Results: The differences between the two methods (QuickPro vs. DNEye® Scanner 2 + subjective refraction) showed statistically significant but clinically irrelevant differences: $\Delta M = - 0.20 \pm 0.35$ D ($p < 0.001$); $\Delta J0 = 0.07 \pm 0.14$ D ($p < 0.001$); $\Delta J45 = - 0.02 \pm 0.13$ D ($p = 0.445$). A subjective refraction based on the aberrometer measurement (DNEye® Scanner 2) took 10.55 ± 2.34 min while a QuickPro measurement 6.77 ± 2.14 min.

Statistically significant differences were found for the addition values (EyeRefract VX160: $+1.06 \pm 0.90$ D, trial frame: $+0.70 \pm 0.80$ D, $p < 0.001$) as well as its measurement time (EyeRefract VX160: 2.18 ± 0.84 min, trial frame: 4.36 ± 1.60 min, $p < 0.001$).

Conclusions: The refraction determination with the EyeRefract VX160 requires significantly less time for both the QuickPro measurement and the addition determination than a conventional procedure. In around 90% of all cases, QuickPro algorithm achieved precise measurement results across all correction values, which correspond to those of a conventional refraction determination.

ABSTRACT BODY:

Purpose: Bimatoprost implant 10 µg (Durysta) is a biodegradable, intracameral implant (cylindrical diameter ~200 µm, length ~1.1 mm) that releases bimatoprost steadily to lower intraocular pressure and eventually converts to water and CO₂. The implant elutes bimatoprost for ~4 months but the polymers in the implant matrix may last longer. We evaluated the rate of biodegradation of the implant in our randomized, controlled phase 3 clinical trials.

Methods: Two 20-month, phase 3 trials (NCT02247804, NCT02250651) randomized 1 eye per patient with open-angle glaucoma or ocular hypertension to an intracameral 10- or 15-µg bimatoprost implant administered on Day 1, Weeks 16 and 32 or topical timolol 0.5% BID. Estimated implant size on gonioscopy as a percentage of the initial size was recorded. We pooled data for the 10-µg implants placed on Day 1 in both trials for analysis. The population mean implant size (expressed as the percentage of the initial size) over time was modeled with a nonlinear mixed-effects model with repeated measures (MMRM) approach. The rate of biodegradation was defined as the decrease in implant size (expressed as a percentage of the initial size) per month.

Results: A total of 230 eyes were included in the analysis. Implant size data were best fit to a model that considered inter-patient variability and included an exponential function for the implant size decrease (Figure). The estimated mean (± standard error) percentage decrease in implant size from baseline was 24.1% ± 2.3% at Week 28 and 80.2% ± 1.5% at Week 52. The estimated mean rate of implant biodegradation was 3.7%/month through Week 28, 10.2%/month after Week 28 through Week 52, and 2.4%/month after Week 52 through Month 20.

Conclusions: The estimated mean size of 10-µg bimatoprost implant administered on Day 1 in phase 3 trials decreased according to an exponential function, which allows one to predict the size of a single or multiple implants in the AC. Clinical studies are in progress to further understand implant biodegradation and the ideal timing for implant re-administration.

TITLE: Enzyme-modified nanoparticles as a possible strategy for safe and effective vitreous liquefaction

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Minnaert, K. Peynshaert, A. Harizaj, M. Wels, F. Sauvage, S. De Smedt, K. Remaut, Laboratory of General Biochemistry and Physical Pharmacy, Universiteit Gent Faculteit Farmaceutische Wetenschappen, Gent, BELGIUM|

Commercial Relationships Disclosure (Abstract): An-Katrien Minnaert: Commercial Relationship: Code N (No Commercial Relationship) | Karen Peynshaert: Commercial Relationship: Code N (No Commercial Relationship) | Aranit Harizaj: Commercial Relationship: Code N (No Commercial Relationship) | Mike Wels: Commercial Relationship: Code N (No Commercial Relationship) | Félix Sauvage: Commercial Relationship: Code N (No Commercial Relationship) | Stefaan De Smedt: Commercial Relationship: Code N (No Commercial Relationship) | Katrien Remaut: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: When people age, liquefaction of the vitreous can result in Posterior Vitreous Detachment (PVD), routinely treated by a vitrectomy. Unfortunately, this procedure is invasive and risky since it might lead to complications such as retinal tears. As an alternative, we explored enzymatic vitreolysis both as a replacement or pre-treatment to vitrectomy. To this end, we aimed to immobilize enzymes on the surface of nanoparticles (NPs) to minimize enzyme-induced toxicity caused by retinal penetration and thus generate safe and effective vitreous liquefaction.

Methods: NPs and enzyme were incubated for 24 hours at room temperature under continuous stirring. Next, multiple centrifugation cycles were performed in order to remove the free enzyme. The activity of the enzyme-modified NPs in vitro was evaluated by measuring substrate-FITC-fluorescence with a plate-reader. The fluorescence intensity of the FITC-labeled substrate increased upon degradation by the enzyme. Additionally, ex vivo activity experiments in bovine vitreous were performed using single particle tracking (SPT). SPT measurements allow mobility tracking of fluorescent particles. We used fluorescent beads which are immobile in vitreous but are able to diffuse upon vitreous liquefaction. Finally, potential penetration of the enzyme-modified NPs into the retina upon injection in bovine vitreo-retinal explants was determined with confocal microscopy. Necessary controls with non-modified NPs and/or free enzyme were performed in every experimental set-up.

Results: We repeatedly succeeded in generating stable 300 nm NPs with an in vitro activity of 170 units/100 μ L sample. SPT experiments validated that we could generate sufficient vitreous liquefaction. Upon treatment of the bovine vitreous with enzyme-modified NPs, the mobility of injected fluorescent beads increased enormously. As expected, microscopy imaging showed clear alignment of the enzyme-modified NPs at the inner limiting membrane (ILM) while no penetration to the retina could be observed. Finally, we could not see significant structural retinal changes in the vitreo-retinal explants upon treatment with the enzyme-modified NPs.

Conclusions: This study showed that enzyme-immobilization is a promising technique for effective vitreous liquefaction. Future goals include extensive toxicity studies both ex vivo and in vivo to provide more information about the safety of this therapy.

ABSTRACT BODY:

Purpose: To develop and evaluate ML models employing systemic and/or retinal imaging features for predicting whether patients with mild NPDR will develop CSME within 2 years from baseline.

Methods: Systemic and retinal imaging features (optical coherence tomography and color fundus photographs) from 348 patients (129 female; mean age, 60.9 years) with mild NPDR (Diabetic Retinopathy Severity Scale [DRSS] 20–35) and type 2 diabetes enrolled in a cohort study (NCT00763802) were pooled. Data were acquired 6 months (M6) and 2 years (M24) after baseline. Linear regression models were evaluated for predicting these events using systemic data only, imaging features only, and both combined. Area under the receiver operating characteristics (AUROC) curve was employed as a performance metric.

Results: Table 1 presents a summary of data acquired at baseline, M6, and M24. Twelve patients developed CSME in the study eye by M6, and 34 patients by M24. When using data obtained at baseline, CSME at M24 was predicted with an AUROC = 0.550 (95% CI, 0.521, 0.580) with systemic data; 0.727 (95% CI, 0.700, 0.753) with imaging features; and 0.734 (95% CI, 0.708, 0.760) with both combined. When using data from M6, CSME at M24 was predicted with an AUROC = 0.536 with systemic data, 0.734 with imaging data, and 0.713 with both combined. When using data combined from both M6 and baseline, CSME at M24 was predicted with an AUROC = 0.508 with systemic data, 0.749 with imaging features, and 0.738 with both combined. These results are summarized in Table 2.

Conclusions: Our results indicate that development of CSME in patients with mild NPDR can be more accurately predicted with retinal imaging features than with systemic data on their own. When predicting the development of CSME by M24 using data obtained at M6 only, the performance was not significantly different compared with using both baseline and M6. In the future, we plan to extend the evaluation to larger datasets, allowing more confident conclusions regarding the performance and predictive potential of the different types of data. Such predictive models of CSME in patients with NPDR could be employed to inform personalized monitoring and follow-up.

ABSTRACT BODY:

Purpose: Postmenopausal women have a high incidence of DED, probably due to sex hormone imbalances. This study evaluated efficacy of a 3-month daily treatment with artificial tears containing trehalose and hyaluronic acid in peri- and postmenopausal women with moderate and severe DED

Methods: This was a post hoc analysis of peri- and postmenopausal women (ages 42-54 and ≥ 55 years, respectively) with an Ocular Surface Disease Index (OSDI) ≥ 18 who had participated in a Phase III (NCT02023268) and a Phase IV (NCT02617095) studies assessing the efficacy of artificial tears containing trehalose (30 mg/mL) and hyaluronic acid (1.5 mg/mL) on the signs and symptoms of DED Patients instilled one drop of the artificial tears in each eye 3 to 6 times daily and were evaluated at baseline and after 84 ± 7 days for DED symptom severity (measured with the OSDI), visual acuity (Snellen optotype), hyperemia (MacMonnies scale), tear break-up time (TBUT, fluorescein), corneal and conjunctival staining (Oxford and Van Bijsterveld scales), tear production (Schirmer's test), and symptoms (visual analogue scale).

Results: A total of 59 women were analyzed (16 perimenopausal; 43 postmenopausal, mean \pm SD age= 48.6 ± 4.2 and 66.9 ± 8.0 years, respectively). After 84 days of treatment, the OSDI (mean \pm SD) decreased from 59.2 ± 24.7 to 22.9 ± 17.3 in perimenopausal and from 52.6 ± 20.7 to 29.1 ± 24.3 in postmenopausal women (both $p < 0.0001$). Visual acuity remained unchanged in both groups. Conjunctival hyperemia, TBUT, and corneal and conjunctival staining with fluorescein or lissamine green improved significantly in both groups (all $p < 0.0001$). Tear production also increased in peri- ($p = 0.0101$) and postmenstrual women ($p = 0.0005$). Conjunctival hyperemia, TBUT, and corneal and conjunctival staining (Oxford scale) improved more significantly in peri- than postmenopausal women. Severe symptoms at baseline and absence of symptoms at day 84 were also reported more frequently by peri- than postmenopausal women.

Conclusions: Signs and symptoms of DED improved significantly in peri- and postmenopausal women treated for 3 months with artificial tears containing trehalose and hyaluronic acid, suggesting that it is an effective treatment for eye dryness in this population. Improvement was often significantly greater in peri- than in postmenopausal women.

ABSTRACT BODY:

Purpose: Corticosteroids are valuable for controlling ocular inflammation. Their use is limited due to their side effects, including the induction of steroid-induced glaucoma and ocular hypertension (OHT). While the mechanism of this is unclear, fibrosis and excess collagen deposition in the trabecular meshwork (TM) have been described in patients with steroid-induced glaucoma. Compounds that inhibit Rho kinases (ROCK inhibitors) have been shown to reduce deposition of collagen in cultured TM cells. ROCK inhibition also lowers intraocular pressure (IOP) in vivo by increasing aqueous humor TM outflow. We have shown (IOVS 61(7):2953 June 2020) that a rho kinase inhibitor coupled to a corticosteroid reduces inflammation in animal models. To further investigate this new class of molecules, and to optimize activity and stability, a series of novel molecules were synthesized and tested.

Methods: Aerie successfully developed the ROCK inhibitor netarsudil as a treatment for glaucoma (Rhopressa™). Molecules from that research that contain hydroxyl groups were esterified to short chain diacids that were then coupled to steroids. To demonstrate timely enzymatic release of these two moieties, esterase assays have been performed, including with porcine-liver esterase. Retention of ROCK inhibitory activity and steroidal activity were demonstrated in kinase assays and cell lines. Compounds were evaluated for aqueous solubility and stability.

Results: Compounds A-E demonstrated considerable variability in both formulation stability and esterase sensitivity. Multiple compounds displayed potent, often single-digit nM cellular activity in one or more in vitro whole cell assays. Compound A demonstrated an extrapolated stability and activity profile that is suitable for progression. These molecules also demonstrated excellent thermal stability, and sufficient solubility to allow for ophthalmic formulation.

Conclusions: This proprietary class of ROCK inhibitor-linked corticosteroids has demonstrated potent enzymatic and cellular ROCK inhibitory activity, cellular steroidal activity, suitable in vitro and ex vivo metabolism, formulation stability under conditions needed for manufacturing, and anti-inflammatory and IOP-lowering activity in animal models. Compound A in this class of molecules is under further study for the treatment of ocular inflammatory disease.

ABSTRACT BODY:

Purpose: To explore the relationship between IRF/SRF and best-corrected visual acuity (BCVA) in patients with nAMD treated with IVT-AFL to guide treatment extension decisions.

Methods: ARIES (NCT02581891) was a multicenter, randomized, Phase 3b/4 study that compared the efficacy of 2 different IVT-AFL T&E dosing regimens over 2 years in treatment-naïve patients with nAMD. This post-hoc analysis explored the relationship between presence of fluid (SRF and IRF) and BCVA by describing absolute BCVA by fluid subgroups at baseline (BL) and by fluid status at fixed visits (Weeks [w] 4, 8, 16, 52, and 104).

Results: The per-protocol set comprised 210 patients (two treatment arms combined). Absence of SRF at BL was associated with lower BCVA (5–10 less letters) than if SRF was present; furthermore, at every timepoint, the absence of SRF was associated with poorer BCVA (letters) than if SRF was present (no SRF vs SRF: 64.5 vs 67.2 [w4]; 66.3 vs 68.5 [w8]; 66.4 vs 70.7 [w16]; 68.3 vs 73.6 [w52]; 65.4 vs 72.9 [w104]). Presence of IRF at BL was associated with

lower BCVA (7–9 less letters) than if IRF was absent; furthermore, at most timepoints, presence of IRF was associated with poorer BCVA (letters) than if IRF was absent (IRF vs no IRF: 61.2 vs 65.9 [w4]; 66.6 vs 66.8 [w8]; 59.0 vs 69.3 [w16]; 66.2 vs 70.0 [w52]; 70.1 vs 67.4 [w104]). The presence of both SRF+IRF at BL was associated with lower BCVA (6–8 less letters) than if only SRF was present but was associated with a higher BCVA (3–9 more letters) than if only IRF was present. Absence of SRF+IRF was not associated with better BCVA (letters) at any timepoint (no fluid vs fluid: 64.7 vs 66.8 [w4]; 66.5 vs 67.7 [w8]; 67.3 vs 69.2 [w16]; 68.5 vs 72.6 [w52]; 65.3 vs 71.9 [w104]).

Conclusions: In ARIES, IVT-AFL T&E was effective at reducing fluid and improving vision in treatment-naïve nAMD eyes regardless of fluid type. Post-hoc analyses showed that good functional outcomes were achieved in the presence of SRF, whereas IRF was consistently associated with poorer functional outcomes. These findings indicate the need to differentiate SRF and IRF as surrogate markers for BCVA, in order to guide treatment extension decisions.

ABSTRACT BODY:

Purpose: Retinal rods count photons to provide for vision when the lighting is very dim. To do so, they must generate reproducible single photon responses (SPRs). The rod outer segment has a multilayered structure built from disks containing one or more incisures. We seek to understand how outer segment length, disk diameter and incisures impact SPR reproducibility

Methods: A fully space-resolved mathematical model of rod phototransduction and single cell recordings were used to analyze how the location of rhodopsin photoisomerization on the disk surface affects SPR amplitude and kinetics. In addition, the contribution of an axial concentration gradient of bicarbonate to response variability was evaluated electrophysiologically.

Results: Modeling showed that a photoisomerization at the edge of the disk edge elicits a larger, faster SPR than a photoisomerization in the disk center. This is because local depletion of cGMP at the disk rim, near the plasma membrane, closes more ion channels with a shorter delay compared to the changes that occur after a photoisomerization at the disk center. These variations, arising primarily in the rising phase of the SPR, increase in significance with disk diameter. A symmetric pattern of incisures attenuates the variability. Single cell recordings of large salamander rods confirmed that photoisomerizations at the disk edge gave rise to faster SPRs than photoisomerizations occurring randomly on the disk surface.

Bicarbonate is known to accelerate SPR recovery. It is taken up at the rod synapse, after which it diffuses to the outer segment where it is extruded by an anion exchanger.

Electrophysiology recording of long outer segment toad rods demonstrated faster rising and recovery phases at the base vs tip of outer segment without bicarbonate. Surprisingly, this difference was attenuated with bicarbonate

Conclusions: Randomness in the radial location of rhodopsin photoisomerization on the disk contributes to SPR variability, particularly for large disk diameters, but variability can be attenuated by incisures. Randomness in the longitudinal location of the photoisomerization contributes additional variability to the SPR. Bicarbonate produces the SPR less variable though the outer segment.

ABSTRACT BODY:

Purpose: The Pan American Health Organization (PAHO) has identified trachoma as a potential public health problem in Perú. We performed a cross-sectional study to determine the prevalence of trachoma in Alto Amazonas, Perú.

Methods: We selected 22 communities via probability-proportional-to-size sampling after excluding urban areas. In a random selection of approximately 30 households per community, all children aged 1-9 were examined for trachomatous inflammation—follicular (TF) and trachomatous inflammation—intense (TI), and individuals aged 15+ years were evaluated for trachomatous trichiasis (TT), i.e., upper lid trichiasis, using the World Health Organization's (WHO) 2018 amended trachoma grading system. Each child's right conjunctiva was swabbed and tested for Chlamydia trachomatis DNA.

The community level prevalence of TF, TI, and ocular C. trachomatis was adjusted for age in one-year bands and TT prevalence was adjusted using 5-year age bands. The overall prevalence of each outcome was the mean of the age-adjusted community level prevalence. 95% confidence intervals were calculated using bootstrapping methods with resampling at the community level (10,000 replications).

Results: One community refused. The location and number examined in the other 21 communities are shown in Figure 1. 617 selected households were enumerated, with 873 children aged 1-9 and 1313 adults 15+ eligible for examination of whom 778 (89.1%) and 1003 (76.4%) were examined, respectively. On average, the prevalence of TF among 1–9-year-olds was 32.6% and the prevalence of ocular C. trachomatis was 0.8% (Table 1). The prevalence of TT among individuals ≥15 years was 0.06%.

Conclusions: The overall prevalence of TF was above the WHO 5% threshold for active trachoma as being a public health problem. Consequently, the area is eligible for the implementation of trachoma elimination interventions, including annual mass administration of antibiotics for at least 5 years. The discrepancy between high TF and low ocular C. trachomatis prevalence requires further investigation.

Hoffmann-La Roche Ltd. :Code E (Employment) | Jian Dai: Commercial Relationship(s);Genentech, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: To develop an interpretable machine learning (ML) model to predict anti-VEGF treatment requirements for patients with neovascular age-related macular degeneration (nAMD).

Methods: Patients from the ranibizumab 0.5 and 2.0 mg as-needed arms of HARBOR (NCT00891735) who received monthly anti-VEGF injections during a 3-month initiation phase were included. Boundaries of five retinal layers, intra- and subretinal fluid, subretinal hyperreflective material (SHRM), and pigment epithelial detachment (PED) were automatically segmented using ML-based algorithms from spectral-domain optical coherence tomography (SD-OCT) volume scans acquired at each visit. Segmentation results were used to extract quantitative features of layer and fluid features (69 layer and 36 fluid features). BCVA and central subfield thickness (CST) measured at the 3 visits were also included. Low and high treatment groups were defined as requirement of ≤ 5 or ≥ 16 injections, respectively, in the 21 months after the initiation phase. Extreme gradient-boosting ML model was used for binary classification (low or high treatment) using stratified 5-fold cross-validation. Feature importance was analyzed using SHapley Additive exPlanations (SHAP).

Results: Data from 363 patients were analyzed. Low and high treatment groups included 82 and 83 patients, respectively, with mean (\pm SD) area under the receiver operating characteristic curve scores of 0.81 ± 0.06 and 0.80 ± 0.08 (Fig 1). Low treatment need was most strongly associated with low presence of detected PED at month 2. High treatment need was most strongly associated with low presence of SHRM at month 1, low presence of IRF at day 0 and presence of IRF at month 1 (Fig 2).

Conclusions: This exploratory study showed the feasibility of identifying low or high treatment needs for patients with nAMD using predefined imaging features from automated fluid and layer SD-OCT segmentations. Further confirmation of model performance will contribute to future development of personalized healthcare algorithms.

TITLE: Retrobulbar blood flow in rat eyes in acute ocular hypertension

SESSION TITLE: Animal imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.H. Silverman, R. Urs, G. Tezel, X. Yang, I. Nelson, Ophthalmology, Columbia University Irving Medical Center, New York, New York, UNITED STATES|J.A. Ketterling, Lizzi Center for Biomedical Engineering, Riverside Research, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ronald Silverman: Commercial Relationship: Code N (No Commercial Relationship) | Raksha Urs: Commercial Relationship: Code N (No Commercial Relationship) | Gulgun Tezel: Commercial Relationship: Code N (No Commercial Relationship) | Xiangjun Yang: Commercial Relationship: Code N (No Commercial Relationship) | Inez Nelson: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Ketterling: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Most studies of the effect of acute elevation of intraocular pressure (IOP) on ocular blood-flow have focused on retinal and choroidal flow. This study determined the effect of acute changes in IOP on blood flow velocity in the retrobulbar arteries and veins supplying and draining the eye in a rat model.

Methods: We inserted a 30-gauge needle into the anterior chamber of Sprague-Dawley rats and increased IOP in 10 mm steps to 60 mmHg and then returned to 10 mmHg. After 1 minute at each pressure level (and 3 minutes after return to 10 mmHg), we used a 128-element, 18 MHz linear array probe to acquire plane wave ultrasound data at 3000 images/sec for 1.5 sec. Each image was formed by compounding transmits at 6 angles over ± 6 degrees. After applying a singular value decomposition filter to suppress echo data from slow-moving or stationary tissues, we generated color-flow Doppler images, identified retrobulbar veins and arteries and produced spectrograms from which systolic, diastolic and mean flow velocity and resistance indices were determined (Fig 1). Twenty eyes (1 eye per rat) were examined.

Results: Baseline mean arterial and venous velocities averaged 30.9 ± 10.8 and 8.5 ± 3.3 mm/sec, respectively. Arterial velocity progressively decreased at and above an IOP of 30 mmHg (Fig 2). At 60 mmHg, mean arterial velocity dropped by 55% with respect to baseline, venous velocity decreased by 20% and pulsatility index increased by 75%. Arterial and venous velocities and resistance indices returned to near baseline after IOP was restored to 10 mmHg.

Conclusions: Ocular hypertension directly compresses the retinal and choroidal vasculature, but only indirectly affects the retrobulbar circulation. Our results show progressively decreasing retrobulbar arterial velocities and increasing pulsatility at and above an IOP of 30 mmHg. Venous flow velocity decreased as well, but not as profoundly. The increase in retrobulbar arterial pulsatility index is consistent with compression of retinal vessels. Although the more moderate decrease in venous velocity could be artifactual due to reduced sensitivity to slow-flow, it may be attributable to a decrease in retrobulbar venous lumen diameter as venous blood pressure dropped with decreased volumetric outflow.

ABSTRACT BODY:

Purpose: To develop ML models to predict treatment outcomes in patients with nAMD using baseline (BL) characteristics and optical coherence tomography (OCT) imaging data from patients treated with faricimab in the phase 2 AVENUE (NCT02484690) trial.

Methods: 185 faricimab-treated eyes (80% training; 20% test) were included. 5-fold cross-validation was performed on the training set. Age, gender, best-corrected visual acuity (BCVA), central subfield thickness (CST), low-luminance visual acuity, and OCT images on study day 1, together with treatment assignment, were included in the model. Regression and binary classification models were developed to predict BCVA at month 9 and CST reduction of >35% at month 9, respectively. Symbolic models (linear model and extreme gradient boost tree) were trained on BL characteristics, and deep neural networks (DNNs; based on Inception-v3 with ImageNet weights) were trained on B-scans. Image data and BL characteristics were merged using: (1) a model stacking approach, which uses the prediction from the DNN as one of the input features for the symbolic model, and (2) a model averaging approach, which averages predictions from the DNN using OCT volume and from the symbolic model using BL characteristics.

Results: The BL linear model had an R^2 score of 0.30 and area under the receiver operating characteristic (AUROC) of 0.87. The BL DNN showed an R^2 score of 0.079 for BCVA regression and AUC of 0.70 for CST reduction binary classification. After model stacking with linear model, R^2 score and AUC were 0.32 and 0.87, respectively. The model averaging approach with linear model showed an R^2 score of 0.27 and AUC of 0.85.

Conclusions: The results suggest that the most predictive features for both BCVA and CST at month 9 were captured in BL measurements, and adding image data did not show significant improvements after stacking or averaging given the sample size. This pilot study highlights the potential for ML to support clinicians to make treatment decisions for optimal patient outcomes. To fully explore the predictive capacity of models using image data and ascertain benefits of combining image data with BL characteristics, the methodology needs to be validated on a larger data set.

TITLE: Variability of Retinal Oxygen Metrics in Healthy and Diabetic Subjects

SESSION TITLE: Multidisciplinary imaging technologies and applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Rahimi, S. Leahy, M. Shahidi, Ophthalmology, University of Southern California, Los Angeles, California, UNITED STATES|N.P. Blair, Ophthalmology, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mansour Rahimi: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Leahy: Commercial Relationship: Code N (No Commercial Relationship) | Norman Blair: Commercial Relationship: Code N (No Commercial Relationship) | Mahnaz Shahidi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have reported alterations in total retinal blood flow (TRBF), oxygen delivery (DO_2), oxygen metabolism (MO_2), and oxygen extraction fraction (OEF) due to various retinal diseases. The purposes of the current study were to determine intra- and inter-visit variabilities and establish normal 95% confidence intervals (CIs) for these metrics.

Methods: Twenty-two non-diabetic healthy and 14 diabetic subjects diagnosed with either no diabetic retinopathy (DR) or untreated mild non-proliferative DR participated in the study. Imaging was performed at one visit in healthy subjects and two visits in diabetic subjects. Retinal vascular oxygen saturation (SO_2) and multiple TRBF measurements were obtained using our oximetry system and Doppler optical coherence tomography, respectively. DO_2 , MO_2 , and OEF were calculated from SO_2 and mean TRBF. Intra-visit variability of TRBF was determined by the standard deviation (SD) of multiple measurements, averaged over data in each group. Normal 95% CIs for all metrics were determined in healthy subjects. Inter-visit variability was determined by the difference between measurements at two visits (6 ± 3 months apart), averaged over data in diabetic subjects.

Results: Intra-visit variability of TRBF measurements was 8 μ L/min in both healthy and diabetic subjects. Mean TRBF was 44 ± 15 μ L/min (CI: 37 to 51) in healthy subjects. Inter-visit variability in mean TRBF was 3 μ L/min (CI: -1 to 8) in diabetic subjects. DO_2 and MO_2 were 8.3 ± 2.9 μ LO₂/min (CI: 7.0 to 9.6) and 3.2 ± 0.9 μ LO₂/min (CI: 2.8 to 3.6) in healthy subjects, respectively. In diabetic subjects, inter-visit variabilities of DO_2 and MO_2 were 0.6 μ LO₂/min (CI: -0.3 to 1.5) and 0.1 μ LO₂/min (CI: -0.7 to 0.5), respectively. OEF was 0.40 ± 0.08 (CI: 0.36 to 0.43) in healthy subjects. Inter-visit variability in OEF was 0.03 (CI: -0.09 to 0.02) in diabetic subjects. Mean TRBF, DO_2 , MO_2 , and OEF measurements obtained at both visits in diabetic subjects were within normal CIs and not significantly different than those in healthy subjects ($P > 0.30$). There was an inverse correlation between mean TRBF and age in healthy subjects ($r = -0.45$; $P = 0.03$, $N=22$).

Conclusions: The findings established variabilities and normal baselines for TRBF, DO_2 , MO_2 , and OEF measurements, providing a basis for detecting and monitoring changes due to diseases.

ABSTRACT BODY:

Purpose: As swept-source optical coherence tomography (SS-OCT) evolves, so do the laser acquisition components. Faster laser speeds allow for shorter scan acquisition times, but one trade-off is a reduction of signal that may influence image quality. The purpose of this study was to evaluate images from both the 100 kHz and 200 kHz scanning speeds of a dual-laser SS-OCT system to verify if there were any significant differences in macular thickness measurements.

Methods: Subjects were scanned multiple times with the PLEX[®] Elite 9000 (ZEISS, Dublin, CA) SS-OCT device at both 100 kHz and 200 kHz speeds. A sample of patients from two retinal clinics, predominantly representing eyes with macular degeneration or diabetic retinopathy, were imaged using the Angio 6 x 6 mm scan pattern. Macula thickness measurements were made utilizing the internal limiting membrane (ILM) and retinal pigment epithelium (RPE) as the upper and lower thickness limits respectively. Mean thickness and SDs were determined for the regions of the standard ETDRS target centered at the fovea. Linear regression and Bland-Altman plots were used to evaluate the macular thickness values for the two speeds on the first scan taken and paired t-tests were used to determine p-values.

Results:

Macular thicknesses of 37 diseased eyes from 24 subjects were measured. The mean differences between the macular thickness measurements for the 100 kHz and 200 kHz scanning speeds were less than one micron in most ETDRS regions. No statistical difference was found in any of the regions as shown in Table 1. An example of the regression and Bland-Altman plots for the Central region can be seen in Figure 1.

Conclusions: This study demonstrated that capturing SS-OCT images with the faster scanning speed did not create any significant differences for the measurement of macular thickness in diseased retinas. The faster 200 kHz scan speed should be appreciated by both technicians and patients with shorter scan times and will not make a difference in clinical decision making.

ABSTRACT BODY:

Purpose: Understanding the coexistence of visual and cognitive impairment in older adults could inform prophylactic strategies for age-related cognitive change. Hence, we evaluated the longitudinal associations of vision with cognitive change in two community-based cohorts of older adults.

Methods: In participants of two centers of the ARIC study, presenting and corrected distance visual acuity (DVA), and contrast sensitivity (CS) were measured, for both, better- and worse-seeing eyes. Factor scores for global cognition, memory, executive function and language domains were calculated for ARIC study visits 5, 6 and 7. We quantified the associations of vision measures with cognitive outcomes, stratified by community/race, using generalized estimating equations.

Results: In our entire cohort (n=989), mean (SD) baseline age was 74 (4) years, with 37% males and 45% black Jackson community participants, with the remainder white Washington County community participants.

As hypothesized, we observed that after accounting for potential confounders, in the better-eye, worse presenting DVA was associated with a greater 10-year decline in global cognition, memory, and executive function in Washington County/white group (Table 1). Worse corrected DVA was associated with a greater 10-year decline in executive function in Washington County/white group. Better CS was associated with a less 10-year decline in global cognition, and executive function in Washington County/white group. None of these associations were confirmed in black Jackson participants, and these associations differed by community/race in the full cohort (Table 1).

Weaker associations were observed when worse-eye measurements were used (Table 2).

Conclusions: Our study supports a functional link between some vision measures and cognitive outcomes in older adults, but in only one of the two communities studied. It suggests the potential benefits of maintaining visual function for better cognitive health.

ABSTRACT BODY:

Purpose: Previous study of Parkinson's disease (PD) using optical coherence tomography angiography has described retinal vascular changes at the capillary level. Our cross-sectional analysis aimed to assess the larger retinal vessels in a wider field of view using ultra-widefield imaging (UWF) for retinal vascular manifestations of PD.

Methods: UWF imaging with a scanning laser ophthalmoscope (California, Optos, Marlborough, MA) was performed on 22 patients (31 eyes; mean age=68, SD=7; 64% male) with a clinical diagnosis of PD and 33 controls (51 eyes; mean age=80, SD=6; 61% male). Patients with confounding medical or ocular comorbidities were excluded. The retinal vasculature was analyzed with specialized software (Vasculature Assessment Platform for Images of the REtina; Univs. of Edinburgh and Dundee, UK) measuring vascular network complexity [fractal dimension (D_0)], tortuosity, and average rate of change of vessel width from posterior to anterior (Figure 1). D_0 was measured in a consistent region of interest (Standard ROI) in each image and further subdivided into 2 other ROI (Figure 2).

Results: Comparison of PD and control patients showed no evidence of significant differences in age or sex. No evidence of significant differences in retinal vascular network complexity in any ROI was observed in PD compared to controls. Venular tortuosity was greater in the inferonasal ($p=0.046$) and superonasal quadrants ($p=0.039$) in PD compared to controls. No evidence of statistically significant differences in tortuosity of the retinal venous system was found in any temporal quadrant, or of the arteriolar system in any quadrant. There was no evidence of changes in the average rate of change of vessel width, stratifying by arterioles and venules and by quadrant.

Conclusions: Persons with PD may have more tortuous retinal venules compared to controls. Further analyses of the retinal vasculature using UWF imaging may offer additional insight as well as the potential identification of PD by retinal vascular phenotyping.

ABSTRACT BODY:

Purpose: The aim of this study was to investigate the impact of the OrCam MyEye device on the quality of life in patients with inherited retinal dystrophies (IRD). The OrCam is a portable visual aid device, which is mounted to the frame of eyeglasses, that translates visual information to auditive feedback (e.g. text-to-speech, barcode and facial recognition).

Methods: This prospective, observational study included 20 patients with low vision (BCVA < 20/200 Snellen) due to retinitis pigmentosa (n = 9; 45%) or cone-rod dystrophies (n = 11; 55%). After receiving extensive instructions on the OrCam, patients tested the OrCam for \pm 5 weeks. Interviews were conducted before and after OrCam usage, which included the Dutch version of the NEI-VFQ-25, a modified version of the Dutch Activity Inventory (D-AI), and the OrCam Function Questionnaire (OFQ).

Results: At final visit, a significant improvement in the 'near vision' subscale of the NEI-VFQ-25 was observed ($p < 0.001$), which did not differ between retinitis pigmentosa or cone-rod dystrophy patients ($p = 0.446$). No significant changes were seen in the priority scores of the different goals of the D-AI. The OFQ showed an overall improvement in performing vision-related tasks ($p < 0.001$), although patients reported more difficulty in using the OrCam during lower light situations.

Conclusions: The OrCam MyEye is a promising low vision aid for patients with a IRD that have rehabilitation needs in reading domains. Other functionalities of the OrCam, in the current state, were reported to be less effective, suggesting that these are areas for potential improvement.

ABSTRACT BODY:

Purpose: To assess and compare long-term reproducibility of optical coherence tomography angiography (OCTA) vascular parameters and spectral-domain optical coherence tomography (OCT) thickness parameters in stable glaucoma, glaucoma suspect, and healthy eyes.

Methods: A total of 88 eyes (15 healthy, 38 glaucoma suspect, and 35 non-progressive POAG) of 68 subjects were enrolled who had at least 3 visits within 1 to 1.5 years and both OCT and OCTA (Optovue Inc, Fremont, California, USA) imaging on the same day. A series of vascular and thickness parameters were measured including macula whole image vessel density (wiVD), optic nerve head (ONH) circumpapillary capillary density (cpCD), macular whole image ganglion cell complex (wiGCC) and circumpapillary retinal nerve fiber layer (cpRNFL). Non-progressive POAG eyes were defined using Guided Progression Analysis software (Carl Zeiss Meditec, Inc., Dublin, CA) and fundus photos performed (minimum follow-up of 5 years). A random effects analysis of variance model was used to estimate intraclass correlation (ICC) coefficients and long-term variability estimates. Intra-class correlation (ICC), root mean squared error (RMSE), within-subject test-retest standard deviation (Sw), and coefficient of variation (CV) analyses were obtained to determine long-term reproducibility of OCTA and OCT measurements.

Results: No significant cpRNFL thinning, cpC loss or pfVD loss was observed ($p=0.137$, $p=0.137$, and $p=0.094$, respectively), while pfGCC thinning was detectable over time ($p<0.001$). ICC was lower for OCTA (pfVD 0.823 (95% confidence interval: 0.736, 0.888) and cpCD 0.871 (0.818, 0.912)) compared to OCT (pfGCC 0.995 (0.993, 0.997) and cpRNFL 0.975 (0.964, 0.984)). RMSE was 1.43 and 1.41 for pfVD and cpCD, and 0.65 and 1.41 for pfGCC and cpRNFL. Sw was 1.17 and 1.22 for pfVD and cpCD, and 0.57 and 1.22 for pfGCC and cpRNFL. CV was higher for OCTA parameters (pfVD 2.48 and cpCD 2.61) compared to OCT parameters (pfGCC 0.56 and cpRNFL 1.79).

Conclusions: OCTA-measured macula and ONH vascular parameters have good long-term reproducibility, supporting the use of this instrument for longitudinal analysis. OCTA long-term reproducibility is lower than OCT measured thickness parameters.

TITLE: Low-does atropine might affect alpha ganglion cell signaling in the mouse retina

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Wang, F. PAN, The Hong Kong Polytechnic University, Kowloon, HONG KONG|F. PAN, Centre for Eye and Vision Research Limited, Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): Qin Wang: Commercial Relationship: Code N (No Commercial Relationship) | Feng PAN: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Atropine was used to retard myopia progression in clinic, while its effect on retina is unclear. Therefore, we explored the impact of atropine from concentrations 0.05 μ M to 500 μ M on retinal ganglion cells (RGCs) in the mouse retina.

Methods: Adult C57BL/6J mice, Kcng4-YFP mice, Cx36-knockout mice were used in this study. Retinas (n=5) were removed and immersed in 800 μ M (0.05%) atropine sulfate for 30 minutes and liquid chromatography-tandem mass spectrometry (LC-MS/MS) was used to detect atropine concentration in retina. Alpha RGCs (n=10) were injected with Neurobiotin to show morphology. In electrophysiological recording, retinas were directly applied in atropine and stimulated with 525nm full-field light. ON (n=5) and OFF α RGCs (n=5) were applied with 0 μ M, 100 μ M, 300 μ M, 500 μ M atropine subsequently for does-dependent test. For time and concentration-dependent test, alpha RGCs were recorded before and after application of 0.05 μ M (n=8), 0.5 μ M (n=8), 10 μ M (n=8), 100 μ M (n=9) atropine respectively.

Results: Around 400-fold reduction was detected in retina after 800 μ M atropine applied in cornea and choroid side (1960.0 ± 524.2 nmol/L). No morphological changes were observed after superfusion in 1 μ M atropine for 30 minutes. Atropine over 100 μ M had a does-dependent inhibition effect on light-evoked response in ON α RGCs (300 μ M p=0.048, 500 μ M p=0.001) and OFF α RGCs (300 μ M p=0.048, 500 μ M p=0.003). Application of 100 μ M, 10 μ M, 0.5 μ M, 0.05 μ M atropine had no effect on spike frequency and time latency of original ON or OFF light-evoked responses. Synchronized firing pattern between OFF RGCs was not changed in 0.5 μ M atropine. However, ON responses were induced in certain OFF α RGCs (20% in 0.05 μ M, 37% in 0.5 μ M, 40% in 10 μ M, 33% in 100 μ M). Atropine of 50 μ M extended the threshold of joint inter-spike interval (ISI) distribution of α RGCs.

Conclusions: Atropine of high concentration had inhibition effect on α RGCs firing response, while low-dose atropine did not interfere with spike frequency, synchronized pattern, and threshold of joint ISI distribution of ON and OFF α RGCs. However, atropine induced ON responses from certain OFF RGCs, which suggested unintended consequences on retinal information processing.

TITLE: Approaches to the accuracy in ROP diagnosis

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Pererva, M. Kovalevskaya, Ophthalmology, Voronezhskij gosudarstvennyj medicinskij universitet imeni N N Burdenko, Voronezh, RUSSIAN FEDERATION|

Commercial Relationships Disclosure (Abstract): Oxana Pererva: Commercial Relationship: Code N (No Commercial Relationship) | Maria Kovalevskaya: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To find approaches to the accuracy in retinopathy of prematurity (ROP) diagnosis.

Methods: Group #1 I stage (n=7, 7 eyes), group #2 II stage (n=6, 6 eyes), group #3 III stage (n=4, 4 eyes), group #4 IVA stage (n=3, 3 eyes), group #5 posterior aggressive ROP (PAROP) (n=2, 2 eyes), group #6 (control) - immature retina (n=6, 6 eyes). We use the best pix from RetCam Shuttle (Clarity MS, USA) video, modeling wide-field image, identifying missed the "mute" zones, the localization of the macula and checking the index of traction (Tm), the zone and extension, fractal dimension (Df) and complexity of vascular systems (CVS) (A-1 creation of a preliminary capillary plexus, B-2 normal vascularization, C-3 pathological vasculogenesis). Tm is width-to-length attitude of ellipse (optic nerve head to temporal branches of the retinal vessels). Our original method is a way of stitching images when examining children without anesthesia. Automatic wide-field fundus image algorithm: adaptive filtering, separation of the green channel, applying a Gaussian blur filter, local histogram equalization, the general transformation map. Support of the program for stitching images was at the first stage, the work was done due to the personal contribution of the researcher's. Statistical methods: Mann-Whitney U-test, Spearman's rank correlation coefficient (SPSS)

Results: Result format: Median(25%-quartile;75%-quartile). Group #1 Df 1,31(1,3;1,34), Tm 0,79(0,79;0,83), CVS 1(1;1,25). Group #2 Df 1,38(1,36;1,39), Tm 0,76(0,71;0,78), CVS 1,5(1,5;2). Group #3 Df 1,46(1,45;1,47), Tm 0,68(0,64;0,78), CVS 2,5(2,5;2,63). Group #4 Df 1,55(1,55;1,56), Tm 0,62(0,62;0,66), CVS 3(3;3). Group #5 Df 1,66(1,65;1,66), Tm 1(1;1), CVS 3(3;3). Group #6 Df 1,27(1,27;1,27), Tm 0,95(0,91;0,99), CVS 1(1;1). Strong correlation between Df and stages ($p=0,85$, $p=0,01$); negative correlation Tm and stage ($p=-0,62$, $p=0,01$) except PAROP; strong positive correlation CVS and stage ($p=0,91$, $p=0,001$) were determined. Platform modules for a wide-field image for macula area, morphometry and isolation of the vascular nodules with neural network have been developed.

Conclusions: The developed algorithm fits new ROP screening and treatment control criteria and can be used to identify the stage of the ROP as a holistic picture of the disease on one platform.

ABSTRACT BODY:

Purpose: Split detection imaging in adaptive optics (AO) ophthalmoscopy allows for visualization of cone inner segments, even when retinal pathology disrupts photoreceptor waveguiding. Due to the small field of view of individual AO images, adjacent images are typically montaged. Overlapping images in each montage then must be sorted so that the image with the highest quality is visible and used for further analyses of the cone mosaic. This sorting is currently a laborious manual task. Here, we propose an edge-based measure that enables automated ranking of image quality in AO split detection images.

Methods: Our measure is based on the Canny edge detection algorithm, as implemented in Matlab (2020a). For each image, we run the edge detection and evaluate the proportion of the image occupied by detected edge pixels. Our method has a single threshold parameter which can be used statically to set the detection level, or adaptively chosen to produce a specified percentage of edge pixels. We compared rankings of image quality generated using the proposed approach against those of two human graders, and against two published image quality assessment methods (BRISQUE and PIQE). Using AO split detection montages from 5 choroideremia subjects, we identified 29 image locations, each with a minimum of 4 overlapping images. Each grader ranked every possible pair of images within each location (469 comparisons). The pairwise rankings were then aggregated into an overall ranking for each location using the Bradley and Terry model.

