annotated test data of late-stage FECD ($r=0.94$, $p=5.84 \times 10^{-12}$).

Conclusions: Semi-supervised learning by the use of limited numbers of annotated data of early-stage FECD enables the generation of a deep neural network for analyzing different disease phases of late-stage FECD. Our data suggests that semi-supervised learning can be applicable to multiple clinical settings; e.g., reduction of the time and cost of preparing annotated data and expanded indication (to very early or late stages) of a deep neural network.

ABSTRACT BODY:

Purpose: To investigate patient-level disparities in uveal melanoma (UM), the most common primary intraocular tumor in adults.

Methods: We analyzed 14,674 UM cases from 2004-2016 National Cancer Database records. Enucleation, brachytherapy, and proton beam utilization were analyzed over time. We performed logistic regression analyses to assess odds of worse stage at diagnosis, use of brachytherapy or proton beam versus enucleation, and use of proton beam versus other radiation. Patient-level variables included diagnosis year, tumor stage and location, age, sex, comorbidities, insurance, income, metropolitan residence, distance to hospital, hospital type and location (by census division), and treatment at multiple hospitals.

Results: Brachytherapy and proton beam use increased from 2004-2016, while enucleations declined. Patients who were nonwhite (OR=1.2, $p<0.01$), uninsured (OR=1.7, $p<0.01$), and who were treated at academic centers had higher odds of presenting with worse-stage disease. By contrast, those in the highest income quartile had lower odds of worse stage at presentation (OR=0.9, $p<0.05$). Patients with public (OR=0.7, $p<0.01$) or no insurance (OR=0.4, $p<0.01$), or who were treated at community cancer programs (annual caseload<500, OR=0.2, $p<0.01$) were less likely to receive radiation over enucleation, while those with higher incomes, metropolitan residence, treatment at academic centers, or treatment at facilities on the East and West coasts were significantly more likely to be treated via radiation. Metropolitan and high-income patients, and those treated at academic centers or facilities in the Pacific region were significantly more likely to receive proton beam over other types of radiation, while those treated at hospitals in the Middle Atlantic were less likely to receive proton beam (OR=0.2, $p<0.05$). Enucleation was predominant in Central US regions, brachytherapy in the Middle Atlantic, and proton beam in the Pacific (Figure 1).

Conclusions: Although utilization of enucleations for UM has decreased over time and utilization of brachytherapy and proton beam has increased, substantial treatment differences persist based on factors such as patient income, insurance status, and—especially—geography, with radiation therapies most common in Coastal regions. Further work is needed to evaluate treatment availability and ensure equitable access to UM care.

ABSTRACT BODY:

Purpose: Primary cilia are thin microtubule-based projections that extend from the plasma membrane of quiescent cells. Photoreceptor cells contain a specialized primary cilium called the outer segment, which is responsible for light capture. In general, human mutations present in core ciliary components cause syndromic diseases collectively termed ciliopathies. Interestingly, a subset of these mutations leads to non-syndromic retinal dystrophy. In this study, we identified a human patient with late-onset retinitis pigmentosa caused by a novel frameshift mutation resulting in early truncation of the CEP162 protein. CEP162 is localized to the distal-end of centrioles and required for ciliogenesis. To understand its underlying role in retinal dystrophy, we investigate how the human CEP162 mutation affects protein localization and cilia formation in patient derived human fibroblasts and mouse photoreceptors.

Methods: Control and patient derived human fibroblasts were analyzed for CEP162 mRNA expression, non-sense mediated decay, CEP162 protein stability and localization, and primary cilia formation and structure. Additionally, CEP162 staining was performed on mouse retinal cross-sections.

Results: Our analysis of the patient's fibroblast revealed that while truncated mutant CEP162 protein was expressed, it was not localized to the centrosomes. Absence of CEP162 from the basal bodies resulted in reduced ciliation in the patient fibroblasts compared to control. Interestingly, in patient fibroblasts CP110, a negative regulator of ciliogenesis, accumulated at the basal body. Further analysis revealed that although CEP290 was recruited to the basal body polyglutamylated tubulin was absent suggesting that ciliogenesis was halted at the stage of axoneme extension prior to transition zone assembly. Correlative light and scanning electron microscopy (CL-SEM) also showed stalled ciliary structures in the patient fibroblast compared to the control. Immunohistochemistry from mouse retinal cross-sections revealed endogenous CEP162 is localized to the distal end of the basal bodies at the base of the outer segment.

Conclusions: Our results indicate a novel role for CEP162 mediated axoneme extension, prior to transition zone assembly, as well as establish CEP162 as a retinal dystrophy gene.

ABSTRACT BODY:

Purpose: Novel variants found in the retinal dystrophies require definitive pathogenicity classification for informed patient dialogue and access to current and future clinical trials and therapies. We use patient-derived induced pluripotent stem cells (iPSCs) differentiated to retinal pigment epithelium (iPSC-RPE) and retinal organoids (iPSC-RO) to contribute to pathogenicity determination in these cases, and as a platform to test novel therapies. Here, this approach was undertaken in a family with a novel intronic variant in RPGR, which was reported by the diagnostic laboratory as a variant of uncertain significance.

Methods: iPSC patient clonal lines, formed from fibroblast samples, were used to culture iPSC-RPE and iPSC-RO, through proneural induction methods. Fibroblast and iPSC-RPE cells were used to determine presence of aberrant splicing through cDNA sequencing. RPGR gene and protein expression studies were undertaken using qRT-PCR, and immunofluorescence in iPSC-RPE and ROs was utilised to explore protein interactions and localisation.

Results: The novel intronic RPGR variant was shown to alter typical exon 12 splice acceptor site function. Gene expression of RPGR in patient iPSC-RPE and iPSC-ROs was decreased. RPGR protein analysis revealed decreased expression and mislocalisation in primary cilia and the photoreceptor cilium. Additionally, iPSC-ROs showed other photoreceptor protein mislocalisation.

Conclusions: Investigation of this novel patient RPGR variant in iPSC-RPE and ROs has revealed abnormal splicing, with decreased gene and protein expression, and abnormal photoreceptor protein localisations. This work has aided in variant classification to likely pathogenic, providing genetic information and eligibility for future treatments for the affected individuals.

ABSTRACT BODY:

Purpose: BRM421 is a synthetic peptide comprising 29 amino acids derived from Pigment Epithelium-Derived Factor (PEDF) with neurotrophic and anti-inflammation properties. We performed two clinical studies to confirm the early onset of efficacy in subjects with different dry eye severities.

Methods: The first-in-human (FIH) study and second-in-human (SIH) study were multi-center, double-masked, randomized, vehicle-controlled, Ora CAE® screened studies. The FIH study evaluated 157 subjects. It comprised 5 visits in approximately 5 weeks. Based on the FIH study results, the SIH study evaluated 220 subjects in 4 visits in approximately 3 weeks.

Results: The FIH study showed that BRM421 treatment significantly improved sign in corneal sum (Ora Calibra® scale) in moderate to severe patients (higher baseline fluorescence corneal stain and central corneal staining score) at Visit 4 on Day 14 (BRM421 n=18, Placebo n=13, p=0.02). Significant improvement was also observed in symptom (ODS dryness, Ora Calibra® scale) on Day 14 (BRM421 n=22, Placebo n=22, p=0.01). In addition, the BRM421 group had superior Tear Film Break-Up Time at Visit 5 on Day 29 (p=0.03). The data suggest that BRM421 has an early onset of action; hence, the SIH study was designed for 4 visits. In the SIH study, BRM421 showed trending efficacy in sign (BRM421 n=81, Placebo n=83, p=0.11). Significant improvement was observed in the secondary endpoint of symptom in VAS–Eye Dryness (BRM421 n=108, Placebo n=111, p=0.02) and VAS-Burning (p=0.003) at Visit 3 on Day 8. Significant improvement was also observed in the Ora Calibra® Ocular Discomfort & 4-Symptom Burning/Stinging (BRM421 n=108, Placebo n=110, p=0.02) and Dryness (p= 0.03) in patient diary records on Day 8.

Conclusions: Both clinical studies confirmed consistent early onset of BRM421 treatment effects of sign and symptoms. The post hoc analyses showed improved efficacy in favor of BRM421 in a more severe patient population. The findings warrant further study of BRM421 Ophthalmic Solution in subjects suffering from dry eye syndrome.

ABSTRACT BODY:

Purpose: There are limited treatment options for aniridia. 3D-printing may provide cost-effective, cosmetically acceptable iris implants for individuals with aniridia. The purpose of this study was to develop a proof-of-concept workflow for the fabrication of prosthetic irises using slit lamp photography, computer aided design (CAD) and 3D-printing.

Methods: High resolution external ocular slit lamp photographs taken from healthy volunteers who had primarily green, blue, or brown irises to be representative of the overall population. Images were transferred to Photoshop Software Suite where the irises were isolated for additional processing. The isolated image of the iris was then transferred to Computer Aided Design (Auto CAD) software where it underwent additional processing into a vector file, followed by subsequent extrusion of iris detail. This extruded design was then sliced and used for 3D-printing. To match the color of inks used in the 3D-printed design, photos of the eye were white balanced in Photoshop in order to derive Cyan-Magenta-Yellow-Black (CMYK) values. A matrix of pigment concentrations was created to develop silicone inks (OOMOO 30 Smooth ON silicone rubber) with CMYK values that matched those derived from high resolution photos. 3D-printing of iris prototypes was accomplished with Envisiontec 3D-Bioblotter, which is designed for high resolution and automated bio-fabrication. A disc with a diameter of 34mm and circular pupil opening diameter of 3.5mm was printed. After partial curing, the additional detail of the design for the prototype was printed onto this disc. For the prototype, a simplified human-derived iris design was printed in black (iris detail) and white (base disc) but moving forward color of the disc will be matched to the most common secondary color of the healthy volunteer's iris image.

Results: Using images of six volunteer irises (3 brown, 2 green, 1 blue) we identified 9 shades for brown in tandem with 3 different shades that are used to calibrate the color matrix. We have four brown variations (dark, light, yellow, and red) that are within this color matrix. Our workflow produced a prototype iris (currently in black and white) with abovementioned dimensions derived from an external ocular slit lamp photograph.

Conclusions: Future work will focus on miniaturization, use of color-matched inks, expansion of human iris matching, and tests for biocompatibility and safety.

ABSTRACT BODY:

Purpose: Brolucizumab was FDA approved for the treatment of neovascular age-related macular degeneration (nAMD) in 2019. This multi-center real-world retrospective study evaluated the safety and efficacy of brolucizumab in patients diagnosed with nAMD.

Methods: In this multi-center retrospective study, both treatment-naïve patients and patients switched to brolucizumab from other anti-VEGF agents were evaluated. Information collected included demographics, number of previous treatments or if treatment naïve, ETDRS visual acuity, central retinal thickness (CRT) and changes in pigment epithelial detachments (PED), if applicable. Improvements in PED height and retinal fluid are evaluated as a proportion of patients. Improvements in visual acuity, CRT and PED height are evaluated as averages. Observed and calculated data is reported.

Results: A total of 282 eyes were evaluated after treatment with brolucizumab for nAMD. The mean [SEM] age of patients was 81.2 [0.51] years. The majority of patients were switched from other anti-VEGF agents after persistent disease activity (63.9%), followed by a desire to elongate treatment intervals (32.3%). Patients received an average of 2.4 [0.06] injections. Over half of the patients treated with brolucizumab discontinued the agent (54.4%), with 86% of these doing so out of caution after reports of intraocular inflammation (IOI) or occlusive vasculitis. A total of 14 patients experienced an adverse event: 10 cases of IOI, one case of occlusive vasculitis and 3 cases of pain. In patients who received at least three treatments of brolucizumab, the proportion of patients with intraretinal fluid (IRF), subretinal fluid (SRF), and PEDs decreased, (34.5% to 27.2%), (49.8% to 31.6%), (59.8% to 54.6%), respectively. Improvements in visual acuity (62.4 [0.94] letters to 64.5 [1.25] letters), CRT (312.4 [6.32] mm to 269.8 [7.31] mm) and PED height (236.0 [15.98] mm to 206.7 [12.9] mm) were also calculated.

Conclusions: Brolucizumab demonstrated efficacy in naïve as well as previously treated patients with nAMD through various measures, by achieving improvements in the proportion of patients without IRF, SRF and PEDs, and improving visual acuity, CRT and PED height. Overall, 10 patients had IOI and one patient had occlusive vasculitis. Further studies are needed to continue evaluating real-world safety and efficacy outcomes of patients treated with brolucizumab.

ABSTRACT BODY:

Purpose: Aging is a primary risk factor for dysregulated routine ocular surface immune responses, which can lead to autoimmune diseases, such as Dry Eye. Our knowledge of how aging impacts the delicate regulation of healthy and essential immune responses is very limited. Lipid mediators, such as the lipoxin circuit, have emerged as important resident pathways that regulate leukocyte and T cell functions and homeostasis in the retina and ocular surface. The goal of this study was to characterize how aging impacts lipid mediator circuits that regulate immune response in the ocular surface and eye.

Methods: Healthy 3-5 months old and 20-27 months old C57BL/6J male and female mice were housed under standard conditions. Eyes, lacrimal glands, draining lymph nodes, spleen, serum and bone marrow were collected for HPLC/LC/MS/MS-based lipidomic analysis. Gene expression of cyclooxygenase, lipoxygenase and lipoxin receptors in tissues was assessed by QPCR. Leukocytes were isolated from zymosan-induced peritonitis in young and aged mice to define leukocyte lipidome and expression of lipid mediator pathways and receptors.

Results: Lipidomic and QPCR analyses identified marked sex- and tissue-specific changes in aged mice. Specifically, 5-LOX and 15-LOX pathways, the lipoxin circuit and levels of prostaglandins were markedly altered in aged mice and showed sex-specific differences. Impaired 5-LOX activity and capacity to generate LXA₄ was a phenotype of leukocytes from aged mice.

Conclusions: Execution of healthy routine innate and adaptive immune responses depend on tight regulation of effector cells and return to immune homeostasis. Lipid mediator circuits, such as lipoxins and prostaglandins, are important local signals that control the threshold of activation, amplitude and duration of an immune response. Their formation and receptors are dynamically and tightly regulated. The data indicates that in healthy mice, aging alters the balance of lipid mediator circuits in leukocytes, lymph nodes, lacrimal glands and eye, which may set the stage to initiate dysregulated immune responses.

Tammy Hsu: Commercial Relationship: Code N (No Commercial Relationship) | Dilraj Grewal: Commercial Relationship: Code N (No Commercial Relationship) | Divakar Gupta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Coronavirus disease 2019 (COVID-19) has impacted individuals seeking preventative, follow-up, and emergent ophthalmic care. In this retrospective study, we assessed the impact of COVID-19 on inpatient and emergency department (ED) ophthalmology care at a large tertiary academic hospital in the United States.

Methods: We analyzed 570 ED and inpatient ophthalmology consults from March 13th to May 15th in 2020 and over the same period in 2019. Our primary endpoints were the number of consults and the percentage of consults that were 'vision-threatening' between the time periods. Our secondary endpoints were the demographics of the patients, relation to trauma, relation to an exacerbation of a chronic ocular condition, if the consult required surgical intervention, and time to surgery.

Results: The total number of ED and inpatient consults decreased by 35.2% in 2020 compared to 2019. The total number of visually threatening diagnoses decreased, 97 in 2019 to 83 in 2020. The proportion of presentations with visually threatening diagnosis increased from 28.0% to 37.1% ($p=0.0237$). In 2020, there were a higher proportion of consults related to trauma (31.7% compared to 23.4%, $p=0.0289$), and consults requiring surgical intervention (19.6% compared to 12.4%, $p=0.0192$). The time to surgery was similar between time periods studied ($p=0.902$). There was not a significant difference in proportion of consults resulting from exacerbations of chronic ocular conditions ($p=0.554$).

Conclusions: The volume of ophthalmic consults to our tertiary eye center and ED declined during the COVID-19 pandemic. There was an increase in the proportion of visually threatening diseases indicating a higher overall acuity seen by the consulting service. There was a total decrease in visually threatening diseases (despite an increase in numbers of consults from trauma), suggesting that some patients may have avoided urgent ophthalmic care due to fear of COVID-19 and the lockdown. Further research is needed to characterize the effect of COVID-19 and the regional stay-at-home order on emergent ophthalmic care delivery so we can better prepare for later stages of the pandemic and also for future pandemics.

TITLE: Repeat Ranibizumab Injections in Retinopathy of Prematurity

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y.H. Lee, A.J. Weiner, I. Tsui, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yoon Lee: Commercial Relationship: Code N (No Commercial Relationship) | Adam Weiner: Commercial Relationship: Code N (No Commercial Relationship) | Irena Tsui: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The objective of this case series is to discuss the role of repeat intravitreal ranibizumab (IVR) in treating posterior retinopathy of prematurity (ROP). To our knowledge, there are only 2 other reported cases using repeat intravitreal injections (IVI) for ROP.

Methods: We report 2 cases of premature infants born at gestational age (GA) 23-24 weeks (w) with birthweight (BW) of 540-601g at university neonatal intensive care units who were treated with IVR (0.25 mg/0.025 mL) for recurrent posterior ROP followed by delayed laser for anterior recurrence.

Results: First case is a female (GA = 23-2/7w, BW = 540 g) with bronchopulmonary dysplasia (BPD) and sepsis. Exam at post-menstrual age (PMA) 31-3/7w showed zone 1, stage 3, no plus in both eyes (OU) and was treated with IVR OU. Repeat IVR was given OU at 38-0/7w for recurrence (zone 1-2, stage 2, pre-plus OU). Laser was performed OU at 47-4/7w for zone 2, stage 3 with pre-plus OU. The following week, patient had worsening plus OU and was treated with additional laser. ROP regressed OU at follow up.

Second case is a female (GA = 23 4/7w, BW = 601 g) with BPD, sepsis, and hypotension. IVR OU were given at 34-1/7w for vitreous hemorrhages (VH) OU and zone 1, stage 3 with plus OU. OS was reinjected at 39-1/7w for worsening VH and zone 1, stage 2, pre-plus and OD at 40-1/7w for zone 1, stage 2, pre-plus. At 51-1/7w, ROP reactivated (anterior zone 2, stage 3 without plus) and laser was performed. ROP regressed OU at follow up.

Conclusions: Repeat IVI was selected over laser because of posterior recurrence. A second IVI was performed to allow further peripheral vascularization of the retina, with the added benefit of avoiding general anesthesia in critically ill infants until they are older. IVR was chosen because it has a shorter systemic half-life compared to bevacizumab, theoretically causing less side effects. However, ranibizumab has been associated with earlier ROP recurrence compared to bevacizumab.

In conclusion, this case series demonstrates the use of repeat IVR in posterior recurrence of ROP. As advances in neonatal care continue to evolve and infant viability extends to younger GA, the use of repeat IVI for ROP may be increasingly necessary. Future studies could seek to determine the safest and most effective agent, dose, and interval for repeat IVI.

ABSTRACT BODY:

Purpose: To examine the diagnostic power of a new version of multifocal pupillographic objective perimetry. The new test has 18 test-regions per eye, which match the ETDRS retinal thickness grid used in OCTs, and tests both eyes concurrently in 80-seconds.

Methods: We recruited 34 AMD patients and 26 normal control subjects, mean ages (\pm SD) of 72.6 ± 7.06 and 73.1 ± 8.17 years respectively. Among our 68 patient eyes the distribution of eyes per AREDS step was: AREDS1: 28, AREDS2: 18, AREDS3: 13 and AREDS4: 9. The 9 AREDS4 eyes were all neovascular-AMD. Given that the severity was often different between eyes the Receiver Operator Characteristic plot analysis was done by eye rather than by subject. We also estimated Effect-sizes as Hedge's g. The new M18 test matches the pattern of the of the ETDRS grid with two stimuli that bi-sect each grid sector. The 18 stimuli/eye thus assess the central 6 mm (20 deg). We used an FD-cleared prototype of the Konan Objectified Analyser (OFA). Both eyes are tested concurrently in 80 s. We obtained % Areas under the Curve (%AUC) for ROC plots for diagnosis of AREDS group vs. controls. Separate %AUCs were calculated for the mean of the worst 3, and the worst 9, per-region response delays. %AUCs are also done for Best Corrected Visual Acuity (BCVA).

Results: BCVA showed no diagnostic power for AREDS1 and 2 (Table 1), whereas M18 per-region delays provide values in the range of 72.8 ± 6.65 to 84.3 ± 4.21 (mean \pm SE) (Table 2). AREDS3 and 4 were diagnosed at 86.8 ± 5.33 to 92.9 ± 3.93 . Effect-sizes (right two columns of Table 2) up to 2.48 were found.

Conclusions: The M18 test provided superior %AUC performance compared to BCVA. Reasonable diagnostic power was found, even for AREDS 1. M18 stimuli are easily compared with retinal thickness data obtained for the ETDRS grid pattern given that pairs of M18 stimuli exactly match each of the ETDRS grid regions popular with OCT manufacturers, thus allowing simple structure-function comparisons.

ABSTRACT BODY:

Purpose: We reported that the retinal pigment epithelium (RPE) preferentially metabolizes proline to support the retina. RPE could also use lactate released by the retina, which spares glucose for the retina. In this study, we aim to understand the relationship of proline with lactate and glucose in RPE metabolism, and the metabolic communications between RPE and the retina using ^{15}N labeled proline.

Methods: To study how RPE uses glucose, lactate and proline, we incubated mature human RPE cells with 5.5 mM glucose, 5 mM ^{13}C lactate or 5 mM proline in DMEM. After incubation for 24 and 48 hours, we compared the metabolites in the remaining medium. We also incubated freshly isolated mouse retina and RPE/choroid with ^{15}N labeled proline and other amino acids. To study the proline utilization in vivo, we retro-orbitally injected 150 mg/kg ^{15}N proline in mice and collected retina and RPE at 15, 30 and 60 min to trace ^{15}N proline and its derived metabolites.

Results: Lactate supplementation increases ~40% more glucose remaining in the medium compared to glucose alone group at 24 hours. The addition of proline further increases the amount of leftover glucose (~63%). The RPE consumes similar amounts of proline and lactate when they are provided in the same concentration. Unlike lactate, proline supplementation significantly increases non-essential amino acids (NEAAs) such as aspartate and glutamate in the medium. Incubation of RPE/choroid with ^{15}N proline confirms that ^{15}N is rapidly incorporated into NEAAs to release into the medium. Retina could not utilize ^{15}N proline directly but consumes ^{15}N proline derived NEAAs from the medium. Tracing in vivo shows the concentrations of ^{15}N proline derived NEAAs peak at 30 min and quickly drop afterwards in RPE. However, in the retina, the concentrations of NEAAs were gradually elevated or maintained after 30 min, supporting that RPE uses proline to generate NEAAs for the retina.

Conclusions: Proline enhances glucose sparing by the RPE in the presence of lactate. In addition, RPE uses proline to synthesize NEAAs, thereby increasing the nutrients available to the retina.

TITLE: OCTA biomarkers of CNV secondary to aged-related macular degeneration following intravitreal aflibercept

SESSION TITLE: AI in the retina/ AMD imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Kim, J. Park, K. Kim, S. Yu, Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, KOREA (THE REPUBLIC OF)

Commercial Relationships Disclosure (Abstract): Eung Suk Kim: Commercial Relationship(s);Bayer:Code F (Financial Support) | Jong Beom Park: Commercial Relationship: Code N (No Commercial Relationship) | Kiyoun Kim: Commercial Relationship: Code N (No Commercial Relationship) | Seung-Young Yu: Commercial Relationship(s);Bayer:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To investigate prospectively long-term functional and anatomical outcomes for fixed regimen of intravitreal aflibercept in patients with CNV by quantitative analysis based on OCT and swept-source OCT angiography.

Methods: 33 patients who are diagnosed as CNV are enrolled for prospective, single arm, interventional study. At first, 3 intravitreal aflibercept injections by monthly and 5 intravitreal aflibercept injections by fixed every 2 months regimen were done. Investigation of functional and anatomical outcomes were performed every 1 week later after intravitreal aflibercept injection. Analysis of 33 eyes with follow-up for 49 weeks were done for BCVA(ETDRS), CST, PED volume, CNV area, vessel density and vessel length density prospectively.

Results: Average baseline of age was 72.38 ± 8.82 and BCVA(ETDRS) was 50.27 ± 23.57 . There were significant correlation between last vessel length density and last BCVA($r = -0.765$, $p = 0.006$), last CNV area and last CST($r = -0.743$, $p = 0.009$), total change of vessel density and last CST($r = -0.651$, $p = 0.030$), total change of vessel density and first change of CST($r = 0.709$, $p = 0.022$). As a result of multiple regression analysis, the dependent variable, last CST, was statistically significant with a variable as total change of CNV vessel density in the independent variable.

Conclusions: Fixed 2-months regimen of aflibercept improved both visual and anatomical outcomes in patients with neovascular AMD at 49 weeks. Also OCTA biomarkers can be used for evaluating neovascular AMD.

ABSTRACT BODY:

Purpose: Pseudoexfoliation (PEX) syndrome is an age-related disease that may affect all vascular structures of the body due to the accumulation of degraded abnormal fibrillar deposits in the intraocular and extraocular tissues. This vascular structure may generate the inflammation environment and alter the morphological or functional protein structure of platelets. In this study, we tested the relationship between clot dynamics and platelet activation markers. The aim of our study is to find specific biomarkers with a diagnostic and prognostic value that will independently predict the PEX syndrome.

Methods: Two groups were included in this study, 1- Patients with ocular PEX syndrome (n=19) 2- Sex-matched individuals without ocular PEX syndrome (n=19). Ophthalmological examination and complete blood count measurements were performed in all participants aged between (40-75) years. Patients with von Willebrand disease, platelet dysfunction, diabetes, and ones using anticoagulant drugs were excluded. Peripheral blood was collected, analyzed by ROTEM (EXTEM, INTEM, and FIBTEM) tests, and flow cytometry was performed to analyze the expression of CD 41a, CD42b, CD61, CD62p, and PAC-1. A one-tailed Mann-Whitney test was used for statistical analysis.

Results: Analysis of the ROTEM data showed that the FIBTEM coagulation time (67.4 vs 60.3s; $P < 0.05$) and the FIBTEM alpha angle (73.3 vs 70.0; $P < 0.05$) increased in the PEX patients compared to the control group. Flow cytometry findings showed that there was a significant difference in the CD62p surface expression ($P < 0.0001$) and PAC-1 surface expression ($p=0.018$) between the PEX patients and the control group. Furthermore, analysis of antigen-binding capacity showed a significant difference only in the CD62p marker ($P=0.0178$).

Conclusions: To the best of our knowledge, this study is the first to examine clot dynamics and platelet activation markers in PEX patients. ROTEM results illustrated the higher contribution of functional fibrinogen in clot formation in the PEX patients. Flow cytometry data show that platelet activation markers are significantly elevated in PEX patients, suggesting the presence of a prothrombotic state. Further studies are recommended to investigate the exact role of platelets and functional fibrinogen in the initiation or development of PEX syndrome.

ABSTRACT BODY:

Purpose: To compare in vivo measurements of oxygen saturation (sO_2) between healthy and glaucomatous eyes using visible-light optical coherence tomography (vis-OCT).

Methods: Eight eyes of 8 healthy volunteers and five eyes of 5 glaucoma age-matched patients were enrolled into our pilot study. For each eye, one pair of retinal major artery and vein in superior and inferior regions near the optic nerve head (Figure) were scanned during the same session with our prototype vis-OCT (8192 x 16 samplings in $1 \times 1 \text{ mm}^2$). Spectroscopic analysis was performed using short-time Fourier transformation (STFT). Wavelength-dependent OCT amplitudes from the same depth location across adjacent A-lines, all within the blood vessels, were averaged and then fitted to hemoglobin absorption profile based on Beer-Lambert's law. Highest artery and vein sO_2 values in superior or inferior regions were recorded as the sO_2 measurements for each eye. Wilcoxon's paired signed rank test was used to compare the age-matched healthy and glaucomatous subjects. Correlation between vein sO_2 and visual field mean deviation (MD) recorded at the same visits was calculated using Spearman correlation coefficient (r). Results were compared with conventional structural OCT measurements, retinal nerve fiber layer (RNFL) and ganglion cell inner plexiform layer (GCIPL) thickness measured using Cirrus HD-OCT (Zeiss, Dublin, CA).

Results: Table 1 and Table 2 show demographics and measurements on 5 age-matched pairs of healthy and glaucomatous eyes. Artery sO_2 showed no difference between healthy and glaucomatous eyes, while vein sO_2 was marginally higher in glaucomatous eyes than healthy eyes (Table 2). Vein sO_2 and RNFL and GCIPL thicknesses all showed statistically significant correlation with MD (Table 3). When comparing the correlation between vein sO_2 , RNFL and GCIPL, no statistical difference was detected between any combination (Fisher's paired test).

Conclusions: Glaucomatous eyes had marginally higher oxygen saturation in the veins compared to healthy eyes, while there was no difference in oxygen saturation in the arteries, suggesting less oxygen consumption in the retina with glaucomatous damage. Vis-OCT sO_2 measurement may have a potential as a clinical glaucoma biomarker in parallel with RNFL and GCIPL thickness. Further study with a larger sample size is warranted.

ABSTRACT BODY:

Purpose: Previous cross-sectional studies have demonstrated a thinner retinal nerve fiber layer (rNFL) and macular ganglion cell complex (GCC) in persons with Alzheimer's Disease/cognitive impairment. Here, we examine the association of these OCT parameters with longitudinal changes in cognition in a biracial population-based sample of older adults participating in the Atherosclerosis Risk in Communities (ARIC) study.

Methods: Non-demented Black ARIC participants from Jackson, MS, and White ARIC participants from Washington County, MD, were enrolled in the Eye Determinants of Cognition (EyeDOC) study, in which peripapillary and macular OCT imaging was performed on a randomly selected eye between 2017 and 2019. Changes in cognition were derived from a 10-test neurocognitive battery administered to each participant three times between 2011 and 2020. Primary analyses examined the association of rNFL and GCC thickness with longitudinal changes in global cognition in the full cohort, using linear mixed effect models incorporating spline terms, adjusting for age, sex, education, smoking history, hypertension, diabetes, physical activity, and intraocular pressure. Additional analyses examined change within cognitive domains (memory, executive function and language) and were stratified for participants at each study site.

Results: A total of 914 participants (407 from Jackson; 507 from Washington County) had adequate OCT imaging and complete cognitive data. Mean participant age was 74 years at the initial cognitive examination and 64% were female. Neither GCC thickness ($p=0.53$) nor rNFL thickness ($p=0.76$) was associated with a greater rate of decline in global cognition scores. Likewise, neither GCC nor rNFL thickness were associated with the rate of decline in the memory, executive function, or language domains ($p>0.4$ for all). Similar results were observed when analyses were stratified for Jackson and Washington County participants.

Conclusions: In this biracial cohort of non-demented older adults, lower rNFL and GCC thickness was not associated with declines in cognition. These results suggest that OCT parameters may not have utility in predicting the risk of future cognitive decline in all populations.

ABSTRACT BODY:

Purpose: To determine variations in the levels of both excitatory (L-glutamate) & inhibitory (GABA) neurotransmitters (NTs), Histaminergic NTs (histamine and 1-methyl histamine), Adrenergic (noradrenaline, adrenaline, DOPA & dopamine), Cholinergic (acetylcholine) and Serotonergic (serotonin and N-acetyl serotonin) NTs in primary glaucomatous versus cataract patients.

Methods: This preliminary case-control study involved the three age-matched groups of patients with primary open angle glaucoma (POAG, n=14), primary angle closure glaucoma (PACG, n=21) and cataract patients (control, n=19). Patient's aqueous humor (70 to 100 µL) was collected by paracentesis during the trabeculectomy and cataract surgery and the plasma (2 ml) of the same patients was collected one hour before the surgery, stored at -80 degree. Aqueous humor and plasma were subjected for ultrasensitive LC-MS/MS analysis for the quantification of neurotransmitters.

Results: Baseline intraocular pressure and cup-to-disc ratio was found significantly elevated in both the glaucomatous groups as compared to the control group. In aqueous humor, histamine was found to be significantly elevated (5-fold, $p<0.0001$) whereas 1-methyl histamine was significantly decreased ($p<0.05$) in POAG as compared to the control. Significant increase in L-glutamate and GABA has been observed among both the glaucomatous patient groups as compared to the cataract control. Adrenaline was found to be elevated only in the PACG group (2.7-fold, $p<0.05$). Significant difference was observed among the compared plasma NT levels between the groups.

Conclusions: This study demonstrated the prominent role of histaminergic system apart from autonomic mechanisms in the progression of glaucoma. Elevated L-glutamate and GABA showed their release could be the result of the retinal ganglionic cell death. Further studies are required to evaluate the effects of histamine on Müller cell dysfunction.

TITLE: Chronic stress induces mitochondrial movement and turnover in zebrafish cone photoreceptors

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.M. Rutter, S.E. Brouckerhoff, R. Hutto, Biochemistry, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kaitlyn Rutter: Commercial Relationship: Code N (No Commercial Relationship) | Susan Brouckerhoff: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Hutto: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Despite chronic stress and high metabolic demands, photoreceptors remain viable to perform their essential function throughout a lifetime. Maintaining healthy pools of mitochondria is crucial in photoreceptor health and identifying mitochondrial quality control and turnover mechanisms can yield insight into photoreceptor robustness. Photoreceptors may have specialized adaptations in response to mitochondrial stress.

Methods: We generated zebrafish lines that expressed mitochondrially-targeted fluorophores specifically in cone photoreceptors: Tg(gnat2:Su9-mKate2) and Tg(gnat2:Su9-TagBFP). To visualize Müller glia cells, we used the Tg(GFAP:TdTomato) zebrafish line and cone cell bodies were visualized with the Tg(gnat2:eGFP) zebrafish line. Zebrafish larvae were imaged on a Leica SP8 confocal microscope at 6dpf following 48 hours of being maintained at 16°C (cold stress) or 28°C (normal temperature). To assess if mitochondria were within acidic compartments, zebrafish larvae were incubated in 10µM LysoTracker Green for 2 hours prior to imaging. Results are reported as mean ± SEM.

Results: Mitochondria in zebrafish cone photoreceptors are found in a dense cluster in the ellipsoid of the cell. Rarely, photoreceptor mitochondria can move away from the mitochondrial cluster towards the synapse, and this is observed much more frequently following cold stress. These mislocalized photoreceptor mitochondria are typically observed in the photoreceptor layer but can also be observed in other areas of the retina. We found that 23.3% ± 5.1% (n = 7 zebrafish) of photoreceptor mislocalized mitochondria colocalized with Müller glia. Mislocalized mitochondria are more likely to colocalize with LysoTracker Green (8.4% ± 0.6% of ellipsoid mitochondria vs 28.3% ± 4.2% of mislocalized mitochondria (n = 7 zebrafish)) suggesting increased mitochondrial turnover upon movement away from the ellipsoid.

Conclusions: Zebrafish photoreceptors can traffic some mitochondria away from the ellipsoid in response to stress, and these mislocalized mitochondria are more likely to be acidic, which suggests they may be in lysosomes. This may be a protective mechanism in response to mitochondrial stress that aids photoreceptor health and longevity.

TITLE: Autophagy in the limbal epithelium during UV-induced stem cell damage

SESSION TITLE: Corneal epithelium and Corneal tissue engineering and regenerative medicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Volatier, C. Cursiefen, M. Notara, Experimentelle Augenheilkunde, Uniklinik Köln, Köln, Nordrhein-Westfalen, GERMANY]

Commercial Relationships Disclosure (Abstract): Thomas Volatier: Commercial Relationship: Code N (No Commercial Relationship) | Claus Cursiefen: Commercial Relationship: Code N (No Commercial Relationship) | Maria Notara: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To characterise autophagy in the limbal and conjunctival epithelium as well as in pterygium.

Methods: Limbal sections from healthy donor corneas and excised pterygium were immunostained for autophagy markers ATG5, ATG7, ATG12, mTOR, and LC3B as well as stem cell marker p63a. Cells were also extracted from each of the aforementioned tissues to compare conjunctival, limbal epithelial, and pterygium cell behaviour in culture.

Results: The mean age of pterygium donors was 60 ± 21 ; all were males. The mean age and sex of healthy donors is unknown. p63a+ epithelial cells have a high concentration of mTOR both in vitro and in vivo. Pterygium in comparison showed an absence of mTOR both in vivo and in vitro. Further investigation via immunofluorescent microscopy of the downstream components of the autophagy pathway showed that ATG7 was absent in the limbal epithelial cells while present in pterygium. LC3B was absent in pterygium but present in limbal epithelia. When comparing both pterygium and limbal epithelium to conjunctiva, it was found that the distribution of autophagy-related proteins in conjunctival epithelium did not resemble either tissue.

Conclusions: The autophagy response is usually inhibited by mTORC1 and this inhibition is normally removed when low cellular energy is detected by AMPK. The absence of mTOR in pterygium confirms that autophagy is dysregulated in the corneal tumour. The absence of ATG7 in healthy p63a+ limbal epithelial suggests that therapeutic strategies could aim to restore healthy epithelial autophagy by targeting either mTOR or ATG7.

ABSTRACT BODY:

Purpose: The corneal drug penetration is commonly detected by measuring fluorescence profile of labelled drug in corneal tissues by cryosection. However, such method requires sacrificing animals and the data is often debased by artefacts. Although ocular fluorophotometer may provide a better alternative, problems of Inner Filter Effect (IFE) and low resolution have been reported. This study reports a modified Fluorotron to circumvent this issue to allow quantitative measurement of both the absorption and penetration of riboflavin into the cornea. Using the new approach, the penetration depth of riboflavin by ultrasound-mediated delivery was characterized.

Methods: The objective lens of ocular fluorophotometer was stabilised with plexiglass and the angle was increased between excitation and emission paths from 28 degree to 53 degrees that resulted in decreasing depth of focus to about 85 microns. The modified fluorophotometer was used to detect porcine eyes (Epi-on) which were soaked in 0.5% riboflavin for 30 minutes followed by washing and 0.025% riboflavin solution for 15 minutes by dropping different concentration riboflavin separately. The cryosection method was employed after ultrasound-mediated riboflavin delivery with different operating parameters of sonification which will be used to validate the result in modified fluorophotometer.

Results: The riboflavin penetration profile of cornea which detected by the modified fluorophotometer can have a higher resolution and minimized IFE (Fig.1). We anticipate that the modified fluorophotometer will expedite the optimization of new modalities, such as mediation by ultrasound, in corneal drug delivery.

Conclusions: This modified Fluorotron fluorophotometer can detect the riboflavin penetration depth and concentration across the corneal sections with higher resolution and minimized IFE. The absorption and penetration of riboflavin in cornea by ultrasound-mediated delivery is distinguishable in cryosection fluorescence microscope image.

ABSTRACT BODY:

Purpose: To determine the feasibility of using en face OCT images to reliably delineate choroidal lesion boundary and measure total choroidal lesion area.

Methods: Pigmented and amelanotic lesions of the choroid were imaged with a PLEX Elite 9000 SS-OCTA device. The full thickness choroidal en-face image was generated using the minimum projection of the region between the RPE/BM complex and the choroidal-scleral interface. Lesion boundaries were defined by a masked human grader and lesion area calculated in MATLAB. Clinical determination of en face lesion area was made by the treating physician on color fundus images or at the time of dilated exam and recorded in disc diameters. Clinical ultrasound measurements of maximal transverse and longitudinal base diameter were used to calculate the en face lesion area using the formula for an ellipse. Agreement in lesion area determined by each method was evaluated by intraclass correlation coefficient (ICC).

Results: Seventeen lesions were imaged by OCT: 8 choroidal melanomas, 4 choroidal nevi, 5 choroidal hemangiomas. In the en-face image, all lesions appeared as homogeneous white regions without characteristic pattern of large choroidal vessels. 3 lesions had borders extending beyond the SS-OCT image window and were not included in area analysis. The agreement between OCT and fundus exam area was poor (ICC=0.03). The agreement between US and fundus exam was moderate (ICC =0.51). The agreement between US and OCT on the 4 lesions with same day imaging was excellent (ICC=0.99). Three lesions with mixed pigmentary components measured much smaller by fundus exam than by OCT or US.

Conclusions: Pigmented and amelanotic fundus lesions can be identified in the SS-OCT choroidal en face projection. The resulting image provides a new method for lesion area measurement with excellent agreement to US measurements and could be useful for longitudinal monitoring. Larger studies with same day exam, SS-OCT, and ultrasound measurements will be required to verify the extent of agreement suggested by this pilot study.

ABSTRACT BODY:

Purpose: Patients with Fuchs endothelial corneal dystrophy (FECD) often harbor expansion of a trinucleotide CTG repeat in the TCF4 gene, thus suggesting that TCF4 is a potential causative gene for FECD. We previously reported that the expression of TCF4 is upregulated in the corneal endothelium of FECD patients. The purpose of this present study was to elucidate the involvement of TCF4 in the pathophysiology of FECD via proteomic analysis of an FECD cell model.

Methods: Corneal endothelial cells (CECs) isolated from FECD patients were immortalized using both SV40 and hTERT to produce an immortalized FECD cellular model (iFECD). TCF4 was knocked out using CRISPR/Cas9 in iFECD (TCF4^{-/-} iFECD). Total proteins were isolated, detected by mass spectrometry, and analyzed by use of the SEQUEST[™] search algorithm through Proteome Discoverer software against Human RefSeq protein database. For functional enrichment analysis, the gene ontology (GO), KEGG, and Reactome pathways were investigated. In addition, the GeneMANIA Cytoscape plug-in was used to clarify protein-protein interaction (PPI) and hub proteins, which are involved in the knockout of TCF4.

Results: Ninety differentially expressed proteins (DEPs) ($|\log_2$ fold change| > 0.5 and P value < 0.05) were identified among a total of 6510 identified proteins, including 52 upregulated and 38 downregulated proteins. GO pathway analysis revealed enrichment of extracellular matrix (ECM) organization, response to oxidative stress, and cell motility, KEGG pathway analysis revealed enrichment of ECM-receptor interaction, and Reactome pathway analysis demonstrated that multiple proteins related to collagen, integrin, and glycosaminoglycan were downregulated by loss of TCF4. Finally, GeneMANIA identified 20 hub proteins and showed that 5 of those 20 proteins were related to ECM.

Conclusions: Functional and pathway enrichment analyses revealed that TCF4 is involved in ECM-related pathways in the corneal endothelium of FECD. Our findings indicate that TCF4 plays an important role in the pathophysiology of FECD, probably by inducing excessive production of ECM proteins.

ABSTRACT BODY:

Purpose: This study investigated the differential gene expression of BMPs in chick retinal pigment epithelium (RPE) during recovery from lens-induced defocus and form-deprivation treatments.

Methods: 14-day old White-Leghorn chicks wore monocular +10 or -10 D lenses or diffusers for 2 or 48 h. The lenses and diffusers were then removed and eyes allowed to recover for 0, 15 min, 2, 24, 48, or 96 h, after which RPE was collected from sacrificed birds. RPE gene expression of BMP2, 4, and 7 was examined using real-time PCR and expression levels in treated and their contralateral control eyes compared.

Results: BMP2 gene expression was up-regulated with the +10 D lens treatment, after both 2 and 48 h. For the 2 h treatment groups, gene expression up-regulation was maintained 15 min into the recovery period, but decreased rapidly thereafter to reach the same level as in contralateral control eyes, with the exception of a short term rebound (up-regulation), 24 h into the recovery period. Meanwhile, for the 48 h treatment groups, BMP2 gene expression decreased gradually from up-regulation at $739 \pm 121\%$ to down-regulation at $72 \pm 14\%$ over the recovery period. BMP2 gene expression was down-regulated with both -10 D lens and FD treatments, after both 2 and 48 h. BMP2 gene expression continued to be down-regulated 15 min into the recovery period, changing to up-regulation after 2 h of recovery, with the time required for gene expression to return to the same level as in the contralateral control eyes varying with the initial treatment duration. Similar gene expression patterns were observed for BMP4 and BMP7, although the changes were generally smaller.

Conclusions: The dynamic changes in BMP gene expression in chick RPE during recovery from three visual manipulations widely used in studies of eye growth tend to follow similar trends in induced refractive error and/or choroidal thickness changes. Thus this study provides further evidence for the role of the RPE as an important signal relay, and RPE-derived BMPs as critical signaling molecules in eye growth regulation.

ABSTRACT BODY:

Purpose: The aqueous humor (AH) liquid biopsy has been established as an enriched source of tumor-derived cell-free DNA (cfDNA) for retinoblastoma (RB). Use of this AH liquid biopsy allows for genomic analysis of eyes throughout treatment and at enucleation. Previous AH studies have focused on highly recurrent RB somatic copy number alterations (SCNAs) including gain of 1q, 2p, 6p, and loss of 13q and 16q; in this retrospective study, we provide a comprehensive, whole-genome analysis of RB SCNAs and their associated clinical features.

Methods: Patients diagnosed with RB between 12/2014-10/2020 from whom AH was obtained via clear corneal paracentesis were included. Shallow whole-genome sequencing of AH cfDNA was performed to assess for SCNAs. Mann-Whitney U and Fisher's exact tests were used to examine the relationship between SCNAs and clinical findings.

Results: 68 eyes of 64 patients were included. 33 eyes were enucleated (16 primarily; 17 secondarily after chemotherapy) and 35 were salvaged. The most common non-highly recurrent RB SCNAs were 12p loss (8 eyes; 11.8%), 16p loss (8 eyes; 11.8%), 5p gain (7 eyes; 10.3%), 17q gain (6 eyes; 8.8%), 18q gain (6 eyes; 8.8%), 17p loss (5 eyes; 7.4%), 20q gain (5 eyes; 7.4%), and 22p gain (5 eyes; 7.4%). The prevalence of specific non-highly recurrent SCNAs differed between primarily and secondarily enucleated eyes (Fig 1). Focal MYCN amplification was present in 3 eyes, and all were enucleated (2 primarily, 1 secondarily). Of secondarily enucleated eyes, 6 eyes had AH sampled during conservative management and immediately following enucleation; 4 eyes demonstrated new SCNAs at secondary enucleation that were not present in earlier AH samples. Eyes with sphere or cloud seeding had significantly more SCNAs (4.64 ± 4.76) than eyes with dust or no vitreous seeding (2.70 ± 3.72 ; $P=0.022$). Eyes with an endophytic tumor growth pattern (without retinal detachment; RD) were significantly more likely to have one or more SCNA (84.6%) than eyes with an exophytic tumor growth pattern (with RD) (57.5%; $P=0.030$).

Conclusions: The AH liquid biopsy platform is an efficient method of whole-genome RB SCNA analysis, and SCNAs are associated with numerous clinical findings in RB eyes. Prospective analyses are encouraged to further elucidate the clinical relevance of specific SCNAs in RB.

TITLE: Corneal Crosslinking to Regress Pathological Corneal Neovascularization Before High-Risk Keratoplasty

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Hos, F. Schaub, Y. Hou, W. Zhang, F. Bock, C. Cursiefen, Universitat zu Koln, Koln, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Deniz Hos: Commercial Relationship: Code N (No Commercial Relationship) | Friederike Schaub: Commercial Relationship: Code N (No Commercial Relationship) | Yanhong Hou: Commercial Relationship: Code N (No Commercial Relationship) | Wei Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Felix Bock: Commercial Relationship: Code N (No Commercial Relationship) | Claus Cursiefen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal neovascularization is the main risk factor for graft rejection after high-risk penetrating keratoplasty (PK). Corneal crosslinking (CXL) has been shown to regress pathological corneal neovascularization and to reduce the risk of graft rejection after high-risk PK in mice. The aim of this work was to analyze whether CXL of the corneal periphery sparing the limbus ("peripheral CXL") is also able to regress corneal neovascularization in patients.

Methods: This case series included 5 patients with progressive corneal neovascularization and the need for high-risk PK because of graft rejection and/or keratitis. Peripheral CXL was performed prior to or directly in combination with PK, and corneal neovascularization was assessed morphometrically on slit-lamp images. Patients were followed up to determine the incidence of adverse effects and graft rejection.

Results: No intraoperative or postoperative complications were observed. Peripheral CXL resulted in a significant reduction of corneal neovascularization (mean reduction of $70.5\% \pm 22.7\%$). Revascularization was not observed. All transplants remained clear and without immune reactions (mean follow-up 16.4 ± 14.9 weeks, range 4-42 weeks).

Conclusions: Peripheral CXL is able to reduce pathological corneal neovascularization in patients and might therefore be a novel treatment option to reduce graft rejection rates after high-risk PK.

ABSTRACT BODY:

Purpose: To quantify the expression of different cytokines (IL-1 β , IL-4, IL-6, IL-10, IL-17, IFN- γ), neurotrophic factors (BDNF, VEGF) and Fractalkine (CX3CL), released by retinal glial cells, at different times after unilateral laser-induced ocular hypertension (OHT), both in OHT eyes and their contralateral eyes respect to naïve eyes.

Methods: Six groups of albino Swiss mice (a naïve group and five OHT groups) were analyzed. Animals were sacrificed at different time-points after OHT laser induction (1, 3, 5, 7 and 15 days) and both treated OHT eye and contralateral untreated eye were studied. The samples obtained were processed in two different ways: i) multiarray kits (MILLIPLEX MAP Mouse Cytokine/Myokine Magnetic Bead Panel) were used to quantify the expression of cytokines, and ii) Double immunolabelling were performed in retinal sections to determinate which cells expressed the different molecules analyzed. In multiplexed study 12 animals per group were used and 5 animals in each group for immunohistochemistry study.

Results: Compared to naïve, in OHT eyes, were observed a significant increase in the expression of : i) IFN- γ at 3, 5 and 15 days; ii) IL-4 at 1, 3, 5 and 7 and IL-10 at 3 and 5 days (which coincided with the downregulation of IL-1 β at days 1, 5, and 7); iii) IL-6 at 1, 3 and 5 days; iv) VEGF and Fractalkine at 1 day; and v) BDNF at 1, 3, 7 and 15 days. In contralateral eyes, the significant changes were: i) increase of IL-1 β at 1 and 3 days and decrease at 7 day (which coincided with the downregulation of IL-4 at 3 and 5 days and the upregulation at 15 days); ii) increase of IL-6 at 1, 5 and 7 days and decrease at 15 days; iii) increase of IL-10 at 3 and 7 days; and iv) increase of IL-17 at 15 days. Immunohistochemical study shown that microglia expressed IL-1 β , IFN- γ , IL-4, IL-6, IL-17 and fractalkine, and that the macroglia (astrocytes and Müller) expressed IL-1 β , BDNF and VEGF. IL-10 were expressed by retinal ganglion cells axons.

Conclusions: Unilateral laser-induced ocular hypertension causes changes in the expression of anti- and pro-inflammatory molecules associated with inflammatory process, mainly 3 days after OHT induction, both in OHT eyes and in contralateral eyes, which may confirm the implication of the immune system in glaucoma.

ABSTRACT BODY:

Purpose: Galectin 3 (Gal3) is a galactosidase-binding protein acting on different aspects of inflammation related to the response to stress stimuli, which expression is highly sensitive to corticoids. It has been recognized as a biomarker for cardiovascular diseases. It mediates the vascular pro fibrotic effect of aldosterone. In the human eye, we found it localized in retinal Muller glial cells, the retinal pigment epithelium and in the choroid. In this multicentre retrospective case-control study we measured Gal3 levels in the serum of patients with central serous chorioretinopathy (CSCR).

Methods: Serum levels of Gal3 were measured in CSCR patients (N= 155) with acute (N=76) and chronic (N=79) disease and in age and sex-matched controls (N=153). Presence of epitheliopathy on multimodal imaging approach allowed to differentiate chronic from acute CSCR. All patients had active disease defined by the presence of subretinal fluid at the time of the blood sample. Patients with concomitant ocular pathologies were excluded, as were samples with CRP > 5 mg/L, creatinine > 100 µmol/L, and/or urea > 7.5 mmol/L. Human Gal3 was measured with a specific Elisa Kit (BGM Galectin-3 Assay, BG Medicine Galectin-3 Kit – RUO Product n°:12727). Descriptive, comparative and correlative statistics were performed on Prism (Graphpad; San Diego), using Dunn test for quantitative values.

Results: Gal3 serum levels were significantly reduced in patients with CSCR compared to the control group (mean difference 1,250; IC 95% 0,06-2,43; p=0,03), and this level was even lower in patients with acute CSCR compared to controls (mean difference 2,063; IC 95% 0,74-3,18; p=0,004). Gal3 was significantly lower in the population younger than 45 years compared those older than 45 years, irrespectively of the group (mean difference 14,02; IC 95% 11.23-16.82; p<0,0001). Acute CSCR patients showed lower levels of Gal3 compared to chronic CSCR (mean difference 2,602; IC 95% 1,08-4,11; p<0,0001), independently from the age group.

Conclusions: Galectin 3 serum levels are reduced in patients with CSCR, similarly to what has been recently observed for lipocalin 2. This reduction is particularly important in patients with acute CSCR and could be an important biomarker for diagnosis and follow up of these patients. Age was an important factor in analyzing the variations of this protein, as with other inflammation markers commonly used in medicine.

ABSTRACT BODY:

Purpose: Self-examination low-cost full-field optical coherence tomography (SELFF-OCT) can place the control of ophthalmic therapies into the hand of the patient. Regular self-examination by volumetric OCT imaging of the retina can detect retinal changes in age-related macular degeneration (AMD) and other diseases in such early stages that optimal treatment is possible. First clinical studies showed that 77% [1] to 86% [2] of all self-examined eyes resulted in interpretable retinal OCT volume scans. Necessity for anti-VEGF treatment of AMD could be determined with 94% sensitivity and 95% specificity [2]. During the recording time of 1.3 seconds, motion of the eye can considerably degrade image quality. Depending on severeness, planes in the volume will be shifted laterally or axially, SNR will be reduced or en-face planes are completely missing.

[1] von der Burchard C, et al. Graefes Arch Clin Exp Ophthalmol, 2020, DOI: 10.1007/s00417-020-05035-6.

[2] von der Burchard C, et al. Ophthalmology, 2021, submitted

Methods: SELFF-OCT records interferograms of en-face plane, which contain not only information on the retinal structure but also on the iris position. The imaging process and the possibility to detect ocular motion from a recorded volume were analyzed theoretically and experimentally in a phantom and in self-measurements of patients.

Results: The SELFF-OCT data contained accurate position information. Accuracies better than 4 µm laterally and 30 µm axially were demonstrated. An algorithm quantified both lateral and axial changes of the retina position in the recorded images. The accuracy is on par with modern eye-trackers, but was achieved without any additional optical components. A complete loss of the OCT signal was also successfully identified.

Conclusions: Due its special technology and the intended hand-held use, SELFF-OCT is more sensitive to motion artifacts than clinical OCT devices. Currently, 20% of the recorded volumes cannot be analyzed, and part of them contain motion artifacts. Automated detection can identify invalid volumes. Since acquisition of a volume takes only 1.3 seconds, remeasuring is possible in these cases. Integrated into the self-measurement process (i.e. repeat measurement until a valid scan was obtained) will increase success rate. Furthermore, automated artifact correction in postprocessing in cases of light and especially lateral movement will improve image quality and diagnostic accuracy.

ABSTRACT BODY:

Purpose: To evaluate optical coherence tomography (OCT)-based risk factors for progression to late Age-related macular degeneration (AMD) in a population-based of the elderly Amish.

Methods: A total of 1339 subjects (2668 eyes) were enrolled in this multicenter, prospective, longitudinal, observational study as part of the population-based Amish eye study. 666 subjects (49.7%) returned for a two-year follow-up visit and underwent complete ophthalmic exam, OCT (Spectralis 20°X20°), infrared reflectance images (IR) & color fundus photography. Baseline OCT images were reviewed for presence of drusen volume $> 0.03 \text{ mm}^3$ in the central 3mm ring, intraretinal hyperreflective foci (IHRF), hyporeflective drusen core (hDC), subretinal drusenoid deposits (SDD), drusenoid pigment epithelium detachment (PED), subfoveal choroidal thickness, drusen area, volume within 3, 5-mm circles centered on ova. Presence of SDD/reticular pseudodrusen (RPD) were also evaluated on IR images, including in regions outside the OCT scan field. Two year follow-up images were evaluated for presence of late AMD (geographic atrophy/macular neovascularization). These features at baseline were correlated with 2-year incidence of late AMD development by logistic regression.

Results: Twenty-one (1.5%) of 1332 eyes progressed to late AMD at 2 years. Mean age of study subjects was 65 ± 10.17 (\pm SD) years and 410 were female. Univariate logistic regression showed drusen area, volume in 3 & 5-mm circles, subfoveal choroidal thickness, drusen volume $\geq 0.03 \text{ mm}^3$ in 3-mm ring, SDD, IHRF, and hDC were all associated with an increased risk for development of late AMD (odds ratios (OR) and 95% confidence intervals shown in table 1). Multivariate regression model identified that drusen volume in the 3-mm circle (OR:2.59, $p=0.049$) & presence of IHRF (OR:57.06, $p<0.001$) remained as independent and significant risk factors for progression to late AMD.

Conclusions: This population-based study confirms previous findings from clinic-based studies that high central drusen volume and IHRF are associated with an increased risk of progression to late AMD. These findings may of value in risk stratifying patients in clinical practice or identifying subjects for early intervention clinical trials.

ABSTRACT BODY:

Purpose: To develop an easy and xenogeneic free culture system of oral mucosa stem cells

Methods: Tissue and blood collection. Oral mucosa biopsies were obtained from deceased organ donors following Spanish laws. Platelet Rich in Growth Factors (PRFG) used for media supplementation and PRGF fibrin membranes were obtained from voluntary donors and processed using a commercial kit (Endoret®)

Cell culture. 3-4 mm² biopsies were cut in fragments and cultured as explants in a 12 well culture plate

Culture media. Cells were expanded in two different media: DMEM/F12 (2:1), 5 µg/ml insulin, 8.33 ng/ml cholerich toxin, 24 µg/ml adenine, 1.3 ng/ml triiodothyronine, 0.4 µg/ml hydrocortisone, 40 µg/ml vancomycin-amikacin, 0.5 µg/ml amphotericin B and either 10% SBF or 10% PRGF

Data analysis. Expansion efficiency of SBF and PRGF cultures were compared quantitatively and qualitatively PRGF membrane in vivo assay. Confluent cultures of epithelial cells expanded in PRGF were subcultured on 4 cm² PRGF fibrin membranes (2.5 x 10⁵ cells/cm²), cultured for 72h and grafted in the subcutaneous space of nude mice. After 21 days, animals were euthanized and tissue samples were subjected to immunohistochemical analysis Immunofluorescence. Cultures and tissues were fixed with 4% paraformaldehyde and immunofluorescence studies were performed using anti-p63, anti-CK5 and anti-CK14 monoclonal antibodies

Results: Cell culture. 93±5% and 91±9% of cultures were successfully expanded from initial biopsies cultured in SBF and PRGF, respectively. The expanded cells showed epithelial cells, fibroblast or a mix of both. Pure epithelial cell cultures without contaminant fibroblasts were observed in 61±6% of SBF cultures and in 69±13% of PRGF cultures.

Data analysis showed that there were no statistically significant differences between the media

Immunofluorescence. Oral mucosal epithelial cells were positive against CK5, CK14, and p63 either cultured with SBF or PRGF. Cells cultured on the PRGF membrane still retained their morphological and phenotypic markers

In vivo assay. Oral mucosal epithelial cells remained viable and retained its characteristic morphology and phenotypic markers without any apparent tissue defect in the in vivo model

Conclusions: It is possible to isolate oral mucosal epithelial stem cells without the need of xenogenic factors. These cells could be grafted and represent a potential alternative for ocular tissue engineering

ABSTRACT BODY:

Purpose: To correlate regional macular thickness, with per-region macular sensitivities and delays as measured by multifocal pupillographic objective perimetry (mfPOP), commercially known as ObjectiveField Analyser (OFA), in Type-2 diabetes (T2D) patients without and with off-centre mild diabetic macular oedema (DMO).

Methods: We recruited 33 T2D patients (59.2 ± 10.5 y, 17 males). Mean OFA values within inner and outer macular regions were sorted according to retinal thickness. This allowed structure-function correlations to be computed relative to the degree of DMO, wherever it was. A generalised linear mixed-effects model determined which variables contribute to clinical diagnosis of DMO.

Results: The mean sensitivity difference compared to normal in T2D patients was negative and the mean delay difference positive indicating declining sensitivity and prolonged delay relative to normal. Peripheral OFA hypersensitivity and shorter delays than normal were seen with shorter diabetes duration. For DMO patients outer macular thickness was correlated significantly with inner- and outer-macular OFA sensitivity and delay, all $p < 0.0012$, but inner thickness was not correlated. The same was true for diabetic patients without DMO (median p-value was 0.001). A Mixed-effects logistic regression model determined outer thickness and OFA sensitivity ($p = 0.043$), male gender ($p = 0.313$) and time in the study ($p = 0.001$), contributed independently to the odds of a clinical diagnosis of DMO.

Conclusions: The mean sensitivity difference decreased, and mean delay difference increased in diabetic patients compared to normal in later-stage disease. Outer macular thickness correlated significantly with inner and outer OFA sensitivity and delay, while the inner macular thickness did not. As a clinical end-point outer thickness and functional measures may be a better indication of eye health in diabetic eye disease than is provided by visual acuity or other central functional measures.

ABSTRACT BODY:

Purpose: Vitreous opacities are collagen aggregates that form in the vitreous body due to myopia and/or age-related structural changes (i.e. fibrous liquefaction) which cast shadows on the retina, impacting vision. Current therapies are based on laser treatment with an yttrium garnet laser (YAG) or vitrectomy. The efficacy of YAG laser vitreolysis is unproven and vitrectomy remains invasive with associated side effects).

We propose a nanotechnology-based treatment of floaters using the plasmon properties of gold nanoparticles (AuNPs). AuNPs bind to vitreous opacities, and when exposed to pulsed-laser light (typically a nanosecond laser), heat up and generate vapour nanobubbles (VNBs) due to the evaporation of the surrounding water. These VNBs then burst, providing sufficient mechanical energy to fragment and destroy the opacities.

Methods: In Vitro: Type I collagen fibers were prepared as artificial floaters and human vitreous opacities were obtained from patients after vitrectomy. Samples were mixed with Hyaluronic (HA) coated AuNPs (10 nm) and irradiated with a pulsed laser (<7ns; 561 nm) at different fluences. Dark field imaging was performed to assess effects. In Vivo: Type I collagen fibers were injected intravitreally in rabbits so that they were located close to the retina (<500 µm). 5 days later, HA-AuNPs were injected. Three days after the injection of AuNPs, fibers were irradiated with a nanosecond laser (<7ns; 530 nm). Photoacoustic imaging was performed to assess binding of gold on the injected fibers, and optical coherence tomography was performed to assess destruction of the fibers.

Results: HA-AuNPs can diffuse in the vitreous and bind to collagen fibers and vitreous opacities.

Type I collagen fibers and vitreous opacities could be completely destroyed in vitro and ex vivo at a fluence of 4.5 J/cm². In vivo, collagen fibers could be destroyed after 7 scans at a fluence of 1.9 J/cm². Preliminary retinal toxicity assessment (TUNEL and H&E staining) did not reveal significant changes compared to untreated rabbits.

Conclusions: This approach can effectively and rapidly destroy vitreous opacities ex vivo and collagen fibers in vivo, using lower energy levels than YAG therapy and paves the way for the vitreolysis with pulsed-lasers and nanotechnologies

ABSTRACT BODY:

Purpose: Although the outer retina is the primary area affected in age-related macular degeneration (AMD), secondary alterations in the inner retina have been suggested. To test this hypothesis, we evaluated the Ganglion Cell Complex (GCC) thickness in subjects with AMD.

Methods: A total of 620 eyes of 310 elderly (>age 50) Amish individuals who were enrolled in a population-based study were included in this post-hoc analysis. All subjects underwent complete ophthalmic examination, optical coherence tomography (Cirrus OCT, 6x6mm, 512 x 128) and flash color fundus photography. Foveal central subfield retinal thickness, mean retinal thickness, mean macular volume, and mean thickness of the GCC were obtained using the instrument software. The color fundus images were graded according to the Beckman classification as: Stage 0 (normal), Stage 1 (normal aging), Stage 2 (early AMD), Stage 3 (intermediate AMD), and Stage 4 (late AMD). The GCC thickness between groups were compared in a pairwise fashion using t tests.

Results: Among the 620 eyes, 408 eyes were normal, 67 eyes had early AMD, 101 eyes had intermediate AMD, and 44 eyes had late AMD. The mean age was significantly (<0.0001) lower in the normal group (62.43 years) compared to the AMD group as a whole (71.88 years). After adjusting for age, there was no significant difference in retinal thickness ($p = 0.16$) or retinal volume ($p = 0.14$) between the study groups. However, the mean GCC thickness was significantly ($p < 0.05$) lower in all AMD groups [early AMD: 73.94 μ m; intermediate AMD: 76.55 μ m; late AMD: 58.80 μ m] compared to normals (78.22 microns).

Conclusions: Eyes with AMD show lower GCC thickness compared to normal eyes, with the most severe reduction observed in eyes with late AMD. Alterations in the inner retina during the progression of AMD warrant further study.

ABSTRACT BODY:

Purpose: To report the effect of photodynamic therapy (PDT) on choroidal indices in patients with central serous chorioretinopathy (CSC).

Methods: Patients with a confirmed diagnosis of CSC managed at a tertiary care center, who underwent PDT with subsequent resolution of the subretinal fluid were analyzed. The PDT procedure was performed by the same physician. Enhanced depth imaging optical coherence tomography (EDI-OCT) scans of the study population were captured and analyzed before and after the resolution of the subretinal fluid. 5-line high definition scans centered on the foveal center were utilized. Image J (Version 1.52a, NIH) was utilized to segment the choroidal layer in each of the b-scan to evaluate: 1) Subfoveal Choroidal Thickness (SFCT); 2) Choroidal Volume (CV); and 3) Choroidal Vascularity Index (CVI). Multiple linear regression was used to compare the choroidal indices at the two time points.

Results: Six patients with a confirmed diagnosis of CSC that demonstrated resolution of subretinal fluid after receiving PDT were analyzed. The mean age of the study population was 62 (Range: 45-68 years). Five (83.33%) patients were male. The mean (SD) SFCT, CV, and CVI before the PDT of the study population was 310.35 (97.84), 1.64 (0.35), and 0.648 (0.009), respectively. Following the resolution of the subretinal fluid, the mean (SD) SFCT, CV, and CVI of the study population were 240.43 (95.25), 1.61 (0.31), and 0.649 (0.008), respectively. Multiple linear regression demonstrated a statistically significant decrease in SFCT ($R^2=91$, $p=0.045$), CV ($R^2=97$, $p=0.021$) and increase in CVI ($R^2=98$, $p=0.015$) after PDT.

Conclusions: PDT is associated with significant changes in the choroidal structure in CSC patients. Choroidal indices may be employed to monitor disease progression.

ABSTRACT BODY:

Purpose: We investigated the microRNAs (miRNAs) expression in the anterior lens capsules of patients with senile cataract and compared it to that in the anterior lens capsules of healthy controls. Moreover, we compared the differences in miRNAs expression according to the types of cataracts.

Methods: Individual lens epithelium samples were collected from 33 senile patients and 10 controls. The cataract patients were classified into cortical, nuclear, posterior and anterior subcapsular and mixed. The expression of 12 different miRNAs in lens epithelium was measured using real-time polymerase chain reaction, and compared between the senile cataract patients and controls. The differences of miRNA levels according to cataract type were analyzed.

Results: The expression levels of let-7g-5p, miR-23a-3p, miR-23b-3p, and miR-125a-5p were significantly upregulated in patients with senile cataract when compared with those in the control group ($P < 0.05$). The expressions of let-7a-5p, let-7d-5p, miR-16-5p and miR-22-3p were significantly downregulated in the senile cataracts ($P < 0.05$). Let-7a-5p, let-7d-5p, let-7g-5p and miR-23b-3p had significant difference in expression between nuclear and anterior subcapsular cataracts.

Conclusions: The 8 differentially expressed miRNAs may be involved in the pathogenesis of senile cataract, in particular, related to oxidative stress and autophagy.

ABSTRACT BODY:

Purpose: Alzheimer's disease (AD) presents retinal neurodegenerative changes even before they appear in the brain, suggesting the retina as an accessible biomarker of AD. The present work is a diachronic study using spectral domain optical coherence tomography (SD-OCT) to determine the total retinal thickness and retinal nerve fiber layer (RNFL) thickness at 6, 9, 12, 15, 17, and 20 months old, in an APP^{NL-F/NL-F} mouse model of AD compared to wild type (WT) animals.