Results: For the pairwise comparisons, the inter-grader agreement was 0.75. The agreement of the automated approaches {Proposed-Threshold, Proposed-Percent, BRISQUE, PIQE} were {0.67, 0.67, 0.52, 0.59} relative to Grader 1 and {0.68, 0.71, 0.43, 0.51} relative to Grader 2. The Spearman correlation of the aggregated rankings across all 29 locations was 0.75 between Grader 1 and 2. The correlation of the aggregated rankings for the automated approaches were {0.60, 0.61, 0.20, 0.34} relative to Grader 1 and {0.59, 0.61, 0.08, 0.21} relative to Grader 2.

Conclusions: Our proposed edge-based image quality assessment generates quality rankings that are comparable to those of trained manual graders, and substantially outperforms two existing methods. This method has potential to reduce manual input to AO montages, thus enabling higher volumes of cone mosaic analyses.

ABSTRACT BODY:

Purpose: Despite its importance in systemic diseases such as diabetes, the posterior eye is difficult to examine for non-specialists. To improve eye care in non-ophthalmology settings, we developed a semi-automated approach with potential for posterior eye disease screening, coupling a robotically-aligned optical coherence tomography system and a deep learning (DL) algorithm to classify the images.

Methods: Between August and October 2020, patients seen at the Duke Eye Center and healthy volunteers (age \geq 18) were imaged with a custom, robotically-aligned OCT (RAOCT) system following clinical eye exam (Fig 1). Using transfer learning, we adapted a preexisting convolutional neural network (Szegedy C, et al. CVPR 2016) to train a DL algorithm to classify OCT images as normal vs. abnormal. The model was trained and validated on two publicly available OCT datasets (Kermany DS, et al. Cell 2018; Srinivasan PP, et al. BOEx 2014) and two of our own RAOCT volumes. For external testing, the top-performing model based on validation was applied to a representative averaged B-scan from each of the remaining RAOCT volumes. The model's performance was evaluated against the reference standard clinical diagnosis. Saliency maps were created to visualize the areas contributing most to the model predictions.

Results: The training and validation datasets included 87,697 OCT images, of which 59,743 were abnormal. The top-performing DL model had a training accuracy of 96% and a validation accuracy of 99%. For external testing, 43 eyes of 27 subjects were imaged with the RAOCT system. Compared to clinical diagnoses, the model correctly labeled 18 out of 22 normal averaged B-scans and 18 out of 21 abnormal averaged B-scans. In the testing set, the model had an AUC for the detection of pathology of 0.92. For the correctly predicted scans, saliency maps identified the areas contributing most to the DL algorithm's predictions, which matched the regions of greatest clinical importance (Fig 2).

Conclusions: This is the first study to combine a DL model with a robotic OCT system, demonstrating a potential platform to automate eye disease screening.

TITLE: Predictors of visual recovery after post-injection endophthalmitis

SESSION TITLE: Endophthalmitis/ trauma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.K. Dong, Central Michigan University College of Medicine, Mount Pleasant, Michigan, UNITED STATES|R.A. Shields, Associated Retinal Consultants, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Libing Dong: Commercial Relationship: Code N (No Commercial Relationship) | Ryan Shields: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Acute infectious endophthalmitis is a known complication following intravitreal injections, occurring at a rate of 0.016% to 0.056% per injection. Given their extensive and persistent use, we sought to evaluate factors associated with worse visual outcomes after post-injection endophthalmitis.

Methods: A retrospective, consecutive case series was conducted on patients treated for post-injection endophthalmitis at Associated Retinal Consultants (ARC) P.C. (Royal Oak, Michigan) from January 2013 thru December 2019. The main outcome measure was change in visual acuity before and after endophthalmitis. Univariate modeling was performed to assess factors associated with visual change.

Results: One hundred and forty six patients were identified who developed post-injection endophthalmitis. The median age at presentation was 78.1 years. The most common indication for treatment was neovascular age-related macular degeneration in 101 patients (69%), followed by proliferative diabetic retinopathy/diabetic macular edema in 29 (20%). Ranibizumab was injected in 68 patients (47%), Aflibercept in 56 patients (38%), bevacizumab in 10 (6.8%), dexamethasone implant in 9 (6.2%), and the remaining 3 (2%) with combination therapy. The median number of injections prior to developing endophthalmitis was 22 (range 1 to 107). The mean time from injection to endophthalmitis development was 4.5 days (range 1 to 17). The vast majority of patients (139 of 146) were treated with an immediate vitreous biopsy and intravitreal antibiotics (TAI) while 7 (of 146) underwent an immediate vitrectomy. Biopsy cultures were obtained in all 146 patients with 56 cultures (39.5%) yielding growth. The mean follow-up time after endophthalmitis development was 839 days (range 34 to 2560). Mean initial logMAR visual acuity (VA) was 0.5 (Snellen 20/63), while mean final LogMAR VA was 0.92 (Snellen 20/166). Risk factors for vision loss after endophthalmitis included culture positivity ($p = 0.017$) and need for vitrectomy ($p = 0.001$). The cumulative number of injections ($r = -0.007$, $p = 0.47$) was not associated with significant vision loss after endophthalmitis (Figure 1).

Conclusions: Although frequently done at recurrent intervals, cumulative injections are not associated with worse visual outcomes following endophthalmitis. Factors that were associated with poor visual prognosis included the culture positivity and the need for a vitrectomy in the post infection period.

ABSTRACT BODY:

Purpose: We showed (Transl Vis Sci Technol. 2020;9(8):27), in a 3-decade follow-up of a patient with Retinitis Pigmentosa (RP), that while the Retinal Blood Vessel Arborization (RBVA) seemed immutable at the optic nerve head (ONH), there were suggestions of vessel movements more peripherally, as the disease progressed. We aimed at further documenting this claim.

Methods: Fundus photographs of patients (N=10) affected with a well-defined retinal degeneration were selected from our ERG databank. To be included, patients had to have at least 3 follow-up visits over a 5-year span at least. Fundus pictures were digitized (Epson Perfection v600 Photo Scanner) and processed (Adobe Photoshop) to extract the arterial and venous RBVAs. These RBVAs were compared intra-individually by overlapping the RBVAs of the 1st visit to next ones using retinal landmarks (i.e., ONH & fovea-macula). Movements were quantified using vessel overlap percentages and angular measurements of displacement at predetermined eccentricities. Results were then correlated with clinical tests such as: visual acuity (VA), visual fields (VFs) and electroretinography (ERG). Standardization of the RBVA method was tested on 18 normal subjects.

Results: The control group had a mean RBVA-overlap value (measures repeated at a 5-week interval) of $96.5 \pm 1.1\%$. In patients, the overlap % at each follow-up visits were always significantly smaller than normal ($p < .05$) and the overlap gradually decreased as the retinal degeneration progressed. As a rule, angular displacements (direction and speed of displacement) were not significantly different between arteries and veins ($p > .05$). Comparing the displacement of the RBVA (overlap % and angular displacement) with other signs of disease progression we noticed a strong correlation with the VF changes (mostly constriction) and ERG measurements [rod and cone b-waves amplitude and Hölder exponent (a Time-Frequency Domain descriptor of the ERG)]. No correlations could be obtained with the VA.

Conclusions: Our study clearly demonstrates that movements of the RBVA is a measurable clinical sign of a progression in retinal degenerative disorders similar to visual field constrictions and ERG attenuations. It remains to be determined if this new diagnostic sign could detect the onset of a retinal degenerative process at an earlier time, a finding that could be helpful in pedigree studies and genetic counseling.

ABSTRACT BODY:

Purpose: Dry eye is a common, symptomatic disease which can significantly decrease quality of life. Inflammation is considered a major part of dry eye disease pathogenesis. Dendritic cells are immune cells that serve a unique role inducing primary immune responses and controlling inflammation on the ocular surface. However, the association between dendritic cell density and dry eye symptoms is not well understood. This study aimed to investigate the relationship between ocular surface discomfort and corneal inflammatory cells in individuals with no and mild to severe dry eye symptoms.

Methods: In-vivo corneal confocal microscopy (IVCM) images from 41 participants (26 females and 15 males), aged 18 to 76 years (mean: 40 ± 15 years) were analyzed. Five to eight images from the central cornea (CC) and four images from inferior whorl (IW) were analyzed for the dendritic cell densities (DCD). For assessment of ocular discomfort, participants were evaluated with the Dry Eye Questionnaire 5 (DEQ-5) and Ocular Surface Disease Index (OSDI) to measure ocular discomfort relating to 3 subcategories covering symptoms, visual function, and environmental triggers. Associations between the DCD and ocular discomfort were determined using Spearman's rho correlation. A p-value < 0.05 was considered statistically significant.

Results: The average OSDI and DEQ-5 scores were 22 ± 16 and 9 ± 5 with a range of 0 to 62 and 0 to 17, respectively. The mean DCD in the CC and IW was 35 ± 41 and 33 ± 81 with a range of 0 to 196 and 0 to 502 cells/mm², respectively. There was a moderate association between DCD at the CC and IW ($r = 0.60$, $p < 0.01$). DCD, at both locations, had no association with DEQ-5 ($r = -0.02$, $p = 0.19$), OSDI ($r = -0.08$, $p = 0.61$) or its 3 subcategories including symptoms ($r = -0.06$, $p = 0.70$), visual function ($r = -0.01$, $p = 0.95$) and environmental triggers ($r = -0.05$, $p = 0.73$). Moreover, no association was found between age, gender and DCD ($r = -0.18$, $p = 0.26$; $r = -0.10$, $p = 0.55$).

Conclusions: DCD had no relationship with ocular discomfort in this study cohort. While DCD in CC and IW indicated correlation, neither OSDI nor DEQ-5 questionnaire showed association with corneal DCD.

TITLE: Structural and Functional Outcomes Following Naked Versus ICG- or IVK-Assisted ERM Peeling

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.L. Podolny, B. Quiram, P.A. Quiram, VitreoRetinal Surgery, PA, Woodbury, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amelia Podolny: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Quiram: Commercial Relationship: Code N (No Commercial Relationship) | Polly Quiram: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many vitreoretinal surgeons elect to mark the internal limiting membrane (ILM) for removal during epiretinal membrane (ERM) peeling. While this practice is thought to reduce ERM recurrence, the reported toxicity of ILM-staining substances remains a concern given the variable visual significance of recurrent ERMs. We sought to examine structural and functional outcomes after surgery for ERM, comparing unassisted “naked” peels to assisted peels utilizing indocyanine green (ICG) or intravitreal Kenalog (IVK) for ILM marking.

Methods: A retrospective analysis was conducted on all adult patients who underwent pars plana vitrectomy and ERM peel with or without ILM marking at a single vitreoretinal surgery practice from 2014 to 2016. The primary endpoints of central macular thickness (CMT) and best-corrected visual acuity (BCVA) were pre- and postoperatively assessed, and outcomes at 1 month, 3 month, and last follow-up after surgery were compared between the two groups. Presence of residual unpeeled ERM, 3-month postoperative cystoid macular edema (CME), and ERM recurrence were evaluated secondarily.

Results: 189 eyes in 183 patients met the inclusion criteria; 120 unassisted and 69 assisted (48 ICG + 21 IVK) operations were performed. Postoperatively, CMT significantly decreased for both groups (-52.9 μ m assisted, $p < 0.001$; -37.6 μ m unassisted, $p < 0.001$), and BCVA significantly improved by the same amount in both cohorts (20/45 to 20/35 assisted, $p = 0.002$; 20/43 to 20/33 unassisted, $p < 0.001$). The instance of residual ERM was greater in the unassisted cohort, but these findings were not statistically significant (68% vs. 57%, $p = 0.054$). The assisted group demonstrated significantly higher rates of CME at 3 months after surgery (17.4% vs. 3.33%, $p < 0.001$), a trend that was observed for both ICG- (16.7% vs. 3.33%, $p = 0.002$) and IVK-assisted (19.0% vs. 3.33%, $p = 0.005$) subgroups as well. ERM recurrence, however, only occurred in the unassisted cohort (8.33% vs. 0%, $p = 0.014$).

Conclusions: Regardless of visual assistance during surgery, CMT and BCVA significantly improved after membrane peeling. Interestingly, patients who underwent ICG- or IVK-assisted peels exhibited a higher incidence of CME after 3 months. Further study is needed to determine if more extensive ERM/ILM peeling may increase the presence of postoperative CME. ERM recurrence was noted only in the unassisted cohort.

TITLE: Reduced oxygen extraction in the retinal periphery when the arterial blood pressure is increased by isometric exercise in normal persons

SESSION TITLE: Diabetic retinopathy/retinal pharmacology/physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Bek, S.K. Jeppesen, Ophthalmology, Aarhus Universitetshospital, Aarhus, DENMARK|

Commercial Relationships Disclosure (Abstract): Toke Bek: Commercial Relationship: Code N (No Commercial Relationship) | Signe Jeppesen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent evidence suggests that the smaller retinal vessels are significantly involved in the regulation of retinal blood flow and that this regulation may differ among the macular area and the retinal periphery. An alternative to studying blood flow regulation in smaller retinal vessels that are difficult to resolve is to assess the metabolic consequences of changes in the microcirculation using oximetry.

Methods: In twenty normal persons aged (mean \pm SD, range) 30.1 \pm 3.8, 24-37 years, the oxygen saturation and diameter of retinal arterioles and venules to the macular area and the retinal periphery were studied before and during an increase in the arterial blood pressure induced by isometric exercise.

Results: The isometric exercise increased the mean arterial blood pressure by (mean \pm SEM) 10.0 mmHg \pm 1.1 mmHg, but induced no significant changes in the diameter of the arterioles ($p=0.83$). The isometric exercise had no significant effect on the oxygen saturation in the arterioles supplying the macular area and the retinal periphery ($p>0.42$ for both comparisons). However, there was a significant increase in the oxygen saturation in venules draining the retinal periphery to reduce the oxygen extraction from (mean \pm SEM) 36.0 \pm 2.3% to 30.6 \pm 2.1% ($p=0.002$), but no significant change in the pre-existing low oxygen extraction in the macular area that changed from (mean \pm SEM) 18.2 \pm 3.0% to 16.2 \pm 1.9% ($p=0.37$).

Conclusions: Minor changes in the arterial blood pressure can induce changes in retinal rheology with significant regional variation. The finding may help explaining regional variations in manifestations of retinal vascular disease such as hyperpermeability in the macular area and capillary occlusion in the retinal periphery.

ABSTRACT BODY:

Purpose: Artificial intelligence (AI)-based diagnosis of retinal diseases using a single imaging method of color fundus photography (FP) or optical coherence tomography (OCT) has been fully investigated.

Although bi-modal imaging examinations using both FP and OCT could provide more comprehensive retinal information than their single-modal counterparts, which might improve the accuracy of AI to detect retinal diseases, the feasibility and performance of bi-modal imaging-based AI diagnosis of retinal diseases have not been extensively investigated.

The purpose of this study is to evaluate the performance of a bi-modal imaging-based AI system in detecting multiple retinal diseases using both FP and OCT images.

Methods: The AI-based system was trained using 573 scans (from 400 patients) centered on macula, validated using 192 scans (from 140 patients), and tested using 209 scans (from another 146 patients). Each scan that captured with Topcon 3D OCT-1 Maestro (Topcon Corp., Japan) consists of one FP and one corresponding radial OCT scan, which further consists of 12 OCT B-scans. Using both images and additional summarized clinical data, at least two ophthalmologists confirmed the diagnosis of each scan, including diabetic retinopathy (DR), dry age-related macular degeneration (AMD), wet AMD, epiretinal membrane (ERM), pathologic myopia (PM), macular oedema (ME), and normal (Fig 1). Performance of this system was measured in terms of sensitivity and specificity, and average precision (AP) per diagnosis.

Results: The bi-modal image-based AI system had a mean AP for the detection of multiple retinal diseases of 0.84 (95% confidence interval [CI], 0.80 - 0.87), a sensitivity of 0.88 (95% CI, 0.84-0.93), and a specificity of 0.91 (95% CI, 0.88-0.95) (Fig 2). Compared with the bi-modal image-based AI system, the mean AP was 0.74 when the AI system was trained with only FP images (95% CI 0.69-0.78), and 0.81 when with only OCT images (95% CI, 0.77-0.84) (Fig 2).

Conclusions: AI-assisted diagnostic system based on bi-modal imaging method showed significantly better performance than that based on FP, and relatively better performance than that based on OCT. The additional information provided by bi-modal imaging method could be used for not only diagnosis, but also perhaps therapeutic decision, which needs further study.

Grossniklaus, Ophthalmology and Pathology, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ogul Uner: Commercial Relationship: Code N (No Commercial Relationship) | Thonnie See: Commercial Relationship: Code N (No Commercial Relationship) | Eszter Szalai: Commercial Relationship: Code N (No Commercial Relationship) | Hans Grossniklaus: Commercial Relationship: Code N (No Commercial Relationship) | Gustav Stålhammar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is the most common primary intraocular malignancy. Mutations in BRCA1 associated protein-1 (BAP-1) is correlated with increased metastatic risk and has been assumed to occur late in tumor progression, though the latter has not been well-studied (Fig. 1). We investigated the spatial and temporal characteristics of UM BAP-1 mutagenesis using mathematical modeling.

Methods: Enucleated eyes with UM were obtained from Emory Eye Center (USA) and St. Erik Eye Hospital (Sweden). After BAP-1 immunohistochemistry, digital image analysis was used to measure each tumor cell size and grade BAP-1 immunoreactivity. Tumor size and DNA sequencing data from The Cancer Genome Atlas were added. A computational model of the proportion of BAP-1 mutant cells as a function of total tumor size was created in SPSS-26, with the ANOVA F-test used for curve fitting.

Results: A total of 156 tumors were included and 8.3 million tumor cells were measured. Tumors with a BAP-1 mutation had significantly larger mean volume than those without (2109 vs. 1552 mm^3 , $p=0.03$). Similarly, tumor cells with loss of BAP-1 expression had significantly larger mean volume than those with retained expression (801 vs. $524 \mu\text{m}^3$, $p=0.04$). The growth of the BAP-1 mutated clone was best fitted to a logarithmic curve (F-score 7, $p=0.01$), with the proportion of mutants to total number of cells described as $-73.6+18.2 \times \ln(\text{tumor volume in } \text{mm}^3)$. The mutation occurred within a UM's second mitosis at a tumor age of 0.8 to 2.8 years and volume of <1 to 37 mm^3 , depending on the UM doubling time used in the calculation. The largest volume corresponds to a lesion with 2 mm in thickness and 6 mm in diameter.

Conclusions: The BAP-1 mutation occurs within 2 tumor doublings, explaining early seeding of liver micrometastases. BAP-1 mutant cells are larger in size and the mutagenesis follows a logarithmic function, a variant of the Gompertzian tumor growth model. Our findings challenge the notion that the critical mutation occurs late in UM and underscores the importance of conducting BAP-1 testing at UM diagnosis.

ABSTRACT BODY:

Purpose: The myocardin-related transcription factor/serum response factor (MRTF/SRF) pathway is a master regulator in fibrosis. We have previously shown that MRTF-B siRNA significantly decreased fibroblast contraction in vitro and conjunctival fibrosis in vivo. Drug delivery is a major hurdle to clinical translation and our aim was to test the efficiency and safety of a novel lipid CL4H6 as a delivery system for MRTF-B siRNA.

Methods: Lipid nanoparticles (LNPs) were prepared by mixing CL4H6 with the helper lipid DOPE and DMG mPEG2k in a molar ratio of 50:50:1. The targeting peptide cY was added to the LNPs and MRTF-B siRNA or control IRR siRNA at a weight ratio of 4:1 (peptide:siRNA). Nanoparticle size, zeta potential and morphology were determined by dynamic light scattering, laser Doppler anemometry and transmission electron microscopy, respectively. SiRNA encapsulation efficiency was measured using the RiboGreen assay. We tested the effects of four LNPs (LNP+MRTF-B siRNA, LNP+cY+MRTF-B siRNA, LNP+IRR siRNA and LNP+cY+IRR siRNA) at three siRNA concentrations (25, 50, 100 nM) on MRTF-B gene expression using real-time qPCR and on cell viability in human conjunctival fibroblasts. We further assessed their functional effects using a 7-day collagen contraction assay. We analysed our results using the student's t-test.

Results: Targeted LNP+cY+MRTF-B siRNA had a size of 211.2 ± 1.9 (SEM) nm, a zeta potential of $+6.9 \pm 0.2$ mV, 0.11 ± 0.02 polydispersity index and were spherical in shape (Fig. 1). siRNA encapsulation efficiency increased from $92.5 \pm 0.7\%$ for non-targeted LNPs to $99.3 \pm 0.1\%$ for targeted LNP+cY+MRTF-B siRNA ($p=0.0005$). Both LNPs effectively silenced the MRTF-B gene in vitro, with the targeting peptide not affecting the silencing efficiency (LNP+cY: 56.5%, 62.1% and 81.5% versus LNP: 55.8%, 77.7% and 80.2%, at siRNA concentrations of 25, 50 and 100 nM, respectively). Targeted LNP+cY+MRTF-B siRNA ($p=0.857$) and LNP+MRTF-B siRNA ($p=0.219$) were not cytotoxic at 50 nM siRNA concentration compared to LNP-IRR siRNA or untreated cells. LNP+cY+MRTF-B siRNA significantly decreased matrix contraction after a single transfection by 27.2% ($p<0.0001$) at day 3 and 10.7% ($p=0.0010$) at day 7, compared to LNP-IRR siRNA.

Conclusions: Targeted CL4H6-MRTF-B siRNA-loaded LNPs represent an efficient and safe therapeutic approach to prevent conjunctival fibrosis after glaucoma filtration surgery.

TITLE: How do RA and SLE patients differ while on long-term hydroxychloroquine therapy?

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Xu, I.M. MacDonald, Ophthalmology and Visual Sciences, University of Alberta, Edmonton, Alberta, CANADA|

Commercial Relationships Disclosure (Abstract): Manlong Xu: Commercial Relationship: Code N (No Commercial Relationship) | Ian MacDonald: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The long-term use of hydroxychloroquine (HCQ) can cause irreversible retinopathy. We performed a prospective study to investigate whether rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients differ in their resilience to HCQ toxicity.

Methods: Patients with RA and SLE referred to the Eye Institute of Alberta and screened for HCQ retinopathy were identified prospectively over a 20-month period. All patients underwent multifocal electroretinography (mfERG), fundus photography, fundus autofluorescence and spectral-domain optical coherence tomographic (OCT) imaging as part of their visits. Data collected included clinical diagnosis, age, sex, HCQ use (daily dose, total dose, duration of use), co-morbid maculopathy, and tamoxifen use. Patients with co-morbid maculopathy were excluded from the analysis. Patients who received a total dose of ≥ 2 kg of HCQ and had no evidence of retinopathy were a priori referred as the "resilient group".

Results: A total of 177 patients were recruited in the study; 8 were excluded due to co-morbid maculopathy, leaving 169 (118 RA and 51 SLE) for analysis. Thirty-six patients were in the resilient group. This group had received a significantly higher total dose (2.36 ± 0.45 vs 1.10 ± 0.54 Kg), duration of use (20.01 ± 5.23 vs 10.60 ± 5.11 years), daily dose (4.70 ± 1.53 vs 3.98 ± 1.29 mg/kg body weight), and had a higher proportion of SLE patients (50% vs 25%) compared to the rest of the cohort (all $p < 0.05$). Comparison between RA and SLE patients reveals that the SLE group had received a significantly higher total dose, duration of use, and had a higher percentage of resilient patients (all $p < 0.05$); they were also 5 years younger on average and had more females (both $p < 0.05$). Nevertheless, no significant difference was found in the percentage of resilient patients among different age groups (< 50 vs $50-69$ vs ≥ 70 years) and between genders (both $p > 0.05$). In terms of HCQ retinopathy cases, the RA group ($n=118$) had 5 (4.2%) suspect, 1 (0.8%) likely, and 3 (2.5%) confirmed cases of toxicity, whereas, the SLE group ($n=51$) had only 1 (2.0%) likely case and no suspect or confirmed cases.

Conclusions: While this is a small study, there would appear to be a significant difference between RA and SLE patients as to their relative resilience to HCQ toxicity based on their underlying clinical diagnosis.

TITLE: Initial Results of the PanOptix Intraocular Lens: A Comparison of Intermediate and Near Vision Acuities of PanOptix and Monofocal Lenses

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Kingrey, Brown University Warren Alpert Medical School, Providence, Rhode Island, UNITED STATES|J. Boomer, T. George, University of Kansas Medical Center, Wichita, Kansas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Brandon Kingrey: Commercial Relationship: Code N (No Commercial Relationship) | Jeff Boomer: Commercial Relationship: Code N (No Commercial Relationship) | Tameka George: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the intermediate and near vision of cataract surgery patients implanted with the PanOptix intraocular lens, and to compare these visions with the acuities of patients implanted with standard monofocal IOL.

Methods: A retrospective comparative study was conducted to determine the postoperative vision in patients implanted with either the PanOptix IOL or a standard monofocal lens. The first 174 eyes implanted with the PanOptix lens from a single surgery center were included in this study. A randomly selected cohort of 103 eyes implanted with a monofocal lens from the same surgery center were included as a comparative control group. The lens power of both the PanOptix and monofocal lens was calculated with the IOL Master using the Barrett 2 formula. Three weeks after cataract surgery and lens implantation, visual acuity was measured using the Snellen chart, Jaeger chart at arm's length, and Jaeger chart at 14 inches.

Results: Among patients implanted with the PanOptix lens, 135/174 (78%) were I5 or better and 96/174 (55%) were I3 or better for intermediate vision. For near vision, 169/174 (97%) had J5 or better and 157/174 (90%) had J3 or better. Among patients implanted with the standard monofocal lens, 25/103 (24%) were I5 or better and 6/103 (6%) were I3 or better for intermediate vision. For near vision, 23/103 (22%) were J5 or better and 5/103 (5%) were J3 or better. Postoperative intermediate and near visual acuities were statistically different between both groups (p value < .001). If spectacle independence is defined as a combination of visual acuity of 20/50, I5, and J5 then 134/174 (77%) of patient's implanted with the PanOptix lens were spectacle free compared to 13/103 (13%) of patients implanted with the monofocal lens.

The preoperative refraction was not statistically significant between the PanOptix and Monofocal groups. 172/174 (99%) of patients in the PanOptix group had 20/50 distance vision or better at three weeks post-op compared with 98/103 (95%) of patients in the monofocal group, and this difference was also not statistically significant.

Conclusions: The intermediate and near vision of the PanOptix lens was far superior to that of the monofocal lens group with similar distance acuities for both. The PanOptix lens allowed for spectacle independence for a large percentage of patients.

ABSTRACT BODY:

Purpose: Neural network performance relies on large, high-quality training sets. In medical image recognition tasks, small datasets and high inter-labeler variance frequently limit models' diagnostic accuracy. In this study, we compare the efficiency of training neural networks to predict disease severity using "comparison" labels versus the traditional method of using diagnostic "class" labels from a retinopathy of prematurity retinal image dataset.

Methods: 100 fundus images were each assigned "class" labels indicating plus disease severity per the majority vote of 3 experts between either "Plus", "Pre-plus" or "No Plus". Additionally, all combinations of image pairs within the set were assigned "comparison" labels reflecting relative disease severity obtained from 5 experts (4950 labels total). Deep learning models were first trained with "class" labels from up to 60 randomly sampled images, and validated on a set of 20 images with "class" labels. Then, this process was repeated using "comparison" labels. All models were then evaluated on a test set of 5561 pre-labeled fundus images in two binary classification experiments: "Normal vs. Abnormal" and "Plus vs. Non-plus". For each model, predictive performance was measured by area under the receiver operating curves (AUC).

Results: For a given number of images, models trained on "comparison" labels consistently outperformed those trained on "class" labels. For the same number of labels, the performance of "class" and "comparison" labels was similar, but models trained on class labels exhibited wider confidence intervals by up to 0.2% in "Normal vs. Abnormal" experiments and 0.4% in "Plus vs. Non-plus" experiments (Figure 1).

Conclusions: "Comparison" labels are more informative per image than "class" labels. Further, the inherent subjectivity of "class" labels generates higher variability in model performance. This offers a solution for training highly accurate image classification models with fewer data.

ABSTRACT BODY:

Purpose: Rabbits regenerate their corneal endothelium readily after lesioning. Humans regenerate their corneal endothelium slowly if at all. FGF1 is an important growth factor in the development of the eye and stimulates regeneration. The purpose of this study was to measure the endogenous FGF1 levels in rabbits and humans to ascertain whether differing FGF1 levels might be involved in the differing levels of regeneration.

Methods: Ocular tissues from rabbit, other species, and human eye tissues were analyzed for FGF1 content using a specific and sensitive ELISA and by western blotting.

Results: The levels of FGF1 in the aqueous humor of rabbits is significantly higher than humans (1.1 ng/ml vs 33 pg/ml, $p < 0.05$). FGF1 levels in aqueous do not appear to be correlated with age. Rabbit Descemet's membrane (+endothelial cells) contains 18 ng/g tissue. Other ocular structures in the rabbit also contain significant levels of FGF1 including the lens and iris/ciliary body.

Conclusions: Human aqueous humor has a low concentration of FGF1 while rabbit aqueous contains much higher FGF1. The levels of FGF1 in rabbit tissues are sufficient to generate a biological effect, while those in humans are not. This may help explain the differences in corneal regeneration between the two species.

ABSTRACT BODY:

Purpose: To devise a low-tech, low-cost, robust, and minimally obtrusive navigational traveling aid - the Visual Impairment Subtle Touch Aid (VISTA) - for people with visual impairments by combining ultrasonic range detection with proportional vibrational output.

Methods: A navigational aid (Fig. 1) was devised using a sensing belt equipped with independent ultrasonic sensors (Ultrasonic HC-SR04 Distance Measuring Transducers) for distance measurements. The sensors were mounted using mobile clips to allow for user adjustability. The sensing belt was connected to a stimulation belt affixed to the ribcage. The stimulation belt used vibrating minidisc motors with vibration relating to (e.g., proportional to) the sensed distance between the belt wearer and surrounding obstacles. Each distance measuring sensor was connected to its assigned set of vibrating minidisc motors via its own Arduino Nano that performed the conversion of the sensed distance to motor vibrations. The proof-of-concept VISTA device was validated through preliminary testing on blindfolded, but fully sighted, persons and one blind person (all authors) in navigating a novel environment without any additional aids, such as a cane.

Results: While scaling the vibrational strength seemed intuitive at first, the near-field "perception" proved insufficient. Through programming the vibrational output to pulse at different intervals depending on the distance from nearby obstacles, i.e., temporal pulsecoding or frequency encoding as opposed to amplitude encoding, the need for a differentiating output was met. In preliminary tests, the devised ultrasonic-sensor-equipped belt and vibration-actuator-equipped vibration belt combination (i.e., VISTA) was capable of informing users of surrounding obstacles in real time while navigating a hallway with several turns.

Conclusions: VISTA is currently limited to level environments, especially indoors: Curbs or stairs still pose significant issues to the user without training or supplementary aids, as these obstacles are below the sensor range and therefore not detected. Miniaturization of VISTA would allow a higher density of sensors on the belt. While certainly not intended as a replacement for the widely and successfully used cane, VISTA may serve as an additional, minimally obtrusive navigational travel aid for the visually impaired to augment the spatial experience of their environment.

ABSTRACT BODY:

Purpose: Visual prosthesis stimulation strategies generally assume a retinotopic mapping of the stimulating electrodes. We investigated perceived phosphene locations versus retinotopic electrode positions in retinal prosthesis recipients to validate this assumption.

Methods: Three end-stage retinitis pigmentosa (RP) recipients (S1-3) of a 44-channel suprachoroidal retinal implant (NCT03406416) performed a mapping task for a subset of electrodes. In each trial a single electrode (or a shorted pair) was activated for 500ms and the subject was instructed to move their eyes (head-fixed) to the location of the phosphene. Perceived phosphene locations were expressed as the change in eye position ($^{\circ}$ of visual arc) between stimulus onset and the end-point of the resulting saccade. Predicted phosphene locations were estimated by comparing electrode locations in fundus photos with theoretical projections in the Drasdo-Fowler schematic eye. In addition, participants performed a square localisation task (10° wide targets, $n=24$) on a 42" touchscreen, and pointing precision was compared to the error between predicted and perceived phosphene locations in the mapping task.

Results: In S1 and S2, phosphene locations correlated well with retinotopic electrode locations. Variability in phosphene location for S1 and S2 was correlated with the eccentricity of the electrode from the fovea (S1: $R^2=0.69$; S2: $R^2=0.81$), suggesting more eccentric electrodes produced less spatially distinct phosphenes. For S3, phosphene locations did not correlate with electrode locations and there was little distinction between the measured locations of different phosphenes, indicating large or spatially indistinct phosphenes. This was associated with worse pointing precision in the target localisation task for S3 compared to S1 and S2 (Kruskal-Wallis $p<0.001$). Variability in phosphene location was not correlated with electrode eccentricity in S3 ($R^2=0.02$). S3 had a more clinically advanced form of RP than S1 and S2.

Conclusions: Retinotopic position was predictive of perceived phosphene location for two of three subjects in an eye-tracker mapping task. In the third subject all phosphenes appeared in a similar region of the visual field and functional performance was worse, presumably due to the distortion of retinal morphology expected with advanced RP. Accurate mapping of spatial perception may improve camera-to-electrode mapping strategies.

ABSTRACT BODY:

Purpose: To evaluate the long-term effect of subthreshold nanosecond laser (SNL) treatment on progression to late age-related macular degeneration (AMD).

Methods: The Laser Intervention in the Early Stages of AMD (LEAD) study is a 36-month trial where 292 participants with bilateral large drusen were randomized to receive SNL or sham treatment in one eye at 6-monthly intervals up to 30-months. After the completion of the LEAD study, the two largest recruiting sites (who recruited 212 participants) offered remaining participants an opportunity to enrol in a 24-month observational extension study, with no further treatments performed. The difference in the time to develop late AMD between those randomized the SNL or sham treatment for participants at these two sites (referred to as the “extension study”) was examined.

Results: Overall, there was no significant difference in rate of progression over a 60-month period in those randomized to the SNL compared to sham group (adjusted hazard ratio [HR] = 0.63; 95% confidence interval [CI] = 0.36 to 1.09; P = 0.098), being a similar finding seen in the 36-month LEAD study. However, there continued to be evidence of treatment effect modification based on the coexistence of reticular pseudodrusen at baseline (RPD; adjusted interaction P = 0.007). Namely, progression was significantly slowed with SNL treatment for those without coexistent RPD (adjusted HR = 0.34; 95% CI = 0.16 to 0.71; P = 0.004), but it was not significantly different for those with RPD (adjusted HR = 1.81; 95% CI = 0.67 to 4.88; P = 0.239).

Conclusions: A 24-month observational extension study to the LEAD trial confirmed that SNL treatment did not significantly reduce the overall rate of progression to late AMD. However, the persistence of a potential beneficial treatment effect in those without coexistent RPD over a longer follow-up duration of 24 months without additional treatment is encouraging. These findings provide further justification for future trials to examine the potential value of SNL treatment for slowing progression in the early stages of AMD.

TITLE: The Impact of Frailty on Perioperative Outcomes after Open-Globe Injury in the Geriatric Population

SESSION TITLE: Cornea Trauma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R.K. Henry, A. Uppuluri, P.D. Langer, M.A. Zarbin, N. Bhagat, Institute of Ophthalmology and Visual Science, New Jersey Medical School, Newark, New Jersey, UNITED STATES|R.K. Henry, Rutgers Robert Wood Johnson Medical School, New Brunswick, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Roger Henry: Commercial Relationship: Code N (No Commercial Relationship) | Aditya Uppuluri: Commercial Relationship: Code N (No Commercial Relationship) | Paul Langer: Commercial Relationship: Code N (No Commercial Relationship) | Marco Zarbin: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Frailty is a state of diminished physiological reserve limiting resolution of homeostasis following a stressor. Frailty is emerging as a powerful risk stratification tool that has been validated across multiple surgical specialties. This study tested the hypothesis that frailty is a risk-factor for perioperative complications following open globe injury (OGI) in the geriatric population.

Methods: This population-level retrospective study analyzed all cases of OGI among geriatric patients (≥ 65 years old) in the US within the Nationwide Inpatient Sample from 2002 to 2014. Patients were dichotomized as either “frail” or “non-frail” using the previously-validated Johns Hopkins Adjusted Clinical Groups (ACG) frailty-defining diagnosis indicator. Baseline characteristics, ocular complications, and clinical outcomes were compared based on frailty status. Multivariable regression tested the association of frailty with mortality and endophthalmitis.

Results: 9144 geriatric OGI patients were identified, 514 (5.6%) of whom were frail. Compared to their non-frail counterparts, frail patients were on average slightly older, (84.0 years vs 80.4 years, $P < 0.001$), female-predominant (75% versus 61%, $P < 0.001$), and of different racial profile ($P < 0.001$). Enucleation rates were higher among frail patients (10.5% versus 7.3%, $P = 0.006$), as were rates of endophthalmitis (3.1% versus 1.7%, $P = 0.022$), in-hospital mortality (5.6% versus 1.7%, $P < 0.001$), length of stay (mean LOS, 9.78 days vs 4.39 days, $P < 0.001$), and total charges billed (\$84,113 versus \$39,911, $P < 0.001$). Rates of orbital floor fracture, globe rupture, and phthisis were not significantly different. On multivariate analysis frailty was a significant independent predictor of endophthalmitis (odds ratio, OR 2.364, 95% CI 1.325-4.218) and in-hospital death (OR 4.244, 95% CI 2.772-6.499, $P < 0.001$).

Conclusions: Among the US geriatric population admitted for OGI (2002-2014), 5.6% had frailty-defining comorbidities. This cohort was slightly older (mean 84 years), predominantly female (75%), and at higher risk for enucleation (10.5%), endophthalmitis (3.1%), and in-hospital death (5.6%) while requiring greater hospital resources (mean LOS 9.78 days, mean total charges \$84,113). Awareness of the impact of frailty on perioperative complications may facilitate risk stratification, perioperative planning, and allocation of resources for this high-risk population.

TITLE: Quality of life impact of eye diseases: a Save Sight Registries study

SESSION TITLE: Visual Function, Vision QoL and visual impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Kandel, V. Nguyen, M.C. Gillies, S.L. Watson, Save Sight Institute, Sydney Medical School, Faculty of Medicine and Health, The University of Sydney, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Himal Kandel: Commercial Relationship: Code N (No Commercial Relationship) | Vuong Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Mark Gillies: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Watson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the quality-of-life (QoL) impact of eye diseases (keratoconus; age-related macular degeneration, AMD; retinal vein occlusion, RVO; and diabetic macular edema, DME) using the Impact of Vision Impairment (IVI) questionnaire, and to determine the relationship between the IVI scores and visual acuity.

Methods: A cross-sectional study was conducted utilizing the Save Sight Registries data. Rasch analysis was conducted on the IVI data using the Andrich Rating Scale Model. Univariate analysis included Welch's t-test, one-way ANOVA, and Pearson's correlation coefficient.

Results: The IVI was completed by 1693 patients; 336 with keratoconus, 1147 AMD, 150 RVO and 60 DME. 735 (54.2%) patients with retinal conditions had received intravitreal therapy. Participants had a mean \pm SD age of 68.0 \pm 22.2 years and 842 (49.7%) were female.

The IVI scales (overall; visual functioning, VF; emotional, EM) had robust psychometric properties including well-functioning response categories, unidimensionality (variance explained > 50%, eigenvalue of the first contrast <3.0), excellent measurement precision (person separation index > 2.0) and satisfactory fit statistics (MnSq, 0.7 to 1.3).

In a group-wise analysis, female patients had lower VF (1.8 vs 2.3), EM (2.3 vs 2.7) and overall (1.7 vs 2.1) logits IVI scores (all $p < 0.05$). The differences in mean VF scores between the diseases were not significant (Keratoconus 2.0, AMD 2.0, RVO 2.1, DME 2.1 logits; $p = 0.998$). Keratoconus patients had worse mean EM scores (Keratoconus 1.7 vs AMD 2.7, RVO 2.7, DME 2.5 logits; all pairwise $p < 0.05$). Similarly, keratoconus patients had worse mean overall IVI score in logits (1.7) than AMD (2.0), RVO (2.0), and DME (1.9), however, the differences were not statistically significant ($p = 0.06$). The IVI overall and subscale scores were similar between retinal conditions (all $p > 0.05$). Pearson's correlations of IVI scores were higher with visual acuity in the better eye (VF 0.41, EM 0.27, overall 0.37) than in the worse eye (VF 0.28, EM 0.24, overall 0.28). Correlations with visual acuity were stronger for VF than for EM subscales.

Conclusions: The IVI was a psychometrically robust QoL questionnaire. Keratoconus patients had worse IVI scores, particularly low EM scores, than patients with retinal diseases. The low strength of correlations between visual acuity and QoL scores, although statistically significant, suggested a complex relationship.

ABSTRACT BODY:

Purpose: To evaluate the toxicity of amphotericin B in OptisolTM-GS corneal storage media (Bausch & Lomb) on corneal epithelial cells (CECs).

Methods: Cornea specimens were dissected from Japanese white rabbit eyes, and then refrigerated at 4°C in OptisolTM-GS, with or without amphotericin B. Storage medium was divided into the following 5 groups (4 corneas per group): Group 1 (control) without amphotericin B (OptisolTM-GS only), and Groups 2, 3, 4, and 5, which included amphotericin B at the concentration of 2.5, 5, 25, and 50 µg/ml, respectively. After 7-days storage, CEC morphology and migration were evaluated. Hematoxylin and eosin staining, immunohistochemical staining (ZO-1), and terminal deoxynucleotidyl transferase-mediated dUTP-digoxigenin nick-end labeling (TUNEL) assay were performed using 7 µm cryosections obtained from the preserved corneas. For the purpose of migration assay, 3 corneal blocks (8 x 3 mm each) from 1 preserved cornea were cultured with Dulbecco's modified eagle medium and Ham's F12 nutrient mixture for 24 hours in a 12-well plate, and the area of CEC migration (2 mm at the central region) onto the stromal surface was then measured.

Results: In Groups 3, 4, and 5, CEC deformity and vacuolation was observed in all preserved specimens. However, CEC morphology was maintained in Groups 1 and 2. The expression of ZO-1 was significantly decreased in the preserved corneal specimens in Groups 4 and 5. TUNEL labelling index (mean±SD) revealed increased CEC apoptosis in Group 3 (48.6±8.7%), which was further aggravated in Groups 4 (59.9±9.0%) and 5 (60.0±7.3%), compared with the control group (33.4±5.8%). The mean CEC migration was inhibited in Group 3 (0.93±0.21mm²), and also in Groups 4 (0.73±0.27mm²) and 5 (0.66±0.12mm²) in a dose-dependent manner, compared with the control group (1.16±0.18mm²).

Conclusions: When added to OptisolTM-GS, amphotericin B was found to be toxic to CECs and inhibit CEC migration. However, our findings revealed that at a concentration of under 5 µg/ml, amphotericin B can be considered safe for use in corneal transplant surgery.

ABSTRACT BODY:

Purpose: To develop an automated tool for choroidal neovascularization (CNV) detection using deep learning (DL) algorithms.