Methods: Total retinal thickness and RNFL thickness were determined in male APP^{NL-F/NL-F} (n=55) and WT (n=41) animals. The mean total retinal thickness was analyzed following the Early Treatment Diabetic Retinopathy Study sectors. RNFL was measured in six sectors of axonal ring scans around the optic nerve. Microglial and astroglial activation was evaluated at 17-months-old, by analyzing vertical retinal sections immunostained with Iba-1 and GFAP.

Results: In the APP^{NL-F/NL-F} group compared to WT animals, for total retinal thickness was observed: i) At 6-months-old, a significant thinning in the outer temporal sector; ii) at 15-months-old a significant thinning in the inner temporal and in the inner and outer inferior retinal sectors; iii) at 17-months-old, a significant thickening in the inferior and nasal sectors in both inner and outer rings; and iv) at 20-months-old, a significant thinning in the inner ring of nasal, temporal and inferior retina and in the outer ring of superior and temporal retina. In RNFL thickness, a significant thinning in the global analysis and in nasal and inner-temporal sectors at 6 months old were observed. In addition, in the APP^{NL-F/NL-F} group we found activation of microglial cells (thicker somas and processes and amoeboid forms) and astroglial cells (higher GFAP+ immunostaining with astrocyte clusters in certain areas).

Conclusions: In the APP^{NL-F/NL-F} model, the thickness of the retina over time exhibited a thinning, probably produced by neurodegeneration alternating with the thickening possibly caused in addition to the deposits by neuroinflammation observed in some areas of the retina in this model. These changes over time are similar to those found in the human retina and could constitute a biomarker of AD. The APP^{NL-F/NL-F} AD model can provide us a

better understanding of the different retinal alterations during the progression of AD.

ABSTRACT BODY:

Purpose: The complex pathophysiology of DME results in extracellular fluid accumulation and in decreased visual function. Light-based Photobiomodulation (PBM) provides a non-invasive treatment strategy that directly targets the underlying pathology through light-sensitive cellular cascades. The Valeda Light Delivery System is successful in the treatment of AMD (cf. LIGHTSITE I & II). We here present an observation of novel PBM therapy in early DME patients with the Valeda System.

Methods: A total of 28 eyes from 18 DME patients (67% male; 57.3±14.0 yrs) with good vision but OCT evidence of macula edema were assessed for functional (BCVA), anatomical (CRT, RV, presence of IRF, SRF and HE), and safety outcomes (integrity of EZ, IZ, ELM and RPE) following one series of PBM treatments (3x per week for 3-4 weeks) with the Valeda Light Delivery System. Assessments were conducted at baseline (BL), immediately following the final (9th) treatment and at follow up visits out to approx. 6 months. Presence of ERM, VMT and DRIL in the OCT and patients' subjective evaluations (via questionnaire) were recorded as well.

Results: After initial treatment with PBM, 28.6 % and 40 % eyes showed a resolution of inner retinal fluid and hard exudates, respectively. Retinal thickness (CRT) remained stable, from 302±58 µm at BL to 296±47 µm after 9th treatment. In all eyes, photoreceptors and RPE remained intact during the treatment and up to 6 months follow-up. At the same time, visual acuity remained stable at 0.1±0.1 logMAR. Most patients noted a considerable improvement in their subjective vision and reported less problems in everyday life and were more confident and more positively biased towards the development of the disease even up to 6 months.

Conclusions: Anatomical benefits suggest disease-modifying effect with PBM treatment with the Valeda in early DME patients. These study subjects typically had good vision and nearly normal CRT and RV but clear evidence of macular edema. PBM treatment demonstrates potential as a novel, non-invasive, cost-effective and well-tolerated approach for treatment of early DME patients. Moreover, the early treatment may provide a viable option to stabilize the functional and anatomical parameters and prevent the progression of the DME disease.

TITLE: Single particle analysis of extracellular vesicles in aqueous humor from pediatric diseased eyes: a pilot study

SESSION TITLE: Blood flow/ Ischemia/reperfusion/Aqueous humor dynamics/IOP

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Peng, L. Xu, J.L. Berry, The Vision Center, Children's Hospital of Los Angeles, Los Angeles, California, UNITED STATES|C. Peng, L. Xu, Department of Biological Sciences, Dornsife College of Letters, Arts, and Sciences, University of Southern California, Los Angeles, California, UNITED STATES|J.L. Berry, Roski Eye Institute, Keck School of Medicine, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chen-Ching Peng: Commercial Relationship: Code N (No Commercial Relationship) | Liya Xu: Commercial Relationship(s);Children's Hospital Los Angeles:Code P (Patent) | Jesse Berry: Commercial Relationship(s);Children's Hospital Los Angeles:Code P (Patent)

ABSTRACT BODY:

Purpose: Extracellular vesicles (EV) are detectable in aqueous humor (AH) from adult patients in previous studies. However, the presence of EVs in AH from pediatric diseased eyes has not been explored. Also, the expression profile of exosomal tetraspanins (CD9, CD63 and CD81) on AH EVs remains unclear. Herein, we measure the concentration of the pediatric diseased eye-derived AH EVs and analyze their size distribution and the phenotypic expression levels of exosomal tetraspanins of AH EV at single vesicle resolution.

Methods: AH samples were obtained from 3 congenital cataract, 3 congenital glaucoma and 5 retinoblastoma (RB) eyes. Plasma samples were obtained from 2 RB patients. Unprocessed, enrichment-free 10uL AH samples or 1uL plasma samples were subjected to Nanoparticle Tracking Analysis (NTA) (Nanosight NS300, Malvern Panalytical) for size distribution and concentration, and to Single Particle-Interferometric Reflectance Imaging Sensor (SP-IRIS) (Exoview R100, Nanoview Biosciences), for interferometric sizing and fluorescent-based immunophenotyping of exosomal marker expression (CD81, CD9, and CD63, including CD41a, which detects platelet derived vesicles).

Results: By NTA, the concentration of AH EVs is within $2.65E+09$ - $1.58E+10$ particles/mL with a major population in a mean modal size of 93.3 ± 19.8 nm across diseases in contrast to the $1.55E+11$ - $2.56E+12$ particles/mL with a mean modal size of 60.2 ± 2.1 nm detected in plasma samples. SP-IRIS analysis revealed that CD9+, CD63+ and CD81+ EVs were detected across all AH samples using the Exoview R100 platform. Platelet-derived CD41a+ EVs could only be detected in the plasma EVs. In addition, we identified an enrichment of a single-positive CD63+ EV population in AH across all disease groups (50.9% and 13.6% CD63⁺ EV among all fluorescent positive EVs in AH and plasma, respectively) suggesting a unique phenotypic exosomal tetraspanin expression pattern in AH.

Conclusions: Exosome size ranged-EVs are readily detectable in unprocessed AH with a dominant mono-CD63+ EV in AH regardless of pediatric eye disease types. These novel findings uncover a new path on AH exosomal biomarker research focusing on CD63+ EVs.

ABSTRACT BODY:

Purpose: To examine the diagnostic power of two new forms of rapid objective perimetry in patients with multiple sclerosis (MS).

Methods: We tested 44 MS patients aged 60.7 ± 10.1 y (mean \pm SD), 13 of them with progressive disease, the remaining 31 with relapsing remitting. The 40 normal control patients were aged 60.2 ± 12.5 y. EDSS scores were assessed by J B-G who is a neurologist. We used two variants of multifocal pupillographic objective perimetry: W12 and W20, which had 12 or 20 stimuli/eye that sampled the central 60 degrees of each visual field. Both eyes were tested concurrently in 80 seconds. We used an FD-cleared prototype of the Konan objectiveFIELD Analyser (OFA). The main variable of interest was the asymmetry between eyes in the per-region response delays. We calculated % Areas under Curve (%AUC) for Receiver Operating Characteristic (ROC) plots. Separate %AUCs were calculated for the mean of the worst 4, and worst 12, per-region response delay asymmetries for each of 3 EDSS groups: < 2.5 ; 2.5 to < 4.5 ; and ≥ 4.5 , compared to controls. We also estimated Effect-sizes as Hedge's g.

Results: The measured %AUCs increased with disease severity, reaching 94.4 ± 3.16 for EDSS3 (Table). Both methods had similar performance although W20 was better for the less severe EDSS1 patients. The Hedge's g values indicated 'large' to 'huge' Effect-sizes. An interesting sub-analysis compared subjects who had experienced Optic Neuritis (ON, N=30) and those who had not (no-ON, N=14). The resulting %AUCs were very similar for both tests. For No-ON and ON, W12: 86.9 ± 5.24 vs 86.0 ± 4.46 ; and W20: 87.2 ± 5.45 vs 86.8 ± 4.36 .

Conclusions: The relatively large %AUCs and Effect-sizes for the EDSS 1 group possibly indicates an ability to diagnose and monitor disease condition in early-stage disease. The results for ON vs. no-ON suggest that the tests are more biased towards disease progression rather than the history of acute inflammation. This is similar to our earlier multifocal VEP data that used related stimuli [Annals Neurology, 57, 904-913].

ABSTRACT BODY:

Purpose: To make a valid comparison between the effect of patching therapy and dichoptic video gaming in children with amblyopia: preliminary results after 24 weeks of treatment.

Methods: In this prospective Randomized Clinical Trial all newly diagnosed children with amblyopia were recruited by ten treating orthoptists in four clinics. Exclusion criteria were previous amblyopia treatment, strabismus angle >30PD, neurological disorder, nystagmus and other eye disorders. The research orthoptist examined the child according to the study protocol using the crowded tumbling E-chart to measure visual acuity (VA). If necessary, a refractive adaptation period of 16 weeks was carried out prior to randomization. After informed consent they were randomized to patching therapy: 2 hrs/day; compliance was monitored electronically using the Occlusion Dose Monitor; or dichoptic video game therapy: 1 hr/wk under direct supervision at the outpatient clinic. VA was assessed every 6 weeks by the research orthoptist during the study period of 24 weeks. Main outcome measure was improvement in VA (logMAR units/time period). In addition, quality of life data was collected using the adjusted Child Amblyopia Treatment Questionnaire (CAT-QoL).

Results: One-hundred children were recruited; 29 subjects refused participation, 2 were excluded. After refractive adaptation period, 27 subjects attained interocular VA <0.2 logMAR. Thirty-five children were included for randomization; 18 were boys (51%). During the study 3 children dropped out of the patching group and 10 out of the gaming group, resulting in 22 (22%) children completing the full study period. Mean age was 6.4±2.8 years. These children had mean VA at start of treatment of 0.43±0.31 logMAR in the amblyopic eye and 0.07±0.15 logMAR in the fellow eye. Mean VA after 24 weeks of treatment improved to 0.20±0.29 logMAR in the amblyopic eye and 0.03±0.13 logMAR in the fellow eye. Nineteen children were interviewed for the CAT-QoL and 18 parents filled out the same questionnaire independently.

Conclusions: After 24 weeks of patching or gaming treatment mean VA improved with 2.3 logMAR lines in the amblyopic eye. Depending on the results from the CAT-QoL, in-depth interviews will be conducted investigating experiences of parents whose child had either received occlusion therapy or gaming therapy.

ABSTRACT BODY:

Purpose: The purpose of the present study is to develop a culture system for human corneal endothelial cells (hCEC) replacing the use of xenogeneic components by a standardized kit in Ophthalmology to obtain human Platelet Rich in Growth Factors (PRGF) and to evaluate the adequacy of this culture system by the study of functionality markers, Transendothelial electrical resistance (TER) and gene expression.

Methods: 12 corneas discarded for transplantation were used for this study 6 per each group. Corneal endothelium was dissected following the Schwalbe line and was conditioned for 2-7 days at 37 °C in a culture plate with 4 mL of PRGF or SBF culture medium:

PRGF Medium: Optimum I, 10 v/v% PRGF, 200 mg/L CaCl₂ and 10 U/mL penicillin, 10 µg/mL streptomycin.

SBF Medium: Optimum I, 8 v/v% fetal bovine serum (FBS), 200 mg/L CaCl₂, 0.3 mM ascorbic acid 2-phosphate, 0.04% chondroitin sulfate, 20 ng/mL nerve growth factor, 5 ng/mL epidermal growth factor and 10 U/mL penicillin, 10 µg/mL streptomycin.

Conditioned endothelium was digested with TrypLE for 90 min at 37 °C. After that, the loosened cells were centrifuged at 0.4 g for 10 min, the supernatant was removed and the cells were seeded on a culture plate previously treated with FNC coating mix®.

Cellular growth was assessed by phase contrast microscopy until confluence. Both hCECs cultured with basal or conventional medium were used for TER evaluation. Confluent cultures were fixed using ice-cold methanol for 10 min. Then, immunocytochemistry of major corneal endothelial markers (Na⁺/K⁺ ATPase, ZO-1, connexin-43 and vimentin) were performed. Additionally confluent cultures of hCECs were loosened with accutase and used for gene expression analysis for the same expression markers.

Results: hCECs obtained from both PRGF and SBF supplemented cultures proliferated until confluence showing positive staining for connexin-43, vimentin, ZO-1 and Na⁺/K⁺ ATPase, responsible these last two for endothelial barrier and pump functions, respectively. In addition, similar gene expression levels and TER values were observed in PRGF and SBF hCECs cultures.

Conclusions: hCECs can be obtained using a PRGF culture medium avoiding the use of animal derived substances.

ABSTRACT BODY:

Purpose: Alzheimer's disease (AD) is a progressive neurodegeneration in which cerebral amyloid angiopathy develops, resulting in vascular changes. In recent works, alterations and deposits in the choroids and retinas of patients with AD have been observed that correlate with the disease's progression. Novel techniques for the study of ocular vascularization, such as the Laguna ONhE and the angio-optical coherence tomography (OCTA), tests that can be performed in these patients (non-invasive and without contrast), will allow the study of ocular vascular changes caused by AD

Methods: Seventeen patients with mild AD (mAD) and 49 healthy controls, which after a complete eye examination did not present any ophthalmological diseases, were studied for the coefficient of hemoglobin (Hb) in the optic nerve head by Laguna ONhE, and for thickness of the choroid and foveal avascular zone (FAZ) of the retina by the OCTA. For the statistical study, the Mann-Whitney test was used.

Results: The Mini Mental State Examination of the mAD patients was 24.00 ± 5.32 , while the control group was 29.40 ± 1.83 , with a significant difference ($p < 0.001$) between them. In the Hb coefficient of the optic nerve head there was no significant difference when comparing both groups, although in the papillomacular bundle there was a slight increase in the Hb coefficient in mAD patients. However compared to the control, the choroid in the mAD patients showed a significant thinning ($p < 0.05$), while the FAZ did not change.

Conclusions: In patients with mAD, a significant decrease in the choroidal vascular system was found, while the retinal system and the Hb of the optic nerve head did not exhibit any changes in the mild stages of AD. These results are showing that choroidal changes potentially could be an early biomarker of amyloid angiopathy which may be used for the diagnosis and follow-up of AD.

ABSTRACT BODY:

Purpose: To assess cone photoreceptor survival in the human eye with age-related macular degeneration (AMD), using adaptive optics scanning laser ophthalmoscopy (AOSLO) and spectral-domain optical coherence tomography (SDOCT).

Methods: AOSLO was performed to image cones in central 20° of the retinae. A 2-dimensional normative macular cone density map was obtained in 29 eyes of 18 subjects aged 67.1 ± 10.8 years without evidence of any macular disease. In 10 eyes of 7 patients with intermediate stage AMD including 5 eyes with predominantly subretinal drusenoid deposits (SDD) and 5 eyes with classical drusen but without SDD, AOSLO and SDOCT were acquired 4 times over 39.6 ± 3.3 months. Retinal regions absent of AMD lesions were ascertained by reflectivity and packing structure of the cones imaged by AOSLO, and by the integrity of the cross-sectional structure in SDOCT. Cone density change was evaluated using linear regression at 1174 loci in these regions. The change of the proportion of retinal loci with cone density lower than normal values was estimated among the locations where cone density could be measured at both the baseline and the 4th visit, including 197 loci in eyes with SDD and 268 in eyes with drusen but without SDD.

Results: Cone density decreased over time at 98.3% (1154/1174) of the examined locations. In eyes with SDD, cone density declined with a slope of -160 ± 75 cones/degree²/year in the central 5° of the retina and with a slope of -59 ± 24 cones/degree²/year in the 5°-10° surrounding annular zone. In eyes with drusen but without SDD, cone density reduction slopes were -98 ± 48 cones/degree²/year in the central 5° and -27 ± 18 cones/degree²/year in the 5°-10° annular zone, respectively. Over the follow-up period, the percentage of retinal locations with cone density lower than normal (Z-score < -2) in eyes with SDD increased from 16% (32/197) to 59% (117/197). In contrast, in eyes with drusen but without SDD, this number changed from 1.5% (4/268) to 16.4% (44/268).

Conclusions: AOSLO revealed cone density reduction over time in retinal regions that were not clinically impacted by AMD lesions. Eyes with SDD showed an accelerated rate of cone density decrease compared with eyes with only classical drusen, suggesting a different natural history of photoreceptor degeneration in AMD of different phenotypes, and implying more severely impaired visual function.

ABSTRACT BODY:

Purpose: To investigate associations between residual subretinal fluid (SRF) volumes, quantified using artificial intelligence (AI) and treatment outcomes in a SRF-tolerant treat and extend (T&E) anti-VEGF regimen in neovascular age-related macular degeneration (nAMD).

Methods: In this post-hoc analysis, patients enrolled in the prospective, multicenter FLUID study and randomized in a SRF-tolerant T&E regimen were examined by spectral-domain optical coherence tomography (SD-OCT) imaging and tested for best-corrected visual acuity (BCVA) over a 24 months follow-up. Validated AI-based image analysis tools were used to quantify SRF and intraretinal fluid (IRF) volumes on SD-OCT. 375 visits of 98 patients of the SRF tolerant arm were divided into two subgroups: Extended intervals despite residual SRF, and visits with extension without fluid. BCVA change at the follow-up visit was compared between the groups. The associations of SRF volumes in the central 1mm and 6mm as well as treatment intervals with BCVA change were estimated using generalized linear mixed models.

Results: At visits with extended intervals despite residual SRF an increase in SRF was associated with a significant BCVA reduction at the next visit in the central 1mm (-0.138 letters/nl SRF; $p=0.014$) and the total 6mm (-0.024 letters/nl SRF; $p=0.049$). Visits with extended intervals despite residual SRF had significantly higher SRF volumes in the central 6mm ($p=0.002$) at the following visit, and showed a trend in the central 1mm ($p=0.061$). A statistically significantly negative association between increased treatment interval and change in BCVA was found for residual SRF in 1 and 6mm (-0.250 and -0.233 letter/week interval, respectively, both $p<0.001$).

Conclusions: A fully automated quantitative analysis of extended visits despite residual SRF demonstrated increasing SRF volumes associated with BCVA loss at the following visit. This association contributes to our understanding of the quantitative impact of residual SRF volumes on visual function and highlights the importance of precise and quantitative measurements of fluid volumes as the field determines the most efficacious regimens for individualizing treatment for nAMD with anti-VEGF therapies.

ABSTRACT BODY:

Purpose: The presence of Demodex species can be associated with DED, but the precise relationship remains unclear. The purpose of this prospective, observational, cross-sectional study was to assess the objective ocular surface abnormalities in patients with DED coexisting with Demodex infestation

Methods: This study was performed in accordance to the Declaration of Helsinki after approval by the Bioethics Committee. 180 eyes of 90 patients with DED diagnosed according to TFOS guidelines were recruited for the study. The study group (SG) consisted of 76 eyes of 38 patients with DED and coexisting Demodex infestation confirmed on sampled eyelashes. The control group (CG) consisted of 106 eyes of 53 DED patients. The groups were gender and age matched. Analysed ocular surface parameters included NITBUT, TMH, Meibomian gland drop-out, Bulbar redness were assessed by Keratograph 5M (Oculus). Measurements were performed twice in the morning and in the afternoon.

Results: Distribution of OSDI scores were comparable between groups, as well the results of NITBUT and TMH. Mild DED was the most prevalent among groups (SG: 85,18%; CG: 77,35%). The groups differed significantly in the MG drop out (SG: $0,51 \pm 0,23$; CG: $0,29 \pm 0,12$ $p < 0,001$) and conjunctival and limbal redness in the morning (SG: $1,2 \pm 0,43$; $1,1 \pm 0,53$ vs CG: $0,8 \pm 0,26$, $0,7 \pm 0,2$ $p < 0,0001$; $p < 0,01$ respectively). Parameters which were characterized by significant daily variability were NITBUT ($p < 0,001$), TMH ($p < 0,0001$) in both groups and conjunctival and limbal hyperaemia in the study group.

Conclusions: The infestation of the eyelids with Demodex species is associated with changes of the bulbar redness and anatomic changes of Meibomian gland in patients with DED, which confirm the role of the MGD and inflammation in the disease pathogenesis. Daily variability in NIBUT, TMH and ocular redness should be taken into consideration in DED studies.

TITLE: Corneal collagen cross-linking in children and developmentally delayed populations

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Shareef, A. Elhusseiny, J.T. Kwan, H.N. Saeed, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts, UNITED STATES|O. Shareef, Harvard College, Cambridge, Massachusetts, UNITED STATES|A. Elhusseiny, H.N. Saeed, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Omar Shareef: Commercial Relationship: Code N (No Commercial Relationship) | Abdelrahman Elhusseiny: Commercial Relationship: Code N (No Commercial Relationship) | James Kwan: Commercial Relationship: Code N (No Commercial Relationship) | Hajirah Saeed: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the results of corneal collagen cross-linking (CXL) in developmentally delayed and pediatric patients with keratoconus (KCN) under both general and topical anesthesia.

Methods: Data of individuals with KCN who underwent CXL under both general anesthesia as well as topical anesthesia were analyzed retrospectively by examining patient charts. This study is comprised of individuals who had CXL between January 2019 and November 2020. Differences between patients with and without developmental delay (DD) as well as changes in disease characteristics before and after surgeries were compared using the Pearson χ^2 and t-test.

Results: This study tracked 35 eyes of 22 patients with a mean follow-up of 7.2 ± 6.2 months. Of these 22 patients, 9 (40.9%) had DD. Patients with DD underwent CXL at an older age compared to patients without DD (mean age: 22.1 years vs 17.8 years), although this difference was not statistically significant. The nine DD patients were administered general anesthesia, and the remaining 13 patients without DD were given topical anesthesia. Regarding preoperative characteristics, patients with DD had a BCVA in LogMAR of 0.829 vs. 0.325 ($p = 0.005$). Corneal thickness (CT), sphere, cylinder, K1, K2, and K_m were not significantly different between the two groups. Postoperatively, BCVA in LogMAR for patients with DD was 0.739 and 0.222 in non-developmentally delayed ($p = 0.012$). Sphere, cylinder, K1, K2, K_m , and CT were not significantly different between the two groups.

There was no significant postoperative change in BCVA, K1, K2, K_m , sphere, cylinder, and CT compared to preoperative for the entire cohort of patients. No complications were observed during the procedures. Two patients needed retreatment at 1 and 11 months after initial crosslinking.

Conclusions: CXL under general anesthesia for developmentally delayed patients gives equivalent outcomes in halting progression of topographic parameters as compared to CXL under topical anesthesia for non-developmentally delayed patients. Pre and postoperative BCVA was not equivalent between the groups because of the inability of patients with DD to wear glasses or contact lenses. Early intervention should be considered in DD so that vision can be preserved to the greatest degree possible.

TITLE: Retinal Degeneration Associated with Mutations in the KIZ Gene

SESSION TITLE: Retinitis pigmentosa/ retinal prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. Rivera, I. Erdinst, A. Onala, S. Idan, A. Shemesh, D. Sharon, E. Banin, Ophthalmology, Hadassah Medical Center, Jerusalem, Jerusalem, ISRAEL|

Commercial Relationships Disclosure (Abstract): Jose Rivera: Commercial Relationship: Code N (No Commercial Relationship) | Inbar Erdinst: Commercial Relationship: Code N (No Commercial Relationship) | Asala Onala: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Idan: Commercial Relationship: Code N (No Commercial Relationship) | Aya Shemesh: Commercial Relationship: Code N (No Commercial Relationship) | Dror Sharon: Commercial Relationship: Code N (No Commercial Relationship) | Eyal Banin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Kizuna (KIZ) gene encodes a centrosomal protein and was first reported to be associated with inherited retinal dystrophy (IRD) in 2014. Since then only six cases have been reported worldwide. Here we aimed to characterize genotype and phenotype in what to our knowledge is the biggest cohort of patients with KIZ-associated IRD reported to date.

Methods: Medical records of KIZ patients were retrospectively reviewed, and genetic, clinical, imaging, and electrophysiological data were analyzed.

Results: We identified 18 patients with KIZ mutations: 16 (ages 13-66) have a homozygous p.R76* mutation and 2 (ages 42&50) were compound heterozygous for p.R76* and c.3G>A (p.M1?). From the homozygous group, 13/16 were of Ashkenazi Jewish (AJ) descent, 2 from Morocco and 1 from Turkey. Both compound heterozygous patients were from a mixed background (Bulgaria-Macedonia & Poland-Iraq).

Clinical data was available for 14 patients: 8/14 patients (ages 21-66) had good visual acuity ($\geq 20/40$) in at least one eye up until the last examination and 8/12 patients (ages 25-66) manifested cataracts, commonly posterior subcapsular.

Fundus imaging, available in 11 patients, showed two main phenotypes: 6 patients (5 Homo & 1 het, ages 13-66) manifested relatively mild disease with minimal fundusoscopic changes even at advanced age, although FAF revealed hypoautofluorescent spots and a macular hyperautofluorescent ring. Five other homozygous patients showed more aggressive disease with fundusoscopic features of classic RP, including bone spicule-like pigmentation, attenuation of retinal vessels and optic disc pallor.

On OCT, 4/8 patients (2 mild and 2 with RP-like phenotype) showed a mild ERM, and only one (in the mild group) had cystoid changes. Visual fields showed progressive constriction, reduced to less than 10 degrees by the age of 30 in 7/9 patients. FFERG was still recordable in patients up until 62 years of age, with a rod>cone dystrophy pattern. Interestingly, the Arden ratio on EOG testing was reduced in all 6 patients who performed this test to values lower than predicted by the extent of FFERG loss.

Conclusions: KIZ mutations are an uncommon cause of IRD worldwide, but are not rare among AJ, with a 1:79 carrier rate for the p.R76* mutation. Fundus findings are often mild and can be missed. In an AJ patient, FFERG testing showing a rod>cone pattern of injury and an EOG Arden ratio that is lower than expected may suggest KIZ as the cause of disease.

ABSTRACT BODY:

Purpose: While driving, hazards might appear in the periphery. It is known that peripheral optical errors decrease peripheral contrast sensitivity. This study evaluates how the elevated peripheral optical errors affect hazard perception in the peripheral visual field.

Methods: We evaluated hazard perception, as well as resolution acuity and contrast sensitivity in the 20° nasal visual field of 11 healthy eyes. Two optical conditions were tested with an adaptive optics vision simulator designed for peripheral vision evaluation: 1) Simulated average optical errors in 20° nasal visual field (-0.60 D in spherical equivalent, -0.50 D in cross-cylinder J0 and 0.09 µm horizontal coma for a 4 mm pupil); 2) Simulated elevated optical errors in 20° nasal visual field (-1.20 D in spherical equivalent, -1.45 D in cross-cylinder J0 and 0.09 µm horizontal coma for a 4 mm pupil). Peripheral resolution acuity and contrast sensitivity were evaluated with Gabor gratings. A hazard perception test was developed, wherein the subjects fixated foveally at a moving road scene while peripheral test stimuli were presented 20° nasally. The test stimuli consisted of hazards that were animals, and non-hazards that were plants and rocks. The subjects' task was to respond when a hazard was seen. The test conditions were randomized, and each measurement was performed twice.

Results: The elevated condition significantly reduced the peripheral grating resolution acuity and contrast sensitivity at 1 cycle per degree compared to the phakic condition: on average 0.08 logMAR and 0.25 logCS, respectively. In the hazard perception test, all subjects also showed worse performance with the elevated condition, resulted in increased false positives by 8 % and misses by 13 % together with 0.3 seconds longer reaction time.

Conclusions: This study tested the visual and functional aspects of peripheral optical errors. Improving the peripheral optics increases resolution acuity, contrast and hazard perception in the nasal visual field. Therefore, reducing peripheral optical errors produces visual and functional improvements that may have safety implications.

ABSTRACT BODY:

Purpose: The optical quality in the periphery of the retina in pseudophakic patients implanted with standard intraocular lenses (IOLs) is worse than those in the normal phakic eye (Jaeken et al., IOVS, 2013). This may affect specific visual tasks impacting patient's orientation in space and therefore may pose a hazard to their safety. We have evaluated peripheral astigmatism and contrast sensitivity in a group of patients implanted with a new type of IOL that was designed to provide better peripheral optics and compared results with a group of patients implanted with a standard IOL.

Methods: A new type of IOL (ArtIOLs, Voptica SL, Murcia, Spain) with an inverted meniscus shape designed to improve the optical quality of the pseudophakic eye in the periphery was evaluated. These lenses were implanted in a group of 87 patients undergoing cataract surgery. A control group of 38 patients were implanted with a standard monofocal IOL as reference. Peripheral refraction in the horizontal meridian was obtained using a scanning Hartmann-Shack wavefront sensor. Contrast detection threshold at 45 degrees of visual angle (both horizontally and vertically) was measured psychophysically by means of an adaptive staircase technique, using a 30-arcmin round stimulus 1 m in front of the patient's eyes and a green LED for foveal fixation.

Results: Patients implanted with ArtIOLs presented a reduced amount of peripheral astigmatism as compared with the control group. At 30 degrees, the average cylinder in the control group was 3 D, dropping to 2 D in the ArtIOL's group. At 45 degrees, cylinder mean values were 6 D and 3.5 D respectively. This reduction in astigmatism had a positive impact in contrast sensitivity. In the horizontal meridian, average sensitivity values were 0.07 (SD=0.04) and 0.10 (SD=0.05) for the control and ArtIOL groups respectively. In the vertical meridian, average sensitivity values were 0.06 (SD=0.03) and 0.08 (SD=0.03) for the control and ArtIOL groups respectively.

Conclusions: Patients implanted with a new meniscus-shaped IOL present a reduced amount of peripheral astigmatism compared to patients implanted with standard lenses. This improvement in optical quality leads to a better contrast sensitivity measured at 45 degrees of eccentricity. Further research would be required to evaluate how this IOL may have also an impact in the patient's functional vision.

ABSTRACT BODY:

Purpose: To quantify morphological signs of microglial cell activation and P2RY12, MHC-II and CD68 expression in aged mice (15 month) compared to young adult mice (3 month) and after unilateral laser-induced ocular hypertension (OHT).

Methods: Albino Swiss mice were divided in four groups: young naïve (YN, n=6), aged naïve (AN, n=6), young OHT (YG, n=6), and aged OHT (AG, n=6). In OHT groups both eyes (OHT and contralateral) were studied. Retinal whole-mounts were immunolabeled with anti Iba-1 to quantify: i) Iba-1 + cells number (Ibacn) in outer segments (OS), outer plexiform layer (OPL) and inner plexiform layer (IPL); ii) area of retina occupied by Iba-1 + cells (Iba-1 RA) in the nerve fiber layer- ganglion cell layer (NFL-GCL); iii) cell body area of Iba-1+ cells (Cblbac) in OPL, IPL and NFL-GCL; iv) arbor area of Iba-1+ cells (AAlbac) in OPL and IPL; and v) vertical processes number of Iba-1+ cells (VPIbac) between OS and OPL. Antibodies against P2RY12 (resident microglia), CD68 (phagocytic activity) and MHC-II (microglial activation marker) were also used.

Results: In AN respect to YN the quantitative analysis showed a significant increase in the Cblbac in OPL, IPL and NFL-GCL and a significant increase in the VPIbac. Both OHT eyes and contralateral eyes of YG and AG showed significant increase of Ibacn, Iba-1 RA, Cblbac and VPIbac and decrease of AAlbac, more pronounced in OHT eyes, compared to their respective naïve groups. Comparing AG vs YG showed: i) a significant decrease of Iba-1 RA and VPIbac in OHT eyes; ii) a significant increase of Ibacn (OS) and a significant decrease of Cblbac and AAlbac (IPL), in contralateral eyes. Analyzing the P2RY12, CD68 and MHC-II expression we observed: i) in YN and in YG all Iba-1+ cells were P2RY12+, except perivascular and dendritic cells, but in AG most cells were Iba-1+/P2RY12- and some cells in AN; ii) in AN, AG and YG numerous amoeboid-like CD68+ cells were found but in AG CD68+ cells with ramified appearance were also observed. In YG practically all Iba-1+ cells were MHC-II+, while in GA only some Iba-1+ cells were MHC-II+. However, in YN and AN Iba-1+ cells were MHCII-.

Conclusions: The morphological and expression differences of P2RY12, CD68 and MHC-II found in the microglial cells of AN and AG compared to those of YN and YG show that aging can increase the inflammatory process in glaucoma.

ABSTRACT BODY:

Purpose: The prevalence of many ocular surface diseases (OSDs) increases with age, which together with population ageing, create a need for better understanding of OSD among the elderly. The aim of this study was to describe the clinical characteristics of OSD in a well-defined Finnish elderly population.

Methods: This cross-sectional study included subjects born between years 1933-1956 and living in Savitaipale, Finland. Various ocular surface health parameters were evaluated, including Schirmer's I test, fluorescein tear break-up time (FTBUT), corneal and conjunctival staining, conjunctival redness, blepharitis, Meibomian gland dysfunction (MGD) and Ocular Surface Disease Index (OSDI). The prevalence of various forms dry eye (DE) and their clinical characteristics were evaluated based on adjusting different OSD criteria and comparing them statistically using Wilcoxon rank sum test and two-sample t-test.

Results: The study included 590 subjects (328 women and 262 men), with mean age of 72.1 years (SD=6.3). Lid and tear lipid dysregulation characteristics were following; 16% of subjects had signs of blepharitis (Efron scale ≥ 2), 15% had signs of MGD (Efron scale ≥ 2) and 38% had FTBUT below 10 sec. Over half of all subjects (54%) had signs of conjunctival redness (SILK-HU ≥ 2), while conjunctival (Lissamine) staining and corneal (fluorescein) staining showed signs of epithelium damage for 12% and 29% of subjects, respectively (Oxford scale ≥ 1). Altogether 32% of subjects had Schirmer I test below 10 mm indicating lowered tear flow. OSDI scores suggested that 13% of subjects had mild, 6% moderate and 3% severe DE. Prior to the study, DE had been diagnosed for 30% subjects and 36% used a DE medication of some form. Based on the clinical signs observed, 10% of all subjects suffered from DE and 38% from OSD. When aforementioned groups were compared to subjects with healthy ocular surface, conjunctival and corneal staining as well as OSDI were increased (all $p < 0.001$) while FTBUT was decreased (all $p < 0.001$) among all groups.

Conclusions: DE and OSD are common among the old adult population. Their prevalence is, however, strongly dependent on the criteria and cut-off values of independent parameters. Comparison of the patients' awareness of their disease and the use of artificial tear substitutes with the clinical signs and symptom scores indicates unmet needs for better understanding of factors related to OSD and improved biomarkers in their analyses.

ABSTRACT BODY:

Purpose: To characterize the incidence rate of myocardial infarction (MI) in patients following a new diagnosis of cataract, glaucoma, neovascular age-related macular degeneration (AMD) or proliferative diabetic retinopathy (PDR).

Methods: A retrospective cohort study of all patients aged ≥ 40 years attending a large ophthalmic hospital of ten separate sites across London, United Kingdom linked with secondary care Hospital Episodes Statistics Admissions data between January 1st 2008 and June 1st 2018. Myocardial infarction (MI) was defined by diagnostic code I21 or I22 using the International Classification of Diseases, 10th revision and ophthalmic disease through the local electronic health record system. Crude MI incidence rates and those stratified by age, sex, ethnicity and socioeconomic deprivation (through the Index of Multiple Deprivation 2015) per ophthalmic disease were estimated with 95% Poisson intervals. Adjusted cause-specific and subdistribution hazard ratios (HR) were estimated from Cox proportional hazard and Fine-Gray competing risks regression models respectively.

Results: Of 353,191 patients, 59102 had cataract, 31060 glaucoma, 7262 AMD and 2494 PDR. Crude MI incidence rates were 494.6 (461.2-529.5), 297.7 (270.7-326.5), 528.5 (451.4-613.8) and 1449.8 (1173.3-1766.5) per 100,000 person-years at risk (PYAR) for cataract, glaucoma, AMD and PDR respectively. Patients with PDR had the highest incidence rate of MI across all strata. Incidence of MI rose sharply in young patients with cataract from 35.3 (5.0-108.8) for those aged 40-49 years to 368.8 (288.0-463.6) for those aged 50-59 years per 100,000 PYAR with a corresponding HR of 1.54 (1.43-1.66) per decade of age. Those of Asian ethnicity had increased hazards of MI following cataract diagnosis (cause-specific HR 2.67, 1.98-3.61), glaucoma (2.40, 1.69-3.40) and PDR (3.32, 1.41-7.84). Less deprivation was significantly associated with slightly reduced incidence of MI for those with cataract (HR 0.95, 0.92-0.97 per decile) and AMD (0.92, 0.87-0.97).

Conclusions: In accordance with the cardiovascular consequences of diabetes mellitus, MI incidence rate among patients with newly diagnosed PDR was highest. However, a particularly steep rise was noted in younger patients newly diagnosed with cataract supporting a role for cardiovascular risk-stratification in this group.

TITLE: Development of a thermosensitive hydrogel for sustained drug release and in situ bleb support

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Zhang, J.J. Armstrong, C.M. Hutnik, Western University Schulich School of Medicine & Dentistry, London, Ontario, CANADA|C.M. Hutnik, Ivey Eye Institute, London, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Richard Zhang: Commercial Relationship: Code N (No Commercial Relationship) | James Armstrong: Commercial Relationship: Code N (No Commercial Relationship) | Cindy Hutnik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Anti-scarring agents are integral to glaucoma filtration surgery success. When injected as a solution or applied via sponge, rapid washout from the subconjunctival tissues limits long-term efficacy. Chitosan-based thermosensitive hydrogels (ThermoGels) are injectable liquids at room temperature that solidify into gels at temperatures approximating the subconjunctival space. In this study, we evaluate ThermoGels' thermosensitive properties, resistance to outflow, and biocompatibility with human Tenon's capsule fibroblasts (hTCFs) with the goal to develop an injectable sustained-release anti-fibrotic drug depot and in situ bleb scaffold.

Methods: Hydrogels were prepared by dissolving chitosan in 2% acetic acid, dialyzing to remove the acid, and adding beta-glycerophosphate (β -gp). Various recipes were tested for gelation time vs temperature using the tube inversion test. Biocompatibility was tested by culturing hTCFs on chitosan gels at 37°C. Resistance to flow was tested by measuring afferent pressure when perfusing a gel-filled flow chamber with saline at the rate of aqueous humor production (2.6 μ L/min). Drug release was tested by measuring acetylsalicylic acid (ASA) or bovine serum albumin (BSA) in the effluent when perfusing drug-loaded gels with saline at 2.6 μ L/min.

Results: Gelation time of chitosan/ β -gp solutions is inversely related to temperature and the concentration of β -gp used. 5% and 6% β -gp mixtures gelled the quickest at 37°C. MTT and LDH assays showed that chitosan hydrogels have no significant effect on cellular metabolic activity or necrosis compared to vehicle controls. Perfusion of the hydrogel demonstrated a reproducible, transient increase in afferent pressure of 5.0 ± 1.5 (SD) mmHg compared to no gel. However, this was transient and fully resolved by 9 hours. ASA and BSA were successfully loaded into chitosan gels and perfusion with saline elicited a delayed release of ASA/BSA.

Conclusions: Chitosan/ β -gp hydrogels solidify at eye-surface temperatures or higher, are biocompatible with ocular fibroblasts, do not substantially affect outflow capacity, and can be loaded with small molecules or proteins to act as a delayed-release drug depot. These properties support the potential subconjunctival injection of ThermoGel to provide sustained drug-release and structural support for the bleb.

ABSTRACT BODY:

Purpose: To determine the diagnostic ability of retinal nerve fiber layer (RNFL) thickness to detect glaucoma after compensating the RNFL thickness for demographic and anatomical factors.

Methods: This case-control study enrolled 2699 healthy participants, including Chinese, Indians and Malays to construct an Asian-specific compensation model, which was then tested in 738 eyes without glaucoma and 386 eyes with glaucoma (early, n = 231; moderate, n = 90; and, advanced, n = 65). Participants underwent Cirrus spectral-domain optical coherence tomography (SD-OCT; Carl Zeiss Meditec) imaging of the optic disc and macular cubes. Compensated RNFL thickness was generated based on ethnicity, age, refractive error, optic disc (ratio, orientation and area), fovea (distance and angle), and retinal vessel density. RNFL thickness measurements and their corresponding areas under the receiver operating characteristic curves (AUCs) were obtained.

Results: After applying the Asian-specific compensation model, the standard deviation (SD) of RNFL thickness reduced, where the effect was greatest for Chinese (16.8%), followed by Malays (13.4%) and then Indians (11.7%). Compensated RNFL outperformed measured RNFL for discrimination of early glaucoma (AUC = 0.89 vs 0.85; $P < 0.001$), moderate glaucoma (AUC = 0.94 vs 0.91; $P < 0.001$) and advanced glaucoma (AUC = 0.98 vs 0.96; $P < 0.001$).

Conclusions: Compensated RNFL showed better glaucoma discrimination capability than measured RNFL thickness in a multi-ethnic Asian group. This finding suggests there may be utility in accounting for demographic and anatomical variance in RNFL thickness to improve glaucoma detection.

ABSTRACT BODY:

Purpose: Animal testing remains as the gold standard for the evaluation of potential damages on the ocular surface of topical products. Although alternative methods are currently available via in vitro reconstructed epithelia, these methods base its prediction on destructive test. In this study, we use a cruelty-free in vitro corneal model (CFreeCM) previously developed by our laboratory, and analysed the changes in cell membrane capacitance using the Standardized Operational Procedures detailed in OECD TG 492 for identifying chemicals not requiring classification and labelling for eye irritation. Cell membranes display the ultrastructure of a natural capacitor due to the dielectric properties of the phospholipid bilayer, meaning that cell capacitance can be related to the cell membrane integrity which could be altered after chemical exposure and might lead to ocular irritation

Methods: CFreeCMs were prepared from limbal cells isolated from human normal corneoescleral rims discarded after corneal keratoplasty using animal component-free culture media. Limbal cells were cultured on 1.12cm² Transwell insert and differentiated for 7 days under air-lift conditions. Cell membrane capacitance was evaluated using coupled electrodes connected to a EUCOL U2817A Precision LCR Meter prior to chemical exposure at different frequencies (from 50Hz to 100kHz). Next, 26 chemicals (12 irritants and 14 non-irritants) including liquids and solids were applied in duplicates for 30 minutes or 6 hours respectively. After PBS rinse, CFreeCMs were incubated at 37C for 2 hours for liquids or 18 hours for solids. Finally, cell capacitance was evaluated again and cell viability was assessed using the MTT assay

Results: A prediction model was developed based on changes of cell membrane capacitance and compared to standard classification obtained by the MTT assay. Standard classification according to MTT resulted in 91.6% sensibility (11/12), 64.2% specificity (9/14) and 76.9% accuracy (20/26). Cell capacitance prediction model at 1kHz resulted in 91.6% sensibility (11/12), 78.5% sensibility (11/14) and 88% accuracy (22/26)

Conclusions: Although standard classification based on cell viability is in accordance with OECD TG 492 requirements, classification using cell capacitance resulted in higher specificity and overall accuracy, leading to an optimized non-invasive and non-destructive prediction model of ocular irritancy

TITLE: Outcomes of scleral buckle after failed pneumatic retinopexy

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. He, H. Chen, D. Albiani, A. Kirker, A. Merkur, D. Maberley, Z. Mammo, Ophthalmology and Visual Sciences, The University of British Columbia Faculty of Medicine, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure (Abstract): Bonnie He: Commercial Relationship: Code N (No Commercial Relationship) | Henry Chen: Commercial Relationship: Code N (No Commercial Relationship) | David Albiani: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Kirker: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Merkur: Commercial Relationship: Code N (No Commercial Relationship) | David Maberley: Commercial Relationship: Code N (No Commercial Relationship) | Zaid Mammo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the visual and anatomic outcomes of patients who underwent a scleral buckle (SB) as a secondary procedure for failed primary pneumatic retinopexy (PR) in the repair of rhegmatogenous retinal detachments (RRD).

Methods: This is a retrospective, single-center, consecutive case series of patients from 2009 to 2020 with a RRD who failed a primary PR and underwent a secondary SB repair. Patients with at least six months of post-operative follow-up were included in the study. Demographic information, pre-operative characteristics, parameters of the failed PR, parameters of the subsequent SB procedure, and serial optical coherence tomography (OCT) imaging data were recorded. The data was analyzed using ANOVA with statistical significance level set at 0.05.

Results: A total of 57 patients (59.7% male, mean age of 47 ± 15 years old) were included in our study, with a mean follow-up was 48.6 ± 31.8 months. 26 right eyes and 31 left eyes were identified, and all eyes were phakic. The mean total number of clock hours in the initial RRD was 4.1 ± 1.6 , and 45.6% of patients had macula-off RRD, with over 36% having more than one retinal break. The average time to PR failure was 7.6 ± 11.2 days, and 61% had the secondary SB procedure within a week. Visual acuity (VA) in (LogMar [Snellen equivalent]) at presentation (0.72 ± 0.82 [20/70]) and at time of PR failure (0.51 ± 0.47 [20/65]) were not significantly different ($p=0.487$).

At six months post-SB repair, VA was (0.42 ± 0.37 [20/53]). VA at twelve months and at final follow-up were (0.35 ± 0.34 [20/45]) and (0.27 ± 0.30 [20/37]) respectively, both of which were significantly better than the initial visual acuity ($p=0.032$ and $p=0.002$, respectively). Thirteen patients (13/57, 23%) required at least one additional surgery. Reasons for additional surgery included: non-resolving subretinal fluid on serial OCT (6/13, 46.1%), new breaks (5/13, 38.5%) or proliferative vitreoretinopathy (2/13, 15.4%). The average time to secondary surgery was $84. \pm 201$ days.

Conclusions: Among phakic patients who fail PR for RRD, SB remains a viable alternative with acceptable anatomical and functional outcomes at six months and one year follow-up respectively.

ABSTRACT BODY:

Purpose: To assess the changes in anterior prelaminar depth (PLD) following adduction, abduction and IOP elevation in high tension glaucoma (HTG), normal tension glaucoma (NTG), and ocular hypertensive (OHT) subjects.

Methods: We recruited 221 subjects (Chinese ethnicity and more than 60 years old) which comprised of 93 HTG, 87 NTG, and 41 OHT subjects. For each subject, we imaged the ONH using Spectral-domain optical coherence tomography (OCT) under the following conditions: (1) primary gaze, (2) 20° adduction, (3) 20° abduction and (4) primary gaze with acute IOP elevation (to ~40 mmHg) achieved through ophthalmodynamometry. For each OCT volume, we automatically segmented the prelaminar tissue (PLT) using deep learning. We calculated the PLD for each volume with respect to the Bruch's membrane opening (BMO) reference plane and calculated the change in PLD of each subject under loads (2)-(4) with respect to the baseline primary gaze (1).

Results: Under IOP elevation, we observed an increase in PLD (posterior displacement) with an average change of (+12.8 ± 30.1 micron) across all subjects (Figure 1). Additionally, we found that PLD of HTG eyes were significantly more sensitive to IOP elevation (+17.24 ± 29.2 microns) as compared to PLD of NTG eyes (+7.4 ± 28.8 microns, p<0.05, Figure 2a) and OHT eyes (+7.9 ± 35.3 micron, p<0.1). Under adduction, we observed a decrease in PLD (anterior displacement) with an average change of (-15.5 ± 32.3 micron) across all subjects (Figure 1). Additionally, we found that PLD of NTG and OHT eyes were more sensitive to adduction (NTG: -18.8 ± 38.2 micron, OHT: -15.0 ± 40.3 micron) as compared to PLD of HTG eyes (-8.0 ± 29.8 micron, p<0.05, Figure 2b). Abduction did not result in significant changes in PLD (Figure 1).

Conclusions: Using PLD changes as the mode of measurement, we found that NTG and OHT subjects were more sensitive to adduction as compared to IOP elevation and HTG subjects were more sensitive to IOP elevation as compared to adduction. These preliminary results could provide clues to the different pathophysiology of between NTG and HTG which warrants further investigation.

ABSTRACT BODY:

Purpose: Diabetic macular edema (DME) is the primary cause of irreversible vision loss among individuals with diabetes mellitus (DM). We developed, validated, and tested a deep-learning (DL) system for classifying DME and for retinal abnormalities other than DME simultaneously using images from three common commercially available optical coherence tomography (OCT) devices.

Methods: We trained and validated two versions of a multi-task network, one based on three-dimensional (3D) ResNet-34 and another based on two-dimensional (2D) ResNet-18, to classify DME (center-involved DME [CI-DME], non-CI-DME, or absence of DME) and other retinal abnormalities (their presence or absence) using 3D volume-scans and 2D B-scans respectively. A total of 73,746 OCT images, representing 2,444 eyes from 1,238 subjects with DM, were used for training and primary validation. These images include 3,788 3D volume-scans from Cirrus OCT, 30,515 2D B-scans from Spectralis OCT, and 39,443 2D B-scans from Triton OCT. External testing was performed using 3,218 volume-scans from Cirrus OCT, 18,295 B-scans from Spectralis OCT, and 5,468 B-scans from Triton OCT across seven independent datasets under different clinical settings.

Results: In classifying the presence or absence of DME, the DL system achieved AUROCs of 0.937 (95% CI 0.920–0.954), 0.958 (0.930–0.977), and 0.965 (0.948–0.977) for primary datasets obtained from Cirrus, Spectralis, and Triton OCTs respectively, in addition to AUROCs greater than 0.906 for the external datasets. For the further classification of the CI-DME and non-CI-DME subgroups, the AUROCs were 0.968 (0.940–0.995), 0.951 (0.898–0.982), and 0.975 (0.947–0.991) for the primary datasets and greater than 0.894 for the external datasets. In classifying the presence or absence of other retinal abnormalities, the AUROCs were 0.948 (0.930–0.963) 0.949 (0.901–0.996), and 0.938 (0.915–0.960) among images obtained from the Cirrus, Spectralis, and Triton OCTs, respectively, in primary datasets. The performance in external datasets remained excellent, with the ranges for AUROCs being 0.901–0.969.

Conclusions: We demonstrated excellent performance with a DL system for the automated classification of DME, highlighting its potential as a promising second-line screening tool for patients with DM, which will create a more effective triaging mechanism to tertiary eye clinics.

ABSTRACT BODY:

Purpose: To analyze postoperative refraction and postoperative anterior chamber depth (pACD) in a cohort of patients implanted with the fixOflex intraocular ring in conjunction with a monofocal intraocular lens (IOL). Moreover, to analyze the intraoperative time for the ring implantation and to report on the intraoperative complications.

Methods: The fix-O-flex (EYE-PCR B.V, The Netherlands) intracapsular ring is implanted prior to the intraocular lens to facilitate its centration while maintaining the anatomical shape of the peripheral capsule. It has an external diameter of 9.8 mm, axial thickness of 1.7mm and retainers to fasten the optical part of the IOL. In a prospective clinical trial to assess the safety and efficacy of the fix-O-flex ring, seventy two (72) patients were randomly enrolled. Patients were selected randomly from the patients that presented with cataract at the Elnour Eye Center (Alexandria, Egypt). An informed consent was obtained from all patients. The patients received the ring through a 2.4 mm incision and the IOL (Tecnis ZCB00, J&J, NJ) was implanted after the ring had expanded in the capsule and its optical part was secured in the ring's retainers. Both the IOL calculation (Haigis formula) and postoperative lens position (pACD) were obtained from the Lenstar 900 optical biometer (Haag Streit AG, Germany). Patients were followed at the 1 day, 1 week, 1, 3, 6 and 12 months postoperatively. We report on the interim results following the 1-month postoperative follow up.

Results: Mean Best Spectacle corrected Visual Acuity at the 1-month postoperative interval was 0.82 (SD 0.18). Mean spherical equivalent refraction was -0.94D (SD 0.88). Mean pACD was 4.65 mm (SD 0.73). The difference between pACD at 1 month and day 1 was not statistically significant ($p=0.021$) indicating a stable postoperative lens position. Mean time duration for ring implantation was 1.29 minutes (SD 0.31) (1min 17 sec). In 5 patients (6.9%) the ring required additional manipulations for centration after injection. In one case the IOL was implanted behind the ring. No serious adverse events were reported.

Conclusions: The Fix-o-flex ring provides an open capsule space for IOL implantation. Biometry and refraction were stable postoperatively. Implantation was fast and safe. Intraoperative complications involved the position of the ring and the IOL after implantation and were controlled by surgical manipulations.

ABSTRACT BODY:

Purpose: A common hallmark of Multiple Sclerosis (MS) is the thinning of retinal layers that contain retinal microglia. Microglia are the immune cells of the central nervous system which carry out their dynamic age- and disease-related neuromodulatory functions by dynamically shifting between five distinctive morphotypes (ramified, hyper-ramified, activated, rod and amoeboid). Here, we sought to develop automated algorithms to identify differences in the total and distinct microglia morphotype densities between experimental MS induced by cuprizone (CPZ) treatment, and untreated controls.

Methods: The MS-modelled male C57 mice were given CPZ (0.2%w/w) mixed with chow for 4 months (m) until their sacrifice at 6m or 28m. Age-matched controls (Ctrl) were fed standard chow. Post-sacrifice, mouse eyes were enucleated, the retinas dissected, immunostained, whole-mounted and then imaged. Automated cell counting and morphotyping methods including supervised machine learning algorithms (SVM-C) were developed to quantify densitometric differences. Non-parametric statistical analyses were performed on the collected data (n: 6mCPZ=7; 6mCtrl=15; 28mCPZ=10; 28mCtrl=7).

Results: The SVM-C produced performance accuracies of 87.9-100% for each morphotype with AUC >0.99. Experimental groups did not significantly affect the total retinal microglia densities. However, there were more ramified ($p<0.05$) and amoeboid (ns) cells in old diseased (28mCPZ) retinas compared to young diseased (6mCPZ) and old healthy (28mCtrl) retinas. Also, there were significantly more rod microglia ($p<0.01$) in young animals (6mCtrl and 6mCPZ) compared to old animals (28mCtrl and 28mCPZ). There were no significant differences between the densities of young animal groups whilst there were between the old, with significantly less activated, hyper-ramified and rod cells ($p<0.05$) in 28mCPZ.

Conclusions: The SVM-C worked with a high accuracy and discriminative power. No differences in the total densities suggest that age- and CPZ-induced morphotype density differences might occur as a result of morphological changes rather than proliferation. The current study did not investigate the functional associations, although ramified and amoeboid morphotype trends may suggest increases in debris detection and phagocytosis with the increase of age and CPZ-induced experimental MS.

ABSTRACT BODY:

Purpose: To study the relationship between the retinal shape measured using OCT and the off-axis refractive error in adults.

Methods: A prospective clinical study was performed including the 32 eyes of 16 adult subjects at the age of 23-62 years old (age 39.00 ± 13.22 ; mean \pm SD, SE = -3.15 ± 2.38 D) have been examined using an OCT with auto-alignment (3D-OCT-1 Maestro, Topcon, Tokyo) and retinal shape modeling (prototype software, Topcon, Tokyo) functions. The RPE position in horizontal 12mm scans centered on the fovea was used to represent retinal shape after alignment correction considering corneal curvature, axial length, and eye movement. The off-axis refraction data were obtained from an open-view auto refractometer (Grand Seiko, Japan) by measurements from 5 angles in the horizontal plane (-30° , -15° , 0° , 15° , 30°). Both retinal shape profiles and the refraction levels were then fitted into curves, and the first order (slope) and the second order (curvature) coefficients were used for the analysis.

Results: We found strong correlations between the slopes of left and right eye in the OCT retinal shape data between left and right eye in slopes (CC = -0.903 p-value < 0.001), in curvatures (CC = 0.893 , p-value < 0.001). In the off-axis refraction data fitting the slopes (CC = -0.511 , p-value = 0.061) relation was not significant, while curvatures (CC = 0.736 , p-value = 0.003) correlated strong between left and right eyes, conforming the expected properties. In relations between the retinal shape model and the levels of refraction fitting we discovered significant correlations of the curvatures in the right eyes (CC = 0.657 , p-value = 0.045) and the left (CC = 0.774 , p-value = 0.001).

Conclusions: Both OCT retinal shape model fitting and off-axis refraction error fitting confirm the expected properties, such as contralateral reflective symmetry in slopes and symmetry in the curvatures, therefore confirming the accuracy of the measurements. Significant correlations between two models in the curvatures allow us to assume that the OCT retinal shape can be used for the assessment of the off-axis refraction.

ABSTRACT BODY:

Purpose: In keratoconus (KC), structural and compositional changes lead to disruptions of the lamellar organization with thinning and scarring of the cornea. Both genetic and environmental factors have been associated with KC and recent studies suggest that inflammation (e.g. high TNF α levels) could trigger the onset of KC. Therefore, we analyzed human corneas as well as corneas of hTNFtg mice and syndecan-1 and -4 deficient mice.

Methods: Human and mouse corneas were analyzed by TEM and stromal collagen degradation was visualized by the collagen hybridizing peptide B-CHP. Moreover, 3D-cell cultures of human keratocytes were analyzed by TEM and for activity of the cross-linking enzyme tissue transglutaminase (TG). Furthermore, collagenous structures of healthy and KC corneas were analyzed by P-SHG microscopy and OCT analysis was used for 3D imaging of hTNFtg and wt corneas.

Results: Sheets of orthogonally arranged collagen fibrils were found in the stroma of wt mice and human controls. In contrast, lamellae were disrupted and fibril diameter increased in hTNFtg and in both syndecan-deficient mice. Interestingly, stromal morphology of hTNFtg mice was similar to that of KC patients. We found an invasion of macrophages and apoptotic keratocytes. 3D-cell cultures of KC keratocytes generated a structurally altered ECM with reduced TG-activity. Moreover, binding of B-CHP was significantly stronger in KC and hTNFtg mice. In addition, OCT analysis revealed a slightly altered shape of the cornea of hTNFtg mice. Alterations in the Bowman's membrane together with disrupted cell-cell-contacts were found in all mouse models. P-SHG analysis revealed changes in lamellae orientation in KC. The entropy was higher and the orientation index was lower demonstrating a disorganization of stromal lamellae compared to controls.

Conclusions: Disruptions of the lamellar organization of collagen fibrils in hTNFtg and syndecan-1 and -4 deficient mice are similar to KC patients. Thus, inflammation and altered cross-links could be crucial factors for the onset of KC. The strong binding of B-CHP supports our hypothesis of enhanced collagen degradation in the stroma. Thus, hTNFtg mice as model for KC will help to better understand the pathomechanism of KC and P-SHG analysis provides new parameters for characterization of lamellar changes in KC.

TITLE: Therapeutic Effects of Low-Dose Atropine on Myopia Progression in a Real-Life Clinical Setting in Germany

SESSION TITLE: Myopia epidemiology and refractive error

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Schwahn, B. Graff, H. Kaymak, I.I.O. Breyer Kaymak Klabe, Düsseldorf, GERMANY|F. Schaeffel, Institute for Ophthalmic Research, Eberhard-Karls-Universität Tübingen Medizinische Fakultät, Tübingen, GERMANY|H. Kaymak, Experimental Ophthalmology, Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg/Saar, Saarland, GERMANY|

Commercial Relationships Disclosure (Abstract): Hartmut Schwahn: Commercial Relationship: Code N (No Commercial Relationship) | Birte Graff: Commercial Relationship: Code N (No Commercial Relationship) | Frank Schaeffel: Commercial Relationship: Code N (No Commercial Relationship) | Hakan Kaymak: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Several randomized clinical studies (RCTs) have demonstrated the beneficial effects of low dose (0.01%) atropine eye drops on myopia progression in children. However, treatment effects may be different in a routine clinical setting.

Methods: We performed a retrospective analysis of our clinical data from 80 atropine treated and 103 untreated children of white population in Germany with a wide range of myopic refractive errors and ages. Objective refraction and ocular biometry (anterior chamber depth, lens thickness, axial length) were determined at the initial and at later visits. As requested by the parents, children in the treatment group were asked to instill one drop of 0.01% atropine solution in each eye every evening at five days a week. Myopic children who did not undergo atropine treatment served as controls. All children were re-examined about one year later.

Results: Myopic refractions (spherical equivalents) at baseline ranged from -0.625 to -15.25 D (-4.21 ± 2.90 D) in atropine treated children and from -0.125 to -9.375 D (-2.92 ± 1.77 D) in untreated children. Ages at the initial visits ranged from 3.2 to 15.5 years (10.1 ± 2.7 years) in the treated group and from 3.4 to 15.5 years (11.2 ± 3.0 years) in the untreated group. Myopia progression continued in both atropine treated and untreated children. Variability of progression rates was high. A two-factor ANOVA for age and atropine effects on axial length growth confirmed that eye growth rates generally declined with age ($p < 0.0001$). Atropine had a significant inhibitory effect on axial eye growth ($p < 0.0015$) which was independent of age. On average we observed 0.08 mm inhibition per year, equivalent to 28% less compared to average growth rate in untreated children. Interestingly, effects of atropine on refractive states were not significant.

Conclusions: In this real-life clinical setting, the effects of 0.01% atropine were not very distinctive. Myopic progression in individuals did not show obvious differences between atropine treated and untreated children. A statistical analysis over the whole sample confirmed that atropine reduced axial length growth, but to an extent which is of minor clinical relevance. Under the given conditions, the beneficial effects of 0.01% atropine eye drops on myopia may not be obvious in each single child which should be communicated to parents and residents.

TITLE: Autosomal recessive rod-cone dystrophy associated with compound heterozygous variants in ARL3 gene

SESSION TITLE: Genetics, (gen)omics, systems and computational biology in ocular health and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Fu, Ophthalmology, Henan University People's Hospital, Zhengzhou, Henan, CHINA|

B. Lei, Ophthalmology, Henan Provincial People's Hospital, ZHENGZHOU, Henan, CHINA|

Commercial Relationships Disclosure (Abstract): Bo Lei: Commercial Relationship: Code N (No Commercial Relationship) | Leming Fu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: ARL3 (ADP-ribosylation factor-like 3) variants cause autosomal dominant retinitis pigmentosa or autosomal recessive Joubert syndrome. A recent report showed a homozygous variant in ARL3 caused cone-rod dystrophy. We found a family with rod-cone dystrophy and confirmed it was associated with compound heterozygous variants in ARL3 gene.

Methods: Ophthalmic examinations including optical coherence tomography and electroretinogram (ERG) were performed in the 18-year-old male proband and the family members. DNA was extracted from peripheral blood. Targeted next generation sequencing (NGS) was performed for the proband using a custom designed panel containing genes associated with inherited retinal diseases. Sanger sequencing and co-segregation were conducted in the family members. The pathogenic prediction was performed with ACMG guideline. Changes of protein structure mediated by the variants were studied in vitro. ARL3 protein stability and its interaction with RP2 protein were assessed by cycloheximide chase assay and co-immunoprecipitation (Co-IP) assay.

Results: Visual acuity of the proband was 0.25 in the right and 0.20 in the left eye, while his mother and sister was normal. Fundus photography showed peripheral bone spicule pigmentation and ERG revealed severe reduction in scotopic responses and to less extent in photopic responses bilaterally. The proband also had tunnel visual field and dyserythrochloropsia. But he did not have hearing abnormality, mental dysplasia or gait instability. Targeted NGS identified two novel compound heterozygous variants (c.91A>G, p.T31A; c.353G>T, p.C118F) in ARL3. Bioinformatics analysis indicated that the amino acid positions of the two variants are highly conserved among species. LRT, Mutation Taster, SIFT, FATHMM and CADD predicted the variants to be harmful. Protein structure analysis showed the two variants had potential to alter the protein structure. According to the ACMG guidelines, the two variants were likely pathogenic, supported by evidences: PS2, PM1, PM2, PP1 and PP3. In addition, the ARL3 mutations destabilized ARL3 protein, and disrupted the interaction between ARL3 and RP2 in HEK293T cells.

Conclusions: We showed two novel compound heterozygous variants in ARL3 were associated with autosomal recessive rod-cone dystrophy. The two variants in ARL3 could be causative by destabilizing ARL3 protein and impairing its interaction with RP2 protein.

ABSTRACT BODY:

Purpose: 1- To evaluate the comparability of visual field measurements between Heru visual field application (Heru, Miami, FL) as a multiplatform visual field-testing application downloaded on two different commercially available augmented reality devices and the standard automated perimetry in both normal patients and those with visual field defects. 2- Evaluate the reproducibility of Heru VF measurements in normal and pathologic patients.

Methods: This prospective comparative clinical study included 81 eyes, 40 normal eyes and 41 eyes of patients with glaucoma and neuro-ophthalmic diseases (hemianopic, altitudinal and ring scotomas). VF results were obtained using Heru VF software downloaded on Magic Leap 1 (Magic Leap, Plantation, FL; 41 eyes) headset, on Hololens 2 (Microsoft Inc, Redmond, WA; 40 eyes) and Humphrey Field Analyzer (HFA) 800 series perimeter (Carl Zeiss Meditec, Inc, Dublin, CA, USA; 81 eyes). All patients underwent 24-2 test pattern with all 3 testing devices. Correlations of threshold values and mean deviations (MD) obtained using Heru VF and HFA were calculated to determine agreements between them. To evaluate the reproducibility of Heru VF, 39 eyes (27 normal and 12 pathological eyes) were tested twice on the same day with 5-minutes in between, and the intraclass correlation coefficient was calculated.

Results: Mean deviation (MD) and Threshold values obtained using Heru VF software application downloaded on the two different platforms showed strong correlations with those of Humphrey Field Analyzer (HFA) ($R=0.91$ and $R=0.8$, $P < 0.001$, respectively). The Heru VF software was reproducible with ICC of 0.974 (95%CI 0.94-0.987) for MD and 0.8 (95%CI 0.813-0.845) for threshold values in normal eyes and in patients with glaucoma and neuro-ophthalmic diseases.

Conclusions: Central visual field measurements obtained using Heru VF as a multi-platform application downloaded on two different commercially available augmented reality devices were comparable to HFA in normal, glaucoma, and neuro-ophthalmology patients. Heru VF measurements are reproducible in normal and pathologic patients.

ABSTRACT BODY:

Purpose: Treatment options for inherited retinal diseases (IRD), the leading cause of vision loss in persons aged 15 - 45 years have been limited, however, novel gene and molecular therapeutics are now demonstrating significant potential in the treatment of IRDs. RNA therapeutics hold unique promise in these diseases; although achieving safe and efficient delivery of molecular drugs to the retina and the retinal pigmented epithelium in particular, remains a significant obstacle to clinical application. Antisense oligomers (AO) are a well-established class of RNA therapeutic whose potential is yet to be fully realised due to this delivery challenge. We report an AO conjugate that traffics through the vitreous after intravitreal administration, reaching the deepest layers of the retina and localising to the nuclei to modulate gene expression. This class of therapeutic holds substantial promise in the treatment of IRDs.

Methods: We exploit peptide libraries derived from 82 microorganism genomes and 118 synthetic viral genes to identify cell penetrating peptides (CPP) to deliver AO cargos to cells in vitro and to tissues and organs in vivo. The CPPs were screened initially against mammalian cells using a cytosolic extraction method, followed by next generation sequencing and selection using a combination of algorithms known to produce a favourable toxicology and efficacy profile in the eye.

Results: The CPPs were conjugated to an antisense morpholino oligomer designed to mediate exon selection in a reporter mRNA. Standout performance in the latter assay, when administered via intravitreal injection, and a clean toxicology profile identified a lead peptide for our retinal disease program. CPP conjugation to our candidate AO therapeutic and evaluation in IRD patient-derived retinal pigmented epithelium rescued target gene expression and improved cell function.

Conclusions: Notable CPPs in pre-clinical and clinical development include chemical stabilisation or poly-arginine that can limit efficacy or increase toxicity. Our discovery peptides are derived from nature, lack chemical modifications, and yield optimal amino acid sequences with enhanced efficacy and toxicity performance. The lead CPP, HPG_0031, traffics the AO through the vitreous, into the retinal pigment epithelium with no evidence of retinal damage, resulting in enhanced exon skipping and 6-fold lower cytotoxicity than the competitor CPP.

ABSTRACT BODY:

Purpose: Nasal misalignment of cones toward the optic nerve head (ONH) in myopic eyes is believed to be associated with the greater length of the eyeball. However, both physiological explanations at the retinal level and functional evaluation of the practical, visual impact of this photoreceptor misalignment in the daily lives of myopic individuals are limited.

Methods: We developed two microperimetry multi-angle methods to measure the peak location and directionality known as the Stiles Crawford Effect type I (SCE-I). A clinical grade MAIA microperimeter presented Maxwellian-view background and test (Goldman size III) stimuli at various eccentricities, while compensating for eye movements. SCE-I functions were obtained from directional sensitivity measurements, either by controlled translation of the instrument or rotation of the eye, without and with background illumination, respectively. Displacement of the peak of the SCE-I function was compared to objective measurement of foveal axis alignment in relation to pupil entry point with Directional OCT.

Results: Myopic subjects (N = 4) unlike emmetropes (N=3) appeared to show irregular nasal contrast sensitivity, and nasal misalignment of the SCE-I peak toward the ONH. SCE-I functions were corroborated by directional OCT based foveal axis measurements.

Conclusions: The methods described here provide a rather fast and accessible way to measure photoreceptor alignment at various retinal locations, which could be important to characterize - and potentially better treat - functional visual losses experienced by individuals with myopia. Our next step will be to determine alignment of individual photoreceptors using high resolution imaging modalities.

TITLE: Comparing test-retest variability of Compass perimetry with the Humphrey Field Analyzer at the edges of glaucomatous scotomas.

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.E. Majoor, K.A. Vermeer, H.G. Lemij, Het Rotterdams Oogheelkundig Instituut, Oogziekenhuis Rotterdam, Rotterdam, South Holland, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Juleke Majoor: Commercial Relationship: Code N (No Commercial Relationship) | Koenraad Vermeer: Commercial Relationship: Code N (No Commercial Relationship) | Hans Lemij: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The commonly used Humphrey Field Analyser (HFA) shows high measurement variability in glaucoma patients, notably at the borders of scotomas, making it difficult to determine if a scotoma is stable or shows progression. It has previously been suggested that this variability may in part be due to gaze instability. By using an eye tracker that compensates for gaze instability, the Compass fundus perimeter (CMP) might lower the variability at scotoma borders. We therefore aimed to determine the test-retest variability of the CMP at the edges of glaucomatous scotomas and compare it with that of the HFA.

Methods: One eye from each included glaucoma patient was tested with the CMP (24-2 ZEST) and the HFA (24-2 SITA standard) at each of three study days (screening, baseline and follow-up visit) and stratified by mean deviation (MD) into a mild ($-6 \text{ dB} \leq \text{MD}$), moderate ($-12 \text{ dB} \leq \text{MD} < -6 \text{ dB}$) or advanced glaucoma stage ($\text{MD} < -12 \text{ dB}$). Two CMP VF tests were performed at the screening visit for learning purposes. To identify the scotoma borders for each eye, the total deviation plot of the HFA test from the screening visit was used (Figure 1). To assess test-retest variability, the mean absolute difference of the scotoma border points (SBP, i.e., the test points on either side of the scotoma edges) between the baseline and follow-up VF test (3-10 days between tests) was calculated.

Results: 29 eyes (31% women, median (IQR) age 64 (56-72) years) were included for analysis. Median (IQR) time between baseline and follow-up visit was 7 (5-7) days. There were no statistically significant differences in mean absolute SBP difference between the CMP and HFA for all stages combined (1.8 vs 1.9 dB, $P = 0.42$, Wilcoxon signed ranks test) nor for each glaucoma stage separately (mild: 1.6 vs 1.7 dB, $P = 0.70$, moderate: 1.8 vs 1.9 dB, $P = 0.55$, advanced: 1.9 vs 2.2 dB, $P = 0.051$, Wilcoxon signed ranks test). Figure 2 shows a scatter and density plot of the absolute SBP differences between CMP and HFA.

Conclusions: CMP and HFA are equally variable at the edges of scotomas with 24-2 VF testing, suggesting that fixation stability with the CMP eye tracker has no advantage over the HFA for detecting progressing scotomas in glaucoma patients by 24-2 VF testing. Studies are warranted to further evaluate the added value of fixation stability on lowering VF test-retest variability in glaucoma patients.

TITLE: CREB Positively Regulates Multiple Acetylation Transferases to Control p53-Bak/Bax Signal Axis and Mediate Stress-Induced Apoptosis

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.W. Li, L. Wang, Y. Gan, Y. Liu, Zhongshan Ophthalmic Center, Sun Yat-sen University, Guangzhou City, Guangdong Province, CHINA|

Commercial Relationships Disclosure (Abstract): David Li: Commercial Relationship: Code N (No Commercial Relationship) | Ling Wang: Commercial Relationship: Code N (No Commercial Relationship) | Yuwen Gan: Commercial Relationship: Code N (No Commercial Relationship) | Yizhi Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The general transcription factor, CREB has been shown to play an essential role in promoting cell proliferation, neuronal survival and synaptic plasticity in the nervous system. However, its function in stress response remains to be elusive. Here, we present first evidence to show that CREB can positively regulates multiple acetylation transferase to activate p53-Bak/Bax signal axis and mediate stress-induced apoptosis of lens epithelial cells.

Methods: RNA-seq, qRT-PCR, automated western immunoblotting, classic western blot analysis and immunocytochemistry were used to analyze expression patterns of the genes including CREB, p53, Bax, Bak, p300, Gcn5 and Pcaf, Co-IP and immunocytochemistry were used to determine protein-protein interaction. CRISPR/Cas9 technology was used to knockout gene function, Over-expressing vector was used to analyze the effect of gene dose. Gel mobility shifting (EMSA) and ChIP assay were used to determine the CREB control of the acetylation transferases p300, Gcn5 and Pcaf. CellTiter-Glo® luminescent cell viability assay and live/dead viability/cytotoxicity were used to examine apoptosis.

Results: EMSA and ChIP assays reveal that CREB directly controls expression of p300, Gcn5 and Pcaf genes in lens epithelial cells, which enhanced the transcriptional activities of p53. The enhanced p53 activity upregulates two downstream genes: Bax and Bak to mediate CREB-controlled stress response and promotes apoptosis of lens epithelial cells. Dephosphorylation of CREB significantly downregulates its ability to control the above acetylation transferase genes, and as a result attenuates CREB-mediated stress response.

Conclusions: CREB, an important transcription factor mediates stress response in the ocular lens through two major pathways: negative regulation of α B-crystallin but positive regulation of p300/Gcn5/Pcaf-p53 signal axis. This function is important in ensuring normal lens development (Supported by grants from National Natural Science Foundation of China, 81770910, 81970787, 81700821, 81970784, 81900842), the grant from Guangdong province (2019B1515120014) and the Fundamental Funds from the State Key Laboratory of Ophthalmology, Zhongshan Ophthalmic Center, Sun Yat-sen University (3030901010110).

ABSTRACT BODY:

Purpose: Retinal prostheses electrically activate surviving retinal ganglion cells (RGCs) to create artificial vision. Given the incredible neural information transmission from the retina during natural viewing, it is critical to consider how much information RGCs would carry for the prosthetic vision. Recently, we reported ON RGCs transmit richer neural information than OFF RGCs by more heterogeneous spiking responses arising from the same electric stimulus. Here, we quantified neural information changes depending on the levels of heterogeneity across simulated spike trains.

Methods: We used neural computational methods to generate correlated spike trains and calculate the amount of information of those simulated spiking activities. First, we created five groups of 1-sec-long spike trains using a modified version of 'Brian 2', an open-source simulator for spiking neural networks. All groups had the same range of mean firing rate (80 ± 20 Hz) and peak firing rate (200 ± 50 Hz) but different levels of correlations across spike trains in each group. Second, 50 spike trains were randomly chosen until their spike time tiling coefficient (STTC) average reached specific values (i.e., 0.1, 0.3, 0.5, 0.7, and 0.9). Then, the neural information was computed for 200 of random combinations of 15 spike trains.

Results: The average STTCs of the five groups were 0.09 ± 0.07 , 0.31 ± 0.08 , 0.50 ± 0.07 , 0.69 ± 0.06 , and 0.90 ± 0.04 (mean \pm std). The amounts of neural information transmitted by 15 cells of each group were 7.59 ± 0.06 , 7.06 ± 0.09 , 6.14 ± 0.11 , 4.84 ± 0.12 , and 2.33 ± 0.15 bits, respectively. Consistent with our work, more homogeneous spike trains resulted in more reduced information. However, it is notable similar increments in STTCs produced different information reductions. For example, the neural information was slightly decreased by 0.53 bits ($p < 0.001$) for the STTC change from 0.09 to 0.31. In contrast, the information was substantially decreased by 2.51 bits ($p < 0.001$) for the STTC change from 0.69 to 0.90.

Conclusions: Our results showed the level of cell-to-cell spiking heterogeneities significantly impacts on the information transmission: increase in the correlation level leads to decrease in the quantity of neural information. This suggests optimization of spiking correlation in RGC populations may enhance the performance of the prosthetic vision.

TITLE: Bioenergetics Assessment and ECM gene expression in Glaucoma Lamina Cribrosa cells: Role of Metformin

SESSION TITLE: Pharmacological intervention and cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Hurley, M. Imnaten, C.J. O'Brien, Ophthalmology, Mater Misericordiae University Hospital, Dublin, IRELAND|S. Millington-Ward, G. Farrar, Genetics, The University of Dublin Trinity College, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Daire Hurley: Commercial Relationship: Code N (No Commercial Relationship) | Sophia Millington-Ward: Commercial Relationship: Code N (No Commercial Relationship) | Mustapha Imnaten: Commercial Relationship: Code N (No Commercial Relationship) | G. Jane Farrar: Commercial Relationship: Code N (No Commercial Relationship) | Colm O'Brien: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Lamina Cribrosa (LC) is a key site of retinal ganglion cell axonal injury in Open Angle Glaucoma (OAG). Our lab has previously shown human glaucoma LC cells have pro-fibrotic altered gene expression and mitochondrial dysfunction. Metformin has been shown to have anti-fibrotic effects in numerous organ systems. In this study, we aim to assess Metformin's effect on mitochondrial function in glaucomatous LC cells by carrying out a systematic mitochondrial bioenergetic assessment.

Methods: Human LC cells from age matched normal and confirmed glaucoma donors were assessed using a Seahorse XFe96 Analyzer. Glaucoma LC cells were treated with Metformin at different doses: 10mM, 5mM, 2mM, 1mM, 0.5mM, 0.1mM and 0.05mM. Adenosine Triphosphate (ATP) production, Basal Oxygen Consumption Rate (OCR), Maximal OCR and Spare Respiratory Capacity were measured and normalized to total protein content using the Bradford method. In addition, the effect of Metformin on extracellular matrix (ECM) gene expression (Col1A1, α -SMA, and vitronectin) was assessed by real time RT-PCR.

Results: Glaucoma LC cells have lower basal and maximal OCR, lower spare respiratory capacity and lower ATP production than the normal cells. Treatment with Metformin, however, significantly improves Maximal OCR (0.473 ± 0.026 pmol/min vs 0.398 ± 0.083 pmol/min) ($p < 0.05$) and spare respiratory capacity (0.193 ± 0.035 pmol/min vs 0.168 ± 0.046 pmol/min) ($p < 0.05$) in glaucoma cells. Additionally, there is a trend towards improvement of basal OCR and ATP production in treated glaucoma LC cells versus untreated glaucoma LC cells ($p=0.1076$ and $p=0.0655$ respectively). The most effective Metformin dose was 0.1 mM. In addition, Metformin treatment (0.1mM) resulted in a significant ($p < 0.05$) reduction of the ECM gene expression seen in glaucoma LC cells.

Conclusions: We demonstrate evidence of mitochondrial dysfunction and enhanced ECM gene expression in glaucoma LC cells and subsequent improvement with Metformin treatment. These results may provide some explanation as to the reduced OAG glaucoma incidence in those taking Metformin. A better understanding of Metformin's effect on mitochondrial dysfunction and fibrosis may aid the development of a disease modifying agent in OAG.

SUBMITTER (NAME ONLY): Marika Zuanon

TITLE: Developing P2X7 antagonists for the treatment of inflammatory eye disease

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Zuanon, M.T. Young, School of Bioscience, Cardiff University, Cardiff, Wales, UNITED KINGDOM|A. Brancale, School of Pharmacy, Cardiff University, Cardiff, Wales, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Marika Zuanon: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Brancale: Commercial Relationship: Code N (No Commercial Relationship) | Mark Young: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related Macular Degeneration (AMD), glaucoma and Diabetic Retinopathy (DR) are the most common cause of blindness worldwide, with few effective treatments available. All are characterized by a state of chronic inflammation, thought to be at least in part mediated by the P2X7 receptor, an ion channel widely expressed in the eye, which is activated by high concentrations of extracellular ATP present during inflammation. P2X7 activation promotes the release of pro-inflammatory cytokines and cell death, contributing to disease progression and leading to loss of cells critical for vision. Blocking P2X7 activation may present a valid therapeutic strategy to treat chronic inflammation in eye disease.

This study has two main aims; (1) to confirm the involvement of P2X7 activation and signalling in the progression of AMD using retinal pigment epithelial (RPE) cells, and (2) to use structure-based virtual screening methods to develop novel-small molecule P2X7 antagonists.

Methods: For Aim 1, P2X7 expression and function have been evaluated in a human RPE cell line (ARPE-19) using Western blotting and ATP-stimulated fluorescent dye uptake (YO-PRO1). For Aim 2, structure-based screening was performed on human P2X7 molecular models to identify potential hit molecules (from commercially available libraries) likely to bind to orthosteric and allosteric pockets. Potential hits were purchased and tested on 1321N1 astrocytoma cells stably transfected with human P2X7 using ATP-stimulated YO-PRO 1 uptake and the Membrane Potential Red assay (MPR), to assess their ability to inhibit P2X7 activation.

Results: ATP-stimulated YO-PRO1 uptake was observed in non-polarised ARPE-19 cells (EC_{50} in the low millimolar range), consistent with P2X7 expression, but Western blot analysis failed to detect protein, suggesting low expression levels. A total of 30 potential hit molecules were selected and their activity was assessed by YO-PRO 1 and MPR assays. A number of compounds showed a reduction in the response to ATP compared to control when pre-applied at either 10 μ M or 30 μ M.

Conclusions: This work demonstrates that ATP-stimulated activity consistent with that of P2X7 is observed in ARPE-19 cells, despite no protein being detected by Western blot. In addition, this study demonstrates the identification of P2X7 antagonist hit compounds, which have the potential to be developed into novel anti-inflammatory therapeutics.

ABSTRACT BODY:

Purpose: To study atrophy growth rate, its dependence on area, time and retinal regions, using an automated segmentation method in retinal SD-OCT scans.

Methods: 589 SD-OCT volumes of 97 patients (99 eyes) with nonexudative atrophic AMD and at least 1 year follow-up were selected and segmented using an automated atrophy detection algorithm. Total en face atrophic area was calculated for each scan using the segmentation output.

The square root atrophy areas were used to compute the growth rate [mm/year] by fitting a linear model to each patient and averaging across all subjects and patient subgroups: those with small ($<5\text{mm}^2$) and large ($>5\text{mm}^2$) baseline areas as well as those with foveal and extrafoveal atrophy at the baseline. A time-normalized growth map was constructed for each patient and averaged across the whole dataset to obtain progression growth rate with respect to retinal location.

Results: The mean follow-up time was 43 months and the mean area at the baseline was $4.6 \pm 4.2 \text{ mm}^2$. The average growth rate was $0.31 \pm 0.21 \text{ mm/year}$. Despite square root transformation, the growth rate was significantly higher for patients with smaller baseline atrophies and amounted to $0.35 \pm 0.22 \text{ mm/year}$, than for larger ones ($0.26 \pm 0.17 \text{ mm/year}$, $p=0.042$). Baseline atrophy area and the square root area growth rate were correlated ($R^2=0.083$, $p=0.005$). The growth rate decreased both as a function of progressing atrophy area and time since the baseline (Figure 1). Out of 99 eyes, 37 (37%) had foveal involvement at the baseline. The growth was slower for them ($0.22 \pm 0.16 \text{ mm/year}$) than for the eyes with extrafoveal atrophy ($0.38 \pm 0.22 \text{ mm/year}$, $p=0.0002$).

The topological analysis of the growth rate revealed that the atrophy progresses faster in a ring around the fovea, towards the nasal and inferior area relative to the fovea (Figure 2).

Conclusions: The automated atrophy segmentation method enabled analysis of atrophy progression of a large patient dataset. It has shown that growth rate varies significantly across retinal regions, depending on the lesion area and time elapsed since the baseline.

ABSTRACT BODY:

Purpose: To evaluate inter-visit, intragrader, inter-grader, and inter-ocular variability in cone spacing measures at baseline in a clinical trial of sustained-release ciliary neurotrophic factor (CNTF) treatment in retinitis pigmentosa using confocal adaptive optics scanning laser ophthalmoscopy (AOSLO) images.

Methods: A single-center, double-masked clinical trial (NCT01530659) of patients with retinitis pigmentosa or Usher syndrome type 2 or 3 randomly assigned 1 eye in each patient to receive a high- or low-dose (20 or 5 ng/day) CNTF-secreting implant and the contralateral eye to receive sham surgery. AOSLO was used to image the macula in each eye at 2 baseline visits separated by no more than 1 month to identify regions of interest (ROIs) of 100 arcmin² with at least 50 contiguous, unambiguous cones. Cones were marked by 2 independent, trained graders at baseline. Cone spacing Z-scores (standard deviations from the mean of 37 normal subjects) were reported to account for the known relationship between cone spacing and eccentricity from the fovea. Cone spacing Z-scores from all ROIs in each eye were averaged and compared to the contralateral eye of each patient. We computed the agreement intraclass correlation coefficient (ICC) between mean Z-scores of sham- and CNTF-treated eyes.

Results: 22 participants were enrolled ranging in age from 19-66 (mean 39.8±11.9) years, and 13 were male. Intragrader repeatability of measurements for the same visit showed ICC=0.88 and 0.86 for the 2 graders. Intragrader agreement ICC of cone spacing measurements between 2 baseline visits was excellent (0.82, 95% CI=0.80 to 0.83), as was agreement ICC of cone spacing scores between the graders at the baseline visit (ICC=0.78, 95% CI=0.76 to 0.80). The agreement ICC between the mean Z-scores for each of the 2 eyes at baseline was excellent (ICC=0.94, 95% CI=0.86 to 0.97).

Conclusions: Cone spacing measures were repeatable within a single grader at the same visit and between visits separated by no greater than 1 month, and were repeatable between graders. Cone spacing measures were also similar between contralateral eyes of patients with retinitis pigmentosa. Interocular agreement of cone spacing measures suggests the contralateral eye may serve as a control for uniocular treatments. AOSLO cone spacing measurements may be a reliable and sensitive means of monitoring disease progression in patients with retinitis pigmentosa.

ABSTRACT BODY:

Purpose: The repeated invasive intravitreal (IVT) injections and the presence of poor responders of the VEGF blocking agent, the currently only available treatment for wAMD, have raised the need for less invasive dosage and drugs of new mechanism. We previously showed the superior/equivalent efficacy of the non-invasive eye drop of the NOX inhibitor compared to aflibercept (IVT) in CNV animal models. In this study, the eye drop SJP1804 containing 0.25% API was optimized for clinical application and the efficacy of the clinical formulation of SJP1804 for wAMD was evaluated using the mouse and rabbit CNV models.

Methods: SJP1804 (0.25% API) was administered (3 or 6 times/day, which corresponds to 1~3 times/day in human based on human equivalent dose and intraocular PK of the experimental animals) via eye drop for 15 days and 56 days, respectively, in mouse and rabbit CNV models. Additionally, combination therapy of SJP1804 (3 or 6 time/day) and aflibercept (2 mg/eye IVT) was also treated in rabbits. The CNV lesions in both animal models were measured by angiography. And the concentration of API in the rabbit retina/choroid after administration of the SJP1804 was determined by LC-MS/MS.

Results: In both mouse and rabbit CNV models, 3 or 6 times daily eye drops of SJP1804 (0.25% API) significantly reduced the CNV lesions. In details, 3 times daily eye drop of SJP1804 showed equivalent efficacy and 6 times daily eye drop of SJP1804 showed superior CNV lesion reduction compared to 2 mg/eye aflibercept in the rabbit CNV models. Moreover, 3 or 6 times daily eye drops of SJP1804 complemented the weak therapeutic effects of 2 mg of aflibercept in this model. And the data from LC-MS/MS suggested that the drug in eye drop reached to the target region through the trans-sclera pathway.

Conclusions: Taken together, the results showed that excellent efficacy of the clinical eye drop formulation of SJP1804 (0.25% API) in CNV. Considering the fact that the intraocular half-life of various drugs in human is about 2.5 times longer than that in rabbit, it is supposed that 1~3 times/day administration of SJP1804 eye drop is sufficient to exert clinical efficacy. Based on the results, we further designed phase 1 clinical trial of SJP1804 (0.25% API) eye drop in health Korean and Caucasian male subjects for investigating PK, safety and local tolerability.

ABSTRACT BODY:

Purpose: To determine the differences in retinal microglial and ganglion cell behaviour in a SOD1G93A mouse model (SOD) of amyotrophic lateral sclerosis (ALS) compared to the wild type (WT).

Methods: In retinal whole-mounts labelled with anti-Iba-1 (microglial marker) from two experimental groups WT (n=6) and SOD ALS (n=6), were quantified the number of retinal ganglion cells (RGCs) Brn3a+ and the signs of microglial activation in different retinal layers: i) Iba-1 + cells number in outer segments (OS), outer plexiform layer (OPL) and inner complex layer (ICL) constituted by inner plexiform layer (IPL), ganglion cell layer (GCL) and retinal nerve fiber layer (RNFL); ii) area occupied by Iba-1+ cells in OPL and IPL; and iii) arbor area of Iba-1+ cells in OPL and IPL. In addition, the expression of anti-IFN- γ and anti-IL-1 β (pro-inflammatory M1 phenotype) and anti-arginase-I and anti-IL-10 (anti-inflammatory M2 phenotype) were analysed. Animals were sacrificed with 120 days old (advanced stage of the disease).

Results: Compared to WT, the retina of SOD1 ALS mice showed: i) Migrations and reorientation processes of some Iba-1 + cells; ii) a significant increase in the area occupied by each microglial cell in the total area of the retina; iii) a significant increase in arbor area in the outer plexiform layer (OPL) inferior sector; iv) presence of cells with retracted processes; v) areas of cell groupings in some sectors; vi) no significant increase in the number of microglial cells, vii) expression of IFN- γ and IL-1 β ; viii) non-expression of IL-10 and arginase-I; ix) A decrease in number of RGCs.

Conclusions: In the SOD1G93A ALS model at 120 days (advanced stage of the disease), retinal microglial activation occurs, taking a pro-inflammatory M1 phenotype, which affected OPL and inner retinal layers and could be related to the RGCs loss. Although ALS is a disease of motor neurons, it can also affect retinal tissue, where an inflammatory process and death of retinal neurons occurs.

ABSTRACT BODY:

Purpose: The loss of rods in retinitis pigmentosa (RP) results in the loss of expression of rod-derived cone viability factor (RdCVF) encoded by the nucleoredoxin-like 1 (NXNL1) gene which triggers to the loss of cone function. The second product of the NXNL1 gene, the thioredoxin-like protein RdCVFL, expressed by rods and cones repairs oxidative damages. Since the redox power of RdCVFL on cones relies on the metabolism of glucose, we hypothesize that the death of cones results ultimately from a deficit of RdCVFL activity. So, we constructed the RdCVFL^{-/-} mouse that carries specific inactivation of RdCVFL.

Methods: A stop codon was knocked-in to the RdCVFL-specific part of the coding sequence of NXNL1. We quantified the level of malondialdehyde acid (MDA), a marker of lipid peroxidation, in the retinas of RdCVFL^{-/-} compared to RdCVFL^{+/+} (n=9) mice. We also exacerbated the visual phenotype by light damage (LD) during 3 hours with 10,000 lux after light calibration with pigmented animal control. Ten days after the exposure, the thickness of outer nuclear layer (ONL) was measured by optical coherence tomography (OCT), followed by electroretinogram (ERG) recording. After sacrifice of the animals, retinas were collected, followed by cone density measurement using an automated counting platform, e-conome.

Results: The expression of RdCVF mRNA is not affected by the presence of a stop codon in the RdCVFL sequence in RdCVFL^{-/-} mice whereas the retina does not produce the RdCVFL protein as seen by western blotting. The RdCVFL^{-/-} retina displays a 38% increase of MDA and a reduction of 13.5% of cone density compared to RdCVFL^{+/+}. LD reduces the thickness of the ONL by 90% for the RdCVFL^{-/-} retina and only by 10% for the RdCVFL^{+/+} retina. LD reduces both scotopic and photopic ERG by 70%-50% respectively for RdCVFL^{-/-} mouse and only by 20%-0% respectively for the RdCVFL^{+/+} mice. LD reduces cone density by 28% in the RdCVFL^{-/-} retina but not in the RdCVFL^{+/+} retina.

Conclusions: The RdCVFL^{-/-} mouse is highly susceptible to photo-oxidative damage to rods and cones. The reduction of cone density in the RdCVFL^{-/-} retina demonstrates that RdCVFL is essential for cone survival. The RdCVFL^{-/-} model offers an essential model to study the mechanisms of cone cell death in RP.

TITLE: Near infrared autofluorescence (NIR-AF) of the human retinal pigment epithelium (RPE)

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Ach, L. von der Emde, L. Bourauel, Department of Ophthalmology, University Hospital Bonn, Bonn, GERMANY|C.A. Curcio, A. Berlin, Department of Ophthalmology, University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Thomas Ach: Commercial Relationship(s);Roche:Code C (Consultant);Novartis:Code C (Consultant);Novartis:Code F (Financial Support);MacRegen Inc.:Code I (Personal Financial Interest) | Leon von der Emde: Commercial Relationship: Code N (No Commercial Relationship) | Leonie Bourauel: Commercial Relationship: Code N (No Commercial Relationship) | Christine Curcio: Commercial Relationship(s);Heidelberg Engineering:Code F (Financial Support);MacRegen Inc.:Code I (Personal Financial Interest);Genentech:Code F (Financial Support) | Andreas Berlin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Using super-resolution microscopy, NIR autofluorescence (AF) signals of the RPE were attributed to melanin and melanolipofuscin granules in RPE cell bodies (Ach et al., ARVO 2020). In human RPE cell bodies, melanolipofuscin are more frequent than melanosomes (PMID: 32433758) which also impacts clinical NIR-AF image interpretation. Here, we report the NIR-AF signal of RPE cells including apical processes to further evaluate its contribution to clinical NIR-AF imaging.

Methods: Retinal tissue cross-sections (10 µm thick) from five human donors (age range: 64-86 years) with normal maculas determined by ex vivo imaging by optical coherence tomography and confirmed by histology were imaged using a confocal microscope (white light laser source [excitation wavelengths in nm: 488, 635, 750, 780]; hybrid detector for optimized imaging in the NIR range; plan-apochromatic 40X 1.46 oil immersion objective; z-stacks in ~0.5µm steps). In addition, bright field images were taken to capture optically dense melanin pigment. RPE cells within areas of attached neurosensory retina at the fovea and perifovea were scanned. Finally, images were post-processed using FIJI.

Results: Both 750 nm and 780 nm excitation, lead to NIR-AF emission from the RPE cell body, though very weak compared to short wavelength excitation from the same areas. In addition, individual spindle-shaped melanosomes are visible in the apical processes of the RPE cells, exhibiting a bright NIR-AF signal, but clearly lacking AF in the short and mid wavelength range (480 – 635 nm).

Conclusions: There are probably two sources of RPE NIR-AF signals: spindle-shaped melanosomes in the apical processes as well as melanolipofuscin granules and more roundish melanosomes within the RPE cell bodies. The numerical predominance of melanolipofuscin granules within the cell bodies suggests that this signal is the leading source of NIR-AF imaging. These histological findings should be considered in the interpretation of future clinical NIR-AF imaging studies.

TITLE: Retinoblastoma signalling pathway inhibitor CDKN2B is regulated by promoter methylation in the lamina cribrosa region in primary open angle glaucoma

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.B. Eivers, C.J. O'Brien, UCD Clinical Research Centre, Mater Misericordiae University Hospital, Dublin, IRELAND|C.J. O'Brien, Department of Ophthalmology, Mater Misericordiae University Hospital, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Sarah Eivers: Commercial Relationship: Code N (No Commercial Relationship) | Colm O'Brien: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary open angle glaucoma (POAG) is characterized by a loss of retinal ganglion cells and structural changes at the optic nerve head (ONH). Fibrosis in the form of extracellular matrix (ECM) deposition occurs at the lamina cribrosa (LC) region of the ONH and glaucomatous LC cells exhibit an increase in ECM and profibrotic factors, along with dysregulation of cellular growth and responses. Genome wide association studies have identified several single nucleotide polymorphisms within the 9p21 gene locus that are associated with glaucoma risk. The cyclin D Kinase inhibitor (CDKN)2B gene is located within this locus and encodes a key cell cycle regulator involved in inhibiting the Retinoblastoma (Rb) signalling pathway. Alterations in this pathway are typically associated with dysregulation of the cell cycle. In particular, gene silencing of CDKN2B by promoter hypermethylation is observed in several cancers and has been reported in fibrotic diseases. The aim of this study is to investigate if CDKN2B is regulated by promoter methylation in the LC in POAG.

Methods: LC cells were cultured from age-matched control and confirmed glaucomatous donors (GLC). Promoter methylation was analysed using a methylated DNA immunoprecipitation (MeDIP) assay. Gene expression was quantified using quantitative real-time PCR. GLC cells were treated with the methylation inhibitor 5-azacytidine (0.3 μ M) for 24 hours.

Results: The promoter region of CDKN2B was found to be significantly methylated in GLC cells ($P < 0.05$) compared to controls following MeDIP analysis. Expression of CDKN2B was decreased in GLC cells compared to controls, in concurrence with increased promoter methylation observed in GLC cells. Treatment of GLC cells with 5-azacytidine upregulated CDKN2B and decreased expression of the ECM gene collagen (COL)1A1. Additionally, gene expression of Rb pathway components cyclin (CCN)D1, cyclin D kinase (CDK)4, CDK6 and the transcription factor E2F1 were found to be increased in GLC cells compared to controls.

Conclusions: These results show that the promoter of CDKN2B is methylated in the LC in POAG, resulting in downregulation of a key cell cycle regulator within the Rb pathway. Coupled with an increase in expression of the other main players in this pathway, this may explain, at least in part, dysregulated cell cycle control observed in fibrotic GLC cells.

ABSTRACT BODY:

Purpose: The associations between Alzheimer's disease (AD) and glaucoma are inconsistent in the current literature. We aim to assess the association between AD and glaucomatous optic neuropathy (GON) using artificial intelligence (AI) predicted continuous scores from optical coherence tomography (OCT) volumetric scans.

Methods: This study included 2,269 volumetric optic disc OCT scans measured with Cirrus HD-OCT (Carl Zeiss Meditec, Dublin, CA) from 440 eyes of 233 AD subjects and 1,158 OCT scans from 271 eyes of 136 cognitively normal subjects. GON score was calculated from each OCT scan using a validated AI deep-learning algorithm. GON score was a continuous variable ranged from 0 to 1, and a more significant score represented a higher probability of GON. In addition, average and quadratic retinal nerve fiber layer (RNFL) thicknesses were also extracted from the OCT device.

Results: There was no significant difference in AI-based GON scores between AD and cognitively normal subjects (0.28 ± 0.31 vs. 0.30 ± 0.33 , $p = 0.20$). However, AD subjects had significant thinner RNFL average ($85.97 \pm 17.65 \mu\text{m}$ vs. $90.35 \pm 13.71 \mu\text{m}$, $p < 0.001$), temporal ($67.39 \pm 17.02 \mu\text{m}$ vs. $74.31 \pm 21.35 \mu\text{m}$, $p < 0.001$), nasal ($66.06 \pm 15.28 \mu\text{m}$ vs. $67.68 \pm 12.12 \mu\text{m}$, $p = 0.002$), inferior ($106.46 \pm 29.58 \mu\text{m}$ vs. $112.54 \pm 23.91 \mu\text{m}$, $p < 0.001$) and superior ($103.96 \pm 25.79 \mu\text{m}$ vs. $106.86 \pm 21.31 \mu\text{m}$, $p = 0.001$) thicknesses. A simple linear regression test showed that the association between AD and AI-based GON scores was insignificant ($p = 0.199$). GON score is equal to $0.297 - 0.015 \times (\text{diagnosis})$ when diagnosis is 1 (AD) or 0 (normal). Pearson's correlation showed that GON scores had moderate and inverse correlation with RNFL average ($R = -0.524$, $p < 0.001$), superior ($R = -0.495$, $p < 0.001$), and inferior ($R = -0.556$, $p < 0.001$) thickness, as well as weak and inverse correlation with RNFL temporal ($R = -0.210$, $p = 0.001$) and nasal ($R = -0.220$, $p < 0.001$) thickness. AD was only weakly and inversely associated with RNFL average ($R = -0.125$, $p < 0.001$), temporal ($R = -0.174$, $p < 0.001$), and inferior ($R = -0.103$, $p < 0.001$) thicknesses.

Conclusions: Although AD subjects had thinner RNFL thickness than cognitively normal subjects, AD is not associated with AI-based GON score. Further research is still warranted to confirm the null association between AD and GON.

ABSTRACT BODY:

Purpose: To drain from the eye, aqueous humor (AH) passes through micron-sized pores in the inner wall endothelium of Schlemm's canal (SC). SC pores are reduced in glaucoma, which may contribute to increased AH outflow resistance and elevated IOP. To investigate pore formation mechanisms, we previously developed a fluorescent assay to label pores in SC cells (Braakman et al. ARVO, 2014). The cells are stretched, which triggers pore formation, and exposed to fluorescent avidin that crosses the cell body at pore locations to create a fluorescent "hotspot" on the substrate that can be imaged by confocal microscopy. This technique produces high volumes of image data that must be examined by a trained human observer to identify individual pores. Because cultured SC cells form immature intercellular junctions, pores are often difficult to discern from noisy junctional labelling, and pores themselves are relatively sparse. These difficulties make pore labeling time consuming and labor-intensive. To increase efficiency, we developed an automated machine learning algorithm to detect SC pores in fluorescent images.

Methods: The algorithm consisted of a custom pre-processing block for interest point detection, a Histogram of Oriented Gradients feature extractor and a RUSBoost classifier (Seiffert et al. IEEE, 2008). This architecture was trained and tested on separate datasets derived from ~1,500 manually labelled pores and ~65,000 non-pore objects, obtained from 300 previously analyzed images of two SC cell strains, one normal (SC67) & one glaucomatous (SC57g).

Results: Our trained algorithm significantly accelerates SC pore detection relative to identification by a human observer (0.2 s vs. ~8 min per 0.2mm² image containing ~60 cells). Based on a testing set of 100 pores and 20,000 non-pores, our algorithm achieves 80% recall, 16% precision and 4% false positive rate (FPR) on SC pores.

Conclusions: Machine learning algorithms maximize the value of fluorescent pore detection in SC cells. The high recall indicates that the algorithm can successfully identify most pores. The low FPR indicates that the algorithm has high discriminative capacity, but the low precision prevents the algorithm from being used as a stand-alone pore detection tool. However, our algorithm can be used to rapidly identify candidate pores to pass to a human observer, accelerating the process of pore detection in SC cells.

TITLE: The significance of double layer sign in eyes with choroidal neovascularization secondary to central serous chorioretinopathy

SESSION TITLE: Imaging of posterior segment II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.M. Hagag, R. Rasheed, S. Sivaprasad, Moorfields Eye Hospital NHS Foundation Trust, London, UNITED KINGDOM|A.M. Hagag, S. Sivaprasad, Institute of Ophthalmology, University College London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Ahmed Hagag: Commercial Relationship: Code N (No Commercial Relationship) | Rajna Rasheed: Commercial Relationship: Code N (No Commercial Relationship) | Sobha Sivaprasad: Commercial Relationship(s);Heidelberg Engineering:Code C (Consultant);Allergan:Code C (Consultant);Boehringer:Code F (Financial Support);Boehringer:Code C (Consultant);Roche:Code C (Consultant);Novartis:Code C (Consultant);Oxurion:Code C (Consultant);Bayer:Code C (Consultant);Apellis:Code C (Consultant);Optos:Code C (Consultant)

ABSTRACT BODY:

Purpose: To identify the OCT characteristics of eyes with double layer sign (DLS) that are associated with the presence of OCT angiography (OCTA)-confirmed choroidal neovascularization (CNV) in eyes with central serous chorioretinopathy (CSCR)

Methods: In this retrospective study, consecutive patients with a clinical diagnosis of CSCR with available OCT and OCTA scans were included. The presence or absence of DLS on OCT defined as a shallow RPE elevation with a minimum length of 1000µm and a maximum height of 100µm in the same frame were recorded. In eyes with DLS, further qualitative characteristic features on OCT including sub-RPE reflectivity and homogeneity, RPE layer irregularity, photoreceptor layers disruption, and subretinal hyperreflective material (SHRM) were graded and analyzed to explore whether one or more of these features can accurately identify CNV. The presence of CNV was confirmed by OCTA. Logistic regression was used to determine the OCT associations of CNV in cases with DLS.

Results: One hundred and sixty-three eyes with CSCR (age, 55.1±12.2 years) from 132 patients were included in this analysis. DLS was identified in 94 eyes (57.7%) and CNV was detected in 54 eyes (33.1%). Within the DLS group, 46 eyes (48.9%) had CNV. None of the dimensional parameters of the DLS were significantly associated with CNV on univariable regression. However, hyperreflectivity and nonhomogeneity of the sub-RPE space in the DLS were strong predictors of CNV (Table 1). The presence of SHRM and the absence of serous pigment epithelial detachment (PED) in the OCT scan were also significantly correlated (Table 1) with the detection of CNV on OCTA. Although RPE irregularity and photoreceptor disruption were commonly present in the CSCR eyes, they were not associated with CNV. On multivariable model, only hyperreflectivity (OR, 12.2, p=0.001) and nonhomogeneity (OR, 22.2, p=0.005) of the sub-RPE space, and absence of serous PED (OR, 8.2, p=0.02) were identified as independent OCT predictors of the presence of CNV on OCTA in eyes with DLS (Table 1). The combined significant OCT features had a sensitivity and specificity of 96% and 67%, respectively.

Conclusions: Double-layer sign with nonhomogeneous hyperreflective sub-RPE space indicated higher probability of the presence of CNV. Interestingly, serous PED seemed to be a protective sign against the development of CNV in CSCR.

Commercial Relationships Disclosure (Abstract): eyal gal: Commercial Relationship: Code N (No Commercial Relationship) | Joan Gispets: Commercial Relationship: Code N (No Commercial Relationship) | Arnold Willkins: Commercial Relationship: Code N (No Commercial Relationship) | Liat Gantz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Astigmatism blurs the retinal image of a spot along a particular orientation rendering an elliptical shape. The Wilkins Egg and Ball Test (WEBT) was created based on the hypothesis that astigmatic patients encounter difficulty differentiating between oval and circular targets. In WEBT, patients are asked to identify a circle hidden in a row with nine ovals. This study examined the utility of WEBT in identifying patients requiring astigmatic correction in three cohorts; participants with astigmatism, participants with keratoconus and normal participants with induced astigmatism.

Methods: Non-astigmatic participants (N=27, mean age:27±5, range:20-36, 8 male), participants with astigmatism (N=28, mean age:36±10, range:18-36, 9 male) with mean spherical equivalent (SE) corrections of -4.16±4.25, and mean cylindrical corrections of 2.80±0.76 DC (range: -2.00 DC to -4.00 DC), and keratoconic participants (N= 7 eyes, mean age:37±13, range:26-54, 2 female) with mean SE corrections of 0.27±2.20 DS, mean cylindrical corrections of -3.32±3.33 DC (range: -0.75 DC to -10.70 DC), were recruited. Participants detected the circle in each of the ten rows of each page, while the search time (sT) and number of errors(noE) were recorded. Non-stigmatic participants were examined under five conditions (baseline, and induced cylinder at four primary meridians) and participants with keratoconus and astigmatism were examined under corrected and uncorrected conditions, in random order. The sT and noE of varying conditions were compared using the Friedman test.

Results: In non-astigmatic participants, sT was significantly quicker and the noE was significantly lower in the baseline condition (38±9 sec, 0.97±1.5 errors) compared with all induced cylinder conditions (approximately 54±19 sec, 2.35±2.2 errors, p<0.05 for all except for the induced 90 deg astigmatism condition). Astigmatic participants were 6 sec faster and had one less error on average in the corrected condition. Keratoconic participants were 12 sec faster and had three less errors on average in the corrected condition. However, these differences were non-significant.

Conclusions: The potential of WEBT for detection of uncorrected astigmatism remains uncertain, though preliminary results in the clinical population are promising. More participants are being recruited to draw definitive conclusions.

ABSTRACT BODY:

Purpose: To automatically classify retinal atrophy according to its etiology, using fundus autofluorescence (FAF) images, using a deep learning model.

Methods: In this study, FAF images of patients with advanced dry age-related macular degeneration (AMD), also called geographic atrophy (GA), and genetically confirmed inherited retinal diseases (IRDs) in late atrophic stages [Stargardt disease (STGD1) and Pseudo-Stargardt Pattern Dystrophy (PSPD)] were included. The FAF images were used to train a multi-layer deep convolutional neural network (CNN) to differentiate on FAF between atrophy in the context of AMD (GA) and atrophy secondary to IRDs. Three-hundred fourteen FAF images were included, of which 110 images were of GA eyes and 204 were eyes with genetically confirmed STGD1 or PSPD. In the first approach, the CNN was trained and validated with 251 FAF images. Established augmentation techniques were used and an Adam optimizer was used for training. For the subsequent testing, the built classifiers were then tested with 63 untrained FAF images. The visualization method was integrated gradient visualization. In the second approach, 10-fold cross-validation was used to determine the model's performance.

Results: In the first approach, the best performance of the model was obtained using 10 epochs, with an accuracy of 0.92 and an area under the curve for Receiver Operating Characteristic (AUC-ROC) of 0.981. Mean accuracy was 87.30 +/- 2.96. In the second approach, a mean accuracy of 0.79 +/-0.06 was obtained.

Conclusions: This study describes the use of a deep learning-based algorithm to automatically classify atrophy on FAF imaging according to its etiology. Accurate differential diagnosis between GA and late-onset IRDs masquerading as GA on FAF can be performed with good accuracy and AUC-ROC values.

ABSTRACT BODY:

Purpose: The cortex and the retina share many characteristics, including embryologic origin, biochemistry, neurotransmitter communication and microvasculature. To better understand whether visual pathway changes reflect a relationship with cognitive function, we evaluated correlation between retinal structural (OCT), neuropsychological (trail making test, TMT; digit span) and visual functional (multifocal visual evoked potentials, mfVEP) measurements in healthy aging subjects.

Methods: In this cross-sectional, observational clinical study, 74 healthy participants with a mean (SD) age of 67.5 (9.0) years were enrolled from the Optic Nerve and Cognitive Decline (ONDC) study. All participants underwent OCT peripapillary ring scan protocol for RNFL analysis and mfVEP for amplitude and latency assessment. They were also subjected to TMT testing for attention and executive function and digit span neuropsychological examination for working memory assessment. A total of 148 eyes were included for correlation analysis between OCT and mfVEP. Averaged mfVEP measures were used to analyze the relationship with TMT. Correlations between OCT, TMT and mfVEP parameters were analyzed using partial correlation and controlled for age and gender ($P < 0.05$).

Results: At study entry, a significant correlation between digit span total score and mfVEP latency ($r = 0.39$, $P = 0.001$) was observed. The mfVEP amplitude showed mild but significant correlations with global ($r = 0.25$, $P = 0.005$), temporal superior ($r = 0.18$, $P = 0.05$), temporal inferior ($r = 0.23$, $P = 0.01$) and nasal inferior ($r = 0.3$, $P = 0.001$) sectoral RNFL thickness. The TMT-test A also demonstrated negative correlation with mfVEP amplitude ($r = -0.26$, $P = 0.04$).

Conclusions: Our results suggested a significant correlation between mfVEP latency and working memory. MfVEP amplitude was also significantly correlated with global and sectoral RNFL thickness changes as measured by OCT as well as cognitive function characterized by the attention and executive function assessments. These findings indicate that the mfVEP measurements may parallel cognitive decline in the aging population. Further studies are planned in confirmed cognitively impaired subjects.

TITLE: Vergence and accommodation responses in the control of intermittent exotropia

SESSION TITLE: Ocular dysmotility and misalignment: Basic and Clinical studies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Mestre, S. Neupane, T. Candy, School of Optometry, Indiana University, Bloomington, Indiana, UNITED STATES|V. Manh, K. Tarczy-Hornoch, Division of Ophthalmology, Seattle Children's Hospital, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Clara Mestre: Commercial Relationship: Code N (No Commercial Relationship) | Sonisha Neupane: Commercial Relationship: Code N (No Commercial Relationship) | Vivian Manh: Commercial Relationship: Code N (No Commercial Relationship) | Kristina Tarczy-Hornoch: Commercial Relationship: Code N (No Commercial Relationship) | T Rowan Candy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine how young patients with intermittent exotropia (IXT) use vergence and accommodation when controlling their deviation.

Methods: Vergence and accommodation responses of 25 subjects with IXT (5-31 years) and 17 age-matched typical participants were recorded using simultaneous Purkinje image eye tracking and eccentric photorefractometry (PowerRef3). They watched a movie on a 7x7 cm screen, moving between 80 and 33 cm, in binocular and monocular viewing. Data were averaged over 2s windows of stable gaze and refraction during the 8s periods at each viewing distance. Periods of deviation were identified objectively using gaze position in monocular viewing. Fusional ranges were measured at the 80cm distance with a Risley prism. Fusional limits were defined objectively as the last prism for which subjects maintained alignment. Accommodative change during this test was assessed as the difference in refractive state between no prism and the fusional limit prism.

Results: 18 IXT participants were aligned throughout the binocular periods at distance and near viewing. Across all participants, vergence and accommodative responses to the change in binocular viewing distance were 10.20 ± 1.96 pd and 1.52 ± 0.51 D for IXTs, and 10.25 ± 1.75 pd and 1.44 ± 0.38 D for controls. Responses in monocular viewing were reduced to 6.95 ± 5.23 pd and 1.00 ± 0.51 D for IXTs, and 4.79 ± 2.13 pd and 1.03 ± 0.34 D for controls. For participants who deviated spontaneously in binocular viewing at 80cm and had uncorrected hyperopia of <1 D, the mean change in eye alignment was 18.39 ± 8.15 pd, accompanied by 0.09 ± 0.23 D of accommodative change. This was similar to the change in refractive state during monocular viewing at 80cm of control subjects (-0.01 ± 0.12 D). 12 IXT patients and 9 controls had fusional divergence limits of 10.12 ± 6.35 PD and 8.62 ± 3.80 PD, respectively, beyond their dissociated position with refractive changes <0.64 D. Fusional convergence limits from the dissociated position were 32.60 ± 10.41 PD for IXTs and 21.93 ± 9.52 PD for controls (3 reached the maximum prism), typically with <1.00 D increase of accommodation.

Conclusions: Most emmetropic or optically corrected IXTs were aligned in binocular conditions with wide fusional ranges, accompanied by only small changes in refraction. This suggests accommodative convergence is not uniquely responsible for control of the deviation in IXT and alignment is not achieved at the expense of focus.

TITLE: Contribution of ^{99m}Tc -DTPA SPECT/CT in the evaluation of thyroid-associated ophthalmopathy in patients with thyroid carcinoma

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Sun, Z. Zhang, C. Yan, Shanxi Eye Hospital, Taiyuan, Shanxi, CHINA|

Commercial Relationships Disclosure (Abstract): Bin Sun: Commercial Relationship: Code N (No Commercial Relationship) | Zhaoxia Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Chunfang Yan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Thyroid-associated ophthalmopathy (TAO) is most often seen in patients with autoimmune thyroid disease. But thyroid carcinoma with concurrent TAO is rare. The aim of this study was to evaluate ^{99m}Tc -DTPA SPECT/CT in pre-existing TAO in the patients with thyroid carcinoma.

Methods: 12 thyroid carcinoma patients (40~50 years) presented with ophthalmopathy. All patients received thyroidectomy and/or radioiodine (RAI) with the pathological characteristics of papillary thyroid carcinoma. Levothyroxine substitutive therapy was used after thyroidectomy to keep euthyroid. The activity of TAO was determined by means of the clinical activity score (CAS) and ^{99m}Tc -DTPA SPECT/CT. All active TAO patients received periocular injection of triamcinolone acetonide (TA, 20mg 3 weeks intervals, 5 times total) and support treatment (Selenium Yeast 25 μg Bid; Aescuvén forte 150mg, Bid). Data were obtained from a follow-up survey. GO-QOL surveys were used in all patients with TAO.

Results: All 12 patients with thyroid carcinoma accompanied with moderate-severe active TAO (CAS \geq 4). The clinical manifestations of 8 patients worsened after thyroidectomy and/or RAI treatment. Main symptoms were eyelid retraction (100%), exophthalmos (100%) and restricted ocular motility (80%). Compared with the normative values, obvious enlargement of multi-rectus muscles was involved in all patients. ^{99m}Tc -DTPA SPECT/CT were positive in all patients and ^{99m}Tc -DTPA accumulated intensively in site of rectus muscles involved. Thus, TAO substantially reduced QOL of the patients. After periocular injection of TA, the symptoms of TAO were improved. With the stabilization of ophthalmopathy, CAS and the uptake ration (UR) of ^{99m}Tc -DTPA scintigraphy were decreased accordingly in all patients (P<0.05). QOL of the patients with TAO was improved.

Conclusions: ^{99m}Tc -DTPA SPECT/CT played a critical role in the evaluation of the clinical activity of these middle-aged TAO patients with papillary thyroid carcinoma, who presented more severe and more active signs compared with age-matched TAO patients with Graves' Disease (GD). Prominent extraocular muscles involvement, rather than expansion of the orbital fat compartment should be the main subtype. Periocular injection of TA was suggested to provide improvement of ophthalmologic symptoms and QOL in thyroid carcinoma patients with TAO.

ABSTRACT BODY:

Purpose: In the eye, fibrillary structures play vital roles for the eye functioning. Polarization sensitive optical coherence tomography (PS-OCT) is an in-vivo fibrillary tissue imaging tool. We developed a novel scheme of PS-OCT, named as triple input PS-OCT (TIPS-OCT), and investigated the fibrillary structures in the posterior eye of a non-human primate.

Methods: A Rhesus Macaque was anaesthetized and scanned using the proposed TIPS-OCT.

Results: In the peripapillary region of the sclera, we observed that a thin layer of radial fiber structure was distributed from the inner side and transited to thicker, multi-directional, interweaving circumferential fiber structure. The transition boundary can be clearly seen around the ONH.

In the macular region, we observed that the sclera was significantly thicker and primarily contained two orthogonally interweaving fibrillary structure. Fibrils from different directions were observed to entangle under the fovea spot, probably thickening and strengthening the sclera around the macular region.

Conclusions: TIPS-OCT provides new insight to understand the retinal fibrillary structure in vivo.

ABSTRACT BODY:

Purpose: To evaluate macular microvascular changes following Internal Limiting Membrane (ILM)-peeling surgery for Epiretinal Membrane (ERM) or Macular Hole (MH).

Methods: A retrospective study, total of 30 patients (30 eyes), 20 patients diagnosed with epiretinal membrane and 10 with macular hole, were evaluated with SS-OCTA after ILM peeling during PPV. Perifoveal microvascular change and nonperfusion area were measured by Matlab from the 6mmx6mm and 12mmx12mm SS-OCTA images excluding FAZ and optic discs. The presence of Dissociated Optic Nerve Fiber Layer (DONFL) was evaluated using en-face SS-OCTA images.

Results: Total of 30 eyes, the best corrected visual acuity after surgery was significantly improved from 0.56 ± 0.36 (logMAR) to 0.32 ± 0.31 (logMAR). In epiretinal membrane, superficial layer nonperfusion area was significantly decreased ($p=0.047$). In macular hole, the perifoveal vessel density in superficial layer after surgery showed a significant decrease ($p=0.045$), and the deep perifoveal vessel density and the deep nonperfusion zone showed a tendency to decrease, but not statistically significant. DONFL was observed in 7 out of 10 patients diagnosed with macular hole, but in 4 out of 20 patients diagnosed with epiretinal membrane. The correlation between perifoveal microvascular change and DONFL was not statistically significant.

Conclusions: Perifoveal vessel density after ILM peeling surgery tend to decrease in macular hole and epiretinal membrane. It was observed more significant in macular hole.

ABSTRACT BODY:

Purpose: To investigate predictors on optical coherence tomography (OCT) and fundus autofluorescence (FAF) for future progression of hydroxychloroquine (HCQ) retinopathy after drug cessation

Methods: Among the 80 eyes of 41 Korean patients with HCQ retinopathy with follow-up period over than 2 years, progression of HCQ retinopathy was judged as increase in photoreceptor defect size on OCT and increased or newly appeared hypo- or hyperautofluorescence on FAF. Several characteristic features on OCT and FAF were assessed and compared between those without and with progression in the eyes with HCQ retinopathy.

Results: Eyes with newly developed retinal pigment epithelium (RPE) defects or those with expanded RPE defects showed choroidal hypertransmission, without definite defective RPE/Bruch's membrane complex line, compared to the area without such change in the same eye or those without such progression. Complete photoreceptor loss, including the outer nuclear layer, external limiting membrane and ellipsoid zone, was significantly associated with future appearance of adjacent RPE defects. On FAF, double hyperautofluorescent rings on FAF was noted in those with progression, which was significantly different between those with and without progression to severe stage. The eyes with these signs showed continuous progression over the follow-up period following drug cessation.

Conclusions: Choroidal hypertransmission and complete photoreceptor loss on OCT and double hyperautofluorescent rings on FAF might indicate subclinical damage of the RPE in eyes with HCQ retinopathy, which later becomes overt in subsequent periods. These signs may be clinically useful for prediction of future behavior, continuous progression, in HCQ retinopathy.

ABSTRACT BODY:

Purpose: To validate a deep learning algorithm (DLA) for 360° angle assessment on swept source OCT (SS-OCT, CASIA-1000, Tomey Corporation, Nagoya, Japan).

Methods: This was a reliability analysis from a cross-sectional study. An independent test set of 39,936 SS-OCT scans from 312 phakic subjects (128 SS-OCT meridional scans per eye) was analyzed. Participants above 50 years old with no previous history of intraocular surgery were consecutively recruited from glaucoma clinics. Indentation gonioscopy and dark room SS-OCT were performed. Gonioscopic angle closure was defined as non-visibility of the posterior trabecular meshwork in $\geq 180^\circ$ of the angle. For each subject, all images were analyzed by a deep learning-based network based on the VGG-16 architecture, for gonioscopic angle-closure detection. Area under receiver operating characteristic curves (AUC) and other diagnostic performance indicators were calculated for the deep learning algorithm (index test) against gonioscopy (reference standard).

Results: Approximately 80% of the participants were Chinese, and more than half were women (57.4%). The prevalence of gonioscopic angle closure in this hospital-based sample was 20.2%. After analyzing a total of 39,936 SS-OCT scans, the AUC of the DLA was 0.85 (95CI%:0.80-0.90, with sensitivity of 83% and a specificity of 87%) to classify gonioscopic angle closure with the optimal cut-off value of $>35\%$ of circumferential angle closure.

Conclusions: The DLA exhibited good diagnostic performance for detection of gonioscopic angle closure on 360° SS-OCT scans in a glaucoma clinic setting. Such an algorithm, independent of the identification of the scleral spur, may be the foundation for a non-contact, fast and reproducible 'automated gonioscopy' in future.

ABSTRACT BODY:

Purpose: Micron-sized pores are conduits for aqueous humor flow across Schlemm's Canal (SC) endothelium. SC pore reduction in glaucoma contributes to increased outflow resistance and elevated IOP. SC pore formation is triggered by mechanical stretch (Braakman, EER 2014) and stretch increases intracellular $[Ca^{2+}]_i$ by opening stretch-activated Ca^{2+} channels. Ca^{2+} regulates vesicle exocytosis and membrane fusion in neurons and other cell types. As membrane fusion is necessary for transcellular "I" pore formation, we hypothesize that stretch-induced Ca^{2+} influx promotes I-pore formation in SC cells.

Methods: In this study, we compare I-pore formation between SC cells depleted of $[Ca^{2+}]_i$ using BAPTA vs. vehicle treated SC cells exposed to the same level of mechanical stretch. Human SC cells were isolated from 2 non-glaucomatous donors (SC69 and SC75) and characterized following established protocols (Perkumas & Stamer, EER 2012). SC cells were seeded (8×10^3 cells/cm²) onto 6mm \varnothing islands of biotinylated gelatin on elastic PDMS membranes and cultured for 24hrs. Test samples were incubated with 5 μ M BAPTA-AM (30 min) and 1 mM EGTA (5min) in Ca^{2+} free PBS at 37°C. Samples were exposed to 0% or 20% equibiaxial stretch for 2 mins followed by incubation with streptavidin (SA) for 2 mins and then fixed. I-pores were identified based on transcellular movement of SA across the cell body where it binds to the underlying biotinylated substrate. SA labelling patterns were imaged at 20x by epifluorescence microscopy. One masked observer (JB) identified I-pores and measured the area of SA labelling within the perimeter ("pore area") normalized by total cell area (N = 229 and 206 cells in SC69 and SC75). Statistical significance was determined by 3-way ANOVA.

Results: Without BAPTA, increasing stretch from 0% to 20% led to doubling of pore area (0.0025 ± 0.007 vs. 0.0041 ± 0.008 ; $p = 0.004$). BAPTA decreased pore area at both 0% and 20% stretch (0.0021 ± 0.001 and 0.0035 ± 0.002 ; $p < 0.001$) relative to vehicle. BAPTA eliminated the increase in pore area in response to stretch ($p > 0.7$).

Conclusions: Transcellular pore formation is mechanosensitive in SC cells and is triggered by stretch. Ca^{2+} is a necessary component of pore formation, such that depletion of $[Ca^{2+}]_i$ inhibits formation of transcellular pores in SC cells exposed to stretch. This suggests that alterations in $[Ca^{2+}]_i$ may contribute to impaired pore formation in glaucomatous SC cells.

ABSTRACT BODY:

Purpose: This study aims to test the applicability of machine learning (ML) to the analysis of full-field electroretinography (ERG) for the identification of clinically relevant phenotypic subtypes in patients diagnosed with ABCA4-retinopathy (Stargardt disease).

Methods: Patients with ABCA4-retinopathy who had undergone full-field were ascertained. All patients had a molecularly confirmed, likely-disease causing, genotype in the ABCA4 gene and a clinical presentation consistent with ABCA4-retinopathy. All ERGs adhered to the International Society for Clinical Electrophysiology of Vision (ISCEV) standard. Based on interpretation of the dark-adapted strong flash (DA 10.0) ERG, light-adapted single flash cone (LA 3.0) ERG and 30Hz flicker (LA 30Hz) ERG, data were subdivided into three groups by two experienced electrophysiologists: normal (group 1 n=344), consistent with cone dystrophy (group 2 n=45) or cone-rod dystrophy (group 3 n=210). For model development, ERG data were divided 80/20 at patient level into training and test datasets. Individual ERG traces, their derivatives, patient age, and pupil size were input into three logistic regression models corresponding to each of the above stimuli. The collated probabilities from an individual patient's ERG traces were input into a further model generating one phenotype prediction.

Results: Expert analysis and ML methods predicted phenotypic subtypes with 88.2% to 94.2% concordance in the unseen ERG data. In a 5-fold cross validation average test group accuracy was 91.1% with a kappa value of 0.83. Combining phenotypes 2 and 3 in a binary classification gave an average accuracy of 93.8%, sensitivity of 0.93, and specificity of 0.94.

Conclusions: Machine learning classification and human analysis of ERG phenotypes in ABCA4-retinopathy show a high degree of concordance. Machine learning methods have the potential to deepen understanding of retinal dysfunction and disease, previously dependent on specialist expertise and extensive training.

ABSTRACT BODY:

Purpose: To evaluate the therapeutic effects of topical RCI001 on mouse models of environmental and inflammation-mediated dry eye disease (DED).

Methods: We used a scopolamine-induced environmental dry eye model in a dry chamber with 8-week-old BALB/c mice and 12-week-old NOD.B10.H2b mice, a model for primary Sjogren syndrome. The eyes of mice were topically treated with RCI001 and phosphate-buffered saline (PBS) twice a day for a week. Clinical findings such as ocular surface staining and tear production were assessed. Conjunctival goblet cell densities and inflammatory cytokines in the ocular surface and lacrimal gland were also analyzed.

Results: Topical application of RCI001 eyedrops resulted in a significant improvement of ocular surface staining and tear secretion in two mouse models, compared to the PBS-treated group. Although conjunctival goblet cell densities were not different between RCI001-treated and PBS-treated group, the expression of proinflammatory cytokines in the ocular surface and lacrimal gland of NOD.B10.H2b mice were repressed by RCI001, compared to PBS.

Conclusions: Topical RCI001 application showed significant therapeutic effects in two DED models via stimulating tear secretion and modulating inflammation.

ABSTRACT BODY:

Purpose: Usher syndrome type 2A (USH2A) is a genetic disease characterized by bilateral neuro-sensory hypoacusia and retinitis pigmentosa (RP). While several methods including electroretinogram (ERG) describe retinal function in USH2A patients, structural alterations can be assessed by Optical Coherence Tomography (OCT). According to a recent collaborative study, RP can be staged considering visual acuity, visual field area and ellipsoid zone (EZ) width (Iftikhar et al., 2019). The aim of this study was to retrospectively determine RP stage in a cohort of patients with USH2A gene variants and to correlate the results with age, as well as additional functional and morphological parameters.

Methods: In 26 patients with established USH2A genotype, RP was staged according to recent international standards (Iftikhar et al., 2019). The cumulative staging score and the grade were correlated with patients' age, amplitude of full-field and focal flicker ERGs, and the OCT-measured area of Sub-RPE illumination (SRI, Figure 1).

Results: RP cumulative score and grade were positively correlated ($r = 0.6$) with patient age. Both parameters were negatively ($r = -0.45$) correlated with log10 ERG amplitudes and positively correlated ($r = 0.50$) with SRI.

Conclusions:

RP severity score is correlated with age and additional morpho-functional parameters not included in the international staging system, and can reliably predict their abnormality at different stages of disease.

ABSTRACT BODY:

Purpose: To establish precise topographic structure-function relation in neovascular age-related macular degeneration (nAMD) by correlating AI-quantified fluid and photoreceptor (PR) alteration with retinal sensitivity (RS) as assessed by microperimetry (MP).

Methods: Morphology and function of n=38 eyes of 38 consecutive patients with nAMD were analyzed at the treatment-naïve stage and one month following an aflibercept loading dose. SD-OCT data was acquired using Spectralis OCT. Intraretinal fluid (IRF), subretinal fluid (SRF) and PR volumes were quantified using fully automated segmentations based on deep learning. RS was measured using a fovea-centered grid of 45 locations on the Nidek MP-3. Locations were registered to OCT volumes to precisely assess co-located morphology, which we report as nanoliters (nl) within a cuboid volume corresponding to MP-locations (Figure 1). Mixed models were computed to analyze the effect of IRF, SRF and PR volumes on RS at the corresponding location.

Results: RS and morphology at MP-locations are summarized in Table 1. Results of mixed models are reported per nl of fluid/PR. At baseline RS increased with PR volume (fovea: +5.73 dB; parafovea: +6.13 dB; perifovea: +2.95 dB, all $p < 0.001$). IRF corresponded to decreased RS by -1.51 dB ($p < 0.001$) and -1.13 dB ($p = 0.002$) in the fovea and parafovea. For SRF, a decrease in RS by -1.88 dB ($p < 0.001$) and -2.15 dB ($p < 0.001$) was revealed in the para- and perifovea. By month 3 the positive association of RS with PR was even stronger in the fovea, parafovea and perifovea (+11.34 dB; +8.94 dB; +8.32 dB, all $p < 0.001$). A significant effect of fluid remained for IRF in the parafovea (-7.86 dB, $p = 0.023$) and SRF in the fovea (-1.65 dB, $p = 0.012$). Reduction of foveal fluid expectedly corresponded to significantly increased RS by +0.59 dB ($p = 0.011$) for IRF and +0.53 dB ($p = 0.028$) for SRF. Furthermore, reduction of parafoveal SRF resulted in a RS gain of +0.82 dB ($p = 0.012$). Interestingly, increase in PR corresponded to increased RS in the fovea (+1.88 dB, $p = 0.003$), but decreased RS in the para- and perifovea (-1.61 dB and -2.01 dB, $p = 0.022$ and $p = 0.008$).

Conclusions: PR integrity is essential for topographic function. Resolution of foveal fluid and SRF in the parafovea corresponds to RS gains. In summary, retinal morphology, assessed by automated methods, shows meaningful correspondence with precise topographically corresponding RS.

ABSTRACT BODY:

Purpose: Retinal laser treatments lack an objective dosing control, particularly for sub visible irradiations becoming more and more popular. However, laser effects vary largely due to inter and intraocular variations of light scattering and pigmentation at the fundus, leading to strong variations of the induced temperatures. We developed an optoacoustic method to determine the temperature rise during laser irradiation and demonstrated the technique in a clinical trial. The method was now been extended with an automatic closed-loop feedback control system in order to automatically obtain a desired target temperature preselected by the ophthalmologist.

Methods:

A commercial treatment laser (532nm) is used. The laser fiber is coupled to a control unit containing a pulsed probe laser (523 nm, 75 ns, 3 kHz) to excite thermoelastic pressure waves at the retina, and a fast modulator to modify the power of the therapy laser with a frequency of 3 kHz. Both beams are transmitted by the same fiber to a laser slitlamp. The acoustic amplitudes contain the current retinal temperatures and are recorded by an ultrasonic transducer embedded in a standard contact lens. A control software calculates the required laser power in real-time in such a way that the desired temperature rise is reached. Experiments were performed on freshly enucleated pig eye globes and RPE-choroid-sclera explants. Target temperatures between 40°C and 70°C were selected for irradiation times between 50 and 200 ms and a spot diameter of 200 µm.

Results: Depending on the control settings, the aim temperature was reached within 10-100 ms. Thereafter it is kept constant until the end of the irradiation period. For an irradiation time of 100 ms for example, target temperatures of 40, 50 and 60 °C were achieved with accuracies of 1.6 +/- 1.4 % after 78 +/- 9 ms, 2.1 +/- 1.1 % after 74 +/- 12 ms and 5.0 +/- 2.6 % after 41 +/- 20 ms, respectively. When adjusting the controller towards a fast temperature rise, target temperatures were reliably reached within 30 ms with fluctuations thereafter of about +/- 1 °C around the target temperature.

Conclusions: A device automatically controlling the temperature rise during retinal laser therapies has been developed and demonstrated. It can be adapted to every commercially available continuous wave retinal laser. The method allows a reliable thermal impact for visible or subvisible coagulations and especially for sublethal hyperthermia.

ABSTRACT BODY:

Purpose: Deep learning technologies hold great potential to transform and optimize decision support systems in healthcare. As we advance deep learning research and its applications in ophthalmology, massive amounts of high-quality pre-labelled data will be required for model training. Yet, publicly available large databanks for this purpose are limited and the process of generating such datasets can be prohibitively costly both in time and effort. To ease this challenge and to support the democratization of deep learning research, we built and make publicly available a large data set of high-quality labelled optical coherence tomography images along with a repository of supporting analytical toolkits.

Methods: One-hundred and fifty volumes split evenly between intermediate age-related macular degeneration (AMD), diabetes[MVC1] retinopathy, and normal controls were obtained using the Heidelberg Spectralis. From this dataset, 20 volumes (19-69 B-scans/volume; 1668 total scans) from each disease class were labeled for the location of the ILM, INL/OPL boundary, top of the IS/OS, the inner and the outer boundary of the RPE using a custom-built image labelling platform. All images were graded independently three times by a team of experienced graders. A subset of 200 images were graded twice for presence/location of fluid and classes of drusen. All images were adjudicated and corrected if needed to ensure all grades match layer definitions. Agreement between graders was determined using DICE, Intersection over Union (IoU) and Interclass Correlation Coefficients (ICC).

Results: A total of 5004 grades were produced for the presence and location of 5 retinal interfaces and corresponding 6 layers. The agreement between graders for the retinal layers is shown in Table 1, separated by disease. Labels for fluid presence at the B-scan and bounding box tags are also generated and available.