Methods: We evaluated 8527 optical coherence tomography (OCT) images from 521 patients in the as-needed arms of the HARBOR trial (NCT00891735) that evaluated ranibizumab in neovascular age-related macular degeneration (nAMD). Disease activity in the study eye was defined as fluid on OCT (eg, intraretinal fluid, subretinal fluid, subretinal pigment epithelial fluid) or if a patient's visual acuity decreased by ≥ 5 letters from the previous visit. Consequently, disease activity could be defined solely by the presence of retinal fluid associated with underlying CNV on OCT without the requirement of a decrease of ≥ 5 letters relative to the previous visit. In this subset of visits, study eye OCT scans of $1024 \times 512 \times 128$ voxels collected from a Zeiss Cirrus machine were flattened toward the retinal pigment epithelium (RPE) layer, and cropped to 384 pixels above and 128 below the RPE. To accommodate the GPU memory constraints, the central 15 B-scans were selected as representatives. As such, the input size of each scan to the network was $512 \times 512 \times 15$. 3618 scans from diseased eyes and 4909 from eyes without disease were split into training and test sets in a 4:1 ratio using stratified sampling. 5-fold cross-validation was applied only using the training set to optimize parameters. A Squeeze-and-Excitation (SE)-embedded MobileNet was designed to classify eyes with and without CNV. MobileNet greatly reduces model size using depth-wise separable convolutions and the SE module contributes by adaptively recalibrating channel-wise feature response. Weighted cross-entropy was used as a loss function because the number of samples in each class was unbalanced. Data augmentation, including rotation, translation, and flipping, was applied during training.

Results: The model was evaluated on a test set of 1706 images from 102 patients and achieved an area under the receiver operating curve of 0.81 ± 0.012 , with accuracy of 0.76 ± 0.027 , sensitivity of 0.66 ± 0.028 , and specificity of 0.83 ± 0.029 .

Conclusions: Our study demonstrated that a prototype DL model can accurately detect CNV disease activity based on changes in the retinal anatomy on OCT. While this algorithm needs to be validated on other datasets, it could potentially be applied for remote and automated monitoring of nAMD.

ABSTRACT BODY:

Purpose: Rod-Cone dystrophies (RCD) are inherited neurodegenerative diseases characterized by an initial loss of rod photoreceptors (rods) followed by loss of cone photoreceptors (cones) eventually causing blindness. Greater than 1.5 million individuals worldwide are affected by RCD with >65 genes identified. The NXNL1 gene encodes 2 proteins produced by rods, rod-derived cone viability factor (RdCVF) and its full-length isoform, thioredoxin RdCVFL, also expressed by cones, that support cone survival by promoting glycolysis and preventing oxidative damage, respectively. SPVN06 is a novel AAV-based drug candidate encoding both human RdCVF and RdCVFL within the same vector. A single subretinal administration of SPVN06 is expected to protect against cone degeneration in RCD patients independent of the causative mutation. SPVN06 nonclinical safety was evaluated in a 1-month pilot toxicology and biodistribution study in non-human primates.

Methods: Four female cynomolgus monkeys received a bilateral subretinal injection of vehicle (n=1) or SPVN06 (n=3) at 1×10^{11} vg/eye (100 μ L). The animals were observed for one month. A limited toxicological assessment was conducted to assess systemic and ocular safety. Parameters evaluated included clinical observations, body weights, clinical pathology, organ weights and macroscopic observations. Ocular, brain, and liver tissues were microscopically assessed. A comprehensive ocular evaluation including indirect ophthalmoscopy, slit lamp biomicroscopy, intraocular pressure (IOP) measurements, fundus imaging, optical coherence tomography (OCT) and full-field electroretinography (ffERG) was conducted.

Results: There were no systemic effects on any of the parameters assessed. Ophthalmoscopic and microscopic observations were characterized by only minimal posterior uveitis and localized RPE hypertrophy confined to the dose site.

Conclusions: This one-month toxicology and biodistribution pilot study in NHP demonstrated that SPVN06 is well tolerated at 1×10^{11} vg/eye, 100 μ L, following subretinal administration. This study is informing the nonclinical development of SPVN06, a novel AAV-based drug candidate, expected to prevent cone degeneration in RCD patients independent of the causative mutation.

ABSTRACT BODY:

Purpose: Previous genome-wide association studies (GWAS) show that a substantial proportion of genetic risk for autoimmune disease falls within accessible regions of the cell types associated with the disease. Chromatin accessibility provides critical information about DNA cis- and trans-regulatory elements. Despite its importance, much remains to be learned about the noncoding genome and epigenetic regulation in autoimmune eye diseases and pathogenic immune cells. Therefore, we map an epigenetic landscape of chromatin accessibility in peripheral blood from healthy individuals and patients with Vogt-Koyanagi-Harada (VKH) and Behcet's disease.

Methods: This study involved healthy individuals (N=12), patients with VKH disease (N=12), and Behcet's disease (N=13) at Zhongshan Ophthalmic Center, China. Peripheral blood mononuclear cells (PBMCs) were collected and processed using a single-cell assay for transposase-accessible chromatin sequencing (scATAC-seq). The data were aligned to the GRh38 reference genome and quantified by the Cell Ranger pipeline. We employed UMAP, a nonlinear dimensionality reduction method to visualize the data, and MACS2 to perform peak calling. We identified each cell type-specific transcription factor (TF) activity using ChromVAR.

Results: We generated high-dimensional scATAC-seq data in PBMCs and identified diverse epigenetic regulatory landscapes. A detailed analysis of the landscape of healthy individuals showed distinct transcription factor activities in double-negative B cells and unraveled the regulatory trajectory of B cell development. A significant decrease in the frequency of Th2 cells in Behcet's disease patients was noticed compared to healthy individuals ($p=0.0146$). Integration of scATAC-seq data with autoimmune disease GWAS datasets revealed target cell types as well as pathogenic TFs for VKH and Behcet's disease, such as those related to NF- κ B and STAT family.

Conclusions: The application of scATAC-seq enables unbiased identification of cell type-specific active DNA regulatory elements. This study characterizes epigenomic profiles of peripheral immunity and unveils the regulatory programs of VKH and Behcet's disease. These data represent a valuable resource for testing diagnostic and therapeutic strategies against autoimmune eye diseases.

ABSTRACT BODY:

Purpose: Inflammation plays an important role in diabetic macular edema (DME) and contribute to vascular permeability and edema by release of inflammatory cytokines, but little is known about the inflammatory roles of different circulating immune cells among DME patients. We utilized single-cell RNA sequencing (scRNA-seq), an unbiased and high-throughput single cell technology, to clarify phenotype and function of peripheral immune cells in DME.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from DME patients and healthy donors. Single-cell RNA libraries were prepared using the Chromium Single Cell 5' v2 Reagent (10x Genomics) kit. Raw sequence read quality was assessed using FastQC software. Cell Ranger Software was used to generate each sample's gene counts and aggregate them together. R package Seurat v3 was used for data normalizing, clustering, dimensionality reduction, differential expression analysis, and visualization.

Results: We constructed a single-cell RNA atlas comprising 62,916 PBMCs collected from 4 healthy controls and 4 DME patients. We investigated the distribution of the major immune cell lineages, including monocytes, DCs, NK and T, and B cells, using uniform manifold approximation and projection (UMAP). We characterized the expression of canonical lineage markers and other genes specifically upregulated in each cell cluster. Our differential expression gene (DEG) analysis showed that monocytes were enriched of genes participating in the cytokine pathway and inflammation activation. Compared to healthy controls, CD14++ inflammatory monocytes in DME patients had high expression levels of inflammatory genes such as IL1 β , TNF, JUN, FOS, and NF- κ B; and higher expression levels of chemokines, including CCL3, CCL4, and CXCR4. Gene Ontology (GO) and pathway analysis of the DEGs demonstrated that TNF, interleukin signaling, and NF- κ B signaling pathways were enhanced in DME patients.

Conclusions: We reveal a landscape of peripheral blood immune cell subsets in DME patients. CD14++ monocytes exhibit features of chronic stimulation and participate in chronic inflammation through producing inflammatory cytokines. Therapeutic interventions targeting chronic inflammation in monocytes may lead to improved outcomes in patients with diabetic macular edema.

ABSTRACT BODY:

Purpose: Prevalence and severity of glaucoma varies between ethnicities. It has been previously shown that ocular vessel density (VD) varies among healthy subjects of different ethnicities. To further elucidate the potential role of VD in glaucoma we examined ocular VD in Caucasian, African American (AA), and Latin at similar stages of glaucoma severity.

Methods: 150 glaucoma eyes of which 46 eyes (30 subjects) were Caucasian, 71 eyes (43 subjects) African American, and 33 eyes (19 subjects) Latin were included in the analysis. Comorbidities known to affect the systemic or local micro- or macro-vasculature and medications that are known to modify vessel diameter were excluded. Disease severity distribution was similar across ethnicity groups. All eyes had comprehensive ophthalmic examination, Cirrus HD-OCT (Zeiss, Dublin, CA) and OCT angiography (OCTA; Angioplex, Zeiss) qualified scans of the macula and optic nerve head regions (200x200 OCT cube scans and 3x3mm / 6x6mm OCTA scans). VD as provided by the device's native software in the inner vascular plexus was used for the analysis. Statistical analysis was performed using mixed-effects models accounting for ethnicity, age, axial length, visual field mean deviation (MD), OCT signal strength (SS), disc area and intra-subject correlation. Tukey-adjusted p-values for pairwise ethnicity comparisons were obtained.

Results: No significant difference was detected in age and MD among ethnicities (Table 1). Caucasian subjects had the longest AL and thinnest RNFL, and Latin subjects had the largest disc area and cup-to-disc ratio (CDR; Table 1). No significant differences were detected among ethnicities in ONH VD in any of the scan types and regions. In the macula, Caucasians had significantly higher VD in the center of both scan sizes in comparison with both AA and Latin

(Table 2). Caucasian eyes also had significantly higher VD in the full 3x3 scan in comparison with AA eyes. There were no significant differences in the rest of the macular VD measurements among the 3 groups.

Conclusions: Macular VD in glaucoma subjects varies among ethnicities and might play a role in the varying disease behavior among ethnicities. Differences in foveal avascular zone size might explain our findings but further investigation is warranted.

ABSTRACT BODY:

Purpose: Ocular pain is a common symptom of dry eye disease (DED). Our previous work has demonstrated increased levels of the neuropeptide substance P (SP) in DED. SP preferentially activates the neurokinin 1 receptor (NK1R) to mediate an inflammatory response. However, the direct effects of SP in ocular pain in DED are unknown. The purpose of this study was to determine the contributions of SP to ocular pain and inflammation in DED through antagonism of NK1R.

Methods: DED was induced in 6 week old C57BL/6 female mice by housing them in a controlled environment chamber for 14 days. Eye wiping test was performed to evaluate pain after instillation of hypertonic saline (2M NaCl) on days 0, 2, 4, 7, 10, and 14 during DED induction. L-733,060 (1µg/µl), an NK1R antagonist, was administered topically twice per day from day 0 to day 14 after DED induction. Cornea, draining lymph nodes (dLNs), and trigeminal nerve ganglion (TG) were collected on day 14. SP expression in TG and cornea were measured by ELISA. The frequency of MHC-II^{high}CD11b⁺ cells in dLNs was assessed using flow cytometry.

Results: Eye wipe behavior was significantly increased in the DED group compared to the normal group ($P < 0.001$) and the peak was reached on day 4 ($P = 0.02$). Application of L-733,060 to DED mice led to significantly decreased eye wipe behavior at day 4 and 14 ($P = 0.03$). Corneal SP expression levels were 25% lower in the L-733,060 group compared to the untreated DED group ($724 \pm 24 \text{ pg}/100 \mu\text{g}$ vs. $976 \pm 82 \text{ pg}/100 \mu\text{g}$, $P = 0.051$) at day 14. In the TG, no difference in SP level was observed amongst groups ($P = 0.97$). Additionally, the L-733,060 group showed significantly fewer MHC-II^{high}CD11b⁺ cells compared to the untreated DED group at day 14 ($2.82 \pm 0.26\%$ vs. $4.46 \pm 0.24\%$, $P = 0.001$).

Conclusions: Our data demonstrate that antagonism of NK1R simultaneously reduces ocular pain and suppresses inflammation in a murine model of DED, suggesting SP blockade as a new therapeutic strategy in the management of DED.

ABSTRACT BODY:

Purpose: Thousands of phacoemulsification surgeries are performed on eyes with exudative age-related macular degeneration (exAMD) in the United Kingdom each year. Controversy over phacoemulsification's influence on exAMD disease activity limits the information which can inform clinicians' and patients' management decisions. This observational study aims to resolve this by reporting on intravitreal injection (IVI) frequency as a pragmatic marker of exAMD disease activity in a large cohort.

Methods: A cohort of eyes with exAMD (n=327) that underwent phacoemulsification at a single tertiary centre from 2014-2019 were identified. Cases were matched by length of exAMD diagnosis at a specified 'time-zero' within the follow-up of pseudophakic eyes with exAMD (n=327). Data concerning demographics, visual acuity (VA) and intravitreal injection frequency (IVI) before and after 'time-zero'/phacoemulsification were collected. The primary outcome was change in IVI frequency following 'time-zero'/phacoemulsification which was analysed through a 2-tailed Mann Whitney U-test and univariate and multivariable linear regression.

Results: Following 'time-zero'/phacoemulsification' mean reduction in annual IVI frequency was 0.6 injections/year (95%CI 0.4,0.9) and 0.4 injections/year (95%CI 0.1,0.7) in the comparison and phacoemulsification cohorts respectively. Mean VA gain 12 months after phacoemulsification was 11.3 (95%CI 9.2,13.4) early treatment of diabetic retinopathy study (ETDRS) letters, with 214 eyes (65.4%) gaining ≥ 5 ETDRS letters after surgery. On multivariable linear regression, phacoemulsification during follow-up was found to significantly ($p=0.015$) independently increase annual IVI frequency by 0.39 (95% CI 0.07,0.71) injections, with minimal overall direct and indirect effects ($R^2=0.01$). Multivariable linear regression with final VA as the dependent variable found no significant influence from baseline demographics or length of exAMD diagnosis.

Conclusions: Whilst phacoemulsification appears to have a statistically significant independent exacerbating effect on exAMD disease activity, this effect is too small to be considered clinically significant. Phacoemulsification should be offered to patients regardless of exAMD diagnosis and independently of their gender, age and length of exAMD diagnosis.

ABSTRACT BODY:

Purpose: We sought to determine prevalence and types of strabismus in children with craniosynostosis, as well as effects of major and minor cranial suture involvement and craniofacial surgery. Limited published data describe these prevalences.

Methods: Retrospective cohort study of children with craniosynostosis over an 11-year period. Primary outcomes were prevalence and types of strabismus overall, among subtypes of craniosynostosis determined by imaging and intraoperative findings, and pre/post craniofacial surgery.

Results: 726 children with craniosynostosis were studied; mean age 2.9 years (SD 3.7), mean follow-up 3 years (SD 3), 37% syndromic/genetic association. 44% had sagittal fusion, 41% coronal, 31% metopic, 11% lambdoid, 9% minor suture(s). 82% had one major suture fused, 17% had 2-4 sutures. 56% underwent craniofacial surgery. Overall, 261 (36%) children had strabismus, of whom 18% had exotropia, 12% esotropia, 11% vertical, 20% inferior oblique overaction. Considering pre-craniofacial-surgery exams, if one major suture was fused, strabismus risk was 15-18%, except for coronal, which was 47%. Strabismus prevalence increased with number of fused major sutures (30% for 1, to 70% for all 4). Craniofacial surgery increased strabismus (26% versus 33%, $p=0.03$), but some pre-op strabismus resolved postoperatively. Vertical strabismus was associated with unilateral (36%) versus bilateral coronal synostosis (9%, $P<0.001$). Exotropia was associated with minor suture fusion (32% vs. 16%, $p=0.01$).

Conclusions: Craniosynostosis carries a 36% risk of strabismus, a 15-fold increase versus the general population, and this risk varies with number and type of sutures involved.

ABSTRACT BODY:

Purpose: To evaluate the potential impact of pegcetacoplan on nascent geographic atrophy (GA) lesions by analyzing their progression in patients who received either intravitreal pegcetacoplan monthly (PM) or sham treatment (S) in the phase 2 multicenter, randomized, single-masked, sham-controlled FILLY study through a post-hoc analysis.

Methods: Patients from the PM (n=42) and S (n=69) arms of the FILLY study who did not develop exudative AMD and completed the month 12 study visit were included in this analysis. The evaluation was based on examination by masked readers of optical coherence tomography (OCT) scans outside a perimeter of 500 microns from the GA border according to the Classification of Atrophy Meetings (CAM) guidelines. The primary outcome measures were a) progression from large drusen to incomplete/complete retinal pigment epithelium (RPE) and outer retina atrophy (iRORA and/or cRORA) and b) progression from iRORA to cRORA at baseline, 6 months, and 12 months.

Results: At baseline, large drusen were observed in 81% (33/41) of patients in the PM group and 74% (49/66) of patients in the S group; iRORA was present in 46% (19/41) and 55% (36/66) of patients in the PM and S groups, respectively. At 12 months, progression from large drusen to iRORA/cRORA occurred in 22.6% (7/31) and 33.3% (15/45) of the PM and S groups, respectively (p=0.31). At the lesion level, these rates were 9.1% (11/121) and 11.9% (21/177) in the PM and S groups, respectively. Progression from iRORA to cRORA was 50.0% (9/18) and 81.8% (27/33) in the PM and S groups, respectively (p=0.02), indicating a lower rate of progression from iRORA to cRORA (39% reduction) in pegcetacoplan-treated eyes. At the lesion level, these rates were 35.5% (11/31) and 64.3% (45/70) in the PM and S groups, respectively.

Conclusions: Eyes receiving monthly intravitreal pegcetacoplan had lower rates of progression from nascent GA to GA compared to sham-treated controls, suggesting a potential role for pegcetacoplan earlier in the course of GA.

ABSTRACT BODY:

Purpose: To predict BCVA from CFP images acquired from patients with neovascular age-related macular degeneration (nAMD).

Methods: We performed a retrospective analysis of CFP images and associated BCVA measurements from the phase 3 MARINA (NCT00056836) and ANCHOR (NCT00061594) trials for nAMD. Using the Inception-ResNet-v2 convolutional neural network, a DL regression model was developed to predict BCVA at the concurrent visit from CFP images. A binary classification model was also developed to predict BCVA of < 69 letters (Snellen equivalent of < 20/40) at the concurrent visit from CFP images. Models were trained and tuned via 5-fold cross-validation on 36,541 images from 707 patients in MARINA and tested on an external validation test set of 33,591 images from 413 patients in ANCHOR. Images used for training and testing were acquired from study and fellow eyes at all available visits (screening through month 24). Internal capture fields of F1M, F2, and F3M from left and right stereo views were included, whereas external views of the eye were excluded from the analysis. To remove extraneous information, RGB images were cropped to fit the circular field of view of the CFP and resized to 299 × 299 pixels. To evaluate model performance, the coefficient of determination (R^2) was used for regression, and the area under the receiver operating characteristic curve (AUROC) was used for classification. Predictions for each image were averaged to the patient-eye-visit level. To account for the distance at which BCVA was measured, metrics were calculated for the corresponding chart distances of 2 and 4 m. Models were evaluated based on the in-sample cross-validation tuning set (MARINA) and out-of-sample test set (ANCHOR).

Results: In the regression model, R^2 for predicting BCVA at a chart distance of 2 and 4 m was 0.58 (95% CI, 0.57, 0.60) and 0.60 (95% CI, 0.56, 0.63), respectively, in the test set (Table 1). In the classification model, AUROC for predicting BCVA of < 69 letters at a chart distance of 2 and 4 m was 0.86 (95% CI, 0.85, 0.87) and 0.88 (95% CI, 0.86, 0.89), respectively, in the test set.

Conclusions: Out-of-sample, the identified DL model demonstrates a relatively strong association between the information extracted from the CFP images and visual acuity as measured by BCVA.

ABSTRACT BODY:

Purpose: Brimonidine (brimo) drug delivery system (DDS) has been evaluated as a long-acting therapy for the treatment of geographic atrophy (GA) secondary to AMD. Our objective was to delineate the role of brimo as a cytoprotective agent using a human iPSC-derived RPE in vitro model of dry AMD.

Methods: RPE cells were differentiated from iPSC derived from healthy or albino individuals. iPSC-RPE monolayers were matured for 6 to 8 weeks using a previously published protocol that supports the development of key RPE phenotypic features, including polarized expression of RPE specific markers and cytokine secretion, transepithelial potential and resistance, fluid transport and phagocytosis (Sharma et al., 2019). The effects of melanin binding were assessed by comparing supernatant and cell-associated brimo concentrations in pigmented versus albino iPSC-RPE. Pigmented iPSC-RPE were then challenged with complement-competent human serum (CC-HS) to mimic AMD-like conditions. Challenge with CC-HS induces loss of transepithelial resistance, disrupted RPE morphology and sub-RPE lipid deposition. These changes are characteristic to the phenotypic changes of the RPE in dry AMD. We assessed brimo's ability to prevent CC-HS-induced phenotypic changes.

Results: Dose-dependent binding of brimo to melanin was observed in pigmented iPSC-RPE cells with 2- to 6-fold lower brimo concentrations in the supernatant after 24 hr incubation compared to albino RPE cells. No brimo-induced cytotoxicity was observed at concentrations up to 30 mM. Subsequent experiments were conducted at concentrations of 0.3 and 3 mM. Pretreatment of iPSC-RPE cells with brimo prevented CC-HS-induced transepithelial resistance reduction and deposition of lipid droplets. Further, we observed partial restoration of cyclic adenosine monophosphate (cAMP) and intracellular calcium levels in CC-HS-challenged iPSC-RPE cells treated with 3mM brimo. These data suggest that brimo has cytoprotective properties and preserves key functional RPE characteristics, restoring homeostatic mechanisms in cells challenged by an AMD-like insult.

Conclusions: In conclusion, our results demonstrate the cytoprotective effects of brimo in a validated model of complement-mediated RPE AMD-like physiology and support development of brimo drug delivery system (DDS) as a novel therapeutic for GA secondary to AMD.

ABSTRACT BODY:

Purpose: Dry eye disease (DED) is a chronic, multifactorial disease of the ocular surface. The purpose of this real-world clinical study was to assess the baseline characteristics and treatment outcomes in DED patients treated with lifitegrast for up to 12 months in the US and Canada.

Methods: A retrospective, non-comparative, optometrist and ophthalmologist panel-based chart review cohort study design including patients who initiated lifitegrast treatment between January 1, 2017 (US) or 1 January 2018 (Canada) and June 30, 2019 with an index date defined as the first day of lifitegrast treatment. Signs (corneal staining score; tear film break-up time) and symptoms of DED (eye dryness; blurred vision; ocular burning/stinging; foreign body sensation; ocular pain) were evaluated during the 6-month pre-index period and after 6 and 12 months of treatment with lifitegrast.

Results: A total of 600 lifitegrast-treated DED patients (76% female, mean age [standard deviation (SD)] 57 [13] years) were included in the study. Initial diagnosis of DED was determined by optometrists in 262 (44%) patients and ophthalmologists in 332 (55%) patients. Mean time from DED diagnosis to lifitegrast prescription was 23.3 months (SD 42.7) overall, and 31.5 (55.0), 23.8 (35.3) and 22.7 (48.4) for patients who initiated lifitegrast in 2017, 2018 and 2019, respectively. A total of 512 patients (92%) remained on treatment with lifitegrast at the 6-month follow-up period. Signs and symptoms of DED at the 6-month pre-index period (n=600 patients), Month 6 (n=534 patients) and Month 12 (n=320 patients) of follow-up, respectively were: (Fig. 1a-c, percentage of patients): eye dryness ([pre-index; Month 6; Month 12]: 87%; 7%; 3%); blurred vision (59%; 5%; 3%); ocular burning or stinging (55%; 3%; 1%); foreign body sensation (50%; 2%; 2%); ocular pain (12%; 1%;1%); corneal staining score (range 0–15) (median [95% Confidence Interval (CI)]: 6 [6–7]; 2 [1–5]; 2 [1–3]); tear film break-up time (median [95% CI]: 4 [3–12]; 8 [7–9]; 8 [7–8] seconds).

Mean (SD) treatment duration for these patients was 28.5 (10.6), 15.9 (5.2) and 8.8 (2.6) months for patients with index dates in 2017, 2018 and 2019, respectively.

Conclusions: Lifitegrast significantly improved several signs and symptoms of DED in this real-world observational study, with the majority of patients remaining on treatment throughout the 12-month follow-up period.

ABSTRACT BODY:

Purpose: Retinal neuron dysfunction and cell death have been observed across many visual impairment diseases (including age-related macular degeneration, retinitis pigmentosa, glaucoma, and diabetic retinopathy) and treatment options are limited. This study aimed to determine the neuroprotective effect of the investigational drug, risuteganib (RSG), in cultured retinal neuron (RN) cells exposed to excitotoxic damage and retinal degeneration in an experimental optical nerve clamp rat model.

Methods: In RN cells, excitotoxic damage was induced by kainic acid (KA). Primary mouse neuronal cells (n=8) were exposed for 24 h to culture medium only (SSB), 50 μ M KA, or KA + 1mg/mL RSG added either 24 h before or after KA treatment. After treatment, the number and viability of cultured cells were measured using WST-8 and LDH assays. The student's t-test was used for statistical analysis. In an optical nerve clamp study, a total of eight rats were evaluated to assess the protection of ganglion cells. Animals were intravitreally injected 1.28 mg RSG (n=5) or SSB (n=3) 24 h before 60-minute optic nerves crush (ONC), followed by 48 h rest and ganglion cell survival assessment. Wilcoxon Matched-pairs signed ranks test was used for statistical analysis.

Results: Exposure to KA decreased the viability of cultured cells by 40 ± 1.0 % ($P < 0.05$). The cells treated with RSG either before or after KA showed significantly less damage (10 ± 1.5 or 18 ± 1.0 % viability reduction, respectively; $p < 0.05$). LDH assay showed none of the experimental conditions had a detectable alteration in membrane cell structure. Eyes from rats subjected to ONC and injected with vehicle had 10.09 ± 8.622 ganglion cells per field, while those treated with RSG demonstrated 19.46 ± 8.406 ganglion cells per field ($p = 0.0001$).

Conclusions: Our findings showed RSG induced a clear reduction in the cytotoxic effect generated by an excitotoxic condition in cultured retinal neurons. This effect is more prominent when RSG was applied previously to excitotoxicity generated by KA. Additionally, a statistically significant ganglion cell protective effect was observed in the ONC rat model. Altogether, these findings suggest RSG may have neuroprotective properties relevant to human retinal diseases. Nonetheless, additional studies are needed to further clarify this mechanism of action.

ABSTRACT BODY:

Purpose: We studied time series trends for incidence rates of rhegmatogenous retinal detachment (RRD) repair, retinal break (RB) treatment, posterior vitreous detachment (PVD), and cataract surgery (CS) to investigate seasonal variation and differences among age, race, and sex using the IRIS Registry.

Methods: RRD repair, RB treatment, and CS were based on CPT codes. PVD diagnosis was based on ICD-9/10 codes. Daily incidence rates were calculated during a 5 year period (2014-2018) and defined as the ratio of number of patients diagnosed with RRD, RB, PVD, and CS to the total number of patients followed on a given day. CS group was included as a comparison for seasonal variation given its elective nature. Rates were stratified by decade of life (DOL), sex, and race.

Results: A total of 2,996,982 patients were diagnosed with incident PVD. Patients undergoing RRD repair (n=248,765), RB treatment (n=367,323) and CS (n=6,132,138) were included. The mean daily incidence for RRD, RB, PVD, and CS were 0.5, 0.7, 5.1, 12.2 per 100,000 patients, respectively (Figure 1). The highest incidence of RRD was in the 5th and 6th DOL. Men had higher incidence of RRD repair than women, whereas women had higher incidence of PVD. RRD incidence was higher in Whites compared to others. Time series showing seven day moving average point incidence for RRD repair, RB treatment and PVD by sex and age demographics is shown in Figure 2. Seasonal variation in RRD repair, RB treatment, PVD, and CS corresponded to national holidays with larger fluctuations in winter months.

Conclusions: The higher incidence of RD repair and RB treatment in men compared to higher PVD incidence in women may suggest an inherent sex-related risk. The seasonal variation associated with holidays was less pronounced for RRD repair and RB treatment.

ABSTRACT BODY:

Purpose: Complement dysregulation is implicated in geographic atrophy (GA). Complement component 3 (C3) is the convergence point for all three activation pathways. NGM621, a potent ($K_D=0.34$ nM) monoclonal antibody that inhibits C3 cleavage and blocks the complement cascade and downstream effects, is under development to reduce GA progression. The Phase 1 study (NCT04014777) evaluated the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of NGM621.

Methods: Fifteen enrolled patients had GA secondary to age-related macular degeneration in at least one eye, were ≥ 50 years of age, and had GA lesion area of ≥ 2.5 mm² and ETDRS best-corrected visual acuity (BCVA) between 54 and 4 letters in the study eye. In the single-dose cohort (n=9), intravitreal NGM621 (2, 7.5, or 15 mg) was

administered to three patients per dose; in the multidose cohort (n=6), patients received two 15-mg doses 4 weeks apart. Patients were monitored and assessed for 12 weeks. Assessments included BCVA, intraocular pressure (IOP), optical coherence tomography, fundus autofluorescence, serum NGM621 concentrations, and systemic complement activity (CH₅₀).

Results: All 15 patients completed the study; 60% were men, the median age was 80.0 years (68-90), the mean (SD) GA lesion area measured 14.9 mm² (10.8), and 86.7% of lesions involved the fovea at baseline. There were no observed drug-related AEs, no SAEs or deaths, no endophthalmitis, no intraocular inflammation, and no cases of choroidal neovascularization in any eyes. The maximum evaluated dose, 15 mg, was well tolerated in the single-dose and multidose cohorts. As expected, IOP showed acute increases 15 minutes after injection, returned to normal levels within 60 minutes, and was not meaningfully impacted over time. Serum exposures appeared dose proportional, indicating linear PK in the studied range. NGM621 serum exposure was below concentrations that produce systemic complement inhibition at the highest intravitreal dose of 15 mg, and all patients were ADA negative at all time points. GA lesion area and BCVA were generally stable over the 12-week study duration.

Conclusions: In this Phase 1 dose-escalation study, NGM621 up to 15 mg was well tolerated and had a favorable PK/PD profile in patients with GA. NGM621 is being further studied in GA in the ongoing Phase 2 CATALINA study (NCT04465955).

ABSTRACT BODY:

Purpose: Endophthalmitis is a rare but serious postoperative complication following ocular surgery. We performed a retrospective observational study to investigate whether same-day bilateral cataract surgery is associated with increased risk of endophthalmitis.

Methods: IRIS® Registry patients who underwent cataract surgery between 2013 and 2018 were evaluated for development of endophthalmitis within two weeks of surgery. Multivariable logistic regression models were fit to assess the risk of endophthalmitis associated with same-day surgery adjusting for age, sex, insurance type, and history of common eye disease (age-related macular degeneration, diabetic retinopathy, and glaucoma) at the subject level, and to assess whether these covariates were associated with different risk of endophthalmitis between the two surgery types. Potential cases of bilateral endophthalmitis were identified and records from these patients were reviewed to confirm endophthalmitis was bilateral.

Results: There were 5,573,639 patients who underwent cataract surgery. A total of 165,609 (3%) had same-day bilateral cataract surgery and 5,408,030 (97%) had unilateral or delayed sequential bilateral surgery. A total of 3,083 (0.055%, 95%CI [0.053, 0.057]) developed postoperative endophthalmitis. Of these patients, 74 (0.045% [0.035, 0.056]) had same-day surgeries and 3,009 (0.056% [0.054, 0.058]) had unilateral or delayed bilateral surgery. Same-day bilateral cataract surgeries were not associated with increased risk of postoperative endophthalmitis (OR: 0.79 [0.60, 1.01]). The risk profile of postoperative endophthalmitis was similar between the two surgery groups (Figure). The six (0.0001%) cases of bilateral endophthalmitis that occurred were all in the delayed sequential group.

Conclusions: Rates of postoperative endophthalmitis were similar to previous literature and the rate of bilateral endophthalmitis was low. Same-day bilateral cataract surgery was not associated with increased risk of endophthalmitis after cataract surgery and did not lead to any cases of bilateral endophthalmitis.

ABSTRACT BODY:

Purpose: To compare manual measurements of optic nerve head ovality index (OI) and rotation angle based on the clinical disc margin identified on optic disc photographs with automated measurements based on Bruch's membrane opening (BMO) from optical coherence tomography (OCT) scans in healthy, non-myopic and myopic eyes.

Methods: 201 healthy or glaucomatous eyes of 166 study participants enrolled in the Diagnostic Innovations in Glaucoma Study were stratified by level of axial myopia (non-myopic, mild-myopic and high-myopic with axial length > 26 mm). Using ImageJ software, the clinical disc margin of each photograph was manually annotated and the major axis length, minor axis length and angle of major axis from horizontal axis of the annotation were measured and used to derive OI, rotation angle and direction. These derived values were compared to those generated from automated, custom-programmed BMO-based techniques using segmented OCT volumes. R^2 values from linear mixed effects models were used to describe the associations between manual, photograph-based and automated, OCT-based assessment.

Results: Average (95% CI) axial length was 23.3 mm (23.0 mm, 23.3 mm), 24.8 mm (24.7 mm, 25.0 mm) and 26.8 mm (26.6 mm, 27.0 mm) in non-myopic, mild-myopic and high-myopic eyes, respectively (ANOVA, $p \leq 0.001$). The R^2 association (95% CI) between manual photograph-based and automated OCT-based assessment of disc OI for all eyes was 0.26 (0.16, 0.36; $p < 0.001$). This association was weakest in non-myopic eyes (0.09 [0.01, 0.26; $p = 0.016$]), followed by mild-myopic eyes (0.13 [0.02, 0.29; $p = 0.004$]) and strongest in high-myopic eyes (0.40 [0.19, 0.60; $p < 0.001$]). No significant associations were found between photography- and OCT-based assessment of rotation angle with R^2 values ranging from 0.00 (0.00, 0.08) in non-myopic eyes to 0.03 (0.00, 0.21) in high-myopic eyes (all associations $p \geq 0.33$).

Conclusions: Weak associations between manual photograph-based and OCT BMO-based assessment of optic disc ovality and lack of associations between assessment of disc rotation angle indicate that measurements based on these methods cannot be used interchangeably and results should not be directly compared.

ABSTRACT BODY:

Purpose: The Flatten Inaccessibility survey was administered from April 3 to 13th, 2020 to investigate the experiences of adults with low vision or blindness during the COVID-19 pandemic. Using this data, we aimed to look at characteristics associated with concerns accessing and utilizing healthcare during the pandemic among participants.

Methods: Survey questions related to healthcare access and utilization included: (1) getting to a pharmacy for prescriptions, (2) ability to maintain their eyecare regimen, and (3) concerns regarding caregiver access should they be hospitalized for COVID. Responses of "strongly agree" or "agree" were classified as having a concern. Multivariable logistic regression was used to determine the association between demographic characteristics and age of onset of visual impairment (VI) with each concern.

Results: 1,921 participants responded to the survey, of whom 65% were blind and 35% had low vision. Table 1 presents demographic characteristics.

In regression analysis, females (OR=1.4, 95% CI=1.08-1.74) were more likely to have concerns regarding access to a pharmacy to get prescriptions than males, but no gender differences were noted for maintaining eyecare regimen or caregiver access. As compared to participants with congenital VI, participants with adult-onset VI were more likely (OR=1.8, 95% CI= 1.32-2.45) to report concerns regarding their ability to maintain their eyecare regimen, but no differences were observed for pharmacy or caregiver access. Participants with onset of VI at 2-18 years of age (OR=1.6, 95% CI= 1.16-2.14) and >18 years (OR=1.3, 95% CI= 1.00-1.69) were more likely to report concern regarding access to a caregiver if hospitalized than those who had congenital VI. Participants with additional disabilities were more likely to report concerns across all three healthcare questions (Pharmacy access: OR=1.8, 95% CI= 1.43-2.23; Eyecare regimen: OR=1.7, 95% CI= 1.32-2.23; Caregiver: OR=1.73, 95% CI= 1.39-2.14) compared to those with vision loss only.

Conclusions: Our data found that among Americans with low vision or blindness, older adults, females, people with adult onset VI, and multiple disabilities were more likely to report concerns with healthcare access and utilization during the COVID-19 pandemic. This study provides information that may aid policymakers as they shape the pandemic response for people with vision loss.

ABSTRACT BODY:

Purpose:

Prior incisional glaucoma surgery is a known risk factor for graft failure and decreased visual function after penetrating keratoplasty (PK). However, little is known about the risk factors regarding specific types of glaucoma surgery and role of intraocular pressure (IOP)-lowering medications on graft outcomes. We aimed to determine an association between PK outcomes and glaucoma surgical and medical interventions.

Methods:

In this retrospective cohort study, electronic medical records at Wills Eye Hospital were queried for PKs performed between May 1, 2007 and September 1, 2018 in patients with glaucoma incisional surgery prior to PK. We obtained details of the type of glaucoma surgeries, topical and systemic treatments, and IOP before and after PK. The main outcome measures included graft failure and rejection.

Results:

We identified 148 PKs of 148 eyes (148 patients) who had glaucoma surgery prior to PK. IOP-lowering medications established by 3 months after PK and type of glaucoma surgery are shown in Table 1. The mean baseline IOP and maximum postoperative IOP for this population were 15.5 (SD=5.3) and 25.9 (SD=8.4) mmHg, respectively. Graft rejection was associated with maximum postoperative IOP ($p=0.011$) and IOP difference ($p=0.015$), defined as the difference between baseline IOP and maximum postoperative IOP. Graft failure was associated with higher maximum postoperative IOP ($p<0.001$), higher baseline IOP ($p=0.041$), IOP difference ($p=0.017$), and younger age ($p=0.006$). We did not detect a significant association between prior tube shunt surgery and graft rejection, but this relationship approached statistical significance ($p=0.093$). Other relationships that approached statistical significance include graft failure and use of topical carbonic anhydrase inhibitors (CAIs) ($p=0.070$) and the use of systemic CAIs among patients with tube shunts in the anterior chamber ($p=0.052$).

Conclusions: In patients with a history of glaucoma surgery prior to PK, increased IOP both before and after PK is associated with worse graft outcomes. Future studies are needed to determine a possible relationship between graft failure and postoperative use of CAIs or prior tube shunt placement. Our results suggest that medical and surgical risk factors should be considered when optimizing PK outcomes in patients with prior glaucoma surgery.

ABSTRACT BODY:

Purpose: Visual impairment (VI) and physical limitations are common in the older population. However, their associations are yet to be explored in adults 70 years and older. We report the distribution of VI, contrast sensitivity impairment (CSI) and their associations with physical disability and quality of life (QoL) in an aging population-based sample.

Methods: In this cross-sectional analysis, participants from the Atherosclerosis Risk In Community cohort were recruited for the Eye Determinants of Cognition Study, including 494 black participants from Jackson, MS and 558 white participants from Washington County, MD. Distance presenting, corrected, and near VI was categorized as mild (20/40-20/60) and moderate or greater (<20/60) using better-eye acuity. CSI was categorized as moderate (1.04-1.50 logCS) and severe or profound (<1.04 logCS). Physical ability was assessed using the short physical performance battery (SPPB) and self-reported functional limitations, difficulty with activity of daily living (ADL) and instrumental ADL (IADL), physical QoL scores were derived from Short Form 12v2 Health Survey. Associations of VI, CSI with physical abilities were explored overall and by community.

Results: Mean age was 80 years, 63% were female, and 15% had distance presenting VI. Corrected VI (2.6% vs 5.5%), near VI (19% vs 38%), and CSI (70% vs 80%) were less prevalent in Jackson (all $P < 0.05$). Overall, moderate or greater near VI was associated with higher rates of IADL disabilities (prevalence ratios [PR]=1.54, 95% confidence interval [CI]: 1.18-2.02) and lower SPPB scores. Similarly, significant associations were found between moderate or greater presenting VI with functional limitation and lower SPPB scores; and between CSI with functional limitation, and lower physical QoL and SPPB scores. Stratified analysis showed stronger associations in Jackson than Washington County, e.g., Jackson participants with severe & profound CSI showed higher rates of IADL disabilities ($PR_{\text{Jackson}} = 2.11$, 95% CI: 1.13-3.95; $PR_{\text{Washington}} = 1.15$, 95%CI: 0.50-2.66).

Conclusions: Distance VI, near VI and CSI were associated with poor physical function and reduced QoL. These associations should be understood in the context of the communal differences. They call for public health endeavors to address VI and CSI to optimize physical ability and QoL in the older adults with poor vision.

ABSTRACT BODY:

Purpose: Ophthalmic diagnostic imaging is indispensable to clinical practice. Historically, metadata harmonization between different device manufacturers and modalities has been challenging due to insubstantial compliance with the universal Digital Imaging and Communications in Medicine (DICOM) standards, which presents hurdles to patient clinical record linkage. Here, we retrieved and integrated patient-level DICOM file meta-data from two major ophthalmic imaging manufacturers and linked them with corresponding clinical and demographic data in the American Academy of Ophthalmology IRIS® Registry (Intelligent Research in Sight).

Methods: DICOM files of six different posterior segment imaging modalities were acquired from multiple ophthalmic practices. Extracted metadata revealed both 'standards conformant' and 'private manufacturer' metadata tags. Following manual tag inspection, we implemented a programmatically scalable metadata harmonization process of consolidating the tags. This conformed to DICOM standards where possible. Adhering to HITRUST guidelines, proprietary heuristic patient matching algorithms linked these DICOM files with patient records in the IRIS® Registry.

Results: 1,842,633 DICOM files from 58,517 unique patients were available. 1,512,373 images from 48,443 unique patients were successfully linked to existing IRIS® patients. The patient match rate was 82.78%; this likely resulted from a combination of image 'test' patient exclusion, patient detail mismatch between electronic systems, and possible algorithmic parameter aberrations. Each manufacturer's DICOM files contained 127 and 77 metadata tags respectively, both consisting of standard and private tags. The resulting consolidated list consisted of 170 metadata tags.

Conclusions: Using demographic identifiers from DICOM metadata, we created an automated pipeline to comprehensively and accurately connect longitudinal real-world clinical data to various image modalities from multiple manufacturers at the patient and visit level. This curation process has produced a large, enriched and multimodal IRIS® Registry, enabling enhanced research and advanced analytics. As imaging dependence and digital data capture grows, standards compliance will be critical to advancing the virtuous cycle of data-driven clinical insights to improve quality of care and enable novel ophthalmic drug and device development approaches.

ABSTRACT BODY:

Purpose: Some studies show that yellow filters improve contrast processing; others fail to replicate such results. This exploratory study aimed to evaluate the effects of a yellow filter on contrast sensitivity under light scattering conditions and different spatial scales.

Methods: Twenty-four participants (19 to 46 years; mean 31.0 ± 9.5 SD; 13 females) with corrected-to-normal vision were recruited for the study. Light scattering was induced by 0.6 Bangerter foil, and Kodak Wratten 12 filter was used as an exemplar of yellow filters. Using the Freiburg Vision Test ('FrACT'), we measured monocular broadband contrast sensitivity using a 50 arcmin Landolt C under three experimental conditions: Naked eye, Bangerter foil, and Bangerter foil with Yellow filter. In a subset of subjects (13 out of 24), we repeated the measures using 25 and 100 arcmin stimuli. All testing was performed using an eight-alternative forced-choice paradigm (eight cardinal directions of the C opening). The stimuli were viewed at a gamma-calibrated CRT screen at a viewing distance of 3 meters.