Conclusions: This dataset and subsequent web listing (AI4eyes.org) serve as the beginning of a providing a common database by which to benchmark novel tool development. The platform also provides tools for uniform labelling, thereby lowering the burden on new entrants. The hope is that this platform will continue to expand through our work and others to provide an ever growing depository of images and labels for groups looking to develop artificial intelligence tools, as well as a source for tools to help new groups begin.

ABSTRACT BODY:

Purpose: Our environment is continuously enriched in pollutants that contribute to increase the prevalence of diseases or even the emergence of new pathologies. The effects of chronic low-doses exposure to endocrine disruptors (EDs) on the retina remain unclear. Bisphenol A (BPA) is an ED widely used in the production of polycarbonate plastics leading to organ dysfunction and/or cancers. The aim of this study is to assess the effect of BPA on retina following low-dose perinatal exposure and to elucidate underlying mechanism of action.

Methods: Five µg/kg of BPA was administered to 5-day-pregnant rats 3 times a week. At weaning day 21, newborns received the same dose of BPA until post-natal day 30. Eyes were collected for histology, immunohistochemistry and transcriptomic analysis.

Results: No alteration in the retina structure was noticed by histology. However, a statistically significant modification in the thickness of the inner plexiform layer and the outer nuclear layer were noted (respectively -24% and +12%). Quantification of retinal cells using specific markers demonstrated a statistically significant increase in the number of cones (11.7 %) and a decrease in the number of bipolar cells and retinal ganglion cells (respectively, 21.3% and 10.4%). The number of amacrine and horizontal cells were unmodified. Pre-synaptic dendrites of bipolar cells displaying length reduction with BPA treatment, all synaptic vesicles were stained with synaptophysin. The vesicles distribution in the ONL increased up to 57.2% in BPA condition. Transcripts analysis revealed 1,395 genes significantly regulated in BPA retina compared to control ($p \geq 0.05$; $FD \pm 1.2$). Canonical ingenuity pathways analysis showed significantly regulation of pathways involved in cell-cell junctions, neurogenesis, hormones signaling, protein G signaling, visual cycle, responses to neurotransmitters and to hypoxia. Androgen signaling, G beta Gamma signaling and dopamine receptor signaling pathways were significantly activated (Z -score > 2).

Conclusions: Our results show that low-dose perinatal exposure of BPA induce slight modifications of the cones-bipolar-retinal ganglion cells ways network, corroborated by the wide transcriptional pathways variations. In conclusion, BPA induces slight retinal cell modifications which may contribute to increase the prevalence of neurodegenerative diseases.

TITLE: Epithelial-mesenchymal transition markers upregulation in corneal epithelial cells after UV-B irradiation which is irreversible with Resveratrol

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Meshko, M. Domday, S. Brosig, C. Cursiefen, M. Notara, ophthalmology, Uniklinik Köln, Köln, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Berbang Meshko: Commercial Relationship: Code N (No Commercial Relationship) | Marieke Domday: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Brosig: Commercial Relationship: Code N (No Commercial Relationship) | Claus Cursiefen: Commercial Relationship: Code N (No Commercial Relationship) | Maria Notara: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Epithelial-mesenchymal transition (EMT) is a common feature for fibrotic eye disease including pterygium. UVB irradiation mediates EMT through upregulation of TGF β 1 and 2 but Resveratrol inhibits this later one. We aim to assess UVB radiation's effect in transforming limbal epithelial cells into myofibroblastic cells. And investigate whether the Resveratrol can inhibit limbal cells EMT induced by UVB or not In Vitro.

Methods: HCE-T cell line was cultured at the density of 2×10^4 cells /cm². When cells reached around 80-90% confluence, they were irradiated at a wavelength of 0.03 J/cm² UVB on two consecutive days or not irradiated. Two days after the irradiation, the protein was isolated, and immunoblotting was performed. Western Blot signals were quantified using ImageJ, and significance was calculated by two-tailed student t-test in Excel using the two-sample unequal variance setting.

For resveratrol experiment the same process was repeated, before 3 hours of irradiation cells incubated in 2% serum media and 0 or 50 or 100 μ M of Resveratrol. After 2 cells were fixed with PFA4% and Immunocytochemistry staining with aSMA, vimentin and β -Catenin was performed.

Results: Western Blot data showed that β -Catenin was significantly down-regulated in irradiated cells. The β -Catenin/Actin ratio of 1 ± 0.04 in non-irradiated cells was decreased to 0.060 ± 0.004 and 0.08 ± 0.04 in irradiated cells 2 days and 3 days after irradiation, respectively (2d post irr. $p=0.0006$ and 3d post irr. $p=0.00001$), while two and three days after irradiation, vimentin expression was 22- and 20-fold increased, respectively. Changes were significant ($p=0.007$ (2d post irr.) and $p=0.0016$ (3d post irr.)).

Immunocytochemistry showed increased aSMA and vimentin expression after irradiation versus non irradiated cells, but Resveratrol did not prevent the expression of aSMA, vimentin. The β -Catenin expression was unchanged.

Conclusions: UV-B irradiation of corneal epithelial cells induced EMT-related events by downregulation of β -catenin and upregulation of vimentin in HCE-T In Vitro. Resveratrol did not affect the UV induced changes related to EMT.

ABSTRACT BODY:

Purpose: Stargardt disease (STGD1) is a frequent inherited retinal disease (IRD) affecting ~1/8,000 people. Significant advances have been made over the recent years in elucidating the molecular basis of STGD1, with over 600 pathogenic coding variants and with a substantial number of deep-intronic splicing variants in the disease gene ABCA4. The cis-regulatory domain of ABCA4 is unexplored so far and may represent an attractive target for non-coding disease-causing or modifying variants. By mapping and functionally validating ABCA4 putative cis-regulatory elements (CREs), we aimed to gain more insights into ABCA4 expression regulation.

Methods: In order to identify candidate CREs, we integrated published and in-house human retinal epigenomics datasets. CRE predictions were based on chromatin accessibility (ATAC-seq), chromosome conformation capture combined with ChIP-seq (Hi-ChIP), histone modifications (ChIP-seq) and transcriptomics data (RNA-seq), all generated on human donor retina. To functionally validate in silico predicted CREs, dual luciferase reporter assays using pGL4.23 vectors were performed in hTERT RPE-1 cells. A chromatin interaction profile of the ABCA4 locus was obtained via UMI-4C experiments on neural retina and RPE from human donors.

Results: A total of 21 predicted CREs were cloned both in their native and reverse orientation in order to assess their regulatory effect in vitro. Five regions showed an increase of reporter activity, three of which display active enhancer marks (H3K4me1 and H3K27ac) in photoreceptors, and three regions showed a significant decrease in luciferase activity. The UMI-4C data showed a decrease in background compared to previously generated 4C-seq data (Gómez-Skarmeta et al., unpublished data) and an improved sensitivity and resolution. The generation of replicates and reverse experiments to confirm the interactions are currently ongoing.

Conclusions: Using an integrated approach based on data mining of retinal datasets, in vitro functional validation of putative retinal CREs and targeted chromosome conformation capture (UMI-4C), we have gained insight into the cis-regulatory landscape of ABCA4. The CREs identified and validated here can represent targets of non-coding pathogenic and modifying variants in cases with unsolved ABCA4-associated disease. An improved annotation of tissue-specific cis-regulatory domains of IRD genes may advance the interpretation of non-coding variants.

ABSTRACT BODY:

Purpose: To demonstrate the benefit of objectively quantifying intra- (IRF) and subretinal fluid (SRF) in real-world clinical routine OCT monitoring in eyes with nAMD using an automated deep learning-based algorithm.

Methods: Data from five databases of the Vienna Imaging Biomarker Eye Study (VIBES) registry from 2007-2018 (electronic patient records, treatment database and 2 OCT devices) were analyzed using the Vienna Fluid Monitor. Matching all entries and filtering for active nAMD by baseline (BSL) OCT of suitable quality for automated IRF, SRF and CST segmentation led to inclusion of 1127 eyes. Visual acuity (VA) and OCT data at BSL, month (M) 1-3 and years (Y) 1-5, age, gender and number of treatments were included in the analysis. Subanalyses compared the performance of the algorithm to manual analysis of the Vienna Reading Center in a subset of 20% of eyes.

Results: Mean CST was 358µm at BSL and decreased to 280-303µm over the entire follow-up. IRF/SRF volumes were highest at BSL (IRF: 22/77/107nl in 1/3/6mm area; SRF 14/86/263nl in the 1/3/6mm area). IRF decreased to a mean of 4-5nl at M1-M3 in the 1mm area and increased to 11nl at Y1 and to 16nl at Y5. SRF decreased to a mean of 3-5nl at M1-M3 in the 1mm area and remained below 7nl until Y5. IRF was the strongest parameter to reflect the course of visual acuity over time (Figure). When compared to manual expert analysis the Vienna Fluid Monitor found large amounts of fluid (IRF/SRF=39/23nl 1mm; 186/350nl total volume) in reading center determined presence and almost no fluid (IRF/SRF=2/1nl 1mm; 16/21nl total volume) in determined absence of both IRF and SRF (accuracy/sensitivity/specificity ~0.80).

Conclusions: Deep learning-based automated fluid quantification in clinical routine images is well-suited to objectively, reliably and rapidly measure treatment response and may guide clinical management in nAMD. The Vienna Fluid Monitor introduces expertise at reading-center level to a clinical routine setting while saving valuable time of the examiner. Automated volume measurements of retinal fluid compartments in a real-world dataset over a period of 5 years suggests IRF volume as the most practical parameter for treatment decisions.

Commercial Relationships Disclosure (Abstract): Kealan McElhinney: Commercial Relationship: Code N (No Commercial Relationship) | Mustapha Irnaten: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Wallace: Commercial Relationship: Code N (No Commercial Relationship) | Colm O'Brien: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) is an age-related fibrotic condition and a leading cause of irreversible blindness worldwide. POAG-related damage is initiated within the lamina cribrosa (LC) region of the optic nerve head, driven by the pathological activation of resident LC cells. LC cells bear striking similarities to proliferative, apoptotic-resistant myofibroblasts known to be responsible for organ fibrosis. Myofibroblast dysregulation is linked to targeted proteasomal degradation of p53 by the E3 ubiquitin-protein ligase MDM2 (mouse-double-minute-2) thus negating p53's important regulatory role in cell-cycle/apoptosis. This project aims to evaluate the role of p53, MDM2, and the ubiquitin-proteasomal pathway in glaucomatous LC cells.

Methods: Primary human normal LC (NLC) and glaucoma LC (GLC) cells (n=3 donors) were cultured under standard conditions and treated for 48 hours with RG-7112 (p53-MDM2 interaction inhibitor, Abcam). The p53-MDM2 ubiquitin-proteasomal pathway was analysed by real-time polymerase chain reaction (qRT-PCR) for gene expression and protein levels via western blotting.

Results: MDM2 gene expression levels were significantly elevated ($p=0.006$) in GLC cells (1.00 ± 0.12) versus NLC cells (0.89 ± 0.08). p53-MDM2 inhibitor RG-7112 treatment caused a further significant ($p=0.001$) increase in MDM2 transcription levels in GLC cells (1.17 ± 0.04). p53 transcription levels were equivocal between GLC cells (0.88 ± 0.09) and NLC cells (0.87 ± 0.08), with RG-7112 treatment leading to a significant increase ($p=0.028$) in p53 transcription levels in GLC cells (0.95 ± 0.06). Western blot analysis showed significant decreased protein expression levels of p53 (0.76 ± 0.09) ($p=0.047$) and increased protein expression of MDM2 (1.57 ± 0.33) ($p=0.042$) in GLC cells compared to NLC. Interestingly, p53-MDM2 inhibitor RG-7112 treatment increased p53 (1.14 ± 0.43) ($p=0.267$) and decreased MDM2 protein expression levels (0.92 ± 0.25) ($p=0.06$) in GLC cells.

Conclusions: Our data suggests the ubiquitin-proteasomal pathway is significantly dysregulated in GLC cells with MDM2 led p53 protein degradation negatively impacting its key role as "guardian of the genome". Targeting the p53 ubiquitin-proteasomal pathway in lamina cribrosa fibrosis may lead to future novel therapeutic interventions.

ABSTRACT BODY:

Purpose: Treatment options for Diabetic Retinopathy (DR) are limited making research into alternative therapeutics of utmost need. The finding that the deregulation of the retinal Renin-Angiotensin System (RAS) triggers hallmarks of DR, support a role for RAS in this pathology.

We have previously characterized the ACE/AngII/AT1R axis and found it to be over-activated in retinal pigmented cells (RPE) cells (Simão et al., 2016; 2017). We aim to investigate the potential benefit for DR of a gene therapy approach promoting the activation of the protective axis of the RAS, the ACE2/Ang (1-7)/Mas.

Methods: A plasmid containing the human gene of ACE2 (pEPito-hCMV-ACE2) was used to transfect RPE cells (D407), with pEPito-hCMV-eGFP used as control. The cellular localization and expression of ACE2 in RPE cells was analyzed by immunocytochemistry and Western blot. The expression of components from the protective axis of RAS, PEDF, VEGF, and pro-inflammatory markers TNF- α and IL1- β were evaluated by Western blot or ELISA, and the levels of ROS were assessed using an oxidative stress indicator.

Results: The transfection of RPE cells with pEPito-hCMV-ACE2 significantly increased the expression of ACE2 and Mas receptor. Moreover, ACE2 localized in both the perinuclear and cytoplasmatic compartments of RPE cells. We found no differences in the levels of Ang (1-7) or expression of PEDF, VEGF or IL1- β when ACE2 is overexpressed in RPE cells. However, the levels of TNF- α in RPE cells transfected with pEPito-hCMV-ACE2 are much lower than those observed in cells transfected with the control (pEPito-hCMV-eGFP), which can be attributed to a protective effect from the ACE2 overexpression. A similar result has been observed for oxidative stress, with a significantly decrease in the levels of ROS in cells overexpressing ACE2.

Conclusions: Overexpression of ACE2 significantly increases the expression of the Mas receptor in RPE cells, with no effect on the levels of Ang (1-7). TNF- α and ROS levels are decreased in RPE cells overexpressing ACE2. Altogether these results point to a protective effect regarding inflammation and oxidative stress by ACE2 overexpression in RPE cells, and suggest a promising gene therapy approach towards the halting progression of retinal damage.

TITLE: A doubling in the occurrence of dry eye symptoms during extreme smoke from wildfires surrounding Sydney, Australia

SESSION TITLE: Dry eye and microbiome clinical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Jaiswal, B. Golebiowski, N. Tein, S. Wang, I. Jalbert, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA

Commercial Relationships Disclosure (Abstract): Sukanya Jaiswal: Commercial Relationship: Code N (No Commercial Relationship) | Blanka Golebiowski: Commercial Relationship: Code N (No Commercial Relationship) | Natasha Tein: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Wang: Commercial Relationship: Code N (No Commercial Relationship) | Isabelle Jalbert: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Wildfires are increasingly frequent and severe and release pollutants which can adversely impact the ocular surface. The Australian fires of 2019-2020 released extreme amounts of smoke, affecting half the Australian population. This pilot study compared ocular surface symptoms, signs and management strategies used in an optometry practice during the wildfires and during a control period.

Methods: Records of patients examined at the optometry clinic at UNSW in Sydney, Australia between October 2019 and February 2020 (fire period when extreme smoke severely reduced air quality) and from same months in 2018-2019 (control) were audited. Records containing ocular surface examinations of patients who had provided prior research consent were included. Ocular surface symptoms, signs and management were extracted from records and compared between the fire period and control period using Chi Square and Mann-Whitney U test. Associations with ambient air quality (PM2.5 level, NSW Department of Planning, Industry and Environment) were examined using Spearman's correlation ($p < 0.05$).

Results: 104 records in the fire period and 74 in the control period were audited. Patient age and sex did not differ between fire and control periods (35 ± 15 years; 44% male). The most common reason for presentation was for general check-up in both the fire (28%) and control period (26%). The symptom of 'dry eyes' was recorded more frequently during the fire (22%) than the control (11%) period ($p = 0.04$), but there were no significant differences in the occurrence of other ocular surface symptoms or clinical signs (Table). There were no differences in the recommended management such as lubricants, lid hygiene or warm compress (Table). Out of the 123 days in each fire and control period, ambient air PM2.5 levels exceeded national air quality standards on 23 days in fire period and zero days in control period, but no associations were evident between PM2.5 level on the date of eye examination and recorded ocular surface symptoms, signs management.

Conclusions: There was more frequent reporting of symptoms of dry eyes during wildfire period than during control (non-fire) period. This was not associated with a clear pattern of exposure and did not lead to increased diagnosis of chronic dry eye disease. Confirmation of these findings using optometry practices from other regions impacted by wildfires is warranted.

ABSTRACT BODY:

Purpose: Longer term “Real-world” visual acuity (VA) outcomes of anti-vascular endothelial growth factor (anti-VEGF) therapy were assessed in neovascular AMD (nAMD), diabetic macular edema (DME), branch and central retinal vein occlusion (BRVO, CRVO)-related macula edema (ME).

Methods: A retrospective analysis was performed on a large database of aggregated, longitudinal, deidentified electronic medical records from a geographically and demographically diverse sample of patients of United States retina specialists (Vestrum Health Retina Database). Treatment naïve nAMD, DME, BRVO-ME and CRVO-ME patients who underwent anti-VEGF injections between 2014 and 2019 were eligible if follow up data was available through at least 12 months.

Results: At 1, 3 and 5 years, in those 67,666, 21,305 and 5,208 eyes with nAMD, after a mean of 7.6, 19.5 and 32 injections, there was a mean change of +3.1, -0.2 and -2.2 letters respectively. At 1, 3 and 5 years, in those 40,832, 7,728 and 1,192 eyes with DME, after a mean of 6.2, 15.4 and 26.0 injections, there was a mean change of +4.7, +3.3 and +3.1 letters respectively. At 1 and 3 years, in those 12,451 and 3,027 eyes with BRVO-ME, after a mean of 7.1 and 18.2 injections, there was a mean change of +9.5 and +7.7 letters respectively. At 1 and 3 years, in those 9,298 and 2,264 eyes with CRVO-ME, after a mean of 7.3 and 18.8 injections, there was a mean change of +8.3 and +6.0 letters respectively. In all 4 conditions, mean letters gained increased with mean number of anti-VEGF injections at each of the aforementioned time periods. In all 4 conditions, patient eyes with baseline VA of 20/40 or better tended to lose VA, and those with progressively worse baseline VA experienced progressive greater gain in VA at 3 years.

Conclusions: Real-world nAMD, DME, BRVO-ME and CRVO-ME patients experience meaningfully worse visual outcomes compared with patients in randomized controlled trials, with nAMD patients tending to lose VA at 3 and 5 years. Across all 4 disorders, mean change in VA correlates with treatment intensity at 1, 3 and 5 years. Patients with better VA at presentation tend to be particularly vulnerable to vision loss. There remains unmet need for more effective therapy with durability to address treatment burden.

ABSTRACT BODY:

Purpose: To examine deep learning-based segmentation of geographic atrophy (GA) lesions and the reliability of derived features.

Methods: Nine hundred and forty pairs of images were taken from 194 patients, with each pair comprising a fundus autofluorescence (FAF) and near-infrared (NIR) image from 1 eye (Proxima B, NCT02399072). Lesions were annotated on the FAF by a grader, and the data were split at the patient level into training (n=155) and validation (n=39) sets. A test set comprising 90 FAF-NIR pairs from 90 patients (Proxima A, NCT02479386) was annotated by 2 graders (G1 and G2). Two multimodal deep learning networks (UNet and YNet) were trained on the training set and tuned on the validation set. The final network was applied to the test set. For each segmentation mask, the lesion area, perimeter, circularity, Feret diameters, and number of lesions were extracted. As a numerical proxy for the FAF pattern, the excess rim intensity (ERI), equal to the mean FAF intensity in a 0.5-mm rim around the lesion minus the mean FAF intensity in a 0.5- to 1-mm rim around the lesion, was also extracted. For all measures except for number of lesions, the relevant metric was computed for the whole segmented area without separating it into different components.

Results: The average Dice score between the network and G1 on the test set was 0.92. The Pearson correlation (r) of area, perimeter, circularity, major Feret diameters, minor Feret diameters, ERI, and number of lesions between the YNet and G1 was 0.98, 0.93, 0.86, 0.87, 0.93, 1.00, and 0.46, respectively. Analogous statistics for the network and G2 and for G1 and G2 are given in Table 1.

Conclusions: Networks trained to segment GA lesions could produce accurate segmentations. When the segmentations were used to obtain the values of area and ERI, the agreement between the networks and human graders was similar to the agreement between two graders. Inferred values of perimeter, circularity, and Feret diameters were less similar, and often varied between models despite similar Dice scores. The inferred number of lesions matched human grading poorly. The variable accuracy of the examined features could be an important factor for their use in predictive models of GA growth.

ABSTRACT BODY:

Purpose: Hemizygous pathogenic variants in CACNA1F lead to defective signal transmission from photoreceptors to bipolar cells and cause incomplete congenital stationary night blindness (iCSNB). Knowledge of inner retinal changes in iCSNB is limited. This study measured macular ganglion cell layer-inner plexiform layer (GCL-IPL) thickness and optic disc pallor to assess if subjects carrying pathogenic variants in CACNA1F have inner retinal thinning and optic atrophy in excess of the expected degree of disc pallor seen in myopia.

Methods: Ocular phenotypic data including distance and color vision, refraction, optical coherence tomography (OCT) GCL-IPL thickness and electroretinogram (ERG) were collected from 22 subjects with molecularly confirmed CACNA1F-iCSNB. OCT data was collected from an age-matched control population (n=87) without organic ocular pathology, subdivided into 3 groups based on spherical equivalent (SE) refractive error: (1) emmetropia or hyperopia: SE $\geq 0D$, (2) low myopia: SE ≤ -0.5 and $> -6.00D$, and (3) high myopia: SE $\leq -6.00D$. ERG parameters were correlated against GCL-IPL thickness. Optic disc photos were evaluated by a pediatric neuro-ophthalmologist noting the presence and extent of disc pallor in clock hours.

Results: Mean patient age was 14.3 years (range 6-58 years); mean refractive error was -6.32D (range -20.50 to +2.50D); 68% (15 of 22) were myopic. Distance vision was universally reduced (mean 0.42 LogMAR) and six had abnormal color vision. Mean GCL-IPL thickness in patients was significantly lower (55.00 μm) compared to controls (84.57 μm) as well as compared to emmetropia or hyperopia (88.25 μm), low myopia (83.07 μm) and high myopia (78.59 μm) control sub-groups ($p < 0.001$). The GCL-IPL thickness correlated with scotopic standard ($p = 0.04$) and bright-flash ($p = 0.014$) ERG b/a ratios, and photopic b-wave amplitude ($p = 0.05$). Twenty-one patients had some degree of disc pallor (bilateral in 19). There was no correlation between GCL-IPL thickness and extent of disc pallor or mutation class. Fifteen putative disease-causing variants were identified: 5 missense, 4 nonsense, 3 frameshift, 2 splice site and 1 silent variant predicted to affect splicing; 5 variants were novel.

Conclusions: This study establishes macular inner retinal thinning and optic atrophy as features of CACNA1F-related iCSNB which are independent of myopia and could impact potential future treatment strategies.

ABSTRACT BODY:

Purpose: Mutations in ABCA4 are the most prevalent cause of monogenic retinal disease and are responsible for a range of phenotypes including Stargardt disease and cone-rod dystrophy. ABCA4-disease is caused by biallelic variants and recent studies have revealed pathogenic hypomorphic common variants and complex alleles (two or more variants in cis). The ability to cheaply and efficiently phase ABCA4 variants is therefore important to establish the biallelic status of variants when diagnosing singleton cases and to facilitate the further investigation of complex alleles. The goal of this study was to develop a cost-effective long-range sequencing method to phase ABCA4.

Methods: Long-range PCR primers encompassing the entire 130kb ABCA4 locus in overlapping blocks of 6-12kb were used to amplify genomic DNA using the Sequel Prep Long-Range PCR Kit. Samples were purified using AxyPrep Mag PCR Clean Up Kit and equimolar concentrations of each amplicon were combined and run on an Oxford Nanopore MinION with a flongle adaptor. Fast5 files were converted to Fastq files using Guppy, trimmed using Porechop and aligned using Minimap. Variants were called using Nanopolish and haplotypes assembled using WhatsHap.

Results: A pilot test involved amplifying 2 previously phased cases (eg. CEPH NA12878) and 2 Stargardt patients with two unphased variants. Initially 23 amplicons ranging between 6kb and 12kb in size and overlapping by a minimum of 2.5kb were used. One sample per flongle achieved an average read depth of ~7500, reducing stochastic effects. This method could be used to successfully phase the ABCA4 gene into 4 phase blocks which confirmed the phasing of previously identified variants in the control samples. The gaps were caused by a lack of variants in the overlap regions so amplicons were redesigned for these regions after analysing WGS datasets to ensure the capture of maximum variation.

Conclusions: This study has designed and tested a long-range, low-cost sequencing strategy to phase ABCA4. This will increase the accuracy of diagnosing individuals which is becoming increasingly important with the advent of therapies. It also has far reaching implications for the investigation into the contribution of complex alleles in ABCA4 related disease.

TITLE: Epiretinal photovoltaic prosthesis with high pixel density

SESSION TITLE: Retinitis pigmentosa/ retinal prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Chenais, M. Airaghi Leccardi, D. Ghezzi, Medtronic Chair in Neuroengineering, Center for Neuroprosthetics and Institute of Bioengineering, School of Engineering, École Polytechnique Fédérale de Lausanne, Geneva, SWITZERLAND|

Commercial Relationships Disclosure (Abstract): Naïg Chenais: Commercial Relationship: Code N (No Commercial Relationship) | Marta Airaghi Leccardi: Commercial Relationship: Code N (No Commercial Relationship) | Diego Ghezzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The theoretical visual acuity offered by retinal prostheses is limited by the use of implantable pulse generators and feedlines on the array. In parallel, the visual angle restored by most prostheses is limited to at best 20 degrees, primarily by reason of low conformability materials and subretinal placement. The combination of these limitations prevents implanted blind patients to benefit from artificial vision in their day-to-day life, as navigation in complex spaces and most of the daily visually-guided manipulation activities require both visual acuity and visual field together.

Methods: Conjugated polymers allow for photovoltaic retinal stimulation with flexible and large arrays, thus opening the possibility for wide-field and high-density arrays freed from external power generator. In this work, we designed a photovoltaic epiretinal implant embedding 10'498 physically and electrically independent miniaturised photovoltaic pixels. Such implant combines a large visual angle, thanks to the flexibility of the organic materials used, and a high pixel density, possible through the patterning of the organic polymer films. Using single-pixel stimulation, minimum separable and grating visual acuity paradigms, we evaluated the spatial resolution of the prosthetic response elicited by this high-density photovoltaic implant in explanted retinal degeneration 10 mouse retinas.

Results: Each of the discrete photovoltaic pixels could elicit reproducible network-mediated response in light-insensitive retinal ganglion cells from $80 \mu\text{W} \cdot \text{mm}^{-2}$. Moreover, the high-density arrangement of the pixels allowed retinal ganglion cells to be stimulated with a 0.3-degree resolution, what corresponds to a 20/480 visual acuity. During both two-points discrimination test and decreasing gratings tests, retinal ganglion cells exhibited desensitized response to repeated stimulation patterns, but marked response to pattern reversals. Such response resolution was observed in ganglion cells whose receptive field diameter exceeded the pixel pitch, suggesting that spatial discrimination can be achieved at the inner retinal level with epiretinal network-mediated stimulation.

Conclusions: In view of the large visual angle (43°) covered by the photovoltaic epiretinal implant, this device could provide artificial vision with high peripheral resolution to retinitis pigmentosa patients, a valuable improvement for obstacle recognition, ambulation, and independence.

TITLE: Characterization of Higher Visual Function Deficits (HVFDs) with a Question Inventory in children with Cerebral Visual Impairment (CVI) and good visual acuity (VA)

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Chandna, S. Foster, Alder Hey Children's NHS Foundation Trust, Liverpool, Merseyside, UNITED KINGDOM|A. Chandna, S. Ghahghaei, Smith Kettlewell Eye Research Institute, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Arvind Chandna: Commercial Relationship: Code N (No Commercial Relationship) | Saeideh Ghahghaei: Commercial Relationship: Code N (No Commercial Relationship) | Susan Foster: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: CVI, the commonest cause of visual loss in children in the developed world with prevalence rising worldwide; manifests with variable VA loss and diverse HVFDs such as difficulty with motion perception and visual environmental clutter. Visual behaviorisms suggestive of HVFDs even in CVI children with good VA, are observed by parents and teachers with adverse effects on daily activities at school and home. Good VA in CVI children often precludes further investigation for HVFDs. We investigated HVFDs in children with CVI and good VA through structured history-taking with HVF Question Inventory (HVFQI) and develop an abbreviated QI for rapid screening.

Methods: Parents of 33 children with CVI (7.0 +/- 2.7 yrs.) with good VA (≥ 0.2 LogMar) and 111 typical children (8.7 +/- 2.8 yrs.) participated. CVI diagnosis was based on integrated assessment of history, eye and neurologic examination and brain imaging. Parents responded to the 51 questions choosing from a 5-point Likert scale: Never, Rarely, Sometimes, Often, Always. 'Not Applicable' (NA) option was available. Initial analysis tested the ability of HVFQI to differentiate between CVI and typicals by calculating average score for each question adjusted for NA responses. Next, the questions that offered best discriminability as a screening tool were determined by scoring across a series of binary divisions along the Likert scale followed by area-under-curve (AUC) analysis for each question and each binary-scoring method.

Results: Children with CVI scored significantly higher than typical children in overall scores and in all binary scoring methods (p-values < 0.001). Three binary-scoring methods gave us the highest AUC values (>0.87) and revealed 11 questions that contributed most to an affirmative result for presence of HVFD. These related to problems with clutter, lower visual field, motion perception and multi-tasking and termed HVFQI-Top11.

Conclusions: Our results confirm the presence of HVFDs and that HVFQI-51 is a sensitive tool able to differentiate children with CVI despite good VA and characterize the spectrum of HVFDs for each child. HVFQI-51 has the potential for; longitudinal studies to document the natural history, effects of habilitative measures and use in other conditions where HVFDs are suspected. We recommend a subset, the HVFQI-Top11, for screening for HVFDs.

TITLE: PAEMA nonviral vectors display enhanced gene transfer ability in retinal cells

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.B. Bitoque, R.L. Sequeira, G.A. Silva, NOVA Medical School, NMS, Universidade Nova de Lisboa, iNOVA4Health, CEDOC, Lisbon, Lisbon, PORTUGAL|A.M. Rosa da Costa, Faculty of Science and Technology, Universidade do Algarve, CIQA – Algarve Chemistry Research Centre, Faro, Algarve, PORTUGAL|

Commercial Relationships Disclosure (Abstract): Diogo Bitoque: Commercial Relationship: Code N (No Commercial Relationship) | Raquel Sequeira: Commercial Relationship: Code N (No Commercial Relationship) | Ana Rosa da Costa: Commercial Relationship: Code N (No Commercial Relationship) | Gabriela Silva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Non-viral vectors present several advantages for retinal gene therapy, in particular by carrying genes above 4.5 kb; however, these still need to be optimized to achieve higher transfection efficiencies. Previous results from our group revealed that entering the nucleus was the bottleneck for our nonviral vectors (Bitoque, et al. Materials Science and Engineering: C, 2018; Bitoque, et al. Bioscience Reports, 2021). Therefore, we aimed to increase the efficiency of a polymeric nonviral vector by conjugating nuclear localization signals (NLSs), which are short amino acid sequences capable of directing molecules to the nucleus.

Methods: To test our hypothesis, we have produced and characterized a nonviral vector by combining a plasmid encoding a reference gene with our NLS-conjugated PAEMA (poly(2-aminoethyl methacrylate polymer). We further tested it in vitro using a human pigment epithelial cell line (D407) to assess its effect on cell viability and transfection efficiency and in vivo in the rd10 mouse. All experimental procedures were carried out according to the Portuguese, European Union, FELASA, and the Association for Research in Vision and Ophthalmology (ARVO) regulations for the use of animals in ophthalmic and vision research.

Results: We have found that PAEMA can be efficiently modified to incorporate NLSs, and this modified polymer efficiently complexes plasmid-based expression systems, with size and charge adequate for cell entry. We have further confirmed this polymer to be capable of protecting its load from degradation but adequately releasing it 24 hours after cell entry. Furthermore, in RPE cells, the qualitative (fluorescence microscopy) and quantitative (flow cytometry) analysis of the transfection efficiency show that PAEMA conjugated with NLSs is able to increase the expression of the gene of interest by 63%. Lastly, intravitreal injection of PAEMA-NLSs polyplexes in the retina of rd10 mice has shown in vivo compatibility, and negligible, fast-resolving, inflammatory response. Further studies are focused on the capacity of the optimized polymer to deliver the β subunit of PDE6 gene to the nucleus of retinal cells.

Conclusions: Overall, these results demonstrate the potential of PAEMA nonviral vectors for retinal gene therapy, in particular for overcoming the nuclear bottleneck for an efficient delivery.

ABSTRACT BODY:

Purpose: We aim to better understand the practices of ophthalmologists during the COVID-19 pandemic period in France, and particularly in the management of patients with exudative AMD

Methods:

During the months of June and July 2020, French ophthalmologists were invited to answer an online questionnaire evaluating the adaptation of their practice during the pandemic period (March to May 2020) and more particularly the management of exudative AMD . The questionnaire consisted of 40 questions.

Results: 107 ophthalmologists responded to the online questionnaire. Ophthalmologists treated an average of 146 participants with exudative AMD per month (median: 80). 89.5% of participants maintained their activity during this period. 90.2% selected the patients to be called, on the basis of their medical reports. 9.8% saw only emergencies. All ophthalmologists adapted their practices and 43.5% systematically took patients' temperatures. 91.8% spaced the intervals between appointments to 15 minutes or more. 49% did not check visual acuity. 41.8% only controlled OCT when absolutely necessary. 80% of ophthalmologists adapted the therapeutic regimens to fixed or Treat-and-Extend regimens based on the last treatment interval. For 25%, pharmacological and / or pharmacokinetic properties were important for the choice of the molecule used. 82.5% of practitioners observed a significant worsening of exudative AMD due to a lack of follow-up during the confinement period

Conclusions: This survey allowed us to better understand the practices of ophthalmologists for patients with exudative AMD during the beginning of the pandemic period of Covid-19 in France. Health conditions have prompted all ophthalmologists to quickly change their reception and care practices

ABSTRACT BODY:

Purpose: The effect of noncoding variants is often unknown in the absence of functional tests. The purpose of this study was to characterize an ABCA4 intron 7 variant, c.859-25A>G, identified in Palestinian probands with a clinical diagnosis of Stargardt disease (STGD) or cone-rod dystrophy (CRD). We assessed the effect of this variant on the ABCA4 mRNA and retinal phenotype, and investigated its prevalence in inherited retinal dystrophy (IRD) cases from Palestine.

Methods: Molecular inversion probe (MIP)-based sequencing of ABCA4 was performed in 876 probands with STGD or CRD collected worldwide. In silico analysis of DNA variants was performed using SpliceAI. The effect of variant c.859-25A>G was investigated using in vitro splice assays in HEK293T cells using ABCA4 exon 7-11 midgenes. ABCA4 sequencing data was obtained or re-analyzed from another 890 Palestinian IRD cases using MIPs-based sequencing, whole exome sequencing, and targeted Sanger sequencing. The ophthalmologic characteristics were examined using retinal imaging techniques, including optical coherence tomography and also full field electroretinography.

Results: smMIPs-based ABCA4 sequencing revealed the c.859-25A>G variant in three Palestinian probands living in, or originating from, the city of Hebron. SpliceAI predicted a significant effect on the nearby splice acceptor site, and splice assays revealed an exon 8 deletion and two upstream elongations in mRNA. None of these products yields a functional ABCA4 protein. ABCA4 genotyping in 890 Palestinian cases revealed another 48 affected persons carrying this variant, all living in or originating from the Hebron area. Haplotype analysis in 22 of 38 homozygotes revealed a shared genomic segment. Homozygotes for variant c.859-25A>G show an average age at onset of 5.4 years confirming that this is a severe variant. The mean logmar best corrected visual acuity for these cases was 1.1. Of the 38 homozygotes 25, 7, and 6 cases had a clinical picture compatible with CRD, STGD1 and retinitis pigmentosa (RP) respectively.

Conclusions: ABCA4 variant c.859-25A>G results in multiple severe splice defects and CRD, RP or early-onset STGD1 in homozygotes. It was found in 50/892 IRD cases in Palestine and represents the most frequent IRD-causing variant to date in Palestine.

ABSTRACT BODY:

Purpose: Retinal vein occlusion (RVO) is often complicated by sight limiting macular oedema (MO). Intravitreal injections (IVIs) of anti-vascular endothelial growth factor (anti-VEGF) carry some clinical risk to patients but improve MO and vision for many. A significant minority show partial or no response despite many IVIs. If treatment outcomes could be forecast at RVO presentation, such patients may decline anti-VEGF treatment. This prognostic accuracy study aimed to test the feasibility of such forecasts using Random Forest technique (RF).

Methods: A retrospective dataset of RVO treated with anti-VEGF IVIs for MO was assembled from the electronic medical record (EMR) of a large provincial UK ophthalmology centre. 412 eligible eyes were identified (212 left eye, 194 CRVO, 205 male, mean age 72.6, mean delay between diagnosis and treatment 110.9 days) with a mean visual acuity (VA) at treatment initiation of 50.3 early treatment diabetic retinopathy study (ETDRS) letters and a mean VA of 58.8 letters following 1 year of treatment. Fovea centred optical coherence tomography slices, taken at treatment initiation, were included. The dataset was divided 80:20 for training and testing. Features of the images were extracted using Histogram Oriented Gradient feature descriptor. To evaluate the performance of the RF model, 11 different ophthalmology doctors provided similar VA forecasts for two subsets (n=41) of the RF test set (n=82).

Results: The mean absolute error (MAE) of the RF model is 14.3 (SD=16.2), which was not significantly different to the pooled MAE of 16.7 (SD=22.4) from all clinicians' forecasts (p=0.42). The root mean squared errors were 19.55 and 23.53 for the RF model and pooled clinician forecasts respectively. The best performing clinician achieved a MAE of 14.8, which was not significantly different to the RF model's MAE of 12.9 on the same subset (p=0.35).

Conclusions: Such a RF model can match ophthalmologists in their ability to forecast VA outcomes for RVO complicated by MO undergoing 1 year of anti-VEGF treatment. The error reported here is too great to be of clinical use, but further work is required to establish if larger datasets and more powerful techniques could help to support patients' treatment decisions.

Commercial Relationships Disclosure (Abstract): Isabel Fabelo Hidalgo: Commercial Relationship: Code N (No Commercial Relationship) | Consuelo Fernández-Nuñez: Commercial Relationship: Code N (No Commercial Relationship) | Nicolás Pérez-Llombet Quintana: Commercial Relationship: Code N (No Commercial Relationship) | Oswaldo Esteban Duran Carrasco: Commercial Relationship: Code N (No Commercial Relationship) | Maria Alberto-Pestano: Commercial Relationship: Code N (No Commercial Relationship) | Marta Alonso Plasencia: Commercial Relationship: Code N (No Commercial Relationship) | Rodrigo Abreu-Gonzalez: Commercial Relationship(s);Nidek:Code C (Consultant);Novartis:Code C (Consultant);Allergan:Code C (Consultant)

ABSTRACT BODY:

Purpose: To determine normal values of mesopic and scotopic retinal sensitivity obtained by microperimetry , using MP3s microperimeter (Nidek, Gamagori, Japan), in a healthy population. Secondly, to assess the association among retinal sensitivity, gender and age.

Methods: Microperimetry was performed using the Nidek MP3s system (Nidek, Gamagori, Japan) with a 13-point fovea-centered pattern in mesopic and scotopic mode in volunteers which did not present fundoscopic alteration or structural OCT changes compatible with maculopathy. All of them presented a corrected visual acuity of 1.0 on a decimal scale (0.00 Log Mar) and a spherical equivalent less than +/- 5.0 D. A intraclass correlation coefficient (ICC) was performed to evaluate mesopic and scotopic microperimetry reliability.

Results: We analyzed 102 eyes of 54 patients (62.7% male and 37.3% female) with a mean age of 49.8 +/- 15 years old (p=.14) The mesopic and scotopic mean retinal sensitivity (MRS) was 28.55 ± 3.3 dB (95% CI=[27.87-29.23]) and 15.72 ± 1.9 dB (95% CI=[15.35-16.09]) respectively, showing a significant statistical difference (p <0.05).

There were no statistical significant differences related to gender and MRS in both microperimetry modes. Regarding to age we divided the patients into quartiles (<39 y; 40-53 y; 54-67 y; >67 y). MRS was higher in the <35 years old group (mesopic: 30.3 ± 1.7 dB and scotopic: 16.3 ± 1.3 dB) and lower in the >67 years old group (mesopic: 26.7 ± 2.2 dB and scotopic: 13.8 ± 1.8 dB (p= .0001).

The reliability analysis of both tests, using the intraclass correlation coefficient (ICC), revealed an excellent reliability of the mesopic microperimetry with a Crombach alpha of 0.958 (ICC = 0.958, f = 23.893, p <0.0001) and a good reliability of 0.841 (ICC = 0.841, f = 6.305, p <0.00) in scotopic microperimetry.

Conclusions: With the results of our study, we may conclude that there is no difference in mean retinal sensitivity related to gender, in the mesopic and scotopic tests, and that it decreases with age.

ABSTRACT BODY:

Purpose: To investigate the frequency of myocilin (MYOC) mutations in patients diagnosed with Primary Open Angle Glaucoma (POAG) from a West Yorkshire clinic.

Methods: Patients were diagnosed with POAG by an experienced ophthalmologist. Genomic DNA was extracted from peripheral blood. PCR and direct Sanger Sequencing was used to analyse the coding exons and splice recognition sites of the MYOC gene. The frequency of the variants in the general population was investigated using the gnomAD database and their pathogenicity assessed using prediction programs PolyPhen2, SIFT, PROVEAN, CADD, BLOSUM62, MutationTaster and Human Splicing Finder.

Results: 12 out of 219 patients (5%) analysed had a MYOC mutation that was predicted to be pathogenic and could possibly account for their disease phenotype. The patients between them had 8 MYOC mutations including a novel frameshift (p.Lys484Argfs), previously identified nonsense (p.Gln368Stop) and non-synonymous (p.Glu352Lys, p.Lys398Arg and p.Thr419Ala) mutations as well as synonymous variants (p.Thr204Thr, p.Thr285Thr and p.Glu396Glu) that are predicted to affect splicing.

Conclusions: MYOC mutations are likely to account for 5% of the POAG cohort studied, which is consistent with findings in previously published studies. This leaves an enriched cohort of cases for systematic screening of the other known genes that cause POAG.

TITLE: Biomechanical effects of Scleral crosslinking using Rose Bengal/Green-light and Rivoflavin/UVA

SESSION TITLE: Molecular and Structural

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Villegas, J. Germann, S. Marcos, Instituto de Optica Daza de Valdes, Madrid, Comunidad de Madrid, SPAIN|

Commercial Relationships Disclosure (Abstract): Lupe Villegas: Commercial Relationship: Code N (No Commercial Relationship) | James Germann: Commercial Relationship: Code N (No Commercial Relationship) | Susana Marcos: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Scleral collagen crosslinking (SXL) has been proposed as a therapeutic treatment for prevention of progressive myopia. In this study, we compare the effects of Rose Bengal-Green Light (RGX) and Rivoflavin-UVA (UVX) crosslinking in scleral stiffening through a hydration-stiffness correlation.

Methods: 35 eyes from adult New Zealand white rabbits (2.5-3.5 kg) were treated with either RGX (523nm 0.25W/cm², 400s) or UVX (370nm, 3mW/cm², 30min). Posterior nasal (NR) and temporal (TR) regions were crosslinked (24-48h post-mortem). One side of the globe was SXL and the other kept as control. Strips (3mmx20mm) were extracted and brought under hydration-tensile and tensile tests. In hydration-tensile tests, strips from control and treated regions were dehydrated (24h, room temperature), re-hydrated using 10uL/min phosphate-buffered saline solution (PBS) and mounted in a uniaxial stretcher (CellScale, Canada). In tensile tests, samples were mounted after extraction. Part of the specimens were immersed in PBS (n=54) and the rest kept in air (n=24) while subjected to a stress-recover test. The Young's modulus (YM) was calculated between 0% and 12% strain and stress-strain curves were plotted as a derivative marker for SXL strength. T-test was used to test treatment and hydration-induced differences in scleral biomechanics.

Results: RGX and UVX produced an increase in stiffness (115% and 296% (TR), respectively) compared with untreated sclera. At 8% strain, the YM of UVX samples was significantly higher than the untreated ones (16.11±0.94 vs 3.36±0.69MPa (TR), and 15.76±1.28 vs 3.15±0.49MPa (NR) P<0.001), and significantly higher than RGX samples (7.24±0.70MPa (TR) and 10.44±0.96MPa (NR) P<0.001). Tensile behavior is influenced by PBS immersion during the mechanical test. Control samples processed in air were twice (TR) and 1.5 times (NR) stiffer than ones in PBS (P<0.05). Hydration and stiffness are inversely correlated in TR (r=-0.6, P< 0.05) and directly correlated in NR (r=0.7, P< 0.05) for untreated and treated samples.

Conclusions: Posterior scleral stiffening with RGX and UVX treatment in rabbit is affected by a combination of treatment, region, and hydration. These results provide a method for in vivo studies to determine the efficacy of SXL-induced stiffening to help treat myopia.

ABSTRACT BODY:

Purpose: To investigate predictors of retinal pigment epithelium (RPE) tear development after anti-vascular endothelial growth factor (VEGF) therapy or photodynamic therapy (PDT) for neovascular age-related macular degeneration (AMD) using swept source optical coherence tomography angiography (SS-OCTA)

Methods: This prospective, observational study included treatment-naïve eyes with neovascular AMD in consecutive patients who were followed for 1 year after receiving the initial treatment at Kyoto University Hospital between June 2017 and June 2019 and who underwent SS-OCTA examinations (PLEX Elite 9000, Dublin, California) prior to the treatment. Eligible eyes were classified into eyes with or without RPE tear development during 1-year observation period. They were matched for 1:2 ratio using propensity scores. The area of choroidal neovascularization (CNV) and RPE detachment (PED) were measured from OCTA and optical coherence tomography (OCT) en face images, respectively. Specific OCTA-derived parameters, which represent vessel caliber and complexity of CNV, were also analyzed.

Results: In 8 of 164 eyes (4.9%), RPE tear developed (RPE tear group). After matching, 16 eyes without RPE tear were analyzed (no RPE tear group). The ratio of CNV/PED area was significantly lower in the RPE tear group than in the no RPE tear group (0.24 ± 0.13 vs. 0.52 ± 0.26 , $P = 0.01$). The PED area was broader (9.07 ± 5.79 mm² vs. 4.29 ± 5.47 mm², $P = 0.01$), and PED height was greater in the RPE tear group (413.6 ± 224.4 μm vs. 231.8 ± 218.3 μm, $P = 0.02$). There were no significant differences in specific OCTA-derived parameters between the two groups.

Conclusions: Neovascular AMD with pre-treatment broad PED, high PED, and small CNV area relative to PED area may have a high risk of RPE tear development after the therapy. Vessel caliber or complexity of CNV may not be associated with RPE tear development.

ABSTRACT BODY:

Purpose: Nonarteritic anterior ischemic optic neuropathy (NAION) is the most common acute optic neuropathy in those older than 50. There is no blood diagnostic test or effective treatment for NAION, and the etiology for progression of vision loss in some patients remains unclear. We investigated the suitability of blood inflammatory proteins as biomarkers and potential therapeutic targets of NAION.

Methods: We conducted a prospective case-control study including 18 patients with NAION (n=5 acute, n=13 chronic) and 9 age-matched controls. NAION was confirmed by clinical exam and optical coherence tomography. Subjects underwent peripheral blood collection; plasma was isolated within 2h and analyzed using a 76-plex array of cytokines, chemokines and growth factors.

Results: In acute NAION, there was increased peripapillary retinal thickness on optical coherence tomography consistent with optic disc edema. Plasma profiling revealed significant changes of the levels of 20 inflammatory proteins in NAION. Analysis of these 20 proteins using principal component analysis (PCA), hierarchical clustering and Spearman correlation generally segregated controls and NAION. In acute NAION, Eotaxin-3, MCP-2, TPO and TRAIL were the top biomarker candidates. In chronic NAION, out of 10 top-ranked molecules, IL-1a and CXCL10 emerged as the strongest therapeutic targets. Statistical analysis of the 20 top-ranked molecules in NAION revealed that there was only 15% overlap in acute and chronic NAION. Longitudinal data from one patient demonstrated an evolving inflammatory pattern from acute to chronic NAION matching that of the PCA.

Conclusions: Profiling of 76 immune molecules in plasma of NAION patients revealed significant inflammation in acute NAION. Surprisingly, there was even more inflammation in chronic NAION, which may be related to neurodegeneration. Of the 20 significantly changed molecules, there was little overlap between the acute and chronic NAION groups, so a larger study to better delineate immune changes over time in the same NAION patients can help elucidate potential therapeutic targets for treatment of patients with visual deterioration.

TITLE: Long-term incidence and risk factors for Atrophy in Acquired Vitelliform Lesions (AVL)

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Chandra, S. Sivaprasad, National Institute of Health Research Moorfields Biomedical Research Centre, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|S. Chandra, S. Gurudas, S. Sivaprasad, University College London Institute of Ophthalmology, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Shruti Chandra: Commercial Relationship: Code N (No Commercial Relationship) | Sarega Gurudas: Commercial Relationship: Code N (No Commercial Relationship) | Sobha Sivaprasad: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: AVL are infrequent manifestations of multiple disorders with undetermined risk for progression to advanced disease. We performed a retrospective, observational clinical study to determine the time to atrophy and baseline predictors for atrophy in eyes with AVL.

Methods: Both eyes of consecutive patients registered between Jan 2009 to Jan 2014 with diagnosis of AVL confirmed by multimodal imaging and minimum follow-up of 5 years were included. AVL secondary to cuticular drusen, tractional maculopathy, paraneoplastic, infectious, and inflammatory pathologies were excluded. Serial optical coherence tomography (OCT) scans and fundus autofluorescence were graded and analysed. Main outcome measure was time to the first OCT evidence of MA stratified by presenting visual acuity (VA) and AVL lesion subtypes. Secondary outcome included risk factors for incident MA. Turnbull's estimator was employed, and time censored at 5 years. Multivariable Weibull parametric proportional hazards models was used to assess association of risk factors with MA, following adjustment for baseline lesion type. Hazard ratios were reported with 95% CI's.

Results: Total 188 eyes (100 patients) met the inclusion criteria. A further 19 eyes were excluded due to atrophy or choroidal neovascularization at baseline. Incident MA was detected in 35/169 (20.7%) eyes by 5 years. Stratified by baseline VA, 42.9% eyes with VA \leq 54 letters developed atrophy within 2 years and 78.6% within 5 years of first diagnosis by multimodal imaging. In contrast, only 26.9% and 8.6% eyes with VA 55-70 and >70 letters developed atrophy by 5 years, respectively. For eyes in pseudohypopyon and vitelliruptive stage, 35.9% and 36% eyes developed MA by 5 years. In adjusted analysis, baseline factors associated with increased risk of atrophy included VA ≤ 70 letters (HR 4.87; 95% CI 1.82-13.04), log-maximum lesion area (HR 4.59; 95% CI 2.53-8.34), presence of subretinal drusenoid deposit (HR 2.71; 95% CI 1.16 -6.32) and disrupted external limiting membrane (HR 2.34; 95% CI 1.07-5.10).

Conclusions: Baseline VA ≤ 70 letters attributes higher risk for atrophy and VA ≤ 54 accelerates time to incident MA. Baseline presence of SDD, disrupted ELM and larger lesion area led to higher risk of MA. These results provide prognostic indicators for MA in patients with AVL.

TITLE: The Genetic Testing Landscape in Europe 2020

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Galvin, P. Stratieva, A. Daly, Retina International, IRELAND|

Commercial Relationships Disclosure (Abstract): Orla Galvin: Commercial Relationship(s);The Allergan Foundation:Code F (Financial Support) | Petia Stratieva: Commercial Relationship(s);The Allergan Foundation:Code F (Financial Support) | Avril Daly: Commercial Relationship(s);The Allergan Foundation:Code F (Financial Support)

ABSTRACT BODY:

Purpose:

While potential treatments are emerging for Inherited Retinal Diseases (IRDs), the genetic characteristics of IRDs mean a genetic diagnosis is a prerequisite for inclusion in clinical trials. For many however, treatment options are only one element. Patients are very concerned about inheritance patterns, and disease progression, and can take action on these points. Yet, there are a number of barriers to accessing genetic testing services for IRDs which can vary from region to region. To advocate effectively for equitable, affordable, accessible and timely genetic testing for IRDs it was first necessary to investigate the genetic testing landscape from a processes and systems perspective.

Methods: A dual approach of desktop research supplemented by a survey of ophthalmic and/or genetic specialists across 18 countries was employed. A survey was conducted in an interview style via zoom. Information was provided by: Medical Geneticists, Clinical Laboratory Geneticists, Ophthalmologists/Retinal Specialists – Clinical Researchers.

Results: Genetic services (testing and counselling) for IRDs vary substantially among countries from an awareness, accessibility and affordability perspective. Methods of genetic testing vary and can include cerebral MRI, Sanger sequencing or Next Generation Sequencing, Whole Exome Sequencing or Whole Genome Sequencing and for some genes SNP array or MLPA. Affordability is a barrier for patients in countries without any payment scheme (e.g., Poland) and in countries where only a targeted population is covered (e.g., Bulgaria). Where genetic testing is not covered by healthcare systems or insurance, participation of research projects is in some regions an alternative, however usually the number of patients who could benefit is limited, with patients often advised to send their samples for examination abroad, or travel themselves for full examination outside their country of origin.

Conclusions: There is huge disparity in the approach to genetic testing for IRDs. Greater awareness of genetic testing services is required among the health sector as a whole, and among the eye care professional community. A revised approach to the provision of genetic testing services is required to ensure equitable access and reimbursement, which will empower patients through knowledge, aid discovery, improve access to clinical trials, expedite innovation, improve access to therapy and the delivery of care.

TITLE: Investigating the metabolic effects of basal mineral calcification on human RPE cell culture

SESSION TITLE: Metabolism of the RPE and retina

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C.N. Brown, E. Emri, I. Lengyel, Queen's University Belfast School of Medicine Dentistry and Biomedical Sciences, Belfast, Belfast, UNITED KINGDOM|E. Emri, Roche Diagnostics International AG, Rotkreuz, Zug, SWITZERLAND|

Commercial Relationships Disclosure (Abstract): Connor Brown: Commercial Relationship: Code N (No Commercial Relationship) | Eszter Emri: Commercial Relationship(s);Roche:Code E (Employment) | Imre Lengyel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Calcification is increasingly becoming recognized as an important contributor to the clinical appearance of age-related macular degeneration (AMD). In this study, we studied the effects of various calcium minerals on human retinal pigment epithelial (RPE) cell.

Methods: Human RPE cells (hRPE; 85,000 or 125,000 cells/cm² seeding density) were cultured in the presence or absence of 25 µg/cm² hydroxyapatite (HAP) or whitlockite (WHT), embedded in the Geltrex coating of 0.33cm² Transwell membrane inserts, and were maintained in culture for up to 4 weeks. Cell phenotype was assessed by qualitative monitoring of cell pigmentation and measuring trans-epithelial electrical resistance (TEER). Metabolic alterations were assessed using the Seahorse XF Cell Energy Phenotyping Kit to determine the mitochondrial (oxygen consumption rate (OCR)) and glycolytic (extracellular acidification rate (ECAR)) respiratory capacity of the hRPE cells.

Results: Based on visual assessment of pigmentation, control cells began to differentiate earlier than cells cultured on any of the seeded minerals (2 vs 3 weeks, respectively). TEER for HAP and WHT was significantly lower than that of control cells at both 2 weeks and 4 weeks (45.7±0.9 and 49.6±0.8; 44.6±1.6 and 46.9±0.4 vs 53.1±0.9 and 63.5±2.7 Ω*cm², respectively; p<0.05). Cells cultured on HAP and WHT had significantly higher ECAR values at baseline compared to control cells at 2 and 4 weeks (36.6±3.6 and 39.4±2.1; 35.4±2.3 and 36.9±1.8; vs 24.9±1.7 and 28.7±1.1 mpH/min/10,000 cells, respectively; p<0.05). After stress induction the cells grown on HAP and WHT had significantly lower OCR values compared to control cells, at 4 weeks only (219.0±22.2; 203.3±11.6 vs 299.2±9.2 pmol/min/10,000 cells, respectively; p < 0.05) with no significant difference observed at 2 weeks.

Conclusions: When sub-RPE minerals are present, the RPE appears to utilise the glycolytic respiratory pathway under resting conditions, and continues to do so after differentiation is initiated. Cells grown in the presence of calcium-phosphate minerals also show reduced mitochondrial respiration under stress compared to cells grown naturally, but only after differentiation appears to have started. These indicate that the mitochondrial respiration pathway is detrimentally affected by the presence of calcification in vivo, which is consistent with the notion that mitochondrial changes are involved in AMD.

ABSTRACT BODY:

Purpose: Myopia is a growing global ophthalmological concern. One preventative treatment of myopia under development is scleral cross-linking (SXL), where the posterior sclera is stiffened to retard axial length growth. The optimal location and microscopic effects of SXL are still under investigation.

Methods: A total of 18 freshly enucleated rabbit eyes were treated ex vivo with one of two treatments on either the nasal (N) or temporal (T) posterior sclera: (1) Rose Bengal/green irradiation (RGX, 0.25 W/cm^2 , 6.6 min 532nm irradiation, 2.5 min installation) (N, n=6; T, n=6); (2) Riboflavin/UVA irradiation (UVX, 3 mW/cm^2 , 30 min 370nm irradiation, 1 hr installation) (N, n=3; T, n=3). The untreated N or T side of the globe was used as a control. After treatment, scleral pieces ($1.25 \text{ cm} \times 2.5 \text{ cm}$) were extracted from the globe and optically cleared with Murray's clear (1:2 Benzyl Alcohol-Benzyl Benzoate mix). Images were taken of the collagen fibers through the depth of the tissue ($150 \mu\text{m} \times 150 \mu\text{m}$ en face, 250-300 μm depth) with a custom-built, second harmonic generation microscope and analyzed with an order coefficient (OC), which quantized how uniform the direction of the fibers was (1 for uniform direction and 0 for even distribution).

Results: The average OC values were 0.400 ± 0.008 (N) and 0.413 ± 0.007 (T) in untreated tissue, 0.421 ± 0.007 (N) and 0.407 ± 0.014 (T) in RGX-treated tissue and 0.417 ± 0.012 (N) and 0.422 ± 0.010 (T) in UVX-treated tissue. On average, in untreated sclera, OC was 3.2% larger in the temporal than in the nasal side ($p < 0.01$, student t-test). In the nasal sclera, RGX and UVX treatments produced a statistically significant increase in OC ($p < 0.01$), by 5.1% and 3.9% respectively ($p < 0.01$, t-test) and in the temporal sclera, RGX decreased OC by 1.5% and UVX increased by 2.2% ($p < 0.05$, t-test), compared to untreated tissue. UVX produced a significantly larger increase in OC than RGX (by 3.4%, $p < 0.05$) on the temporal side ($p < 0.05$, t-test), but there were no significant differences between UVX and RGX treatments on the nasal side.

Conclusions: Scleral collagen organization varies geographically, with the posterior temporal sclera exhibiting higher order than the nasal sclera. Both RGX and UVX SXL treatments further significantly increased collagen order in the temporal sclera, but not consistently in the nasal sclera. These findings indicate that selecting the treatment area may be critical to optimize the efficiency of SXL.

TITLE: Sustained hyperglycemia impairs corneal re-epithelialization after alkaline injury through modulation of the ocular surface, systemic Immunity and intestinal microbiome

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Bu, Y. Chan, A.C. Lo, K.C. Shih, The University of Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): Yashan Bu: Commercial Relationship: Code N (No Commercial Relationship) | Yau Kei Chan: Commercial Relationship: Code N (No Commercial Relationship) | Amy Lo: Commercial Relationship: Code N (No Commercial Relationship) | Kendrick Shih: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

- 1) To compare corneal re-epithelialization rates, ocular surface and systemic immune response after corneal alkali burn injury between Akita (diabetic) and wild type (WT) mice.
- 2) To compare gut microbial diversity patterns between diabetic and WT mice at baseline and 72 hours after alkaline burn injury and to correlate this with ocular surface findings.

Methods: Heterozygous $Ins2^{Akita}$ mice were used as a mouse model of Type I diabetes, with WT C57Bl6/J mice serving as controls. Alkaline burn injury was induced on the right eye of mice under general anesthesia. The cornea was examined with slit lamp with fluorescein stain under cobalt blue light. Tear samples were collected using Schirmer's strip paper to determine ocular surface cytokine secretion by protein microarray assay. T cell profile on the ocular surface, in the peripheral blood and intestine were analyzed by flow cytometry. Intestinal microbiome diversity pattern was characterized using shot gun sequencing technique.

Results: Sustained hyperglycemia was associated with prolonged corneal wound healing after cornea alkali burn injury. Furthermore, diabetic mice had significantly lower tear angiopoietin-2(Ang-2), insulin growth factor-1(IGF-1) and vascular endothelial growth factor A (VEGF-A) levels after injury compared to controls. In the peripheral blood, significantly elevated levels of CD4+ T cells was seen in WT mice at day 3 after injury, but not in Akita mice.

Meanwhile, significantly higher levels immature CD4+CD8+ T cells were found on the ocular surface of Akita mice compared to controls after injury. Regarding microbial diversity, Akita mice were found to have higher abundance of microbiota composition as compared to WT mice from the CHAO1 index of alpha diversity at day 3 after the injury.

Conclusions: Diabetic mice have shown significantly impaired corneal wound healing response after injury compared to controls. This is associated with the altered ocular surface immunity in diabetic mice. Baseline and post-injury differences in intestinal microbiome composition and diversity may play a role in the altered immune response in diabetes. The presence of systemic chronic inflammation and immature T cell population on the ocular surface of diabetic mice may lead to attenuated post-injury T cell response in diabetic mice.

TITLE: T148 Phosphorylation on α A-crystallin Controls Functional and Structural Biochemical Properties

SESSION TITLE: Genetics, (gen)omics, systems and computational biology in ocular health and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z.B. Sluzala, P.E. Fort, Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, Michigan, UNITED STATES|Z.B. Sluzala, P.E. Fort, Neuroscience Graduate Program, University of Michigan, Ann Arbor, Michigan, UNITED STATES|A. Phadte, Thomas Jefferson University, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zachary Sluzala: Commercial Relationship: Code N (No Commercial Relationship) | Ashutosh Phadte: Commercial Relationship: Code N (No Commercial Relationship) | Patrice Fort: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Earlier studies from our lab have shown that the molecular chaperone protein α A-crystallin demonstrates neuroprotective properties that are regulated by S/T148 phosphorylation. While this phosphorylation has been implicated in the anti-apoptotic activity of α A-crystallin, its influence on the structural and functional biochemistry of the protein remains unclear. The present study sought to characterize the effects of S/T148 phosphorylation on the biochemical properties of α A-crystallin, with emphasis on its solubility, oligomeric structure, and chaperone function.

Methods: Differentiated R28 retinal neurons were transfected with plasmids encoding expression of either Wild-type (WT), phosphomimetic (148D), or non-phosphorylatable (148A) mutants of α A-crystallin. Protein solubility was then assessed under normal or metabolic stress (serum starvation) conditions using the triton solubility method. Additionally, purified recombinant α A-crystallin proteins (WT, 148D, and 148A) were used to assess the impact of the phosphorylation on the oligomerization and chaperone function using Native gel electrophoresis and chaperone activity assays.

Results: Protein solubility was measured as a ratio of insoluble α A-crystallin relative to the total content for each construct and condition, and normalized to WT. While no differences were observed under normal and short metabolic stress conditions, longer stress duration revealed differences in solubility, with 148A becoming dramatically more insoluble than 148D ($p < 0.01$, $n = 6$), and 148D becoming slightly (though not significantly) more soluble than WT α A-crystallin. Consistent with changes in solubility, analysis of the recombinant proteins using native gel analysis revealed a shift towards smaller-size oligomers for the 148D mutant, and towards larger-size oligomers for the 148A mutant respectively. Chaperone function analysis of the recombinant proteins also confirmed a significantly increased chaperone activity of the phosphomimetic mutant compared to the WT and non-phosphorylatable mutant ($IC_{50} = 4.4 \mu g$ (148D) vs $8 \mu g$ (WT) and $7.1 \mu g$ (148A)).

Conclusions: The results of this study strongly support a critical role for T148 phosphorylation on the structural and functional biochemistry of α A-crystallin, shedding light on the mechanisms of regulation of the anti-apoptotic role of α A-crystallin.

Nickerson, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|J.H. Boatright, Atlanta VA Center for Visual & Neurocognitive Rehabilitation, Decatur, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Vivian Summers: Commercial Relationship: Code N (No Commercial Relationship) | Salma Ferdous: Commercial Relationship: Code N (No Commercial Relationship) | Kristie Liao: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Donaldson: Commercial Relationship: Code N (No Commercial Relationship) | Isabelle Gefke: Commercial Relationship: Code N (No Commercial Relationship) | Yong-Kyu Kim: Commercial Relationship: Code N (No Commercial Relationship) | Debresha Shelton: Commercial Relationship: Code N (No Commercial Relationship) | Jana Sellers: Commercial Relationship: Code N (No Commercial Relationship) | Shanu Markand: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Boatright: Commercial Relationship: Code N (No Commercial Relationship) | John Nickerson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age is usually examined in a young versus old group in research. We looked at the gradual changes of retinal pigmented epithelium (RPE) over time in wild type C57/BL6J mice to examine when changes take place. The goal of this is to expand upon established knowledge of aging effects on the RPE.

Methods: We looked at both male and female wildtype C57/BL6J mice. They were split up into four groups: G1 (<0.5 years), G2 (1.0 – 1.5 years), G3 (1.5 – 2.0 years), G4 (>2.0 years). We used electroretinogram (ERG) to collect c-wave data which looks at the visual function of the RPE. We also hand counted the number of Ionized calcium binding adaptor molecule 1 (IBA-1) in concentric circles that divided the flatmount into five zones. Imaris was used to determine the amount of alpha catenin within cells to be used as an indicator of change across the groups. We looked at the number of total nuclei across groups. All results were analyzed by using one or two-way ANOVAs with Tukey's posthoc test, n's were between 3-10.

Results: The data that we have analyzed show that there is an increase in the number of IBA-1 cells between groups 1 and 4 in the two outermost zones. There was also an increase in the number of IBA-1 cells across all groups from our most central zones to our most outer zones. There were no significant increases in the total number of IBA-1 positive cells across groups. Cytosolic alpha-catenin increased between groups 1 and 4, and groups 3 and 4. Total number of nuclei in RPE cells, and RPE morphometrics, and c-wave data were not significantly different.

Conclusions: The lack of statistical difference in c-wave data between groups 1 through 3 would be indicative that the RPE visual function does not change with age. While we don't see an increase in the total number of IBA-1 positive cells with age, we do see an increase in the number of IBA-1 positive cells with age in the outer zones of the flatmount. This could be indicative of where these cells where damage is occurring. The change in the outermost zones could be indicative of where the RPE begins to break down first with age. The cytosolic alpha-catenin increased between groups 1 and 4, and groups 3 and 4. Alpha catenin in the cytosol could be attributed to the breakdown of RPE-cell borders with age. Total number of nuclei in RPE cells, and RPE morphometrics show cells remain relatively unchanged with age.

TITLE: Mechanical analysis of an ocular globe, a required complexity during inflation test?

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. ISSARTI, C. Koppen, J.J. Rozema, Department of Ophthalmology, Antwerp University Hospital, Antwerp, BELGIUM|I. ISSARTI, C. Koppen, J.J. Rozema, Antwerp University Faculty of Medicine and Health Sciences, Antwerp, BELGIUM|

Commercial Relationships Disclosure (Abstract): IKRAM ISSARTI: Commercial Relationship: Code N (No Commercial Relationship) | Carina Koppen: Commercial Relationship: Code N (No Commercial Relationship) | Jos Rozema: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the effect of varying the structure of biomechanical models on corneal deformation under progressing intraocular pressure (IOP).

Methods: A 3-D finite element model of an ocular globe was implemented to evaluate corneal deformation under various mechanical conditions during inflation testing. The eye model includes the cornea, limbus, sclera, iris, lens, muscles, anterior chamber and vitreous. The Ogden hyper-elastic model ($\mu=0.458$ kPa, $\alpha=136.14$) was suggested for the corneo-limbal structure, the Yeoh isotropic ($C_1=0.81$, $C_2=56.05$, $C_3=2332.26$ (MPa)) model for the sclera, the anterior chamber was modeled as a fluid cavity with progressing pressure [0-25 mmHg], while other eye components were incorporated as linear elastic material, each with different density and viscosity. This study investigates the interplay between several cases, including: Case 0 : restrained limbus; Case 1: unrestrained limbus with restrained sclera, Case 2 (Reference): unrestrained limbus and restrained sclera; Case 3: unrestrained limbus with restrained posterior sclera and free anterior sclera; Case 4: unrestrained limbus with restrained anterior sclera and free posterior pole; Case 5: effect of anterior chamber; Case 6: effect of vitreous; Case 7: effect of anterior chamber and vitreous; Case 8: effect of iris; Case 9: effect of Lens; Case 10: effect of muscle.

Results: The maximum apical displacement and maximum stress under IOP=15 mmHg was 0.22 mm, 0.013 MPa, the cornea underwent an increased stiffness above IOP>7 mmHg (Figure 1.a, Figure 2.a)). Cases 1,2 & 4 resulted in nearly similar displacements, with a slight increase when the limbus is unrestrained. Case 3 leads to reduced stiffness (25%), with increased displacement. Adding individual eye components (Cases 5-7), results were nearly similar to the reference. The presence of the iris slightly decreases the displacement, but leads to higher stress on corneal periphery. Meanwhile, the contribution of the muscles and lens together cannot be neglected as it reduces the corneal displacement with 50% (Figure 1.c-d, Figure 2.b)).

Conclusions: As the lens, iris and muscles each provide major contributions to the corneal deformation model, it is highly recommended to account for such internal eye contributions during ex vivo experiments.

ABSTRACT BODY:

Purpose: Corneal endothelial dysfunction leads to visual impairment and a requirement for corneal endothelial transplant. There is a worldwide donor cornea shortage, so biosynthetic graft alternatives are being developed using in vitro expanded corneal endothelial cells. Our poly-ε-lysine (pεK) hydrogel is highly tunable and its properties can be controlled by the nature and percentage of the cross-links and the density of the peptide to produce a panel of hydrogels with different properties. We have chosen a hydrogel with excellent optical and mechanical properties for this application and here we investigate the functionality of the biosynthetic graft using porcine corneal endothelial cells in a rabbit model of endothelial damage.

Methods: Hydrogels were synthesised from pεK crosslinked 60% with nonanedioic acid and then punched into 8mm circles. Gels were seeded with primary porcine corneal endothelial cells at a density of 1×10^5 cells/gel and cultured for 3 weeks. Immunocytochemical staining (ZO-1 and Na+K+ATPase) was performed to assess the phenotype of cells on gels. PεK hydrogels (+ and – cells) were transplanted into the right eyes of New Zealand white rabbits with Descemet's membrane and endothelial layer removed. A group with no gel acted as control. Optical coherence tomography (OCT) imaging and pachymetry was used to measure corneal thickness for the experimental period (3 weeks). Photographs of rabbit corneas were taken to assess corneal clarity and eyes were dissected for histological analysis.

Results: Porcine corneal endothelial cells adhered to the pεK hydrogels and formed monolayers expressing ZO-1 and Na+K+ATPase. OCT imaging showed control unoperated corneas had a mean thickness of 399.5mm (SD27.6) and the corneas with Descemet's membrane and endothelial layer removed (no gel) had a mean thickness of 1052mm (SD77.1). Corneas with attached gels (no cells) were 583.5mm (SD 251.0) and attached gels with cells were 451mm (SD37.4).

Conclusions: Cellular pεK grafts show good cell compatibility, handleability and are able to function to thin the cornea to near control levels after 3 weeks in a rabbit in vivo model of endothelial damage.

ABSTRACT BODY:

Purpose: Genomic studies of our Australian retinal dystrophy cohort are providing molecular diagnoses in >60% of families examined. However, curation can often be challenging when assessing novel variants. This is especially relevant where there are strict inclusion criteria for gene therapy, such as voretigene neparvovec recently approved for use in Australia for retinal dystrophy due to RPE65 mutations. Patient-derived iPSC-RPE cells provide a valuable resource for investigation of genes with retinal-specific expression. This study investigates the pathogenicity of a novel RPE65 synonymous variant detected in trans with a previously reported pathogenic variant on clinical genomic testing in two affected siblings with early onset retinal degeneration.

Methods: iPSC cells were generated from the peripheral blood of a carrier of the RPE65 synonymous variant, and cells were differentiated to RPE. Pluripotency and RPE differentiation were examined with gene expression markers using qRT-PCR (ThermoFisher, USA) and immunohistochemistry. Minigene studies were performed with cloning of the genomic region of interest into a p.ExonTrap vector (MoBiTec, Germany), before transfection into HEK293 cells. RNA was extracted from iPSC-RPE cells and transfected HEK293 cells, and RT-PCR and Sanger sequencing were performed to investigate aberrant transcripts.

Results: Analysis of iPSC and subsequent RPE lines showed gene expression consistent with pluripotency and presence of RPE-specific markers respectively. Studies of iPSCs using SNP microarrays confirmed genomic stability. Analysis of RNA from both patient-derived iPSC-RPE and minigene studies demonstrated exon skipping from the RPE65 transcript, resulting in a mutant RPE65 allele of only 22 amino acids. There was concomitant reduction in RPE65 expression.

Conclusions: Modelling of the RPE65 synonymous variant in both iPSC-RPE and minigene assays demonstrated a RPE65 loss of function allele. These findings facilitate the reclassification of the novel synonymous variant from a variant of uncertain significance to a likely pathogenic variant, in turn providing eligibility for access to voretigene neparvovec gene therapy. This study demonstrates the importance of synergistic stem cell research and diagnostic genomics, especially in the era of gene therapies.

TITLE: Biofeedback fixation training in amblyopia

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.T. Barboni, O.A. Maneschg, Z.Z. Nagy, J. Németh, Ophthalmology, Semmelweis Egyetem, Budapest, HUNGARY|M.T. Barboni, O.A. Maneschg, J. Németh, Bionic Innovation Center, Budapest, HUNGARY|

Commercial Relationships Disclosure (Abstract): Mirella Barboni: Commercial Relationship: Code N (No Commercial Relationship) | Otto Maneschg: Commercial Relationship: Code N (No Commercial Relationship) | Zoltán Nagy: Commercial Relationship: Code N (No Commercial Relationship) | János Németh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patients with strabismic amblyopia referred to surgical treatment of strabismus often show disturbed visual fixation. The purpose of the present study was to investigate fixation stability before and after surgical treatment of strabismus and the effects of biofeedback fixation training on fixation stability of amblyopic adult eyes.

Methods: Participants were 12 patients with strabismus (mean age = 29.6 ± 8.5 years; 6 females) and 12 healthy volunteers (mean age = 23.8 ± 1.5 years; 9 females). The protocol included ophthalmological and microperimetric follow-ups. Biofeedback fixation training (MAIA; CenterVue, Padova, Italy) was delivered monocularly to the amblyopic eye once per week for six months. Trained retinal locus was selected as either the spontaneous preferential retinal locus or as a fixation point closer to the anatomical fovea after the surgical treatment of strabismus. Group differences were evaluated using ANOVA. Paired comparisons between amblyopic, fellow, and control eyes were performed using Bonferroni post-hoc analyses.

Results: Baseline measurements showed significantly altered fixation stability ($p < 0.001$) in amblyopic eyes compared to control eyes. Fixation stability did not significantly change after the surgical treatment of strabismus ($p = 0.622$). On the contrast, biofeedback fixation training applied to operated amblyopic eyes resulted in more stable fixation for all four subjects trained so far with 50% of average improvement.

Conclusions: Fixation stability is impaired in amblyopic adult eyes, also after the surgical treatment of strabismus. The present report highlights the beneficial use of biofeedback fixation training as a therapeutic option to improve fixation stability in amblyopic eyes after the surgical treatment of strabismus. Alternatively, this method could be associated with standardized treatments to improve monocular and binocular vision in patients with amblyopia as an attempt to enhance the treatment effect.

TITLE: Distortion-corrected retinal curvature using a Fourier domain mode locking (FDML) laser ultrawide-field optical coherence tomography (OCT)

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Tan, F. Zheng, J. Chua, L. Schmetterer, Singapore Eye Research Institute, Singapore, SINGAPORE|R.P. McNabb, A.N. Kuo, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Bingyao Tan: Commercial Relationship: Code N (No Commercial Relationship) | Ryan McNabb: Commercial Relationship: Code N (No Commercial Relationship) | Fei Hui Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Chua: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Kuo: Commercial Relationship: Code N (No Commercial Relationship) | Leopold Schmetterer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To measure the distortion-corrected retinal curvature with a ultrawide-field OCT system using an ultrafast Fourier domain mode locking (FDML) laser.

Methods: An ultrafast swept-source OCT system (OptoRes, Germany) using a 1.6MHz FDML laser (central wavelength: 1060nm) was used for dense imaging of an ultrawide field of view (FOV, ~65 degree) of the posterior eye. The imaging FOV was calibrated with a custom-built phantom eye. A total of 13 eyes from 11 healthy volunteers, with spherical equivalent (SE) refraction from -1D to -7D, and axial length (AL) from 23.1 mm to 26.8 mm, were imaged thrice without mydriasis. Retinal pigment epithelium (RPE) was segmented automatically using MATLAB. Ocular biometrics, including AL, central corneal thickness and corneal curvature were acquired with the IOL Master700. Ocular biometrics and system parameters were fed into a ray tracing algorithm using ZEMAX and MATLAB, for correction of the optical and display distortions and mapping the RPE segmentation into spatial location. The radius of curvature (Rc) of the retina was calculated by finding the best sphere fit to the corrected RPE.

Results: The mean \pm standard deviation (SD) of Rc in 13 eyes was 12.86 ± 0.19 mm. A high repeatability was obtained for Rc measurements (intraclass correlation coefficient, ICC = 0.96). Rc was correlated with the AL ($r = -0.389$), but not correlated with the SE ($r = -0.015$) (Figure 1). Figure 2 shows the original RPE elevation maps and their corrected retinal shapes in eyes with mild (SE=-2.25D) and moderate (SE=-4.25D) myopia.

Conclusions: The distortion-corrected measurements of Rc using an ultra-fast widefield OCT can provide the true retinal curvature with high repeatability. This suggests that wide-field OCT may be used to monitor retinal curvature changes in myopia over time.

Commercial Relationships Disclosure (Abstract): Huibert Simonsz: Commercial Relationship: Code N (No Commercial Relationship) | Hans Hoeve: Commercial Relationship: Code N (No Commercial Relationship) | Eveline Heijnsdijk: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kik: Commercial Relationship: Code N (No Commercial Relationship) | Anna Horwood: Commercial Relationship: Code N (No Commercial Relationship) | Inger Úhlen: Commercial Relationship: Code N (No Commercial Relationship) | Gwen Carr: Commercial Relationship: Code N (No Commercial Relationship) | Mandy Nordmann: Commercial Relationship: Code N (No Commercial Relationship) | Harry de Koning: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vision screening programs vary in organization, location, screening tests, screening professionals, referral criteria and coverage, which makes comparison of their cost-effectiveness difficult. We develop a web-based application that calculates their cost-effectiveness.

Methods: The EUSCREEN APP at www.euscreen.org simulates the path followed by a child within a vision screening program consisting of several screening steps. Users enter demographic data like birth figures, tests used, screening location, screening professionals etc. The model simulates this screening program and calculates the number of tests, number of referrals to diagnostics, number of cases detected, costs of screening until referral, costs of diagnostic assessment, total costs, costs per test and costs per case detected. Then the user adjusts variables to see what effect a change of age of screening, screening test, number of screening steps, screening professional etcetera has.

Results: The accuracy of the prediction depends upon the quality of the input data. Notably, the sensitivity and specificity of a screening test at a specific age, performed by a given professional with a given training and a given experience are difficult to estimate and are the most critical component of the model. Costs of screening, diagnostic assessment and treatment are calculated from salaries, overhead, visual acuity charts and other material, housing etc. Combination of vision screening with other screening or with school attendance reduces cost components. Photorefractive and prescription of glasses at age 1 or 2 may precede measurement of visual acuity at age 4-6. As the model is also intended for use in Low-Income Countries, questions check if lack of healthcare infrastructure, competing healthcare priorities, lack of awareness of advantages of prevention and long travel distances render vision screening unacceptable, inappropriate or unsustainable.

Conclusions: The EUSCREEN APP for cost-effectiveness of vision screening programs will assist professionals in their decisions to introduce, modify or disinvest childhood vision screening programs. Utility and quality of life, effectiveness of treatment, newborn vision screening, type and severity of amblyopia and orthoptic training need to be added. Ubiquitous lack of data collection in vision screening makes it difficult for the user to know the correct input values.

ABSTRACT BODY:

Purpose: Cystoid macular edema is a known cause of central vision loss in retinitis pigmentosa (RP) patients as the disease progresses. A retrospective chart review was performed to investigate whether clinical and/or spectral-domain optical coherence tomography (SD-OCT) data could be used to correlate with visual acuity outcomes.

Methods: The medical records of 60 eyes from 30 patients from the University of Florida Eye Center database were reviewed. Best corrected visual acuity (BCVA), central retinal thickness (CRT), total macular volume (TMV), presence or absence of epiretinal membrane, and presence or absence of ellipsoid zone in the fovea and in the macula (EZ) at the first visit and one year follow up were collected and analyzed. The relationship between predictors and outcome variables were assessed using simple correlation analysis.

Results: The mean age of the 30 patients (9 male, 21 female) included in the study was 46.8 ± 18.9 (range, 10-80 years). Sex does not correlate with measurements. Aging has a negative effect on BCVA and EZ fovea. BCVA at 1st visit was significantly correlated with CRT ($r = -0.38437$, $p = 0.0024$) and EZ foveal sparing at the 1st visit ($r = 0.65218$, $p < 0.0001$). CRT is an indicator of CME and has a negative effect on EZ fovea. ERM has no correlation with BCVA, CME, CRT, TMV or EZ. Multiple regression analysis showed that TMV at the first visit is significantly correlated with BCVA changes at one year visit ($r = -0.31972$, $p = 0.0128$).

Conclusions: The results of our study suggest that in patients with retinitis pigmentosa, visual acuity outcomes are correlated with CRT and the condition of the EZ fovea. Thinner retina has EZ fovea depleted and worse BCVA. The baseline TMV can serve as a predictor of BCVA change at the end of one year. Eyes with higher baseline TMV end up with worse BCVA after one year. Aging is correlated with decreasing BCVA and disruption/disappearance of EZ fovea.

ABSTRACT BODY:

Purpose: Corticosteroids are a strong risk factor for central serous chorioretinopathy (CSC). However, the underlying pathophysiological mechanisms are unclear. CSC has been proposed to result from choroidal hyperpermeability. Therefore, choroidal endothelial cells (CECs), which are important for barrier function, are of particular interest. This study describes the effect of cortisol on human CECs, in order to identify potential target genes involved in CEC hyperpermeability as seen in CSC patients.

Methods: Human CECs from 10 individuals (5 males, 5 females) were isolated from cadaveric anonymous donor eyes by magnetic-activated cell sorting. Cells were treated with either cortisol (10^{-6} M) or vehicle (0.01% ethanol) medium, and subsequently whole transcriptome analysis was performed on a Novaseq Illumina platform.

Results: Bioinformatic analysis showed upregulation of 153 genes and downregulation of 169 genes. Classical corticosteroid target genes were upregulated in human CECs and included FKBP5 (log2 fold change 6.8) and TSC22D3 (log2 fold change 4.5). The strongest induced gene by cortisol was ZBTB16 (log2 fold change 7.0).

Conclusions: In summary, this study describes 322 genes regulated by cortisol in primary human CECs. This includes classical corticosteroid target genes, but also a subset of these genes that has been previously linked to endothelial cell dysfunction. Functional assays based on genes of interest found in this study may help to expand the understanding of mechanisms behind the induction of CEC hyperpermeability by corticosteroids, as observed in CSC patients.

ABSTRACT BODY:

Purpose: To analyze the impact of the 1st wave COVID-19 on macular diseases' management in ophthalmology department of "Centre hospitalier intercommunal de Créteil (CHIC)" and correlate it with patients' demographic and clinical features

Methods: Retrospective cross-sectional study. During the lockdown period from March 17th to May 11th, 2020, we analyzed the activity in the medical retina and more specifically intra-vitreous injections (IVIs) and compared it to that of the same period in 2019. The impact of patients' demographic and clinical features (age, sex, visual acuity (VA), retinal disease, therapeutic strategy) on this activity was evaluated

Results: In 2019, the number of IVIs carried out between March 17th and May 11th, combining all indications was 2189. In 2020, this number was 953 corresponding to a decrease of 56.46 %, statistically significant ($p < 0.05$). During the 1st wave, 767 patients (1020 eyes) were scheduled for at least one IVI. 833 eyes of 615 patients received 1 or 2 scheduled IVIs (Group 1). 187 eyes of 152 patients did not receive any IVIs (Group 2). 83.06% out of the patients in group 1 received all the scheduled IVIs (1 or 2). 16.94% received only a single IVI when they were scheduled to receive a 2nd injection. In group 1, the average age is 76 y. Female patients represent 59.67%. Average VA before lockdown was 63.52 letters. This remained stable after, at 63.15 letters. The therapeutic strategy used before lockdown was Pro re nata (PRN) in 62.46% and Treat and extend (TAE) in 30.56%. Age related macular degeneration (AMD) was the most common disease (61.13%). In group 2, the average age is 76 y. Female patients represent 58.55%. Average VA before lockdown was 60.77 letters. It was reduced to 50.63 letters after. The predominant therapeutic strategy was PRN (47.05%) followed by TAE (32.62%). AMD was the most common disease (56.68%)

Conclusions: The COVID-19 lockdown severely impacted management of macular diseases by IVIs at CHIC. The short-term impact on VA is significant in the absence of treatment. The impact is not statistically different with respect to age, gender, and retinal disease. However, regarding therapeutic strategy, PRN seems to have enabled a better observance. These results underline the importance of sensitizing patients to treatment observance. They can also contribute to develop effective management strategies for macular diseases during times of crisis

ABSTRACT BODY:

Purpose: Mucous membrane pemphigoid (MMP) is a heterogenous group of immunobullous disorders affecting the orificial mucous membranes including the ocular (OcMMP), oral and aerodigestive regions. MMP is associated with significant ocular morbidity due to conjunctival shrinkage where visual loss is secondary to ocular surface failure, secondary glaucoma and complex cataract. Cataract surgery is challenging due to difficult access, poor visualisation and risk of postoperative epithelial breakdown and disease progression. We describe an ocular surface optimising protocol that aims to minimise post-operative complications and improve patient outcomes.

Methods: Cataract surgery was performed on 73 consecutive eyes (47 OcMMP patients, aged (50-87) years, 25 (53%) Female, 35 (74.5%) biopsy-positive) presenting to a regional tertiary centre between 2005 and 2019. Optimisation was achieved by ensuring all patients were free of inflammation for a minimum of 3 months prior to surgery, followed by preconditioning of the ocular surface with topical non-preserved dexamethasone eyedrops for 2 weeks, intravenous methylprednisolone on the day of surgery, intra-operative hydroxypropylmethylcellulose corneal protection, amniotic membrane to the corneal surface, and post-operative topical non-preserved dexamethasone, chloramphenicol, and lubricants. Six-month outcomes are reported using generalised linear models adjusted for longitudinal and inter-eye correlations

Results: Of the 47 patients, 34 (72.3%) required systemic immunosuppression. At the time of surgery, >50% forniceal foreshortening was observed in 44 (60%) eyes with 35 (74%) eyes requiring intraoperative lid sutures. There was significant improvement in visual acuity by >0.7 LogMar (P=0.000). While there were no statistically significant differences between pre- and postoperative inflammation, scarring, morbidity and dryness scores (all p>0.05), one patient demonstrated progressive scarring at 6-months follow-up and 14(19%) eyes required serum eyedrops for increased ocular surface staining. No cases of corneal perforation, microbial keratitis or endophthalmitis were recorded.

Conclusions: Cataract surgery can be safely performed in OcMMP patients with advanced conjunctival scarring but requires careful preoperative optimisation and post-operative ocular surface management for good patient outcomes. Good vision may be temporary due to the progressive nature of the underlying disease.

Thanuja: Commercial Relationship: Code N (No Commercial Relationship) | Sudhir Ranganath: Commercial Relationship: Code N (No Commercial Relationship) | Sangly Srinivas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress (OS) is implicated in the pathophysiology of Fuchs Endothelial Corneal Dystrophy (FECD). It is known to induce microtubule disassembly in other cell types, leading to remodelling of the apical junctional complex via actomyosin contraction and eventually to barrier failure (Srinivas; EER, 2012). This study aims to investigate the impact of experimental oxidative stress on the barrier properties of the corneal endothelium (CE).

Methods: All experiments were carried out with primary cultured cells of porcine/bovine CE. For oxidative stress, cells were exposed to H_2O_2 (100 μ M, 1 h) after holding the cells in a culture medium containing 2% serum for 24 hrs. Immunocytochemical techniques were employed to assess the disassembly of the microtubules and the organization of ZO-1. The loss of barrier function was assessed by TER, which was measured by electric cell-substrate impedance sensing with bovine CE grown on gold electrodes that were coated with an ECM cocktail. In these experiments, the culture medium was supplemented with 50 μ M Riboflavin (Rf) and exposed to UV-A (365 nm; 30 min, 0.5 mW/cm²) to induce the Type-1 photochemical reactions and thereby cause an in situ release of H_2O_2 .

Results: Exposure to H_2O_2 for 1 h led to microtubule disassembly (immunocytochemistry with α -tubulin), which could be inhibited by pre-treatment with 10 μ M of SB-203580 (a p38 MAPK inhibitor; 1 h). In independent experiments, exposure to H_2O_2 led to a loss of the contiguous appearance of ZO-1 (Fig. 1B), which marks the breakdown of tight junctions. Accordingly, a sustained loss of TER (over 10-12 h) was induced when cells on gold electrodes, bathed in Rf-supplemented medium, were exposed to UV-A. Inclusion of catalase (7000 U/mL), which prevents the accumulation of H_2O_2 , abolished the loss in TER induced by UV-A.

Conclusions: We have demonstrated that acute oxidative stress induces microtubule disassembly, leading to a destruction of apical junctional complex and barrier integrity in cultured CE. The effects of p38 MAPK confirms a role for the stress kinase downstream of oxidative stress. Thus, the response to oxidative stress is reminiscent of the TNF- α -induced breakdown of barrier failure reported in CE (Srinivas; EER, 2012).

Commercial Relationships Disclosure (Abstract): Eliza Barnwell: Commercial Relationship: Code N (No Commercial Relationship) | Margaret Greven: Commercial Relationship: Code N (No Commercial Relationship) | Barlett Hayes: Commercial Relationship: Code N (No Commercial Relationship) | Rajiv Shah: Commercial Relationship: Code N (No Commercial Relationship) | Craig Greven: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare endogenous endophthalmitis characteristics among patients who inject drugs with endogenous endophthalmitis from other causes.

Methods: This retrospective study included all cases of endogenous endophthalmitis diagnosed and treated at a single academic institution over a seven-year period, from February 2013 until February 2020. 62 eyes of 52 patients were included, with a mean follow-up time of 8.6 months. 23 cases were related to intravenous drug use (IVDU) and 29 cases were due to other endogenous etiologies. The primary outcome was final visual acuity (VA).

Results: Overall, mean presenting VA on presentation was logMAR 1.81 (Snellen 20/1291) and at final follow-up was logMAR 1.60 (Snellen 20/796). IVDU-related cases were more likely to have improvement in VA following treatment compared with cases due other etiologies (OR=2.85, p=0.049). Patients with IVDU-related endophthalmitis were significantly younger at time of diagnosis (mean 39 years) than those with other etiologies (mean 60 years, p<0.00001) and had significantly longer duration of symptoms before diagnosis (mean 28 days) compared to other etiologies (mean 8 days, p=0.005). Out of the IVDU-related cases, only 30% had a known infectious site in addition to ophthalmic findings, while 86% of cases due to other etiologies had a known infectious site. Overall, Staphylococcus aureus was the most commonly isolated pathogen in vitreous cultures (n=6) as well as in blood cultures (n=13). Confirmed or suspected fungal etiology was more likely in the IVDU-related cases (OR=5.96, p=0.003).

Conclusions: In this case series, patients with endogenous endophthalmitis have high ocular morbidity despite appropriate treatment. Patients with endogenous endophthalmitis due to IVDU are significantly younger with longer duration of symptoms prior to diagnosis compared to patients with endophthalmitis from other etiologies. In many cases, patients with IVDU-associated endophthalmitis have ophthalmic findings only; therefore, it is important to have a high index of suspicion in a young, otherwise healthy patient.

TITLE: Clinical profile of patients with necrotizing scleritis and the risk of surgical intervention

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Mechels, T.J. Ferguson, S. Srivastava, Ophthalmology, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Keegan Mechels: Commercial Relationship: Code N (No Commercial Relationship) | Tanner Ferguson: Commercial Relationship: Code N (No Commercial Relationship) | Sunil K. Srivastava: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Necrotizing scleritis is an uncommon, destructive inflammatory condition that often has a systemic association. We performed a retrospective case-series to observe the demographics, clinical features, and disease associations of a group of patients identified with necrotizing scleritis.

Methods: This is a retrospective review of all necrotizing scleritis documented as a diagnosis in the EMR of a single tertiary referral center (n=17) between July 2014 and September 2020. Demographic data, clinical exam findings, operative reports, and clinic notes from rheumatology at the same center were reviewed by the authors of this study.

Results: A total of twenty-two eyes of seventeen patients (22/17) were included in this study. 9 of the 17 patients were female (52.9%). The average age of the patients was 70.1 years with 6/17 over the age of 70. 12/17 patients (70.6%) had a systemic disease association, the most common of which was rheumatoid arthritis (7/12) followed by granulomatosis with polyangiitis (4/12). 3/17 patients (5/22 eyes) had an infectious cause of scleritis. Best-corrected visual acuity was worse than 20/200 in 7/22 eyes at presentation. Anterior uveitis was noted in 4/22 eyes at presentation, and panuveitis was also noted in 4/22 eyes at presentation. At the time of presentation, 4/22 eyes required surgical repair. The average age of these patients was 71.3 years. Of these patients, three had a diagnosis of rheumatoid arthritis (RA) and one had infectious scleritis secondary to *Pseudomonas aeruginosa*. Two of the three surgical RA patients were not on steroid-sparing agent prior to surgical intervention. Of the 18 eyes that at presentation did not require surgery, none of these eyes warranted repair after starting immune suppression.

Conclusions: Necrotizing scleritis can be a devastating diagnosis with a host of ocular complications that can accompany it, including perforation requiring patch grafting. Aggressive immune suppression is often warranted to avoid perforation necessitating surgical intervention.

ABSTRACT BODY:

Purpose: Rab28 is a small farnesylated G-protein associated with human autosomal recessive cone-rod dystrophy (CRD). Rab28 localises to cone photoreceptor outer segments (OS) which are modified cilia. Knockout of murine or zebrafish Rab28 diminishes OS phagocytosis (OSP) by the retinal pigment epithelium (RPE). As Rab28 function and regulation of cone OSP are poorly understood, this study further investigates the molecular mechanism by which Rab28 functions in zebrafish cone photoreceptors and its role in OSP.

Methods: Genetic, biochemical, behavioural and imaging approaches interrogated the function of Rab28 in zebrafish cone photoreceptors using a rab28 knockout (KO) model and transgenic strains overexpressing gnat2:egfp-rab28. Visual behaviour was analysed using optokinetic response, contrast sensitivity and visual acuity assays. For TEM analysis of shed OS, phagosomes were manually counted, and the density calculated as phagosomes per μm of RPE. Proteomic profiling of rab28 knockout and sibling eyes collected at ZT 4, ZT 9 and ZT 17 was performed by mass spectrometry (MS). Retinoid profiling was carried out by HPLC.

Results: At 15 days post fertilisation (dpf), rab28 KO zebrafish display a 55% reduction ($N=3$, $p<0.001$) of shed OS material at morning (ZT 4) and evening (ZT 17) OSP peaks. Overexpression of Rab28 specifically in cones rescues the OS shedding defect in rab28 KO fish ($N=3$, $p<0.001$). Real-time PCR identified *cerkl*, *mertka* and *abcf1* genes to maximise expression prior to one or both OSP peaks. Proteomic analysis demonstrates loss of zebrafish Rab28 leads to reduced levels of phototransduction cascade components and core ciliary BBsome proteins ($N=3$, $p<0.05$). Visual cycle retinoid levels are also reduced ($N=3$, $p<0.03$) in larval and adult rab28 KO retinae inferring a direct or indirect role of Rab28 in the visual cycle. We observed no visual impairment in juvenile rab28 KO fish.

Conclusions: Our findings indicate that Rab28 regulates phagocytic processes at the ciliary/OS membrane, thereby providing insight into the mechanisms of RAB28-associated cone-rod dystrophy and cone OSP regulation.

TITLE: Regenerating the ocular retinal vasculature using endothelial progenitors is modulated by miR-130

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. McKeown, J. Guduric-Fuchs, R.J. Medina, A. Stitt, Queen's University Belfast, Queen's University Belfast, Belfast, Belfast, GB, academic, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Stuart McKeown: Commercial Relationship: Code N (No Commercial Relationship) | Jasenka Guduric-Fuchs: Commercial Relationship: Code N (No Commercial Relationship) | Reinhold Medina: Commercial Relationship: Code N (No Commercial Relationship) | Alan Stitt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ischemic retinopathies are significant causes of vision loss. A strategy to repair damaged vasculature and reperfuse the hypoxic retina is a valid and important goal. Many groups have sought to harness the reparative potential of endothelial progenitors in a cell therapy strategy. In the current study, we have built upon our previous work showing that endothelial colony forming cells (ECFCs) can integrate into the murine vasculature and drive a regrowth of patent vessels in the ischaemic retina. Based on transcriptomics of hypoxia-exposed ECFCs we have identified that miR-130 regulates angiogenesis-related gene expression events. The current study has sought to determine the role of miR-130 in ECFCs and whether this miRNA can be manipulated to improve vascular repair.

Methods: ECFCs were isolated from umbilical cord blood and categorised via flow cytometry, as well as cellular morphology. Cells were fixed and stained for vinculin to identify focal adhesions (FA). FA were then enumerated, and the cells adhesion assessed via a modified MTT assay. Overexpression (OE) of miR-130 or a control-mimic (c-mim) was then induced in ECFCs, the effect of this OE was then assessed. These, miR-130 OE ECFCs were applied to the ex vivo choroidal explant model to assess their ability to interact with, and possibly improve, sprouting choroidal vasculature. Explants were imaged daily to determine total sprouting distance. In the murine oxygen-induced retinopathy (OIR) model miR-130 OE or c-mim OE ECFCs were administered intravitreally and the impact on ischemic retinopathy assessed.

Results: Cells OE miR-130 had a greater number of FA compared to untreated cells and C-mim OE cells ($P<0.001$) as well as greater adhesion ($P<0.05$). In the ex vivo choroid angiogenesis model, explants exposed to miR-130 OE cells had a significantly greater sprouting distance ($P=<0.001$) than explants grown in co-culture with C-mim OE cells, non-transfected cells or no cell controls. In the murine OIR model, administration of miR-130 OE cells led to a reduction in the avascular area of retinas that was significantly greater than that achieved by non-transfected control cells ($P<0.05$).

Conclusions: Whilst ECFCs have previously demonstrated vasoreparative potential in the eye, an ability to improve their function in the ischaemic retina would be valuable. Augmentation of ECFCs via miR-130 OE enhances the efficacy of this cell therapy.

ABSTRACT BODY:

Purpose: It is well established that children born preterm are at increased risk for ophthalmologic complications including altered fundus morphology. However, there is a lack of knowledge how children born moderate-to-late preterm (MLP, gestational age 32-36 weeks) with no retinopathy of prematurity (ROP) are affected later in life. This study intends to evaluate foveal parameters such as foveal avascular zone (FAZ) area, vascular density (VD) of a determined area surrounding the fovea and foveal thickness of adolescents born MLP and compare the results with age-matched controls born full-term.

Methods: In an ongoing, prospective population-based cohort study, 37 adolescents born MLP (19 female, 18 male; mean age 15.9 years) were examined with optical coherence tomography (OCT) and OCT angiography (OCT-A) (Topcon DRI OCT-1Triton Plus, Tokyo, Japan). Exclusion criteria were the following: children with chromosomal abnormalities, syndromes, severe malformations, ROP and mothers with severe chronic disease. FAZ and VD were obtained by OCT-A scans and measured using Fiji image processing software. All these foveal measurements were adjusted for the axial length related ocular magnification by usage of the Littmann formula. Foveal thickness was obtained from the OCT scan. The results of the foveal parameters from the MLP individuals were compared with the results from 25 healthy controls (mean age 16.1 years). Statistical analyses (Mann-Whitney's U-test and Spearman's rank correlation coefficient analysis) were made using the software IBM SPSS Statistics 26 (IBM Corp., Armonk, NY, USA).

Results: There were significant differences in size of FAZ and foveal thickness between the two study groups; FAZ area (mm^2) MLP group (mean \pm standard deviation (SD)) $0.21 \pm 0.10 \text{ mm}^2$ compared with controls (mean \pm SD) $0.27 \pm 0.09 \text{ mm}^2$, foveal thickness (μm) MLP group (mean \pm SD) $251.89 \pm 19.03 \mu\text{m}$, controls (mean \pm SD) $240.60 \pm 17.77 \mu\text{m}$ ($p=0.025$ and $p=0.032$, respectively). A strong correlation between FAZ area and foveal thickness was found in the MLP group ($r=-0.782$, $p<0.0001$). The VD measurements showed no significant differences.

Conclusions: Our results show that adolescents born MLP, without having ROP as infants, have a smaller FAZ area and an increased foveal thickness compared with age-matched full-term controls. Additionally, FAZ area and foveal thickness were negatively correlated within the MLP group.

ABSTRACT BODY:

Purpose: Cell transplantation into the mouse retina has been shown to result in the transfer of cytoplasmic material between donor and host photoreceptors. Here we assessed whether material transfer can also occur between endogenous photoreceptors in a horizontal fashion under normal physiological conditions.

Methods: Retinal wholemounts and sections of cone-specific GFP reporter mice, wild-type mice and primary human retinas were used for immunohistochemistry using cone- (cone arrestin; PNA) and rod- (Nr2e3) specific antibodies. GFP signals and immunostainings were imaged using structured illumination-, spinning disc-, confocal- or stochastic optical reconstruction (STORM) microscopy. By computational estimation the distance between cone axonal processes and rod cell bodies was assessed.

Results: In retinas of cone-GFP mice, approximately 2000 GFP⁺ cells/retina with rod-specific morphology, location and marker expression were detected in close proximity to GFP⁺ cone axons. Quantification of the distance between the cell bodies of GFP⁺ rods and GFP⁺ cone axons revealed an average distance of approximately 1.1µm, which is significantly lower than the distance that would be expected given a random distribution of rods in relation to cones (ca. 4.24 µm). Indications for thin protrusions formed between the cell body of GFP⁺ rods and GFP⁺ cone axons were observed by spinning disk microscopy within retinal wholemounts. The presence of GFP⁺ nanotube-like connections between rods and cones could be confirmed on retinal sections by STORM super resolution microscopy. Expression of cone-specific markers could be further observed in distinct rod cell-bodies in wild-type mice and human retinal sections.

Conclusions: Using cone-specific reporter mice and super-resolution microscopy, we identified previously undescribed direct cell-cell connections presumably mediating the horizontal transfer of cytoplasmic material between rod and cone photoreceptors. The extent of cellular material exchange and its biological significance remains to be explored in further studies.

ABSTRACT BODY:

Purpose: Proteomic analysis of vitreous is capable of identifying proteins and pathways known to play critical roles in retinal disease. However, the number of samples required to generate statistically meaningful comparisons across groups remains unknown. In addition, the methods used to merge data from multiplex tandem mass tag mass spectrometry (TMT-MS) studies remains to be assessed and validated. The purpose of this study was to determine the proper algorithm to merge data across multiple 10-plexes and to identify the number of samples required to produce statistically reliable differential expression and pathway analyses.

Methods: Vitreous was derived from patients undergoing repair of epiretinal membrane or non-clearing vitreous hemorrhage secondary to proliferative diabetic retinopathy (PDR). Samples were processed according to protocols previously developed by our group. Samples were analyzed either individually (biological replicates) or as a pooled mixture of multiple samples, which was then aliquoted into smaller volumes (technical replicates). Samples were then distributed across five total 10-plexes in two TMT-MS experiments. Multiple algorithms were used to normalize the data across plexes. Validation of the normalization algorithm, differential expression, and power analyses were performed using the single normalized data matrix. This study was approved by the University of Michigan and Penn State College of Medicine institutional review boards and adhered to the tenets of the Declaration of Helsinki.

Results: The total number of unique proteins was 1,152 in experiment 1 and 1,191 in experiment 2. The average coefficient of variation (CV) across technical replicates was 4.2%. The average CV across patients was 36.9%. Power analysis revealed that 6 samples are required to achieve a power level of approximately 0.80 for proteins with log2 fold change of at least 1.194. As expected, differential expression and pathway analyses demonstrated significant activation of metabolic pathways and inhibition of neuroprotective pathways in PDR samples.

Conclusions: These data demonstrate minimal technical variability and low biological variability using TMT-MS to interrogate of human vitreous samples. In addition, methods to merge data across multiple 10-plex runs have been validated. As such, this vitreous proteomic analysis pipeline has been validated and allows for quantitative, cost-effective, and scalable analysis.

TITLE: A Living Biological Bandage for management of corneal injuries

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Poon, K.C. Shih, Y. Chan, Ophthalmology, University of Hong Kong, Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): Stephanie Poon: Commercial Relationship: Code N (No Commercial Relationship) | Kendrick Shih: Commercial Relationship: Code N (No Commercial Relationship) | Yau Kei Chan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A large percentage of corneal opacifications are caused by chemical injuries, for which current conventional treatment strategies are costly, and may even result in complications, including immunological rejection after transplantation or glaucoma. Cell sheet engineering via an Aqueous-Two-Phase-System (ATPS) is an emerging technique which may act as a more economical alternative to construct an epithelial bandage for healing of corneal epithelial wounds. The purpose of this study is to increase the rate of re-epithelialisation in corneal epithelial defects, using a cellular construct that is delivered to the injured ocular surface with the help of a contact lens. We investigate the properties of the corneal epithelial cell sheet, and quantify the efficacy of the cell sheet therapy via an in vitro chemical injury model and an ex vivo porcine cornea model.

Methods: A primary human corneal epithelial cell line was used for in vitro experiments. The cell sheet was formed between a liquid-liquid interface, which was formed with a Poly(ethylene glycol)(PEG)-rich layer on top and a Dextran(DEX)-rich layer at the bottom. The cell density used for constructing the cell sheet, as well as the time for incubation, were optimised. We carried out in vitro tests to investigate the properties of the cell sheet as well as its viability in the ATPS components. We also measured the efficacy of cell sheet transplantation in healing a chemical injury wound on a Transwell model. In addition, an ex vivo porcine cornea model was adopted to examine the integration, proliferation properties, and retention of the cell sheet on a de-epithelialised cornea.

Results: Upon measuring the percentage area of defect on the in vitro chemical injury model on set time points throughout a 7 day observation period, we found the cell sheet to significantly reduce the time required for wound healing compared to the control group without transplantation performed. In addition, our ex vivo model illustrated strong adherence of the transplanted cell sheet on the de-epithelialised porcine cornea.

Conclusions: Our current results illustrate potential for the ATPS cell sheet engineering technique to be used as a management strategy for ocular injuries. Future work points towards the conducting in vivo experiments to assess the efficacy and physiological outcomes of the cell sheet transplant method for wound repair.

TITLE: Proteomic alterations in the rat retina responding to the hypobaric hypoxic stress

SESSION TITLE: Blood flow/ Ischemia/reperfusion/Aqueous humor dynamics/IOP

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Xin, Department of Ophthalmology, Sichuan Provincial People's Hospital, Chengdu, Sichuan, CHINA|

Commercial Relationships Disclosure (Abstract): Xiaorong Xin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: High-altitude retinopathy (HAR) is initiated by hypobaric hypoxia and characterized by retinal function deficits. However, the exact molecular mechanisms involved in HAR remain incompletely understood. Our current investigation is to utilize the proteomic analysis to profile the proteomic changes in rat retina exposed to hypobaric hypoxia and evaluated the protective efficacy of hesperidin (HSD) on the hypobaric hypoxia-induced impairment to the retina.

Methods: In the present study, we undertook an approach to mimic 5000m altitude with a low-pressure oxygen cabin. SD rats were randomized into control group, hypobaric hypoxia (HH), and HSD intervention group. Retinas were dissected following different treatments for 7 days. A quantitative comparison of the proteome in the retina was performed through TMT labeling, HPLC fractionation, LC-MS/MS and PRM analysis.

Results: A total of 154 and 259 proteins were upregulated, 216 and 54 proteins were downregulated when compared the HH group with the control, HSD with HH group respectively. Subcellular distribution of deferentially expressed proteins were mostly localized in the cytoplasm, nucleus, followed by extracellular, plasma membrane and mitochondrion. Hypobaric hypoxia-triggered down-regulation of proteins in the retina were mainly related with cellular process, biologic regulation, stimulus response, multicellular-organismal process, metabolic and developmental process. HSD dramatically inhibited the hypobaric hypoxia-induced stress by upregulation of proteins mainly associated with the above-mentioned biological activities. Proteins including glial fibrillary acidic protein(GFAP), aldehyde dehydrogenase,dimeric NADP-preferring (ALDH3A1), neurofilament light polypeptide (NEFL), collagen alpha-1(Colla1) were downregulated in the hypobaric hypoxic condition but enhanced by HSD intervention, which were validated by PRM assay. ECM-receptor interaction and PI3K-Akt signaling pathway were identified to be the most relevant pathways related with retina affected by either hypobaric hypoxia or HSD intervention through the KEGG pathway enrichment analysis.

Conclusions: Our proteomic analysis suggests that hypobaric hypoxia exerts a pathological impact on the rat retina through affecting protein function. The intervention of HSD elicits a protective response to the hypobaric hypoxia-induced stress on the rat retina.

ABSTRACT BODY:

Purpose:

Pterygium is a frequent benign condition, and the standard medical practice is to discard the sample when excised. Ocular surface squamous neoplasia (OSSN) co-existence in pterygium biopsies is variable between cross-sectional studies. A higher correlation is observed amongst people from lower latitudes and Caucasians. Data on the association of OSSN and pterygium in Latinos are sparse. The purpose of this study is to estimate the frequency of coexisting OSSN in pterygium biopsies in people from Chile.

Methods: Samples from adult patients who underwent a pterygium removal surgery during the first semester of 2018 were prospectively collected and sent for pathological examination. Patients with clinical suspicion of OSSN were excluded. All biopsies were evaluated by an ocular pathologist. Co-existence of OSSN was compared between central (33°S, similar distance from equator to Los Angeles, CA, USA) and southern latitudes (41°S, similar to Chicago, IL, USA). This investigation was approved by the Ethics Review Board.

Results: A total of 55 surgeries from 54 patients were performed. The average age was 55±12 years and 50.91% were women. Grade one conjunctival intraepithelial neoplasia was found in two cases (both female, 53 and 54 years-old), corresponding to 3.63% of excised lesions. OSSN was found in two patients from central Chile and in none from southern Chile (p=0.54).

Conclusions: To the best of our knowledge, this is the first study reporting association of OSSN and pterygium in a Latino population, with 3.63% prevalence in the study sample. This data suggests that excised pterygium from Chile should be submitted for pathology evaluation. We note the additional observation that a higher proportion of OSSN was observed in central Chile compared to southern Chile, although this was not a statistically significant finding and a larger cohort of patients is needed to be able to further study this hypothesis. Aside from increasing the number of patients, future studies could include data from a third distinct latitude in northern Chile.

ABSTRACT BODY:

Purpose: To demonstrate that gene enhancement therapy of the AHOP following a single intracameral AAV injection results in long-term stable IOP control by preventing extracellular plaque formation in the trabecular meshwork (TM) of a well-established canine OAG model.

Methods: Six ADAMTS10-mutant dogs with early stages of OAG were injected unilaterally with a 75-100µL volume of single-stranded AAV2(Y444F)-smCBA-hADAMTS10 vector ($1.25-1.61 \times 10^{12}$ vector genomes). Clinical outcome measures were monitored for 24-48 months, including weekly diurnal IOP, repeated aqueous humor (AH) flow measurements, and high-resolution imaging of retina and optic nerve head (ONH) by optical coherence tomography (OCT). IOP analysis consisted of pairwise comparisons of treated vs. fellow control eyes while accounting for dog-to-dog variation. Safety monitoring included routine clinical ophthalmic examinations and AH analyses (protein concentrations, cell counts, and neutralizing AAV antibody titers). Ocular tissues were examined by routine light and transmission electron microscopy (TEM).

Results: IOP decreased significantly and was less variable for the entire 24- to 48-month observation period in 5/6 ADAMTS10-mutant dogs in treated vs. fellow control eyes (16.6 ± 7.5 vs. 29.7 ± 8.7 mmHg; $p < 0.0001$). Outflow facility was significantly higher and more variable in treated (0.34 ± 0.15) vs. untreated (0.23 ± 0.08) eyes ($p < 0.01$). OCT imaging showed that ONH morphology remained unchanged over time in successfully treated eyes, but degeneration/cupping progressed in untreated controls. Mild anterior uveitis with positive neutralizing antibody titers developed in the serum of all dogs as well as in the AH of AAV-treated but not untreated fellow eyes. TEM examination of the TM revealed almost complete prevention of extracellular plaque formation in treated vs. untreated eyes.

Conclusions: Long-term, stable IOP control can be achieved for at least 4 years following a single intracameral injection of AAV in a clinically relevant canine OAG model. These findings are consistent with reduced extracellular TM plaque formation and increased AH outflow facility.

ABSTRACT BODY:

Purpose: Emmetropia has been reported as a predictor of myopia onset. But the distribution of myopiogenic factors among emmetropic children has not been well understood. This study aimed to investigate the factors for myopia among preschoolers and the associations with emmetropia.

Methods: Since launch of the Yilan Myopia Prevention and Vision Improvement Program (YMVIP) in August 2014, we have promoted outdoor activities and conducted a countywide population-based, annual cross-sectional study in all kindergartens in Yilan County, Taiwan. Eye examinations, including cycloplegic autorefraction, have been provided for all preschoolers aged 5-6 years. Demographics, medical history, parental history, near work habits, screen time and outdoor activity was collected by questionnaire. Refractive status was determined according to the cycloplegic spherical equivalent (SE) of the eye with less SE and classified into myopia ($SE \leq -0.5D$), emmetropia ($0.5D > SE > -0.5D$), or hyperopia ($SE \geq 0.5D$).

Results: Among 20,419 preschoolers from 2014 through 2019, a total of 18,621 (9,715 [52.2%] boys) were finally included. Of those, 2,003 (10.8%), 5,057 (27.2%) and 11,561 (62.0%) were myopic, emmetropic and hyperopic. Most of association factors for myopia identified by multinomial logistic regression, including male (odds ratio [OR], 1.25; 95% CI, 1.13-1.37), caregiver myopia (OR, 1.76; 95% CI, 1.58-1.96), screen time ≥ 1 hour/weekday (OR, 1.20; 95% CI, 1.09-1.32), exposure to the YMVIP promoting outdoor activity (one-year exposure: OR, 0.80; 95% CI, 0.69-0.94; two-year exposure: OR, 0.46; 95% CI, 0.41-0.52), and higher education level of caregiver (OR, 0.79; 95% CI, 0.72-0.88), were also significantly associated with emmetropia (male [OR, 1.22; 95% CI, 1.14-1.30], caregiver myopia [OR, 1.42; 95% CI, 1.32-1.53], screen time ≥ 1 hour/weekday [OR, 1.15; 95% CI, 1.07-1.23], exposure to the YMVIP promoting outdoor activity [one-year exposure: OR, 0.84; 95% CI, 0.74-0.94; two-year exposure: OR, 0.62; 95% CI, 0.56-0.68], and higher education level of caregiver [OR, 0.87; 95% CI, 0.81-0.94]).

Conclusions: Emmetropia and myopia share similar risk factors in a preschooler population and the associations of these myopiogenic factors with emmetropia are weaker than with myopia, which may indicate the tendency of emmetropia toward myopia among preschoolers.

ABSTRACT BODY:

Purpose: Even though iron is essential for retinal homeostasis, its overload is involved in most of pathogenic mechanisms associated with many retinal diseases¹. In glaucoma, progressive retinal ganglion cell (RGC) death has been associated with dysregulation of iron homeostasis. Apo-Transferrin (apo-TF) is an endogenous iron transporter that neutralizes free toxic iron (III) in biological fluids and also delivers iron to cells by binding to its receptors. In various models of retinal degeneration, we previously demonstrated that local administration of apo-TF is neuroprotective, controlling iron-induced oxidative stress and regulating other iron unrelated pathways without undesirable side-effects unlike chemicals iron chelators¹. The purpose of this study was to evaluate the effects of apo-TF on RGCs death induced by various stresses that mimic glaucoma pathogenesis.

Methods: Retinas from adult rats were harvested and placed on polycarbonate membrane with RGCs facing up. Retinal explants were then subjected for 24 hours to hypoxia (CoCl_2 100-500 μM) or excitotoxicity (NMDA 100-500 μM). Apo-TF (50 mg/mL) was added to the medium during the 24-hour stress induction period. RGC survival was quantified by Brn3a immunolabeling on flat-mounted retinas and quantification of LDH release at 24 to 96 hours post exposure. Markers for necrosis (RIP3) or apoptosis (Cas-8, Apaf-1, Cas-3, Bcl2) were evaluated by western blot at 6 to 96 hours post exposure.

Results: Both CoCl_2 and NMDA induced a dose-dependent reduction in RGCs density with LD50 around 100 μM . CoCl_2 induced a gradual increase of Apaf-1- and activated caspases along with a parallel reduction in Bcl2 and a necrosis activation peak at 24 hours. Conversely, NMDA induced a rapid increased in RIP3 and Apaf-1 in the very first hours of intoxication followed by a delayed activation of Cas-8 and Cas-3 with maximal activation at 72 hours. Incubation with apo-TF prevented CoCl_2 -induced RGC hypoxia (+109% RGCs; -33% LDH release) reducing Cas-3 activation. Similarly, apo-TF partly preserved RGCs against NMDA-induced excitotoxicity (+35% RGCs; -26% LDH release) reducing levels of necrotic and apoptotic markers to normal.

Conclusions: These results indicate that apo-TF can promote RGC survival by interfering with cell death mechanisms involved in glaucoma pathogenesis.

ABSTRACT BODY:

Purpose: We have shown Nuclear distribution protein C (NUDC) has a critical role in the maintenance of post-mitotic rod photoreceptors by regulating outer segment (OS) disk diameter through interactions with actin. Here we test the hypothesis that NUDC is critical in microtubule cargo movement by examining the localization of rhodopsin and arrangement of mitochondria in the inner segment in the absence of NUDC mouse photoreceptors.

Methods: We have previously generated the NUDC floxed mouse and bred them with the rod-cell specific Cre recombinase (iCre75) mouse to produce NudC^{+/-} or NudC^{-/-} in rod photoreceptors. The retinas of the resulting mice were isolated and examined by electroretinography (ERG), transmission electron microscopy (TEM), immunohistochemistry (IHC), and quantitative PCR (qPCR) of mRNAs involved in fission and fusion of mitochondria.

Results: ERG analysis uncovered very low a- and b-wave amplitudes in 3wk-old NudC^{-/-} mice under scotopic conditions. IHC staining of retinal cryosections taken from NudC^{-/-} mice demonstrate disorganized microtubules in the inner segment (IS) of rod photoreceptor cells along with rhodopsin mislocalization in the IS, outer nuclear layer and synapse. Instead of long, fused mitochondria that align to the IS plasma membrane, TEM images of ultrathin NudC^{-/-} mouse retinal sections show mitochondria localized throughout the entire IS cytoplasm instead of adjacent to the plasma membrane as in wild type rods. Differences in expression of key genes critical for mitochondrial fission and fusion as measured by qPCR were statistically insignificant.

Conclusions: We have found that the protein NUDC is critical in rod photoreceptor OS disk formation and for mitochondrial localization in the IS. Our data are consistent with the hypothesis that NUDC governs disk dimension through actin regulation and mitochondrial localization through microtubule regulation, stressing the key importance of this protein in the cytoskeleton of photoreceptors in development and during homeostasis.

ABSTRACT BODY:

Purpose: Pathological neovascularization (NV) remains one of the main challenges in the treatment of proliferative diabetic retinopathy (PDR). Current therapies for PDR target NV yet often lead to off-target effects on healthy blood vessels. We previously demonstrated that pathological vasculature in the retina selectively engages programs of cellular senescence. This study aims to understand the molecular signatures of diseased vessels in order to elucidate new drug targets.

Methods: Ischemic retinopathy was studied in the proxy mouse model for PDR, oxygen-induced retinopathy (OIR) using C57Bl/6J mice. Pups were exposed to 75% O₂ from post-natal day (P)7-P12 and 21%O₂ P12-P17. The BCL-xL small molecule inhibitor, UBX1967, was administered intravitreally at P12. In vitro studies were performed using human retinal microvascular endothelial cells. Quantitative PCR, single-cell (sc) and bulk RNA-Seq were used for transcriptomic analyses. Protein expression was studied by means of Western blot or tissue immunolabelling. All animal studies complied with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research and were approved by institutional ethical committees.

Results: Pathological neovascularization is associated with expression of the anti-apoptotic BCL-2 protein family members. Senolysis via inhibition of BCL-xL suppresses neovascularization, accelerates the recovery of ischemic regions and is accompanied by a decrease of the senescence-associated secretory phenotype. Using scRNA-Seq, we observe an OIR-specific subpopulation of Col1a1-positive endothelial cells that localizes to regions of pathological NV and that is not present after BCL-xL inhibition.

Conclusions: Inhibition of BCL-xL with UBX1967 suppresses retinal pathological NV and targets Col1a1-positive subpopulations of endothelial cells. These data highlight the use of senolytics as potential therapies for PDR.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is an established risk factor for glaucoma. Steady-state IOP stems from a balance between aqueous humor (AH) production (AHp) and drainage. AHp results from the interaction among hydrostatic, osmotic and oncotic pressure differences determining a net fluid motion across ciliary epithelium (CE) bilayer from the stroma (S) to the aqueous side (AQ). The role of transcellular and paracellular (P) transport in AHp is difficult to disentangle experimentally, thus, we propose a mathematical model to investigate the contribution of each mechanism to AHp

Methods: AHp is described by a compartment model solving iteratively the coupled interaction between ion electrodiffusion and AH fluid motion until convergence. The model includes S, a cell cytoplasm (C) representing the CE bilayer, P and AQ sides. A tight junction separates S from P to prevent large size proteins from flowing into the AQ. Ion transport is modeled through active and passive membrane transporters and carbonic anhydrase (CA)-mediated intracellular CO₂ hydrolysis. Cell electroneutrality is ensured by a fixed intracellular negative charge. Simulations are performed under a transepithelial potential difference of 1mV (AQ negative) and hydrostatic pressures of 20 and 15 mmHg in S and AQ

Results: Fig. 1 shows a scheme of AHp including membrane protein transporters driving primary active, secondary and passive ion transport. Transporters are not evenly distributed according to membrane diverse functional roles. Fig. 2 shows the scheme on which arrows represent the AH velocity vector across membranes. Model seems to indicate a much higher P velocity than C velocity. Results also indicate a flow of water from C into P and water recirculation from AQ into C. Model predicts a total AH volumetric flow rate (VFR) of 2.74 μ L/min, in accordance with physiological data

Conclusions: Simulations suggest that P transport significantly contributes to total AH VFR. They also indicate that osmotic pressure gradients determine a passive water flow from C into P and a water back flow from AQ into the cell. Results support the use of the proposed model as a mathematical virtual laboratory, noninvasively complementing the animal model, to test the efficacy of IOP lowering medications to decrease AHp

ABSTRACT BODY:

Purpose: Mucous Membrane Pemphigoid is a multi-system autoimmune scarring disease involving mucosal sites, including the ocular surface (OcMMP) and gastrointestinal tract. Loss of tolerance to epithelial basement membrane proteins (BMP), and generation of autoreactive T cell and/or autoantibodies to BMP are central to the disease process. Mechanisms on how and where the T cells first become autoreactive is unknown.

The gut microbiome plays a critical role in the development of the immune system and has been shown to activate ocular autoimmune T cells. The aims of this study were to 1) compare the gut microbiome profiles of OcMMP patients with age- and gender-matched controls, and to 2) examine the relationship between the gut microbiome diversity and ocular inflammation in OcMMP.

Methods: Faecal samples were collected from 50 OcMMP patients attending a tertiary referral centre and 40 healthy controls and DNA extracted, amplified for the V4 region of the 16S rRNA gene and sequenced using Illumina Miseq platform. Sequencing reads were processed using bioinformatics pipeline available in the mothur v.1.44.1 software.

Results: OcMMP patients had lower alpha diversity compared to healthy controls (HC) [Median observed OTUs in OcMMP: 214 (IQR: 173 – 276) vs HC: 317 (277 – 549), $p < 0.0001$; Median Shannon Index in OcMMP: 3.05 (2.54 – 3.45) vs HC: 3.60 (3.18 – 4.01), $p < 0.0001$]. Reduced number of observed OTUs were correlated with conjunctival inflammation (R^2 : 0.1, $p = 0.03$). Alpha-diversity was not significantly associated with duration of disease, treatment, clinical scoring of scarring and morbidity, or immunofluorescence results. The linear discriminant analysis effect size scores indicated that Streptococcus, Lachnospiraceae, and Eggerthella were enriched in OcMMP patients whilst Oxalobacter, Clostridia, uncultured genus-level group (UCG) 014, Christensenellaceae R-7 group, UCG 002, 003, 005, NK4A214 group and butyrate-producing bacteria such as Ruminococcus, Lachnospiraceae, Oscillospiraceae, Coprococcus, Roseburia were enriched in healthy controls (\log_{10} LDA score < 2 , FDR-adjusted $p < 0.05$).

Conclusions: OcMMP patients have gut dysbiosis correlating with ocular inflammation, providing the framework for future causative studies on the role of the gut microbiome in OcMMP.

ABSTRACT BODY:

Purpose: Alzheimer's disease (AD) is a neurodegeneration that constitutes the most common type of dementia in the world. The main features associated with AD are amyloid protein plaques β ($A\beta$) and tau protein neurofibrillary tangles, which lead to a microglial cell-mediated neuroinflammation in the brain. The retina as a window to the brain can also be affected in AD, presenting some molecular and cellular changes such as microglial activation. The aim of the present study was to analyze microglial changes in retinal whole-mounts in the triple-transgenic AD mouse model (3xTg-AD).

Methods: Whole retinal mounts were processed with anti Iba-1 to perform a quantitative morphometric analysis of microglia activation in the 3xTg-AD mice and wild-type mice (n=8 in both group), which allows the visualization of the whole microglial cell, as well as its location along the extension of the retina in different layers. A quantification of Iba-1+ cells and of the cell body area in the outer plexiform layer and in the inner retinal layer complex, constituted by the inner plexiform layer and the nerve fiber layer-ganglion cell layer were performed.

Results: Compared to wild animals, the retina of 3xTg-AD mice shows a thicker microglial cell body area and a higher number of microglial cells. In addition, the microglial retract, migrate, and reorient their processes, changing their location from a parallel position to one that is perpendicular to the surface of the retina as well as well as forming groups in rows or circular clusters.

Conclusions: In the 3xTg-AD model, microglial cells showed several signs of activation, such as increased number and soma size, and retraction and reorientation of their processes, and changes in the cell's location. These morphological changes could represent that in this model of AD a neuroinflammatory process is taking place.

TITLE: p53 plays a regulatory role in DNA damage response of mono- and multi-nucleated retinal pigment epithelial cells

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. ke, L. Gong, M. Zou, R. Qi, D.W. Li, Zhongshan Ophthalmic Center, Sun Yat-sen University, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure (Abstract): qin ke: Commercial Relationship: Code N (No Commercial Relationship) | Lili Gong: Commercial Relationship: Code N (No Commercial Relationship) | Ming Zou: Commercial Relationship: Code N (No Commercial Relationship) | Ruili Qi: Commercial Relationship: Code N (No Commercial Relationship) | David Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Existence of multi-nucleated (MN)retinal pigment epithelial cells(RPE) has been demonstrated inboth human and mouse.In human, specific macular distribution ofMN RPE, and the positive correlation between MN RPE and rod photoreceptors has been reported, suggesting MN RPE reflect physiological functions. Because damaged DNA is detected in RPE from patients with age-related macular degeneration (AMD), here we analyzed the DNA damage response in mono-nucleated (MO) and MN RPE, and explored the regulatory effects of p53, the key DNA damage player, in this process.

Methods: Immunofluorescence (IF) was performed to measure the percentage and distribution of MO and MN RPE cells in 2-month C57BL/6J mice (n=4). To induce DNA damage, 2-month wild-type (n=8) and p53+/- (n=8) mice were exposed to 1 GyX-ray irradiation.The DNA damage repair efficiencywas evaluated by comet assay and immunofluorescence with anti-γ H2Ax (DNA damage marker) at 1- or 3-day post irradiation.

Results: MN RPE cells show higher distribution in the center region of retina (75.4%) as compared with peripheral retina (40.8%). Irradiation-induced DNA damage occurs in both MO and MN RPE cells.IF analysis shows more γH2Ax signals in MN as compared with MO RPE at both 1- (41.2% vs. 27.7%) and 3-day post irradiation (9.2% vs. 6.1%). Comet assay shows that the overall DNA double strand breaks were repaired with less efficiency in p53+/- RPEas compared with wild type mice at 3-day after irradiation, but the MO and MN RPE cells exhibited similar repair efficiency in both WT and p53+/- mice.

Conclusions: MN RPE appears to repair DNA less efficiently than MO RPE cells upon X-ray irradiation, and p53 is required for DNA damage repair in both MO and MN RPE. (Supported by National Natural Science Foundation of China (#82070969, #81770910, #81970787) and the Fundamental Research Funds for the Central Universities (#19ykpy153)).

TITLE: Ocular murine cytomegalovirus (MCMV) gene expression in aged BALB/c mice following systemic MCMV neonatal infection

SESSION TITLE: Immunity and Host Defense

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Zhang, X. Zhang, J. Xu, B. Marshall, Department of Cellular Biology and Anatomy, Augusta University Medical College of Georgia, Augusta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ming Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Xinyan Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Jinxian Xu: Commercial Relationship: Code N (No Commercial Relationship) | Brendan Marshall: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our previous studies have shown that systemic neonatal murine cytomegalovirus (MCMV) infection of BALB/c mice can spread to the eye with subsequent establishment of latency in the choroid and RPE. MCMV latency in the choroid/RPE was associated with the upregulation of several inflammatory/angiogenic factors, and the development of AMD-like pathology in a progressive manner, including loss of choroidal capillaries, deposits in basal aspects of the RPE, degeneration of RPE and photoreceptors and eventually, choroidal neovascularization (CNV) in later life. The purpose of this study was to determine if the development of AMD-like pathology is associated with reactivation of viral gene expression.

Methods: MCMV (50 pfu per mouse) or medium as control were injected intra-peritoneally (i.p.) into BALB/c mice at <3 days after birth. At 8 and 18 months p.i., optical coherence tomography (OCT) examinations were performed to monitor the integrity of retinal structure using an Envisu R2210 system. MCMV or medium injected mice were sacrificed and eyes were collected and examined by realtime-RT-PCR for expression of 26 virus genes related to latency.

Results: The mean retinal thickness in MCMV latently infected aged mice was significantly lower than in eyes of age matched controls at both 8 and 18 months p.i. Severe photoreceptor degeneration (including disappearance of the entire outer nuclear layer in some areas) and CNV lesions (average 2 per eye) were observed in 7 and 4 eyes respectively of 26 total eyes. Among 26 genes studied, 17 were expressed in some eyes from MCMV infected mice at both 8 and 18 months p.i. These included immediate early genes (IE1 and IE3) and genes functioning in anti-apoptotic (M37, M38.5, MM41 and M45) and immune evasion (M04, M138, M152). In addition, 2 genes (M18 and M82) were expressed only in aged eyes at 18 months p.i.

Conclusions: Virus gene expression during MCMV ocular latent infection may significantly alter homeostasis of the latently infected cell and the surrounding cellular environment and therefore induce the development of AMD-like pathology.

ABSTRACT BODY:

Purpose: GAP junction channels are formed from connexin protein subunits. Three major connexin protein subunits (Cx43, Cx46 and Cx50) have been shown to play important roles in lens growth, differentiation and maintenance of lens transparency through biochemical and genetic studies using transgenic animals and cell lines. However, aging dependent changes of these proteins in normal and cataract patients have not been individually analyzed. In this study, we report the aging-dependent changes in cataract patients of ages from 50s to 80s, and also compared the expression patterns of these proteins in young and aged mice.

Methods: Automated western immunoblotting was used to analyze the changes of connexin protein subunits (Cx43, Cx46 and Cx50) in individual cataract patients aged from 50-years to 89-years. Over 120 cataract patients were divided into 4 groups: 50-59 years old (50s), 60-69 years old (60s), 70-79 years old (70s) and 80-89 years old (80s). The capsular epithelia isolated during surgical operation were frozen immediately and then used for extraction of total proteins.

Results: From transparent lenses to cataract lenses, Cx43 level is significantly upregulated. In contrast, Cx46 and Cx50 are distinctly downregulated. From 50s to 70s, three types of connexin proteins remain relative stable. However, from 70s to 80s, the levels of the connexin proteins are significantly downregulated. Differences between male and female individually are not statistically significant.

Conclusions: The three types of connexin proteins display distinct changes from transparent lens to cataract lenses, and also age-dependent changes from 50s to 80s. These changes are closely associated with their function alterations which contribute to cataractogenesis (Supported by the grants, #81770910, #81970787, #81900842 and #81970784 from the National Natural Science Foundation of China, the grant, 2019B1515120014 from the Natural Science Foundation of Guangdong Province and the Fundamental Funds,3030901010110 of the State Key Laboratory of Ophthalmology of Zhongshan Ophthalmic Center, and the Graduate Scholarship from Sun Yat-sen University).

ABSTRACT BODY:

Purpose: Choroidal vascularity index (CVI) and choroidal thickness (CT) are novel biomarkers for the evaluation of choroidal vasculature. Although well established, comparative analysis of CT and CVI at different choroidal sectors in healthy eyes have not been performed. Aim of this study was to compare the sectorial choroidal vascularity index and thickness of the macula between two eyes in healthy subjects

Methods: This prospective study included 50 eyes of 25 healthy subjects who underwent a comprehensive ophthalmic examination and enhanced-depth spectral-domain optical coherence tomography for both eyes. CVI and CT measurements were obtained using a validated algorithm for each sector using an early treatment diabetic retinopathy study map. A comparison of corresponding sectors between two eyes and multivariate analysis was performed.

Results: The mean age was 50.4 ± 13.2 years with 13 females and 12 males. There was no statistical difference in mean CVI and CT values between corresponding sectors of both eyes (central CVI $P=0.74$, CT $P=0.77$; inner superior CVI $P=0.74$, CT $P=0.87$; inner temporal CVI $P=0.87$, CT $P=0.80$; inner nasal CVI $P=0.16$, CT $P=0.74$; inner inferior CVI $P=0.84$, CT $P=0.55$ outer superior $P=0.87$, CT $P=0.83$; outer inferior $P=0.89$, CT $P=0.68$; outer temporal $P=0.72$, CT $P=0.83$; outer nasal $P=0.66$ CT $P=0.90$). Age was the only significant factor on multivariate regression ($R^2=0.31$) Example of CVI maps of two eyes of the same subject has been uploaded as figure.

Conclusions: We report a significant positive relationship between age and sectoral values, whereas gender remained insignificant in both groups. Intra-sectoral (within the same eye) and inter- sectoral (between right and left eye) analysis of CT and CVI values yielded no significant difference. These results would be applicable to explore various chorioretinal diseases to evaluate sectoral choroidal changes.