Results: A repeated-measures ANOVA on the 50 arcmin data revealed the main effect of condition ($p < 0.001$) whereby Bangerter foil significantly reduced contrast sensitivity by 0.32 ± 0.07 log units ($p < 0.001$) and the addition of Yellow filter partially reversed this reduction by 0.05 ± 0.08 log units ($p = 0.003$). In addition, there was a significant correlation between the reductions of contrast sensitivity induced by the Bangerter foil and its reversal induced by the Yellow filter ($p < 0.001$). An ANOVA, conducted on the subset of subjects who completed the study on all three scales, revealed a significant interaction between the scale and condition $F_{2,24} = 3.4$, $p = 0.048$, whereby the beneficial effects of the yellow filter increased with finer scale.

Conclusions: We have demonstrated the benefit of a yellow filter on contrast sensitivity under scattering conditions. The correlation between contrast sensitivity decrease induced by the Bangerter foil and its partial reversal associated with the Yellow filter usage indicate that subjects more susceptible to scattering may benefit more from yellow filters. Finally, the scale dependence shows that the yellow filter's benefit is most relevant when the processing of fine detail is required.

ABSTRACT BODY:

Purpose: Topical nonsteroidal anti-inflammatory drugs (NSAIDs) are effective for the treatment of postoperative inflammation but have known limitations with respect to their tolerability and safety. Caution is recommended in patients with dry eye disease, diabetes, and systemic immunologic disorders due to an increased risk of corneal complications. There is a need for alternative delivery mechanisms that overcome the limitations of topical NSAIDs. Here we report the first clinical results with a novel sustained-release ketorolac implant in subjects undergoing cataract surgery.

Methods: A Phase 1, open-label study was conducted to assess the safety and efficacy of OcuRing-K™ (ketorolac ophthalmic implant) for treatment of postoperative inflammation after cataract surgery. Five subjects underwent cataract extraction with intraocular lens (IOL) implantation. Prior to IOL insertion, the OcuRing-K™ was applied to one haptic of the IOL, which was then inserted into the capsular bag using the standard surgical technique. No additional anti-inflammatory medications were administered. Subjects were evaluated postoperatively 1, 7, and 28 days after surgery. Inflammation was assessed by anterior chamber cell (ACC) score using the SUN scale. Postoperative pain was assessed using a visual analog scale (VAS).

Results: OcuRing-K™ was successfully implanted in five subjects without complication. In all five subjects, IOLs were observed to be centered on the visual axis without tilt, and OcuRing-K™ implants were visualized in their proper position on the IOL haptic at all visits. The mean postoperative ACC scores were 0.6 and 0.4 at days 1 and 7, respectively, and no ACC was observed in any subjects by day 28. All subjects were pain-free at days 1, 7, and 28. No treatment-related adverse events were reported. No subjects required rescue therapy with topical anti-inflammatory medication.

Conclusions: These results represent the first evidence of the safety and efficacy of OcuRing-K™ for use in cataract surgery. Although this was an open-label study with no comparators, the minimal inflammation observed and absence of pain among all subjects are highly consistent with the known anti-inflammatory and analgesic properties of ketorolac. These findings support the potential of the OcuRing-K™ implant as a safe and effective alternative to NSAID eye drops for use in cataract surgery.

ABSTRACT BODY:

Purpose: To investigate the association between calcific nodules with progression in age-related macular degeneration (AMD) and examine their impact on visual function using microperimetry.

Methods: This study involved 280 eyes from 140 participants with bilateral large drusen. Multimodal imaging (MMI) and microperimetry were performed at baseline, and then every 6 months for 3 years. Baseline optical coherence tomography (OCT) scans covering a 20°x20° region were used to identify calcific nodules, defined as a hyporeflective core within a drusenoid lesion. The area of drusenoid lesions containing calcific nodules seen on OCT scans was then measured on color fundus photographs (CFPs). The main outcome measures were progression to late AMD determined on MMI, and mean microperimetric sensitivity. The association between the extent of drusen with calcific nodules and these outcomes was then evaluated, with and without adjustment for potential confounders.

Results: A total of 20 (7%) eyes from 12 (9%) individuals were found to have calcific nodules at baseline. The presence and extent of calcific nodules were significantly associated with an increased risk of progression to late AMD ($P = 0.034$) and lower microperimetric sensitivity at baseline ($P = 0.006$). However, these associations were no longer significant ($P \geq 0.200$ for all) after adjusting for total drusen volume from OCT imaging, presence of pigmentary changes on CFPs, and age.

Conclusions: The presence and extent of calcific nodules at baseline was not independently associated with an increased risk of progression in AMD or with lower microperimetric sensitivity, after adjusting for important confounders of AMD disease severity and risk of progression.

ABSTRACT BODY:

Purpose: Compare the speed of glaucoma progression as measured by global visual field (VF) and optical coherence tomography (OCT) metrics.

Methods: Glaucoma suspect, pre-perimetric glaucoma (PPG) and perimetric glaucoma (PG) participants of Advanced Imaging for Glaucoma study,¹ who had at least 7 visits with visual field (VF) and OCT ONH scan, were analyzed. Severity was staged by the modified Hodapp-Parrish-Anderson Criteria. Eyes with significant cataract progression were excluded. Spectral-domain OCT (RTVue, Optovue) and VF testing were performed every 6 months. The nerve fiber layer (NFL) thickness was measured from ONH scan. The NFL mean deviation (MD) were VF-equivalent dB-scale quantities based on sectorwise nonlinear regression of NFL thickness with VF deviation using cross-sectional data over a wide range of glaucoma severity.² Linear regression was used to estimate the glaucoma progression speed.

Results: Seventy-five glaucoma suspect eyes (VF MD -0.1 ± 1.2 dB), 160 PPG eyes (0.2 ± 1.3 dB), 77 early PG eyes (-0.9 ± 1.6 dB) and 20 moderate+severe PG (-10.8 ± 3.2 dB) eyes were analyzed. The follow-up duration was 54 months \pm 8 months (mean \pm SD). For both VF MD and NFL MD, the speed of progression increased monotonically with glaucoma severity (Table 1). For overall NFL thickness, the progression speed was greatest in the PPG and early PG stages, but slowed down at the moderate+severe stages. The ratios of progression speed for NFL thickness relative to VF were significantly different between stages ($p < 0.006$, one-way ANOVA). The ratios of progression speed for NFL MD relative to VF MD was generally slower (0.58-0.72), but not significantly different across disease stages ($p = 0.08$). The progression speed of both NFL-MD and VF-MD were associated with baseline parameters (faster progression in eyes with more severe disease at baseline), while progression speed of NFL thickness was not (Table 2).

Conclusions: Compared to VF MD, NFL thickness tends to overestimate the progression speed in the early stages of glaucoma and underestimate it in the later stages. Clinicians should be aware of the discrepancy in the apparent speed of disease progression as measured by structural and functional metrics, which strongly depend on the stage of disease severity. Converting the NFL thickness profile to NFL MD may provide a progression metric more consistent with VF MD over a wider range of glaucoma severity.

ABSTRACT BODY:

Purpose: This study was a retrospective, observational clinical study to compare refractive results of manifest refraction and wavefront (WF) refraction for patients with keratoconus.

Methods: The manifest and WF refractions of 613 eyes diagnosed with keratoconus were analyzed. Refractive parameters (sphere, cylinder, axis, and spherical equivalent) were compared based on stratified cohorts of increasing maximum keratometry (Kmax) (Kmax<50 diopters (D), 50-55D, 55-60D, >60D). The percentage of WF refraction axes (against-the-rule (ATR) (60-120°), with-the-rule (WTR) (0-30° and 150-180°), oblique (OBL) (30-60° and 120-150°)) that correctly corroborated with manifest refraction axes were compared, and more specifically, the percentage of patients with WF axes $\pm 10^\circ$ of manifest axes were analyzed.

Results: In the entire cohort, there was no difference between wavefront and manifest spherical refraction (P=0.07). However, cylindrical refraction and spherical equivalent were significantly different (both P<0.001). In the stratified subgroups, there was more cylindrical refraction measured on wavefront than manifest refraction for all Kmax subgroups (all P<0.001). Similarly, wavefront spherical equivalent was more myopic than the manifest spherical equivalent in the Kmax <50D, 50-55D, and 55-60D subgroups (P=0.01, <0.001, <0.001, respectively). Overall, 56.61% of WF refraction axes (ATR, WTR, or OBL) correctly corroborated with manifest refraction axes, and only 34.4% of WF refraction axes were within $\pm 10^\circ$ of manifest refraction axes. In the Kmax subgroups, 62.1%, 54.7%, 56.7%, and 48.5% of WF refraction axes correctly corroborated with manifest refraction axes in the Kmax <50D, 50-55D, 55-60D, and >60D subgroups, respectively. Additionally, 38.5%, 37.4%, 32.9%, and 18.2% of WF refraction axes were $\pm 10^\circ$ of the manifest refraction axes in the Kmax <50D, 50-55D, 55-60D, and >60D subgroups, respectively.

Conclusions: WF refraction is a convenient tool for obtaining refractive parameters of patients, but physicians should be cognizant that there can be significant differences between WF and manifest refraction for patients with keratoconus. In particular, as the severity of keratoconus increases, the reliability of the wavefront astigmatism measurements appears to decrease.

ABSTRACT BODY:

Purpose: To report the genotype and clinical features of RHO-associated retinitis pigmentosa (RHO-RP) in Japanese patients.

Methods: Multiplex polymerase chain reaction-based target sequencing of 83 known causative genes of RP or whole exome sequencing with target analysis of retinal disease-associated genes were performed in 782 patients with RP in Kyushu University Hospital. Pathogenic variants of RHO gene were detected in 19 patients. Clinical information including age, best-corrected visual acuity (BCVA), Goldmann perimetry, fundus photography, and optical coherence tomography were retrospectively obtained from the electronic medical charts. Visual outcomes were compared between classical and sector phenotypes and among variants.

Results: The mean age at the first visit was 53.9 ± 14.4 years, with the mean follow-up of 7.1 ± 3.6 years. Classical RHO-RP phenotype was associated in 16/19 (84.2%) participants, and p.Pro23Leu and p.Pro347Leu variants were noted in 4 and 2 patients, respectively. Three patients with sector RHO-RP harbored p.Ala164Val (n=2) and p.Asn78Ile (n=1) variants. In classical RHO-RP, mean BCVA decreased from 0.60 to 1.10 logarithm of the minimum angle of resolution (logMAR) over the follow-up period; whereas, in sector RHO-RP, BCVA was relatively preserved as 0.05 and 0.09 logMAR respectively at the first and last visit. Among p.Pro23Leu, p.Pro347Leu and p.Ala164Val variants, patients with p.Pro347Leu variant exhibited early onset and severe vision loss in earlier ages. Macular complications such as epiretinal membrane and cystoid macular edema was observed in 5 classical RHO-RP and 1 sector RHO-RP patients.

Conclusions: p.Pro23Leu, but not p.Pro23His, was the frequent variant causing RHO-RP in Japanese patients. As reported in previous Europe and US studies, patients with p.Pro347Leu variant showed more severe phenotype, and variants causing sector RHO-RP were associated with a good prognosis.

ABSTRACT BODY:

Purpose: Pre-operative dry eye represents a risk of sub-optimal refractive results following cataract or refractive surgery thus identification of at-risk individuals in the standard population is essential to optimising outcomes. Tear film osmolarity (TFO) is an objective measure of dry eye however minimal literature is available to provide an understanding of incidence of hyperosmolarity in the standard population and the relationship with subjective dry eye parameters and clinical variables. Our retrospective study presents a novel analysis of the largest current sample of TFO in a normal population and post-refractive subgroup.

Methods: 1404 patients (n=47 post-refractive, n=1357 standard) undergoing screening for refractive surgery from 2017 to 2020 were reviewed. Routine examination included dry eye testing with TFO (TearLab, San Diego, CA, USA) and the Ocular Surface Disease Index questionnaire (OSDI, Allergan Irvine CA, USA). Patients were instructed to refrain from topical eye drops minimum two hours before the appointment. Bivariate correlation was used to indicate a relationship between continuous variables and chi-square test between categorical variables. Mean, median and range values were provided for continuous variables.

Results: Mean TFO in the standard population was 299.1 ± 11.9 mOsm/L with 82.3% of eyes < 308 mOsm/L indicating normal tear film homeostasis. Mean inter-eye TFO difference was 8.17 ± 8.60 mOsm/L with 65.2% of eyes ≤ 8 mOsm/L. Mean TFO in the post-refractive subgroup was 299.7 ± 11.0 mOsm/L with a mean inter-eye difference of 9.0 ± 6.9 mOsm/L. Post-refractive surgery patients indicated higher mean OSDI values of 15.3 ± 14.5 compared to the remainder of the population 9.7 ± 10.6 ($p=0.012$). Significant correlation was demonstrated between TFO scores and OSDI classification for the standard population only ($p=0.005$, $r=0.077$). Contact lens use correlated inversely with TFO and OSDI scores ($p=0.000$) whilst artificial lubricants correlated with OSDI scores in the post-refractive group only ($p=0.000$, $r=0.131$).

Conclusions: TFO and OSDI scores indicate that the majority of the standard population fall within normal ranges. The impact of our findings may resonate with cataract and refractive surgeons as a reasonable percentage of individuals will be diagnosed with tear film hyperosmolarity and represent a risk for reduced post-operative outcome and ocular comfort.

ABSTRACT BODY:

Purpose: To evaluate the potential added predictive value of the quantity and location of hyperpigmentary abnormalities (HP) for progression of age-related macular degeneration (AMD).

Methods: 140 participants with bilateral large drusen were followed longitudinally at six-monthly intervals for up to 36 months. They underwent multimodal retinal imaging to determine late AMD development. Baseline colour fundus photographs were graded for the presence of any pigmentary abnormalities. All pixels containing HP were then manually labelled on these baseline images, and the quantity of HP within and outside the central 3mm diameter region centred on the fovea was determined. Two predictive models that included age and any pigmentary abnormalities, one with and one without the quantitative parameters of the HP extent, were developed and evaluated.

Results: HP were detected in 81 (29%) eyes, all of which (100%) had HP inside the central 3mm region, and 41 (51%) eyes had HP outside the central 3mm region. The quantity of HP within the central 3mm region ($P = 0.036$), but not outside ($P = 0.361$), was independently associated with progression to late AMD. The addition of the quantity of HP within the central 3mm to a predictive model including presence of any pigmentary abnormalities and age did not significantly improve its performance (area under the receiver operator characteristic curve [AUC] = 0.81), compared to the model without it (AUC = 0.80; $P = 0.23$). The sensitivity of these two predictive models were 54% and 46% respectively at 90% specificity ($P = 0.32$).

Conclusions: The extent of HP within the central 3mm was associated with AMD progression at the population level. However, its addition to a model based on presence of any pigmentary abnormalities and age did not result in an improved predictive performance at the individual level in our cohort. Further analysis of spatial patterns of HP, would provide additional parameters to improve the model.

ABSTRACT BODY:

Purpose: Macular OCT B-scans may contain various pathologies and identification of these pathologies using Artificial Intelligence-assisted technologies may help doctors diagnose macular diseases more quickly. For an accurate yet fast clinical decision support system, it is essential to develop a robust algorithm with high sensitivity that can detect the presence of multiple pathologies. This could be attempted with two different approaches such as 1) Monolithic DNN, and the proposed 2) Modular DNN. With monolithic DNN, a single DNN is involved to absorb features that are required to train all the pathologies – the usual way of handling the typical multi-label classification task. The idea of modular DNN is to dedicate a single and potentially smaller DNN for each pathology that yields individual outputs and then combines these outputs of several DNNs to arrive at conclusions.

Methods: For training and evaluating the performance of the monolithic and modular DNN based algorithms, a total of 598 CIRRUS macular OCT cubes from 598 patients were collected. The labeling was done at the B-scan level with 8 pathologies (one or more per B-scan) by two retina specialists. Ungradable B-scans were excluded from the dataset. The dataset was then divided into train and test with 80-20 split at patients' level.

Fig. 1(a) table depicts the list of 8 pathologies and their corresponding samples used for training and evaluating both algorithms while 1(b) shows the distribution of pathologies. For both methods, inception_resnet_v2 DNNs were used – 1 for monolithic DNN and 8 for modular DNN (Fig. 1(c)).

Results: The performances of both the algorithms were evaluated on the hold-out test set. The monolithic DNN achieved maximum 75.36% AUC for RPE Elevation while modular DNN achieved maximum 98.85% AUC for Intraretinal Fluid. Fig 2 shows the achieved AUCs for modular DNN for all 8 pathologies.

Modular DNN based algorithm outperforms monolithic DNN significantly for all pathologies. The proposed approach provides a flexibility to include or exclude pathologies for designing any customized workflow.

Conclusions: In this study, we determined the modular DNN architecture-based algorithm outperformed a monolithic DNN based algorithm for the multi-pathology classification task with no loss of generality.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) is one of the most common causes of blindness, and a screening using fundus images helps to detect DR at early stage. Various types of fundus cameras are available today, with differences in their image quality, portability, and field of view. To screen a large population, it is essential to develop an automated DR screening system that is device agnostic. We evaluate how different, device-specific solutions can be fused when the training data and underlying algorithms differ.

Methods: From previous studies, we obtained two deep learning models with different model architecture. One model (M_{HH}) was trained exclusively on fundus images captured with a low-cost hand-held fundus camera (VISUSCOUT®100; ZEISS, Jena, Germany). The second model (M_{TT}) was trained on fundus images recorded with different table-top fundus cameras manufactured by various companies.

We evaluated individual models and combination strategies on two datasets: one from hand-held cameras (VISUSCOUT®) and one from table-top cameras (seen in Messidor-2 dataset). We analyzed three fusion techniques: score level fusion, decision level combination, and system level combination. For the weighted score level combination, the optimum weights were found experimentally between 0 to 1. In decision level combination, a modified OR logic was used for referable DR. For the system level combination, the metadata of the image was used to find out whether the image was captured using VISUSCOUT or a table-top fundus camera for routing the image to the appropriate algorithm. These strategies are visualized in Fig. 1.

Results: Fig. 2 shows the diagnostic efficacy in AUC %. Every single model performs well in the data regime it was trained on (M_{HH} on data from hand-held cameras, M_{TT} on table-top camera data) but accuracy drops significantly when tested with data coming from different device. For fusing both models into a single system, we observe best screening results with score level fusion, being clearly superior to decision level or system level fusion and insensitive to the data type.

Conclusions: DR screening systems which have been trained on different device data and with different deep learning models can be fused with various combination techniques for higher system performance.

ABSTRACT BODY:

Purpose: The human corneal stroma is a hydrated extracellular matrix (ECM) with 80% water, 13.6% collagen, and 0.9% glycosaminoglycans (GAGs) containing specialized fibroblast-like cells in the matrix. Its collagen is mainly type I collagen fibrils weaving together. The most abundant GAG in the normal cornea is keratan sulfate (KS), chondroitin sulfate (CS), and dermatan sulfate (DS). They form proteoglycans with a core protein in the spaces among the major collagen fibrils. GAGs can absorb and retain large amounts of water. Hyaluronan (HA) is a non-sulfated-GAG with well-known effects on corneal wound healing. We are developing in situ-forming semi-interpenetrating polymer network-based gels to mimic corneal stromal ECM for corneal regeneration and report on our recent data on the biological responses to them in vivo.

Methods: We mixed CS, DS, HA, or their combinations with type I collagen (Col) at a Col-to-GAG ratio of 2:1 and then used FDA approved NHS ester chemistry to crosslink collagen. The GAGs are therefore physically but not covalently integrated in the gel. The crosslinker for collagen here is a bifunctional PEG succinimidyl ester. The Col-to-crosslinker ratios used were 3:4 or 3:8. Gels without GAGs (Col-PEG) are also used as controls. The mixture is then added to a corneal defect of New Zealand White Rabbits under ambient conditions and allowed to gel over 5 minutes without using a catalyst or light activation. A contact lens and tarsorrhaphy were then applied. The treated cornea was monitored by OCT, topography, slit lamp, and fluorescein staining photography. The cornea was collected for immunofluorescence staining, histology, qPCR, and western blot 7 days later.

Results: No ocular inflammation or damage was found in the surrounding epithelial, stromal, and endothelial layers for all experimental eyes. Both collagen gels containing CS and HA promoted corneal epithelial wound healing compared to the collagen-only gels, and those containing HA were observed to be the most transparent. Stiffer gels (Col:crosslinker=3:4) facilitated curvatures closer to pre-operative curvatures.

Conclusions: We found that integration of CS and HA within collagen gels promoted corneal epithelial wound healing compared to collagen gels alone, while stiffer gels more closely facilitated native corneal curvature restoration. Future studies will focus on further optimization of gels in rabbit models.

ABSTRACT BODY:

Purpose: Retrospective, cross-sectional study, quantitatively and qualitatively comparing automated retinal image segmentation using cross platform OrionTM software to proprietary software on retinal images captured using Heidelberg HRA+OCT

Methods: Retinal layer segmentations of normal, intermediate dry AMD and diabetic macular edema eyes were performed using Spectralis[®] HRA+OCT and automated OCT segmentation software OrionTM. Quantitative comparisons were made between the volumes of Nerve fiber layer (NFL), Ganglion cell layer (GCL), Inner plexiform layer (IPL), Outer plexiform layer (OPL), Inner nuclear layer (INL), Outer nuclear layer (ONL), total inner retinal layer (INLY) and total outer retinal layer (OUTLY). A qualitative comparison of accuracy was made by graders who compared software segmentation to manual segmentation.

Results: In normal eyes, all retinal layer volumes calculated by the two softwares were moderate-strongly correlated (Pearson correlation, $r > 0.4$) except OUTLY. However, differences were statistically significant except in GCIPL and OUTLY. Qualitative analysis done using Wilcoxon test showed that OrionTM was significantly better than Heidelberg in the segmentation of NFL and INL layers ($p \leq 0.01$). In dry AMD eyes, GCIPL, INL, ONL, INLY, TRV layer volumes were moderate-strongly correlated ($r > 0.4$) between softwares and their differences were statistically significant except GCIPL. Qualitatively, OrionTM generated significantly better segmentation only for the NFL ($p \leq 0.05$). In eyes with DME, all layer volume values were moderate-strongly correlated ($r > 0.4$) between softwares and their differences were statistically significant except OPL and OUTLY. Qualitatively, OrionTM was significantly better at segmenting INL and OPL layers ($p \leq 0.01$).

Conclusions: Layer volumes correlated well between OrionTM and Heidelberg softwares but were, in general, significantly different suggesting that they used different retinal landmarks for segmentation. Qualitatively, when comparing to the gold standard of manual segmentation, OrionTM segmented normal and diseased retina more accurately. Findings suggest that the cross-platform OrionTM retinal layer segmentation software can be used reliably to study the retinal layers in normal and diseased eyes.

ABSTRACT BODY:

Purpose: Wavelength defocus plays an important role in the process of emmetropization. This study aims to explore the potential mechanism underlying retinal response to the wavelength defocus of different signs.

Methods: In this study, guinea pigs were randomly divided into 3 groups that received different lighting conditions (12:12 light cycle) for 8 weeks: white light, short wavelength light, and long wavelength light. Refraction and axial length were measured, and RNA-seq was adopted to analyze gene expression in the retina.

Results: Compared with the control group, the long wavelength light exhibited reduced refraction and increased ocular axial length, whereas the short wavelength light showed an opposite trend. RNA-seq showed that compared with the control group, 184 differently expressed genes (DEGs) in the short wavelength group were primarily enriched in the pathways including tyrosine and retinol metabolism, whereas 171 DEGs in the long wavelength group were mainly enriched in the fat digestion and absorption. There were 268 DEGs between the short and long wavelength group, which were associated with extracellular matrix remodeling. We also found that 7 DEGs in the guinea pigs retina in response to wavelength defocus were overlapped with human myopia candidate genes, suggesting functional overlap between DEGs in retina upon exposure to wavelength defocus and genes causing myopia in humans.

Conclusions: This study identified retinal targets and pathways involved in the response to wavelength defocus, as well as providing attractive targets for the development of anti-myopia drugs.

ABSTRACT BODY:

Purpose: DL techniques can be used to detect abnormalities in OCT B-scans. The performance of such an algorithm is dependent on quality of both data and its labels. The sources of data could be either from a clinical study or busy eye clinics. While the image quality, disease prevalence, age of subjects etc. can be well controlled within scope of a clinical study, the same may not be applicable when collected from the eye clinics. The involvement of multiple labelers may introduce inconsistencies while creating labels, because each expert has their own clinical judgment and differs depending on how and where (Primary, Secondary or Tertiary clinics) they practice. In this abstract, we discuss the effects of the above aspects on classification performance.

Methods: To assess the effect of data source, we gathered macular OCT cube data during clinical studies and from eye clinics. Next, to measure the effect of labelling variability, the data were labelled at B-scan level by five labelers. Among five labelers, two of them (labelers X & Y in Fig. 2) had similar expertise levels practicing in the same hospital, while the rest (labelers A, B & C) were from three different eye clinics. Data from each labeler was split into training and test sets. An Inception_V1 model was developed on the training set for each labeler, and the performance was evaluated on all test sets. Fig 1(a) and 2(a) show the number of samples used for trainings and evaluations.

Results: Fig 1(b) shows that evaluating a model using data from clinical trials does not always indicate good generalizability and may over-estimate the model accuracy. Training on 'uncontrolled' data sources leads overall to improved performance in a typical clinical setting, even if such a model underperforms in the clinical trial setting. From Fig 2(b), we observe that models perform well on data labelled by experts with similar background. It shows strong differences in accuracy for abnormality prediction with labelers from different backgrounds, showing significant AUC drop.

Conclusions: We conclude that prediction models are not easily transferable across labelers from different backgrounds. Furthermore, model accuracy from clinical trial model may not be transferrable to busy clinical environments.

TITLE: Effect of the power and time of application of fogging lenses in the control of accommodation

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Turull Mallofre, M. Aldaba, C.E. García-Guerra, J. Goset, J. Pujol, Centre for Sensors, Instruments and Systems Development, Universitat Politècnica de Catalunya, Barcelona, Catalunya, SPAIN|

Commercial Relationships Disclosure (Abstract): Aina Turull Mallofre: Commercial Relationship: Code N (No Commercial Relationship) | Mikel Aldaba: Commercial Relationship: Code N (No Commercial Relationship) | Carlos García-Guerra: Commercial Relationship: Code N (No Commercial Relationship) | Joan Goset: Commercial Relationship: Code N (No Commercial Relationship) | Jaume Pujol: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: An essential factor for a successful refraction assessment is the control of accommodation. Fogging is a technique for relaxing accommodation using plus power lenses instead of drugs. However, the optimal amount of power and time of application of plus lenses remain unclear. This study tested which power and time of application of fogging lenses are more adequate to achieve the maximum relaxation of accommodation (RoA).

Methods: We analyzed the accommodative response of 20 young adults, 7 males and 13 females, between 18 and 30 years old when lenses of different amount of plus power were placed in front of the patient's eye. For each patient, six different fogging lens powers relative to the manifest refraction were tested (+1D, +1.5D, +2D, +2.5D, +3D and +4D). Each lens was placed in front of the eye for 55s while the patient was looking at a VA chart placed at 6m. During that time, changes in accommodation were monitored at 10Hz frequency by means of a Hartmann-Shack aberrometer. During measurements contralateral eye was occluded. Lenses were presented in a random order, with a wash-up time between trials of 90s.

Results: The mean age of participants was 24.7 ± 3.4 years, with a mean refractive error in terms of spherical equivalent of -0.59 ± 1.37 D ranging from -4.25D to +1D. The mean RoA for all lenses was -0.05 ± 0.22 D and the mean time for achieving the maximum RoA was 24.75 ± 16.52 s.

Analyzing the cases in which the RoA was at least 0.12D, the mean RoA was 0.23 ± 0.08 D with a mean time to achieve the maximum RoA of 19.94 ± 11.52 s. Lenses that produced a better RoA were those with powers between +1D and +2.5D. Conversely, when analyzing the cases in which the RoA was under -0.12D, meaning that accommodation was activated, the mean RoA was -0.29 ± 0.17 with a mean time to get the maximum accommodation of 40.86 ± 11.18 s. Lenses that produced a higher activation of accommodation were +3D and +4D.

Conclusions: Real time monitorization permits to determine power and time of fogging lenses. Better results were obtained for powers between +1D and +2.5D and a time of application of approximately 20s. The countereffect of high-power fogging lenses was seen in lenses of +3D and +4D, that could lead accommodation to the resting state due to the high blur. Further research with a larger sample should be performed to confirm these preliminary results.

ABSTRACT BODY:

Purpose: Retinal shape can be derived from distortion-corrected optical coherence tomography (OCT) scans. This parameter is of potential use in myopia research and in retina-related pathologies. The purpose of the study is to evaluate the metrological aspects of retinal shape estimation from OCT images covering a 90° field of view.

Methods: A total of 20 right eyes with refractive errors ranging from 0 to -11 diopters were imaged with a swept-source OCT system (PLEX® Elite 9000; ZEISS, Dublin, CA). Three horizontally and vertically oriented line scans were acquired. An ultra-widefield add-on lens was mounted to the system to image a 90° field of view. OCT images were adjusted to more accurately depict the anatomical structure of the retina using an image transform derived from an optical model (MATLAB 2020a; The MathWorks, Inc., Natick, MA, and OpticStudio 20.3.1; Zemax, LLC, Kirkland, WA), as seen in Fig1. The retinal radius of curvature (RRC) was calculated from the distortion-corrected scan. Median \pm interquartile range (IQR) and the coefficient of repeatability for the RRC were calculated. A simulated tolerance analysis was performed to identify the imaging parameters likely responsible for within-subject variations. Correlation analysis between axial length and RRC was conducted.

Results: Horizontal and vertical retinal curvatures calculated were 12.53 ± 1.37 mm and 12.83 ± 1.28 mm with coefficients of repeatability of 1.11mm and 0.49mm, respectively. The tolerance analysis predicted the axial length to be the most sensitive parameter in the retinal curvature calculation, which can lead to up to 28% error for 0 diopter refractive error. The working distance offset (8.2%), corneal radius (1.25%), crystalline lens refractive index (0.5%), x-offset (0.65%) and head tilt (0.33%) had less of an effect, resulting in a total root mean square error of 8.34%. Correlation analysis showed significant correlations for axial length with horizontal ($R=0.74$, $p<0.001$) and vertical RRC ($R=0.61$, $p=0.005$).

Conclusions: Calculations of retinal shape are more repeatable in the vertical than horizontal scan direction. Axial length and an offset in working distance have the biggest impact on retinal shape estimation determined with 90° field of view OCT imaging. Horizontal and vertical RRC correlate positively with axial length.

ABSTRACT BODY:

Purpose: The low prevalence of certain retinal disease features compromises data collection for deep neural networks (DNN) development and, consequently, the benefits of automated detection. We robustify the detection of such features in scarce data settings by exploiting hierarchical information available in the data to learn from generic to specific, low-prevalence features. We focus on reticular pseudodrusen (RPD), a hallmark of intermediate age-related macular degeneration (AMD).

Methods: Color fundus images (CFI) from the AREDS dataset were used for DNN development (106,994 CFI) and testing (27,066 CFI). An external test set (RS1-6) was generated with 2,790 CFI from the Rotterdam Study. In both datasets CFI were graded from generic to specific features. This allows to establish a hierarchy of binary classification tasks with decreasing prevalence: presence of AMD findings (AREDS prevalence: 88%; RS1-6: 77%), drusen (85%; 73%), large drusen (40%; 24%), RPD (1%; 4%). We created a hierarchical curriculum and developed a DNN (HC-DNN) that learned each task sequentially. We computed its performance for RPD detection in both test sets and compared it to a baseline DNN (B-DNN) that learned to detect RPD from scratch disregarding hierarchical information. We studied their robustness across datasets, while reducing the size of data available for development (same prevalences).

Results: Area under the receiver operating characteristic curve (AUC) was used to measure RPD detection performance. When large development data were available, there was no significant difference between DNNs (100% data, HC-DNN: 0.96 (95% CI, 0.94-0.97) in AREDS, 0.82 (0.78-0.86) in RS1-6; B-DNN: 0.95 (0.94-0.96) in AREDS, 0.83 (0.79-0.87) in RS1-6). However, HC-DNN achieved better performance and robustness across datasets when development data were highly reduced (<50% data, p-values<0.05) (1% data, HC-DNN: 0.63 (0.60-0.66) in AREDS, 0.76 (0.72-0.80) in RS1-6; B-DNN: 0.53 (0.49-0.56) in AREDS, 0.48 (0.42-0.53) in RS1-6).

Conclusions: Hierarchical curriculum learning allows for knowledge transfer from general, higher-prevalence features and becomes beneficial for the detection of low-prevalence retinal features, such as RPD, in scarce data settings. Moreover, exploiting hierarchical information improves DNN robustness across datasets.

ABSTRACT BODY:

Purpose: The rigidity and low A-scan rate of spectral-domain optical coherence tomography (SD-OCT) is prohibiting a manifold use of OCT during ophthalmic surgery. We present a versatile swept-source OCT (SS-OCT) engine, addressing a multitude of use cases, from axial eye length measurements to live volumetric visualizations at MHz A-scan rates.

Methods: We developed a flexible SS-OCT engine and an add-on module to couple its sample arm to an ophthalmic surgical microscope. The engine includes a 1060nm tunable MEMS-VCSEL whose sweep repetition rate can be alternated between 100kHz, 400kHz or 1MHz. To increase the effective A-scan rate on cost of axial resolution, we scanned at twice the speed and mathematically divided each sweep into two halves. The 100kHz A-scan mode was used for high resolution B-scan and axial eye length measurements with an axial resolution of 6.3µm and an imaging depth of 29mm in tissue. For 4D live imaging, effective A-scan rates of 800kHz and 2MHz allowed us to realize fields of view (FOVs) of 3.1-15.7mm with imaging depths of 4.3-10.5mm and an axial resolution of 12.6µm. We imaged anterior segment and retina mimicking phantoms, as well as ex vivo porcine eyes. All data was processed and rendered live.

Results: Using the same instrument, we acquired full eye scans, anterior and posterior segment B-scans, as well as 4D-OCT scans with volume rates of up to 17vol/s. Fig.1 shows an ocular biometry scan of a test eye captured at an A-scan rate of 100kHz. Each B-scan consisted of 1024 A-scans. Sampling such enormous depths of 29mm in real-time allows for ocular distance measurements or solid state z-tracking. In Fig.2A-H an image sequence of a 17vol/s live rendered volume series can be seen. It visualizes an incision of a porcine cornea displayed at different viewing angles and zooms. An A-scan rate of 1MHz and axial resolution of 6.3µm resulted in a FOV of 3.1mm. To further enhance depth perception, depth is color-encoded from red (top) to blue (bottom) and the z-direction is indicated by an arrow.

Conclusions: We demonstrated SS-OCT's potential to address multiple ophthalmic imaging applications with a single device. 4D OCT can be used for enhancing depth perception and visualizing sub-surface structures during surgery, while imaging at lower rates enables full eye OCT for high resolution B-scan imaging and biometry scans.

ABSTRACT BODY:

Purpose: Toll-like receptor 3 (TLR3) and the retinoic acid-inducible gene I (RIG-I) like RNA helicase gene family are pattern recognition receptors in viral infection which recognize double-stranded (ds) RNA viruses and activate innate immunity. Both polyinosinic-polycytidylic acid [poly(I:C)] and polyadenylic-polyuridylic acid [poly(A:U)] are synthetic analogs of dsRNA that interact with TLR3, however, only poly(I:C) triggers the RIG-I like RNA helicase gene family. The purpose of this present study was to investigate the barrier function in immortalized human corneal epithelial (HCLE) cells and human conjunctival epithelial (HCjE) cells via stimulation of TLR3 by synthetic dsRNA.

Methods: HCLE and HCjE cells were first cultured on 12-mm Transwell[®] inserts (Corning[®]), and then stimulated with 25µg/ml poly(I:C) or 25µg/ml poly(A:U). To block TLR3, 40µM TLR3/dsRNA Complex Inhibitor (Sigma-Aldrich) was then added to the medium. After stimulation for 24 hours, transepithelial electrical resistance (TER) was measured. The flow mechanism was evaluated on poly(I:C) stimulation by dividing into the following four groups: 1) control group, 2) poly(I:C) in both apical and basal chambers group, 3) poly(I:C) in an apical chamber group, and 4) poly(I:C) in a basal chamber group. After stimulation for 1 hour, all poly(I:C) was changed into the culture medium, and measurement of TER was performed.

Results: Poly(I:C) and poly(A:U) stimulation increased TER after 24-hours ($p<0.01$). In comparison to the control group, the TER increase in the HCLE cells and HCjE cells in the poly(I:C) group was 73.6% and 94.4%, respectively, while the TER increase in the HCLE cells and HCjE cells in the poly(A:U) group was 49.2% and 12.3%, respectively. In all cells in both groups, the TER increase was blocked by TLR3 inhibitor ($p<0.01$). Evaluation of the poly(I:C) flow mechanism revealed that TER increased in all groups stimulated with poly(I:C) ($p<0.05$) at 3 hours, and that the increase remained until 24 hours.

Conclusions: The barrier function of ocular surface epithelium increased, specifically through TLR3. The reaction between poly(I:C) and TLR3 might possibly occur inside the cells. This increased barrier function acts as one of the host defense mechanisms against viral infection.

ABSTRACT BODY:

Purpose: To examine the role of ocular dominance on monovision corrections, using different eye dominance tests. The ultimate goal is to determine the most appropriate test to determine the dominant eye to optimize monovision.

Methods: 14 presbyopic subjects (53 ± 5 yo; SE 0.55 ± 1.33 D) participated, performing measurements at far (F, 4m) and near (N, 40cm) distances. A wearable binocular simulator (SimVis Gekko, 2Eyes Vision) was used to induce different monovision corrections. The following tests were performed: (1) Monovision Preference test (MP, best-perceived quality of grayscale natural images for 2.00 D monovision in OS/OD) at F and N; (2) Clinical Aiming Dominance (AD) at F; (3) Clinical Sensory Dominance (SD) with two levels of monocular blur, 0.50 and 1.50 D at F; (4) Binocular Rivalry (BR, fraction of predominance) using orthogonal Gabor patches at F & N (both eyes best corrected); (5) Multifocal Acceptance Score (MAS-2EV) with 4 perceptual scores (PS, 0-10 range) of perceived image quality at F/N of day/night real-world scenes for monovision (2.00 D near add in OS/OD); (6) Visual Strehl (VS) in OD/OS, from Laser Ray Tracing aberrometry.

Results: AD and SD matched in 71% of the subjects for SD1.50D (50% for SD0.50D). 78% of the subjects showed the same SD with 1.50D and 0.50D blur. VS ranged from 0.88-0.01 OS & 0.96-0.02 OD, and BR from 0.31-0.74 OS & 0.26-0.69 OD, with interocular differences >0.24 , and >0.20 in 43% and 35% of the subjects, respectively. MP at F & N were negatively correlated ($r=-0.89$, $p<10^{-4}$). Highest MP was obtained using dominant eye (far vision) selected from AD only in 36% of the subjects, SD1.50D in 65%, SD0.50D in 86% and BR in 79%. BR at F matched with subjects' preferences in AD (57%), SD0.50 (64%) and VS (50%). MAS-2EV scores were highly correlated with MP, both at F & N ($r=0.71$ & 0.82 , $p<0.004$ both). Selecting the eye for far in a monovision correction based on SD1.50, SD0.50, BR and VS (more aberrated eye) improved MP and MAS-2EV F scores by 54.9% over a flipped correction, except for AD which produced lower scores.

Conclusions: Eyes with high VS and BR interocular differences exhibited the largest differences in MP or MAS-2EV when reversing monovision. SD0.50 was the best ocular dominance predictor of optimal vision at far with monovision. Given the high discrepancies across ocular dominance tests, direct task/perception tests with simulated monovision appear most suited to select a correction.

TITLE: Prediction of ranibizumab injection frequency in patients with macular edema due to retinal vein occlusion during as-needed dosing period of BRAVO and CRUISE Phase 3 trials

SESSION TITLE: AI in the retina: Prediction models

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Li, F. Benmansour, F. Hoffmann-La Roche Ltd, SWITZERLAND|V. Steffen, M. Friesenhahn, Z. Haskova, Genentech, Inc., California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yun Li: Commercial Relationship(s);F. Hoffmann-La Roche Ltd:Code E (Employment) | Verena Steffen: Commercial Relationship(s);Genentech, Inc.:Code E (Employment) | Fethallah Benmansour: Commercial Relationship(s);F. Hoffmann-La Roche Ltd:Code E (Employment) | Michel Friesenhahn: Commercial Relationship(s);Genentech, Inc.:Code E (Employment) | Zdenka Haskova: Commercial Relationship(s);Genentech, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Despite anti-VEGF being the standard-of-care for treatment of macular edema due to retinal vein occlusion (RVO), data show that many patients require long-term, frequent injections to maintain the gains achieved during the initial monthly treatment (tx) period, highlighting the need for more durable treatment options in RVO. Here we retrospectively investigated baseline (BL) and early tx response variables for association with ranibizumab (RBZ) tx frequency during the as-needed (PRN) dosing period of the BRAVO and CRUISE trials.

Methods: BRAVO and CRUISE compared RBZ monthly dosing vs sham during the first 6 months (M) followed by PRN RBZ dosing from M6 to M12 in patients with macular edema due to branch and central RVO (BRVO/CRVO), respectively. Post hoc statistical and machine learning methods were applied to identify features predictive of RBZ injection frequency required for vision maintenance during the PRN dosing period. We tested average of BCVA values at BL, M1, M2 and M3, BCVA change from BL to M3, and 13 pre-specified imaging features for their impact on predictive accuracy, measured by area under the receiver operating characteristic curve (AUC).

Results: BRVO and CRVO patients (overall, n = 419; 0.3 mg, n = 211; 0.5 mg, n = 208) across treatment groups received 3.3 ± 2.1 RBZ injections during the PRN dosing period. The best predictor of injection frequency was the average of BCVA values at BL, M1, M2 and M3 (overall AUC = 0.76 [0.71, 0.81]; 0.3 mg AUC = 0.80 [0.73, 0.86]; 0.5 mg AUC = 0.73 [0.66, 0.80]). Adding BCVA change from BL to M3 did not increase predictive performance significantly. Adding the pre-specified imaging variables increased performance of the statistical model (overall AUC = 0.84 [0.80, 0.88]; 0.3 mg AUC = 0.85 [0.80, 0.91]; 0.5 mg AUC = 0.82 [0.76, 0.88]).

Conclusions: The BRAVO and CRUISE RVO population was heterogeneous and required different treatment frequency following the initial 6 monthly doses. The average of BCVA values at BL, M1, M2 and M3 was associated with the greatest predictive signal of future injection need. Imaging features increased predictive performance of the model. Clinicians may find the individual modeling predictions helpful when considering options for the long-term management of patients with RVO.

ABSTRACT BODY:

Purpose: Drivers with Age-Related Macular Degeneration (AMD) may experience difficulties in many driving situations because of their vision loss. Advanced Driver Assistance Systems (ADAS) have the potential to mitigate these difficulties and maintain driving safety. Using a telephone questionnaire, we identified the driving difficulties and ADAS technology preferences of drivers with and without AMD.