ABSTRACT BODY:

Purpose: The EAGLE trial provides evidence supporting the use of initial early lens extraction (ELE) as a first-line intervention for patients with primary angle closure glaucoma (PACG) or primary angle closure (PAC) with high intraocular pressure (IOP). We assess baseline parameters associated with better long-term IOP control using data from the EAGLE trial.

Methods: The EAGLE trial was a multicenter randomized controlled study comparing ELE with laser peripheral iridotomy (LPI) in patients who did not have cataract and had newly diagnosed PAC with IOP \geq 30mmHg or PACG. Good responders were defined as IOP $<$ 21mmHg at 36-month follow up without using any medications and requiring no additional surgery.

Results: A total of 369 patients (182 in ELE arm and 187 in LPI arm) who completed the 36-month follow up visit were included in this study. Among 419 randomized participants, only one study eye randomized to ELE underwent trabeculectomy (0.5%) while six had trabeculectomy in the LPI arm (2.8%). After ELE, 66% met our pre-defined good response criterion at 36 months with significantly longer drops/surgery-free survival time as compared to only 18% in the LPI arm ($p < 0.05$). Using a multi-variate Cox proportional hazards model, patients randomized to LPI [Hazard ratio (HR) (95% CI)=2.52 (1.92-3.31)], non-Chinese [HR=1.52 (1.14-2.05)], those who used glaucoma drops before [HR=1.48 (1.12-1.95)] and those who had higher baseline IOP [HR=1.02 (1.00-1.03) per 1mmHg] were less likely to maintain long-term good IOP control over 36 months. Other baseline characteristics such as age, gender, diagnosis (PACG versus PAC), presence of peripheral anterior synechiae, anterior chamber depth, baseline visual field and visual acuity were not associated with long-term IOP control.

Conclusions: Patients with PACG/PAC are more likely to maintain drops-free good IOP control with initial ELE surgery than LPI. Chinese ethnicity, higher baseline IOP and using glaucoma drops prior to randomization are predictors of worse long-term IOP response.

TITLE:

Neurovascular coupling in the human retina evaluated by adaptive optics ophthalmoscopy

SESSION TITLE: Adaptive optics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Castro Farías, M. Paques, Centre Hospitalier National d'Ophtalmologie des Quinze-Vingts, Paris, Île-de-France, FRANCE|F. Rossant, ISEP Ecole d'ingénieurs du numérique, Paris, Île-de-France, FRANCE|C. Lavia, Università degli Studi di Torino, Torino, Piemonte, ITALY|

Commercial Relationships Disclosure (Abstract): Daniela Castro Farías: Commercial Relationship: Code N (No Commercial Relationship) | Carlo Lavia: Commercial Relationship: Code N (No Commercial Relationship) | Florence Rossant: Commercial Relationship: Code N (No Commercial Relationship) | Michel Paques: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

Neurovascular coupling (NVC) is the capability of vessels in neural tissue to adapt to neuronal demand. Here we report the results of flicker-induced dilation of retinal arterioles in normal subjects using adaptive optics ophthalmoscopy (AOO).

Methods:

The command program of the internal fixation light of a commercially available flood-illumination adaptive optics camera (rtx1, Imagine Eyes, Orsay, France) was modified to accommodate a 28°x20° flickering yellow light emitting diode, which is the light used for fixation target. The clinical procedure comprises 3 basal images before stimulation (taken within ± 60 seconds), followed by 3 periods of flickering stimulation at 15Hz during 20 seconds each; the image was captured during the last 2 seconds of the stimulation cycle. AOO images of arterial segments of at least 250 μm long in the posterior pole were segmented offline using a custom software (AOV image, developed by Florence Rossant). The protocol was approved by an ethical committee (Comité de Protection des Personnes).

Results:

21 eyes of 21 controls (10 females and 11 males; mean age \pm SD 38.4 years \pm 12.7) were examined. The average diameter of the arteries lumen was 85.1 μm (\pm 20.4). The difference between the basal measurements ranged from -2.22% to +2.86% with an average of +0.17%. Flicker-elicited dilation ranged from +0.83% to +6.63% with an average of +2.98%. The average wall to lumen-ratio of the vessels was of 0.24. Dilation was independent from age and size of vessel, but was inversely correlated with WLR ($p < 0.05$) (Figure 1).

Conclusions:

AOO-based NVC analysis offers a novel approach of the evaluation of the vasomotricity of retinal vessels. The vasodilation was found comparable to that reported using other methods, with the additional advantage of analyzing local changes and the concomitant measurement of the WLR. The latter was found to be inversely correlated to flicker-induced vasodilation. This may be an indication that microvascular tone may influence flicker response.

ABSTRACT BODY:

Purpose: Dexamethasone (Dex) is frequently used to treat inflammation. Though Dex has many advantages, it has side effects including elevated intraocular pressure (IOP) and glaucoma. About 40% of general population may develop ocular hypertension (OHT) upon prolonged glucocorticoid treatment which is due to damages in the trabecular meshwork (TM). This type of secondary glaucoma is called glucocorticoid-induced glaucoma (GIG). Identifying the key molecules responsible for glucocorticoid-induced OHT and GIG is crucial since they can be used to develop novel glucocorticoids without causing side effects. Our published studies using perfusion cultured bovine eyes suggested that inhibition of the canonical Wnt signaling pathway promotes glucocorticoid-induced OHT and glucocorticoid responsiveness. Therefore, we hypothesize that activation of canonical Wnt signaling prevents the side effects of glucocorticoids.

Methods: Aqueous humor and TM tissues were collected from patients and donor eyes for analyzing DKK1 expression using ELISA and immunofluorescence, respectively. Luciferase assays were performed in GTM3 and NTM5 cells using the GRE or TCF reporter kit to study the activity of the glucocorticoid receptor (GR) signaling or Wnt signaling pathway. Primary human TM (HTM) cells were treated with or without Dex, Wnt3a and/or GSK3 β inhibitors, and whole cell lysates and conditional medium were used for western immunoblotting (WB).

Results: We found elevated canonical Wnt signaling inhibitor Dkk1 in the aqueous humor and TM of glaucoma patients. At signaling level, we found that Dkk1 positively regulated GR signaling. We also observed that Wnt signaling activators decreased GR signaling in HTM cells using luciferase assays. Similarly, activation of GR signaling inhibited Wnt signaling. At protein level, Dex-induced extracellular matrix (ECM) was inhibited by Wnt activation using Wnt activators or Dkk1 knockdown in primary HTM cells. In contrast, inhibition of canonical Wnt signaling by β -catenin knockdown increased Dex-induced ECM proteins. At physiological level, we found that adenovirus-mediated Wnt3a expression decreased Dex-induced OHT in mouse eyes.

Conclusions: Wnt and GR signaling inhibit each other in the TM, and canonical Wnt signaling activators have the potential to prevent the side effect of glucocorticoids.

ABSTRACT BODY:

Purpose: To assess whether smoking, alcohol consumption, body mass index (BMI), blood pressure (BP) and glycaemic traits have a causal role in the risk of advanced age-related macular degeneration (AMD).

Methods: We used two-sample inverse-variance weighted, MR-Egger and weighted median mendelian randomisation methods to investigate the association between modifiable risk factors (smoking, alcohol consumption, BMI, BP and glycaemic traits) and the risk of advanced AMD (neovascular AMD or geographic atrophy). Summary level genetic association data for advanced AMD (n=16,144) were obtained from the International AMD Genomics Consortium (IAMDGC) genome-wide association study (GWAS). Genetic instruments composed of single nucleotide polymorphisms associated with modifiable risk factors at genome-wide significance ($P < 5 \times 10^{-8}$) were obtained from published GWASs.

Results: Genetically predicted lifetime smoking was associated with increased advanced AMD risk (odds ratio (OR) per unit increase of the lifetime smoking index 1.49; 95% CI 1.13-1.95; $P=0.004$). Specifically, a one-standard deviation (SD) increase in log odds of ever smoking was associated with higher risk (OR 1.26; 95% CI 1.13-1.40; $P<0.001$), while a one-SD increase in log odds of smoking cessation (former versus current smoking) was associated with lower risk (OR 0.66; 95% CI 0.50-0.87; $P=0.003$). A one-SD increase of log-transformed alcoholic drinks per week was suggestive of an association with higher risk of advanced AMD (OR 1.57; 95% CI 1.03-2.40; $P=0.04$). There was insufficient evidence to suggest associations with genetically predicted BP, BMI and glycaemic traits (figure).

Conclusions: This study provides genetic evidence that ever smoking is causal for advanced AMD risk, while smoking cessation is protective. The evidence also suggests that increased alcohol intake is a causal risk factor. Public health messages regarding the adverse consequences of smoking and excessive alcohol consumption should include warnings about the risk of blindness.

ABSTRACT BODY:

Purpose: To compare central vs. peripheral visual field sensitivities and delays in neovascular AMD (nAMD) and earlier-stage fellow eyes using FDA-cleared multifocal pupillographic objective perimetry (mfPOP).

Methods: We recruited 18 nAMD patients testing both eyes concurrently. Practitioner directed intravitreal anti-VEGF injection was administered monthly for 14 to 28 visits. Diagnostic procedures included mfPOP, Matrix 10-2 perimetry, and OCT. The macular mfPOP variant had 44 interleaved stimuli/eye presented from fixation to 15^o eccentricity. We examined correlations between central and peripheral mfPOP per-region sensitivities and delays within eyes, and between nAMD eyes and untreated fellow eyes.

Results: Twenty-three eyes of 18 patients were tested (14 females, 77.8%). In treated eyes central sensitivity decreased over time by -2.23 ± 0.051 dB/month ($p < 0.0002$). Untreated fellow central sensitivity declined at -0.17 ± 0.07 dB/month ($p = 0.033$). Treated eyes showed quicker central responses by 13.08 ± 3.77 ms than untreated eyes ($p = 0.001$). Based on peripheral sensitivities and delays we have identified two patient categories: positive types with hypersensitivity and longer delays, and negative types with hyposensitivity and shorter delays compared to normal controls. When analysed separately mfPOP data showed an ability to predict the need for anti-VEGF injection. Among the positive eyes peripheral sensitivity increased by 9.88 ± 4.41 dB ($p = 0.042$) before treatment, and delays increased by 3.49 ± 1.75 ms/month ($p = 0.049$). For the negative eyes, the peripheral sensitivity dropped, and the delay was shorter a month before the treatment by 9.38 ± 3.59 ($p = 0.013$), and a month following treatment it improved towards normal values (shorter by 8.50 ± 2.71 ms, $p = 0.004$).

Conclusions: We observed decreased central sensitivity, and coincident peripheral hypersensitivity. In the untreated fellow eyes, the central sensitivity decreased and delay increased progressively until treatment was needed. Based on peripheral responses the eyes could be divided into positive and negative groups. The predictive value of mfPOP improved after the positive and negative eyes were analysed separately. Diagnostic sensitivity and delay changes could precede active disease by 1 to 3 months. We conclude that mfPOP may be a potential biomarker to predict the need for anti-VEGF injections in nAMD.

TITLE: Purposeful Pneumatic Induced Resorption of Submacular Fluid in Macula-off Retinal Detachments

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Chaili, J. Fitzpatrick, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|A. Pirouz, S. Grant, S. Adrean, Retina Consultants of Orange County, Fullerton, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Siyang Chaili: Commercial Relationship: Code N (No Commercial Relationship) | John Fitzpatrick: Commercial Relationship: Code N (No Commercial Relationship) | Ash Pirouz: Commercial Relationship: Code N (No Commercial Relationship) | Scott Grant: Commercial Relationship: Code N (No Commercial Relationship) | Sean Adrean: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate visual outcomes in eyes with macula-off retinal detachments (RD) with purposeful submacular fluid retention after vitrectomy to allow for slow pneumatic macular flattening.

Methods: Retrospective study of 139 patients with macula-off RD. Patients were included if repaired with primary vitrectomy (VIT) or VIT with scleral buckle (SB). Patients were excluded if they had >6 wks to surgery, prior vitreous surgery, SB alone, drainage retinotomy or perfluorocarbon, development of proliferative vitreoretinopathy (PVR), <6 mon follow up, or other macular pathology. Patients underwent 3-port pars plana VIT with SB. Subretinal fluid was aspirated from pre-existing retinal breaks during air-fluid exchange (AFX). At the end of surgery fluid remained in the posterior pole and SF6 or C3F8 gas was then introduced with proper head positioning.

Results: Subretinal fluid was reabsorbed and gas fill was observed at post-op day 1. Mean baseline vision was 20.0±24.4 ETDRS letters (20/400) for 127/198 included patients. Of 71 excluded patients, 12 developed PVR. Primary repair success rate was 91.4% (127/139). Mean time to surgery was 8.6±7.9 days. At 6 months post-op, mean vision improved to 62.9±17.9 letters (20/60), an increase of 43.1±28.0 letters (8.6 lines) which was better than baseline ($p<0.001$). Best achieved vision averaged 72.6±13.2 letters (20/30-2), an increase of 52.8±25.1 letters (9.5 lines), at an average of 14.1±11.0 months later ($p<0.001$ vs baseline & 6 months post-op). Mean time to final follow-up was 25.8±26.5 months. Patients with $\geq 20/40$ vision increased from 3.1% at baseline to 44.9% at 6 months post-op to 74.8% at best achieved vision. Conversely, patients with $\leq 20/200$ vision decreased from 78.7% at baseline to 14.2% at 6 months post-op to 4.7% at best achieved vision.

Conclusions: Good visual outcomes may be achieved and maintained even if the duration of the macular detachment is longer than several weeks. Leaving fluid in the macula at the end of the surgery may allow the RPE pump to more physiologically remove submacular fluid, and for the photoreceptor/RPE microvilli interdigitation to anneal with better retinotopic organization, promoting visual recovery.

ABSTRACT BODY:

Purpose: The ability to interpret the artificial visual stimulus created by the Argus II retinal prosthesis can vary with the user's perceptual capabilities. Outcomes and proficient use may be improved through consistent training with self-administered rehabilitation tools in the home setting. An individualized 3D printed tool that allows the user to integrate both tactile and visual stimulus could help deliver personalized, in home ultra-low vision rehabilitation. This study investigates the feasibility of training with an individualized tool designed to improve shape and pattern recognition as well as spatial awareness.

Methods: Using CAD software, a board with an integrated grid for holding colored tokens was designed and printed using a 3D printer (Figure 1). Additionally, a holder was designed and printed to support the board at a comfortable angle, facilitating image capture by the Argus II camera. The initial board grid and tokens was mailed to the patient, and feedback describing visualization were shared. This iterative design cycle was repeated three times, until a token size, color and board grid spacing was achieved, such that the patient could easily visualize the tokens and create shapes and patterns. Using a mobile phone, the patient transmitted videos and photos of shapes and patterns, with audio descriptions of the visualization experience (Figure 2).

Results: A custom visual-tactile rehabilitation tool was created based on an interactive design process, with detailed feedback from a collaborating Argus II recipient. The patient was able to utilize the board for various visual exercises utilizing tactile feedback and provide constructive criticism for design improvement. The customized angle of the board minimized neck strain and reduced glare. This customizable tool introduced variability in daily exercises aimed to improve perception capabilities of patients implanted with the Argus II retinal prosthesis.

Conclusions: Incorporating a customized visual tactile tool for ultra-low vision rehabilitation at a patient's home can improve interpretation of the visual precepts delivered by the Argus II retinal prosthesis. In addition, the interactive, exploratory design process, increased patient engagement, with self-report indicating an increased Argus II retinal prosthesis utilization.

TITLE: Elucidating the role of the aryl hydrocarbon receptor and the insulin-like growth factor 1 receptor in Thyroid Eye Disease orbital fibroblasts.

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Woeller, E. Roztocil, C. Hammond, M. Gonzalez, S.E. Feldon, Department of Ophthalmology, University of Rochester Medical Center, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Collynn Woeller: Commercial Relationship: Code N (No Commercial Relationship) | Elisa Roztocil: Commercial Relationship: Code N (No Commercial Relationship) | Christine Hammond: Commercial Relationship: Code N (No Commercial Relationship) | Mithra Gonzalez: Commercial Relationship: Code N (No Commercial Relationship) | Steven Feldon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In Thyroid Eye Disease (TED), the connective tissue behind the eye becomes inflamed and enlarged. As orbital tissue expands, patients develop proptosis, diplopia, optic neuropathy and in severe cases, blindness. Cigarette smoking increases the chances of developing TED by more than 7-fold. Currently, there is no cure for TED and targeted treatments are limited. The insulin-like growth factor 1 receptor (IGF1R) and the aryl hydrocarbon receptor (AHR) pathways are implicated in inflammation and TED tissue remodeling. The goal of this work is to better define these pathways so that novel therapeutics can be identified.

Methods: Orbital fibroblasts (OFs) were treated with the IGF1 with or without cigarette smoke extract. The endogenous AHR ligand FICZ was used to activate AHR in OFs. IGF1R expression was depleted by IGF1R specific siRNA. AHR knockout OFs were generated using CRISPR/Cas9n. Cell proliferation was measured by BrdU incorporation and inflammatory cytokine production was analyzed by RT-qPCR and ELISA. Activation of downstream signaling cascades known to be upregulated in TED and involved in tissue remodeling (PI3K/Akt and MAPK/Erk) were detected by Western blot.

Results: IGF1R activation induced proliferation and PI3K/Akt signaling in OFs while smoke exposure increased inflammatory cytokine levels. Ligand activation of AHR reduced PI3K/Akt, MAPK/Erk signaling and cell proliferation. In contrast, knockout of AHR resulted in increased proliferation, increased inflammatory cytokine expression and elevated MAPK/Erk signaling.

Conclusions: These studies show that AHR can block IGF1R mediated proliferation and PI3K/Akt signaling in OFs. AHR also reduces MAPK/Erk signaling driven by cigarette smoke exposure. These data suggest that the AHR pathway is a promising target to attenuate detrimental signaling and tissue remodeling that occurs in TED.

TITLE: Estimating Patient Demand for Oculoplastic Surgeons in the United States Using Google Search Trends

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Tamm, H. Pakhchanian, D. Belyea, C. Geist, Ophthalmology, The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, UNITED STATES|R. Raiker, West Virginia University School of Medicine, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Brendan Tamm: Commercial Relationship: Code N (No Commercial Relationship) | Rahul Raiker: Commercial Relationship: Code N (No Commercial Relationship) | Haig Pakhchanian: Commercial Relationship: Code N (No Commercial Relationship) | David Belyea: Commercial Relationship: Code N (No Commercial Relationship) | Craig Geist: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oculoplastic surgeons who undergo an accredited fellowship have the expertise necessary to manage myriad facial and orbital surgeries. With the aging Baby Boomer population, demand for cosmetic and non-cosmetic eyelid and facial procedures is likely to grow, and patients may use search engines to identify potential oculoplastic surgeons for their healthcare needs. Currently, the United States is facing a severe shortage of oculoplastic surgeons with an unequal distribution across the United States. The regional public demand for ASOPRS-trained oculoplastic surgeons remains unknown and is the topic of this investigation.

Methods: Google Trends was queried for data from 2004-2019 to find the average relative search volume (RSV) for the term “blepharoplasty” in each state. The number of oculoplastic surgeons from each state was acquired through the ASOPRS directory, and then divided by the 2019 Census Bureau population estimates to find the concentration of specialists per capita values. The RSV values were then divided by the per capita values to estimate the demand index of oculoplastic surgeons for each state.

Results: The relative demand index (RDI) was highest in Montana, New Mexico, North Dakota, South Dakota, and Wyoming as these states all have zero ASOPRS oculoplastic surgeons. RDI is lowest in the District of Columbia (5.0), Utah (12.0), and Wisconsin (12.0). The greatest specialist concentration per 10,000 people was in DC (0.0798), Rhode Island (0.0377), and Utah (0.0343), and lowest in Hawaii (0.00706), Louisiana (0.0107), and Idaho (0.0112). The highest search volumes (RSV) were in Hawaii (100) Florida (92), and California (89), and lowest in Vermont (45), Idaho, Iowa, Wisconsin, and Wyoming (all at 50).

Conclusions: The findings highlight which populations may be saturated and which may have a significant unmet need for ASOPRS-trained oculoplastic surgeons and the essential services that they provide. Strikingly, multiple states are without any ASOPRS oculoplastic surgeons and would greatly benefit from their addition to the healthcare community.

ABSTRACT BODY:

Purpose: SNPs close to GJD2, a gene encoding a gap junction protein, have been consistently found to influence the risk of refractive error (RE) and myopia. To functionally investigate the pathophysiological link between GJD2/Cx36 and RE, we evaluated biometrical, optical, and electrophysiological changes in gjd2 deficient zebrafish eyes.

Methods: Here, we studied depletion of two zebrafish GJD2 orthologues, gjd2a (Cx35.5) and gjd2b (Cx35.1). The expression profiles of both genes were assessed by IHC and single-cell RNA-seq. Axial length (AL) was measured by SD-Optical Coherence Tomography (SD-OCT) (n=40) at 1.5-3 months post fertilization (mpf). RE was measured between 1.5-9mpf (n=20). Cataracts were visualized by SD-OCT and differential interference contrast microscopy. A linear mixed model was used to evaluate differences between mutant and WT control fish for AL, RE and lens opacity. Electroretinograms (ERGs) were recorded in 2.5 mpf fish (n=22) and differential B-wave amplitudes analyzed by one-way ANOVA.

Results: Our expression studies showed that both gjd2a (Cx35.5) and gjd2b (Cx35.1) are expressed in the fish retina; only Cx35.1 (gjd2b) is also expressed in the lens.

Depletion of gjd2a led to hyperopia, characterized by decreased AL (~50µm at 1.5-3mpf, P<0.001) and corresponding ascending RE relative to WT (~+2D at 1.5mpf to ~+8D at 9mpf, P<0.001). ERG showed a decreased B-wave amplitude in gjd2a mutants (p<0.001).

We found no alterations in axial length in the gjd2b mutants between 1.5-3mpf. However, we observed a progressive and severe nuclear cataract affecting 100% of the eyes at 6mpf (~28% increase in opacity, p<0.001). The cataract was accompanied by a myopic shift in refractive status (~-5D at 1.5mpf to ~-10D at 9mpf, p<0.001) and late-onset increase in AL (~77µm at 6mpf, P<0.001).

Conclusions: This work in zebrafish showed that both gjd2a (Cx35.5) and gjd2b (Cx35.1) cause changes in refractive status, thereby providing the first evidence for a functional role of GJD2 in refraction. Both mutants showed biometrical and optical alterations, interestingly, in opposite directions. The absence of Cx35.5 led to hyperopia and a significant electrophysiological defect, whereas the absence of Cx35.1 resulted in a severe opacification of the lens and, as a result, a myopic defocus and late-onset axial elongation. We conclude that aberrant electrical gap junction signaling

leads to defective emmetropization.

ABSTRACT BODY:

Purpose: The aim of this multicentre retrospective study was to review the outcomes of a large group of patients treated with systemic biologic therapy.

Methods: Retrospective chart review of patients with refractory non-infectious active uveitis treated with adalimumab was conducted. The main outcome measures were ability to reduce prednisolone dose, ability to taper immunosuppressives, final visual acuity and time to treatment failure or relapse.

Results: Forty-Six (46) uveitis patients on adalimumab were included in the study. There were 26 (56.5%) male patients and 20 (43.5%) female patients with 43 (93.5%) patients having bilateral active uveitis. The most common anatomical uveitis phenotype was panuveitis (n=17, 37.0%), followed by anterior uveitis (n=12, 26.1%), posterior uveitis (n=10, 21.7%) and intermediate uveitis (n=7, 15.3%). The most common diagnosis of patients on adalimumab was idiopathic uveitis (undifferentiated) (n=19, 41.3%). During follow-up, 35 (76.1%) patients were able to taper and discontinue corticosteroids, while 10 (21.7%) patients were able to taper corticosteroids <7.5mg per day. One (2.2%) patient required a prednisolone dose of 10 mg and one (2.2%) is on a weaning dose of steroids expected to be below 7.5mg/day. The mean visual acuity at the latest follow-up of the worse eye was logMAR 0.42 (SD 0.72), while the mean visual acuity of the better eye was logMAR 0.19 (SD 0.34). Of the 89 eyes, 21 (23.6%) eyes improved by at least 2 lines, 5 eyes (5.6%) deteriorated by 2 or more lines while vision was unchanged in the remaining 6 (70.8%) eyes. The person-years to recurrence was 1 in 12.47 person-years for adalimumab, with a 17.4% (8 patient) relapse rate. In this study, the length of time between diagnosis and commencement of adalimumab was shorter if diagnosed in 2016 or later, compared to diagnosis prior to 2016 (p<0.001). There were no serious adverse events.

Conclusions: This study highlights the importance of commencing adalimumab early in patients with sight threatening or poorly controlled uveitis to maximise visual outcomes, decrease ocular complications, and to reduce prednisolone dosage.

TITLE: Readability Analysis of Laser Eye Surgery (LASIK) Online Patient Educational Material.

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Geist, Ophthalmology, The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, UNITED STATES|R. Raiker, Ophthalmology, West Virginia University Health Sciences Center, Morgantown, West Virginia, UNITED STATES|E. Flynn, H. Pakhchanian, Ophthalmology, The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Erin Flynn: Commercial Relationship: Code N (No Commercial Relationship) | Haig Pakhchanian: Commercial Relationship: Code N (No Commercial Relationship) | Rahul Raiker: Commercial Relationship: Code N (No Commercial Relationship) | Craig Geist: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Laser-Assisted In Situ Keratomileusis (LASIK) is a popular ophthalmic procedure many patients with poor eyesight consider getting. With the easy accessibility of the internet, many patients will use it gain more knowledge about the procedure and determine whether they should get it or not. However, there is scant information on how easy it is for patients to easily understand online patient educational materials (PEM). The goal of this study was to analyze the readability of online PEM on LASIK.

Methods: Using the google search engine, the term "LASIK" was searched, and the top 10 results were picked for analysis. Results that meant for medical professionals and results containing extraneous text not pertinent to the procedure were excluded. The body of text from each website was then analyzed using ten validated tests for readability assessment: Flesch Reading Ease Test (FRE), Flesch-Kincaid Grade Level (FKGL), Simple Measure of Gobbledygook (SMOG), Coleman-Liau Index (CLI), Gunning Fog Index (GFI), New Dale-Chall Readability (NDC), FORCAST, Fry Graph Readability (FG), Raygor Readability Estimate (RRE), and New Fog Count (NFC).

Results: The mean (SD) readability scores were 46 (10.2), 11.2 (2.1), 13.3 (1.6), 11.7 (1.7), 13.5 (2.0), 11.6 (2.5), 11.4 (0.5), 13 (2.7), 12 (2.8), 9.9 (1.9) for FRE, FKGL, SMOG, CLI, GFI, NDC, FORCAST, FG, RRE, and NFC, respectively. All ten of the mean readability scores were well above the fourth to sixth grade reading level as recommended by the National Institute of Health and the American Medical Association for PEM.

Conclusions: These findings demonstrate that the average patient would have difficulty comprehending PEM based on LASIK, thus hindering their ability to make informed decisions on whether they should get the procedure. It's crucial that healthcare workers consider spending more time in designing PEM that's easily understandable as this will lead to better outcomes and improved patient satisfaction.

ABSTRACT BODY:

Purpose: To analyse 10 years data of corneal and conjunctival pathology specimens, from a tertiary eye care corneal service in the UK.

Methods: This retrospective single-centre study was conducted from August 2010 to December 2019, to analyse demographics, characteristics and type of corneal samples sent to the ocular pathology department (Sheffield, UK) as part of the clinical practice at tertiary care hospital in the UK.

Results: 1376 corneal and conjunctival specimens were analysed from 534 patients which includes 324 (60.7%) males with mean age 58.3 (SD 20.3; range 05-103 years); 680 (49.2%) samples were taken from right eye, 1175 (85.3 %) were corneal and 201 (14.7 %) were conjunctival pathology specimens. Patient to sample ratio was 1:2.5 (534/1376) while 345 (64.6%) patients had more than one sample. 905 (65.7%; 99.5% corneal) were corneal/conjunctival impression cytology, followed by 274 (19.9%) corneal tissues and 195 (14.1 %) conjunctival tissue. Most common corneal clinical diagnosis was limbal stem cell deficiency (LSCD; n=569; 41.3%), followed by corneal regrafts (n=71; 5.2%) and Fuchs' endothelial dystrophy (n=64; 4.7%). Most common conjunctival diagnosis was pterygium (n=50; 3.6%), followed by ocular surface neoplasia (n=39; 2.8%) and conjunctival necrosis due to chemical burn (n=13; 0.9%). Maximum number of samples were sent in 2014 (n=224; 16.3%) related to a higher proportion of corneal impression cytology specimens as part of an autologous limbal stem cell transplantation study. Moreover, in most of the cases there was a strong agreement between clinical and pathology diagnosis (n=1214; 88.3%).

Conclusions: In our service there were more samples from males and most of the patients had more than 1 sample. More than two thirds of samples were corneal and mainly taken for impression cytology to assist in the diagnosis of limbal stem cell deficiency and assessment of response to limbal transplant treatment, after chemical burn. Most of the time clinical and pathological diagnosis was in agreement, however, there was disagreement in 162 (11.7%) samples, mainly related to a slight disparity in severity grading of LSCD.

Close collaboration with an ocular pathology service is an integral part of corneal service provision in the UK and must be encouraged. It provides essential diagnostic support to be able to deliver a safe and efficient corneal service to patients.

TITLE: Asynchronous Electrical Stimulation Improves Spatial Resolution with Subretinal Electrodes

SESSION TITLE: Retinitis pigmentosa/ retinal prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Li, National Tsing Hua University, Hsinchu, TAIWAN|

Commercial Relationships Disclosure (Abstract): Wun-Ting Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Electrical stimulation using retinal prosthesis has been a promising strategy for helping patients with retinal degenerative diseases such as retinitis pigmentosa (RP) and age-related macular degeneration (AMD). However, multiple electrodes applying stimulation simultaneously in retinal prosthesis decreases spatial resolution, which is one of the major challenges. In this study, we recorded the spiking response of retinal ganglion cells (RGCs) under two neighboring stimulating electrodes either applying electrical stimulations synchronously or asynchronously to assess the crosstalk effect.

Methods: The retinas dissected from adult C57BL/6J mice were placed onto a microelectrode array (MEA) with the photoreceptor (bottom) side down. Whole-cell current clamp recordings were used to record the spiking responses of RGCs. An anodic-biphasic voltage pulse from 0.1 V to 2.4 V was delivered from one electrode or two neighboring electrodes synchronously or asynchronously.

Results: When the dominated stimulating electrode (under the recorded cell) and the subordinated stimulating electrode (the neighbor electrode) stimulated the RGC synchronously, the threshold voltage required to activate the RGC was lowered comparing to the dominated stimulating electrode alone. In the dominated stimulating electrode leading experiment, the spikes resulting from the subordinated stimulating electrode were significantly less than the one from the subordinated electrode alone. In the subordinated stimulating electrode leading experiment, the spikes resulting from the dominated stimulating electrode decreased as the delay time of the dominated stimulating electrode increased. By separating these recorded RGCs into two groups based on their membrane potential (MP) changes, the cells with hyperpolarized MP had less spiking responses than the cells with depolarized MP after stimulation.

Conclusions: Although both neighboring electrodes stimulating the RGC synchronously can decrease the threshold voltage, nearby cells were also stimulated by the neighboring electrodes, which reducing the spatial resolution . In this study, we demonstrate that two neighboring electrodes stimulated the RGC asynchronously can effectively prevent cells from generating unwanted spikes. Among these RGCs, cells that exhibit long-term hyperpolarization after stimulation were more difficult to generate the second spike by the neighbor electrode.

ABSTRACT BODY:

Purpose: Heat shock proteins play important roles in mediating cellular stress responses and protect the internal milieu against damage. Changes in the expression levels of these proteins are often related to various human diseases. In the present study, we have analyzed different heat shock proteins including HSP90, HSP70, HSP60 and HSP40 in human normal and cataractous lenses of different age groups (from 50 years old to 89 years old).

Methods: Normal human lenses of 50 and 60 years old, and cataractous lenses of different age groups (from 50 years old to 89 years old) were used as material. Mouse lens epithelial cell line, aTN4-1 cells were used to knockdown HSP90 through CRISPR/Cas9 technology. Automated western immunoblotting was used to analyze the changes of different heat shock proteins in normal or cataractous lenses. CellTiter-Glo® luminescent cell viability assay and live/dead assay were used to detect apoptosis. ChIP and EMSA were used to analyze HSF1/HSF4/SP4 control of HSP90 gene expression.

Results: Among the 4 heat shock proteins, HSP90 is the most abundant and HSP40 is the least abundant (about 15-fold less than that of HSP90) in both normal and cataractous lenses. Compared with HSP90, HSP70 and HSP60 are about 8-fold less in both normal and cataract patients. Compared with normal lenses, HSP90 and HSP40 are downregulated in cataractous lenses. In contrast, HSP70 and HSP60 are upregulated from transparent lenses to cataractous lenses. In different age groups of cataractous patients, the levels of HSP90, HSP70 and HSP40 remain relatively stable from 50s to 70s. HSP60 displays significant downregulation from 60s to 70s. From 70s to 80s, HSP70 displays significant downregulation, and HSP60 resumes its level detected in 50s and 60s. In mouse lens epithelial cells, CRISPR/Cas9-mediated knockdown of HSP90 enhances oxidative stress-induced apoptosis.

Conclusions: our results demonstrated that HSP90 is a dominant heat shock protein in the ocular lenses and plays an important role in preventing stress-induced apoptosis and cataractogenesis. (Supported by the grants, #81770910, #81970787, from the NSFC, the grant, 2019B1515120014 from the NSFG and the Fundamental Funds, 3030901010110 of the State Key Laboratory of Ophthalmology of Zhongshan Ophthalmic Center, and the Graduate Scholarship from Sun Yat-sen University).

TITLE: The role of the EPCR pathway in protecting endogenous repair cells in the choriocapillaris

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Peixoto, S. Chambers, S. McKeown, L. Allen, P. Bertelli, R.J. Medina, A. Stitt, School of Medicine, Dentistry and Biomedical Science, Queen's University of Belfast, Belfast, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Elisa Peixoto: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Chambers: Commercial Relationship: Code N (No Commercial Relationship) | Stuart McKeown: Commercial Relationship: Code N (No Commercial Relationship) | Lynsey-Dawn Allen: Commercial Relationship: Code N (No Commercial Relationship) | Pietro Bertelli: Commercial Relationship: Code N (No Commercial Relationship) | Reinhold Medina: Commercial Relationship: Code N (No Commercial Relationship) | Alan Stitt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A key feature of age-related macular degeneration (AMD) is atrophic pathology in the choriocapillaris (CC). It could be considered that loss of the CC, at least in part, relates to the age-related decline in endogenous vascular repair mechanisms creating hypoxia in the outer retina. We hypothesised that the CC harbours vessel-resident endothelial progenitors which could become senescent and dysfunctional with age and impair normal homeostasis and repair. Recently, the endothelial protein C receptor (EPCR) has been identified as a marker of progenitors known as endothelial colony forming cells (ECFCs). This study aimed to investigate EPCR and its ligand, APC, in ECFCs in the context of the CC.

Methods: Mouse choroidal flatmounts were investigated for presence of EPCR. Western blot, RT-PCR, flow cytometry, 3D-tube formation in matrigel, choroidal explant, immunofluorescence for Lectin/CD31/CD201, b-galactosidase staining, xCelligence system. For multiple comparisons, we used one-way analysis of variance (ANOVA) and paired two tailed t-test analysis. $p \leq 0.05$ were considered significant.

Results: EPCR was present in sub-populations of cells in the murine CC and in choroidal explants. ECFCs senescence lead a significant decrease in the gene and protein expression of EPCR ($p=0.0002$). ECFCs exposed to hypoxia (1% and 5% O_2) showed a marked decrease in the EPCR gene and protein expression when compared to normoxic conditions ($p=0.002$). APC treatment prevented hypoxia-induced decrease in ECFC tubulogenesis and improved barrier function ($p \leq 0.05$). The knockdown of EPCR by siRNA lead a significant reduction in tubulogenesis ($p < 0.0001$), and this was also accompanied by decreased expression of eNOS and CCBN2 ($p < 0.0001$). We also observed an alteration of quiescent markers but not the senescence pathway. Choroidal explants exposed to EPCR siRNA showed a significant decrease of the sprouting in the matrigel and the treatment with APC re-established the vessel growth.

Conclusions: EPCR is present in the CC which may relates to ECFC-like cells resident in these vessels. Regulation of the EPCR-APC pathway impact on progenitor function and could be a potential therapeutic avenue to enhance endogenous repair of the CC, especially in the context of AMD.

ABSTRACT BODY:

Purpose: To evaluate the efficacy and safety of transplantation of the Peripheral blood mononuclear cell (PBMC) induced pluripotent stem cell (iPSC)-derived corneal endothelial-like cells into corneal endothelial failure animal model

Methods: PBMC iPSCs were generated using the iPS Reprogramming Kit with StemPro-34 medium and cultured under standard iPSC culture condition. Differentiation of iPSCs into corneal endothelial-like cells via neural crest cells (NCC) was induced using a conditioned medium in vitro. After 10 days culture of NCC with human endothelium serum free media, the phenotype of iPSC-derived corneal endothelial-like cells was detected by immunofluorescence. Related cell markers of iPSC-derived corneal endothelial-like cells were analyzed by quantitative real-time PCR. The cultured iPSC-derived corneal endothelial-like cells were transplanted into the rabbit anterior chamber by direct cell injection.

Results: After 10 days culture of NCC with human endothelium serum free media, corneal endothelial cell-related markers, including zonula occludens-1 (ZO-1) and Na^+/K^+ ATPase, were expressed in the iPSC-derived corneal endothelial-like cells, showing well preserved hexagonality. The expression of ATP1A1, COL8A1, and AQP1 was higher in the iPSC-derived corneal endothelial-like cells, compared with the NCC and PBMC iPSCs. In animal experiment, increased corneal transparency was achieved after anterior chamber injection of the iPSC-derived corneal endothelial-like cells. PCR from the genomic DNA extract of central cornea which was enucleated 3 weeks after cell injection showed a positive result for human mitochondrial band, whereas negative band noted in the non-treated rabbit.

Conclusions: This preclinical study confirmed the therapeutic ability of the iPSC-derived corneal endothelial-like cells in vivo. Our findings demonstrated that iPSC-derived corneal endothelial-like cells could be a promising source for cell therapy in corneal endothelial dysfunction.

ABSTRACT BODY:

Purpose: To determine the feasibility of using soft hydrogel contact lenses as non-invasive sources for dopamine measurements

Methods: This pilot study included 20 patients, age 18-30 years old, with myopia -0.75D to -5.00D. Three different designs of soft hydrogel lenses (single vision spherical and dual focus in Omafilcon A and extended depth of focus in Etafilcon A) lenses were worn for an 8-hour period and then collected, initially in 1ml saline and then dry. The tear envelopes containing the dopamine were extracted and these extracts analysed using a direct competitive chemiluminescent enzyme linked immunosorbent assay (ELISA) dopamine kit (ENZO Life Sciences UK)

Results: Minimal variation was observed between the lens types in terms of the dopamine level recovered for analysis Omafilcon A 442.1 ± 82.7 pg/ml and Etafilcon A 455.1 ± 67.7 pg/ml ($p=0.038$)

Data, as would be expected due to the different sampling methods, is higher than a previously reported study using Schirmer strips and capillaries as shown in Table 1.

The assay method has sufficient sensitivity to detect dopamine in tear fluid (down to the pStep 1: Title/Bodyicogram/ml level as shown in Table 1).

Conclusions: The findings demonstrate that a soft hydrogel contact lens can be used as a non-invasive sampling vehicle to remove the tear envelope and allow dopamine detection from the anterior ocular environment. Different lens types did not adversely affect the recovery rate from the tear envelop.

By combining different sampling methodologies this will enable a greater understanding of the diurnal and longitudinal variation in dopamine levels using both snapshot assessment via Schirmer strip, ophthalmic sponge or capillary tube and non-invasive tear envelop sampling. This will provide insights into the role of dopamine and other neurotransmitters to better understand factors involved in myopia progression.

TITLE: Topical Insulin - Utility and results in refractory Neurotrophic Keratopathy in stages 2 and 3

SESSION TITLE: Corneal stromal wound repair and healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.M. Soares, C. Arêde, J. Fernandes, C. Ferreira, J. Sequeira, Ophthalmology Department, Centro Hospitalar Vila Nova de Gaia e Espinho, PORTUGAL|

Commercial Relationships Disclosure (Abstract): Ricardo Soares: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Arêde: Commercial Relationship: Code N (No Commercial Relationship) | Joana Fernandes: Commercial Relationship: Code N (No Commercial Relationship) | Catarina Ferreira: Commercial Relationship: Code N (No Commercial Relationship) | Joaquim Sequeira: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the clinical progression of patients with refractory Neurotrophic Keratopathy (NK) in stages 2 and 3 that were treated with topical insulin

Methods: Retrospective case-series analysis of 20 patients (21 eyes - 13 to 92 years of age) with NK in stages 2 and 3 that were treated with off-label topical insulin from October of 2018 to October 2020. Patients included were refractory to standard medical and/or surgical treatment. Primary outcome of the study was the complete resolution of the persistent epithelial defect or ulcer. The secondary outcomes were improvement of visual acuity and increase in corneal transparency. Patient data including best corrected visual acuity (BCVA), corneal transparency, corneal sensitivity and previous treatments were analysed. Every patient applied topical insulin drops (1 unit /1 mL) 4 times per day, a therapeutic contact lens and prophylactic fluoroquinolone drops. Treatment was continued until NK persistent epithelial defect (PED) or ulcer resolved and then tapered accordingly. Patients discontinued treatment if condition did not improve or worsened within 30 days. Anterior segment photos images were taken on each visit. Data was compared before and after treatment in both groups (NK stage 2 and stage 3) using paired t-test and p-value significance level was set at 0.05.

Results: Nineteen of twenty-one eyes (90%) had complete resolution of NK PED and/or ulcer within 7-45 days of follow-up. Both patients that did not fully respond to treatment had contact lens fitting problems and treatment was stopped although some improvement was noted. A temporary tarsorrhaphy was performed in one of these patients, to no avail. When insulin drops were re-introduced with a tarsorrhaphy in place, full reepithelialisation was achieved. Visual acuity significantly improved after treatment [$p < 0.05$]. However, as expected, higher improvements in BCVA were seen in patients with NK stage 2 when compared to NK stage 3. Corneal transparency also improved in both groups albeit it increased more in NK stage 2 eyes once again. No side-effects were reported during full extent of treatment.

Conclusions: Our results suggest that topical insulin drops could be an effective therapeutic in refractory NK due to its high efficacy, accessibility, low-cost and low morbidity. However, more investigation in this area is warranted.

ABSTRACT BODY:

Purpose: Aging is associated with various degenerative changes in the retina, including some of the most destructive and widespread ocular pathologies, such as glaucoma or age-related macular degeneration. As neurodegeneration is by nature evolving, distinguishing it from normal aging of the tissue is crucial. 2D histology (eg sectioning of tissues) may miss spatial information, since the manifestation of aging can be focal. Furthermore, the combined investigation of the aging retina and choroid is interesting since these structures are interdependent. Here we chose to use immunohistochemistry and confocal imaging to search for anatomical changes in retinal and choroidal cells across human donor's tissues.

Methods: Five human donors with no registered ocular diseases were analyzed. Peripheral retina and choroid underwent immunohistochemistry allowing investigation of different cell types and the protein expression patterns. As choroid and RPE are highly pigmented tissues, an original depigmentation protocol was developed and performed before immunohistochemistry. Retinal and choroidal samples were then whole-mounted and imaged using a confocal microscope, allowing 3D reconstruction of the cells population and structures of interest.

Results: Observing photoreceptors, we observed a clear degradation of the cellular anatomy and opsin localization with increasing age. Cones and rods presented nuclei displacement towards the RPE and opsin mislocalization toward the IPL, a pattern which was clearly age-dependant. The oldest subjects also presented a high density of Iba1 positive migratory cells (phagocytes).

Ghost capillaries segments (acellular and/or obstructed) were conspicuous in the extreme periphery of the retinal vascular network, shrinking its maximal extension.

RPE cells increased in size, and more RPE cells detached from the Bruchs membrane during tissue preparation. With age, the choriocapillaris density dramatically decreases, cell repartition changes (especially smooth muscle positive cells) and the whole tissue thins.

Conclusions: We are initiating here a systematic study of the manifestations of normal aging of retinal and choroidal tissues using immunohistochemistry. Microglial infiltration in the outer retina, ghosts capillaries, enlargement of RPE cells and modification of the photoreceptor intracellular arrangement were the most striking features.

ABSTRACT BODY:

Purpose: Combined structure-function index (CSFI) which derives retinal ganglion cells (RGC) estimates by combining standard automated perimetry (SAP) and optical coherence tomography (OCT) measurements into an age-adjusted algorithm, has been proven to significantly correlate with histologically derived count. In this prospective cross-sectional study, we investigated the relationship between estimated RGC count and steady state pattern electroretinogram (ssPERG) parameters in glaucoma suspects (GS).

Methods: Ten subjects (60% female, 20 eyes) were enrolled in this study conducted at the Manhattan Eyes, Ears, and Throat Hospital. Subjects were divided into two groups of GS with normal RGC function and GS with RGC dysfunction based upon ssPERG testing results. All study subjects underwent comprehensive ophthalmologic examinations including OCT, SAP and ssPERG. RGC counts were estimated using the CSFI, a statistical model that combines structural [OCT-derived average retinal nerve fiber layer thickness (aRNFLT)] and functional [SAP-derived mean deviation 24-2 (MD)] parameters. The following ssPERG parameters Magnitude (Mag), MagnitudeD (MagD) and MagnitudeD/Magnitude ratio (MagD/Mag ratio) were used in the analysis.

Results: Independent sample t-tests revealed that all ssPERG parameters, estimated RGC count, aRNFLT, and MD were significantly reduced in GS with RGC dysfunction relative to control subjects ($p < 0.015$ for all parameters). A significant reduction in estimated RGC count was found in the GS with RGC dysfunction (752103 ± 97827 vs 1023711 ± 99364) respectively ($p < 0.001$). Pearson and partial (age-adjusted) correlation analyses revealed that all ssPERG parameters significantly correlated with MD ($r > 0.46$, $p < 0.049$). MagD and MagD/Mag ratio significantly correlated with aRNFLT ($r > 0.47$, $p < 0.044$), with average ganglion cell layer and inner plexiform layer (GCL/IPL) thickness ($r > 0.47$, $p < 0.042$). Pearson and partial (age-adjusted) correlation analyses revealed stronger linear relationships between all ssPERG parameters and estimated RGC count ($r > 0.58$, $p \leq 0.009$) than between ssPERG and independent measures of CSFI.

Conclusions: Glaucoma suspects with RGC dysfunction present with decreased estimated RGC count when compared to controls, and ssPERG parameters correlate stronger with the estimated RGC count than with independent measures of CSFI.

ABSTRACT BODY:

Purpose: Fabricating thermoresponsive hydrogels from decellularized tissues is a trending approach to develop novel therapeutic biomaterials for tissue engineering purposes. There are differences in the characteristics of the produced hydrogel related to the source of the tissue as well as the decellularization and solubilization protocols. Detailed characterization of the hydrogels will support the efforts to optimize their application as biomaterials for tissue engineering and therapeutics. Here, we fabricated an in-situ thermoresponsive hydrogel from decellularized porcine cornea extracellular matrix, COMatrix (COrneal Matrix), and characterized its structure and thermoresponsive rheological behavior (heat-induced Sol-Gel transition) as well as exploring its protein composition using proteomic approaches.

Methods: The COMatrix hydrogel was fabricated by decellularization and partial digestion of porcine cornea. The gelation was induced by mild-heat (37°C). The turbidimetric gelation kinetics was evaluated by pre-warmed spectrophotometer. The rheological gelation kinetics and properties of COMatrix was evaluated with a temperature controlled rheometer. The protein composition of COMatrix was mapped using mass spectrometric proteomics.

Results: COMatrix forms a transparent gel (10 minutes gelation time) after in-situ curing with heat, characterized by alteration in light absorbance and rheological indexes. . The highest elastic shear modulus (G') and highest viscous modulus (G'') for 25 mg/ml hydrogels were 83.3±4.2 Pa and 12.9±7.2 Pa for 25 mg/ml samples. The rheological characterization of heat-formed COMatrix gel shows similar behavior to common biomaterials utilized in tissue engineering. The fibrillar structure of COMatrix gel was observed by scanning electron microscopy as the density of fibers attenuates in lower concentrations. Mass spectrometric proteomic analysis revealed that COMatrix hydrogel is rich in extracellular matrix proteins with known regenerative properties such as lumican, keratocan and laminin in addition to structural collagen proteins.

Conclusions: COMatrix hydrogel is a naturally driven biomaterial with favorable biomechanical properties and protein content with potential application as a therapeutic biomaterial in ocular regeneration and tissue engineering.

ABSTRACT BODY:

Purpose: Smartphone use by children is increasing rapidly, but the ocular impacts are unknown. This study examined the effect of 1 hour of smartphone use on symptoms, tear film and blinking in children.

Methods: Forty-five children aged 6–15 years (mean 10.1 ± 2.6 years; 20M:25F) with healthy eyes and no binocular vision problems completed this prospective study. Children played games on a smartphone continuously for 1 hour and were masked to the study purpose. Symptoms were measured before and after using Symptoms Assessment in Dry Eye (SANDE), Instant Ocular Symptoms Survey (IOSS), Numerical Rating Scale (NRS). Tear film lipid layer thickness (LLT) (LipiView® interferometer.), tear meniscus height (TMH) and non-invasive tear break-up time (NIBUT) (Oculus® Keratograph 5) were assessed at the same timepoints. Spontaneous blink rate (blinks per minute) and interblink interval (time of full eyelid opening, seconds) were assessed in situ, at baseline (during conversation) and throughout the 1 hour of smartphone gaming, using a novel wearable eye tracking headset (Pupil Labs GmbH). Blink rate and interblink interval were compared between baseline and at 10 minutes intervals during smartphone use with repeated measures ANOVA and post hoc comparisons with Dunnett's test and Bonferroni correction. Associations were examined using Pearson correlation.

Results: Ocular surface symptoms increased following 1 hour of smartphone use (SANDE +7.3 units, $p=0.01$; NRS overall +6.6, $p=0.01$; NRS comfort +8.5, $p=0.01$; NRS tiredness +11.2, $p=0.004$; IOSS +1.3, $p<0.001$), but tear film (LLT, TMH, and NIBUT) remained unchanged. Mean group blink rate reduced from 20.7 ± 9.9 blinks/min during conversation to 7.4 ± 5.2 blinks/min within 10 minutes of smartphone use ($p<0.001$), and interblink interval increased (3.1 s vs 8.4 s; $p<0.001$). Blink rate and interblink interval remained unchanged throughout 1 hour of smartphone use. There were no significant associations between changes in blink rate, interblink interval and symptoms.

Conclusions: Blinking in children can be successfully assessed in situ using a wearable eye tracking device. Smartphone use quickly resulted in dry eye symptoms, slowed the blink rate to one-third, with much longer open eye periods between blinks. In the short-term, this was not accompanied by disturbances to the tear film.

ABSTRACT BODY:

Purpose: Age-related dysfunction and/or death of retinal pigment epithelial (RPE) cells have been associated with various eye diseases, such as age-related macular disorders (AMD). Identifying age-related gene expression changes in the RPE may help shed light on pathogenic mechanisms that affect age-related vision loss or blindness.

Methods: RNA was collected from mouse RPE at 4 different time points of ages: 6 months (M), 12 M, 18 M, and 21 M. Mice, all male and the same genotype background, were kept on identical diet and light exposure regimes. PolyA RNA-Sequencing was performed on three-four mouse RPE replicates per age group. An un-stranded, paired end (PE) library preparation was performed. Samples were multiplexed on the Illumina's sequencer for 75 cycles. An average sequencing coverage of 22.3 million high-quality reads was achieved across all replicates and age groups. The STAR aligner was used to align PE reads and featureCount was used to quantify gene expression. SmartSVA was applied to account for hidden confounding factors on gene expression and normalize between samples. To perform differential gene expression, we used a combination of two programs: ImpulseDE2 and DESeq2. ImpulseDE2 implements an impulse-based model to capture "monotone" and "transient" changes across the time points. The likelihood-ratio test (LRT) implemented in DESeq2 was applied to compare among all four time point combinations. Genes with Benjamini-Hochberg adjusted P-value <0.05 in both methods were considered a set of high confidence genes whose expression changes with age. g:Profiler was used for enrichment of transcription factor (TF) regulation.

Results: There were 352 high confidence genes ($q < 0.05$), whose expression significantly increased (average 5-fold) or decreased (average 8.3-fold) between 6 M to 21 M in mouse RPE. These genes formed five clusters with different patterns of up or downregulation in early and late ages. The 352 genes were enriched for targets of 111 TFs ($q < 0.05$), including ZF5 found to be associated with Stargardt disease and E2F transcription factor 1 (E2F1) associated with AMD.

Conclusions: We present a new methodological process for identifying genes differentially expressed across different time points with RNA-Seq data. In addition, this study identified age-related genes in mouse RPE that can be used to further investigate the role of aging in eye disease.

ABSTRACT BODY:

Purpose: To evaluate the ability of a novel Bayesian deviation map of macular ganglion cell complex (mGCC) thickness to discriminate between healthy and glaucomatous eyes. Our Bayesian modeling improves glaucoma diagnosis by accounting for the known structural relationship between the macula and the circumpapillary retinal nerve fiber layer (cpRNFL).

Methods: The study included data from 1279 eyes of 393 patients for which mGCC scans were available. The most recent pairs of images for the left and right eye was used per patient for cross-sectional analysis. Macular thickness measurements were analyzed on the 8-by-8 posterior pole grid, while cpRNFL measurements were derived from the 768-point circle scan. A Bayesian linear mixed model was constructed with a novel prior incorporating clinical knowledge of the structural relationship. We compared the Bayesian deviation map to a raw version to assess discrimination between healthy and glaucoma cases. Abnormality was defined as the proportion of negative deviations. Discrimination was measured using both area under the receiver operating characteristic curve (AUC) and partial AUC (pAUC) in the clinically relevant 85-100% specificity range.

Results: Of the 393 pairs of images, 333 were those of glaucoma patients and 60 of healthy ones. The Bayesian model was trained on a random 80% subset, with 20% held out for testing. Five-fold cross validation (CV) was used for more robust assessments. There was a notable improvement in the average pAUC of the Bayesian deviation map (0.49; 95% confidence interval [CI] 0.32-0.75) compared to the raw map (0.44; CI 0.25-0.79). For 95% specificity, average sensitivity of the Bayesian map was .42 (CI 0.30-0.75) versus .32 (CI 0.23-0.78) for the raw map.

Conclusions: A novel Bayesian deviation map incorporating structural relationships between macula and peripapillary RNFL performed significantly better to detect glaucomatous damage in the macula.

TITLE: Serial Analyses of Clinical Spectrums and Outcomes in Chinese Women with Pregnancy-induced Optic Neuritis

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Zhou, S. Wei, Chinese PLA General Hospital, Beijing, Beijing, CHINA|

Commercial Relationships Disclosure (Abstract): Huan fen Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Shihui Wei: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to investigate the clinical spectrums and outcomes in pregnancy-related optic neuritis (ON).

Methods: We analysed the clinical subtype and prognosis of women with pregnancy-related ON during pregnancy or within 1 year postpartum or after abortion in the neuro-ophthalmology department of the First Medical Centre at the Chinese People's Liberation Army General Hospital (PLAGH) from January 2014 to December 2017.

Results: A total of 54 patients, including 21 (38.9%) idiopathic ON (ION), 27 (50.0%) aquaporin-4 (AQP4)-ON and 6 (11.6%) myelin oligodendrocyte glycoprotein (MOG)-ON patients, who experienced 58 informative pregnancies and 67 episodes of pregnancy-related ON were assessed. Among the ON attacks, there were 11 (16.4%) during pregnancy and 56 (83.6%) within 1 year postpartum or after abortion, including 33 (49.3%) in the first trimester. Fourteen (25.9%) patients with ON onset before pregnancy had a higher relapse rate during PP1 than within 1 year before pregnancy ($p=0.021$). Twenty-four (85.7%) eyes with ION and nine (100%) with MOG-ON had significantly better visual outcomes ($p\geq 0.5$) than those with AQP4-ON (14, 35%) ($p<0.001$ and $p<0.001$, respectively). Two AQP4-ON patients respectively had a premature birth and a low baby weight. There were no birth defects or stillbirths.

Conclusions: The study demonstrated that there is a significant increase in ON attacks after delivery especially during the first trimester. MOG-ON had extremely better visual recovery. AQP4-ON was the most common subtype of pregnancy-related ON, which should be given more additional attention about the complications.

ABSTRACT BODY:

Purpose: There are only few reports on ocular symptoms and manifestations in association of COVID-19 disease. The objective of this study is to describe ocular manifestation in the anterior and posterior segment of the eye and additionally analyze viral prevalence in tears of patients with COVID-19 disease.

Methods: Hospitalized patients with COVID-19 treated from April 16th to December 15th 2020 at the university hospital in Kiel, Germany, were prospectively screened for ocular manifestations or any abnormalities in anterior and posterior segment. Reverse transcriptase-polymerase chain reactions (RT-PCR) from conjunctival swabs (Schirmer strip method) were analyzed for SARS-CoV-2 in all patients.

Results: 37 (25 male, 12 female) patients were enrolled in this study. 1 out of 37 patients demonstrated conjunctivitis; 6 patients demonstrated chemosis of conjunctiva, all 7 of them were ventilated. One patient who was hospitalized with atypical branch retinal vein occlusion was tested positive for systemic COVID-19 in routine nasopharyngeal screening although completely asymptomatic. He was therefore recruited for the study. His conjunctival swabs were positive in both eyes. Interestingly, this patients showed general symptoms of COVID-19 pneumonia 5 days later and was hospitalized.

All other patients were negative for SARS-CoV-2 in the conjunctival swabs.

In 11 out of 37 patients vascular alterations and potentially disease specific manifestations of fundus were found: retinal hemorrhages in one or both eyes in 5 patients, cotton-wool spots in 5 patients, tortuosity in 5 patients. One patient demonstrated branch artery occlusion, one with branch retinal vein occlusion (the patient mentioned above). In this patient, it is noteworthy that atypically many cotton-wool spots were present, leading to a pizza-like fundus appearance (image 1).

Conclusions: This study suggests that the risk of viral transmission via tears is low. However, the findings might suggest that tears are infectious at an early, preclinical disease stage. Various vascular fundus abnormalities were found in the study including hemorrhages, cotton-wool spots, tortuous vessels and vascular occlusion. Due to the study design, it is unclear whether these were correlated to systemic comorbidities, or whether they were caused or exacerbated by COVID-19. However, given the numerous vascular side-effects of COVID-19 disease, some correlation is thinkable.

ABSTRACT BODY:

Purpose: Using accurate and robust markers to evaluate the course of rod-cone dystrophy, also known as Retinitis Pigmentosa (RP), remains pivotal for a better understanding of the disease and for the evaluation of new treatments. Using the data collected in the PHENOROD 1 study (NCT03975543), we analyzed the correlation between structural and functional parameters.

Methods: Data was extracted from 110 medical records (between 2007 and 2019) of patients followed at the National reference center for rare diseases of Quinze-Vingts Hospital (Paris, France). The evidence of mutations in RHO, PDE6A, or PDE6B, at least 2 visits, and no other condition impacting vision than RP were the inclusion criteria for this study. Intra-ocular pressure, best-corrected visual acuity (BCVA), color vision alteration on the panel D-15, static and kinetic visual field, the preservation of the hyper reflective outer retinal bands on spectral-domain optical coherence tomography (SD-OCT), and the size of the ring of increased short-wavelength fundus autofluorescence (SWAF) were analyzed. Correlations between all parameters were evaluated using linear regressions and Pearson correlation coefficient.

Results: The strongest correlation was observed between the SD-OCT and the static Visual Field results. The length of preserved External Limiting Membrane (ELM) was positively correlated on both eyes to the foveal sensitivity at 30° ($r=0.93$). Positive but weaker correlations were also found between the preserved horizontal ellipsoid zone width and the foveal sensitivity at 10° ($r=0.71$). However, BCVA measures were poorly correlated with other functional markers such as static or kinetic visual field (respectively $r=0.37$ and $r=0.53$ for BCVA (LogMAR) vs the kinetic VF diameter using the II1e isopter or the static VF foveal sensitivity at 30°. This weak correlation was also observed when using structural markers from the SD-OCT and SWAF ($r=0.21$ and $r=0.37$ for respectively the correlation of BCVA (LogMAR) / EZ length and BCVA (LogMAR) / horizontal inner diameter of the hyper autofluorescent ring).

Conclusions: Strong correlations were observed between functional and structural parameters evaluated on patients with RP. These results could help defining new composite markers to evaluate the disease severity. They are also of interest when evaluating the efficacy of new therapies for treating patients with a slow disease progression.

ABSTRACT BODY:

Purpose: The objective of this study is to identify epidemiologic trends in consumer product-related open globe injuries (OGIs) in adult patients over 20 years of age.

Methods: This study utilizes data from the 2000-2019 National Electronic Injury Surveillance System (NEISS), a database created by the United States Consumer Product Safety Commission to collect data on consumer product-related injuries. Cases of open globe injury were identified based on the description of the injury provided in the "narrative" variable and the admission status of the patient. Patients were divided into two age groups: 21-64 years of age and 65+ years of age (elderly). IBM SPSS 23 was used to perform statistical analysis.

Results: Between the years 2000 and 2019, there were 14,880 weighted cases of consumer product-associated OGIs. The average age of patients with OGIs was 52.8 years, 47.7 years in men versus 66.0 in women ($p < 0.001$). Of the injuries, 72.2% occurred in men, and 70.4% occurred in patients between 21 and 64 years of age. Majority (82.9%) of the OGIs in the younger cohort, occurred in men; however, most (53.2%) of the OGIs in the 65+ cohort were noted in women ($p < 0.001$). With respect to day of the week, 30.5% of OGIs in adults over 20 years of age presented to the ED over the weekend. OGIs in the 21-64 cohort mainly involved home workshop equipment (20.2%), sports and recreation (16.2%), and non-nail construction materials (12.8%); in the elderly, OGIs most commonly involved furniture (30.6%), non-nail construction materials (22.4%), and sports and recreation (6.8%). In men, OGIs involved home workshop equipment (20.8%), sports and recreation (16.9%), and non-nail construction equipment (11.9%); by comparison, in women, furniture (26.2%), non-nail construction materials (25.5%), and bathroom fixtures (6.2%) were commonly associated products. In the elderly, 1.9% of OGIs were associated with wheelchairs, and they were all seen in women.

Conclusions: Majority of OGIs in the 21-64 years age cohort were seen in men; however, in the 65+ cohort, most OGIs occurred in women. Home workshop equipment, sports and recreation, and non-nail construction materials were the top 3 consumer product categories that caused OGIs in adults over 20 years of age. Almost 4% of OGIs in elderly women were a result of wheelchair traumatic injury.

TITLE: The E3 Ligase PIAS1 Regulates p53 Sumoylation to Control Stress-Induced Apoptosis of Lens Epithelial Cells through Proapoptotic Regulator Bax

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Nie, H. Chen, L. Wang, M. hou, D.W. Li, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure (Abstract): Qian Nie: Commercial Relationship: Code N (No Commercial Relationship) | Huimin Chen: Commercial Relationship: Code N (No Commercial Relationship) | Ling Wang: Commercial Relationship: Code N (No Commercial Relationship) | min hou: Commercial Relationship: Code N (No Commercial Relationship) | David Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The protein inhibitor of activated STAT-1 (PIAS1) is one of the well-known SUMOylation E3 ligases and has been shown implicated in different biological processes including control of apoptosis. We previously demonstrated that apoptosis of lens epithelial cells (LECs) induced by stress factors acts as the common cellular basis for non-congenital cataractogenesis. Whether PIAS1 is implicated in the stress-induced lens pathogenesis remains elusive. Here we present evidence to show that PIAS1 is implicated in the stress-induced lens pathogenesis. Mechanistically, PIAS1 controls p53 sumoylation at K386 residue to control stress-induced apoptosis through the proapoptotic regulator Bax.

Methods: Mouse lenses were treated with glucose oxidase (GO) to induce cataract formation. QRT-PCR and western blot were used for analyzing gene expression. Both in vitro mutagenesis and sumoylation as well as Co-IP were used to confirm PIAS1 catalysis of p53 sumoylation. PIAS1 expression construct was generated to establish PIAS1 expression stable line. CRISPR/Cas9 technology was used to silence PIAS1, p53 or Bax expression. CellTiter-Glo® luminescent cell viability assay was used to detect apoptosis.

Results: In the GO-induced cataract model, expression of PIAS1 was significantly downregulated. While overexpression of PIAS1 in mouse LECs accelerates apoptosis, its knockout enhanced viability. Downstream PIAS1, we have identified that members of the Bcl2- family play an important role.

Conclusions: PIAS1 is implicated in stress-induced pathogenesis of the ocular lens. PIAS1 regulates stress-induced apoptosis of lens epithelial cells through control of p53 sumoylation and its downstream target, the proapoptotic target, Bax. ABSTRACT BODY:

Purpose: Building an expert system for automatic detection of conversion from non-exudative age-related macular degeneration (AMD) to exudative neovascular AMD using optical coherence tomography (OCT) imaging data in a real-world setting.

Methods: 907 AMD patients (40 944 OCT stacks) were labelled as either “early/intermediate”, or “advanced non-neovascular”, or “advanced neovascular non-exudative” or “advanced neovascular exudative AMD” based on their first visit in our database. Eyes exhibiting diseases other than AMD were excluded. All images labelled as “advanced neovascular exudative AMD” were categorized as “post conversion”, the remaining labels were categorized as “pre conversion”. Different inputs (single B-scans, sets of B-scans as separate images, sets of B-scans as 3-dimensional volume) to ML models were evaluated focusing on reliable detection of “post conversion” stage. Special attention was devoted to model performance evaluation, where datasets were split into train and test sets ensuring that distribution of critical attributes is preserved between the sets.

Results: The primary validation dataset comprised of 347'573 B-scans (13 342 OCT stacks) of 304 patients (33.2% male, 66.8% female), with a mean age of 79 years (7.6 SD) at first visit. The mean follow-up time was 3.6 (3.141 SD) years, 12'382 out of 13'342 OCT stacks were labelled as “post conversion”. The model using sets of B-scans as separate images achieved an area-under-curve (AUC) of 0.9138 in differentiating post conversion from pre conversion OCT stacks. 10 465 of 12 382 OCT stacks labelled as post conversion were correctly classified, while 810 of 960 OCT stacks labelled as pre conversion were correctly classified as non-converted (Figure 1).

Conclusions: Our ML model using a clinically heterogeneous OCT data set can effectively detect conversion from non-exudative to exudative neovascular AMD. Considering the limited amount of data, the relatively simple ML model architecture and the time-efficient labelling process, the achieved ML model performance seems very promising. Further training is required to evaluate whether our proposed ML model can achieve even higher performance and will be able to predict the time to/from conversion.

ABSTRACT BODY:

Purpose: PHACES Syndrome includes Posterior fossa malformations, infantile Hemangiomas (95% facial, IFH) with Arterial, Cardiac, Eye and Sternal anomalies. Data on ophthalmic involvement are limited with variable prevalence. We aim to present a large cohort of patients with PHACES highlighting prevalence, spectrum of anomalies and outcomes of ophthalmic involvement.

Methods: A retrospective, non-comparative, single-institutional observational case series was performed. All patients with documented PHACES syndrome diagnosed and managed between 2000-2019 at a single tertiary referral center were reviewed. Data collected included gender, age, diagnostic criteria (Major and minor), IFH distribution, ocular presentation, ophthalmic/visual interventions, follow-up and visual acuity. Primary outcome measures were the frequency and spectrum of ocular involvement. The secondary outcomes were final visual acuity (Poor visual outcome was defined as final visual acuity worse than 20/200), long-term ocular sequelae and need for surgical intervention. Simple descriptive statistics calculating frequencies and mean was utilized.

Results: Forty-three infants [33 females (77%), mean presenting age 8 weeks] were reviewed. Six infants (14%) had primary congenital ocular anomalies. These included diagnostic criteria [optic nerve anomalies (6), anterior segment dysgenesis (1) and retinal vascular anomalies (1)], and non-diagnostic abnormalities [persistent pupillary membrane (2)]. Twenty-nine infants (67%) had secondary ophthalmic involvement due to IFH [ptosis (20 mild, 9 severe), proptosis (9), strabismus (6)]. After mean follow-up 8.7 years post-IFH diagnosis, 8/29 children required surgical intervention [Strabismus (6), entropion (2), ptosis (2), optical iridectomy (1)], all with orbital/conjunctival hemangioma ($p=0.03$). Final visual acuity ranged between 20/20 to 20/80 in 26/29 and $<20/200$ in 3/29 children (all had optic nerve anomalies). One child died from associated cardiac compromise.

Conclusions: Identifying common ophthalmic associations in PHACES syndrome was impactful for both diagnostic and vision rehabilitation purposes. Monitoring for and management of periocular IFH complications showed promising visual acuity outcomes.

ABSTRACT BODY:

Purpose: Lymphangiogenesis is involved in several diseases like corneal graft rejection, tumor metastasis, and dry eye disease. The healthy cornea is an avascular and alymphatic tissue with a distinct limbal lymphatic vascular arcade. The genetic background significantly influences the architecture of this limbal lymphatic arcade and of corneal lymphangiogenesis. The Collaborative Cross (CC) population is a large panel of recombinant inbred mouse strains derived from a genetically diverse set of eight founder strains.

Methods: Using the lymphatic vessel architecture at the limbal border of the normally avascular cornea, a quantitative trait under strong genetic influence, was used here as a model system to identify new candidate genes regulating lymphangiogenesis. Quantitative trait locus (QTL) analysis was used to combine phenotypic information (e.g. vessel area) and genotypic data (e.g. molecular markers) to reveal possible candidate genes contributing to the observed variation in the analyzed trait. Whole mounts of naïve corneas from 9 different CC mice were stained with the lymphatic vessel marker LYVE-1. The vessel area, number of branching points, endpoints, and sprouts were analyzed using cellF.

Results: The comparison of the different CC strains showed a significant difference in lymph vessel area between the CC mice and the high-lymphangiogenic C57BL/6 mice. We identified CC lines showing significantly lower lymphatic vascularized area, whereas other lines showed significantly higher lymphatic vascularized area compared with C57BL/6 mice. In the QTL analysis, we identified eight loci with a LOD score >5 associated with the morphometric parameters investigated which contain promising genes. For instance, we identified on chromosome 7 two loci, one of them harboring tyrosinase, thus confirming the results from earlier C57BL/6 x BALB/c intercross and validating the approach using CC mouse lines.

Conclusions: Using CC mice we identified several new loci associated with the morphometric parameter that contain promising genes that may play important roles in the regulation of lymphangiogenesis. Overall, our findings show that CC mice are a valid and powerful tool for the identification of new endogenous modulators of lymphangiogenesis. These modulators may serve as novel therapeutic targets for eye diseases associated with pathologic lymphangiogenesis.

ABSTRACT BODY:

Purpose: This study aims to assess: (a) the feasibility of GlauCAT in a busy glaucoma clinic; and (b) the correlation of patients' responses on five QoL domains with the severity of glaucoma.

Methods: We conducted a cross-sectional study of 138 English-speaking adults aged ≥ 18 years attending a tertiary eye center glaucoma clinic. Patients with a history of intraocular surgery 90 days before enrollment and/or with cognitive impairment were excluded. GlauCAT, a tablet-based survey, uses item banks and CAT methods to measure the impact of glaucoma and its treatments on five QoL domains listed in Table 1. The domain scores ranged between 1-100, with higher scores representing better QoL outcomes. Feasibility was assessed using a 4-point satisfaction survey and the percentage of patients who completed GlauCAT without assistance. Differences in scores between glaucoma severity groups were assessed using the Kruskal-Wallis test.

Results: 69.6% of patients who completed GlauCAT did so without assistance. The satisfaction survey score had a mean of 3.49 ± 0.53 ; no statistically significant difference in mean scores was found between the severity groups ($p=0.8$). The mobility domain score was higher, with a mean of 93.3 ± 8.6 , in the glaucoma suspect group compared to 91.7 ± 11.9 in the early glaucoma group and 79.5 ± 27.1 in the moderate-severe group ($p=0.001$). The same trend was observed in the concerns domain; the moderate-severe glaucoma group had a significantly lower mean score of 69.8 ± 19.8 , followed by the early glaucoma group with 81.1 ± 14.5 and the glaucoma suspects group with a mean of 86.3 ± 8.9 ($p=0.001$). There was also a significant difference in activity limitation scores by severity group, with higher scores in the glaucoma suspect group (mean 87.0 ± 15.3) than in the moderate-severe glaucoma group (mean 72.8 ± 25.1 , $p=0.003$). The ocular comfort and emotional well-being domains were not statistically significantly different between the three groups of glaucoma severity ($p=0.776$ and $p=0.149$, respectively).

Conclusions: Patients with more severe disease reported greater limitations. GlauCAT is a promising tool for assessing and monitoring glaucoma patients' QoL, as it can be self-administered with high patient satisfaction.

ABSTRACT BODY:

Purpose: Visual cancellation tasks evaluate how individuals identify relevant information among clutter. This work examined how visual search is affected by healthy aging and AMD in the Bells test cancellation task.

Methods: 98 participants from the SilverSight French cohort were included in this study: 43 young adults (YA, 30 ± 4.8 years), 12 middle-aged adults (MA, 51.2 ± 5.9 y), 36 older adults (OA, 74.4 ± 4.4 y), and 7 individuals with AMD (78.6 ± 7.8 y). Participants had to find and cancel 35 bell symbols among 280 distractors while wearing a mobile eye-tracker. We examined the number of cancellations, test duration, the time and distance between cancellations, search efficiency (Q-score) and organization (Best-R). Fixation number, duration and dispersion, inter-fixation duration and distance as well as scan-path metrics were extracted from gaze data. All save the AMD group underwent a visuo-cognitive screening, including UFOV, TMT, figural and working memory tests.

Results: OA made fewer cancellations than YA and were less efficient than both YA and MA groups (lower Q-score). Successive cancellations of OA were further apart in both time and space, compared to YA. OA were also slower than YA to complete the test and more variable than YA in both inter-cancellation time and distance. OA made more fixations and showed longer scan-path lengths, compared to YA. All healthy participants showed similar search orders (Best-R values), fixation duration and dispersion, inter-fixation time and distance, and % of the scene covered during the search. Search efficiency and test duration correlated significantly with selective visual attention (UFOV 3), processing speed (TMT part A), figural memory, and working memory span.

AMD patients had lower performance, compared to age-matched visually healthy subjects, on the cancellation task on all metrics, and they showed larger inter-individual variability. They made longer fixations with greater dispersion amplitudes and fewer fixations in total. Fixations were further apart in both time and space, linked to jumping between PRLs depending on gaze direction.

Conclusions: Visual search degrades with age, in association with attention, processing speed, and memory decline. The deficits in search found in AMD patients are the result of visual system losses overlaid on the normal age-related loss caused by cognitive/attention decline.

TITLE: Comparison of outcomes and complications between navigated laser (NAVILAS) and pattern scanning laser (PASCAL) systems used in the management of treatment-naïve proliferative diabetic retinopathy (PDR).

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sajnani, A. Oh, P. Prasad, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|K. Chen, Ophthalmology, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ravin Sajnani: Commercial Relationship: Code N (No Commercial Relationship) | Angela Oh: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Chen: Commercial Relationship: Code N (No Commercial Relationship) | Pradeep Prasad: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pan-retinal photocoagulation (PRP) is an effective treatment to prevent severe vision loss in PDR. NAVILAS and PASCAL are newer laser delivery systems that can more efficiently deliver PRP, but little is known about how these two systems compare in post-treatment sequelae. The aim of this study was to evaluate the differences in visual outcomes and complications between the NAVILAS and PASCAL systems used in PDR treatment.

Methods: We completed a retrospective study comparing 30 laser-naïve eyes (24 patients) treated with NAVILAS compared to 14 eyes (13 patients) treated with PASCAL. Exclusion criteria included receiving an anti-VEGF (anti-vascular endothelial growth factor) injection in the 3 months preceding laser treatment, concomitant vitreous hemorrhage (VH) at the time of treatment, having already been planned for surgery by the laser treatment date, and any pre-existing retinal vascular pathology (i.e. central retinal artery/vein occlusion). Best-corrected visual acuity (BCVA) and intraocular pressure were measured on the date of initial PRP and at 6-9 months. The number of additional laser treatments (PRP fill), anti-VEGF injections, episodes of VH, and surgeries within a year of initial laser treatment were compared between the two groups.

Results: Age, pre-treatment visual acuity, and glycated hemoglobin (HbA1c) were similar between the groups. Both groups had a similar change in BCVA at 6-9 months (logMAR $+0.12 \pm 0.33$ standard deviation in the NAVILAS group vs $+0.27 \pm 0.64$ in the PASCAL group; $p=0.73$). There was a similar need for PRP fill (NAVILAS 43% vs PASCAL 50%; $p=0.68$) and anti-VEGF injections (47% vs 50%; $p=0.52$). Both groups had a similar incidence of VH (30% vs 21%; $p=0.72$) and development of neovascular glaucoma (3% vs 7%; $p=0.54$). Rates of subsequent surgery were also similar between groups (27% vs 29%; $p=1.00$).

Conclusions: Treatment of PDR with PRP by either NAVILAS or PASCAL delivery systems appears to yield similar visual and complication outcomes by one year.

ABSTRACT BODY:

Purpose: Traumatic optic neuropathy (TON) is a common, untreatable injury resulting in blindness. Prior candidate treatments for TON do not address secondary injury mechanisms, namely the generation of reactive oxygen species (ROS). We hypothesize that by addressing these secondary mechanisms via an injectable drug delivery vehicle loaded with a ROS scavenger, methylene blue (MB), greater neuronal cell survivability can be achieved.

Methods: Alginate hydrogels were synthesized at various polymer and crosslinker concentrations using design of experiments. Hydrogels were formed by internal crosslinking with insoluble calcium carbonate and proton donor, D-glucono-lactone. Viscoelastic properties of hydrogels were characterized using dynamic shear rheology. The cytotoxicity and ROS scavenging ability of the hydrogels loaded with MB concentrations of 0.0, 0.05, 0.25, 0.50, 1.0, and 2.0 g/L were analyzed through MTS and DCF assays, respectively, on ARPE-19 cells. A two tailed student t-test was used for statistical analysis.

Results: By varying components of the gels, a significant influence on complex shear modulus and gelation time were observed. Lower concentration (alginate and crosslinker) hydrogels corresponded to lower complex shear modulus whereas higher concentration hydrogels had higher complex shear modulus. Hydrogel swelling and MB release were analyzed. Hydrogels with low alginate concentrations had the most cumulative MB release (~90%); however, no hydrogel completely released all MB within the 12-day in vitro study, due to hydrogel degradation. Two formulations demonstrated excellent cell viability at >95% following 24 hr exposure compared to DPBS control. ROS studies showcased MB as an effective scavenger at concentrations 0.50 g/L and above in which cell viability was maintained ~50% following exposure to 600 μM H_2O_2 . The presence of MB was also found to significantly increase cell survival in the presence of oxidative stress when loaded into low and high concentration hydrogels ($p < 0.01$).

Conclusions: Our results are consistent with our hypothesis that by inhibiting ROS induced damage, higher cell survivability can be achieved. The proposed drug delivery system has the potential to improve upon the limited treatment options for TON. Given the in vitro drug release and biocompatibility results, these hydrogels have potential to deliver MB to protect against ROS. Future work will include long-term and in vivo validation studies.

TITLE: Retinal microcystoid lacunae in autosomal dominant optic atrophy: relation to visual function

SESSION TITLE: Adaptive optics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Eckmann-Hansen, M. Larsen, Ophthalmology, Rigshospitalet Glostrup, Glostrup, DENMARK|C. Eckmann-Hansen, M. Larsen, Kobenhavns Universitet Sundhedsvidenskabelige Fakultet, Copenhagen, DENMARK|

Commercial Relationships Disclosure (Abstract): Christina Eckmann-Hansen: Commercial Relationship: Code N (No Commercial Relationship) | Michael Larsen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the prevalence of microcystoid lacunae in patients with autosomal dominant optic atrophy (ADOA) and their relation to visual function and retinal thickness.

Methods: The study included 159 participants with verified ADOA, with a mean age of 44.35 (SD 19.9, range 7-86) years. Study participants with mutation in the OPA1 gene were assessed for best-corrected visual acuity (BCVA, in ETDRS letters), contrast sensitivity (in logCS), optical coherence tomography (Spectralis, Heidelberg) and adaptive optics fundus photography (RTX-1, Imagine Eyes). Data were analyzed with a mixed model adjusted for age and sex with family and eye as random effects using RStudio statistical software. Optically empty microcystoid spaces in the ganglion cell layer and inner plexiform layer, presumably lacunae left by degenerated ganglion cells, were mapped by inspection of the two sets of images.

Results: 34 patients (21 %) including 19 males and 15 females had microcystoid lacunae, and 125 including 64 males and 61 females did not have microcystoid lacunae. The genotype distribution of the patients with microcystoid lacunae was 16 with c.2826_2836delinsGGATGCTCCA, 4 with c.983A>G, 4 with 2496+4_2496+5delinsGTAAC, 4 with 2614-9A>, 2 with c.1516+5G>A, 2 with c.2708_2711delTTAG, 1 with c.(32+1_33-1)_(678+1_679-1)delG and 1 with c.2707+1G>C.

Patients with and without microcystoid lacunae had a BCVA of 66.2 and 70.0 ETDRS letters (difference -3.82, 95%CI -11.6;4.0, P=0.6), a contrast sensitivity of 1.555 and 1.561 logCS (difference -0.006 (95%CI -0.11;0.10, P=0.9), a nerve fiber layer volume of 0.53 and 0.58 mm³ (difference -0.05, 95%CI -0.10;-0.002, P=0.04) and a ganglion cell layer volume of 0.75 and 0.78 mm³ (difference -0.03 ,95%CI -0.09;0.02, P=0.3), respectively.

Statistical analysis showed moderately reduced visual acuity in patients with microcystoid lacunae. Normal and near-normal visual function was seen only in participants without microcystoid lacunae, who nevertheless were found at all levels of visual function, including severely decreased visual function.

Conclusions: In ADOA, microcystoid lacunae was found in 21% of the study participants, and tended to be found in patients with moderate visual acuity reduction, suggesting that cavities left by dead ganglion cells disappear with decreasing visual function.

TITLE: Apparent viewpoint of shifted view through prisms

SESSION TITLE: Eye Movements and Binocular Vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Jung, E. Peli, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|J. Jung, E. Peli, Department of Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jaehyun Jung: Commercial Relationship: Code N (No Commercial Relationship) | Eli Peli: Commercial Relationship(s);US provisional application U.S. No. 62/571,217 assigned to Schepens Eye Research Institute:Code P (Patent);US patent 7,374,284 assigned to Schepens Eye Research Institute and licensed to Chadwick Optical:Code P (Patent)

ABSTRACT BODY:

Purpose: Field of view (FoV) through prisms (shifted view) brings the view from the blind field into the residual seeing field. This “shift” has been illustrated in the literature as a lateral shift on a flat screen orthogonal to the primary position of gaze. It is not a linear shift in the distance domain but should be interpreted as an angular shift (a rotation of the viewpoint). The apparent viewpoint of the shifted view through the prisms may be located outside of the eye. To understand the viewpoint changes in the shifted view and further investigate the impact on detection, we analyzed and demonstrated the apparent viewpoint of the shifted view.

Methods: We modeled peripheral 57Δ Fresnel (30° power and FoV) and our 100Δ distortion-free multi-periscopic prisms (MPPs; 45° power and FoV) as prescribed for homonymous hemianopia (HH). Rays originating from the eye and deflected through the prisms were traced and extended back by optical ray-tracing simulation (LightTools), which formed an apparent viewpoint. To verify the viewpoint changes, the scene through the prism and the scene without the prism were photographically captured by the camera at the location of the eye and the apparent viewpoint, respectively.

Results: The apparent viewpoint of the shifted view was formed outside of the eye (not only rotated but also translated from the eye). While the apparent viewpoint of the shifted view through 57Δ Fresnel prisms was slightly diverged due to prism distortion, MPP provides a focused apparent shifted viewpoint. The rotation of the viewpoint (toward the prism base) was the same as the nominal prism power. The translation was close to the width of the prism when the prism power and the angular span of the prism are the same (the preferred fitting for HH). The photographic depictions of the shifted view through MPP and the scene without MPP at the translated and rotated camera confirmed the same scene and perspective. However, the scene through the Fresnel prism was further distorted and thus different from the scene captured at the apparent viewpoint.

Conclusions: We demonstrated that the shifted view through the prism is the same as the scene observed by the rotated eye with slight head translation. However, the prism distortion (stronger in higher power refractive prisms) further deteriorates the viewpoint changes.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a leading cause of irreversible vision loss in the elderly. A reduction in RPE phagocytosis of the photoreceptor outer segments (POS) has been implicated in the formation of waste deposits observed in the fundus of patients with AMD and in aging. The aim of this study was to investigate how the phagocytic function of the RPE changes with age using the mouse as a model.

Methods: Using immunohistochemistry and super resolution microscopy, phagocytosis of POS was investigated in murine RPE whole mounts from young (3 months, n=3) and old mice (20-21 months, n=3), which were stained using ZO1 as an RPE marker, rhodopsin for engulfed POS, and cathepsin D for lysosomes. The area of RPE cells, number of nuclei and, number of phagosomes in the basal and apical RPE were quantified in central, mid-peripheral and peripheral eccentricities. Gene expression changes in the RPE phagocytosis pathways were investigated using isolated RPE/choroid from 3 (n=6) and 24 months old (n=6) mice using RNASeq.

Results: With age, the RPE cell size in the periphery increased significantly. The number of cell nuclei decreased with eccentricity, however, there was no effect of age. The amount of rhodopsin-positive phagosomes per RPE cell area increased at all eccentricities with age and it was associated with an increase in phagosome number in the basal RPE cells but not the apical RPE. However, the proportion of phagolysosomes did not change suggesting undigested POS accumulate in the RPE with age. The expression of genes important for phagocytosis during initiation and engulfment such as MERTK and TYRO3 were significantly downregulated (FDR<0.05). Meanwhile, mRNA expression of PLXNB1 and SEMA4D that are involved in the termination of phagocytosis were upregulated significantly (FDR<0.05).

Conclusions: Overall, the results of this study suggest a decline of phagocytotic function in the aging murine RPE. More work is required to determine whether the aging changes observed in this study exacerbate pathology in those predisposed to AMD.

ABSTRACT BODY:

Purpose: Diabetes mellitus (DM) is the leading cause of legal blindness in working age adults worldwide. Diabetic retinopathy has a major impact on vision; thus, it is extensively studied and the primary concern for physicians. However, diabetic patients appear to have more frequent corneal problems compared to non-diabetic patients. Currently, 18% of corneal transplants in the United States come from diabetic donors. We reported young Ossabaw pigs fed a western diet show signs of early diabetic retinopathy.

Methods: Ossabaw pigs have metabolic syndrome and type II diabetes mellitus making them the closest model to study human type II diabetes. In this study, we identify collagen changes in corneal stroma caused by type II DM. Corneal tissue collected from 6 month old Ossabaw mini pigs fed a western diet with high fat/high fructose corn syrup/high choleric content for 10 weeks were used to prepare mRNA for qPCR, and 8 um cryosections for IHC, H and E, and mason trichome stains. Collagen measuring parameters include collagen I (COL I), Collagen III (COL III), and total collagen.

Results: We found altered levels of Col I and II in pigs on western diet compared to regular diet. Masson's Trichome stain showed increased levels of collagen in diabetic corneas compared to healthy age-matched corneas.

Conclusions: Diabetic Ossabaw pig demonstrated notably altered expression of structural parameters suggesting the vulnerability of the corneal tissue to diabetic conditions.

ABSTRACT BODY:

Purpose: To determine for the first time the number, dimensions, branching points, and signal generating organelle contents of apical processes (AP) of human RPE cells using 3D connectomics technology; these membrane specializations function in photoreceptor phagocytosis (PMID 16301) and retinoid processing (PMID 15336505).

Methods: A whole globe of a 21-year-old male Caucasian organ donor with an unremarkable macula was processed via rapid organ recovery. Perifoveal epoxy-embedded RPE was imaged by serial block-face scanning electron microscopy. In our ongoing study the image stack is annotated manually with computer assistance by expert readers using TrakEM (ImageJ).

Results: The 3D dataset displayed complete ultrastructural preservation with fully attached neurosensory retina and allowed the reconstruction of RPE cells. Our initial results from this tissue sample indicate 313 APs originating from the apical part of one RPE cell body and extending into the interphotoreceptor matrix. These interact with outer segments of 38 rod photoreceptors (cones were not accessible). 57% of APs show branching with 21% having one branch, 13% two branches, 8% three branches and 14% four branches or more resulting in a total of 814 endtips of APs. The mean length of a single AP branch was 1694 ± 1558 (standard deviation) nm. APs without branching showed a mean length of 1423 ± 1237 nm from start to endtips. The diameter of an apical process ranged from 135 to 615 nm. APs of one single RPE cell contained 67 melanosomes and 3 lipofuscin granules, which is in range of previously published data by our group.

Conclusions: Our 3D connectomics approach revealed that hundreds of APs derive from the apical part of a single RPE cell body, ensheath photoreceptors and contain the majority of RPE cell melanosomes; the latter are known contributors to OCT reflectivity via Mie scattering.

Results will impact interpretation of clinical OCT images. They will also help elucidate an ultrastructural basis of how rod-mediated dark adaptation is modulated. This functional biomarker for incident age-related macular degeneration localizes to the photoreceptor-RPE-choriocapillary interface (PMID 33344065).

ABSTRACT BODY:

Purpose: Although USH2A-related retinal degeneration is among the most common forms of Usher syndrome type 2 (USH2) and autosomal recessive retinitis pigmentosa (ARRP), prior studies have not described cone structure with high-resolution images. Adaptive Optics Scanning Laser Ophthalmoscopy (AOSLO) is a non-invasive method of visualizing cone photoreceptors with high resolution. We describe baseline cone spacing and explore inter-grader and inter-test variability using data collected in a multicenter, international natural history study of USH2A-related retinal degeneration.

Methods: Two baseline AOSLO montages of the cone mosaic were obtained from each of 14 participants (6 USH2, 8 ARRP; 4 female; 11 white) with USH2A-related retinal degeneration. Two graders masked to disease category measured cone spacing, cone density and an image quality score; poor quality images were confirmed not gradable by a masked clinician. Cone spacing measures were converted to Z-scores based on 37 normal subjects. Inter-test and inter-grader variability were evaluated using intraclass coefficient (ICC) and Bland-Altman plots. Association between cone spacing and clinical characteristics were assessed by linear mixed effects regression.

Results: Median age of participants at enrollment was 38 years (range: 20-59). Median disease duration was 14 years (interquartile range, IQR: 11-19) in USH2 and 6 years (IQR: 4-14) in ARRP participants. Cone spacing ranged from 0.78-2.44 arc minutes. Cone spacing was associated with eccentricity ($P < 0.001$), but no significant difference was observed by clinical diagnosis or disease duration. Bland-Altman plots showed high concordance between

baseline 1 and baseline 2 (mean differences near 0, ICC = 0.71). Grader 2 reported slightly lower values than grader 1 (ICC=0.7). Quality score was higher in baseline 1 than baseline 2 ($P = 0.02$). Greater inter-grader variation was found in regions with poor image quality ($P < 0.001$).

Conclusions: The baseline AOSLO data revealed similar cone spacing between USH2 and ARRP participants. Image quality was significantly lower for the second baseline montage, suggesting one baseline image is sufficient. Adding a qualitative image quality score can be a useful approach to handle inter-grader inconsistencies while minimizing the loss of data.

TITLE: Medium Chain Acylcarnitine Abnormalities Implicate Mitochondrial Dysfunction in Laser-induced Choroidal Neovascularization (CNV) in Brown Norway Rats

SESSION TITLE: Metabolism and protein processing: retina, photoreceptors and RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Han, P. Wei, Ophthalmology, Tianjin Eye Hospital, Tianjin, Tianjin, CHINA|

Commercial Relationships Disclosure (Abstract): Guoge Han: Commercial Relationship: Code N (No Commercial Relationship) | Pinghui Wei: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Acylcarnitine Abnormalities are implicated in the plasma of age-related macular degeneration (AMD) patients, but the mechanism by which peripheral blood lipid dysfunction affecting retinal metabolism remains unclear. We determined whether different forms of acylcarnitine (from C0-C18) concentrations in the retina, which reflecting lipid and mitochondrial metabolism, differed between control and Laser-induced CNV in BN rats.

Methods: Laser-induced choroidal NV (CNV) in rats was examined by fundus fluorescein angiography and permeability assay using Evans blue as tracer. Confirmation of key acylcarnitine identities was conducted using high mass accuracy liquid chromatography-tandem mass spectrometry. Medium chain acyl coenzyme A dehydrogenase (MCAD) was also measured using Western blotting and its enzyme activity was determined by MCAD Activity Assay Kit.

Results: Thirty-two metabolites related to acylcarnitine metabolism were identified in blood and retina from CNV and controls. After multivariable adjustment, C2-carnitine levels were significantly lower in blood of CNV rats compared to controls (0.51 ± 0.02 (standard error) compared to (1.10 ± 0.10) , $p = 0.01$). Decanoyl-carnitine levels were significantly higher in CNV compared to controls (2.84 ± 0.15 compared to 1.01 ± 0.05), $p = 0.01$). Other forms of acylcarnitines examined were not significantly different between cases and controls. Alteration of MCAD expression and activity were evident in the retina of laser induced CNV model.

Conclusions: Increased levels of C10 carnitine were observed in the retina of Laser-induced CNV rats model compared to controls. These changes may be attributed to dysregulated mitochondrial metabolism, reprogrammed lipid metabolism and impaired MCAD activity in the CNV eye. Our findings provide biochemical insights into the mechanisms of age-related ocular changes.

TITLE: Impact of a Vision Screening and Spectacle Correction Program on Educational Development in Preschoolers from Low-Income Communities

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Hennein, C. Lees, A. Nakayoshi, A.G. de Alba Campomanes, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lauren Hennein: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Lees: Commercial Relationship: Code N (No Commercial Relationship) | April Nakayoshi: Commercial Relationship: Code N (No Commercial Relationship) | Alejandra de Alba Campomanes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate educational development in low-income preschoolers who failed vision screening and were prescribed glasses compared to those who passed vision screening.

Methods: This prospective cohort evaluated the difference in a variety of developmental domains through the Desired Results Developmental Profile (DRDP) between low-income preschoolers who failed vision screening and were prescribed spectacle (study group) compared to those who passed (control group) in San Francisco, Alameda and San Mateo County during the 2017 to 2018 academic year. The difference in the domains between the two groups were calculated with a t-test at Fall 2017 (baseline), Winter 2018 and Spring 2018. The difference in the mean change in domain scores between the two groups were calculated from Fall 2017 (baseline) to the end of the academic year (Spring 2018).

Results: Twelve thousand and seven preschoolers were included (n=107 in the study group and n=1100 in the control group). The mean age was 50.2 months (range 34.8 to 66.5 months). One-hundred and ninety children failed vision screening with a true-positive rate of 56.3% (107/190). The mean baseline scores in all eight domains was lower in the study group compared to the control group by a range of 0.9 to 24.9 points; this difference was statistically significantly lower in the "History – Social Sciences (HSS)" (24.9 points; p=0.038) and "Visual and Performing Arts (VPA)" (24.17 points; p=0.039) domains. The mean scores were not significantly different at the Winter 2018 and Spring 2018 timepoints between the two groups. The difference in the mean change in domain scores from Fall 2017 to Spring 2018 between the two groups was higher in the study group in five of the eight domains (range -4.66 to 10.1 points), however this was not statistically significant.

Conclusions: Low-income preschoolers who were prescribed glasses performed worse in all eight categories of development assessments at the start of the academic year, with a significant difference in HSS and VPA. There were no significant differences in scores between the two groups at the mid- and end of the academic year and the study group experienced a larger increase in scores for the majority of domains over the course of the academic year. This suggests that glasses may assist low-income preschoolers in catching up in their educational development assessments.

ABSTRACT BODY:

Purpose: To demonstrate the results of a compact multi-modal and multi-scale retinal imaging instrument with angiographic functional extension and to explore its imaging performance.

Methods: The system has two imaging modes that are operated simultaneously: scanning laser ophthalmoscopy (SLO) and optical coherence tomography (OCT). The field of view of both imaging modes can be changed between a standard large field-of-view mode and a high-resolution small field-of-view mode for cellular resolution imaging using adaptive optics (AO) correction of ocular aberrations. The SLO is operated at a central wavelength of 790 nm and records images at 13 Hz. The swept-source OCT is operated at 1060 nm with an A-scan rate of 200 kHz, which translates to a B-scan rate of 200 Hz. The AO correction is operated in closed loop at 10 Hz. Further, OCT angiography in large and small field-of-view modes can be achieved by acquiring 4 B-scans per position. An intensity based angiographic evaluation is used for the visualization of vessel networks. The dimensions of the entire instrument are 490 mm x 500 mm x 500 mm, including motorized translation stages that enable 3D tracking of the pupil position.

Results: Images recorded in healthy volunteers with the large field-of-view mode (40 deg x 30 deg) show comparable quality as obtained with commercial systems. The attached figure shows representative images recorded with the instrument. The axial and lateral resolution is 7 μ m and 4.4 μ m respectively in AOOCT, while the lateral resolution is 3.3 μ m in AOSLO. Images recorded with the high resolution AO-SLO mode show individual cone photoreceptors at half-degree from fovea and beyond. The high resolution of the OCT allows tomographic and en-face views of individual photoreceptors, discrimination between cone and rod end tip layers, and visualization of the Henle fiber layer border. The angiographic evaluation shows the vessel network and choriocapillaris in both large and small fields of view.

Conclusions: The combination of OCT and AO improves the lateral resolution, thereby enhancing the visualization of individual photoreceptors. The application of OCT angiography further enhances the appearance of the capillaries, e.g. their thickness in the en-face AOOCTA images. This multi-modal and multi-scale approach allows for a rapid identification of regions of interest in the large field-of-view mode and for a more detailed analysis in the high-resolution mode.

ABSTRACT BODY:

Purpose: Recently, we have developed a novel approach to elucidate the early initiating factors that may underlie the pathology of dry age-related macular degeneration (AMD), and specifically its end-stage Geographic Atrophy (GA). Suppression of claudin-5 levels, the most highly enriched tight junction protein at the inner blood-retinal barrier (iBRB), leads to retinal pigment epithelium (RPE)-like atrophy. Here, we sought to characterise novel animal models that allow us to assess the effect of claudin-5 levels on RPE due to varying claudin-5 expression levels in greater detail to identify the kinetics of damage observed and the downstream effectors that lead to RPE atrophy.

Methods: We have compared three novel animal models 1) RNAi based inducible claudin-5 knockdown mice, 2) Cldn5+/- mice and 3) C57BL6/J mice sub-retinally injected with adeno-associated virus (AAV) vectors expressing shRNA targeting claudin-5, or non-targeting control to characterise the effect of constant claudin-5 suppression on retinal and RPE integrity. Each cohort of mice were either fed a normal or high cholesterol diet for varying lengths of time to assess RPE atrophy progression. All mice were imaged by optical coherence tomography (OCT) to examine RPE integrity and fundus fluorescein angiography (FFA) to assess retinal blood vessel integrity and compared to littermate controls. Immunohistochemical, protein and transcript analysis was undertaken following sacrifice.

Results: Assessment of these three mouse models shows that RPE atrophy progression varies depending on the level of claudin-5 expression at the iBRB and is exacerbated when addition of high cholesterol chow was provided as determined by OCT and FFA.

Conclusions: These novel animal models may be beneficial in understanding GA pathology and development in greater detail. Targeted stabilization and regulation of claudin-5 expression at the inner retinal vasculature may have therapeutic potential for preventing GA onset and development.

ABSTRACT BODY:

Purpose: Population receptive field (pRF) mapping methods allows mapping visual field losses due to retinal pathology, as recently shown in a study on retinal scotoma sizes at 3T. MRI scanners operating at ultra-high magnetic field (7 Tesla and above) offer increased sensitivity and specificity of brain activation maps, but also pose additional challenges in image acquisition and subject handling, particularly in clinical populations.

Methods: Ten eyes from 10 patients clinically and genetically diagnosed with Stargardt disease (STGD) (age: 29 ± 9.7 ; 4 female) were included in the study. Data was acquired on a 7 Tesla MAGNETOM scanner using a 32-channel head coil with 1mm isotropic resolution using the CMRR multi-band EPI sequence. Visual stimulus consisted of a moving, flickering bar covering the central 14° visual angle. In addition, patients were examined using optical coherence tomography (OCT, Heidelberg Spectralis) and microperimetry (MP-3, Nidek). Data was analyzed using mrVista to obtain retinotopic maps. Visual field coverage based on above-threshold voxels from the pRF-analysis allows for a direct comparison with retinal sensitivity maps as measured by MP.

Results: Four patients were excluded due to attention deficits or excessive movement during the MRI measurements. All remaining patients had framewise displacement (FD) values of 0.025 ± 0.004 mm and 5068 ± 2162 V1 voxel activated (mean \pm stddev). Figures show MP and pRF results of two exemplary patients with macular scotoma confined to the central 2° visual angle. It can clearly be seen that uncovered areas on the coverage maps obtained by ultra-high-field fMRI resemble areas with functional loss in MP.

Conclusions: This is the first demonstration of ultra-high field pRF mapping in patients with STGD. Coverage maps obtained from pRF data provide information complementary to conventional ophthalmic examination and allow for objective assessment of retinal dysfunction.

ABSTRACT BODY:

Purpose: Laser photocoagulation is widely used in retinal treatment. However, the tissue effect is only partially correlated to laser energy due to inter- and intraindividual alterations in retinal pigment epithelium (RPE) pigmentation. This leads to wide variations in laser effect and decreases treatment reliability and reproducibility. Optoacoustic measurement and control of retina temperature can solve this problem by adjusting the laser power in real-time onto a target temperature. With this temperature-guided irradiation, reliable and reproducible laser-tissue effect can be achieved for non-damaging heating. The aim of the study is to validate a control module by measuring and controlling laser power and real-time temperatures.

Methods: 5 eyes of 3 rabbits received a retinal temperature regulated laser treatment with a conventional 532nm continuous wave (cw) laser (Zeiss VisuLas 532). A custom-build control module (Medical Laser Center Luebeck) was used, which is optically coupled between the treatment laser and the slit lamp. It adjusts the pre-set laser power, depending on the current tissue temperature. Per pre-marked areal (5-6 in each eye) nine 200µm lesions (100ms exposure time) with uprising temperatures (45°C to 69°C in steps of 3°C) were applied. The mean applied laser power and mean real-time temperature over the last 20ms were measured.

Results: For the same target temperature, the controlled laser power showed significant differences. The following shows the mean applied laser power (\pm standard deviation and max/min values) over the last 20ms of irradiation for the target temperatures 51°C (14.8mW \pm 7.2, 31.0mW/0.9mW), 60°C (24.6mW \pm 9.3, 42.4mW/2.2mW) and 69°C (35.00mW \pm 12.8, 56.8mW/4.6mW). The real-time temperature displayed an overall accuracy of 3.5 % to the pre-set target temperature over the last 20ms of irradiation.

Conclusions: The results demonstrate that the control module was able to achieve reproducible and reliable real-time temperature-controlled irradiation. This will allow for more consistent subvisible laser treatment.

ABSTRACT BODY:

Purpose: Lafora disease (LD) is an autosomal recessive progressive neurologic disorder caused by mutations in EPM2A or EPM2B genes, both involved in glycogen structural integrity. Defective function of EPM2A or EPM2B results in accumulation of malformed insoluble glycogen termed Lafora bodies (LBs) in the central nervous system. This study aimed to characterise the retinal phenotype of Epm2a^{-/-} mice to characterize retinal neuronal changes in LD.

Methods: The study was approved by the animal care committee at the Toronto Center for Phenogenomics. Five to seven knockout (KO; Epm2a^{-/-}) and control (WT) littermates were examined at two time points (10 and 14 months, respectively). Mice were injected 0.01 ml/g body weight of anesthetic solution (combination of 100mg/ml Ketamine and 20mg/ml Xylazine). Electroretinogram (ERG) testing was performed following overnight dark adaptation (DA) using Lab Cradle (Diagnosys LLC). A scotopic intensity series ERG was performed (9 steps; 0.0025 cd.s.m⁻² – 10 cd.s.m⁻²) followed by a 10-minute light adaptation (LA; 30 cd.m⁻²). Subsequently, LA ERGs were performed using a 5 cd.s.m⁻² stimulus flash to four stimulus frequencies (5 - 20 Hz). Retinal optical coherence tomography (OCT) and fundus imaging was performed using Phoenix MICRONTM. Periodic acid Schiff-Diastase (PASD) staining of the retina was performed to ascertain LB deposition. After staining, slides were imaged at 40x using 3DHistech Panoramic Flash II Slide Scanner, analyzed using 3DHistech CaseViewer software and LBs were counted using 3DHistech QuantCenter. Regions of interest were selected on the retinal sections, and a scenario was built in QuantCentre that distinguishes LBs from background and other structures.

Results: Retinal photographs were normal in both KO and WT mice. There was no significant difference in DA and LA ERG b-wave amplitudes between KO and WT mice groups at 10 and 14 months. The total retinal thickness was similar in both KO and WT groups. On PASD staining, LBs were observed only in KO mice in inner plexiform layer (IPL) and inner nuclear layers. Upon quantification, average number of LB accumulation in IPL in KO mice were 1743±533 and 2615±915 per mm², at 10 and 14 months, respectively.

Conclusions: This Epm2a^{-/-} mice model demonstrates LB deposition in the bipolar cell nuclear layer and its synapse with retinal ganglion cells. Adaptive optics retinal imaging could visualize them in vivo and serve as a useful biomarker for LD.

ABSTRACT BODY:

Purpose: Rods and cones secrete IRBP, the major soluble protein component of the interphotoreceptor matrix. In addition to protecting and trafficking visual cycle retinoids, IRBP may have a neuroprotective role as there is an inverse relationship between the level of vitreous IRBP and severity of diabetic retinopathy (DR). The mechanism and location of reduced IRBP expression is not understood. Here, we investigated IRBP expression in-vitro in response to glucose and VEGF. Globes from diabetic patients were used to characterize retinal location of IRBP.

Methods: 1.5×10^6 661W and Y79 cells, which express cone and rod-like phenotypes, respectively were treated with 5.5 or 30 mM glucose with or without VEGF (10ng/ml) for 24 hrs. In 661W cells, IRBP and GAPDH mRNAs were quantified by RTPCR, and IRBP in conditioned media by ELISA. Human globes studies were obtained through the NDRI. Death to placement in 10% formalin was <10.5 hrs except in one control. Cases: Diabetes (2 no DR, 4 non-proliferative, 2 proliferative); and normal controls (6 cases). Donors age range was 30-98 yrs. Clinical histories were correlated with gross and histopathology, and serial sagittal sections prepared through the fovea. IHC compared the distribution of IRBP and peanut agglutinin binding matrix domains, with that of the choroidal proteins albumin, and BIGH3.

Results: High glucose (30 mM) resulted in a 1.44 increased IRBP mRNA in 661W cells (vs 1.34 for cells treated with 5.5 mM glucose). IRBP in the conditioned media in high glucose was ~3 X times greater compared to low glucose (13.1 vs 4.5 pg/ml). VEGF reduced IRBP secretion in cells in high (to 5.0 pg/ml) vs low glucose (0 pg/ml). IRBP in the media of Y79 cells were similar (70 vs 74 pg/ml for high and low glucose, respectively). Only a small decrease of IRBP level was noted in Y79 cells with VEGF treatment (69 vs 68 pg/ml). Ocular Pathology showed: Except when the postmortem interval was > 12 hrs, IRBP was restricted to the IPM; albumin and BIGH3 to the choroid. In DR, IRBP was reduced in the IPM, and albumin was often present.

Conclusions: Taken together our studies show that hyperglycemia results a reduction of IRBP within the interphotoreceptor matrix. VEGF mediated reduced IRBP expression may contribute to the pathogenesis of DR.

ABSTRACT BODY:

Purpose: To assess optic cup shape patterns in glaucoma with unsupervised artificial intelligence (AI).

Methods: The first Cirrus OCT scans of the optic nerve head (ONH) from each eye with signal strength ≥ 6 were selected. The optic cup shape was represented as the vertical positions of the inner limiting membrane (ILM) with respect to the lowest ILM vertical position in each eye. Scans with ONH centers deviating more than 0.3 mm from the scan center were excluded. The OCT scans were registered with respect to ONH centers in the right eye format. The Humphrey SITA standard 24-2 visual fields (VFs) tested within three months of the OCT tests were selected. An unsupervised AI method termed non-negative matrix factorization was applied to assess the cup shape patterns. The cup shape patterns were correlated with VF and OCT diagnostic parameters. We compared if using the cup shape patterns improved the prediction of VF loss using linear regression with model selection to remove redundant features.

Results: We determined 14 cup shape patterns (Figure 1) from 9,854 OCT scans. The brighter regions in the cup shape patterns indicate the more informative zones with greater variations across patients. Mean deviation (MD), retinal nerve fiber layer thickness (RNFLT) and ONH related parameters including rim area, disc area, average cup-disc (CD) ratio, vertical CD ratio and cup volume (Table 1) were most negatively correlated with Patterns 5, 4, 4, 12, 14, 14 and 14 (r : -0.15, -0.21, -0.45, -0.42, -0.60, -0.57 and -0.49, $p < 0.001$), and were most positively correlated with Patterns 10, 10, 14, 5, 5, 7 and 5 (r : 0.30, 0.28, 0.39, 0.54, 0.59, 0.52 and 0.78, $p < 0.001$), respectively. The Worse MD and thinner RNFLT were most strongly correlated with higher coefficients of Patterns 10 and 12, which represent inferior and superior cupping. The adjusted multiple r (r_m) to predict MD separately using the cup shape patterns, ONH related parameters, and 12 clock hour RNFLT were 0.50, 0.51 and 0.56, respectively, which the model combining the cup shape patterns and ONH related parameters (adjusted r_m : 0.60, $p < 0.001$) outperformed. The model (adjusted r_m : 0.63) combining all three types of features outperformed ($p < 0.001$) the model combining existing RNFLT and ONH parameters (adjusted r_m : 0.59).

Conclusions: The cup shape patterns correlated with established diagnostic parameters and improved the structure-function relationship in glaucoma.

TITLE: Influence of stimulus size, intensity, & natural eye motion on small-field color perception

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.E. Vanston, A.E. Boehm, W.S. Tuten, A.J. Roorda, School of Optometry and Vision Science Graduate Group, University of California Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): John Vanston: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Boehm: Commercial Relationship: Code N (No Commercial Relationship) | William Tuten: Commercial Relationship(s);University of California, Berkeley:Code P (Patent);University of Pennsylvania:Code P (Patent) | Austin Roorda: Commercial Relationship(s);C. Light Technologies:Code I (Personal Financial Interest);University of Rochester:Code P (Patent);University of Houston:Code P (Patent)

ABSTRACT BODY:

Purpose: Stimulating single cones with spots of 543nm light has been shown to elicit various color sensations. These percepts vary mainly along a red-green axis, yet large fields of this wavelength invariably appear green and highly saturated. It remains unknown what conditions, if any, reliably yield veridical color percepts at the photoreceptor scale. Notably, naturalistic viewing includes eye motion, which causes many cones to sample the stimulus across time. The current study varied stimulus size and intensity under two eye motion conditions in order to better understand how chromatic percepts are constructed from cone signals.

Methods: Stimuli comprised 543nm spots of light presented at ~1 deg temporal eccentricity using an adaptive optics scanning laser ophthalmoscope. This system corrects for the optical aberrations of the eye and provides high-precision eye tracking and stimulus delivery. On each trial small spots of light were delivered to the retina over 500 ms. Stimuli were presented at two sizes (~2 and 4 arcmin, respectively), two intensities (1x and 6x detection threshold), and two eye motion conditions. In the first condition, stimuli were presented to a fixed position on the retina; in the second condition, stimuli were initially presented to a predefined retinal location, but subsequently allowed to drift across the moving cone mosaic. On each trial subjects (n = 3) reported the perceived saturation (rating scale of 1-5) and hue (red, white, or green) of the stimulus.

Results: The mean likelihood that subjects reported green increased for larger and higher intensity stimuli, with size increasing this likelihood from 74% to 85% and intensity increasing it from 72% to 86%. Similar results were found for saturation, with larger size resulting in a 7% increase in mean saturation rating and higher intensity resulting in a 10% increase. Varying eye motion resulted in a difference of only 1% in both measures. The amount of eye motion was found to be uncorrelated to the saturation rating on a trial-to-trial basis.

Conclusions: When small groups of cones were stimulated with 543 nm light, increases in stimulus size and intensity resulted in percepts that appeared more saturated and more consistently greenish, rather than reddish or whitish, in hue. Whether these spots of light were stabilized on the retina or allowed to drift freely across it made little difference in hue or saturation reports.

TITLE: Peripheral refraction measured from through-focus double-pass imaging

SESSION TITLE: Peripheral optics and vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Christaras, H.S. Ginis, Department of Research, Athens Eye Hospital, GREECE|D. Christaras, Institute of Ophthalmology, University College London, London, London, UNITED KINGDOM|P. Artal, Laboratorio de Optica, Universidad de Murcia, Murcia, Murcia, SPAIN|

Commercial Relationships Disclosure (Abstract): Dimitrios Christaras: Commercial Relationship: Code N (No Commercial Relationship) | Pablo Artal: Commercial Relationship: Code N (No Commercial Relationship) | Harilaos Ginis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Peripheral refraction is a relevant information in different areas of clinical optics, such as myopia or cataract. We have developed and validated an optical instrument and a corresponding method for the in-vivo assessment of peripheral defocus and astigmatism from the recording of through-focus double-pass images.

Methods: An optical setup was developed to acquire non-cycloplegic, double-pass through focus images of the eye at 0, 15 and 30 degrees of visual angle. A 2-mm diameter infrared laser diode (780nm) beam was projected on the ocular fundus with the appropriate relay optics via a tunable lens capable of inducing +5D to -18D of defocus. The ocular fundus was then imaged through the full natural pupil of the eye and the same relay optics and the tunable lens on a CMOS sensor. A series of through focus images was acquired at a step of 0.1D and best focus was established by finding the image where peak intensity value was maximum. The magnitude of astigmatism was determined by finding the two defocus images where the ratio of the ellipse's minor axis in their shape was minimized. Astigmatism was then defined as the dioptric difference between those two images and the axis of astigmatism was defined as the axis of the image with the highest defocus value.

Results: Using appropriate off-axis fixation of the subject, the refractive measurement was performed at 0, 15 and 30 degrees of visual angle at a temporal horizontal visual field. The procedure was validated in-vivo in 2 healthy subjects and each measurement was repeated twice to determine the repeatability of the measurement. Repeatability in central and peripheral refraction measurement was within 0.25D sphere and cylinder for both subjects. Both subjects exhibited a myopic periphery with respect to the foveal refraction (-0.7 and -1.4D at 30 degrees). The difference of astigmatism between the 30 degrees field angle and central vision was in the myopic direction for both subject (-3.3 D and -2.6D) respectively where the more refractive axis was horizontal. At each eccentricity the measurement lasted a few seconds.

Conclusions: An instrument and an associated method was developed for the fast, in-vivo assessment of central and peripheral refraction. The refraction obtained from this method pertains to the actual refraction optimizing the double-pass images of the eye and is free of errors associated to refractometry and wavefront sensing at elliptical pupils.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is an eye disorder of malfunctioning tissues in the outer blood-retinal barrier (oBRB): the retinal pigment epithelium (RPE), the underlying "Bruch's membrane" and the adjacent choroidal capillary bed. To understand disease pathology and develop new therapeutic concepts, in vitro models are needed where physiological and morphological changes of tissues can easily be monitored, and conditions can be manipulated. To this end, we developed an organ-on-a-chip model (OOC) of the oBRB based on human induced pluripotent stem cell-derived cells (hiPSC) and evaluate its future use as an in vitro model of drug development for AMD.

Methods: Human iPSC-RPE and iPSC-endothelial cells (EC) were derived based on protocols from Regent et al. (2019) and Orlova et al. (2014) respectively. The PDMS-based OOC was composed of a top channel for RPE culture as a monolayer, and a bottom channel where ECs were cultured in a microvessel of a well-defined geometry patterned within collagen-I using a subtractive method of micropatterning. Expression of cell-cell adhesion markers was analyzed by immunocytochemistry, and barrier function of endothelial cells was assessed with a clinically relevant technique analogous to fluorescein angiography.

Results: OOC was fabricated using injection molding, which minimizes labor intensive fabrication and provides device consistency. Devices were placed on a rocking platform inside an incubator to facilitate gravity driven medium flow in channels. Healthy cell population growth was confirmed by cell-cell adhesion markers. EC barrier was assessed by perfusion of fluorescently labeled dextran where lower permeability compared to only RPE containing devices was observed.

Conclusions: The OOC developed in this study models the outer BRB by recapitulating the tissue microenvironment. integration of iPSC-derived cells from AMD patients could provide insights for individualized testing and the evaluation of new treatments.

ABSTRACT BODY:

Purpose: Post-translational protein arginine methylation is a fundamental modification of many different essential cellular processes. Protein arginine methyltransferase 1 (PRMT1) is a type I member of the PRMT family, and it is critical for catalyzing such modulation. However, its role in mediating corneal epithelial renewal remains unknown. In the present study, we characterize its involvement in corneal epithelial wound healing (CEWH) and thereby gain insight into how it affects this process.

Methods: An Alger brush was used to debride the corneal epithelium in mice. Western blot was performed to detect the PRMT1 protein expression level during CEWH in this tissue. Human corneal epithelial cells (HCECs) were transfected with siRNA targeted to knock down PRMT1 expression using Lipofectamine RNAiMAX. MTS and a scratch wound-healing assay evaluated the effects of PRMT1 on HCEC proliferation and migration, respectively. Flow cytometry determined cell cycle progression. Corneal epithelial-specific Prmt1 deletion mice were generated using the Cre-lox system.

Results: The PRMT1 protein expression level was significantly upregulated during CEWH. Prmt1 deletion significantly delayed in vivo CEWH. Furthermore, downregulation of PRMT1 only inhibited HCEC migration without altering either their cell cycle progression or proliferation.

Conclusions: PRMT1 upregulation promotes CEWH through stimulating cell migration. This association indicates that increasing the protein arginine methylation status warrants further evaluation as a potential option to promote this process in a clinical setting.

ABSTRACT BODY:

Purpose: Many important retinal diseases that would benefit from evaluation with optical coherence tomography (OCT), such as retinal breaks and retinoschisis are frequently located in the peripheral retina. However, clinical OCT imaging is generally confined to capturing the posterior pole. We describe a new method for capturing OCT images of the peripheral retina using a mirrored contact lens.

Methods: An ex vivo porcine eye was set up for standard 25 gauge 3 port pars plana vitrectomy with the Alcon Accurus system (Fort Worth, TX). Using the Leica Proveo 8 with BIOM widefield viewing system (Wetzlar, Germany) we created a retinal break approximately 1 mm posterior to the ora serrata with the vitreous cutter.

Results: Transillumination of the break using the endoilluminator confirmed the peripheral location externally at 5 mm posterior to the limbus - Figure 1A. Using the microscope, we directly visualized the break with a Goldmann-type 3 mirror contact lens – Figure 1B. Our research surgical microscope-integrated OCT (MIOCT) system, consisting of a 400 kHz 1050 nm swept source engine, was directed through the Goldmann 66° mirror and captured B-scans of the retina. We were able to identify retinal vessels, normal peripheral retina and the iatrogenic break within the OCT images– Figure 1C.

Conclusions: Use of a mirrored contact lens to obtain OCT images of the peripheral retina is a promising new technique to evaluate peripheral retinal anatomy. It can be used to identify sites with and without retinal pathology in the periphery. Additionally, this technique has the potential to examine the vitreous base.

ABSTRACT BODY:

Purpose: To develop an automated algorithm for clinical spectral domain OCT (SD-OCT) images, capable of correcting hyperreflective artifacts associated with the instrumental configuration and the patient's eye position.

Methods: The automated pre-processing algorithm (Python Software Foundation, v2.7.4) developed standardizes raw images (flattening, segmentation, normalization) and computes a correction mask from each OCT image. Our approach is based on the Principal Component Analysis (PCA) of the in-depth stromal OCT signal, which enables the statistical computation of the device's point spread function and permits its compensation (Fig.1). The mean stromal intensity depth profile is then extracted and analyzed via our previously developed method designed to quantify the photon mean free path in the stroma (R Core Team, v3.6.3) as objective measure of corneal transparency. We tested our method and associated algorithm on clinical SD-OCT images acquired with an RTVue-100 OCT device (Optovue, Inc.). n=37 normal corneas (aged 33 ± 8 years) were studied (2 images per eye). Patients were chosen according to the inclusion criterion of pre-refractive surgery, implying clear and healthy corneas.

Results: Results are shown in Fig.2. Boxplots depict the photon mean free path values (I_s) obtained by our image-analysis method for each eye imaged. Typical I_s values are on the order of 500 – 1000 μm . We obtain a log-normal distribution of results for data up to the third quartile with a 6.9 % coefficient of variation: $\langle \log(I_s) \rangle = 6.1 \pm 0.4$ dB, Shapiro-Wilk test p-value = 0.5.

Conclusions: Our pre-processing algorithm is capable of robust detection and correction of clinical SD-OCT image artifacts. It enables to determine numerical values of scattering mean free path in vivo using unmodified clinical diagnostic devices. Future steps will include a correlation of our method with clinical data (e.g., corneal densitometry) obtained by other methods (Bland-Altman comparison), as well as with other clinical measures (e.g., visual acuity).

Patent: US20200383775A1:Code P (Patent) | Spyridon Tsoukalas: Commercial Relationship: Code N (No Commercial Relationship) | Alex Pennos: Commercial Relationship: Code N (No Commercial Relationship) | Dimitrios Christaras: Commercial Relationship: Code N (No Commercial Relationship) | Angelos Livir-Rallatos: Commercial Relationship: Code N (No Commercial Relationship) | Pablo Artal: Commercial Relationship(s);VOPTICA SL. Patent US20200383775A1:Code P (Patent)

ABSTRACT BODY:

Purpose: To evaluate peripheral refraction and image quality in a physical model of the pseudophakic eye where the axial position of the intraocular lens (IOL) and the radius of curvature of the retina could be varied. This device is used to compare the performance of a standard Monofocal IOL to a new type of IOL with an inverted meniscus shape designed to improve peripheral image quality.

Methods: The model of the pseudophakic eye had realistic dimensions with a cornea made of PMMA (radius of curvature 7.73mm, conic constant -0.24) an iris at a depth of 3.55mm (3mm pupil) and an IOL holder with variable distance (0.5 to 1.5mm) from the pupil, simulating a postoperative anterior chamber depth ranging from 4.05 to 5.05 mm. The volume of the artificial eye was filled with distilled water. A board level camera (DFM 72BUC02-ML, Imaging Source, Germany) in a water-tight container with a 200µm glass window was introduced to allow direct recording of retinal images. The camera was mounted on a rotating base where the center of rotation was on the optical axis of the system and the radius ranged from 11 to 13 mm to model different retinal radii of curvature. For each field angle (0, 10, 20, 30 and 40 degrees) the retinal image was optimized for spherocylindrical error using trial lenses. Two types of IOLs were evaluated: a standard monofocal (CT Lucia601P, Zeiss, Germany) and a new meniscus shaped one (ArtIOL, Voptica SL, Spain).

Results: The retinal images recorded revealed a deterioration of retinal image quality with field angle. Peripheral defocus ranged from -1.0 D to +7.5 D depending on retinal curvature, IOL position and IOL type. Astigmatism was up to -7.5 D for the standard IOL and was reduced to -3.5D for the meniscus IOL. The condition with the increased IOL depth (5.05mm) required the insertion of a higher power IOL by 1D to maintain central focus without adjusting the overall eye's axial length. The condition of increased chamber depth and increased IOL power resulted to a small (0.5D) decrease in the relative defocus in the periphery. Astigmatism in this condition was higher in the standard IOL (-9.0 D) and remained unchanged for the meniscus type IOL.

Conclusions: The experimental setup allowed the direct recording of the retinal image at large field angles. The meniscus-type IOL exhibited less peripheral astigmatism in all conditions and it was more robust in terms of the axial depth of the IOL than the standard lens.

TITLE: TGF β 2 modulates YAP/TAZ activity in human trabecular meshwork cells through ERK and ROCK signaling pathways

SESSION TITLE: Glaucoma: molecular, biochemical and biomechanical disease mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Li, P.S. Ganapathy, S. Herberg, Ophthalmology & Visual Sciences, State University of New York Upstate Medical University, Syracuse, New York, UNITED STATES|H. Roberts, D.W. Stamer, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Haiyan Li: Commercial Relationship: Code N (No Commercial Relationship) | Haven Roberts: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Stamer: Commercial Relationship: Code N (No Commercial Relationship) | Preethi Ganapathy: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Herberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary open angle glaucoma (POAG) is associated with increased trabecular meshwork (TM) stiffness and elevated levels of transforming growth factor beta2 (TGF β 2) in the aqueous humor. YAP/TAZ are important mechanotransducers and have been implicated in the pathogenesis of POAG. However, the molecular underpinnings of YAP/TAZ activity modulation in TM cells under glaucomatous conditions are not well understood. The purpose of this study is to elucidate how TGF β 2 and substratum stiffness regulate YAP/TAZ in human TM (HTM) cells using viscoelastic biomimetic hydrogels.

Methods: Primary HTM/glaucomatous HTM (GTM) cells were isolated from surgical discard corneal rims/donor POAG globe and validated using accepted protocols. HTM/GTM cells were plated on soft photocrosslinked hydrogels (collagen I, elastin-like polypeptide and hyaluronic acid) or stiff glass coverslips/tissue culture polystyrene and stimulated with 2.5 ng/ml TGF β 2 \pm ERK inhibitor (U0126; 10 μ M)/ROCK inhibitor (Y27632; 10 μ M). YAP/TAZ were knocked down in HTM cells using siRNA. Vinculin, YAP/TAZ, transglutaminase 2 (TGM2), TGF β 2, fibronectin (FN), α -smooth muscle actin (α -SMA) and phospho-myosin light chain (p-MLC) expression were determined by qRT-PCR, immunoblotting and immunocytochemistry analyses.

Results: HTM cells displayed increased vinculin puncta density, cell spreading and YAP/TAZ nuclear localization/activation when cultured on stiff substratum vs. soft hydrogels. On hydrogels, TGF β 2 exposure induced a more rounded HTM cell shape with decreased nuclear aspect ratio ($p < 0.001$). GTM cells and TGF β 2-induced HTM cells showed decreased p-YAP (cytoplasmic; inactive) and increased nuclear YAP/TAZ (active) together with increased downstream TGM2 vs. normal HTM cells. U0126 completely abolished TGF β 2-induced YAP/TAZ expression and nuclear translocation as well as TGM2 activation. Y27632 slightly rescued TGF β 2-induced YAP/TAZ activation. YAP/TAZ depletion using siRNA resulted in decreased expression of TGM2, TGF β 2, FN, α -SMA and p-MLC ($p < 0.001$), all associated with cell contractility and tissue stiffening.

Conclusions: Our data suggest that substratum stiffness and TGF β 2 modulate YAP/TAZ activity in HTM cells under simulated POAG conditions to varying degrees through ERK and ROCK signaling pathways. YAP/TAZ play critical roles in regulating HTM cell contractility associated with HTM stiffness and POAG pathogenesis.

TITLE: Digital Hess Screen test : a novel method for quantitative measurement of strabismus

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Al-Mohamed, I. Kelly-Pérez, A. Prinz, M. Bende, T. Oltrup, M. Leitritz, T. Bende, University-Eye-Hospital Tübingen, Eberhard-Karls-Universität Tübingen Medizinische Fakultät, Tübingen, Baden-Württemberg, GERMANY

Commercial Relationships Disclosure (Abstract): Haroun Al-Mohamed: Commercial Relationship: Code N (No Commercial Relationship) | Ismael Kelly-Pérez Kelly-Pérez: Commercial Relationship: Code N (No Commercial Relationship) | Andreas Prinz: Commercial Relationship: Code N (No Commercial Relationship) | Marvin Bende: Commercial Relationship: Code N (No Commercial Relationship) | Theo Oltrup: Commercial Relationship: Code N (No Commercial Relationship) | Martin Leitritz: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Bende: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To increase the accuracy of Strabismus Measurements using a new fast digital technique based on the Hess test.

Methods: The proposed system is based on the Hess screen test by using dual-coloured glasses to disrupt fusion and to enable a fovea-to-fovea test. It consists of glasses and a PC connected to a beamer. The glasses are coloured blue and red which guarantees monocular vision by disrupting fusion. To make sure the patient has no diplopic images, the room lights must be dimmed. At one side of the glasses is mounted a 9-axis sensor (Adafruit BNO055) which transfers the rotation data of the head via a Bluetooth connection (Adafruit Feather M0 BLE) to the PC. Additional to the 9-Axis sensor, a time-of-flight sensor (Pololu VL53L1X) is mounted to measure the distance of the head to the wall. Via the beamer, two objects on a black background are presented on the wall. Through the movements of the head a simulated red cross can be moved. The aim of the test is to move the cross in the centre of the projection where a blue square is presented.

To simulate the ocular deviations, glasses with different prism dioptres from 1-40 degrees are used during the test. The strabismus test via the designed system was compared with the conventional Hess screen test.

Results: Using a stepper motor the accuracy of the 9-Axis sensor was defined to one degree in pitch, yaw and roll. Using the designed glasses visual gazes up to 25° degrees are possible. Examination time is up to 60 seconds measuring both eyes at a particular gaze. Also it was possible to measure extreme and small-angle strabismus.

Conclusions: This designed system and technique allow to carry out fast and accurate strabismus measurements, the results are close to the given and measured by conventional Hess test. With this technique, the measuring system design can be simplified and the costs reduced.

ABSTRACT BODY:

Purpose: The retinal capillary endothelium experiences marked fluctuations in hyperglycaemia and ischemia as diabetic retinopathy (DR) progresses. This study has assessed the changes of metabolism and related function in human retinal microvascular endothelial cells (HRMEC) exposed to long term high glucose and hypoxia conditions in vitro

Methods: HRMEC obtained from human donors were grown in to 25 mM L-glucose or 25 mM D-glucose (HLG, HDG) for four weeks and then also exposed to hypoxia (1% O₂, 5% CO₂) for 24 hours. The metabolic flux of both the extracellular acidification rate (ECAR) and oxygen consumption rate (OCR) was assessed using the Seahorse XF analyser. To assess in vitro functionality assays such as tubulogenesis, proliferation, and migration, along with barrier analysis using the xCELLigence system were utilised. Pharmaceutical compounds were also utilised to modulate the responses of key metabolic genes

Results: Compared to controls HDG cells demonstrated reduced ECAR from 24.4 to 16.4 (mpH/min) in normoxia and 44.8 and 35 (mpH/min) in hypoxia ($P \leq 0.01$). Furthermore, OCR was reduced in normoxia from 61.4 to 52.9 (pmol/min) ($P \leq 0.05$), however in hypoxia HDG showed increased levels in relation to control 25.8 to 17.3 (pmol/min) ($P \leq 0.01$) assessed by the Seahorse XF analyser. HDG treated HRMECs also displayed decreased tubulogenic capacity in normoxia which further decreased in hypoxia ($P \leq 0.001$). HDG reduced proliferative potential ($P \leq 0.001$) and was shown to increase median cellular size ($P \leq 0.001$). Migration of cells was also reduced in scratch wound assays and migration and barrier formation were shown to be hindered ($P \leq 0.01$). HDG cells demonstrated reduced ECAR from 24.4 to 16.4 (mpH/min) in normoxia and 44.8 and 35 (mpH/min) in hypoxia ($P \leq 0.01$). Furthermore, OCR was reduced in normoxia from 61.4 to 52.9 (pmol/min) ($P \leq 0.05$), however in hypoxia HDG showed increased levels in relation to control 25.8 to 17.3 (pmol/min) ($P \leq 0.01$) assessed by the Seahorse XF analyser.

Conclusions: HRMEC exposed to long term exposure of HDG and then hypoxia appear to have severely affected functionality and altered metabolism. As endothelial cells normally have a remarkable dependency on glycolytic metabolism which allows for growth and repair, these alterations are relevant to vascular pathology occurring in DR.

ABSTRACT BODY:

Purpose: Currently, there are around 18,500 ophthalmologists practicing in the United States. However, the American Association of Medical Colleges (AAMC) estimates a shortage of ophthalmology providers in 2025. It is well known that the prevalence of cataracts, macular degeneration, glaucoma, and diabetic retinopathy is highest in the elderly. There is expected to be an increase in the percentage of population aged 65 and older from 2017 to 2032. Despite this increase in population and the expected shortage of ophthalmologists, little research has attempted to quantify current demand for ophthalmologists on a regional level. This study sought to estimate demand for ophthalmologists using internet search engine data. Furthermore, it compared the level of demand with the number of ophthalmology providers in that area to address whether there is a shortage.

Methods: Google Trends were analyzed from 2004-2019 to find the average relative search volume (RSV) for the term "Ophthalmologist" of each state to determine patient interest. Furthermore, supply of ophthalmologists was identified by utilizing the Medicare Physician Compare National Database. This is a publicly accessible database that quantifies board-certified ophthalmology providers per state who accept Medicare. For each region, the number of providers was then divided by the 2019 Census Bureau population estimates to find the concentration of specialists per capita values. The RSV values were then divided by the per capita values to estimate the demand index of ophthalmologists for each state.

Results: The relative demand index was highest in South Dakota (100), Michigan (83), Delaware (82), Texas (78), and Arizona (76) (Figure 1). The greatest specialist concentration per 10,000 people was in Montana (1.62), DC (0.85), Hawaii (0.40), and Maryland (0.41) and lowest in Oklahoma (0.19), New Mexico (0.19), Texas (0.19) and Wyoming (0.17). The highest search volumes (RSV) were in Delaware (100), Michigan (100), and South Dakota (93) and the lowest volumes were in Alaska (36), Wyoming (27), and North Dakota (36).

Conclusions: With an aging population and an estimated shortage of ophthalmologists, the findings from this study will better delineate areas with an unmet need for ophthalmologists. This can provide helpful information to ophthalmologists when deciding on job allocation or practice building.

ABSTRACT BODY:

Purpose: Detection of motion direction is an essential visual function and a classic model for neural computation. This has been studied intensely in the non-primate retina where starburst amacrine cells (SACs) provide directionally-tuned inhibition to ON and ON-OFF direction-selective retinal ganglion cells (dsRGCs). While SACs are present in primates, their circuitry is largely unknown and the existence of dsRGCs remains an open question. Resolving the long-standing debate over primate retinal direction selectivity requires a detailed wiring diagram of SAC circuitry.

Methods: We reconstructed the structure, synapses and circuitry of ON SACs from a serial block-face scanning electron microscopy volume of macaque central retina. Postsynaptic RGC reconstructions were compared to RGCs labeled by injections of the retrograde tracer rhodamine dextran into the nucleus of the optic tract and dorsal terminal nucleus of the accessory optic system (NOT-DTN).

Results: First, we confirmed that the neural mechanisms supporting direction selectivity in mammalian SACs are conserved in primate. Mechanisms identified included a proximal-distal distribution of input-output synapses along each dendrite, reciprocal inhibition from other SACs and temporally-diverse bipolar cell input. Next, we reconstructed all postsynaptic RGCs. SACs targeted a single RGC type resembling some of the RGCs labeled from the NOT-DTN as well as the mammalian ON-sustained dsRGCs. These RGCs were rare (<1% of all RGCs) with large overlapping dendritic fields that cofasciculated with the SAC plexus. The overlapping RGCs may encode different directions as nearby dendrites rarely received input from the same SACs. The extensive SAC input to the RGCs was directionally tuned, as predicted from the angles of presynaptic SAC dendrites.

Conclusions: Here we show that the necessary machinery for direction selectivity exists within the primate retina, earlier in the primate visual system than classically thought, and implements many of the elementary motion detection strategies found across vertebrate species. Our results shed light on the nature of primate motion processing by identifying which aspects of the mammalian retinal direction selectivity circuit were conserved and which were not. For example, we did not find SAC input to an ON-OFF dsRGC homolog. The RGCs reported here are candidate homologs to the mammalian ON dsRGCs that contribute to optokinetic nystagmus.