Methods: To date, 19 current drivers with AMD (74 ± 10 y) and 29 drivers without AMD (71 ± 6 y) have participated. They rated their perceived driving difficulty and perceived usefulness of technology support in 15 driving situations under both good (daytime) and reduced visibility conditions. They also rated their preferences for 12 existing ADAS technologies and described their experience using those systems. To provide an understanding of the ADAS systems, we sent each participant a training document with descriptions for all ADAS systems to review before and have available during the interview.

Results: Compared with non-AMD drivers, AMD drivers reported significantly more difficulty ($p = .005$) and greater usefulness of technology support ($p = .03$) in all driving situations. Both AMD and non-AMD drivers reported significantly more difficulty ($p < .001$) and greater technology usefulness ($p < .001$) in reduced visibility conditions than in the daytime. Greater driving difficulty correlated strongly with greater perceived technology usefulness ($r = .91$, $p < .001$). Both groups perceived dealing with other road users in their blind spot, experiencing vision loss from glare, seeing unexpected pedestrians, and driving through unfamiliar areas as the most difficult tasks that would benefit from technology support. AMD drivers listed blind spot warning and pedestrian warning as their most preferred ADAS systems, while non-AMD drivers listed rearview camera and blind spot warning. The majority of AMD drivers preferred to have ADAS technologies provide both information and active intervention, while non-AMD drivers were divided between having just information or both. The perceived benefits of ADAS technologies were high in both groups.

Conclusions: This study highlights differences in technology needs and preferences between AMD and non-AMD drivers which will be used to inform future ADAS development and evaluation tailored for drivers with AMD.

TITLE: Deletion of endoplasmic reticulum (ER) Ca^{2+} efflux channel inositol-1,4,5-trisphosphate receptor type 1 or ryanodine receptor 2 promotes ER retrotranslocation/proteostasis in cyclic nucleotide-gated channel-deficient mice

SESSION TITLE: Retinal Degenerations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Yang, H. Ma, M. Butler, X. Ding, Cell Biology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Fan Yang: Commercial Relationship: Code N (No Commercial Relationship) | Hongwei Ma: Commercial Relationship: Code N (No Commercial Relationship) | Michael Butler: Commercial Relationship: Code N (No Commercial Relationship) | Xi-Qin Ding: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies showed that cone death in cyclic nucleotide-gated (CNG) channel-deficient mice involves endoplasmic reticulum (ER) stress-associated apoptosis and dysregulation of ER Ca^{2+} homeostasis. We also demonstrated that expression/activity of ER Ca^{2+} efflux channels inositol 1,4,5-trisphosphate receptor 1 ($\text{IP}_3\text{R1}$) and ryanodine receptor 2 (RyR2) were increased, and ER stress/cone death was reduced after deletion of the two channels. This work investigates whether deletion of ER Ca^{2+} efflux channels promotes ER retrotranslocation/proteostasis in CNG channel-deficient retinas.

Methods: $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}$ and $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}$ mice with cone-specific deletions of Itpr1 (encoding $\text{IP}_3\text{R1}$, $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}/\text{Itpr1}^{\text{fl/fl}}/\text{Hrgp}^{\text{cre}}$) or Ryr2 (encoding RyR2, $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}/\text{Ryr2}^{\text{fl/fl}}/\text{Hrgp}^{\text{cre}}$) mice were used. ER retrotranslocation/proteostasis were evaluated by examining ER retrotranslocation machinery proteins syvn 1 (E3 ubiquitin-protein ligase synoviolin 1), Sel1L (ERAD E3 ligase adaptor subunit), Herpud1 (homocysteine inducible ER protein with ubiquitin like domain 1), Derl-1 (degradation in ER protein 1), and proteasome subunits PA28 α and PSMD11 using immunoblotting. Chemical chaperone tauroursodeoxycholic acid (TUDCA, 500 mg/kg, body weight) or vehicle was given to $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}$ mice by subcutaneous injection every 3 days for 12 days, starting at P5. Retinas were collected at the end of the treatment for immunoblotting.

Results: Expression levels of syvn 1, Sel1L, and Herpud1 were unchanged in $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}$ mice, compared with $\text{Nr1}^{-/-}$ controls. However, deletion of $\text{IP}_3\text{R1}$ or RyR2 significantly increased their expression levels. Derl-1 expression level was increased in $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}$ retinas, and deletion of $\text{IP}_3\text{R1}$ completely abolished the upregulation. Expression level of PA28 α was not different between $\text{Cnga3}^{-/-}/\text{Nr1}^{-/-}$ and $\text{Nr1}^{-/-}$ retinas. Deletion of $\text{IP}_3\text{R1}$ or RyR2 significantly reduced its level. Similar findings were observed after TUDCA treatment.

Conclusions: Our results showed that ER retrotranslocation/proteostasis was increased/improved after deletion of ER Ca^{2+} efflux channels or after treatment with TUDCA. These findings suggest that promoting ER retrotranslocation/proteostasis may represent a promising strategy to reduce ER stress/cone death in CNG channel deficiency.

ABSTRACT BODY:

Purpose: Cannabinoid receptors (CBR) 1 and 2, as part of the endocannabinoid system, were previously reported to be present in the ocular surface. Using activating or inhibiting cannabinoid ligands may affect CBR-functions such as regulating neuro-sensation, inflammation and wound healing, which are also core mechanisms of dry eye disease (DED). This study investigates the effect of several CBR ligands as a topical therapy in an experimental DED mouse model.

Methods: C57/Bl6 female mice were exposed to desiccating stress (DS) for 14 days. CBR ligands tetrahydrocannabinol (THC, agonist), SR141716A and SR144528 (selective antagonists) were formulated in aqueous solution (DMSO and Cremophore EL). Drug formulations or carrier were topically applied 3 times/day from day 1 of DS. To investigate disease severity, tear production, corneal fluorescence staining, and corneal sensitivity tests were performed at day 3, 5, 7, 10. At the end of the experiment, corneal and conjunctival tissues were analyzed regarding the expression of CBR1 and CBR2 by qPCR in naïve, DED-induced, and treated mice. Also, corneal flat mounts were stained with β 3-tubulin, then nerve density and length were semi-automatically quantified from obtained images.

Results: DS increased CBR expressions ($p < 0.05$). In treated mice, a reduced CBR expression was observed compared to DED mice ($p < 0.05$). After 10 days, all cannabinoid-ligands reduced fluorescence staining ($p < 0.01$) compared to untreated and carrier groups. Also, lower expression of IL-1 β in the cornea ($p < 0.05$) was observed. Topical application of CBR1 antagonist and THC maintained corneal sensitivity ($p < 0.05$) compared to DED mice and carrier-treated mice. In contrast to antagonists, THC protected corneal nerve density during desiccating stress ($p < 0.05$).

Conclusions: CBR1 and 2 seem to be involved in DED pathogenesis. Topical application of cannabinoid ligands reduces the expression of CBR1 and 2, which is accompanied with improvements of corneal damage and inflammation. Applying THC protected nerve density, thus maintained corneal sensitivity. Particularly, the selective CBR1 antagonist maintained cornea sensitivity without changing nerve density, which indicated a role of CBR1 in corneal neurotransmission. Therefore, this study facilitates the development of DED therapies based on cannabinoid eye drops.

ABSTRACT BODY:

Purpose: Optineurin (OPTN) mutations contribute to neurodegenerative diseases including glaucoma, with the more severe forms resulting from an E50K mutation in the OPTN gene. However, mechanisms underlying how the OPTN(E50K) mutation leads to glaucomatous retinal ganglion cell (RGC) neurodegeneration have not been fully discovered. Here, we used human pluripotent stem cell (hPSC)-derived RGCs with the OPTN(E50K) mutation as a model to explore cellular pathways that contribute to glaucomatous neurodegeneration.

Methods: The OPTN(E50K) hPSC line was established utilizing clustered regularly-interspaced short palindromic repeats (CRISPR)/Cas9 gene editing approach, in which a knock-in E50K mutation was inserted into a wild-type H7 hPSC line. The OPTN(E50K) and isogenic control hPSCs were differentiated to retinal organoids, followed by dissociation and purification of RGCs. Morphological, functional and protein expression differences in OPTN(E50K) RGCs were identified in comparison to isogenic controls.

Results: OPTN(E50K) RGCs exhibited neurodegenerative phenotypes including reduced soma size, decreased branching and length of neurites, as well as increased excitability compared to isogenic controls. To identify mechanisms triggering disease phenotypes, western blotting demonstrated reduced expression of the OPTN protein in OPTN(E50K) RGCs, indicating a lack of OPTN protein adversely affects autophagy processing. Considering that mTOR activation promotes neural development and regulates autophagy, a downregulation of mTOR signaling was observed as a possible compensatory mechanism for autophagy deficits. To provide direct evidence that mTOR inhibition leads to degenerative phenotypes, pharmacological inhibition of mTor in wild-type RGCs resulted in shorter neurites, a smaller cell body size, and fewer primary neurites than controls. Additionally, these disease-related phenotypes were observed more rapidly in OPTN(E50K) RGCs grown in the absence of insulin, a known mTOR activator, suggesting a role for mTOR signaling deficits in neurodegeneration.

Conclusions: The results of this study indicate that deficiencies in OPTN lead to autophagy deficits and decreased mTOR activation, leading to RGC disease phenotypes. Thus, further studies of this pathway may lead to the identification of new targets for therapeutic approaches to glaucomatous neurodegeneration.

ABSTRACT BODY:

Purpose: The first step of our high-definition central vision occurs in the cone photoreceptors in the fovea, which are tightly packed forming a dense pixel array capable of resolving fine spatial details. Death of foveal cones is the ultimate cause of central vision loss in age-related macular degeneration – a leading cause of blindness – as well as other acquired and inherited retinal degenerative diseases. Although human pluripotent stem-cell (hPSC) based replacement strategies hold promise for vision restoration in such conditions, its effective application is limited due to i) a sparse understanding of cone signaling in the primate fovea and ii) a lack of evidence that organoid cones (OCs) can exhibit light-evoked function similar to primate cones in vivo. In this study, we use primate foveal cones (FCs) as a baseline to compare the light-evoked physiology of OCs.

Methods: We used patch-clamp electrophysiology to record light-evoked responses from >100 cones across several hPSC-derived organoids (differentiated >200 days in vitro) and macaque fovea. We compared the photo-responses and membrane properties of the OCs with that of FCs.

Results: Recordings from individual OCs show robust light-evoked responses from a sizeable fraction of OCs across hPSC-organoids. OCs of different spectral types could be identified, though most of them show mid-wavelength spectral sensitivity. The response shape to brief light flashes show profiles similar to that of adult FCs. The light responses of OCs also demonstrate adaptation at higher background luminance similar to typical cones. Both the size and kinetics of light responses in OCs show variability within and between organoids. Although some of the membrane properties of OCs are comparable with that of adult FCs, a few resemble fetal FCs. These findings provide evidence that OCs mimic several physiological properties of adult FCs.

Conclusions: Our recordings from OCs show physiological light-evoked responses over a wide range of light levels. In addition, we were able to replicate several key features of primate FC photo-responses in OCs. These results provide a crucial first step in establishing hPSC-organoids as sources of bona fide human cones and as model systems for drug testing and for studying deficits in photoreceptor physiology in acquired and inherited macular degenerative diseases and cone and cone-rod dystrophies.

Commercial Relationships Disclosure (Abstract): Freya Mowat: Commercial Relationship: Code N (No Commercial Relationship) | Wojciech Panek: Commercial Relationship: Code N (No Commercial Relationship) | Gilad Fefer: Commercial Relationship: Code N (No Commercial Relationship) | Mark Banghart: Commercial Relationship: Code N (No Commercial Relationship) | Grant Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Hans Westermeyer: Commercial Relationship: Code N (No Commercial Relationship) | Margaret Gruen: Commercial Relationship: Code N (No Commercial Relationship) | Natasha Olby: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aging is an important risk factor for visual decline and retinal disorders such as human age-related macular degeneration. Companion dogs share many aspects of the human lifestyle and environment and develop other age-related ocular disorders such as cataract and vitreous degeneration. We hypothesized that age is negatively associated with retinal function in dogs, as measured by dark- and light-adapted electroretinography.

Methods: Participants included adult companion (pet) dogs with no significant ophthalmic abnormalities. All participants underwent unilateral dark- and light-adapted electroretinography following mydriasis (RetEval, LKC Technologies). We performed statistical analysis using R version 4.0.0 to calculate correlation, R squared, and coefficients of correlation between age and ERG parameters. We calculated the strength of association between ERG measurements and age, or age adjusted for expected lifespan of the breed for purebred dogs.

Results: Median age was 11.3 years for all dogs (n = 29, 21 purebred dogs from 11 breeds, range 6.1-15.4 years). Median percentage of maximum purebred breed lifespan was 62%. (n = 20, range 41-104%). Overall, age was associated to a greater extent with ERG amplitude (P value range 0.004-0.44) than peak time (P value range from 0.13-0.97). Age was significantly associated with the dark-adapted bright-flash a-wave amplitude (R^2 .27, P = 0.004) and b-wave amplitude (R^2 .15, P = 0.04); b/a wave ratio was not significantly associated with age (P = 0.32). Age was also significantly associated with light-adapted 33Hz flicker amplitude (R^2 .25 P = 0.006). When age was represented as a proportion of maximum breed lifespan, age was also significantly associated with light-adapted flash b-wave amplitude (R^2 .09, P = 0.012).

Conclusions: Aging in companion dogs is associated with a decline in both rod- and cone-mediated ERG amplitudes. Further studies are warranted to define the relationship between age-related decline in retinal function and vision and/or retinal structure. Companion dogs could be considered a translational model for human age-related vision impairment.

ABSTRACT BODY:

Purpose: Corneal endothelial dystrophy is currently being experimentally treated with limited descemet's stripping without transplantation. This work sought to test whether the regeneration of the endothelial layer after Descemet's stripping could be accelerated in corneal organ culture by treatment with an engineered form of FGF1 (TTHX1114).

Methods: Human corneas obtained from eye banks were maintained in organ culture. Descemet's stripping was performed to remove the central 4mm of endothelial cells with underlying Descemet's membrane. Corneas were then incubated in the presence or absence of TTHX1114 and the recovery of the endothelial layer evaluated by Trypan Blue and Alizarin Red staining. Lesion healing was quantitated using ImageJ. Invasion and proliferation of endothelial cells in the lesion area were evaluated by EdU incorporation and immunostaining with ZO-1.

Results: In both normal corneas and in corneas with guttae noted by the eye bank, healing of the stripped area without treatment was slow with about 30% of the stripped area healed at 14 days as judged by Trypan Blue. Healing in the presence of TTHX1114 was much more rapid, with 81% and 91% of the stripped area healed in normal and dystrophic corneas, respectively. Comparison of the lesion sizes between treated and control corneas was statistically significant (normal, $p < 0.001$, $n=10$ corneas per group; dystrophic, $p < 0.001$, $n=11$ corneas per group). In the healed areas of the treated corneas, Alizarin Red staining and ZO-1 staining revealed endothelial cells with defined ZO-1 rich cell borders covering parts of the lesion area. The endothelial cells covering the lesion area incorporate EdU indicating that they are actively proliferating.

Conclusions: The healing of Descemet's stripping lesions can be accelerated by engineered FGF1 in human corneas ex vivo in both normal corneas and corneas with signs of endothelial dystrophy.

TITLE: Effects of rosmarinic acid and β -cyclodextrin on lens clarity in adult zebrafish

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Prior, D. Van Gaalen, J. Lacroix, Biology, The King's University, Edmonton, Alberta, CANADA|

Commercial Relationships Disclosure (Abstract): Heather Prior: Commercial Relationship: Code N (No Commercial Relationship) | Dylan Van Gaalen: Commercial Relationship: Code N (No Commercial Relationship) | Jack Lacroix: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study was designed to evaluate the effect of rosmarinic acid and β -cyclodextrin on lens clarity in zebrafish with induced cataracts. As an important model organism, zebrafish offer opportunities to investigate basic as well as medical research questions in the field of cataractogenesis. Recent studies using rat and human lens tissue have shown restoration of transparency and delayed cataract formation in response to rosmarinic acid application. In addition, β -cyclodextrins have been used as stabilizers and carrier molecules when introducing antioxidants into biological systems. We have previously developed a method for the induction of cataracts in adult zebrafish which was used to produce cataracts in our study animals. We treated extracted cataractous and healthy lenses with rosmarinic acid as well as β -cyclodextrin, and assessed lens clarity in response to various treatment combinations compared to controls.

Methods: Adult zebrafish were subjected to unilateral intraocular injection of 3% hydrogen peroxide to induce cataracts. At 24 hours post-injection, fish were anesthetized for observation of cataract severity, and euthanized for extraction of both healthy and cataractous lenses. Extracted lenses were then incubated with various concentrations of rosmarinic acid and β -cyclodextrin. Lens clarity was assessed by photography of the lens placed over a grid and evaluation of opacity against a standardized scale.

Results: Using a scoring scale of 1 to 4, observations showed delayed development of opacification in healthy lenses incubated in some concentrations of rosmarinic acid and β -cyclodextrin when compared to controls, 48 to 72 hours after extraction.

Conclusions: These results support the findings in other species that rosmarinic acid may be an effective agent for preventing lens opacification. This preventative effect was detected in healthy lenses, but treatments did not significantly affect lens clarity in cataractous lenses. In addition, this study demonstrates that our method of inducing cataracts in zebrafish is a tractable experimental system.

ABSTRACT BODY:

Purpose: Wnt/ β -catenin signaling is essential for embryonic eye development, and dysregulation of this system may lead to abnormal formation of both the anterior eye and retina. WNT2B, a ligand and activator of the Wnt/ β -catenin pathway, assists in the development of the lens and peripheral regions of the eye. Humans with WNT2B deficiency have a range of ocular defects including microcornea and colobomas. WNT2B may also assist in retinal progenitor cell differentiation, yet the potential role of WNT2B in retinal vascular or neuronal development is understudied. This project explored the effects of WNT2B on retinal neuronal and vascular formation using Wnt2b-deficient mice.

Methods: Systemic Wnt2b knockout mice were generated by crossing Wnt2b^{flox/flox} (fl/fl) mice with CMV-cre mice to deplete Wnt2b in all tissues. Adult heterozygous (Het) and homozygous (KO) Wnt2b-deficient mice (cre+) were examined and compared to fl/fl mice (cre-) as controls. Eyes were either fixed for retinal flat mount or frozen for cross sectioning. Retinal vascular morphology was assessed in flat mounts with isolectin (vascular endothelium marker) staining. Retinal neuronal morphology was assessed with H&E staining of frozen cross sections. Retinal cell type was determined via immunohistochemical staining with either rhodopsin antibody (photoreceptor marker) or isolectin, and co-stained with DAPI (nuclei marker).

Results: Both Wnt2b Het and KO mice exhibited relatively normal anterior segments with normal shape and size of the iris and lens when compared to fl/fl mice. Formation of retinal blood vessels in both Het and KO mice also appeared normal in both superficial and deep vascular layers. In retinal cross section, large clusters of ectopic cells were observed in the subretinal space around the photoreceptor inner and outer segments in both Wnt2b Het (3 out of 4 mice) and KO (2 out of 4 mice), while fl/fl retinas (from 4 mice) showed normal neuronal layers. Other neuronal layers of Het and KO eyes showed normal organization in both layer thickness and lamination, with no sign of retinal degeneration. The displaced cells were present in 2-month-old and persisted in 5-month-old Het and KO mice and stained positive for rhodopsin antibody while negative for isolectin, suggesting ectopic rod photoreceptor formation.

Conclusions: Our findings suggest that WNT2B is a novel regulator of photoreceptor formation and/or migration during eye development.

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) contributes to dry eye which affects 16 million people in the U.S. Meibum lipids are important for the stability of the tear film. The cholesteryl ester/wax ester (CE/WE) ratio decreases with MGD but it is unclear if or how CE affects meibum structure or tear film stability. The aim of this study was to bridge this gap in knowledge.

Methods: Meibum was collected from a 66-year-old Caucasian and a 29-year-old black donor and CE and WE were separated by MgO column chromatography. The esters were characterized using ¹H-NMR and the structure, conformation and phase transitional parameters of mixtures with a range of CE/WE ratios was determined using Fourier transform infrared spectroscopy.

Results: : CE and WE were completely separated. WE from the older donor A (Awe) was composed of 16 % less straight-chains and 50 % more iso-chains compared with CE from the same donor (Ace). The phase transition temperature and order (stiffness) for WE and CE from the younger donor B, Bwe and Bce, respectively, were higher, $P > 0.0001$, compared to Awe and Ace. Bwe added to Bce, decreased the hydrocarbon chain order, and phase transition temperature of Bce, $P < 0.05$. Increasing amounts of Bce added to Bwe caused the hydrocarbon chain order and phase transition temperature to increase linearly above 20 % Bce. The opposite trends were apparent for the donor A samples. The reason for the opposite trends is that Ace was more fluid, $P = 0.02$, compared to Awe, while Bce was less fluid, $P > 0.0001$, compared with Bwe.

Conclusions: Meibum CE and WE can be completely separated. CE changes the phase characteristics of meibum depending on whether it is more or less ordered, than WE. Changes in the meibum content of CE could explain changes in meibum order with age and MGD which may influence tear film stability. Studies to separate CE and WE from meibum are warranted to determine if/how meibum CE and WE conformation and composition change with age, gender, race and MGD and if the changes are related to tear film stability.

ABSTRACT BODY:

Purpose: Glaucoma is a progressive optic neuropathy characterized by reduced retinal nerve fiber layer (RNFL) thickness. The purpose of this study was to discover aqueous humor (AH) proteomic changes associated with RNFL measurements in Cataract and Glaucoma patients.

Methods: Aqueous humor samples from 100 patients were analyzed using Liquid Chromatography-Mass Spectrometry (LC-MS/MS). RNFL parameters, including mean RNFL thickness and superior, inferior, nasal, and temporal thicknesses, were obtained from electronic medical records. Adjusting for confounding variables including age, sex, race and medications, multiple regression analyses were performed to discover the relationship between the aqueous humor protein levels and RNFL measures.

Results: We detected 356 proteins in 100 AH samples. A total of 19 proteins were significantly associated with mean RNFL thickness, 21 proteins were associated with superior thickness, 19 proteins were associated with inferior thickness, 28 proteins were associated with nasal thickness, and 5 proteins were associated with temporal thickness. There was a huge overlap in these proteins associated with different RNFL parameters. The top 10 proteins include: Limbic system-associated membrane protein, (LSAMP; $\beta = 2.23$), Immunoglobulin kappa variable 1D-33 (IGKV1D-33; $\beta = 1.96$), Testican-1 (SPOCK1; $\beta = 0.72$), matrix metalloproteinase-2 (MMP2; $\beta = -3.02$) Protein unc-45 homolog A (UNC45A; $\beta = -2.28$), Metalloproteinase inhibitor 1 (TIMP1; $\beta = -2.01$), Monocyte differentiation antigen CD14 (CD14; $\beta = -1.63$), Apolipoprotein C-III (APOC3; $\beta = -1.51$), Procollagen C-endopeptidase enhancer 1 (PCOLCE; $\beta = -1.43$), and Lysozyme (LYZ; $\beta = -1.09$).

Conclusions: In this study, we found several AH proteins associated with RNFL measures in cataract and glaucoma patients. These findings provide targets for future studies investigating precise molecular mechanisms and new therapies for glaucoma.

TITLE: Post-occlusion surge and anterior chamber stability in a new phacoemulsification machine with small-bore, dual-durometer aspiration tubing

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Zhou, D. Han, Research and Development, Johnson & Johnson Surgical Vison, Inc., Santa Ana, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jianbo Zhou: Commercial Relationship(s);Johnson & Johnson Surgical Vison, Inc.:Code E (Employment) | Duru Han: Commercial Relationship(s);Johnson & Johnson Surgical Vison, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: As a source of chamber instability during cataract surgery, post-occlusion surge (POS) is related to the compliance of the aspiration tubing. New fluidics packs with a small-bore, dual-durometer aspiration tubing were constructed. This study was to evaluate the performance of these fluidics packs with a new phacoemulsification machine on POS in a laboratory benchtop setting.

Methods: The inner layer of the aspiration tubing of the new fluidics packs uses a stiffer material with a smaller inner diameter than existing products, while the outer layer is soft to maintain flexibility. These packs were tested in a newly developed phacoemulsification console in peristaltic mode, along with existing packs as the control arm. A rigid body, leak-tight fixture with small internal volume and an attached pressure sensor were used to simulate the anterior chamber. A phacoemulsification handpiece with a 20G straight tip and sleeve was inserted tightly into the fixture and connected to a fluidics pack. The occlusion mechanism was created with a solenoid valve. A bottle height to generate a static irrigation pressure of 65 mmHg, an aspiration flow rate of 30 cc/min, and five vacuum presets of 200, 300, 400, 500, and 600 mmHg, were selected for this study. The intraocular pressure (IOP) waveforms were measured and recorded continuously during occlusion and occlusion break.

Results: At the vacuum preset of 400 mmHg, the new fluidics packs performed 20% better in terms of the IOP change, from the static value during occlusion to the trough of the IOP curve post occlusion, than the existing fluidics packs. For the vacuum presets from 300 to 600 mmHg, the new packs performed at least 35% better in surge area, the calculated area between the +20mmHg line and the IOP curve below this line, than the existing packs. The surge area was essentially zero at 200 mmHg vacuum for both types of fluidics packs.

Conclusions: This study demonstrated that the new fluidics pack with small-bore, dual-durometer aspiration tubing performed much better than the existing fluidics pack in post-occlusion surge in a new phacoemulsification machine in terms of the IOP change and the surge area in a laboratory setup, providing improved chamber stability.

ABSTRACT BODY:

Purpose: Artificial outer blood-retinal barrier (oBRB) models present numerous applications in age-related macular degeneration (AMD) disease modeling. A thorough understanding of behaviors by different cell populations in the model has significant implications on the understanding of disease progression. Here, iPSC-derived epithelial cells (RPE) and endothelial cells (EC) within a 3D-bioprinted model of the oBRB were analyzed using single-cell RNA-seq to begin determining how printed choroid and RPE carry out specialized functions compared to their in-vivo counterparts.

Methods: EC, Pericytes, and fibroblasts were suspended in gelatin-based bio-ink, bioprinted onto biodegradable poly(lactic, co-glycolic) acid scaffolds and matured for one week. Afterward, RPE was seeded on the opposite sides of the membrane. The completed tissues were cultured for 6 weeks before enzymatic tissue dissociation and cell isolation using magnetic assisted cell sorting. Single-cell suspensions were used to generate barcoded single-cell gel bead-in-emulsions. Following cDNA amplification and processing, libraries were read using an Illumina HiSeq 3000. The Cellranger software package, Seurat R package, and the Biowulf computing cluster were used to process single-cell sequencing data. Gene set enrichment analysis was performed using GSEA v4.0.3, curated Gene Ontology sets and EnrichR.

Results: Differential expression (DE) analysis of RPE gene expression show a general increase in RPE signature genes in the bioprinted oBRB compared to transwell monolayer culture. tSNE analysis revealed broadly homogenous populations of RPE in oBRB and monolayer cultures. DE analysis of EC populations suggested increases in blood vessel maturation, choroidal maturation, and angiogenesis genes in the oBRB model. tSNE analysis suggested that EC in the oBRB model separated into populations at different stages of blood vessel maturation and an inflammatory population.

Conclusions: RNA-seq data suggests that the RPE monolayer acts as a homogeneous cell population within the 3D bioprinted tissue, while ECs show a greater degree of separation into differential stages of vascular maturation within the tissues. The variable stages of maturation are likely a consequence of a dynamic signaling environment within the printed choroid which would promote angiogenesis, maturation and inflammation.

ABSTRACT BODY:

Purpose: The purpose of this research is to compare refractive outcomes of glaucoma patients who underwent phacoemulsification cataract surgery (Phaco) to those who had cataract surgery with Minimally Invasive Glaucoma Surgery (Phaco + MIGS). Previously, few studies have explored the various refractive outcomes following Phaco + MIGS procedures as compared to Phaco alone.

Methods: This is a retrospective chart review of 243 patients from Edward Hines Jr. VA Hospital and Loyola University Medical Center who had MIGS procedures (iStent® (Glaukos Corp. Laguna Hills, CA) or Kahook Dual Blade® (New World Medical, Rancho Cucamonga, CA, USA) and Phaco (Phaco + MIGS, n= 163) or Phaco alone (Phaco, n= 80). The Phaco group only includes patients from the Edward Hines Jr. VA Hospital. Subgroup analysis was performed based on the severity of glaucoma and race. We performed both independent t-tests and one-way ANOVA tests.

Results: The average difference in post-operative spherical equivalent (SE) to target refraction in Phaco + MIGS vs. Phaco was 0.462 and 0.437, respectively ($p = 0.5$). 65.5% of patients in the Phaco + MIGS group were within 0.5 D of the target refraction compared to 67.5% of the Phaco group. 89% of eyes in the Phaco + MIGS group had a post-op SE within 1 D of the anticipated target refraction vs. 92.5% of eyes in the Phaco group. The Phaco + MIGS African American subgroup ($n = 57$) had 87.8% eyes within 1 D of target vs. 88.2% in the Caucasian subgroup ($n = 110$). The Phaco African American group ($n = 27$) had 92.6% compared to the Phaco Caucasian group ($n = 53$) with 92.5% of eyes within 1 D of target refraction. We performed a one-way ANOVA to compare the effect of severity of glaucoma on refraction. In both the Phaco + MIGS and Phaco groups, there was no significant difference ($p = 0.171$ vs. $p = 0.241$), respectively. 82% of patients in the Phaco + MIGS group with refractive surprise ($> 1D$ from target) had visual acuity (VA) of 20/40 or worse vs. 100% of eyes in the Phaco group. In the Phaco group, average pre-op VA was 20/40 compared to 20/25 post-op. In the Phaco + MIGS group, average VA went from 20/60 pre-op to 20/30 post-op.

Conclusions: Our study showed no significant difference in refractive outcomes in patients who had Minimally Invasive Glaucoma Surgery with phacoemulsification compared to those who had phacoemulsification cataract surgery alone. There was also no significant difference in refractive outcomes based on race or the severity of glaucoma.

Cristina Kenney: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

We evaluated possible adverse impacts of ciprofloxacin (CPFX) on human retinal Müller cells (MIO-M1).

Methods:

MIO-M1 cells were cultured in 96 well plates with the density of 10,000/well. The MIO-M1 cells were treated 48 hours with CPFX concentrations of 30, 60 and 120 mg/ml. 0.1 N solution of hydrochloric acid (HCl) was used as the vehicle control for CPFX. Assays measured levels of cellular metabolism (MTT), mitochondrial membrane potential (JC-1) and reactive oxygen species (ROS).

With the MTT assay, after 48 hours exposure to CPFX, 10 µl MTT assay reagent was added to each well and plates were incubated at 37°C for 2 hours. After adding 100 µl of DMSO to each well, plates were analyzed (signal at 570 nm and reference at 630 nm) with the absorbance reader.

After 48 hour treatment, the JC-1 reagent was added to each well. Plates were analyzed with a fluorescent plate reader at green (EX 485 nm and EM 535 nm) and red (EX 550 nm and EM 600 nm) to determine the red to green ratios that represent the 'live to dead' cells, respectively.

For the ROS assay, fluorescent H2DCF-DA dye was added to each well and plates read at excitation (EX, 492nm) and emission (EM, 520nm) wavelengths using the fluorescent plate reader.

Results:

The mean cellular metabolisms with 30, 60 and 120 mg/ml concentrations were: 84.5 ± 5.8 ($P=0.03$), 76.25 ± 9.1 ($P=0.03$) and 56.75 ± 4.2 ($P<0.0001$), compared to untreated cells (mean= 100 ± 0.5).

The mean of MMP in CPFX-treated cells was: 93 ± 4.8 ($P=0.19$), 85.5 ± 5.8 ($P=0.04$), and 78.75 ± 2.9 ($P=0.0004$), compared to untreated group (mean= 100 ± 0.4).

The ROS levels were not significantly changed after CPFX treatment.

Conclusions:

Exposure to CPFX decreased significantly metabolism and MMP in a dose-dependent manner in MIO-M1 cells.

Clinically relevant concentrations of CPFX impacted MIO-M1 cells in vitro.

Hazen, Biophysics Interdisciplinary Group, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jun Liu: Commercial Relationship: Code N (No Commercial Relationship) | Sunny Kwok: Commercial Relationship: Code N (No Commercial Relationship) | Xueliang Pan: Commercial Relationship: Code N (No Commercial Relationship) | Daniela Druzynski: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Hazen: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Hendershot: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To measure and compare heartbeat-induced corneal axial displacements (CAD) in patients with keratoconus (KCN) and normal controls (NRL) using a high-frequency ultrasound elastography method (Kwok et al, TVST, 2020).

Methods: Twenty-nine eyes in 15 KCN patients (age: 20-66; 8 males, 7 females) and 40 eyes in 20 NRLs with no known ocular diseases (age: 22-67; 6 males, 14 females) were recruited. Topographic and tomographic evaluations were obtained with an Oculus Pentacam to confirm KCN diagnosis. Intraocular pressure (IOP) and ocular pulse amplitude (OPA) were measured using a PASCAL Dynamic Contour Tonometer. A 50-MHz ultrasound probe (FUJIFILM VisualSonics) was used to acquire 1000 cross-sectional scans of the central 5-mm cornea along the naso-temporal axis at 128 frames per second. A correlation-based speckle tracking algorithm (Tang & Liu, JBME, 2012) was used to compute corneal displacements between consecutive frames. CAD was obtained as the average trough-to-peak magnitude of three heartbeat-induced axial displacement cycles.

Results: IOP and OPA were not different between KCN and NRL (IOP: 16.1 ± 3.5 vs 16.3 ± 2.5 mmHg, $p=0.85$; OPA: 2.2 ± 0.9 vs 2.6 ± 0.8 mmHg, $p=0.08$; two-sample t-tests). The CAD in KCN was 52.5 ± 20.8 μm , significantly larger than that (38.3 ± 9.1 μm) in NRL ($p<0.001$, two-sample t-test; Fig. 1). In addition, a positive association between CAD and age was observed in KCN ($r=0.42$, 95% CI= $0.063\sim0.68$, $p=0.02$, $n=29$, Fig. 2), but no significant trend was observed in NRL ($r=-0.10$, 95% CI= $-0.40\sim0.22$, $p=0.54$, $n=40$).

Conclusions: High-frequency ultrasound elastography may offer a tool for clinical biomechanical evaluation of the cornea. Our results showed a larger heartbeat-induced CAD in KCN, suggesting that CAD may be a useful parameter for KCN diagnosis. The increased difference between KCN and NRL with age may indicate progressive corneal weakening in KCN. Future studies are needed to evaluate whether CAD is associated with KCN grade and KCN progression over time.

ABSTRACT BODY:

Purpose: To determine the effect of foot reflexology in primary open angle glaucoma (POAG) patients and the effect of a shoe insert to perform continuous foot reflexology in ocular hypertensive (OHTN) patients.

Methods: This is a prospective pilot study in glaucoma patients and a prospective therapeutic trial in ocular hypertensive patients. Patients were recruited from the Temple Ophthalmology outpatient clinic. Open-angle glaucoma patients were recruited from those about to have selective laser trabeculoplasty (SLT) for additional intraocular pressure (IOP) lowering. OHTN patients were recruited from the clinic. The glaucoma patients performed a 5-minute foot massage on a foot massage board (Figure 1) and the IOP was checked pre-massage, post-massage and 30, 60, 90 and 120 min post massage. OHTN patients underwent a one-month drop washout and then performed a 5-minute massage using a 3D-printed shoe insert (Figure 2) with the identical pressure checks. They then were randomly assigned to wear the shoe insert or a sham insert for one day. IOP was checked before inserting the insert and at the end of the day. The number of steps was recorded each day.

Results: For the glaucoma patients, after the 5-minute foot massage, the IOP significantly decreased up to 10% at 30, 90 and 120 min after massage in the right eye and up to 23% at all time points in the left. For the OHTN patients, IOP significantly decreased 6-13% in both eyes at all time points. For the shoe insert, there was a significant reduction in IOP of 10% for the left eye IOP but not the right eye at 6%. Two OHTN patients did not respond to the all-day shoe insert when they had responded to the 5-minute massage and one patient didn't respond at all.

Conclusions: Foot reflexology significantly lowers IOP in both glaucoma and OHTN patients. The use of this shoe insert to try and replicate the foot massage had promising, but somewhat inconsistent results. A different shoe insert might be better able to replicate the effect of the massage.

ABSTRACT BODY:

Purpose: Accumulated vascular damage contributes to onset and progression of vascular dementia and possibly to Alzheimer's disease. Here we evaluated the feasibility and utility of using retinal imaging of microvascular markers to identify older adults at risk of cognitive disease.

Methods: The Eye Determinants of Cognition (EyeDOC) study recruited a biracial population-based sample from two sites: Jackson, MS, and Washington Co, MD. From 2017 to 2019, optical coherence tomographic angiography (OCTA) was used to capture vessel density (VD) across vascular layers and foveal avascular zone (FAZ) area from a scan of the macula. Image quality was assessed by trained graders. A neurocognitive battery of 10 tests was administered at three time points from 2011 to 2019 and incident MCI/dementia cases were ascertained. Linear mixed effects models were used to evaluate associations of retinal vascular markers with cognitive factor score change over time.

Results: 976 older adults, mean age of 78.7 (\pm 4.4) years, 44% black, were imaged. Gradable images were obtained in 55% (535/976), with low signal strength (66%) and motion artifact (22%) the largest contributors to poor quality. Both worse presenting distance visual acuity ($p < 0.001$) and worse contrast sensitivity ($p = 0.031$) were associated with poor quality images. Among the 480 participants with high quality images and no clinically significant retinal pathology, no associations of VD in any vascular layer or FAZ with longitudinal changes in either global cognitive function or with incident MCI/dementia were found.

Conclusions: In this large biracial community sample of older adults, OCTA-based retinal vascular imaging biomarkers were not associated with cognitive decline, incident MCI or dementia. Challenges with obtaining high quality OCTA images in older community-dwelling adult populations may currently limit the feasibility and utility of OCTA-retinal markers for detecting risk of cognitive disease.

ABSTRACT BODY:

Purpose: Myo/Nog cells play an essential role in normal eye development. Previous studies have shown that they migrate to areas of stress and injury in the retina and are neuroprotective, but their specific role in these areas of stress is unclear. In this study, we observed the behavior of Myo/Nog cells in a congenital murine model of retinitis pigmentosa (C3H mice), which results in the loss of photoreceptor cells within the outer nuclear layer of the retina (ONL).

Methods: C57BL/6J (C57) and C3H/HeJ (C3H) mice were assessed at weeks 2.5, 3, 4, 5, and 6 using scotopic electroretinography (ERG) and histological analysis. Enucleated eyes were fixed in paraformaldehyde and cryo-sectioned. Cryosections were labeled with Myo/Nog specific monoclonal antibodies and TUNEL to detect cell death; and analyzed by fluorescence microscopy.

Results: The decreased amplitude of the A and B waves in the C3H mice in comparison to those of C57 mice was verified with ERG ($p<0.05$). Progressive thinning of the retina in the C3H mice was confirmed by microscopic analysis. While C3H mice initially demonstrated a greater number of photoreceptors at the edge of the retina, by week 4 there were significantly fewer photoreceptors at the periphery in comparison to the mid-periphery and central retina ($p<0.05$). Myo/Nog cells were significantly more numerous in C3H than C57 retinas ($p<0.05$). The majority of Myo/Nog cells were found in the diminishing ONL and choroid. Several of the Myo/Nog cells had phagocytosed apoptotic photoreceptors.

Conclusions: Progressive retinal degeneration and visual deterioration in C3H mice are accompanied by an increase in Myo/Nog cells. They accumulate in parallel with an increase in cell death in the ONL and demonstrate phagocytic properties as they engulf dying cells. These findings are consistent with Myo/Nog cells' behaviors in other forms of retinopathy and injury in other tissues. Future studies will characterize additional functions of Myo/Nog cells in this severe model of retinitis pigmentosa.

ABSTRACT BODY:

Purpose: To improve the performance of the feature agnostic AI-based glaucoma detection algorithm by evaluating an uncertainty score for each prediction.

Methods: We previously developed a 5-layer 3D Convolutional Neural Network (CNN) in using the OCT scans from both eyes of 134 healthy, 779 glaucoma patients on a Cirrus HD-OCT scanner (200x200 ONH Cubes; Zeiss, Dublin CA). In our analysis, we excluded scans with signal strength less than 7 and downsampled the volumes to 64x64x128 voxels.

Uncertainty of AI models can be estimated by computing the effect of randomly ignoring a set of parameters within the network. We randomly zeroed 5% of each of the 5 convolutional layers and computed the entropy in the final score over 20 forward passes. The performance of the approach was assessed using a 10-fold cross validation study.

Results: Over the 10-folds, the model showed an AUC of 0.91 ± 0.027 . In analysing the uncertainty and the probabilistic scores generated by the model (Softmax function) for one fold (see Fig. 1), we observed that a threshold of 0.8 can be used to flag 75% of the false positives and false negatives for further review. On the other hand, only 25% of the healthy controls and 20% of glaucoma patients showed an uncertainty score above that threshold. Fig. 2 summarises the overall uncertainties scores and indicates that low scores are associated with the correctly identified cases while the errors show higher uncertainty scores.

Conclusions: The quantitative uncertainty measure provides supplementary information to clinicians and can be used to flag difficult cases automatically.

Given that the dataset used in this work is highly imbalanced (more positive cases compared to normal cases) the uncertainty score for true negative cases is significantly higher compared to true positive cases. We expect to achieve lower uncertainty scores for normal cases if more data for normal eyes are available.

The uncertainty analysis presented here may aid clinical interpretations of AI-based glaucoma detection outcomes. A separate study will be run to measure this improvement and compare the result with experts' level of uncertainty.

ABSTRACT BODY:

Purpose: The purpose of the current study is to elucidate the epidemiological background of central serous chorioretinopathy, including its incidence and treatment pattern, using a nationwide health insurance claims database of the Japanese population.

Methods: This is a population-based cohort study using a nationwide health insurance claims database, which included the entire Japanese population aged 30 years or older (91 million people) between 2011 to 2018. The National Database of Health Insurance Claims and Specific Health Checkups of Japan (NDB) is a national claim database managed by Japan Ministry of Health, Labor, and Welfare (MHWL). As Japan employs universal health coverage, the NDB covers almost all claims issued in Japan. We accessed all data stored in the NDB under the permission of the MHWL. CSC onset was recorded by age and sex categories per year between 2011 and 2018, and the incidence rate was calculated. We identified laser photocoagulation (PC), photodynamic therapy (PDT) with verteporfin, and anti-vascular endothelial growth factor (anti-VEGF) intravitreal injection to evaluate the transition of the initial treatment pattern. In addition, geographical, climatic, and seasonal variation of incidence rate was also assessed.

Results: During the 8-year period, 247,930 incidences of CSC were identified, among which 75.9 % were male. The crude incidence rate (per 100,000 person-years) in the general population aged 30 years or older was 34.04 (95% CI, 33.90–34.17), that in males was 54.16 (95% CI, 53.91-54.40) and that in females was 15.67 (95% CI, 15.54-15.79). The mean age of onset was younger in males than in females (50.51 ± 12.48 years vs 54.67 ± 13.53 years). Most of the newly diagnosed CSC patients (86.8%) did not receive PC, PDT, or anti-VEGF. The incidence rate showed significant geographical, climatic, and seasonal variations; for example, low incidence was observed in relatively rural, cold, and snowy areas, and in summer and winter.

Conclusions: The current study provides the largest population-based evidence to clarify the detailed epidemiology of CSC. These results could help to understand the pathogenesis and mechanisms of CSC in the future.

TITLE: Aging-dependent gut microbiome dysbiosis is associated with dry eye severity in C57BL/6 male mouse model

SESSION TITLE: Translational Immunology and Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Yoon, M. Kim, Ophthalmology, Seoul National University College of Medicine, Seoul, KOREA (THE REPUBLIC OF)|C. Yoon, J. Ryu, M. Kim, Laboratory of Ocular Regenerative Medicine and Immunology, Biomedical Research Institute., Seoul National University Hospital, Jongno-gu, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure (Abstract): Chang Ho Yoon: Commercial Relationship: Code N (No Commercial Relationship) | JinSuk Ryu: Commercial Relationship: Code N (No Commercial Relationship) | Mee Kum Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Emerging evidence have demonstrated that gut dysbiosis contributes to the pathophysiology or exacerbation of ocular diseases including dry eye disease. However, the relationship between aging-related changes in gut microbiota and dry eye disease have not been elucidated. We investigated the association between aging-dependent microbiome changes and dry eye severity in C57BL/6 male mice.

Methods: Eight-week-old (8W, n=15), one-year-old (1Y, n=10), and two-year-old (2Y, n=8) C57BL/6 male mice were used. Dry eye severity was assessed by corneal staining scores and tear secretion. Bacterial genomic 16s rRNA from feces was analyzed. Main outcomes were microbiome compositional differences among the groups and their correlation to dry eye severity. The Kruskal–Wallis test followed by Dunn's post hoc test was used for comparison between the three groups. Univariate analysis was used to identify the microbiome composition associated with the dry eye severity. Multivariate analysis was used to eliminate confounding age factors.

Results: In aged mice (1Y and 2Y), corneal staining increased and tear secretion decreased with statistical significance. Gut microbiome α -diversity was not different among the groups. However, β -diversity was significantly different among the groups. In univariate analysis, phylum Firmicutes, Proteobacteria, and Cyanobacteria, Firmicutes/Bacteroidetes ratio, and genus Alistipes, Bacteroides, Prevotella, Paraprevotella, and Helicobacter were significantly related to dry eye severity. After adjustment of age, multivariate analysis revealed phylum Proteobacteria, Firmicutes/Bacteroidetes ratio, and genus Lactobacillus, Alistipes, Prevotella, Paraprevotella, and Helicobacter to be significantly associated with dry eye severity.

Conclusions: Our study suggests that aging-dependent changes in microbiome composition are related to severity of dry eye signs in C57BL/6 male mice.

ABSTRACT BODY:

Purpose: Previous studies show that some visual field (VF) defects are detectable via analysis of visual search behaviour, for example: when watching video, or performing daily living tasks. Here, we developed an alternate approach that measures the number of fixations to find targets on a background with spatial frequency content similar to natural scenes (1/f noise). We chose this approach because there is an established theoretical framework linking target detectability in the image to the predicted number of fixations[1]. We conducted a proof-of-concept experiment to test if the method can detect VF loss.

Methods: 21 older adults [aged:61-79 years] and 20 people with a clinical diagnosis of glaucoma [aged:59-84 years] participated. Participants visually searched for a Gabor (6c/°) that appeared in one of 25 possible locations within a 15° (visual angle) 1/f noise background (RMS contrast: 0.20). Gabor contrast was set at the 95% probability of seeing limit estimated from frequency of seeing curves in 28 older controls. The outcome measure was the number of fixations required to find the target, measured using a Gazepoint GP3 eye tracker. Each target was presented 20 times, in randomized and interleaved order. Normative limits (NL: 95%,98%,99%) for the number of fixations at each location was estimated. Procedure performance was assessed by calculating sensitivity (SE) and specificity (SP) for different combinations: NL, target locations with fixations outside NL (varied: 0-25) and number of repeated target presentations (varied: 1-20). The highest Area Under Curve (AUC) (computed as partial AUC (pAUC) for SP higher than 80%) was chosen; from this curve the criteria with highest SE for SP greater than 95% was selected.

Results: Older adults made a median of 2-3 fixations (Interquartile range (IQR):2-4) to locate the target on the 1/f noise for all locations. The VF was flagged “abnormal” when the fixation number was greater than the 99% NL for three or more locations (85% SE, 95.2% SP, 88% pAUC) averaged over two repeated presentations. The median time for controls to perform the task was 46 (IQR:33-65) seconds.

Conclusions: Our prototype test demonstrated effective and efficient screening of abnormal areas in central vision and was well tolerated. While we included people with glaucoma here, the method is designed to generalize to any form of central VF loss.

SUBMITTER (NAME ONLY): Andrew Lam

TITLE: Fixation stability using soft contact lenses versus built-in auto-focus in OCTA of myopes

SESSION TITLE: Imaging of posterior segment I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Lam, K.K. Lau, H. Wong, J.P. Lam, M. Yeung, Center for Myopia Research, School of Optometry, The Hong Kong Polytechnic University, Kowloon, HONG KONG|

Commercial Relationships Disclosure (Abstract): Andrew Lam: Commercial Relationship: Code N (No Commercial Relationship) | Kenny Lau: Commercial Relationship: Code N (No Commercial Relationship) | Ho-yin Wong: Commercial Relationship: Code N (No Commercial Relationship) | Jasmine Lam: Commercial Relationship: Code N (No Commercial Relationship) | Man-For Yeung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: High myopia has been found to be associated with reduced retinal capillary vasculature. Optical defocus could lead to erroneous OCTA measurement. Some OCTA systems have built-in ocular lenses to compensate refractive defocus. We hypothesized that inadequate optical correction could lead to fixation instability, hence affecting OCTA measurements.

Methods: Seventy eyes of 70 myopes (35: spherical equivalent $>-3D$, 35: spherical equivalent $<-6D$) had OCTA measured using a Cirrus SD-OCT. Three measurements were obtained using a 6x6 mm scan (350x350 pixels) centered at the fovea, first with soft contact lens correction, followed by using the built-in Auto Focus correction after removal of contact lenses. Valid OCTA scans had signal strength of ≥ 7 and no obvious artefacts. Fixation stability of the 3 OCTA scans was analyzed in terms of deviation (in pixel) of the fovea from the centre of the 350x350 grid (Figure 1). OCTA metrics, namely vessel length density (VD) and perfusion area density (PD) using the ETDRS format, and foveal avascular zone (FAZ) were averaged from the three OCTA scans and compared between different correction methods.

Results: Low myopes ($-1.89D \pm 0.75D$) and high myopes ($-8.10D \pm 1.34D$) had similar age. Fixation stability of low myopes from three OCTA scans (test-retest repeatability) was similar between the two correction modes (contact lens: 10 pixels vs Auto Focus: 7 pixels). High myopes had poor fixation stability when corrected with Auto Focus (test-retest repeatability: 17 pixels) compared with using contact lenses (12 pixels). Signal strength was higher in low myopes than high myopes when corrected with contact lenses (8.96 vs 8.40) and Auto Focus (8.82 vs 8.17). When combining the two groups, only VD at the outer ring and PD of the entire 6mm circle showed significant difference between the two correction methods. VD and PD results were smaller when using Auto Focus. No significant difference in FAZ was found.

Conclusions: Fixation was more stable in OCTA measurement when myopes were corrected with soft contact lenses, especially high myopes. In general, VD, PD, and FAZ were similar using different correction methods that could be due to using averaged results from three OCTA scans. Multiple OCTA scan averaging approach is recommended.

ABSTRACT BODY:

Purpose: To investigate the relationship between retinal sensitivity (RS), retinal thickness (RT), perfusion density (PD), and the effect of laser treatment over 1 year in patients with BRVO treated with intravitreal ranibizumab injection (IVR) or IVR with laser treatment.

Methods: Patients with BRVO who received IVR at Shinshu University Hospital between 2017 and 2018 were assessed at baseline and 12 months after initial treatment. RS in 34 stimulus locations in the central 10° were assessed using microperimetry (Microperimeter MP-3; Nidek Co., Ltd., Gamagori, Japan). From these same RS locations, RT by optical coherence tomography (OCT) (PLEX Elite 9000; Carl Zeiss Meditec, Inc, Jena, Germany) and PD by OCT angiography were measured. In addition, the presence of superficial and deep hemorrhage in each region was evaluated. Focal laser (MC-500 Vixi; Nidek Co., Ltd.) was applied (multiple times if needed) to areas with residual edema after IVR. Relationship between application of laser treatment and changes in RS, RT, and PD were assessed.

Results: Fourteen eyes of 14 patients (5 men and 9 women aged 72.0 ± 7.7 years, 7 IVR alone and 7 combination) were analyzed. At baseline, RS showed a significant negative correlation with RT ($r = -0.68$, $p = 3.35e-71$, Pearson's correlation coefficient) and a positive correlation with PD ($r = 0.72$, $p = 1.16e-42$). RT and PD were negatively correlated ($r = -0.64$, $p = 1.14e-40$) with each other.

At 12 months, RS showed a significant positive correlation with RT and PD (RT: $r = 0.56$, $p = 5.72e-36$; PD: $r = 0.60$, $p = 2.12e-46$). PD and RT showed a positive correlation ($r = 0.61$, $p = 2.49e-46$) with each other.

Areas with superficial hemorrhage had significantly lower RS than those with deep hemorrhage at baseline and at 12 months (baseline: $p = 0.0025$; 12M: $p = 0.0208$, Mann Whitney test).

There was a significant improvement in RS at 12 months in the IVR monotherapy group ($p < 0.0001$, One-way ANOVA) but not in the combination group ($p = 0.675$). RS was significantly higher in the IVR monotherapy group than in the combination group at 12 months ($p < 0.0001$).

Conclusions: In eyes with BRVO, regions with low PD at baseline had thicker retinas. Twelve months after initiation of therapy, RS improved in the IVR monotherapy arm but not in eyes requiring combination therapy. These findings may be of value in assessing prognosis in eyes with BRVO.

TITLE: Bilateral macular edema (ME) at baseline and 1 year due to diabetic retinopathy (DR), neovascular age-related macular degeneration (nAMD), and retinal vein occlusion (RVO)

SESSION TITLE: Diabetic Retinopathy Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Kulkarni, S. Chang, C. Chuo, E. Finucane, N. Callaway, D. Ferrara, Genentech Inc, South San Francisco, California, UNITED STATES|D. Ferrara, Tufts University, Medford, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Priya Kulkarni: Commercial Relationship(s);Genentech:Code E (Employment) | Shih-Chen Chang: Commercial Relationship(s);Genentech:Code E (Employment) | Ching-Yi (James) Chuo: Commercial Relationship(s);Genentech:Code E (Employment) | Elizabeth Finucane: Commercial Relationship(s);Genentech:Code E (Employment) | Natalia Callaway: Commercial Relationship(s);Genentech:Code E (Employment);Virta Health:Code I (Personal Financial Interest);Pear Therapeutic:Code I (Personal Financial Interest);Vohra Wound Physicians:Code I (Personal Financial Interest) | Daniela Ferrara: Commercial Relationship(s);Genentech:Code E (Employment)

ABSTRACT BODY:

Purpose: The most common causes of ME (DR, nAMD, and RVO) can affect both eyes. Bilateral ME significantly impacts a patient's visual function and ability to perform tasks of daily living. This study aims to understand the prevalence of bilateral ME at initial diagnosis (baseline) for patients with DR, nAMD and RVO, and second eye involvement at 1 year (1yr) for patients with unilateral ME at baseline.

Methods: A retrospective observational claims database study, using Truven® marketscan, in adults (≥ 18 years) with at least one diagnosis of ME between Oct 2016 to Jun 2018 as ascertained by the ICD-10 codes. Patients were categorized into three groups according to ME involvement at initial diagnosis: unilateral (right or left), bilateral or unspecified. Patients with unilateral ME at baseline were followed for 1yr to estimate the bilateral involvement (Figure 1).

Results: Out of 37,827 patients with DR, 23,250 (61%) had an initial diagnosis of bilateral ME, 13,492 (36%) had unilateral involvement; and 1085 (3%) unspecified. Of 13,492 with unilateral ME at baseline, only 2490 had at least 1-yr follow-up. Of these, 573 (23%) developed bilateral involvement at 1yr as follows: 14% within the first 3 months, 5% between 4-6 months, 2-3% between 7-9 months and 2% between 10-12 months.

Extrapolating the observed bilateral involvement rate to all patients with unilateral involvement (36%), 8% developed bilateral macular edema at 1yr.

Bilateral rates for nAMD and ME secondary to RVO estimated in an analogous manner are given in Table 1. Of 30,548 nAMD and 11,953 RVO patients, 9,097 (30%) and 473 (4%) had an initial diagnosis of bilateral ME respectively, with additional 9% and 2% developing bilateral ME by 1yr.

Conclusions: At the initial diagnosis, DR patients had a greater proportion of bilateral ME (61%) compared to nAMD (30%) and RVO (4%). Fewer RVO patients developed bilateral ME by 1yr compared to DR and nAMD patients. In summary, ME secondary to DR and nAMD frequently affect both eyes and regular bilateral monitoring is necessary. Evaluation of risk factors associated with more severe disease and vision threatening complications such as ME is warranted.

ABSTRACT BODY:

Purpose: To evaluate the effect of graft preparation and organ-culture storage on endothelial cell density (ECD) and viability of Descemet membrane endothelial keratoplasty (DMEK) grafts.

Methods: DMEK grafts (n=27) were prepared at Amnitrans EyeBank Rotterdam from 27 corneas (15 donors) that were eligible for transplantation but could not be allocated due to the Covid-19-related cancellation of elective surgeries. Cell viability (by Calcein-AM staining) and ECD of 5 grafts originally scheduled for transplantation, were evaluated on the originally planned surgery day, whereas 22 grafts from paired donor corneas were evaluated either directly post-preparation or after 3-7 days of storage.

Results: Light microscopy (LM) evaluation of all grafts showed an unremarkable endothelial cell monolayer directly after preparation. However, median viable ECD for the 5 grafts initially allocated for transplantation was 18% (range 9-73%) lower than median LM ECD. For the paired DMEK grafts, viable ECD determined by Calcein-AM staining on the day of graft preparation and after 3-7 days of graft storage showed a median decrease of 1% (mean, 5(\pm 11)%) and 2% (mean, 16(\pm 33)%), respectively. Median % graft area populated by viable cells after preparation and after 3-7 days of graft storage was 88% (mean, 85(\pm 12)%) and 92% (mean, 88(\pm 14)%), respectively.

Conclusions: Loss of viable cells may be observed for some grafts within hours after preparation with insignificant additional ECD changes during 3-7 days of graft storage. Implementing an additional post-preparation step in the eye bank to evaluate cell density before graft release for transplantation may help to reduce postoperative DMEK complications.

ABSTRACT BODY:

Purpose: In vivo confocal microscopy (IVCM) is a non-invasive optical imaging modality that enables a histological visualization and provides morphometric information about corneal nerve fiber (CNF) and dendritic cell (DC), that aid clinicians to diagnosis of inflammatory corneal diseases. Quantification of CNF and DCs requires manual annotation or semi-automatic approaches, which are time consuming, non-reproducible, and laborious. The purpose of this research study was to develop deep learning-based models to segment and quantify CNF and DC in IVCM automatically, therefore reducing inter-or intra-observer variability and time associated with manual perception to analyze larger volumes of clinical images.

Methods: A CNF segmentation and DC detection model were developed based on deep learning algorithms U-Net and Mask R-CNN respectively. The CNF segmentation model was trained with 1036 and tested on 183 images while the DC detection model was trained with 446 and tested on 50 images. To analyze CNF morphology, number of nerves, number of branching points, nerves density, nerves length, and tortuosity were measured. An automatic Python-based software was written to compute the morphometric parameters directly from the binary segmented image produced by deep learning model. Moreover, Bland-Altman's statistical analysis was performed to determine the consistency between automatic segmentation and manual annotation.

Results: The CNF segmentation model reliably segments the testing images with an average 83% sensitivity and 91% specificity while the DC detection model detects DCs with an average 92% precision, 95% recall, and 93% F1 score. In Bland-Altman's analysis, the mean of automatic and manual segmentation for all morphometric parameters was close to 0, and more than 95% of the values were within the limit of agreement. To segment and morphometric evaluation of CNF, our developed software took on average 4.5 seconds per image while to detect and count the DCs took on average 3 seconds.

Conclusions: Our developed deep learning-based models demonstrated high consistency between automatic and manual segmentation of IVCM images with rapid speed. The results show that the system has the potential to be implemented into clinical practice for CNF segmentation and DC detection in IVCM.

TITLE: Topographic Effects on AI-Quantified Regional Progression in the FILLY Trial of Pegcetacoplan (APL-2) for Treatment of Geographic Atrophy Secondary to AMD

SESSION TITLE: AI in the retina: Prediction models

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W. Vogl, H. Bogunovic, J. Mai, G.S. Reiter, S. Riedl, D. Lachinov, U. Schmidt-Erfurth, Department of Ophthalmology and Optometry, Medizinische Universität Wien, Wien, Wien, AUSTRIA|

Commercial Relationships Disclosure (Abstract): Wolf-Dieter Vogl: Commercial Relationship: Code N (No Commercial Relationship) | Hrvoje Bogunovic: Commercial Relationship(s);Apellis:Code F (Financial Support) | Julia Mai: Commercial Relationship: Code N (No Commercial Relationship) | Gregor Reiter: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Riedl: Commercial Relationship: Code N (No Commercial Relationship) | Dmitrii Lachinov: Commercial Relationship: Code N (No Commercial Relationship) | Ursula Schmidt-Erfurth: Commercial Relationship(s);Genentech:Code C (Consultant);Heidelberg Engineering:Code C (Consultant);Kodiak:Code C (Consultant);Novartis:Code C (Consultant);Roche:Code C (Consultant);RetInSight:Code C (Consultant)

ABSTRACT BODY:

Purpose: To investigate treatment effects on local progression of Geographic Atrophy (GA) with respect to topographic growth patterns quantified from SD-OCT images by deep learning in age-related macular degeneration (AMD).

Methods: 334 SD-OCT scans of 57 eyes with monthly (AM), 52 eyes with every-other-month (AEOM) treatment and 58 eyes with sham (SM) injection from baseline and 1 year follow up of a Phase 2 clinical trial evaluating pegcetacoplan in patients with GA secondary to AMD (FILLY, NCT02503332) were included. Retinal pigment epithelium loss were automatically segmented using deep learning. Local GA growth rate was determined from the delineated en-face projections of GA as the distance of baseline border points to the closest border point at 1 year. Growth direction was categorized into “towards fovea” when angle between growth direction and direction to fovea was less than $\pm 90^\circ$ and “away from fovea” otherwise.

Mixed effects models grouped by eyes and distance as random factor were used to regress growth speed for each GA lesion border point using treatment and growth direction as covariates.

Results: Using 321,946 GA border points, mean growth for SM was 64 $\mu\text{m}/\text{year}$ (95%CI: 39 to 87), with 18 $\mu\text{m}/\text{year}$ less(95% CI: 5 to 32, $p=.0103$) and 6 $\mu\text{m}/\text{year}$ less(95% CI: -8 to 20, $p=.39$) for AM and AEOM, respectively. For the 195,396 points showing GA growth, the mean growth was 108 $\mu\text{m}/\text{year}$ (95%CI: 86 to 132) for SM and additional reduced growth by 26 $\mu\text{m}/\text{year}$ (95%CI: 6 to 47, $p=.0135$) and 4 μm (95%CI: -16 to 25, $p=0.72$) for AM and AEOM, respectively. Growth towards fovea is reduced by 4 μm (95%CI: 2 to 5, $p<.001$) for SM and additionally by 13 μm (95%CI: 11 to 15, $p<0.0001$) and 12 μm (95%CI: 11 to 14, $p<0.0001$) for AM and AEOM treatment.

Conclusions: Eyes treated with pegcetacoplan showed a significantly slower GA lesion growth rate compared to sham, and an even slower growth rate towards fovea. By assessing local GA growth and direction, the heterogeneity in GA progression is captured in more detail and enables observation of treatment effects with respect to topography. Using deep learning to automatically quantify atrophy in in-vivo OCT images allows for precise and accurate assessment and analysis of GA progression at a large scale and may provide new insight into disease mechanisms and response to novel treatment.

ABSTRACT BODY:

Purpose: This study quantified corneal subbasal nerve tortuosity in dry eye disease (DED) and investigated its correlation with clinical parameters by proposing an aggregated measure of tortuosity (Tagg).

Methods: The sample consisted of twenty-six eyes of patients with DED and Twenty-three eyes of healthy volunteers, which represented separately the dry eye group and the control group. Clinical evaluation of DED and in vivo confocal microscopy analysis of the central cornea were performed. Tagg incorporated six metrics of tortuosity including LC, Cur_max, TC, TSC, DCI, and ICM. Corneal subbasal nerve images of subjects and a validation data set were analyzed using Tagg. Spearman's rank correlation was performed on Tagg and clinical parameters.

Results: Tagg was validated using 1501 corneal nerve images. Tagg was higher in patients with DED than in healthy volunteers ($P < 0.001$). Tagg was positively correlated with the ocular surface disease index ($r = 0.418$, $P = 0.003$) and negatively correlated with tear breakup time ($r = -0.398$, $P = 0.007$). There was no correlation between Tagg and corneal fluorescein staining, the Schirmer I test or corneal sensation.

Conclusions: Tagg was validated for quantification of corneal subbasal nerve tortuosity, and was higher in patients with DED than in healthy volunteers. A higher Tagg may be linked to ocular discomfort and tear film instability.

ABSTRACT BODY:

Purpose: Research has shown that patients in the real world with neovascular age-related macular degeneration (nAMD) or diabetic macular edema (DME) treated with anti-vascular endothelial growth factor (VEGF) achieve lower vision improvements compared to patients in clinical trials. This has been partly attributed to treatment burden, which can impede a patient's ability or willingness to follow their management plan (i.e., adherence). This study aims to better understand the treatment experience of intravitreal anti-VEGF injections from the patient, caregiver, and physician perspectives.

Methods: Patients with nAMD/DME treated with anti-VEGF injections, their caregivers, and retina specialists (RSs) participated in 1:1 exploratory phone interviews in Canada, France, Germany, Italy, Spain and the United States. Interview transcripts were analyzed qualitatively to identify concepts related to treatment experience and drivers of and barriers to following a management plan.

Results: We interviewed 62 RSs, 95 patients (49 nAMD, 46 DME) and 79 caregivers (of 47 nAMD, 32 DME patients). In our sample, RSs estimated the non-adherence rate among their patients to range from 0 to 20%. The majority of nAMD patients and approximately half of DME patients reported never missing an injection visit. All respondents reported similar drivers for following a management plan. Treatment effectiveness was reported as a key driver by ~30-40% of all respondents. The most commonly reported driver by RSs and patients/caregivers were patient education (34%) and the doctor-patient relationship (~60%), respectively. Various barriers to following a management plan were reported: fear of injection, health-related (vision loss, lack of treatment effectiveness), time and travel-related (waiting time, visit frequency, distance to site), and education-related (lack of understanding treatment purpose and procedures). RSs reported additional barriers (comorbidities, insurance coverage) taken into account when making anti-VEGF prescribing decisions.

Conclusions: There was a consensus among patients, caregivers, and RSs regarding drivers of and barriers to anti-VEGF treatment. New therapies offering improved or longer-acting effectiveness along with enhanced patient education may improve nAMD/DME patient adherence to their management plan and achieve better real-world vision outcomes.

TITLE: The effect of dataset size on pretraining and transfer learning for diabetic retinopathy in narrow field to widefield domain shift

SESSION TITLE: Machine learning II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Sarhan, A. Eslami, Carl Zeiss Meditec AG, Munich, GERMANY|M. Sarhan, Technische Universitat Munchen, Munich, Bayern, GERMANY|N. Manivannan, M.K. Durbin, S. Su, A. Covita, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mhd Hasan Sarhan: Commercial Relationship(s);Carl Zeiss Meditec, AG:Code E (Employment) | Niranchana Manivannan: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Mary Durbin: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Susan Su: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code C (Consultant) | Angelina Covita: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Abouzar Eslami: Commercial Relationship(s);Carl Zeiss Meditec, AG:Code E (Employment)

ABSTRACT BODY:

Purpose: To study the effect of the pretraining dataset on the transferred model performance. It has been established that pretraining a deep learning system (DLS) on narrow field (NF) fundus images then transfer the model to widefield (WF) fundus images enhances the performance on WF fundus diagnosis for diabetic retinopathy (DR). We studied the effect of the pretraining dataset size on the transferred model.

Methods: We collected smaller (32k) and larger (120k) NF images datasets using VISUSCOUT® 100 (ZEISS, Jena, Germany) handheld fundus camera. The images were annotated for referable DR (more than mild DR). A DLS (Resnet-50) for each dataset was developed to detect referable DR from the images. For the transfer learning, we collected WF fundus images from 361 subjects (77% normal, 23% referable DR) using tabletop CLARUS™ 500 (ZEISS, Dublin, CA). The images were annotated for referable DR. We split the WF dataset into train/validation/test (80/10/10) sets and evaluated the final model on the test set. The two NF models were fine-tuned on the same training split of WF data and compared together and with directly evaluating WF images on NF models without fine-tuning. Augmentation techniques were used for robustness. We compared accuracy, sensitivity (Sen), specificity (Spc), and area under the curve of the receiver operating characteristics curve (AUC) for evaluation of the performance. Fig. 1 overviews the performed experiments

Results: The pretrained model on the larger NF dataset produced marginally better results on the WF dataset after transfer compared with the pretrained model on the smaller NF dataset on the considered metrics. We observed large confidence intervals for Sen and Spc because of the dataset size limitations. The best model achieved 86.5% AUC, 84.4% accuracy, 90% Sen (95%CI [71%, 100%]), and 83% Spc (95%CI [70%, 95%])

Conclusions: Increasing the NF pretraining dataset size potentially enhances the fine-tuning on the WF dataset. However, this enhancement is limited by the size of the WF dataset. This suggests that increasing the NF pretraining dataset size improves the prediction on WF dataset up to a certain limit where collecting more WF data is required for further improvements.

ABSTRACT BODY:

Purpose: The transient receptor potential cation channel subfamily V member 1 (TRPV1) plays a key role in ocular surface pain. The use of SAF312, a potent non-competitive antagonist of TRPV1, is a novel steroid sparing approach for treatment of ocular surface pain. The study evaluated the in-vitro and in-vivo pharmacology of SAF312.

Methods: Expression of TRPV1 was evaluated in donor human cornea by immunostaining of TRPV1, along with β -tubulin, a marker for corneal neurons. The selective action of SAF312 on TRPV1-mediated Ca^{2+} -flux was assessed by the fluorescent FLIPR assay. The inhibitory action of SAF312 was evaluated in CHO cells expressing human TRPV1 using fluorescent Ca^{2+} -sensitive indicator dyes. The ocular tissue and plasma pharmacokinetic (PK) parameters (C_{max} , AUC, and T_{max}) of SAF312 were described in New Zealand white rabbits following a single dose of bilateral ocular administration (0.5, 1.0, 1.5, and 2.5%; 0.175, 0.350, 0.525, and 0.875 mg/eye/35 μ L, respectively).

Results: TRPV1 was expressed in superficial nerves, nerves in the mid-stroma, and deep stroma indicating a potential role for TRPV1 in nociception within the cornea (Fig 1). TRPV1 is also expressed at a high level in the corneal epithelium. SAF312 was >150-fold selective for TRPV1 when tested against a panel of 18 TRP channels. SAF312 inhibited capsaicin, low pH 2-(n-morpholino)ethanesulfonic acid (MES, pH 5.5), anandamide (AEA), and N-arachidonoyl dopamine (NADA) stimulated human TRPV1 with IC_{50} values of 12, 16, 7.3 and 36 nM, respectively in a selective, non-competitive, and reversible manner. PK analysis of SAF312 in the rabbit ocular tissues and plasma showed the highest exposure in cornea and conjunctiva, followed by aqueous humor, lens, retina, plasma and vitreous humor. The exposure for SAF312 in cornea 12 h after single bilateral 0.5% administration was at least 69-fold and 23-fold higher than the IC_{50} assessed in the cellular assays for capsaicin (12nM) and NADA (36nM), respectively.

Conclusions: SAF312 has been shown to be a selective and potent inhibitor of TRPV1, a key mediator of ocular pain process which is expressed in the corneal neurons, and has potential for further investigation in clinical trials.

ABSTRACT BODY:

Purpose: Resolving individual capillaries of the choriocapillaris with swept source optical coherence tomography (SS-OCT) angiography is challenging and has so far been limited to very small field of views (FOV). We present a MHz SS-OCT prototype, which provides high-contrast choriocapillaris (CC) images over FOV of up to 12mm x 12mm.

Methods: We developed a 1060nm SS-OCT prototype, capable of A-scan rates up to 1.7MHz. Its lateral resolution was 7.8µm and its axial resolution was 9 µm in tissue. We acquired Angio 12mm x 12mm scans with a sampling of 1024 (A-scans) x 1024 (B-scans) x 4 (B-scan repetitions) and Angio 2.2mm x 2.2mm scans with a sampling of 320x300x10. To create CC en face images, we segmented the RPE and integrated over 3 pixels, corresponding to a 20µm slab below the RPE fit. To compare our image quality to state of the art images, we acquired Angio 12 mm x 12 mm and Angio 3 mm x 3 mm scans of the same eye, using the 100 kHz mode of the Plex® Elite 9000 (ZEISS, Dublin, CA).

Results: In Fig. 1a&b Angio 12 mm x 12 mm scans of the CC acquired at 100 kHz (a) and 1.7 MHz (b) are presented side by side. Especially when comparing the magnified views in the blue boxes, one can appreciate significantly more contrast in the higher resolution 1.7MHz images. Fig. 1c-f show Angio scans over smaller FOV with higher sampling density. The Angio 3mm x 3mm scan with the commercial instrument is shown in c&d for the superficial and CC slab respectively. A corresponding Angio 3mm x 3mm image of the superficial slab is shown in Fig. 1f. Fig. 1e shows a 2.2mm x 2.2mm MHz Angio image of the CC at the location indicated by the yellow box in Fig. 1b. This illustrates that not only the sampling rate and lateral resolution, but also the sampling density strongly impact the ability to resolve individual capillaries of the CC.

Conclusions: We demonstrated that MHz A-scan rates paired with improved lateral resolution, can significantly improve the resolution of individual capillaries in the CC over a large FOV. We further show that increasing the lateral sampling and the number of B-scan repetitions can again significantly enhance the contrast of CC images.

ABSTRACT BODY:

Purpose: The clinical and genetic heterogeneity of suspected primary heritable optic atrophy (phOA) poses genetic diagnostic challenges. Patients with suspected phOA were retrospectively analyzed to determine genetic testing yield and clinical correlates.

Methods: Medical records of patients with genetic testing for suspected phOA were reviewed. Sex, age at vision symptom onset (VSO) and OA diagnosis (OAD), clinical diagnosis subgroup, presence of syndromic features, and positive family history were analyzed. Clinical diagnosis subgroups included 1) Dominant Optic Atrophy (DOA) (OPA1 or OPA3), 2) Leber Hereditary Optic Neuropathy (LHON), 3) unspecified isolated OA, and 4) syndromic OA. Probands underwent Sanger Sequencing, Next Generation Sequencing, and/or whole exome sequencing. Molecular confirmation indicated presence of pathogenic variants

Results: Fifty unique probands with suspected phOA were identified (32 male, 18 female). Mean ages were 22±20 years (standard deviation) for VSO and 26±21 years for OAD. Testing confirmed molecular causes in 30% of cases (15/50), including 11/32 males and 4/18 females (not significant; Fisher's exact test). Molecular testing result stratified by clinical diagnosis subgroup confirmed disease-causing genotypes in 6/23 with suspected DOA, 4/6 with suspected LHON, 2/8 with unspecified isolated OA, and 3/13 with suspected syndromic OA. Age at VSO and OAD between molecularly confirmed vs. unconfirmed cases were not statistically different. Isolated OA was reported in 42 probands (84%) and suspected syndromic OA in 8 probands (16%); genetic testing yield was not different between these groups (31% vs. 25% respectively; Fisher's test). Genetic testing yield was 60% for probands with positive family history (9/15) and 19% for singletons (6/32) (p=0.0077; Fisher's test).

Conclusions: Consistent with prior studies, family history was positively associated with testing yield, but was not significantly affected by sex, clinical diagnosis subgroup, or presence of syndromic features. A large prospective phOA cohort is needed to identify and refine clinical associations and drive gene discovery required to improve genetic diagnostic yield among unconfirmed patients.

ABSTRACT BODY:

Purpose: Age-related declines in visual performance increase the risk of morbidity and mortality from falls in humans and are so far untreatable; rats and mice also show reduced vision with age. The cause of age-related declines in visual performance is unclear but evidence ex vivo suggests a link to photoreceptor / retinal pigment epithelium oxidative stress.

Methods: 2 and 24 mo male C57BL/6J mice were non-invasively evaluated for excessive production of paramagnetic free radicals based on whether R1 (= 1/T1) in retinal laminae are reduced after acute anti-oxidant (AO) administration [QUEnch-assiSTed (QUEST) magnetic resonance imaging (MRI)]. Superoxide production was measured in excised retina (lucigenin assay). Acute AO administration was also used to test for age-related oxidative stress-induced thinning of subretinal space (QUEST optical coherence tomography [OCT]) and cone-based visual performance declines (QUEST optokinetic tracking [OKT]).

Results: At 2 mo, no evidence was found in vivo for oxidative stress in any retinal layer. At 24 mo, oxidative stress was localized only to superior outer retina. Yet, no age-related change in retinal superoxide production was noted suggesting that free radical species other than superoxide contributed to the positive QUEST MRI signal at 24 mo. Subretinal space did not show age-related thinning and was unresponsive to AO's. Finally, visual performance declined with age and was not restored by AO's that were effective in QUEST MRI.

Conclusions: Outer retinal oxidative stress appears to be insufficient to explain the reduction in visual performance in 24 mo C57BL/6J mice.

ABSTRACT BODY:

Purpose: To determine the relationship between anthropometric measures and a keratoconus (KCN)-like trait of high spherical dioptric power (≥ 48.0 D).

Methods: Participants of the 1999-2008 NHANES visual exam with demographic, ocular, and anthropometric data were included (Unweighted 20,165; Weighted 173,695,441). Cases had a KCN trait of spherical dioptric power ≥ 48.0 D ($n = 171$) and controls < 48.0 D ($n = 19,994$). Multivariable analyses were performed for pooled and sex-stratified populations accounting for NHANES complex survey design. 3 separate models assessed an outcome of KCN trait with primary predictors of (1) BMI, (2) height, and (3) weight. The independent effects of height were assessed by adjusting for weight residuals in multivariable analysis and similarly for weight adjusted for height residuals.

Results: There was a strong inverse relationship between height and KCN trait in the pooled population ($P < 0.0001$ for trend) and women ($P < 0.0001$ for trend). In pooled analysis, the inverse relationship between height and KCN trait found that for every 1-inch increase in height, there was a 16% reduced odds (OR, 0.84; 95% CI: 0.78-0.91) of KCN trait. In women there was a 19% reduced odds of KCN trait for each 1-inch increase in height (OR, 0.81; 95% CI: 0.74-0.88), but the inverse association was borderline in men (OR, 0.88; 95% CI: 0.76-1.01).

Conclusions: Shorter height is associated with a higher risk of KCN trait of high spherical dioptric power (≥ 48.0 D). Gender plays a role in this relationship with a greater association seen in women than in men. These findings can contribute to improved understanding of the pathogenesis of keratoconus.

ABSTRACT BODY:

Purpose: Bipolar cells in the retina receive photoreceptor information and are responsible for transferring this information to amacrine cells and ganglion cells in the inner retina. The axon terminals of bipolar cells make specialized ribbon synapses with amacrine and ganglion cell processes. Output at these ribbon sites is regulated by distinct subsets of inhibitory synapses. In this study our purpose was to determine the impact of photoreceptor loss on the organization of inhibitory synapses at retinal bipolar cell terminals.

Methods: To understand how retinal bipolar cells alter their inhibitory synaptic connections in response to loss of their primary input partners, we utilized the rd1 photoreceptor degeneration mouse line (mice homozygous for the rd1 mutation) and performed immunolabeling for distinct GABA receptor types. To visualize individual ON bipolar cells, we crossed the rd1 line to the Grm6-tdtomato line, where the mGluR6 promoter drives tdtomato expression in ON bipolar cells. We quantified receptor levels at the one-month and two-month time-point. Images were acquired on a Leica SP8 confocal microscope and stacks were analyzed with Image J (Fiji/NIH) and Amira (Thermo Fisher Scientific). Receptor amounts were determined within individual bipolar cell terminals and protein expression was correlated to mRNA levels by qPCR. We performed single-cell electrophysiology to determine the bipolar cell receptor type-specific responses to GABA puff applications. Markers for OFF bipolar cell types were used to compare synaptic protein levels in the ON vs OFF laminae of the degenerating retina.

Results: We observed bipolar cell type-specific changes in inhibitory synaptic proteins across terminals of the rd1 retina. We also observed compartment-specific alterations in bipolar cell axon terminals as compared to their dendrites in the outer retina. Protein levels of GABA receptor types showed differences across the receptor subsets and across the time points studied.

Conclusions: During retinal degeneration, bipolar cells undergo significant changes in their inhibitory synaptic connectivity and receptor organization. These changes are receptor-type specific, bipolar cell type-specific and compartment-specific.

ABSTRACT BODY:

Purpose: Serine protease inhibitors (SERPINs) are a family of protease inhibitors known to be involved in the pathogenesis of several ocular diseases. In this study, we analyzed the levels of serpin proteins in human aqueous humor (AH) and their association with glaucoma in Caucasian and African American patients.

Methods: Human AH samples from 148 subjects were analyzed using Liquid Chromatography-Mass Spectrometry (LC-MS/MS). There are 36 known members in the SERPIN superfamily. The abundance of each SERPIN was detected, and differential expression analysis was performed in patients with and without glaucoma, and the data stratified by gender and race.

Results: A total of 13 SERPIN proteins, including SERPINA1, SERPINA3, SERPINA4, SERPINA5, SERPINA6, SERPINA7, SERPINA8, SERPINC1, SERPIND1, SERPINF1, SERPINF2, SERPING1, SERPINI1 were reliably detected in human AH. Six SERPIN proteins, including SERPINA4, SERPINA5, SERPINA6, SERPINA8, SERPINC1, and SERPIND1, were found to be differentially expressed in glaucoma patients. Additionally, SERPINA1, SERPINA3, and SERPINA7 were differentially expressed in glaucoma only in male subjects, whereas SERPINA5 was differentially expressed in glaucoma only in female subjects. Similarly, dividing the data based on race revealed three proteins, including SERPINA1, SERPINA8, and SERPING1, were differentially expressed in Caucasian glaucoma patients. In contrast, four proteins, including SERPINA4, SERPINA5, SERPINA6, and SERPIND1, were significantly altered in African American glaucoma patients. SERPINC1 was differentially expressed in both Caucasian and African American glaucoma patients.

Conclusions: A total of 13 out of 36 SERPINs were found in the human AH. Several of these proteins were found to be altered in glaucoma patients in addition to displaying race and gender specific variations.

ABSTRACT BODY:

Purpose: Vision deficits and oculomotor dysfunction have been previously reported in association with concussions or mild traumatic brain injuries. We aim to identify the visual manifestations of post-concussion syndrome using a retrospective, observational clinical study.

Methods: A retrospective chart review study was performed. All patients referred to a neuro-ophthalmology clinic over two years with a post-concussion syndrome diagnosis were included. Patients with abnormal CT or MRI neuroimaging suggestive of moderate or severe traumatic brain injury were excluded. All ocular signs and symptoms, visual field, and OCT imaging of the RNFL and GCL were evaluated. The Circle test assessed stereoacuity. Analysis of the data was performed to determine the prevalence of the studied elements.

Results: Fifty-two patients were eligible for the study. The mean age was 49.65 ± 14.08 years and were predominantly female (69.2%), not Hispanic or Latino (75.6%), and White or Caucasian (79.5%). 50.0% of the patients had multiple office visits. The most common modes of injury were motor vehicle accidents and falls, and 50.0% had multiple concussions, including 13.6% having three or more. 76.3% of the subjects had pre-existing migraines, and 26.9% were taking prescribed opioid medications. Headaches (92.3%) and light sensitivity (91.3%) were the most significant symptoms, and 36.5% of the total subjects had convergence insufficiency or reading difficulties. Severe or moderate loss of stereopsis was found in 72.2% of patients, who tended to be older than those with mild or no stereopsis loss (52.69 ± 13.87 years vs. 40.00 ± 13.15 years; $p = 0.0148$). Visual field testing was unreliable in 42.6% of subjects, while OCT imaging of the RNFL and GCL was normal (95.9% and 88.2%, respectively). The average RNFL thickness was found to be 97.37 ± 10.78 μm .

Conclusions: Headaches and light sensitivity are the most prevalent symptoms in post-concussion syndrome, while the loss of stereopsis and convergence insufficiency are the most common ocular signs.

ABSTRACT BODY:

Purpose: To measure corneal thickness after short-term small and large diameter scleral lens wear.

Methods: Twenty healthy participants were fit on their right eye according to manufacturers' fitting guides with a 15.2mm OneFit 2.0 lens (Blanchard Contact Lens Inc., Manchester, NH) and a 18.0mm BostonSight lens (BostonSight, Needham, MA). Lenses were each worn on the same day for one hour with the order of wear randomized. Central corneal thickness was measured using Pentacam rotating Scheimpflug photography system (Oculus Inc, Wetzlar, Germany) both prior to lens wear and immediately after lens removal. Differences in central corneal thickness are compared before and after lens wear using a paired t-test.

Results: The average age of participants was 29 ± 9 (SD) years old (Range: 22-57 years), with 5 males and 15 females. Corneal thickness after one hour of small diameter lens wear ($554 \pm 30 \mu\text{m}$, $n=10$) compared to before lens wear ($548 \pm 28 \mu\text{m}$, $n=10$), was statistically increased ($P=0.02$, 1.2%). Corneal thickness after one hour of large diameter lens wear ($544 \pm 34 \mu\text{m}$, $n=10$) compared to before lens wear ($531 \pm 30 \mu\text{m}$, $n=30$) was also increased and had statistical significance ($P=0.02$, 2.4%). Small lens wearers then wore the large lens for one hour and had a further, but not statistically significant increase in corneal thickness ($547 \pm 37 \mu\text{m}$, $P=0.5$, 1.4%). Similarly, large lens wearers had a non-statistically significant increase in corneal thickness after an hour of small lens wear ($545 \pm 31 \mu\text{m}$, $P=0.3$, 1.0%).

Conclusions: After one hour of lens wear, both small and large diameter lens wearers experience an increase in central corneal thickness. An additional hour of lens wear in a different lens design also increased central corneal thickness, but not as much as the first hour. Differences in lens diameter and design may influence cornea physiology differently.