ABSTRACT BODY:

Purpose: This ongoing, 2-year, prospective, multicenter, observational study (NIGHT: NSR-CHM-OS1, NCT03359551) investigates the natural progression of choroideremia.

Methods: Enrollment is completed and includes 322 adult males with genetically confirmed choroideremia and active disease visible within the macula. Eyes were classified at baseline into 3 cohorts by best-corrected visual acuity (BCVA): ≥ 74 Early Treatment of Diabetic Retinopathy Study (ETDRS) letters (201 eyes), 34-73 ETDRS letters (382 eyes), and < 34 ETDRS letters (61 eyes). The analyses were conducted on participants who completed the 20-month study (186 participants [368 eyes]). Visits occurred at 4-month intervals; BCVA, preserved area of ellipsoid zone (EZ), preserved area of autofluorescence (PAF), microperimetry, contrast sensitivity, color vision, and reading-speed tests were assessed periodically. Endpoints other than BCVA were assessed only through 12 months (237 participants [468 eyes]).

Results: Change from baseline in most assessments demonstrated a consistent but modest decline. The mean (95% CI) change in BCVA from baseline to Month 12 was 0.9 (0.3, 1.5) and from baseline to Month 20 was -0.5 (-1.2, 0.2). Linear regression suggests BCVA decreases slowly, at approximately 0.5 letters annually, although loss is higher and progresses slightly faster in older individuals. When assessing effects of age on BCVA change over a 20-month period (adjusting for baseline BCVA), participants in their seventies lost ~ 1.9 letters. All other assessments decreased consistently from 4 to 12 months in all 3 BCVA cohorts. Mean (95% CI) change from baseline was -14.65% (-15.58, -13.72) in PAF and -15.07% (-16.39, -13.75) in preserved EZ area; mean (95% CI) change from baseline in microperimetry was -0.56 dB

(-0.77, -0.35). Changes from baseline in contrast sensitivity and color vision were minimal. Reading speed was highly variable.

Conclusions: Participants with choroideremia slowly lose vision. Older patients with a more advanced disease may experience greater decline over a 20-month interval. PAF and preserved EZ area decreased at each visit. Contrast sensitivity, color vision, and reading speed were not reliable measures of disease progression. This study reinforces the importance of BCVA, preserved EZ area, and PAF as measures of natural choroideremia progression.

TITLE: 10-Year Progression of Myelinated Retinal Nerve Fibers. The Beijing Eye Study 2001/2011

SESSION TITLE: Retina and AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. Pan, C. Wei, Y. Wang, J. Jonas, Beijing Tongren Hospital, Beijing, Beijing, CHINA|J. Jonas, Ruprecht Karls Universität Heidelberg, Heidelberg, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure (Abstract): Zhe Pan: Commercial Relationship: Code N (No Commercial Relationship) | Chuan Chuan Wei: Commercial Relationship: Code N (No Commercial Relationship) | Ya Xing Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jost Jonas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the 10-year changes of myelinated retinal nerve fibers (MRNF) and the related systematic and ocular factors in a population-based cohort study.

Methods: Out of 4439 participants aged 40+ years and who participated in the Beijing Eye Study in 2001, 2695 (66.4% of the surviving) individuals were followed in 2011. All participants underwent a detailed physical and ocular examination. Eyes with detected MRNFs at baseline were included into the present study. Changes in the appearance of the MRNFs were examined using a flicker method of fundus photographs taken at baseline and at follow-up. The area covered by the MRNFs was delineated and measured with the Image J program. The progression rate was defined as the ratio of the MRNF area at study end divided by the MRNF area at baseline.

Results: Out of 35 eyes (29 participants) with detected MRNFs at baseline, 23 eyes from 20 individuals (11 women, 55%) were re-examined in 2011. Out of these 23 persons, 17 participants (85%) had unilateral MRNFs, while three participants had bilateral MRNFs. An increase in the size of MRNF area was detected in all 19 eyes with clear images from both visits, while the quality of the fundus photographs of 4 eyes did not allow a quantitative follow-up examination. The mean MRNF area was $4233 \pm 3670 \mu\text{m}^2$ (range: $178\text{--}11643 \mu\text{m}^2$) and $5243 \pm 4092 \mu\text{m}^2$ (range: $196\text{--}13297 \mu\text{m}^2$), at baseline and at follow-up, respectively ($P < 0.001$). The MRNF area increased by $1010 \pm 1026 \mu\text{m}^2$ ($18\text{--}3967 \mu\text{m}^2$) or by $47\% \pm 74\%$ ($9\text{--}315\%$). A more pronounced enlargement of MRNF area was associated with a higher serum concentration of low density lipoproteins ($P < 0.001$, $B = 0.53$, 95%CI: 0.30, 0.77), a MRNF location distant from the optic disc as compared to a peripapillary location ($P = 0.001$, $B = -0.89$, 95%CI: -1.34, -0.44), and a smaller MRNF area at baseline ($P = 0.02$, $B = -0.09$; 95% CI: -0.16, -0.02).

Conclusions: An enlargement of the MRNF area was commonly found in adults in a population-based 10-year follow-up study. The finding is of importance for the natural history and pathogenesis of myelination within the globe, and may perhaps give some clues for the intracranial myelination.

ABSTRACT BODY:

Purpose: Children with vision impairment and their families may find themselves isolated from their peers as they navigate typical developmental challenges in addition to a physical handicap. To assess the perceived need for a social work component in the multidisciplinary care model for pediatric low vision rehabilitation, children and their guardians evaluated in low vision clinics at Cincinnati Children's Hospital Medical Center (CCHMC) and West Virginia University Ruby Memorial Hospital (WVU) were surveyed.

Methods: Survey respondents included 107 guardians and 87 children seen previously for low vision rehabilitation at CCHMC or WVU. Surveys were completed after low vision diagnosis and during or after participation in multidisciplinary vision rehabilitation clinics. Respondents were asked about the desire for additional services or benefits at the time of diagnosis and after including: support and peer groups, summer camps, after school programs, specialized training, and other services. Participants were also asked about emotional response to the diagnosis. Survey data were examined to determine thematic trends in child and guardian responses.

Results: At the time of diagnosis, 93% (100/107) of guardians and 71% (62/87) of children would have preferred referral to at least one service or benefit. At the present time, 82% (88/107) of guardians and 70% (61/87) of children report a desire for additional services. Guardians report feeling "sad" and "overwhelmed" about their child's diagnosis [(41% (44/107) and 53% (57/107) respectively]. Comparatively, 34% (30/87) of children reported feeling "sad" and 31% (27/87) feel "overwhelmed". Only 54% (58/107) of guardians and 39% (34/87) of children report having the knowledge or support to navigate their feelings. Additionally, 54% (58/107) of guardians and 44% (38/87) of children report they would have seen a counselor at the diagnosis visit had one been provided as standard care.

Conclusions: Children with vision impairment and their guardians have mental health concerns and would likely benefit from having access to additional services and programs. We are recommending inclusion of a social worker or other service provider as a standard care component to multidisciplinary vision rehabilitation services after the diagnosis of a visually impairing condition for families to address the mental health needs identified by this survey.

ABSTRACT BODY:

Purpose: Cross-linked actin networks (CLANs) in trabecular meshwork (TM) cells may contribute to increased IOP by altering TM cell function and stiffness. CLANs have been observed in TM cells and tissues, but little is known about their formation or dynamics. We developed a transformed TM cell line that forms spontaneous, fluorescently labeled CLANs. Using live cell imaging, we characterized the actin dynamics of transformed HTM cells treated with latrunculin B.

Methods: A stable cell line was constructed by transducing transformed glaucomatous TM (GTM3) cells with the pLenti-Lifeact-EGFP-BlastR lentiviral vector. CLANs in cells were further increased upon treatment with different concentrations of blasticidin. The transduced GTM3 cells were treated with 1uM latrunculin B for 2 hrs, and time lapse fluorescent images were recorded in 1 min intervals during treatment and 2 hrs after removal of the agent.

Results: The transformed human TM cell line with stably transduced Lifeact-GFP expression cassette demonstrated the morphology of actin stress fibers and the spontaneous formation of CLANs using fluorescent microscopy. The number of CLANs in cell cultures were increased when treated with high concentrations of blasticidin at 10ug/ml ($p<0.05$, $N=3$) and 20ug/ml ($p<0.05$, $N=3$). Using live cell imaging, we found that CLANs were more resistant to actin depolymerization agent latrunculin B, as compared to actin stress fibers.

Conclusions: Live cell imaging of a CLAN forming transformed human TM cell line suggests that CLANs are a stable structure and likely play an important role in elevated outflow resistance and glaucoma.

ABSTRACT BODY:

Purpose: Anti-VEGF therapy is the first-line for diabetic macular edema (DME), although its socioeconomic burden is a serious concern. We therefore investigate the predictors of the treatment frequency in the second year under as-needed intravitreal ranibizumab (IVR) injections for DME.

Methods: In this retrospective study, we reviewed 65 eyes of 60 patients with center-involved DME who received pro re nata (PRN) IVR injections following three monthly loading doses. The central subfield thickness (CST) and qualitative findings were assessed on spectral domain optical coherence tomography (SD-OCT) images. We then investigated whether parameters at baseline or 12-month visit were associated with the treatment frequency in the second year.

Results: The number of ranibizumab injections decreased from 6 (4-8) during the first year to 2 (0-3) during the second year ($P<0.001$), despite the maintenance of functional efficacy from 12- to 24-month visits. The injection numbers during the first year ($\rho=0.259$, $P=0.037$) but not during the second year ($\rho=0.152$, $P=0.226$) were modestly related to logarithm of the minimum angle of resolution (logMAR) improvement at 24 months. Multivariate analyses revealed that CST and hyperreflective walls in foveal cystoid spaces at baseline were associated with the number of IVR injections during the second year ($\beta=0.363$, $P=0.003$ and $\beta=0.234$, $P=0.048$, respectively). The treatment frequency during the second year was also related with CST ($\beta=0.266$, $P=0.012$), hyperreflective walls ($\beta=0.394$, $P=0.002$), and the cumulative doses of ranibizumab injections ($\beta=0.294$, $P=0.006$) at 12-month visit.

Conclusions: CST and hyperreflective walls in foveal cystoid spaces are designated as predictors of treatment frequency of ranibizumab injections during the second year in DME.

ABSTRACT BODY:

Purpose: For decades, male inbred mice have served as the foundation of preclinical studies, even with the availability of established outbred mouse strains, which better represent the genetic diversity observed in humans. Moreover, given differences in the prevalence of ocular diseases between men and women, more focus should be directed at the preclinical level to understand how biological sex affects disease pathogenesis and treatment. For these reasons, we measured critical molecular components of retinal health, including the functional response to light, metabolism, structure, and the proteome, to delineate baseline differences between male and female inbred and outbred mice.

Methods: Adult C57BL/6J (inbred) and Swiss Webster-ND4 (SWND4; outbred) mice were studied. Scotopic electroretinograms (ERGs) were performed to quantify the retinal response to light. We performed mitochondrial stress tests (Seahorse) using ex vivo retinal punches to determine O₂ consumption rates. Next, we performed spectral domain optical coherence tomography (OCT) to quantify retinal layer thicknesses. Quantitative mass spectrometry (MS) and bioinformatics were used to determine protein abundance and phenotypes. This work is compliant with ARVO's Statement for the Use of Animals in Ophthalmic and Vision Research.

Results: Male mice of both strains exhibit more robust a-wave and b-wave ERG amplitudes relative to females (P<0.002). Functional metabolic assays showed that, in both strains, female mice exhibit higher oxygen consumption rates than males (P<0.05). OCT revealed female C57BL/6J mice possess thicker photoreceptor layers than males (P<0.02). Proteomic MS analysis of the retina identified extensive sex- and strain-dependent differences. Of ~3400 and ~3600 retinal proteins identified in inbred and outbred mice, respectively, 107 were differentially expressed (FC >1.5) by strain, and 124 by sex.

Conclusions: Our data indicate that, in the resting state, many distinct sex- and strain-dependent, molecular and structural phenotypes exist in the adult mouse retina that contribute to statistically significant functional differences at both electrophysiologic and metabolic levels. These baseline differences raise serious concerns about assuming the anatomic, physiological, and pathophysiological translational relevance of preclinical results derived from retinal investigations based on a single sex or strain.

ABSTRACT BODY:

Purpose: The cornea, the outermost layer of the eye, is formed by the migration of two waves of neural crest cells, the first wave gives rise to the endothelial layer and the second wave to the stromal one. The epithelial layer has an ectodermic origin. The study of the embryonic formation of the cornea is largely made in two dimensions, restricting the overall comprehension of his development. Recent advances in tissue-clearing techniques enable imaging of fluorescently labeled organs and entire organisms on a cellular level in three dimensions without the need for sectioning.

The objective of our study was to follow the migration of the neural crest cells in mice and zebrafish at different embryonic stages using advanced tissue clearing and three-dimensional imaging technologies. This allowed us to best characterize all steps leading to the formation of the cornea.

Methods: C56BL/6 mice and zebrafish embryos were fixed and analyzed by full-field optical coherence microscopy. After whole-mount immunostaining for Sox10 and β 3 Tubulin, We combined 3-dimensional imaging of solvent cleared organ (3DISCO) procedure (embryos were cleared in successive baths of tetrahydrofuran solution for de-hydration, dilapidation was performed in dichloromethane solution and finally, the embryos were cleared in dibenzyl ether solution), light-sheet microscopy, and Imaris software to 3D map neural crest cells migration within a whole eyeball.

Results: Migrating neural crest cells were observed before they arrived in the cornea; these cells follow the nerves and lose their neural crest marker before penetrating the cornea. Embryonic corneal morphology, organization, and layer formation were observed by FFOCM and 3D imaging. The population of the primary cornea with neural crest cells was associated with layer formation and shape acquisition.

Conclusions: We illustrate here that the combination of the 3DISCO clearing method with light-sheet microscopy, and immunostaining represents a rapid and reliable method to analyze embryonic cornea formation. This technology could also prove extremely useful to study the eye as a whole for a better understanding of eye disorders.

ABSTRACT BODY:

Purpose: During glaucoma, there is a remodeling of the extracellular matrix (ECM) in the optic nerve head (ONH), the site of initial ON damage. ONH derived lamina cribrosa (LC) cells synthesize ECM proteins to support the ONH. However, LC cells are adversely affected in glaucoma and cause detrimental changes to the ONH. LC cells respond to mechanical strain by increasing expression of the profibrotic cytokine transforming growth factor-beta 2 (TGF β 2) and ECM proteins, including collagen. Moreover, microRNAs (miRNAs) regulate ECM gene and protein expression in different fibrotic diseases, including glaucoma. A delicate homeostatic balance between profibrotic and anti-fibrotic miRNAs may contribute to remodeling of the glaucomatous optic nerve head. We want to understand the epigenetic regulation of the ECM in the optic nerve head. The purpose of this study was to determine whether modulation of anti-fibrotic miRNAs alters the expression of ECM in human LC cells.

Methods: Primary human normal (n=3 strains) and glaucoma (n=3 strains) LC cells were derived from human donor eyes. Normal and glaucomatous LC cells were grown to confluency and treated with or without TGF β 2 (5ng/ml) for 24 hours. Differences in expression of miRNAs were analyzed using miRNA qPCR arrays. Primary LC cells were transfected with candidate miRNA mimics, inhibitors, or non-targeting siRNA (10nM) to determine ECM expression levels for collagens I and IV in human LC cells, using immunocytochemistry.

Results: miRNA PCR arrays showed that the miR-29 family was significantly decreased in glaucomatous LC cell strains compared to age-matched controls. TGF β 2 treatment significantly downregulated the expression of multiple miRNAs, including miR-29c-3p, compared to controls in LC cells. LC cells transfected with miR-29c-3p mimics or inhibitors modulated the expression of ECM proteins as seen by immunocytochemistry.

Conclusions: TGF β 2 modulates the expression of several miRNAs in cultured human LC cells that appear to stimulate a profibrotic environment and may be responsible for pathogenic remodeling of the optic nerve head in glaucoma. New therapeutic targets for miRNAs within the ONH could be identified that stop or slow the pathogenesis of glaucoma, preserving ONH structure and function.

ABSTRACT BODY:

Purpose: The corneal stroma accounts for 90% of corneal thickness in humans, and is a major determinant of visual acuity. The rare recessive condition Brittle Cornea Syndrome (BCS), characterised by extreme thinning of the cornea and sclera and general connective tissue dysfunction, results from loss of function mutations in the poorly understood genes ZNF469 or PRDM5. PRDM5 (PR/SET Domain 5), a widely expressed transcription factor, plays an important role in extracellular matrix (ECM) production by skin fibroblasts and in bone. It is an excellent candidate to regulate ECM development and maintenance in keratocytes, the cells that synthesise the corneal stroma. Using an in vitro model of PRDM5 deficiency we aimed to elucidate the mechanisms by which PRDM5 maintains the transcriptional and proteomic profile of keratocytes to influence stromal thickness in health and disease.

Methods: CRISPR-Cas9 genome editing was used to recapitulate human BCS mutations in PRDM5 in a human keratocyte cell line, hTK. Cell lines were subject to transcriptomic profiling, and the impact of PRDM5 mutation upon the composition of cell-derived matrices assessed using western blotting, immunostaining and mass spectrometry.

Results: Homozygous frameshift mutations in PRDM5 created using CRISPR-Cas9 genome editing resulted in premature termination codons preceding all 16 C2H2 zinc finger domains, mimicking the consequences of pathogenic mutations identified in BCS patients. Expression of PRDM5 was reduced in the edited cell lines, and PRDM5 protein was not detected in cell lysates, consistent with nonsense mediated decay of mutant transcripts. The expression of genes with important roles in keratocytes was altered by loss of function of the transcription factor PRDM5, changing the composition of ECM in vitro.

Conclusions: The creation of a cellular model of PRDM5 dysfunction in a keratocyte cell line offers a unique entry point for investigating the poorly understood regulatory processes shaping the stroma in health and disease. Transcriptomic and proteomic analyses highlight pathways that contribute to the development and maintenance of a healthy corneal stroma. Work remains to determine whether these pathways may be modulated for diagnostic or therapeutic benefit in conditions such as BCS or keratoconus where the cornea thins progressively over time. Furthermore, the mechanisms uncovered by this study may have wider implications in connective tissue disorders.

ABSTRACT BODY:

Purpose: RVL-1201 (oxymetazoline 0.1%) is a novel pharmacologic agent administered as a once-daily eye drop for the treatment of acquired blepharoptosis in adults. Phase 3 clinical data support the efficacy of RVL-1201, demonstrating significant mean improvement of superior visual field deficits and elevation of the upper eyelid. Clinically, it is important to define the overall responsiveness of the study population to treatment to fully ascertain the robustness of the treatment effect. The purpose of this analysis was to evaluate the proportion of subjects demonstrating a positive response to once-daily RVL-1201 administration.

Methods: In two randomized, double-masked, placebo-controlled phase 3 clinical studies, N=304 subjects received RVL-1201 or vehicle once daily in both eyes for 42 days. This analysis evaluated the proportion of subjects demonstrating a positive clinical response to RVL-1201 (relative to their pre-dose baseline measurement on treatment day 1), with respect to the primary study efficacy endpoint: number of points seen in the top 4 rows of the Leicester Peripheral Field Test (LPFT). For LPFT assessment, 'any improvement,' '≥50% improvement,' and '≥90% improvement' were defined as a >0% increase, ≥50% increase, and ≥90% increase, respectively, in the number of points seen versus baseline.

Results: Two hours following RVL-1201 instillation on treatment day 14 (n=203 RVL-1201; n=101 vehicle), 87.8% of subjects demonstrated some degree of improvement (>0%) on the LPFT, 40.8% of subjects demonstrated ≥50% improvement, and 16.8% of subjects demonstrated ≥90% improvement on this measure of superior visual field function. In contrast, 60.8%, 18.6%, and 5.2% of subjects in the vehicle group demonstrated any improvement, ≥50% improvement, and ≥90% improvement, respectively.

Conclusions: These data support previously reported efficacy findings from phase 3 clinical studies. A large proportion of subjects demonstrated a positive response to once-daily RVL-1201 administration (superior visual field improvement). These results substantiate RVL-1201 as a potentially promising non-surgical treatment option for patients with acquired blepharoptosis.

ABSTRACT BODY:

Purpose: Presently, there is no FDA approved antiviral therapy for the treatment of adenovirus (Ad) ocular infections, the most common ocular viral infection worldwide. During the COVID-19 pandemic, much attention has been placed on several potential antiviral treatments for SARS-CoV-2 infections. Remdesivir, hydroxychloroquine, ivermectin, and umifenovir (Arbidol) have been touted as potential COVID-19 treatments. The goal of the current study was to determine whether these potential COVID-19 antivirals produced in vitro antiviral activity against a panel of ocular adenovirus types.

Methods: The 50% inhibitory concentrations (IC_{50}) of remdesivir (REM), hydroxychloroquine (HCQ), ivermectin (IVM), and umifenovir (UMF) and cidofovir (CDV) (positive antiviral control) were determined for the human Ad types Ad3, Ad4, Ad5, Ad7a, Ad8, Ad19/64 and Ad37 using standard plaque-reduction assays on A549 cells. Briefly, cells infected with ~100 PFU of the Ad types were treated with final concentrations of the antivirals of 100, 10, 1.0, 0.1, 0.01 and 0.001 μ M. After incubation, the numbers of plaques from each virus/drug concentration were counted and the mean IC_{50} concentrations from 2-3 assays were determined by regression analysis.

Results: The range of mean in vitro IC_{50} concentrations for each antiviral across the range of Ad types are as follows: The positive antiviral control, CDV, ranged from 0.47 - 9.62 μ M; REM ranged from 0.21 - 11.27 μ M; UMF ranged from 3.72 - 64.8 μ M; IVR ranged from 2.60 - 201.3 μ M; and HCQ was > 10 μ M for all Ad types because of toxicity to the A549 cells demonstrated at the 100 μ M concentrations. REM produced lower IC_{50} concentrations than CDV for 5 of 7 Ad types.

Conclusions: REM demonstrated anti-adenovirus activity in vitro in a range similar to that demonstrated by cidofovir. UMF and IVR demonstrated less antiviral activity than CDV and REM. The anti-adenovirus activity of HCQ could not be accurately determined. Further investigation of REM as an antiviral for adenovirus is indicated.

ABSTRACT BODY:

Purpose: Cone dysfunction is a known pathological process in age-related macular degeneration (AMD). However, it is unclear if blue color sensitivity is affected in early stages of AMD. In this study, a new blue color sensitivity test was used to assess visual function in non-advanced AMD subjects.

Methods: Subjects with non-advanced AMD N=14 (grade 1 to 4 on AREDS simplified scale) and normal controls N=25 (AREDS grade 0) with best visual acuity (VA) 20/25 or better during their baseline visit were included. Color contrast sensitivity was tested using a computerized system. Testing was done for the study eye, with best correction in place and non-tested eye occluded. The stimulus was a blue Landolt C target presented on an equiluminant background. Two background levels of high mesopic and low mesopic levels were used. For each background, the stimulus was initially presented at high contrast level which then progressively reduced in contrast. Threshold was determined based on a stair-case method. For each background, the minimum contrast needed to correctly identify the stimulus orientation was recorded as the threshold. Subjects also underwent other common visual tests such as standard ETDRS VA, and low luminance 2.0 neutral density (ND) ETDRS VA.

Results: Blue color sensitivity showed worsening in the non-advanced AMD group compared to age-matched normal group, for both high mesopic and low mesopic levels, although the results did not reach statistical significance. Mean threshold in the high mesopic background was 0.14 ± 0.08 in AMD group and 0.11 ± 0.06 in normal group ($p=0.12$). Mean threshold in the low mesopic background was 0.29 ± 0.15 in the AMD group and 0.22 ± 0.08 in the normal group ($p=0.09$). Both normal subjects and non-advanced AMD subjects showed reduced sensitivity in low mesopic testing condition compared to high mesopic testing. No difference between the two groups were found using other common tests such as standard ETDRS VA and 2.0 ETDRS VA.

Conclusions: Blue color contrast testing could capture subtle color contrast deficits in early/intermediate stages of AMD and may be useful test for assessing color function in AMD studies.

ABSTRACT BODY:

Purpose: Peripapillary halos (PPHs) are peripapillary changes observed in normal eyes and eyes with different disorders. Recognizing the microstructure and mechanism of development of these halos will help clinicians understand the different associated retinal and optic nerve head (ONH) pathologies. We report the in-vivo histologic characterization of PPH in birdshot chorioretinopathy (BSCR) patients.

Methods: Prospective series of 6 eyes of 3 patients with convalescent BSCR. In addition, to complete ophthalmic examinations, patients underwent ONH imaging using swept-source optical coherence tomography (SS-OCT), color and red-free photography, and fundus autofluorescence (FAF).

Results: In SS-OCT scans across the area of PPH, we observed thinning and interruption of retinal pigment epithelium-Bruch's membrane (RPE-BM) complex. These halos are a circumferential form of α - zone RPE-associated crescentic PPH, unlike the PPHs observed with myopia and normal aging that are mainly associated with β -zone atrophy. We hypothesize that circumferential PPH (versus crescentic PPA) is the result of swelling of the ONH associated with BSCR papillitis, due to stretching, thinning, and tearing of the retinal layers attached to and surrounding the border tissue of Elschnig (considered to be the optic disc border). After resolution of ONH edema, the retinal layers no longer are fully attached to the disc border and have an atrophic circumferential ring around the ONH (a halo) that is PPH.

Conclusions: PPH in BSCR patients might be used as a clinical marker for prior inflammatory optic neuropathy.

ABSTRACT BODY:

Purpose:

Cataracts is caused by progressive clouding of the crystalline lens, and the only treatment is surgical replacement of the cataractous lens with an artificial intraocular lens (IOL). There are many specialized equipment (e.g. retinoscopy, aberrometers, optical coherence tomography, biometers) for the diagnosis of cataract; however, the performance of preoperative vision simulators is not sufficient for predicting postoperative visual acuity and existing devices are incapable of correcting aberrations and they are limited to static pinhole exit pupils. Holography is viewed as the ultimate display technology that can offer natural 3D with all required focus and depth cues. In this study, we propose a holographic vision simulator that provides best-corrected visual acuity of the eye with cataracts before the patient goes through cataract surgery.

Methods:

The wave-front computation algorithms in computer generated holography (CGH) enables essential features such as the ability to control the phase, size and shape of the light beam entering through the eye-pupil for an effective cataract vision simulator. Our instrument detects the small, non-cataractous regions on the crystalline lens, and directs the light beam with exit pupil shaping and pupil tracking. Holographic display shows a virtual Snellen Chart at the desired depth through these regions onto the retina, while correcting the existing refractive errors including myopia, hyperopia, and astigmatism.

Results: Ten patients with various degrees of cataracts went through eye examinations before testing the simulator instrument. All the patients demonstrated better visual acuity when tested in our holographic simulator compared to the conventional eye examination. Patients without retina diseases performed 20/40 vision, whereas the patients with AMD or glaucoma performed 20/70 vision.

Conclusions: Our holographic vision simulator was able to predict the postoperative visual acuity level of the patients before going to cataract surgery. Our augmented reality display device overperforms the existing vision simulators. This device can also be used for matching the right patient to the right choice of intraocular lenses (trifocal, monofocal, EDoF). Further studies are needed to optimize the outcomes of this selection process.

TITLE: Internet Search Engine Queries on Blue Light Glasses in the United States

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Bakhtiar, Y. Shah, S. Gad, N. Bhagat, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zahra Bakhtiar: Commercial Relationship: Code N (No Commercial Relationship) | Yash Shah: Commercial Relationship: Code N (No Commercial Relationship) | Steve Gad: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many retailers advertise eyeglasses that filter out blue light from digital devices to prevent eye problems, despite the lack of scientific evidence and contradictory claims that blue light from digital devices cause any eye disease. Patients use search engines to learn about topics such as blue light filtering eyeglasses that are advertised or offered to them. In this study, we characterize the Google search term frequency patterns for insight into the increasing popularity of blue light filtering eyeglasses.

Methods: We conducted a retrospective search query analysis using Google Trends (GT) for the search term “blue light glasses,” and “glasses” as a control. Queries were restricted to web search queries in all categories by Google users in the United States (US), from January 1, 2010 to December 31, 2020. GT search term interest over time is provided as relative query frequency (RQF), which is the interest relative to the peak popularity of the search term for the given region and time period.

Results: There is a pattern of exponentially increased searches for “blue light glasses” since December 2015, with peak popularity in September 2020. The increased RQF in January 2019 (26) and April 2020 (71) may correlate with the total lunar eclipse in the US on January 20-21, 2019, and the start of the Covid-19 pandemic that had many people transition to using digital devices for work and school from home, respectively. The September 2020 peak popularity may correlate with the beginning of the academic year.

The GT pattern for the search term “glasses” was analyzed to determine if the dates of the increased RQFs for “blue light glasses” corresponded to similar dates for “glasses.” GT showed a positive linear trend in searches for “glasses”, with peak popularity in August 2017, which may be associated with the total solar eclipse in the US on August 21, 2017.

Conclusions: Although there is a lack of evidence that blue light from digital devices cause eye disease and that blue light filtering eyeglasses can prevent these eye problems, there is a trend of increasing searches for blue light glasses over time. Retailers increasingly continue to advertise and sell blue light filtering eyeglasses; ophthalmologists should be aware of this trend and educate their patients and the public on the lack of evidence for such eyeglasses, and instead focus on healthy habits that can help prevent eye strain from using digital devices.

ABSTRACT BODY:

Purpose: We have previously demonstrated that plasmacytoid dendritic cells (pDCs) reside in the retina and that their frequency is increased during retinal neovascularization (NV). This study aims to investigate the role of pDCs in retinal NV.

Methods: Oxygen-induced retinopathy (OIR) was induced, by exposing pups to 75% oxygen from postnatal day (P)7 to P12, and then returning them to room air until P17 in order to cause retinal NV. pDCs were depleted by administration of diphtheria toxin (DT) to pDC-DTR (pDC-DTR OIR + DT) mice at P11, with C57BL/6N wild-type mice receiving DT (WT OIR + DT) and pDC-DTR mice receiving PBS (pDC-DTR OIR + PBS) as controls. Retinal vasculature was visualized by immunostaining with isolectinB4, and leakage assessed using FITC-Dextran. pDC effects on human retinal endothelial cells (HRECs) proliferation and tube formation were assessed in vitro using transwell co-cultures. Data were analyzed by one-way ANOVA with Bonferroni's post-Hoc test.

Results: pDC-DTR pups had a similar retinal vascular density and morphology compared to WT at P7, P12, and P17. The area of retinal NV (n=5/group) was increased in pDC-DTR OIR + DT ($7.77 \pm 1.21\%$), compare to pDC-DTR OIR + PBS ($4.12 \pm 0.60\%$; $p < 0.05$) and WT OIR + DT ($4.46 \pm 0.73\%$; $p < 0.05$) mice, particularly in the peripheral retina, with $6.88 \pm 1.42\%$, $2.17 \pm 0.30\%$ ($p < 0.01$), and $2.83 \pm 0.94\%$ ($p < 0.05$), respectively. The area of leakage (n=3/group) was larger in pDC-DTR OIR + DT ($19.91 \pm 3.97\%$), compared to pDC-DTR OIR + PBS ($5.92 \pm 2.27\%$; $p < 0.05$), and WT OIR + DT ($7.41 \pm 1.84\%$; $p < 0.05$) mice. Following 48h of co-culture with 5×10^3 , 10×10^3 , or 20×10^3 pDCs, HRECs proliferation was decreased in a density-dependent fashion to $73.0 \pm 2.63\%$ ($p < 0.01$), $66.4 \pm 1.51\%$ ($p < 0.001$), and $52.7 \pm 1.51\%$ ($p < 0.001$) of control (HRECs alone). The proliferation was decreased to $74.1 \pm 1.57\%$, $52.7 \pm 2.40\%$, and $39.2 \pm 2.10\%$, respectively, at 24 h ($p < 0.001$), 48h ($p < 0.001$), and 72h ($p < 0.001$) after co-culture with 20×10^3 of pDCs in a time-dependent fashion. The tube length was decreased to $69.5 \pm 2.41\%$, and $62.3 \pm 2.98\%$, respectively, at 12h after co-cultured with pDCs at a density of 5×10^3 ($p < 0.01$), and 20×10^3 ($p < 0.05$).

Conclusions: pDCs play an inhibitory role in retinal NV in the mouse model of OIR, via direct inhibition of HRECs, providing new insights into retinal angiogenesis and pDCs function, suggesting therapeutic potential of pDCs for neovascular diseases.

ABSTRACT BODY:

Purpose: It is important to identify sensitive visual function endpoints that can capture visual deficits during early stages of dry age-related macular degeneration (AMD) for development of novel therapeutics for non-advanced AMD. In this study, we report longitudinal follow-up data on subjects whose baseline results on assessing various visual function tests were previously published.

Methods: Subjects with non-advanced AMD N=23 (grade 1 to 4 on AREDS simplified scale) and normal controls N=34 (AREDS grade 0) with best visual acuity (VA) 20/25 or better during their baseline visit were followed up longitudinally one year later. Several visual function tests were re-evaluated including common tests such as standard ETDRS VA, ETDRS VA (2.0 neutral density (ND)), Pelli-Robson contrast sensitivity (CS) and novel tests including the variable contrast flicker (VCF) test and low luminance tablet reading, both developed at Ora. For Ora-VCFTM test the minimum contrast needed to detect the stimulus was recorded as the threshold. For tablet reading, reading speed was recorded in words per minute (wpm). Differences between the groups were compared. Change from baseline visit was calculated.

Results: Longitudinal follow-up data was available for 53/57 subjects from baseline visit. Consistent with results from the baseline visit, at the follow-up visit the Ora-VCFTM test found significant differences between non-advanced AMD (mean 0.59 ± 0.25) and normal controls (0.37 ± 0.15) ($p=0.0002$). At the follow-up visit, the Ora-VCFTM threshold changed by 0.048 in AMD group and 0.068 in normal group ($p=0.79$). Reading speed using low luminance tablet was not significantly different during the follow-up visit (126.2 ± 33.5 wpm in AMD and 134.6 ± 42.6 in normals, $p=0.45$). No difference between the groups were found using the commonly used VA tests in the follow-up visit. The mean ETDRS LogMAR VA was 0.07 ± 0.12 in AMD group and 0.06 ± 0.09 in normal group ($p=0.80$). The mean 2.0ND VA was 0.28 ± 0.14 in AMD and 0.27 ± 0.13 in normal group ($p=0.81$). The mean Pelli-Robson CS was 1.58 ± 0.20 in AMD and 1.74 ± 0.23 in normal group ($p=0.009$).

Conclusions: The Ora-VCFTM contrast sensitivity test using a flickering target, was consistently able to identify visual dysfunction in non-advanced AMD. Ora-VCFTM test could serve as an endpoint for early and intermediate AMD therapeutic trials.

TITLE: Anterior Segment swept source OCT for filtering bleb evaluation after Gel Stent implantation

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Thieme, R. Burk, Ophthalmology, Klinikum Bielefeld Rosenhohe, Bielefeld, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure (Abstract): Claudia Thieme: Commercial Relationship: Code N (No Commercial Relationship) | Reinhard Burk: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The outcome of filtration surgery depends on filtering bleb (FB) persistence. The aim of this study is to evaluate bleb morphology and persistence by anterior segment swept source OCT (ASOCT) after Gel-Stent-Implantation (XENTM).

Methods: ASOCT scans (Anterior ®, OCT II, Heidelberg Engineering) of the FB were recorded in 44 eyes of 44 glaucoma patients (30 primary open-angle-glaucoma (pOAG), 11 secondary open-angle glaucoma with pseudoexfoliation (sOAG with PEX) and 3 with pigmentdispersion; 17 female, 27 male; mean age 71 ±12 years; visual field Median MD 10.3; Median sLV 6.4) at 97 days (±52 days, T1) and 690 days (±242 days, T2) postoperatively. FB morphology was classified as microcystic (m), mixed (mx) or absent (a) according to the ASOCT scans. Correlations between FB classification, postoperative intraocular pressure (IOP) and medical therapy (TX) were analyzed with IBM SPSS Statistics Version 21.

Results: AT T1, FB classification was n=39 (m), n=1 (mx) and n=4 (a). FB classification at T2 resulted in n= 19 (m), n=14 (mx) and n=11 (a). IOD reduction was significant (T0 to T1: mean 6.8±1.3, p=0.000; T0 to T2: mean 7.6±1.9, p=0.000). MED reduction was significant (T0 to T1: mean 2.4±0.2, p=0.000; T0 to T2: mean 2.8±0.5, p=0.000). Bleb classification remained stable in n=18. A change of bleb classification between T1 und T2 occurred in 26 eyes : m to mx (n=13); m to a (n=9); mx to a (n=1); a to m (n=2) and a to mx (n=1).The revision rate at 180 days was 55.6% and at 365 days 72.2%.

Conclusions: By ASOCT scans, most filtering blebs after XEN Gel stent implantation have a microcystic appearance in the short postoperative period. However, bleb appearance may change in the follow up period. Further studies are needed to evaluate long term bleb persistence.

TITLE: Therapeutic Efficacy of BIOP 653.1 in a Rabbit Model of Chronic Retinal Neovascularization

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Bankaitis, J. Prater, D. Culp, Powered Research, LLC, Morrisville, North Carolina, UNITED STATES|D. White, Biophtha, Inc., Suwanee, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eric Bankaitis: Commercial Relationship: Code N (No Commercial Relationship) | Daniel White: Commercial Relationship: Code N (No Commercial Relationship) | Justin Prater: Commercial Relationship: Code N (No Commercial Relationship) | David Culp: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We proposed to test retention of vascular leakage-inhibiting function in a novel anti VEGF/anti IL17a antibody, BIOP 653.1 (Biophtha, Suwanee, GA), versus Aflibercept (Regeneron Tarrytown, NY) in a chronic DL-a-Aminoadipic acid (AAA)-induced vascular leakage model.

Methods: Dutch Belted rabbits were injected intravitreally (IVT) with 1.0 mg of AAA (Sigma) in left (OS) eyes two weeks prior to 50 mL IVT administration of Aflibercept (2 mg; Group 1) or BIOP 653.1 (2.5 mg; Group 2). Right eyes (OD) remained non-AAA-treated in Group 1 and Group 2. Group 2 OD received BIOP 653.1 to assess test article safety. Evaluations at day -2 prior to dose at day 0 confirmed leakage induction and animals were stratified across groups according to leakage severity. Slit lamp biomicroscopy was used to evaluate ocular inflammatory scores (Hackett-McDonald [HM]) alongside monitoring of intraocular pressure (IOP) on days -2, 1, 3, 7, 14 and 28. Fluorescein angiography and fundoscopy were performed on days -2, 7, 14, 21 and 28. Background-normalized total leakage signal was determined by image analysis to quantify changes in leakage signal over time.

Results: AAA-induced vascular leakage occurred in 10/10 rabbits by day -2. Resolution of leakage was comparable between Aflibercept and BIOP 653.1, suggesting that BIOP 653.1 retained leakage-inhibiting anti VEGF function. By day 14 HM scores were elevated in OS eyes treated with BIOP 653.1 compared to Aflibercept-injected OS eyes, and HM scores remained elevated thereafter. Results from IOP measurements and ocular exams were documented.

Conclusions: BIOP 653.1 is a novel multifunctional antibody with anti VEGF and anti IL17a components. Biophtha partnered with Powered Research to determine if anti VEGF activity is retained through BIOP 653.1 engineering and manufacture using an established rabbit model. Here we demonstrate inhibition of vascular leakage by BIOP 653.1 with efficacy comparable to that of Aflibercept. BIOP 653.1 is early in development and a likely candidate for studies to determine half-life and durability of effect. We did not expect effects from the BIOP 653.1 IL17a component due to low sequence conservation between human and rabbit IL17a epitopes. Testing in primates will be needed to assess activity of the BIOP 653.1 anti IL17a component.

ABSTRACT BODY:

Purpose: There is increasing evidence that retinal vascular fractal dimension (D_f) is associated with multiple diseases, like diabetes or cardiovascular events. It is currently unknown whether inter/intraocular D_f variability may affect these associations and to which extent.

Methods: We segmented and classified ~195,000 fundus images available in UK Biobank (UKB) using VAMPIRE and by reproducing a SVM classifier based on the scans' white pixel ratio, largest connected component and number of connected components, respectively. This classifier was trained with 448 UKB images which previously were manually graded for quality. We computed an automated quality score from the SVM encapsulating the clarity, connectivity, and length of each scan. We then derived D_f from ~73,000 good quality scans with VAMPIRE. We estimated Pearson's correlation (r^2) and association estimates between D_f measures of participants with both eyes scanned and those with two scans of the same eye. We used quality-corrected D_f measures, stratified by left-right eye, to calculate r^2 and association estimates with health data from UKB

Results: Although the D_f population mean and S.D. was equal in both eyes (1.48 ± 0.03), we found a moderate interocular r^2 and effect on D_f ($r^2 = 0.61$, $P\text{-val} < 2e-16$ and $\beta = 0.59$). We found a moderate intraocular r^2 in scans of the same eye taken at different times ($r^2_{\text{left}} = 0.59$, $P\text{-val} < 2e-16$ and $r^2_{\text{right}} = 0.61$, $P\text{-val} < 2e-16$), implying that there are participants with irreproducible D_f . Differences in fundus images' quality explained those cases where the D_f disparity of the same eye was higher than a S.D. unit. Interestingly, we found that quality score has the greatest effect on D_f ($\beta_{\text{left}} = 3.4E-02$, $P\text{-val} < 2e-16$ and $\beta_{\text{right}} = 3.3E-02$, $P\text{-val} < 2e-16$). Association estimates with quality corrected D_f were 2 S.D units smaller than no-corrected D_f ones, suggesting that this adjustment improves the estimation and should be included. Lastly, our results show that decreasing D_f is associated and negatively correlated with cardiovascular diseases, i.e. coronary artery disease, as previously reported

Conclusions: This study supports that inter/intraocular variability in D_f is influenced by image quality, which can lead to spurious associations. Obtaining a quality score helps evaluating imaging datasets and controls for this effect in further associations analysis

ABSTRACT BODY:

Purpose: Corneal injury, arising from surgery or trauma, cause tremendous pain. A soft bandage contact lens provides mechanical protection from the blinking lids while allowing the patient to continue to use their normal vision. It would be immensely beneficial if these bandage lenses could also deliver ophthalmic drugs to aid wound closure. Multiple studies have shown elevated levels of matrix metalloproteinase (MMP) enzymes, particularly MMP-9 and MMP-2, in a corneal wound. The purpose of this study was to evaluate the release of a corneal wound healing agent, Bovine Lactoferrin (BLF), from a MMP-9 triggered drug delivery material at a normal corneal temperature that could aid corneal injury.

Methods: Gelatin methacrylate (GelMA) and photoinitiator (Irgacure 2959) were mixed together in PBS to obtain a solution with 30% (w/v) of GelMA. The mixture was incubated at 60°C for 48 hours. BLF was added to the mixture and centrifuged for 10 mins at 5000 rpm. The mixture was incubated for another 30 mins at 60°C before being pipetted into a mould, and then incubated at 4°C for 1 h, and then polymerized in a UV chamber for 5 mins (GelMA+) producing circular shaped discs (diameter = 6 mm, thickness = 650 µm). The samples (n=4) were washed in 1 mL of PBS for 24 hours to remove any loosely bound drug. After washing, the samples were placed in varying concentrations of MMP-9 at 37°C for 5 days. At t = 0, 1, 12, 24, 48, 72, 96, 120 hours, 200 µL of the release media was withdrawn and the amount of BLF determined by ELISA.

Results: The BLF released increased over time ($p < 0.0001$) and with increasing concentrations of MMP-9 ($p < 0.0001$). This indicates that MMP-9 degraded the 30% (w/v) GelMA+ material to facilitate the release of the bound wound healing agent from the polymer network. Overall, the drug release was sustained for the entire 5 day period for all MMP-9 concentrations ($p < 0.001$).

Conclusions: GelMA+ is a biocompatible material that is suitable for delivering therapeutics. The results suggest that increased concentrations of MMP-9 lead to an increase in BLF release. Results support that GelMA+ could be used as an enzyme-triggered ocular drug delivery.

ABSTRACT BODY:

Purpose: We previously reported that hyperactivation of the mechanistic target of rapamycin complex 1 (mTORC1) in the retinal pigment epithelium (RPE) leads to RPE dysfunction, followed by degeneration of the photoreceptor and choroid. The goal of the current project is to investigate the underlying mechanisms that link hyperactive mTORC1 signaling in the RPE and choroid atrophy.

Methods: RPE-specific, TSC1-deficient mice were established by crossing TSC1-floxed mice with transgenic mice with Bestrophin promoter-driven Cre expression. Choroid thinning was examined on both histological sections and cryosections. Flow cytometry analysis was used to characterize and compare cell populations of choroid between RPE-TSC1 deficient mice and littermates. The expression level of target genes were measured at both mRNA and protein levels using q-RT PCR and western blot, respectively. The subcellular and tissue distributions of the proteins were examined using immunostaining on both cryosections of the posterior eye and flat-mounted RPE/choroid or choroid tissue only. The level of secreted vascular growth factors was determined by ELISA. Visual functions were measured by electroretinogram (ERG).

Results: RPE-specific TSC1 deficient mice had choroid thinning. There was a progressive loss of choroicapillary markers. When analyzed for major regulators of choroidal vessel growth and homeostasis, we found increased production of Angiopoietin-2 from RPE with TSC1-deficiency.

Conclusions: Hyperactive mTORC1 in the RPE caused choroid atrophy via RPE-derived Angiopoietin-2. Expression of Angiopoietin-2 in the RPE indicates the paracrine effects in addition to the canonical autocrine regulation of choroidal endothelial function.

ABSTRACT BODY:

Purpose: Current treatment for neovascular age-related macular degeneration includes intravitreal injection of anti-vascular endothelial growth factors (anti-VEGFs). However, clinical experience demonstrates that the efficacy of such therapies is restricted due to the overlapping and compensatory alternative angiogenic pathways. Here, we introduce a new anti-angiogenic molecule (sFLT01-anti-ANG2) that neutralizes VEGF, Placental Growth Factor, and Angiopoietin2 simultaneously and reduces the initiation of associated signaling pathways.

Methods: We investigated sFLT01 molecule components via bioinformatics tools and got access to its sequences. We augmented the nucleotide sequence of sFLT01 by another genetic syntax, against Angiopoietin2. Therefore, we analyzed the tertiary structures of the molecule with MODELLER and Nanome. The best models were applied in docking analysis with ClusPro. The cloning process of the construct in the AAV2 vector was performed and the result was confirmed by PCR and restriction enzyme digestion. RNA extraction and condition media collection were performed following the transfection of HEK293T cell line by AAV2-sFLT01-anti-ANG2. Expression of the gene of interest and its protein output was evaluated by real-time PCR and western blotting respectively. To confirm the functional anti-angiogenic potency of the protein, tube formation assay, phospho-Tie2 assay, and ligand-receptor interaction ELISA were performed

Results: The sFLT01-anti-ANG2 molecule was designed by bioinformatics tools and cloned into the pAAV-MCS vector. HEK293T cells were successfully transduced. RT-qPCR represented that the gene was expressed 4000 fold in HEK293T cell culture. Western blot technique confirmed the presence of this protein in the condition media collected from transfected HEK293T cell culture. The decrease in vascular network observed in tube formation assay showed that the molecule was functional. Also, the reduced amount of absorption observed from phospho-Tie2 assay (0.172.5/1.034,1.0455) and Ang2-Tie2 interaction ELISA assay (0.558/0.995,0.868) demonstrated effective function of this molecule.

Conclusions: We propose that targeting various angiogenic pathways by sFLT01-anti-ANG2 may be a fundamental approach in development of the next generation antiangiogenic therapeutic drugs.

ABSTRACT BODY:

Purpose: Several case series have demonstrated a potential role for the closure of small stage 4 macular holes with topical therapy. Drops have included a non-steroidal anti-inflammatory drug (NSAID), steroid, and/or carbonic anhydrase inhibitor (CAI). We now report the first such case series for the treatment of stage 1 (outer lamellar) macular holes in eyes with PVD.

Methods: A retrospective case series of patients with stage 1 macular holes at two Chicago-based institutions was conducted to evaluate the efficacy of drop therapy, dose response, and loss of effect with premature discontinuation with recommended therapy.

Results: Four eyes in 4 patients were included in this series and all cases had some amount of intraretinal or subretinal fluid contributing to the partial-thickness macular hole. All had posterior vitreous detachment (PVD) and epiretinal membrane. Eyes were started on topical NSAID and steroid, and 3 cases were treated with CAI as well. One patient was unable to tolerate topical difluprednate due to steroid response and progressed to a small stage 4 hole, but after adjunctive oral acetazolamide the hole regressed to a stage 1 hole and then closed completely. All 4 cases had complete resolution of fluid and closure of the macular holes which persisted after tapering of topical therapy. Similar therapy for 4 eyes with stage 1 macular holes that did not have PVD failed to close.

Conclusions: Topical therapy is a relatively benign treatment that can potentially cause resolution of not only small stage 4 macular holes but also stage 1 (outer lamellar) holes in eyes with PVD. This may be due to the reduction in hydrational forces in line with the tractional-hydrational theory of macular holes. Topical therapy may allow some patients avoid vitrectomy surgery. Since stage 1 macular holes can close spontaneously, a randomized clinical trial would be required to prove benefit. Stability of long-term closure also requires further research.

ABSTRACT BODY:

Purpose: Severe inflammation of the cornea abrogates its immunological and angiogenic privilege and eventually leads to corneal blindness. Under these high-risk conditions, vision-restoring corneal transplants have dramatically reduced chances for graft acceptance. Pro-inflammatory macrophages comprise 60 % of all infiltrating immune cells in a rejected graft. We hypothesize that administration of the immunomodulatory protein sCD83 leads to a shift from pro-inflammatory classically activated macrophages (CAM), characterized among others by TNF- α , IL-6 and CD86 expression, to anti-inflammatory alternatively activated macrophages (AAM), characterized among others by CCL22, CCL17, and MSR-1 expression, and thereby promotes corneal graft acceptance.

Methods: In a model of high-risk corneal transplantation (C57BL/6 donor and BALB/c recipient mice), 50 μ g/ml sCD83 was administered locally 2 days prior to keratoplasty (KPL). Macrophages in the draining lymph nodes (dLNs) of the recipient were analyzed by flow cytometry 2 weeks post KPL. The allograft survival was determined by grading the opacity of the grafts weekly for 8 weeks. sCD83 was also administered during cultivation of BMDMs and its effect analyzed in flow cytometry and MLR experiments.

Results: In the dLNs of sCD83-treated recipients, the frequency of MSR-1⁺ AAMs was significantly increased while significant less CD86⁺ CAMs were detected 2 weeks post KPL. 8 weeks post KPL, the number of Foxp3⁺ Tregs in the dLNs was increased and the graft survival was significantly higher in the sCD83 group. In vitro, sCD83 induced a tolerogenic phenotype in BMDMs as the expression of CCL17, CCL22 and MSR-1 was significantly upregulated while the expression of CD83 and CD86 was significantly downregulated. In co-culture experiments showed sCD83-treated BMDMs an impaired ability to induce allogeneic T cell proliferation while increased numbers of Foxp3⁺ Tregs were detected. TNF- α as well as IL-6 concentrations were decreased in co-culture supernatants when BMDMs were treated with sCD83.

Conclusions: Our results are consistent with our hypothesis that administration of sCD83 leads to a shift from CAM to AAM which prolongs allograft survival in a high-risk corneal transplantation model. Thereby, we not only confirmed the important role of macrophages in the transplant setting, but also demonstrated the beneficial potential of their modulation by sCD83 to prolong corneal graft survival.

ABSTRACT BODY:

Purpose: Tau is a microtubule-associated protein that has been involved in glaucoma. Its physiological function in the visual system is unknown. The aim of this study was to investigate the contribution of Tau to the maturation and the plasticity of the intact mouse visual system.

Methods: Western blotting and immunofluorescent analysis of Tau isoform (T3R and T4R) expression were performed on retinae and visual cortices from postnatal day 1 (P1) to P360. To induce visual plasticity, monocular deprivation (MD) was realized by suturing right eyelids. After 5 days of MD, the expression of Tau isoforms, Erk, a modulator of neuronal plasticity, and acetylated tubulin, a microtubule instability marker, was followed in the visual cortex (VC) by Western blotting. Visual function was assessed by electroretinogram (ERG) recordings, optokinetic reflex (OKR) and visual evoked potential (VEP) recordings in the left binocular VC in response to left and right eye stimulations, in young adult (3-5 months) and old (20-24 months) WT and Tau knockout (Tau KO) mice. VEPs were used to calculate an ocular dominance index (ODI). Retinal ganglion cell (RGC) survival was quantified on retinal flat-mounts.

Results: In the first postnatal month, T3R downregulation and T4R upregulation in retinal and VC lysates were associated with the decline in neuronal plasticity occurring during the critical period. ERG recordings and RGC survival showed no difference between WT and Tau KO during aging. The OKR of Tau KO vs WT did not differ. In contrast, the ODI was significantly weaker in Tau KO than in control WT. In MD mice, Western blot and immunofluorescent analyses revealed increased expression of Tau isoforms in the VC of the deprived eye, suggesting an implication of Tau in visual plasticity. The rise in OKR sensitivity induced by MD was statistically higher in Tau KO than in WT during aging, suggesting that Tau limits the activation of neuronal plasticity in the VC. After MD, the ODI of Tau KO was similar to that of WT and to nondeprived Tau KO. Western blot results showed increased levels of Erk in Tau KO relative to WT mice. Interestingly, the Tau KO cortex contained less acetylated tubulin, indicating possible increased microtubule instability in the absence of Tau.

Conclusions: Our results suggest a new function for Tau in the adaptive plastic mechanisms operating in the adult visual brain subjected to sensory experience changes. Tau may limit visual plasticity in adult mice.

ABSTRACT BODY:

Purpose: Pathologic insults like transplant rejection or trauma lead to blindness and to a so called “high-risk situation” with increased rejection rates after subsequent keratoplasty. These insults cause different immunological tissue responses. Aim of this study was to evaluate the impact of different types of corneal injury on hem- and lymphangiogenesis.

Methods: We used 5 types of corneal injury model and naïve corneas as control (n=5 each). The suture model is the intrastromal placement of three 11.0 nylon sutures. A 2 mm filter disc soaked in 1 M NaOH was placed on the central corneal surface for 30s and the eyes were washed with PBS as the alkali burn model. Incision injury was performed in the central cornea with a linear perforating incision with 1 mm length. Corneal grafts were placed into an avascular recipient bed as the normal-risk keratoplasty model (NR-KPL). Corneal grafts were placed into the suture-induced neovascularized recipient as the high-risk keratoplasty model (HR-KPL). C57BL/6 mice were used as donor tissue in KPL and all others were Balb/c mice. 1 week after incision and 2 weeks after all other different injuries, corneas were excised and stained with CD31 and LYVE-1 for the quantification of blood vessels and lymphatic vessels.

Results: HR-KPL and NR-KPL initiated the highest hemangiogenesis (HA), significantly higher than all other groups. Suture placement induced the second most powerful angiogenic response, significantly higher than alkali burn, incision and naïve eyes. Alkali burn evoked the third most powerful HA-response, significantly higher than naïve eyes. The incision model did not induce angiogenesis. Regarding lymphangiogenesis (LA), NR-KPL provoked the highest response, significantly higher than all other groups except HR-KPL. LA in HR-KPL was significantly higher than all other groups except NR-KPL and suture placement. Suture placement and alkali burn had a significantly higher LA compared to incision and naïve eyes. Incision provoked no significant LA compared to naïve corneas. Regarding LYVE-1+ macrophages, only NR-KPL and suture placement showed significantly more infiltration.

Conclusions: Different types of corneal injury cause different types and degrees of neovascularization. In conclusion, different high-risk situations might result in different corneal graft survival rates. Therefore, also the potential clinical treatment of different injuries in the future might need to be customized.

ABSTRACT BODY:

Purpose: To investigate the performance of a pyramid wavefront sensor (P-WFS) for adaptive optics (AO) imaging in visual science. The P-WFS, first introduced in astronomy, promises greater sensitivity and more flexibility than the well-established Shack-Hartmann (SH-)WFS. However, ophthalmic applications of the P-WFS have not met the performance of the SH-WFS so far.

Methods: The P-WFS was implemented as an add-on (see Fig. a)) to a SH-WFS based spectral domain AO optical coherence tomography (OCT) setup. The instrument provides an axial resolution of 4.5 μm at 840 nm central wavelength and an A-scan rate of 250 kHz. For wavefront sensing, part of the imaging light returning from the retina is used. The scanning motion of the imaging beam over the retina creates an averaging effect in the WFS data which is essential for successful AO correction with the P-WFS (see Fig. b)). Retinal images were recorded in the fovea of several healthy volunteers with the P-WFS and the SH-WFS in a single session. En-face visualization of the photoreceptor layer via segmentation and cross-sectional image data allow for a comparison of the two sensor types.

Results: The representative image data displayed in Fig. c) show en-face images of the photoreceptor mosaic and B-scan images obtained with the P-WFS and the SH-WFS. The power spectra of the enface images show the ability of the instrument to resolve the photoreceptors using either sensor type. With the P-WFS, single cone photoreceptors close to the fovea centralis can be visualized in almost the entire fovea clearly matching the image quality achieved with the SH-WFS. It is subject of on-going investigation if the clearer appearance of the photoreceptor cells and the higher clarity of the Yellott's ring obtained for the P-WFS data is due to a general superiority of the sensor in ophthalmic applications.

Conclusions: The suitability of the P-WFS for AO imaging in visual science is demonstrated in vivo with AO-OCT. The parallel implementation of the P-WFS and a SH-WFS allows for a direct comparison of the two sensor types. Photoreceptor cells could be visualized in the fovea with both sensors demonstrating the high resolution capability of the system. The image quality obtained with the P-WFS equals or even outperforms that of the SH-WFS indicating that the P-WFS can be a promising alternative for the SH-WFS in ophthalmic imaging.

TITLE: A computational model of neovascularization in wet age related macular degeneration

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Bradshaw, A. Kjar, M. Cotner, J. Fielding, T. Teeples, Z. Zhang, E. Vargis, Utah State University, Logan, Utah, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kelsey Bradshaw: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Kjar: Commercial Relationship: Code N (No Commercial Relationship) | Michael Cotner: Commercial Relationship: Code N (No Commercial Relationship) | Jacilyn Fielding: Commercial Relationship: Code N (No Commercial Relationship) | Teren Teeples: Commercial Relationship: Code N (No Commercial Relationship) | Zhen Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Vargis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In age-related macular degeneration (AMD), retinal pigment epithelial (RPE) cells overexpress pro-angiogenic proteins, such as vascular endothelial growth factor (VEGF), causing the growth of new blood vessels. This neovascularization can be simulated by developing a computational behavioral model to predict the extent and probable location of blood vessel growth based on the production of VEGF by the RPE. Computational modeling allows for more high throughput, time efficient, and inexpensive experiments than in vitro or animal models.

Methods: The computational model mimics the space between a choroidal parent vessel and the RPE layer as a 2-dimensional matrix. The lower boundary of the matrix represents the RPE layer and serves as a point source of VEGF. The VEGF diffuses towards the upper boundary of the matrix which represents a parent vessel in the choroid from which new blood vessels will grow. Tip cells in the parent vessel react to increasing levels of VEGF by secreting protease. The protease degrades the fibronectin of the extracellular matrix allowing the tip cell to escape the parent vessel and form a new blood vessel. In the computational model, tip cells move in a biased random walk with the probability of moving to an adjacent location based on chemoattractance which is calculated using the concentration of free VEGF, the amount of protease secreted by the tip cell, and the extent of fibronectin degradation. This methodology provides an effective prediction of the extent and location of neovascularization given VEGF production values. These results will then be validated with live imaging HUVEC cell migration studies.

Results: Our model produces a graphical representation of blood vessel growth, as well as 3D graphs of VEGF, protease, and fibronectin concentrations. Consistent with data found in scientific literature, there is a larger extent of blood vessel growth with higher VEGF expression and new blood vessel growth is biased towards higher concentrations of VEGF. These results will be validated by our HUVEC cell migration studies.

Conclusions: With the parameter values found through experimentation, the model accurately predicts blood vessel growth over time when RPE cells are overexpressing VEGF in wet AMD. The computational model reduces test variables and provides parameters for lab experiments saving researcher time and money.

ABSTRACT BODY:

Purpose: Ocular pathologies are the most common sensory impairments that greatly impact quality of life. While direct consequences of the pathologies can now be followed using cutting-edge in vivo imaging, the cellular causes and degeneration of these pathologies still call for histological studies. These studies are currently restricted when trying to reach nanoscale resolution by the availability of rare and expansive microscopes (such as electron or bi-photon microscope).

We recently implemented in the team an innovative histological technic called Expansion Microscopy (ExM). This technique, based on physical, isotropic expansion of tissues, allows nanoscale imaging of biological specimens with conventional microscopes.

Here, we describe the first use of this technique in the human retina, to visualize and render in 3D the anatomy of retinal cells in physiological and pathological conditions.

Methods: Retinas were isolated and fixated in paraformaldehyde, before performing immunohistochemistry. Samples were embedded in an acrylamide gel to which fluorophores were anchored. The tissue was then enzymatically digested, expanded in water and imaged using either confocal or light-sheet fluorescent microscopy.

Results: Thanks to the nanoscale resolution allowed by this technique, we were able to study in 3D for example the anatomy of physiological and pathological cones photoreceptors, from opsin migration to the structural deformation of photoreceptors retinal layer.

Conclusions: By implementing ExM in the eye, this project made subcellular study easily accessible, thus broadening the field of possible nanoscale studies in ocular pathologies.

ABSTRACT BODY:

Purpose: To determine the cumulative incidence rate of second eye progression in patients with unilateral neovascular age-related macular degeneration (nAMD) over 10 years follow-up; and to study the effect of supplement use, genetic variants, and plasma nutritional biomarkers on second eye progression.

Methods: This is a historical prospective cohort study.

We selected 240 patients nAMD in one eye and non-advanced AMD in the second eye. We performed multivariate Cox regression survival analysis for second eye progression. Variables included in the model were the intake of supplements, a genetic risk score (GRS) based on 52 AMD-associated variants, and 24 plasma nutritional biomarkers, including levels and ratios of fatty acids (FA), polyunsaturated fatty acids (PUFA), monounsaturated fatty acids (MUFA), saturated fatty acids (SFA), omega-3 fatty acids (FA ω 3), omega-6 fatty acids (FA ω 6), docosahexaenoic acids (DHA), linoleic acid (LA), and levels of carotenoids, α -carotene, β -carotene, α -lycopene, β -lycopene, β -cryptoxanthin, lutein, zeaxanthin, retinol and vitamin E. The main outcome measure was the development of nAMD in the second eye.

Results: The cumulative incidence rates for second-eye progression to nAMD were 8%, 15%, 25%, 45%, 58% and 68% after 1-, 2-, 3-, 5-, 7-, and 10-years follow-up respectively, showing a declining trend in the progression rate after five years. Supplement use was protective for second eye progression (HR 0.6, P=0.010). Patients with a GRS \geq 4 were at higher risk for progression compared to patients with a GRS \leq 0 (HR 6.7, P=0.021). The highest quartiles of DHA/FA ratio (>1.20) and zeaxanthin level (>0.75 μ mol/L) were found to be protective for second eye progression compared to the lowest quartiles (HR 0.5, P=0.025 and HR 0.5, P=0.019, respectively). Supplement use was no longer significantly associated with second eye progression after correction for plasma DHA/FA ratio and zeaxanthin levels.

Conclusions: The risk of second eye progression in patients with unilateral nAMD is 10% per year in the first 5 years, and declines to approximately 5% per year after 5 to 10 years. Patients should consider taking supplements and adhere a healthy lifestyle to pursue high plasma DHA/FA ratio and zeaxanthin levels in order to reduce the risk of second eye progression and remain eyesight for a longer period.

ABSTRACT BODY:

Purpose: The aim of the study was to compare the most important higher order aberrations provided by the Pentacam AXL Wave and the iTrace.

Methods: Prospective, randomised study with three consecutive measurements per eye and each device, the Pentacam AXL Wave (Oculus) and the iTrace (Tracey Technologies). Each patient completed all measurements at the same day and all measurements had good quality scores.

Forty two patients (34 right and 38 left eyes) ranging in age from 20 to 63 year (mean age was 36 ± 14 years) took part in this study. None of the patients had any known ocular pathology, all eyes were phakic.

The most crucial higher order aberrations (trefoil 30° and 0° , coma 90° and 0° and spherical aberration) of the complete eye were analysed for a 3mm zone. Repeatability was assessed with standard deviation (SD). Bland-Altman analysis was used to assess agreement between the devices.

Results: Repeatability

The mean values of the analysed HOAs and their standard deviations are: trefoil 30° - Wave $-0,021\mu\text{m} \pm 0,011$, iTrace $-0,016\mu\text{m} \pm 0,013$; trefoil 0° - Wave $-0,003\mu\text{m} \pm 0,009$, iTrace $-0,001\mu\text{m} \pm 0,012$; coma 90° - Wave $0,005\mu\text{m} \pm 0,011$, iTrace $0,008\mu\text{m} \pm 0,012$; coma 0° - Wave $0,001\mu\text{m} \pm 0,009$, iTrace $0,008\mu\text{m} \pm 0,012$; sph aberr - Wave $0,011\mu\text{m} \pm 0,005$, iTrace $0,01\mu\text{m} \pm 0,007$. A paired-samples t-test was conducted to compare the means of the devices. Only the differences of the coma 0° were statistically different ($p < .05$).

Agreement

A Bland-Altman analysis revealed the following mean differences, standard deviations and limits of agreement for the two devices ($\text{mean}_{\text{DIFF}} = \text{mean}_{\text{WAVE}} - \text{mean}_{\text{ITRACE}}$): trefoil 30° - $\text{mean}_{\text{DIFF}} -0,005\mu\text{m} \pm 0,029$, $\text{LOA}_{\text{low}} -0,062$, $\text{LOA}_{\text{upp}} 0,052$; trefoil 0° - $\text{mean}_{\text{DIFF}} -0,002\mu\text{m} \pm 0,029$, $\text{LOA}_{\text{low}} -0,059$, $\text{LOA}_{\text{upp}} 0,055$; coma 90° - $\text{mean}_{\text{DIFF}} -0,015\mu\text{m} \pm 0,027$, $\text{LOA}_{\text{low}} -0,068$, $\text{LOA}_{\text{upp}} 0,038$; coma 0° - $\text{mean}_{\text{DIFF}} -0,006\mu\text{m} \pm 0,032$, $\text{LOA}_{\text{low}} -0,068$, $\text{LOA}_{\text{upp}} 0,056$; sph aberr - $\text{mean}_{\text{DIFF}} 0,002\mu\text{m} \pm 0,017$, $\text{LOA}_{\text{low}} -0,031$, $\text{LOA}_{\text{upp}} 0,035$.

Conclusions: In general, the higher order aberrations were rather low what can be explained by the relatively young and healthy study population. The small standard deviations indicate good repeatability for both devices, however, those of the Pentacam AXL Wave tended to be smaller than the ones of the iTrace. Agreement between the devices was high even so this result remains to be confirmed for larger zones and pathological eyes, e.g. keratoconus.

ABSTRACT BODY:

Purpose: To evaluate the peripheral defocus of monofocal intraocular lenses (IOLs), thereby quantifying the accuracy of laser ray tracing (LRT) measurements of peripheral defocus.

Methods: Data were acquired on 14 polymethylmethacrylate spherical optic monofocal IOLs (overall length 12.5 mm, optic diameter 6.0 mm). The power (D) of the IOLs used were 17.5, 18, 18.5, 19, 19.5, 20, 20.5, 21, 22, 22.5, 23, 23.5, 24 and 24.5. IOLs were placed in a custom-built combined LRT and optical coherence tomography (OCT) system (Ruggeri et al, BOE 2018). Ray trace experiments were performed for incidence angles ranging from -30° to +30° in 5° increments using a raster scan (6 mm x 6 mm) with 0.25 mm spacing. An image sensor mounted on a positioning stage below the IOL acquired ray-intercept spots at different axial positions and a custom program calculated the ray slopes from the spot positions. At each angle, lens power was calculated by finding the axial position that minimizes the root-mean-square diameter of the spot pattern formed by the central 169 rays corresponding to the central 3 mm zone. For each IOL, the measured relative peripheral defocus (Figure 1) was compared to the value obtained using optical theory. The theoretical peripheral defocus was the position of the circle of least confusion calculated assuming that the IOL is a thin lens with the aperture stop located at the plane of the lens.