TITLE: Random Forests with Retinal Biomarkers for Diabetic Peripheral Neuropathy

SESSION TITLE: Machine learning I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Benson, X. Guo, S.C. Nemeth, P. Soliz, VisionQuest Biomedical, Albuquerque, New Mexico, UNITED STATES|J. Benson, T. Estrada, Computer Science, University of New Mexico, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jeremy Benson: Commercial Relationship(s);VisionQuest Biomedical:Code E (Employment) | Xiaoshan Guo: Commercial Relationship(s);VisionQuest Biomedical:Code E (Employment) | Sheila Nemeth: Commercial Relationship(s);VisionQuest Biomedical:Code E (Employment) | Trilce Estrada: Commercial Relationship(s);University of New Mexico:Code E (Employment) | Peter Soliz: Commercial Relationship(s);VisionQuest Biomedical:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: This work uncovers relevant biomarkers in digital fundus photographs for classifying Diabetic Peripheral Neuropathy (DPN).

Methods: Our dataset consists of 104 digital fundus photographs from 52 patients that have been graded with the Singapore "I" Vessel Assessment (SIVA) software. Using 75 features obtained with SIVA, we train and test a series of random forest classifiers. We perform 10-fold cross validation and 80/20 split of the data. Monofilament, vibration, nerve conduction study (NCS), and pinprick are alternately used for the reference standard. We report on the classification accuracy of the random forests for each as they serve as ground truth. The top 5 relevant retinal features per reference standard are presented.

Results: For our random forest classification, the average errors across the 10-fold runs were 3.33%, 23.33%, 35.24%, and 29.52%, for monofilament, vibration, NCS, and pinprick, respectively. We provide a sample decision tree using the monofilament-based random forest as an example of the classification subprocess. In this tree, we choose between normal or DPN through a series of Gini index splits on the SIVA retinal features. Our forest is comprised of a thousand trees, where a random subset of all SIVA features is employed. The resulting classifier is the aggregation of these trees (i.e., a forest). We highlight the top SIVA biomarkers across the various reference standards that are present in the forests.

Conclusions: We establish a baseline comparison between digital fundus biomarkers, obtained from the SIVA software process, and various clinical tests for DPN. The Quantitative Sensory Tests (QSTs) of monofilament and vibration show the closest relation in terms of raw classification of DPN, and perform the best when using the features from SIVA in our random forest experimentation. While the performance of the various reference standards ranges in accuracy, there remains a consistent subset of SIVA features that appear throughout the models and lead to the model decision of DPNs versus controls. The insight gained from this work will serve as the foundation for future automated approaches in feature extraction for risk assessment of DPN using retinal images, as there are specific biomarkers that are clearly relevant, regardless of the ground truth.

ABSTRACT BODY:

Purpose: An optimized formulation of pilocarpine (AGN-190584) was developed as a pharmacologic treatment for presbyopia. In a phase 3 efficacy and safety study, a new Patient Reported Outcome (PRO) instrument, the Near Vision Presbyopia Task-based Questionnaire (NVPTQ), was used to evaluate vision-related reading performance and associated satisfaction.

Methods: In this multicenter, double-masked, 30-day study (NCT03804268; n=323), individuals with presbyopia were randomized to bilateral AGN-190584 or vehicle (placebo) once daily. Secondary efficacy endpoints included mean change from baseline in mesopic NVPTQ Performance (range: 0-5) and Satisfaction (range: 0-4) domain scores on 4 paper-based reading tasks at Day 30 Hour 3. Cumulative distribution of change scores was depicted (intent-to-treat population). Proportion of responders to AGN-190584 (participants achieving individual-level meaningful change thresholds of ≥ 0.75 and ≥ 1.00 point improvement from baseline in Performance and Satisfaction scores, respectively) at Day 30 Hour 3 (3 hours after dosing) was assessed.

Results: At Day 30 Hour 3, statistically significant improvements from baseline in both scores were reported with AGN-190584 versus vehicle: the mean score difference (95% confidence interval [CI]) between groups was 0.8 (0.6, 1.1) in vision-related reading performance and 0.8 (0.5, 1.1) in associated satisfaction ($P=.011$ for each). The AGN-190584 group showed consistent separation in improvement compared with the group receiving vehicle. Of the AGN-190584 group, 24.0% (95% CI: 13.0, 34.9) and 26.8% (95% CI: 16.2, 37.5) more individuals reported improvements at individual-level meaningful change thresholds in mesopic Performance and Satisfaction scores, respectively ($P<.001$ for each), versus vehicle.

Conclusions: Analyses of these PRO efficacy endpoints demonstrated significant treatment benefit in patient-centric outcomes in presbyopia. Participants who received AGN-190584 reported greater ability and satisfaction related to near-vision reading compared with participants receiving vehicle supporting the role of a pharmacologic treatment for this condition.

TITLE: Pentosan Polysulfate Sodium Maculopathy: A Big Data Study of Patients with Interstitial Cystitis

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.B. Desjarlais, J.E. Kim, Medical College of Wisconsin, Milwaukee, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eric Desjarlais: Commercial Relationship: Code N (No Commercial Relationship) | Judy Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent studies describe a novel association between pentosan polysulfate sodium (PPS), an oral glycosaminoglycan used for symptomatic control of interstitial cystitis (IC), and pigmentary maculopathy. We used multivariate logistic regression analysis to investigate this relationship in a multicenter cohort of patients with IC.

Methods: The TriNetX Research Network was queried for patients from 30 healthcare organizations who had a diagnosis of IC. The primary outcome measure was any one of six retinopathy diagnoses that may have been used clinically to document PPS-related maculopathy. These included non-exudative age-related macular degeneration (AMD), exudative AMD, drusen, hereditary retinal dystrophy, toxic maculopathy, and unspecified macular degeneration. Logistic regression models comparing groups with and without PPS exposure were fitted, adjusting for covariates including demographics, systemic comorbidities, and exposure to hydroxychloroquine (HCQ), another drug that can cause maculopathy.

Results: There were 18,154 patients in the study, including 1,437 men and 16,717 women with IC. Average age was 54.2 (17.1 SD) years. A total of 4,147 (22.8%) patients had at least one order for PPS. Average duration of PPS therapy was 1.37 (2.37 SD, range 0.00 to 14.33) years. In multivariate logistic regression analysis, there was a statistically significant increase in the odds of retinopathy diagnosis associated with PPS duration (OR = 1.11 per year, 95% CI 1.05 to 1.17, $p = 0.0001$), HCQ duration (OR = 1.20, 95% CI 1.11 to 1.29, $p < 0.0001$), age (OR = 1.08, 95% CI 1.07 to 1.09, $p < 0.0001$), history of smoking (OR = 1.46, 95% CI 1.16 to 1.84, $p = 0.0011$), essential hypertension (OR = 1.75, 95% CI 1.37 to 2.25, $p < 0.0001$), diabetes mellitus (OR = 1.31, 95% CI 1.03 to 1.65, $p = 0.0244$), and significant kidney disease (OR = 1.41, 95% CI 1.11 to 1.77, $p = 0.0040$). Repeat regression with PPS duration as a categorical variable in two-year increments revealed a significant association starting at 5 to 6 years of PPS therapy (OR = 2.23, 95% CI 1.14 to 3.96, $p = 0.0109$).

Conclusions: After adjusting for covariates known to increase the risk of retinopathy, there was a statistically significant increase in the odds of retinopathy diagnoses corresponding with duration of PPS therapy. These findings strengthen the body of evidence suggesting an ocular toxicity related to duration of PPS usage.

ABSTRACT BODY:

Purpose: The VIEW 1 and VIEW 2 studies led to FDA approval of aflibercept for the treatment of neovascular age-related macular degeneration (nAMD) in 2011. In this electronic health record (EHR) based registry study, we replicated the study design from an observational research perspective and evaluated the outcomes using real-world data (RWD) contained in the American Academy of Ophthalmology IRIS[®] Registry (Intelligent Research in Sight), the world's largest single-specialty clinical database.

Methods: The IRIS Registry was queried for eyes older than 50 years with nAMD that were treatment-naïve on the index date. Using structured data (ICD coded, CPT codes, etc.) we excluded a prior diagnosis of nAMD, DME, DR, uncontrolled glaucoma, causes for CNV besides nAMD, prior RD, prior uveitis, prior vitrectomy surgery, prior corneal transplantation and those with missing gender/race information. Cohorts emulated the study arms of the VIEW 1 and VIEW 2 trials: cohort 1 received 2 mg of aflibercept every 4 weeks (2q4), cohort 2 received 2 mg of aflibercept every 8 weeks after 3 monthly injections (2q8) and cohort 3 received 0.5 mg ranibizumab every 4 weeks (rq4). We allowed a buffer of +/- 7 days for treatment schedules. By definition, the number of injections in each cohort was 12 (2q4), 7 (2q8) and 12 (rq4).

Results: The cohorts corresponding to the three arms of the VIEW 1 and VIEW 2 studies included 348 (2q4), 331 (2q8), and 460 (rq4) eyes. We found that 92.5% (2q4), 95.2% (2q8) and 92.6% (rq4) of eyes maintained vision (losing < 15 ETDRS letters), compared to 95.1 to 95.6 (2q4), 95.1 to 95.6% (2q8), and 94.4% (rq4) of eyes in the VIEW studies. We also found that 19.8% (2q4), 28.1% (2q8) and 25% (rq4) of eyes gained 15 or more ETDRS letters and had a mean gain of +3.9 (2q4), +6.9 (2q8) and +5.8 (rq4) ETDRS letters at 12 months. In the VIEW studies, mean BCVA gains were 8.3 to 9.3 letters at 12 months.

Conclusions: This is the first time that RWD has been used in an attempt to replicate the primary outcomes of a clinical trial in ophthalmology. The proportion of eyes losing <15 across the VIEW 1 and VIEW 2 studies was similar to our registry cohort, indicating proof-of-concept, although the mean gains in letters varied across the studies. Benchmarking real-world endpoints versus randomized controlled trials could be a valuable tool in validating the predictive ability of these endpoints as a measure of effectiveness.

ABSTRACT BODY:

Purpose: There are limited studies on mucinous adenocarcinoma of the eyelid (MAE) in the literature. Using a large database, we explore the epidemiologic trends of this entity.

Methods: A retrospective, population-based analysis was conducted using the Surveillance, Epidemiology, and End Results Registry. All patients diagnosed with MAE from 2000-2017 were included. Incidence rate (IR) was calculated in number of cases/million/year. Overall survival (OS) was calculated using the Kaplan-Meier method.

Results: 222 cases were identified, 58.1% of whom were female and 73.8% were white. Overall IR of MAE was 0.14. Annual percent change was 7.34 ($p < 0.001$). There was no difference in IR between males (0.13) and females (0.14) [$p = 0.34$]. IR in the black race (0.247) was significantly higher than in the white (0.12) [$p < 0.001$] and in the Asian/Pacific Islander (0.10) [$p < 0.001$] races. IR in patients older than 65 years old (y/o) [0.74] was significantly higher than in those 22-64 y/o (0.083) [$p < 0.001$] or in those younger than 21 y/o (0.002) [$p < 0.001$]. Stratification based on stage showed that 78.1 % of cases were localized, 4.5 % were regional and 17.4 % were distant. Only 1 bilateral case was identified and the rest of the cases were unilateral.

Conclusions: Mucinous adenocarcinoma of the eyelid incidence is highest in the elderly and black populations and is not affected by sex. Incidence is increasing over the timeframe studied. Most of the cases are diagnosed at a localized stage.

TITLE: An Evaluation of Commercially Available Ophthalmic Surgery Simulators for Continuous Curvilinear Capsulorrhexis Training

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Raval, A. Shrivastava, Ophthalmology, Montefiore Medical Center, Bronx, New York, UNITED STATES|V. Hawn, M. Kim, X. Xie, Yeshiva University Albert Einstein College of Medicine, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Niles Raval: Commercial Relationship: Code N (No Commercial Relationship) | Vivian Hawn: Commercial Relationship: Code N (No Commercial Relationship) | Mimi Kim: Commercial Relationship: Code N (No Commercial Relationship) | Xianhong Xie: Commercial Relationship: Code N (No Commercial Relationship) | Anurag Shrivastava: Commercial Relationship(s);Alcon:Code C (Consultant);Allergan:Code C (Consultant)

ABSTRACT BODY:

Purpose: We aim to provide objective and subjective assessments of three commercially available continuous curvilinear capsulorrhexis (CCC) simulators formally evaluated by cataract surgeons on a variety of task-specific metrics.

Methods: The study was carried out under standard operating room conditions using video-enabled Zeiss Lumera™ microscopes. Expert (>1000 cases) cataract surgeons (N=7) were tasked to perform a 5.5-mm CCC on three simulators (Bioniko™, Kitaro™, and SimulEYE™) in randomized order for a total of three trials on each model. Surgeons were asked to subjectively rate on a modified Likert scale (1-7) how well each simulator approximated human tissue. The duration, size, and number of capsular forceps manipulations ("grabs") were examined and analyzed with multiple regression analyses.

Results: There were statistically significant differences among the simulators and across the three trials for all outcome measures. With respect to grabs, Bioniko required a greater number (6.53 ± 3.14) than both Kitaro (4.90 ± 2.47 , $p=0.01$) and SimulEYE (3.90 ± 1.34 , $p<0.0001$). Trial 1 (6.19 ± 3.57) had a greater number of grabs than both trials 2 (4.33 ± 2.01 , $p=0.002$) and 3 (4.81 ± 1.63 , $p=0.02$). With respect to CCC size (maximum diameter in mm), Kitaro (8.00 ± 0.84) had the largest average compared to Bioniko (5.24 ± 0.60 , $p<0.0001$) and SimulEYE (5.11 ± 0.41 , $p<0.0001$). CCC size was overall larger in trial 3 (6.29 ± 1.56) than in trial 1 (5.94 ± 1.39 , $p=0.003$). Surgeons spent more time (seconds) performing the CCC on Bioniko (41.95 ± 26.70) than on Kitaro (32.05 ± 14.99 , $p=0.02$) and SimulEYE (28.90 ± 15.18 , $p=0.002$) and more time on trial 1 (42.24 ± 25.23) than on trials 2 (28.48 ± 15.87 , $p=0.001$) and 3 (32.19 ± 16.44 , $p=0.01$). Kitaro (4.56 ± 0.84 , $p<0.0001$) and SimulEYE (4.19 ± 0.92 , $p<0.0001$) were rated as more realistic than Bioniko (1.38 ± 0.80) on a Likert scale (1-7).

Conclusions: Each simulator confers its own unique advantages. SimulEYE and Kitaro were thought to most closely approximate real capsular tissue, and surgeons performed the CCC faster on these kits than on the Bioniko model. Surgeons created a 5.5-mm CCC most accurately on the Bioniko and SimulEYE models. In general, surgeons performed faster CCCs across the three trials, suggesting a learning curve. Larger validation studies will help residency programs best utilize training tools for novice surgeons.

Commercial Relationships Disclosure (Abstract): anqi LYU: Commercial Relationship: Code N (No Commercial Relationship) | Ho Ki Kwong: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Silva: Commercial Relationship: Code N (No Commercial Relationship) | Sing-Hang Cheung: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Thompson: Commercial Relationship: Code N (No Commercial Relationship) | Larry Abel: Commercial Relationship: Code N (No Commercial Relationship) | Allen Cheong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patients with central vision loss have to use their peripheral vision to read. For English text, visual span in both the temporal and spatial domains limits reading speed in peripheral vision. It is unknown whether the same is true for Chinese reading. Individual Chinese characters contain more information than individual English letters and can be sequenced horizontally or vertically. This study examined the relationship between visual span and reading of Chinese characters in normal central and peripheral vision.

Methods: 13 young Chinese native readers were recruited. Reading performance in terms of maximum reading speed (MRS) and critical print size (CPS) was examined using the rapid serial visual presentation paradigm at three visual field locations: central vision, 10° left and 10° below fixation. Temporal visual span was measured using trigram character-recognition as described by Cheong et al. (2007), with strings of three-randomly selected Chinese characters presented at a range of exposure durations. Spatial visual span was measured by presenting trigrams at different character position away from the fixation for 200ms. Visual span measurements were made for all three central (horizontal and vertical presentations), 10° left (vertical) and 10° lower (horizontal) visual field locations.

Results: MRS was significantly faster and CPS smaller at central vision than left and inferior vision ($p < 0.001$). No significant differences for MRS or CPS were observed between the two peripheral visual field locations. Temporal visual span in terms of temporal threshold (TTT) was significantly shorter in central vision than inferior or left visual field. Spatial visual span in terms of average recognition accuracy (ARC) at central 5-character positions was significantly higher for central vision than inferior or left visual field. No differences in visual span were found between inferior and left visual field. MRS was significantly correlated horizontal TTT and horizontal ARC for central and inferior vision ($r_s > -0.60$) but not for the left visual field.

Conclusions: Our results support the hypothesis that visual span contributes to reading performance for Chinese characters in central vision and in the inferior field. Surprisingly, this hypothesis does not apply when they read at 10° left visual field, suggesting that other factors might better explain the reduced reading performance at left visual field.

Commercial Relationships Disclosure (Abstract): Brian Peng: Commercial Relationship: Code N (No Commercial Relationship) | Monica Jong: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Naduvilath: Commercial Relationship: Code N (No Commercial Relationship) | Ian Flitcroft: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is now substantial evidence to indicate that environmental factors including time outdoors can influence the development of myopia, particularly in school-aged children. It is well known that urban and rural differences in myopia prevalence exist, but few studies have attempted to characterise the built or natural environment using objective means. The aim of this study is to investigate the relationship between the prevalence of myopia and the quantity of green spaces across different regions of the world, using an objective satellite imaging technique.

Methods: The prevalence of myopia in the 15 to 19 year age group in Australia, Brazil, China, Finland, India, Iran, Japan, Oman, Singapore, South Africa, and the United Kingdom were collected from study data obtained from a systematic review and meta-analysis by Holden et al. (2016). Normalised Difference Vegetation Index (NDVI), an indicator of vegetation density, was derived from Landsat 7 Enhanced Thematic Mapper Plus (ETM+) satellite data. Green space (mean NDVI) was quantified using a 30-kilometre radius buffer surrounding point coordinates corresponding to locations mentioned in the Holden et al. prevalence studies (n = 12) that contributed most to prevalence data. Simple linear regression was used to analyse yearly data, whilst a generalised linear model (GLM) was fit to analyse aggregated NDVI and prevalence data. A mixed effects model was applied to assess the significance of green space when study was a random effect.

Results: The results indicated a negative cubic relationship between surrounding green spaces and myopia prevalence, although the association was weak. The results of the mixed effects model suggested that green space was not significant when the study effects were considered as a random factor (p = .099).

Conclusions: There was no statistically significant association between green space and myopia prevalence in the 15-19-year-old group. Use of a larger sample and standardisation of green space data may improve the robustness of the data. Additionally, use of buffer zones with smaller radii should be considered as they may be more applicable to real life daily green space exposure and potentially reveal a different relationship.

TITLE: Comparison of automated and manual operation of an ophthalmic device

SESSION TITLE: Multidisciplinary imaging technologies and applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Carpenter, A. Bender, K.G. Foote, A. Millan, K. Arianta, N. Manivannan, L. Rothmann, J. Straub, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amanda Carpenter: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Andre Bender: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Katharina Foote: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Alejandro Millan: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Kabir Arianta: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Niranchana Manivannan: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Lukas Rothmann: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Jochen Straub: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Acquiring high quality ophthalmic images typically requires a trained operator in close proximity to a patient. Motorized alignment can enable remote operation, e.g. for physical distancing during a pandemic, and automated alignment can enable quality imaging when a trained operator is not readily available, e.g. in low-resource environments. We evaluated and compared manual and automated operation of an ophthalmic device on a motorized stage.

Methods: We acquired data on 5 normal subjects (10 eyes) by both manual (via a trained operator) and automated operation using a prototype with three off-axis iris cameras (one below and on each side of the device) and a 3-axis motorized stage (Fig. 1). The motorized stage allowed all data to be acquired with a plexiglass shield between the subject and operator for remote operation during the COVID-19 pandemic. Auto-alignment was achieved using custom software to align the device to the patient pupil, with real-time pupil detection via a deep-learning algorithm. Auto-capture was triggered once the pupil was detected at the target location. We evaluated alignment success rate (alignments that triggered a capture), mean \pm SD time to align, and accuracy of alignment (mean \pm SD distance between detected pupil center and target).

Results: Of 24 auto-alignments (1-3 per eye), 23 successfully triggered a capture; 1 failed due to a software bug. All 14 manual alignments (1-3 per eye) proceeded to capture. Time to align for auto-alignment (29 ± 15 s) was significantly faster than for manual alignment (72 ± 37 s). The accuracy of alignment was 0.94 ± 0.59 mm for auto and 0.97 ± 0.41 mm for manual operation. A two-sample t-test assuming independent alignments for auto and manual results did not demonstrate a statistically significant difference in accuracy ($p > 0.05$).

Conclusions: This comparison of manual and auto-alignment and capture for a motorized device indicated that this auto-alignment method is 2.5x faster than motorized manual alignment, saving an average of 40 s per alignment. Auto-operation was comparable in accuracy, and reliable on normal eyes. While further investigations are needed for a clinical population, this method shows promise for utility in a clinical setting.

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) and Leber Congenital Amaurosis (LCA) are rare inherited retinal degenerative disorders (IRD). Visual impairments associated with these disorders have significant impacts on patients' vision-dependent activities of daily living (ADL) and broader health-related quality of life (HRQoL). There is a paucity of evidence exploring the patient experience of RP/LCA and how these impairments impact on patients' lives across different genotypes in Europe. This study aimed to explore the experience of RP/LCA from patient and caregiver perspectives, across different genotypes and ages in Germany and France.

Methods: Thirty semi-structured qualitative concept elicitation interviews were conducted with 9 adults, 5 adolescents, 5 children, and 11 caregivers of children aged 3-11 years in Germany and France. All patients had a clinical and genetic diagnosis of RP/LCA. The sample included different gene mutations linked to RP/LCA: RPE65 (n=11), RPGR (n=5), CEP290 (n=3), AIPL1 (n=2), LRAT, PDE6B, RDH12 and RP2 (n=1 each). Thematic analysis of verbatim interview transcripts was performed.

Results: There was consistency across age groups and RP/LCA genotypes in terms of the most relevant concepts. Night blindness, peripheral vision and contrast sensitivity limitations were the most frequently reported visual function symptoms. Severity of impairments depended on lighting conditions and familiarity of environment. Proximal vision-dependent impacts included limitations to mobility and ADLs. Visual aids used included a white cane and assistive devices. Participants reported impacts on broader HRQoL domains, most commonly emotional well-being, social and work/school functioning. Similar concepts were reported by caregivers of children with RP/LCA.

Conclusions: Visual function symptoms and impacts on vision-dependent ADLs and HRQoL reported by participants were consistent across age groups and genotypes, suggesting the same measures may be appropriate for use in all RP/LCA types. Findings increase the understanding of the qualitative experience of RP/LCA and supported the development of fit-for-purpose patient- and observer-reported outcome measures for use in RP/LCA clinical trials.

TITLE: Selective Micropulse Individual Retinal Therapy development based on the analysis of the micropulse mode testing and computer simulation

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Ivanova, P. Volodin, Laser retinal surgery, FGAU Nacional'nyj medicinskij issledovatel'skij centr Mezotraslevoj naucno-tehniceskij kompleks Mikrohirurgia glaza imeni akademika S N Fedorova, Moscow, RUSSIAN FEDERATION|

Commercial Relationships Disclosure (Abstract): Elena Ivanova: Commercial Relationship: Code N (No Commercial Relationship) | Pavel Volodin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The micropulse mode of serial lasers with short-pulse duration and duty cycle allows one to exert selective impact on the retinal pigment epithelium (RPE). However, there are no standard micropulse modes for treatment, it is difficult to control the level of retinal damage, and individual pre-testing is required. In this study, the development of the Selective Micropulse Individual Retinal Therapy (SMIRT) with a low level of retinal damage and the assessment of the therapeutic effect of CSC (central serous chorioretinopathy) without preliminary testing are addressed.

Methods: This study has been conducted on 73 patients with acute CSC, transparent optical media, aged 30 to 65, with type 1-4 on the Fitzpatrick scale (FS). The testing of the micropulse mode (50 μ s, 2.4%, 10 ms, 100 μ m, 0.4-1.9 W) was performed in 33 patients with 1584 spots analyzed using the autofluorescence (AF) method (488 nm). Another 40 patients were divided into 4 equal groups (10 eyes). In groups 1-3, CSC was treated in the same micropulse mode with the predicted power for the ED of the RPE damage according to AF data of 50%, 70%, and 90%, respectively. The 4th was the control group with no treatment. The testing and treatment were performed with a Navilas577s laser system. Computer simulation was built with the Arrhenius integral to assess the heating and protein denaturation of the RPE and adjacent structures. The Fisher's exact test was used for statistical analysis.

Results: A logistic regression function EDlevel with 3 parameters such as power, age, and FS was constructed based on the AF results for 33 patients. The reverse function was used to predict the required power based on the individual properties according to the chosen ED level. According to computer simulation, for the modes used in groups 1-3, harmful damage to retina and choroid was 35%, 37% and 49% of the damage to the RPE, respectively. Three months later, in groups 1-3 complete resorption of subretinal fluid was observed in 5 ($P<0.35$), 8 ($P<0.023$) and 10 eyes ($P<0.0008$) out of 10, respectively.

Conclusions: In the developed SMIRT, the required power is selected without prior testing, based on the age and FS of the patient. The SMIRT has shown efficacy in the treatment of CSC.

Commercial Relationships Disclosure (Abstract): Yu-Yen Chen: Commercial Relationship: Code N (No Commercial Relationship) | Tzu-Chen Lo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate whether patients with retinitis pigmentosa (RP) have a higher proportion of primary angle-closure glaucoma (PACG) and open-angle glaucoma (OAG) development.

Methods: Using the Taiwan National Health Insurance Research Database from 2001 to 2013, patients with RP were enrolled into the RP group and age- and gender-matched individuals without RP (1:4 matched) were enrolled into the control group. Kaplan-Meier curves were generated to compare the cumulative hazard of subsequent PACG and OAG between the two groups. A Cox regression analysis was performed to estimate the crude and adjusted hazard ratios (HRs) for PACG and OAG.

Results: 6223 patients with RP and 24892 controls were enrolled. During the 13-year study period, 1.61% of RP patients and 0.81% of controls developed PACG (p value < 0.0001). Besides, more proportion of RP patients developed OAG than controls did (1.57% vs. 0.58%, p value < 0.0001). RP group had a significantly higher cumulative hazard of PACG and OAG compared to the control group (p value < 0.0001). The Cox regression model indicated that the RP group had a significantly higher risk for PACG and OAG (adjusted HR= 2.04 and 2.83, respectively).

Conclusions: Patients with RP are at significantly greater risk of developing PACG and OAG.

TITLE: Utility of post-operative review following Nd:YAG laser capsulotomy

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.F. Yang, L. Vander Woude, M.K. Mansfield, M.B. Sherwood, S.S. Iyer, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|A. Walia, Washington University in St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jessica Yang: Commercial Relationship: Code N (No Commercial Relationship) | Logan Vander Woude: Commercial Relationship: Code N (No Commercial Relationship) | Mollie Mansfield: Commercial Relationship: Code N (No Commercial Relationship) | Amit Walia: Commercial Relationship: Code N (No Commercial Relationship) | Mark Sherwood: Commercial Relationship: Code N (No Commercial Relationship) | Siva Iyer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Nd:YAG laser capsulotomy (YAG) is a common procedure with infrequent adverse events. We reviewed intraocular pressure (IOP) measurements 30 minutes after YAG in glaucomatous and non-glaucomatous eyes and a one-week post-op dilated fundus exam (DFE) to detect retinal tear (RT) and detachment (RD). We are interested in the utility of these same day and one-week visits, especially in glaucoma patients and in this COVID-19 era.

Methods: We analyzed 1,406 eyes from 1,138 patients who received YAG from 2011 to 2020 at the University of Florida. Exclusion criteria included YAG performed for reasons other than posterior capsular opacification, IOP not recorded and glaucoma status not analyzed. IOP (pre-op, 30 minutes post-op and at follow-up), follow-up DFE and glaucoma history were recorded. Primary outcome measures were change in IOP at same day and one-week post-op visits and incidence of RT and RD.

Statistical analyses were conducted in IBM SPSS Statistics. Pre-op and same day post-op IOP in all patients (N=578) and in glaucoma patients (N=93) were compared with paired t-test. Univariate regression analysis was performed to assess if glaucoma history predicted which patients would have a rise in IOP of 5mmHg or more. ANOVA was used for comparison of intergroup difference between pre-op, same day post-op, and follow-up.

Results: There was no significant change in mean pre-op and post-op IOP in all patients ($p = 0.557$), nor in the glaucoma patients ($p = 0.194$). Many patients (68.9%, N=404) were given a drop of brimonidine prior to YAG procedure. 69 patients had a rise in IOP of 5 mmHg or more at 30 minutes following YAG, including 13/93 (14%) of glaucoma eyes and 56/485 (12%) of non-glaucoma eyes. An IOP spike of 10mmHg occurred in 9 of these eyes of which 1 eye had glaucoma (1%) and 8 did not (89%). Using binary logistic regression, we found that glaucoma was not predictive for rise in IOP of 5mmHg or more following YAG (OR 1.23; 95% CI=0.64-2.34). No patients had RT or RD detected during one-week follow-up visit.

Conclusions: There is no significant change in IOP in all patients and in glaucoma patients. Glaucoma was not considered a risk factor for rise in IOP. YAG does not seem to increase the risk of RT or RD. In this COVID-19 era, when all practitioners aim to decrease in-person visits, small changes on a large scale can make an impact. If validated, our results bring into question the necessity of post-op visits after YAG.

ABSTRACT BODY:

Purpose: Rod intercept time (RIT) is commonly used as a measure of dark adaptation (DA) response. However, in some age-related macular degeneration (AMD) patients, the sensitivity fails to recover to the requisite threshold within the testing duration for a valid RIT determination. This precludes proper quantification of the DA response. We evaluated whether DA response in such eyes can be quantified using the area under the dark adaptation curve (AUDAC), which can serve as an alternative measure of DA response within the same testing time frame.

Methods: DA was measured using the AdaptDx (Maculogix, Harrisburg PA) 20-minute protocol (which output RIT value) in 136 eyes (AMD: 98, Control: 38). The RIT criterion was 3 log units sensitivity recovery, failing which, the RIT was set at maximum of 20 minutes per protocol. Separately, normalized AUDAC was computed from the DA curve using the trapezoid method with respect to the same measurement limits. Association between AUDAC and RIT in eyes with RIT < 20 minutes was computed using a linear model, which was then used to predict the RIT values in eyes that failed to record a valid RIT value. Furthermore, the AUDAC was evaluated for predicting AMD presence using a logistic regression model, and the accuracy and the F score were compared with that for the AdaptDx threshold (RIT=6.5 min.).

Results: In 101 eyes with RIT < 20 minutes, the median [IQR] values of RIT and AUDAC were 5.8 [6.4] minutes and 0.063 [0.054], respectively, with a strong linear association between the two measures ($p < 0.001$, $R^2 = 0.87$). In 35 eyes that failed to record a valid RIT (RIT set at 20 minutes; 34 AMD, 1 control), there was a large variation in the AUDAC (median [IQR]: 0.276 [0.091]) due to the differences in the underlying DA curves, indicating that DA response can still be measured in these eyes. As expected, the RIT was projected to be >20 minutes in 33 out of the 35 eyes (median [IQR] RIT was 24.1 [7.8] minutes) using the linear model between RIT and AUDAC. When predicting AMD presence, the performance of AUDAC (76.5% accuracy; $F_1=0.84$) was comparable to RIT (78% accuracy; $F_1=0.83$).

Conclusions: In eyes where sensitivity fails to recover to the requisite criterion, including many AMD patients, the DA response cannot be quantified using RIT. AUDAC offers a reliable alternative analytic approach to measuring DA response for all eyes, even those that fail to record a valid RIT value.

ABSTRACT BODY:

Purpose: We previously reported that choroidal $\gamma\delta$ T cells protected the retinal pigment epithelium (RPE) from oxidative injury. Aryl hydrocarbon receptor (AhR) is a key transcription factor for the differentiation and function of interleukin 17 (IL-17)-producing T cells. The goal of the current project is to examine the roles of AhR and IL-17⁺ $\gamma\delta$ T cells in acute and chronic toxicity models of RPE injury.

Methods: AhR-floxed mice were crossed with transgenic mice with Cre expression driven by the RAR-related orphan receptor gamma (Rorc) promoter, to generate AhR knockout in IL-17-producing T cells (Rorc-Ahr KO). Flow cytometry analysis was conducted to verify the IL-17⁺ $\gamma\delta$ T deficiency. Rorc-Ahr KO mice were either treated with sodium iodate or fed on a high-fat, cholesterol-rich diet for 6 weeks to induce acute or chronic RPE injury. Optical coherence tomography (OCT), fundus photography, and electroretinogram (ERG) were used in live animals to determine ocular phenotype. Microglia activation was assessed by immunofluorescence staining of cryosections or RPE flat mounts.

Results: AhR deficiency led to impaired IL-17 production in $\gamma\delta$ T cells. In the chronic RPE toxicity model, the conditional knockout mice had a higher number and more extensive area of subretinal IBA-1⁺ microglia infiltration as indicated by immunostaining on RPE flat-mounts or retinal cryosections. Rorc-Ahr KO had focal RPE pigment loss and atrophy, especially in the peripheral region. Consistent with the pathology findings, Rorc-Ahr KO had reduced scotopic a- and b-wave responses. In the acute toxicity model, fundus photography, OCT, and quantification of RPE flat mounts showed more severe damage in the conditional knockouts.

Conclusions: Deficiency in IL-17 production in choroidal $\gamma\delta$ T cells increased the sensitivity to RPE injury, suggesting IL-17 plays a protective role by controlling microglial activation.

ABSTRACT BODY:

Purpose: To investigate the mechanism of onset and progression of retinitis pigmentosa (RP) due to mutations in Mer tyrosine kinase (MERTK) gene using induced pluripotent stem cells of the retinal pigment epithelium (iPSC-RPE) derived from patients.

Methods: iPSC-RPE were derived from two patients with RP with MERTK gene mutations (MTK) and three normal (NOR) individuals. Morphological differences in the diseased (MTK) and normal (NOR) iPSC-RPE were evaluated using bright field microscopy, transmission electron microscopy, and immunochemistry analyses. Phagocytosis was analyzed with fluorescent bovine photoreceptor outer segments (POS) using flow cytometry and POS-derived protein, rhodopsin, in the iPSC-RPE cells fed POS using western blotting.

Results: There were no morphological differences between MTK and NOR iPSC-RPE. Flow cytometry analysis revealed that the percentage of FITC-positive MTK iPSC-RPE (15.5 ± 6.6 %) was significantly lower ($P = 0.046$) than that of NOR iPSC-RPE (27.3 ± 14.2 %). The relative intensity of rhodopsin in MTK iPSC-RPE (0.51 ± 0.18) was significantly lower ($P = 0.016$) than that in NOR iPSC-RPE (0.82 ± 0.20).

Conclusions: We successfully developed a human cell-based in vitro model of retinal degeneration. In the diseased iPSC-RPE, phagocytosis of POS was found to be deteriorated.

ABSTRACT BODY:

Purpose: Optic nerve sheath fenestration (ONSF) is a surgical procedure that acutely relieves the pressure from cerebrospinal fluid around the optic nerve to preserve vision in patients with papilledema. Decision to utilize ONSF or ventriculoperitoneal (VP)/lumboperitoneal (LP) shunts or to combine both procedures largely remains institution/surgeon dependent. This study tested the hypothesis that ONSF acutely reverses vision loss after surgery and continues to improve months after the surgery.

Methods: Retrospective chart review was performed on 11 years of data from a single hospital system database utilizing current procedural terminology (CPT) for ONSF (2009 – 2020). Patients aged 18 and older who had undergone ONSF procedure for elevated intracranial pressure with severe vision loss were included in the study. Data was reviewed for a reduction in blindness (defined as logMar \geq 1) and Humphrey/Goldmann visual fields immediately post-op, 3-9 months post-op, and at the latest visit.

Results: 34 eyes (24 patients) were included in this study. The average age was 36.0 years old (SD +/- 10.0 years). Nineteen patients were female (79.2%) and seventeen were Caucasian (70.8%). Seventeen of patients had a documented risk factor of obesity (70.8%), and the mean BMI of all patients was 34.2. The mean opening pressure at diagnosis was 39.4 cm H₂O. Average pre-op LogMar was 1.30 and 19 eyes (56%) were legally blind pre-operatively (LogMar \geq 1). Average mean deviation on Humphrey visual field was -21.36 (16 eyes) pre-operatively. 26 eyes (76.5%) had combined ONSF with VP shunt, 2 eyes (5.9%) with ventriculostomy, and 2 eyes (5.9%) with stenting of venous sinus. Immediately after surgery, 45.5% (15) of patients had improved visual acuity, 24.4% (8) had stable visual acuity, and 30.3% (10) had decreased visual acuity. The average post-operative change in LogMar visual acuity was +0.23. There was a 28% reduction in blindness (LogMar \geq 1) immediately after surgery post-op and a 56% reduction in blindness in the most recent exam (average days from surgery to most recent visit: 690 days).

Conclusions: Visual recovery and reduction in blindness (LogMar \geq 1) after an ONSF procedure increases over the postoperative period. It may be that as many as 50% of eyes blinded by IIH will recover useful vision with this surgery.

ABSTRACT BODY:

Purpose: Advanced age-related macular degeneration (AMD) is a devastating blinding disease centring on the retinal pigment epithelium (RPE)/choroid. The current treatments can only slow the progress of the disease. The current big data era affords comparisons of large gene expression datasets generated from large drug perturbation response studies aiming to explore the repurposing of currently available drugs for different diseases. Here, we exemplify the application of such an integrating transcriptomic method to find potential drugs for advanced AMD.

Methods: The publicly available microarray transcriptome (GSE29801) of advanced AMD RPE/choroid was combined with RNAseq (GSE135092) by an integrating quantitative method to extend the assessment of the differential gene expression in advanced AMD RPE/choroid. The resulting significant genes were subjected to over-representation analysis of KEGG pathways to highlight crucial biological processes in advanced AMD. For the purpose of this study, the differentially expressed genes in the significant pathways were then compared with the drug perturbation profile from the L1000 Connectivity Map (CMap), querying the correlation of a predicted response with the differential gene expression profile in advanced AMD RPE/choroid.

Results: We furthered our previous integrative transcriptomic analysis of RPE/choroid to combine transcriptomic data of 35 advanced AMD RPE/choroid samples. The analysis showed 427 genes differentially expressed ($p < 0.05$) with advanced AMD (276 upregulated and 151 downregulated). Among the differentially expressed genes, over-representation analysis highlighted extracellular matrix (ECM)-receptor interaction and focal adhesion as two significant KEGG pathways ($FDR < 0.05$). The 11 significant upregulated genes in ECM-interaction pathway were used to query the correlated drug perturbation in CMap database and identified dihydrofolate reductase inhibitor, vitamin D receptor agonist and MTOR-PI3K inhibitor as potential drug classes by this computational method (CMap enrichment score > 99).

Conclusions: Integrative RPE/choroid transcriptome analysis against the drug perturbation response database predicted three potential drug classes, based on dihydrofolate reductase inhibitor, vitamin D receptor agonist and MTOR-PI3K inhibitor, with potential for repurposing for advanced AMD.

ABSTRACT BODY:

Purpose: Acoustic power measurements of ultrasonic vitrectomy devices and the tissue interaction have not been fully characterized to-date and the unique close ended needle with side port configuration cannot be accounted for in the theoretical calculations. Computational fluid dynamics (CFD) simulations and measurements in water and pig eye reveal the non-linear effects and behavior. This is a significant step in characterizing the power, energy-tissue interaction, and safety of ultrasonic vitrectomy devices.

Methods: Acoustic pressure of 23, 25, and 27 gauge vitrectomy needles was measured in a degassed water tank using a hydrophone (B&K 8103) according to the IEC 61847 standard.

The ocular tissue measurements used a whole pig eye with infusion for IOP control and aspiration of 50 mmHg, with the hydrophone external to the eye.

Whole eye ANSYS simulations estimated the; phase transition, velocity, and pressure with the following parameters: No-slip boundary conditions, saline solution viscosity 1.02×10^{-3} Pa.s, density 1005.3 kg/m^3 , with a transient timesteps of 1 μs .

Results: Pressure decrease was measured with the 23g ported and smaller diameter needles compared to the unported 23g needle ($p < 0.01$), and a decrease in average pressure was observed with the pig eye while increase in pressure variability was measured with higher strokes ($p > 0.05$) (Fig.1).

CFD simulations (Fig. 2) show high pressure increase at the inner needle tip during retraction motion (3157 mmHg) compared to the outer needle tip at extraction motion (< 1200 mmHg), with phase change volume fraction of $> 60\%$ and $< 10\%$, respectively.

Conclusions: The results indicate that ocular tissue has low acoustic energy absorption properties while the IOP may reduce the occurrence of cavitation events which in turn lowers the average power. The CFD simulations further bolster these results by showing that inner needle cavitation events to be the main contributor to the measured acoustic power.

The low acoustic energy-tissue interaction within the low ultrasonic frequency range (< 100 kHz) and power (< 100 mW), further promotes the safety of a posterior ultrasonic vitrectomy device.

ABSTRACT BODY:

Purpose: We aimed to determine the need for corneal crosslinking (CXL) among keratoconus cases using deep learning (DL).

Methods: Two hundred and seventy-four corneal tomography images taken by Pentacam HR[®] of 158 keratoconus patients were examined. All patients were examined two times or more, and divided into two groups; the progression group included eyes showing keratoconus progression that underwent CXL, and the non-progression group consisted of eyes showing no progression. An axial map of the frontal corneal plane, a pachymetry map, and a combination of these two maps were examined and assessed according to the patients' age. Training with a convolutional neural network on these learning data objects was conducted. The area under the curve (AUC), sensitivity, and specificity were examined for detecting the need for CXL.

Results: Ninety eyes showed progression and 184 eyes showed no progression. The axial map, the pachymetry map, and their combination combined with patients' age showed mean AUC values of 0.783, 0.784, and 0.814 (95% confidence interval [0.721 - 0.845], [0.722 - 0.846], and [0.755 - 0.872], respectively), with sensitivities of 87.8%, 77.8%, and 77.8% ([79.2 - 93.7], [67.8 - 85.9], and [67.8 - 85.9]) and specificities of 59.8%, 65.8%, and 69.6% ([52.3 - 66.9], [58.4 - 72.6], and [62.4 - 76.1]), respectively.

Conclusions: Using the proposed DL neural network model, keratoconus progression can be predicted with high sensitivity and specificity on corneal tomography maps combined with patients' age.

ABSTRACT BODY:

Purpose: Diabetic macula oedema (DMO) remains one of the most common causes of visual loss in the industrial working-age population. Intravitreal Ozurdex Implant (dexamethasone 0.7 mg) is an established treatment option for management of DMO with favorable long-term outcomes, however, one of its side effects is increase in intraocular pressure (IOP). The duration of Ozurdex action varies from 3-6 months. The purpose of this study is to investigate the differences in functional and structural outcomes as well as effect on IOP for patients receiving 1, 2 or 3 Ozurdex intravitreal implants in the first 12 months of treatment at 24-month post-treatment initiation in a real-life setting.

Methods: Retrospective study of patients with DMO treated with Ozurdex implants between January 2016 and October 2019, at Sunderland Eye Infirmary, UK. The number of Ozurdex implants injected in the first 12 months of treatment were calculated for each patient.

The primary outcome measures were mean changes from baseline in best-corrected visual acuity (BCVA), central macular thickness (CMT) and IOP at 24 months. Secondary outcomes included proportions of patients with ≥ 10 letters gain or loss; $\geq 20\%$ of CMT gain or loss and final BCVA and CMT.

Results: 89 eyes (74 patients) were included in the study, with 43, 35 and 11 eyes receiving 1, 2 or 3 implants, respectively, in the first 12 months. The baseline BCVA was similar in all 3 groups (55.2, 54.1, 54.8 letters, respectively, $p=0.80$). At 24 months, the group receiving 3 Ozurdex implants demonstrated the highest increase in BCVA of 9.88 letters compared to 1.23 and -1.20 letters for group 1 and 2, respectively, although significance was limited by small sample size ($p=0.24$). Reduction in CMT was $-78.91\mu\text{M}$, $-102.53\mu\text{M}$ and $-189.00\mu\text{M}$ for 1, 2 and 3 Ozurdex implants, respectively ($p=0.08$). There has been a minor IOP change from baseline of -0.76mmHg , 2.47mmHg , 2.13mmHg ($p=0.973$) in 1, 2 and 3 Ozurdex implant groups, yet this was clinically insignificant.

Conclusions: The results of our real-life study showed that early treatment with multiple frequent Ozurdex implants in the first year (3 implants) yielded better functional and structural outcomes at 24 months as compared to patients' groups treated less frequently (1 or 2 implants) though this hasn't reached statistical significance levels with no clinical significant safety concerns.

ABSTRACT BODY:

Purpose: Gluconeogenesis is a process wherein metabolites are diverted from the Krebs cycle to become glycolytic intermediates. Gluconeogenesis is critical for blood glucose homeostasis, and is thought to be restricted to liver, kidney, intestine, and muscle tissue. Previous literature suggests that amphibian retinas are capable of this process, and our goal is to determine whether gluconeogenesis occurs in the mammalian retina.

Methods: We infused male and female C57BL6/J mice with 100mg/kg $^{13}\text{C}_4$ -succinate through jugular catheters and euthanized mice 1, 2, 3, 5, and 12 minutes following the infusion, dissecting and snap-freezing retina and eyecup tissue (EC; a complex of choroid, sclera, and RPE; n=3-5/tissue/time point). Un-infused mice served as a '0 minute' control. At 0 and 5 minutes post-infusion, we also collected liver tissue (n=3).

Frozen samples were derivatized with methoxyamine and TBDMS, and analyzed by gas-chromatography mass spectrometry to determine the abundance of ^{13}C -labeled metabolites in the Krebs cycle (succinate, fumarate, malate, and citrate) and glycolysis (pyruvate, phosphoenolpyruvate, and 3-phosphoglycerate).

Results: Infused $^{13}\text{C}_4$ -succinate populated the bloodstream (>95% of blood succinate was labeled) and led to succinate infiltration in to retina (8% of pool) and EC (57% of pool). Surprisingly, ^{13}C from infused succinate was incorporated into $^{13}\text{C}_3$ -pyruvate, $^{13}\text{C}_3$ -phosphoenolpyruvate, and $^{13}\text{C}_3$ -3-phosphoglycerate in both tissues. These metabolites respectively accumulated at a rate of 0.2 (0.96), 0.13 (0.96), and 0.14 (0.92) % pool/minute (mean slope; R^2) in the retina, and 0.1 (0.59), 0.07 (0.68), 0.09 (0.97) % pool/minute in the EC. There was no observable accumulation of ^{13}C on glycolytic intermediates in liver, thus our observations are not explained by gluconeogenesis in the liver.

Conclusions: Retina succinate pools are far less labeled by succinate than ECs, yet in both tissues the diversion of Krebs cycle intermediates (succinate) to ^{13}C labeled glycolytic metabolites occurred at a similar rate. These data suggest that (a) both tissues are capable of gluconeogenesis and (b) the retina diverts a larger fraction of ^{13}C from succinate to gluconeogenesis than EC tissue. These findings are not recapitulated in liver tissue or ex vivo retina or EC tissue supplied with $^{13}\text{C}_4$ -succinate, suggesting that the cellular environment may dictate the activity of this pathway.

ABSTRACT BODY:

Purpose: To evaluate choroidal melanin distribution in healthy subjects by polarization-sensitive optical coherence tomography (PS-OCT).

Methods: This study involved 57 eyes of 57 healthy Japanese subjects. The presence of melanin in the choroid was determined by using the degree of polarization uniformity (DOPU) obtained by 1 μ m Jones-matrix PS-OCT. Choroidal melanin thickness was evaluated for 5 mm circular region from the foveal center, and compared with age (26 – 84 years), axial length (22.0 – 28.5 mm), choroidal thickness, and choroidal luminal/stromal ratio. To evaluate the distribution of choroidal melanin thickness, circular region was divided into five sectors (center, upper, lower, nasal, and temporal) by modified ETDRS layout.

Results: The mean choroidal thickness and choroidal melanin thickness (mean \pm SD) at 5 mm circular region were $202.5 \pm 80.8 \mu$ m and $68.3 \pm 24.2 \mu$ m, respectively. Mean choroidal thickness showed significant negative correlation with age ($\beta = -0.30$, $P = 0.004$) and axial length ($b = -0.21$, $P = 0.03$), and significant positive correlation with luminal/stromal ratio ($\beta = 0.62$, $P < 0.001$). Mean choroidal melanin thickness showed significant negative correlation with axial length ($\beta = -0.26$, $P = 0.045$) and luminal/stromal ratio ($\beta = -0.60$, $P = 0.001$), and significant positive correlation with choroidal thickness ($\beta = 0.85$, $P < 0.001$). The mean choroidal thickness and choroidal melanin thickness of the nasal sector were significantly thinner than that of all other sectors ($P < 0.001$).

Conclusions: PS-OCT provides an in vivo objective choroidal melanin distribution. Choroidal melanin thickness varies significantly with location, axial length, and choroidal morphology.

TITLE: Sensimed Triggerfish® contact lens sensor for 24-hour intraocular pressure profile-safety and validity.

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sharma, Consultant Ophthalmic Surgeon, Eye Department, University Hospitals Derby & Burton NHS trust, Burton, UNITED KINGDOM|R. Sharma, Asstt Professor (Honorary), University of Nottingham, Nottingham, Nottinghamshire, UNITED KINGDOM|Z. Ong, Nottingham university, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Rohit Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Zun Zheng Ong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

Sensimed Triggerfish® contact lens sensor (CLS), a relatively new device, is designed to monitor 24-hour intraocular pressure (IOP) profile. Currently, the safety, tolerability and validity of triggerfish CLS remains controversial. We performed a prospective observational study (the first such study in the NHS UK) to evaluate the safety, tolerability of CLS in glaucoma patients and whether the CLS measurement can be correlated to IOP measured using Goldmann applanation tonometry (GAT).

Methods: This was an observational single-facility study. 24 voluntary patients (9 females, 15 males) with glaucoma underwent 24-hour continuous measurement of IOP with a Triggerfish® CLS. Clinic letters and communications to the GP (general practitioner) were reviewed to identify any objective and subjective reports of eye symptoms during or after the usage of CLS.

IOP were measured immediately before and after CLS usage using GAT by ophthalmologists. We then compared the changes of IOP measurements (end-initial IOP in mVeq) from CLS and changes of IOP (end-initial IOP in mmHg) from GAT among the 24 patients to look for correlation.

Results: All patients successfully completed the 24-hour measurement of IOP with CLS. The mean age was 69.83 (SD: 7.8). No patient needed emergency visit or discontinuation or removal of the CLS before the prescribed period. The reporting rate of side effects, watering, redness, pain, blurring or discomfort was 0%. At the 3-week follow up clinic, the overall incidence of objective and subjective report of eye symptoms such as ocular pain and blurred vision was 0%. The Pearson correlation coefficient between the difference of IOP measurement from CLS and GAT was $r = -0.173$ ($p = 0.43$), which represented a weak negative correlation.

Conclusions: Our study showed that IOP measurement with 24-hour CLS is safe & well-tolerated in glaucoma patients. There were no short term or permanent complications or side effects reported. Our results showed a weak correlation between Triggerfish data changes and IOP measurements using the GAT. Though CLS cannot totally replace GAT for IOP measurement, this complements & adds useful insight on the innovative continuous 24 hour IOP profile and nocturnal measurements not covered by the static clinic GAT. Bigger, well-designed studies shall help in this exciting topic.

ABSTRACT BODY:

Purpose: With the growing adoption of teleretinal imaging (TRI), it is important to design a TRI-based screening program that is easily accessible over a large geographic area. This study develops a modeling framework that identifies locations to place future TRI screening centers that maximize TRI visits for in-need census tracts in a large, county-wide safety-net system.

Methods: A location-based Monte Carlo discrete event simulation model was developed including all census tracts in Harris County to evaluate patient visits to current TRI screening centers. A total of 500,000 hypothetical patients were generated and tracked over their lifetime under annual TRI screening recommendations. Patient compliance rates were varied based on factors such as race, poverty level, and travel time. The top 20% of census tracts with the greatest need was identified by factors such as total number of visits and minimum travel time to the nearest center. A new potential center was then identified based on a weighted centroid of the top 20% census tracts where the weights are assigned proportional to census tract-specific needs. The simulation was then run again with the new center added to analyze the benefits for patients within the in-need census tracts.

Results: For the top 20% of census tracts, the model identifies a new potential TRI screening center in northwest Harris County in an area that is currently not covered by existing centers (See Fig 1&2). For census tracts in the top 20% that are impacted by the placement of the new center, yearly TRI visits increase by 32.81% (95% CI; 32.21-33.48%) with a reduction in average travel time per impacted patient of 7.96 minutes (95% CI; 7.93-7.99 minutes). Furthermore, average cost (\$)/QALY per impacted patient decreased by \$19.06 (95% CI; \$15.42-\$22.70).

Conclusions: The location model can be a useful tool in designing a TRI-based screening program that maximizes TRI visits for a heterogeneous population over a large geographic area. TRI screening locations can be identified that account for patient-specific compliance data and geodemographic factors. Positive benefits in cost/QALY can be seen on a county-level when new locations are placed strategically.

ABSTRACT BODY:

Purpose: Preservation of central vision is an unmet clinical need in dry age-related macular degeneration (AMD). Chronic oxidative stress impairs the normal functioning of RPE and causes RPE atrophy, leading to loss of macular photoreceptors. The purpose of our study is to determine if buspirone, a partial 5-HT_{1A} agonist receptor agonist, is protective against oxidative stress-induced changes in the RPE.

Methods: The effect of buspirone was evaluated in the sodium iodate model (NaIO₃) of RPE oxidative injury and paraquat-induced oxidative damage in differentiated human ARPE-19 cell culture model. Protection of RPE and photoreceptors in NaIO₃-treated C57BL/6J mice with or without buspirone treatment was characterized by the preservation of outer nuclear layer thickness (mean ± standard error of mean), measured by spectral-domain optical coherence tomography (SD-OCT). RPE/choroid from mice was analyzed by ZO-1 (a phosphoprotein present at tight junctions) and immunostaining of RPE flat-mounts. Quantitative RT-PCR was performed to investigate the effect of buspirone on inducing the expression level of protective enzymes. In response to paraquat-induced cellular toxicities and RPE junctional abnormalities in ARPE-19 cells, the impact of buspirone was assessed by MTT assays and ZO-1 immunocytochemistry, respectively.

Results: Daily intraperitoneal injection (i.p.) of buspirone (30mg/Kg) for 12 days mitigated the thinning of the outer nuclear layer (p<0.0001) in the NaIO₃ model (88.04µm ± 8.009, n=12) compared to vehicle treated eyes (32.83 µm ± 3.861, n=10) determined by SD-OCT. Fluorescent images of RPE flat-mounts stained with ZO-1 tight junction protein revealed the structural preservation of RPE from oxidative damage in buspirone treated mice. Furthermore, buspirone treatment showed an increased trend of expression of key cytoprotective antioxidant genes (Nqo1, Cat, Sqstm1, Gstm1, and Sod2) in the RPE/choroid compared to untreated eyes. MTT assay showed dose-dependent protection of viability in buspirone-treated ARPE-19 cells in culture and preservation of RPE junctional integrity in differentiated ARPE-19 cells in response to paraquat-induced cellular toxicities.

Conclusions: Buspirone provided structural protection of RPE cells from oxidative injury by inducing antioxidant survival pathway. As an FDA-approved drug, repurposing buspirone may be useful in treating dry-AMD.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is an inherited retinal disease, affecting >20 million people worldwide. Loss of daylight vision typically occurs due to the dysfunction/loss of cone photoreceptors, the cell type that initiates our color and high acuity vision. Currently, there is no effective treatment for RP, other than gene therapy for a limited number of specific disease genes. Therefore, we would like to develop a gene-agnostic therapy, aimed at preserving cone photoreceptors and daylight vision, independent of the specific genes that are involved.

Methods: We used adeno-associated virus (AAV) to deliver candidate genes to the eyes of neonatal RP mice. The AAV8 capsid employing cone-specific promoters was used for cell type-specific expression. AAV delivery was via subretinal injections. The initial screen was done in rd1 mice, the fastest RP degeneration strain, followed by infections of the rd10 and rho^{-/-} strains. Rd1 retinas were harvested at P50, flat-mounted and the surviving cones within the central half of radius were quantified. To test for an effect on visual function, optomotor behavioral assays were used on treated rd10 and rho^{-/-} mice.

Results: We found that AAV-Txnip prolongs the survival of cone photoreceptors and improves visual acuity in RP mouse models. The rescue effect of Txnip depends upon lactate dehydrogenase b (Ldhd), and correlates with the presence of healthier mitochondria. A Txnip allele, C247S, which blocks the association of Txnip with thioredoxin, provides an even greater benefit. Moreover, the combination of Txnip.C247S and Nrf2, a therapeutic transcription factor which regulates the oxidative stress response, provides a synergistic effect in rescue.

Conclusions: These and additional observations lead to a model wherein Txnip shifts cones from their normal reliance on glucose, to enhanced utilization of lactate for mitochondrial metabolism, thus benefiting the cones in a condition where the glucose supply is limiting.

ABSTRACT BODY:

Purpose: Previous studies with smaller cohorts have shown decreased vessel density with increasing diabetic retinopathy (DR) severity. Recently, there has been increasing interest in WF fundus photography and fluorescein angiography in the management of diabetic eye disease. We explore the added value of WF SS-OCTA in a large prospective observational study of diabetic patients compared to controls.

Methods: We imaged 402 eyes of 241 patients (70 eyes of 55 control patients and 332 eyes of 186 diabetic patients) using WF SS-OCTA between December 2018 to September 2020. 6x6mm and 12x12mm scans centered on the fovea were analyzed using ARI Network (Zeiss Portal) for vessel density (VD), vessel skeleton density (VSD), foveal avascular zone (FAZ) raw size, circularity and perimeter; and ImageJ for non-perfusion area (NPA) on 12x12mm scans only. Mixed-effects multivariate regression models were used to test for significance.

Results: Among patients with diabetes (median age 59 years), 45 eyes of 24 patients had no DR, 71 eyes of 40 patients had mild non-proliferative DR (NPDR), 45 eyes of 28 patients had moderate NPDR, 28 eyes of 16 patients had severe NPDR, and 133 eyes of 78 patients had proliferative DR (PDR). Trend analysis revealed a progressive decline in VD and VSD with increasing DR severity ($p < 0.05$). PDR patients had an increased FAZ raw size ($\beta = 0.14$, $p = 0.03$), perimeter ($\beta = 0.83$, $p = 0.03$), and irregularity ($\beta = -0.10$, $p < 0.001$). Also, the mild ($\beta = -0.07$, $p = 0.047$) and moderate NPDR ($\beta = -0.10$, $p = 0.01$) group had irregular FAZ on 12x12mm scans. Controlling for DR severity and age, diabetic macular edema was associated with a more irregular FAZ on 6x6mm scans ($\beta = -0.06$, $p = 0.004$). NPDR and PDR had greater NPA versus controls ($p < 0.001$). On receiver operating curve (ROC) analysis, wide-field NPA was the best test to detect the presence of DR, area under the curve (AUC) 0.97.

Conclusions: Herein, we present a comprehensive study of a large cohort of DR patients imaged on the WF SS-OCTA. The enhanced resolution and larger area coupled with a bigger sample size validates prior work that indicated VD reductions with increased DR severity. Furthermore, our work highlights the importance of NPA which can be more readily and repeatedly measured with WF SS-OCTA.

ABSTRACT BODY:

Purpose: During glaucoma, retinal ganglion cell (RGC) axons are damaged, causing the RGCs to die, resulting in the irreversible loss of visual function. There are no FDA-approved drugs or therapies to protect RGCs from death in glaucoma. Unlike in mammals, zebrafish maintain most RGCs after optic nerve injury; however, the molecular underpinnings of RGC neuroprotection are unknown. Here, we sought to identify neuroprotective factors in zebrafish RGCs after injury and determine if macrophages/microglia are required to survive RGCs after optic nerve transection.

Methods: isl2b:GFP zebrafish, in which ~60% of RGCs are labeled, was utilized at ~3 months. Animals underwent an optic nerve transection surgery in the left eye, while the right eye of the same fish went through a sham surgery. To quantify RGC survival after transection, retinal flat mounts were made and imaged using confocal microscopy at 1-14 days post-injury (dpi) and RGC survival over time was quantified using ImageJ software. Retinae were dissociated at 6, 12 and 24 hours post transection and RGCs were sorted and collected by fluorescence-activated cell sorting. RNA-Seq was performed in biological triplicate, and gene expression changes after injury were quantified. After analyzing the RNA-seq data, several pathways were identified to be possibly involved in RGC survival. Pharmacological experiments were performed and the results on RGC survival quantified. Immunofluorescence imaging of transgenic lines labeling specific leukocyte populations was performed to assess the interaction of immune responses and RGC survival after optic nerve transection.

Results: After injury, RGC survival was: $94.44 \pm 5.45\%$ (1dpi); $92.52 \pm 3.54\%$ (3dpi) and $76.35 \pm 2.58\%$ (7dpi), with levels returning to $98.71 \pm 4.82\%$ at 14dpi. Analysis of RNA-seq data indicate JAK/STAT signaling pathway and immune responses were activated after optic nerve transection, amongst other pathways. Local inhibition of the JAK/STAT pathway leads to the reduction of RGC survival, while local suppression of immune responses by dexamethasone rescued RGCs after injury. Furthermore, depletion of macrophages/microglia increased RGC survival after injury.

Conclusions: Zebrafish maintain most RGCs after optic nerve injury. JAK/STAT signaling pathway regulates RGC survival after optic nerve injury. Immune responses play a critical role in RGC survival after injury.

ABSTRACT BODY:

Purpose: Herpetic interstitial keratitis (IK) caused by herpes simplex virus (HSV) or varicella zoster virus (VZV) can cause sight-threatening corneal scarring. This retrospective chart review describes the outcomes of a supervised reduction protocol (SRP) – in which topical steroids and systemic antivirals are only reduced under direct physician supervision, to ensure quiescence before further reduction – for treatment of herpetic IK.

Methods: A cohort of 50 patients with HSV or VZV IK, all treated with SRP between September 2016 and March 2020, were included in the study. Baseline characteristics and details related to ocular outcomes were collected. The primary outcome measures were time from IK diagnosis to quiescence, time from quiescence to IK recurrence, incidence of IK recurrence, and the change in logMAR visual acuity pre-and post-treatment.

Results: The mean follow-up period was 2.7 ± 0.8 years. Quiescence of IK was achieved within 10 weeks of treatment for 47% and 81% of patients in the HSV IK and VZV IK cohorts respectively. Recurrent IK was observed in 38.6% and 50% of patients in the HSV IK and VZV IK cohorts. The mean time from quiescence to recurrence was 170 ± 130 days in the HSV cohort and 300 ± 289 days in the VZV IK cohort. Complete cessation of topical steroids preceded recurrence of IK in 69% and 63% of patients who experienced at least one recurrence in the HSV IK and VZV IK cohorts, respectively. No statistically significant changes in logMAR visual acuity between IK diagnosis and quiescence were detected in either cohort.

Conclusions: The time periods from herpetic IK diagnosis to quiescence and from quiescence to recurrence, as well as the rates of IK recurrence, may be helpful to clinicians attempting to determine a long-term treatment strategy for this patient population. The proportion of patients achieving quiescence within 10 weeks in the HSV IK group was higher than was seen in the seminal Herpetic Eye Disease Study (HEDS), as was the observed IK recurrence rate. The relatively high IK recurrence rates in this study may reflect increased detection of mild, pre-symptomatic IK with the SRP, due to close follow-up. Lack of change in logMAR pre- and post-treatment suggest that patients treated with SRP experienced mild, visually insignificant episodes of IK.

ABSTRACT BODY:

Purpose: Optical Coherence Tomography Angiography (OCTA) is a new diagnostic technology that can help us to a better understanding of diabetic retinopathy (DR) therefore validation of its results is needed.

We tested the hypothesis that DR severity is directly related with the vessel density (VD) and foveal avascular zone (FAZ) parameters measured with OCTA in a prospective observational study.

Methods: We performed a comprehensive ophthalmic examination including best corrected visual acuity (BCVA), anterior and posterior slit-lamp biomicroscopy, retinography, OCTA with RS-3000 Advance AngioScan (Nidek, Gamagori, Japan) and microperimetry with MP-3 (Nidek, Gamagori, Japan) in diabetic mellitus and healthy subjects. Diabetic retinopathy severity was graded following the International clinical diabetic retinopathy disease severity scale. Mean vessel density in the 4,5 x 4,5 mm centered in fovea protocol, FAZ area and FAZ perimeter were calculated and correlated with the DR severity. Also VD was calculated in smaller sectors (in a 9-grid-chart) and correlated with DR severity with Spearman correlation test.

Results: Between healthy and diabetic retinopathy eyes, 210 eyes we analyzed. The severity of the DR was correlated with de mean vessel density in the superficial plexus with a strength of - 0,507 (95% CI=[(-0,601)-(-0,398)]; $p<0,001$) and in the deep plexus with a strength of - 0,606 (95% CI=[(-0,684)-(-0,512)] ; $p<0,001$). By sectors, in the superficial plexus the nasal superior and nasal inferior were correlated with higher strength than the other sectors. In the deep plexus, the most correlated sectors were temporal to fovea, central sector and nasal to fovea.

The severity of the DR was also correlated with de FAZ area and perimeter with a strength of 0,276 (95% CI=[0,146-0,396]; $p<0,001$) and 0,335 (95% CI=[0,189-0,464]; $p<0,001$), respectively.

Conclusions: Diabetic retinopathy is a diabetic microvascular complication that can damage macular capillaries and perifoveal anastomotic arcades along the time. As a result, the vessel density is reduced in the macular area and FAZ area and perimeter are enlarged. This changes can be measured with OCTA and are more obvious as the severity of the DR increases.

Moreover, deep plexus is correlated with higher strength with the severity of the DR, as in previous studies is pointed, the injury of this plexus could be earlier and more severe.

ABSTRACT BODY:

Purpose: Retinal detachment (RD) associated with giant retinal tear (GRT) is a cause of rapidly developing and important vision loss especially in men. The surgical management is challenging for these patients as proliferative vitreoretinopathy (PVR) is often present. The single surgery anatomical success (SSAS) appears to be lower than in patients with simple rhegmatogenous RD (RRD) and the visual recovery is limited. The purpose of our study is to compare the functional and anatomical outcomes of primary surgery in patients with GRT-associated RD to patients with RRD.

Methods: We conducted a retrospective study at CHU de Québec – Université Laval. Medical records of all consecutive patients operated for primary RRD between 2014 and 2018 at our center were reviewed. Among the total cohort of 2247 patients, we included patients with simple RRD and patients with non-traumatic GRT-associated RD. We analyzed pre-, intra- and postoperative data, such as extension of giant tears, number of quadrants affected by the RD, macula and lens status, type of surgeries and best corrected visual acuity (BCVA) during follow-ups and compared them between both groups. We also compared the anatomical success rate of first surgery between GRT-associated-RD and RRD groups.

Results: There were 39 patients (1.7%) with GRT-associated RD and 1661 patients (74%) with RRD. Mean ages were 57.2 ± 8.3 years and 61.8 ± 11.9 years ($p=0.29$), while mean number of affected quadrants were 2.4 ± 0.8 and 2.4 ± 0.9 ($p=0.24$) in the GRT and RRD patients, respectively. In GRT patients, GRT size was 125 ± 39 degrees. Final BCVA was 0.25 ± 0.19 logMAR and 0.31 ± 0.47 logMAR ($p=0.76$) in GRT and RRD patients respectively. The SSAS was 82% (32/39) in the GRT-associated-RD group and 90% (1495/1661) in the RRD group ($p=0.10$). After correcting for other preoperative factors, GRT was an independent risk factor for worse SSAS (odds ratio: 0.422, $p=0.047$).

Conclusions: Our study compares the anatomical and functional results of GRT-associated RD and RRD patients. GRT-associated RD is still a challenge to treat as our results suggest that it may be associated with poorer SSAS than RRD.

ABSTRACT BODY:

Purpose: Reductionist approaches into mechanisms underlying diseases of the outer blood-retinal-barrier (oBRB), such as age-related macular degeneration and diabetic retinopathy (DR) have been hampered by the lack of optimal in vitro models utilizing human cells to provide the 3-D dynamic architecture and allow expression of the in vivo phenotype for both the retinal pigment epithelium (RPE) and the choroidal endothelium (EC). The main limitations of the current oBRB models also arise from the cell sourcing, the lack of a proper Bruch's membrane (BM) analogue, and lack of choroidal microvasculature with flow. Therefore, we aimed to develop an oBRB-on-a-chip biomimetic system to emulate the cellular interactions that occur in retinal inflammatory disorders.

Methods: We have generated a microfluidic device that allows the simultaneous co-culture of RPE with perfusable EC. Taking advantage of the differentiation potential of human pluripotent stem cells (hPSC), we optimized differentiation protocols to obtain hPSC-RPE and hPSC-EC from hPSC. On the other hand, by combining biomaterial engineering and decellularization protocols we designed a BM analogue that favors the co-culture of hPSC-RPE and hPSC-EC.

Results: Differentiated hPSC-RPE showed a phenotype similar to that of mature RPE, while differentiated hPSC-EC showed a mature endothelial phenotype as they showed tubulogenesis properties and expressed endothelial markers. The co-culture of EC with hPSC-RPE cells increased the RPE barrier functional activity, significantly increasing TEER and decreasing the basolateral secretion of VEGF. On the other hand, we developed a decellularization protocol to obtain decellularized BM (dECM-BM) that guarantees DNA removal while preserving collagen and elastin fibers. Moreover, the BM analogue successfully allowed the co-culture of EC and hPSC-RPE cells. Finally, we challenged the oBRB model with glucose oscillations and recapitulated the DR microenvironment.

Conclusions: Our oBRB biomimetic co-culture system recapitulates the complex cellular interactions of the oBRB, inducing an increased RPE barrier functional activity, and allowing for the emulation of inflammatory microenvironments occurring during retinal disease. Overall, this human oBRB in vitro model represents an optimal platform to study the inflammatory processes underlying retinal pathologies.

TITLE: Peripapillary and Fovea Avascular Zone OCT Angiography Parameters in Exfoliation Glaucoma vs Primary Open Angle Glaucoma vs Healthy Eyes

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Zloto, R. Veksler, I. Moroz, H. Goldberg, H. Levkovitch-Verbin, Sheba Medical Center The Goldschleger Eye Institute, Tel Hashomer, Tel Aviv, ISRAEL|

Commercial Relationships Disclosure (Abstract): Ofira Zloto: Commercial Relationship: Code N (No Commercial Relationship) | Ronel Veksler: Commercial Relationship: Code N (No Commercial Relationship) | Iris Moroz: Commercial Relationship: Code N (No Commercial Relationship) | Hila Goldberg: Commercial Relationship: Code N (No Commercial Relationship) | Hani Levkovitch-Verbin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the differences in the peripapillary vascular parameters and foveal-avascular-zone (FAZ) vascularity parameters between primary open-angle-glaucoma (POAG) patients vs. exfoliation-glaucoma (XFG) patients vs. healthy subjects.

Methods: :This is cross-sectional study, comparative clinical-study. POAG and XFG patients and healthy subjects underwent a comprehensive ophthalmic examination, including visual field, optical-coherence-tomography (OCT) and OCT-angiography (OCTA) of the optic-disc and FAZ. Differences in peripapillary vessel-density (VD), perfusion-density (PD), and FAZ area and circularity were examined between groups, as well as correlations between clinical parameters and vascularity parameters for each glaucoma group.

Results: A total of 109 subjects were analyzed, including 45 with POAG, 30 with XFG, and 34 controls. The average peripapillary VDs were lowest among the XFG patients and highest among the controls ($P < 0.05$, ANOVA). The average peripapillary PD of the central ring was lowest in the PXF group and highest in the control group ($P = 0.02$, ANOVA). A significant negative correlation was found between the average peripapillary VDs and PDs of the inner ring and full ring and disease severity of the POAG patients. There was a significant positive correlation between the average peripapillary PDs of the central rings and full ring and the central-macular-thickness of the XFG patients ($P < 0.01$ and $P < 0.04$, respectively, Pearson correlation).

Conclusions: Peripapillary vascular parameters of the POAG and XFG patients were lower compared to those of normal participants. Investigations into the roles of OCTA as a diagnostic parameter for predicting the risk of glaucoma development and progression are warranted.

TITLE: Persistent Hyper-Transmission Defects Detected on En Face Swept Source OCT Images are a Risk Factor for Geographic Atrophy in Eyes with Intermediate AMD

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Laiginhas, Y. shi, M. Shen, W.J. Feuer, G. Gregori, P.J. Rosenfeld, University of Miami School of Medicine, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rita Laiginhas: Commercial Relationship: Code N (No Commercial Relationship) | yingying shi: Commercial Relationship: Code N (No Commercial Relationship) | Mengxi Shen: Commercial Relationship: Code N (No Commercial Relationship) | William Feuer: Commercial Relationship: Code N (No Commercial Relationship) | Giovanni Gregori: Commercial Relationship(s);Carl Zeiss Meditec :Code F (Financial Support);Carl Zeiss Meditec :Code P (Patent) | Philip Rosenfeld: Commercial Relationship(s);Carl Zeiss Meditec:Code F (Financial Support);Carl Zeiss Meditec:Code C (Consultant)

ABSTRACT BODY:

Purpose: To determine if choroidal hyper-transmission defects (hyperTDs) with a greatest linear dimension (GLD) $\geq 250\mu\text{m}$ detected on en face swept source OCT (SS-OCT) images could serve as a risk factor for progression to geographic atrophy (GA) in eyes with intermediate AMD (iAMD).

Methods: This is a retrospective review of a prospective observational case series that included eyes with iAMD imaged with SS-OCT imaging (PLEX Elite 9000, Carl Zeiss Medics, Dublin, CA) at the Bascom Palmer Eye Institute. All subjects underwent 6X6mm scans and en face images were prepared using a slab positioned 64 to 400 μm beneath Bruch's membrane. Two graders independently evaluated all en face images for the presence of hyperTDs. Based on a previous study that defined persistent hyperTDs as having a GLD $\geq 250\mu\text{m}$, all hyperTDs $\geq 250\mu\text{m}$ were identified and tracked. Progression of these eyes to GA, nonexudative macular neovascularization (MNV), and exudative MNV were recorded and graded.

Results: A total of 182 eyes from 134 patients were included with a median follow up of 28 months (range 6-55). At baseline, 29 eyes had at least one hyperTD $\geq 250\mu\text{m}$ and all hyperTDs were found to be persistent. In those eyes without a hyperTD $\geq 250\mu\text{m}$ at baseline, 33 developed hyperTDs $\geq 250\mu\text{m}$ during follow-up and only one was found to be non-persistent. At the last available visit, 17 eyes progressed to GA, 14 eyes progressed to exudative MNV, and 4 eyes had nonexudative MNV. All foci of GA detected on B-scans were previously detected as hyperTDs $\geq 250\mu\text{m}$. A Kaplan-Meier analysis showed that the cumulative risk of developing GA reached 52% following the appearance of hyperTDs $\geq 250\mu\text{m}$. In a time-dependent Cox-survival regression sensitivity analysis, the increased risk of forming GA after detecting a hyperTD $\geq 250\mu\text{m}$ was 45 times greater compared with eyes without a hyperTD $\geq 250\mu\text{m}$ (hazard ratio=45, 95%CI 6-337; $p<0.001$).

Conclusions: Choroidal hyperTDs detected on en face SS-OCT images with a GLD $\geq 250\mu\text{m}$ were found to be persistent and associated with the development of GA. The detection of these lesions may serve as a useful biomarker for assessing eyes at risk for progression from iAMD to late AMD.

TITLE: Inconsistencies in Visual Acuity Data in Electronic Health Records

SESSION TITLE: Visual Function, Vision QoL and visual impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.E. Goldstein, X. Guo, Ophthalmology, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|M.V. Boland, Massachusetts Eye and Ear Infirmary Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Judith Goldstein: Commercial Relationship: Code N (No Commercial Relationship) | Xinxing Guo: Commercial Relationship: Code N (No Commercial Relationship) | Michael Boland: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Challenges exist in harmonizing electronic health record (EHR)-derived data for secondary analysis, yet the problem is rarely studied. We aim to characterize data quality and quantify inconsistencies in EHR-derived visual acuity (VA) data during ophthalmology encounters.

Methods: Retrospective analysis of all VA entries from all eye care encounters across nine clinical locations and 9 subspecialties of the Wilmer Eye Institute between August 1, 2013 and December 31, 2015. Using the pre-defined VA menu options as the standard, we compared the VA entries to the menu options to determine their agreement on an overall and subspecialty level. VA entries were classified into 3 categories: (1) exact match of the VA entry to one of the 24 menu options; (2) partial discordance between the VA entry and the menu options but the entry could be converted to an accepted VA value; (3) total discordance between the VA entry and the menu options and not able to convert it to an accepted VA value.

Results: All VA entries from 513,036 encounters representing 166,212 patients were included. Of the 1,573,643 VA entries, 1,142,738 (72.6%) were an exact match to one of the menu options, 295,943 (18.8%) were partially discordant, and the remaining 134,962 (8.6%) were totally discordant, and classified as missing data. Documented VA entries with providers from comprehensive eye care (86.5%), oculoplastics (81.2%), and pediatrics/strabismus (77.1%) yielded the highest proportions of exact match with the menu options. VA entries during visits with providers from retina (17.5%), glaucoma (14.0%), neuro-ophthalmology (8.8%), and low vision (8.8%) had the highest rates of total discordance / missing VA data.

Conclusions: Inconsistencies exist in VA entries by ophthalmology subspecialty, affecting data quality measures of completeness, correctness and concordance. Transparency regarding data quality may reveal potential biases in VA documentation and should be considered before analyzing data between providers or institutions.

ABSTRACT BODY:

Purpose: Foveal hypoplasia (FH) is characterised by the continuation of inner retinal layers posterior to the foveola. Varying degrees of FH represent the different stages of arrested development of the fovea. The Leicester Grading System for FH divides typical FH into four grades and an additional grade for atypical FH. The grading system has been applied to various disorders including albinism, idiopathic infantile nystagmus (with or without FRMD7 mutations), PAX6 mutations, SLC38A8 mutations and AHR mutations. The grading system is used as a diagnostic and prognostic tool.

To date, it is unclear whether mutations of certain genes are associated with worse foveal morphology and prognosis. Thus, we aimed to perform a comparative study to characterise the genotypic and phenotypic spectrum of FH in the aforementioned genetic aetiologies.

Methods: In this multi-centre study, patients with known genetic associations with FH (n=288) were identified from one centre in UK and two centres in South Korea. Genetic diagnosis was achieved using targeted panel-based sequencing or exome sequencing. Due to the rarity of AHR mutations, we only included cases reported in the literature. Optical coherence tomography of the fovea was obtained in all subjects. Grades of FH (Leicester Grading System) were: Grade 1: shallow foveal pit, presence of outer nuclear layer widening, presence of outer segment (OS) lengthening; grade 2: grade 1 but absence of foveal pit, grade 3: grade 2 but absence of OS lengthening; grade 4: grade 3 but absence of ONL widening.

Results: The most common genetic aetiology for typical FH was albinism (74%), followed by PAX6 mutations (15%) and SLC38A8 mutations (9%). AHR and FRMD7 mutations were rare causes of FH. All grades of FH were seen in albinism and PAX6 mutations. In SLC38A8 mutations, we only observe grade 3 (80%) and grade 4 (20%) FH. In AHR mutations only grade 3 FH has been reported. In cases of FH and FRMD7 mutations only grade 1 FH was observed.

Conclusions: Albinism and PAX6 mutations are associated with much wider spectrum of arrested retinal development, however SLC38A8 mutations, AHR mutations and FRMD7 mutations have much narrower spectrum. Our data suggests that arrested retinal development occurs earlier in development in SLC38A8 and AHR mutations and much later in FRMD7 mutations. However, with albinism and PAX6 mutations the defined time period of foveal developmental arrest is more variable.

TITLE: VFQ Responses in Patients with Argus II Retinal Prosthesis System and the relationship with postoperative visual function testing

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Bansal, N. Ghani, A. Naidu, Department of Ophthalmology, Stony Brook University Renaissance School of Medicine, Stony Brook, New York, UNITED STATES|K. Chaudhary, Department of Ophthalmology, Stony Brook University Hospital, Stony Brook, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jahnvi Bansal: Commercial Relationship: Code N (No Commercial Relationship) | Nimra Ghani: Commercial Relationship: Code N (No Commercial Relationship) | Abhishek Naidu: Commercial Relationship: Code N (No Commercial Relationship) | Khurram Chaudhary: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to analyze responses to the visual function questionnaire (VFQ) given to patients with the Argus II Retinal Prosthesis. Our primary objective is to assess whether the Argus II retinal prosthesis improved the quality of life of patients with profound retinal dystrophy over two years. We also aim to assess whether the VFQ scores correlated with visual function outcomes.

Methods: Five patients with profound retinal dystrophy were enrolled in this single institution cohort study. All surgeries were completed by a single surgeon at Stony Brook University Hospital. A VFQ was given to patients at baseline prior to implantation of Argus II Retinal Prosthesis and at year 1 and year 2 post implantation. Visual function data (Direction of Motion (DOM) and Square Localization (SL)) and OCT images (Cirrus-SD-OCT) were extracted from the Argus II Retinal Prosthesis Post Approval Study. Distances between electrode array-retina gap were measured at each electrode on the array with the Cirrus SD-OCT caliper measurement tool. Visual function tests were performed with the device OFF and ON at each visit. Data analysis was completed using IBM SPSS.

Results: 'VFQ-Social Functioning' score showed a statistically significant increase from M0 to M24 (paired t-test, $p < 0.05$). Spearman's correlation tests showed a strong positive association between direction of motion (DOM) and 'VFQ-Dependency' from M12 to M24 ($r_s = 0.745$, $p < 0.05$). There was additionally a strong negative association between square localization (SL) and 'VFQ-Ocular Pain' from M12 to M24 ($r_s = -0.701$, $p < 0.05$). Finally, a strong, positive association between electrode array-retinal gap distance and 'VFQ-Dependency' was found ($r_s = 0.778$, $p < 0.05$).

Conclusions: This study demonstrates that results on portions of the visual function questionnaire for the Argus II Retinal Prosthesis patients were significantly predicted by visual function outcomes. The VFQ thus can serve as a bridge between the patient's satisfaction with the implant and the clinical data in the form of square localization and direction of motion test accuracy. It is also essential to fully consider the VFQ results when assessing patients postoperatively, and can be helpful when used in long-term management.

ABSTRACT BODY:

Purpose: Eye drop compliance is five times worse in patients with impaired vision than normal vision despite the availability of current visual aids, such as colored bottle caps. The aim of the study is to test a novel 3D tactile label on the neck of the bottle, intended to increase accurate identification of medication and facilitate improved treatment compliance in low vision patients.

Methods: A 3D tactile bottle adaptor was designed in red, blue, green, and yellow color. Each adapter has a square or sphere shape on protruding spikes that varies in number of protrusions, 1, 2, or 3. In phase 1 clinical trial 20 healthy adults (ages 18 – 100 years) were enrolled and asked to wear a low vision simulator. Fogged goggles were used to simulate 20/200 or worse visual acuity, binocularly. Each subject was randomized to a preset group of six combinations of varying colors, protrusions, and shapes. The subjects were asked to identify the characteristics of the tactile devices in three presentations. The evaluations included color, number of protrusions, and shape at the end of the protrusions. Responses and the time to identify each characteristic were recorded.

Results: Accuracy of color identification was 100%, with an average time of 2.13 ± 1.03 seconds to identify. All subjects correctly identified the number protrusions when of one or two protrusions were presented (100%). The mean time taken was 3.13 ± 2.63 and 3.93 ± 4.48 seconds, respectively. Ninety-five per cent of the subjects identified 3 protrusions correctly with an average time taken of 4.53 ± 6.06 seconds. The identification success for square and sphere end pieces were 91.67% and 73.33%, with average time for identification of 9.87 ± 7.56 and 10.87 ± 8.96 seconds, respectively.

Conclusions: The novel 3D tactile adaptor on medication bottles was identified with great accuracy and speed by our low vision simulated subjects. Particularly, the color and number of protrusions were identified with the most accuracy. Although, patients more easily identified the square shaped end piece when compared to spheres, both were still identified relatively accurately and quickly. This data provides the basis for the phase II trial, in which patients with low vision will be tested for accurate medication identification.

TITLE: A computational approach to deriving the empirical frequency-of-seeing curves in patients with glaucoma

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Murotani, Kahoku Eye Clinic, Kahoku, Ishikawa, JAPAN|

Commercial Relationships Disclosure (Abstract): Eiji Murotani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To derive the empirical frequency-of-seeing (FOS) curves in patients with glaucoma from longitudinal visual field data using a probabilistic modeling.

Methods: Series of 15 visual fields were taken from 130 glaucoma patients in the Rotterdam Eye Study (in the public domain). Smooth regression was used to prepare test-retest data for a hypothetical glaucoma patient. The author modeled the test-retest data as a multinomial distribution generated from a biased die with 42-faces (<0 , 0, 1, ..., 40dB). FOS curves, defined as cumulative gaussian function, were incorporated into the bias, based on the possible response sequences at four primary points ($\pm 9^\circ$, $\pm 9^\circ$) during the Humphrey Full Threshold testing. The parameters of FOS curves (luminance of inflection point, slope, and asymptotic maximum response probability) were estimated by a computer program written in the probabilistic programming language stan.

Results: FOS curves corresponding to each sensitivity from 0 to 35dB were successfully derived. As glaucoma progresses, the asymptotic maximum response probability declined monotonically from 99% (35dB) to 14% (0dB). In contrast, the horizontal shift of inflection point stopped spontaneously when the luminance reached approximately 19dB. Consequently, the psychophysical threshold for luminance increment was not changed substantially in moderate to severe stages (Fig. 1).

Conclusions: These results show that visual dysfunction in glaucoma patients is distinctly different from previously proposed. Interestingly, the luminance increment threshold appears to be inherently limited.

Sadek: Commercial Relationship: Code N (No Commercial Relationship) | Paul Langer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The impact of geography on survival rates in patients with conjunctival melanoma (CM) is unknown. Using a population-based study, we analyzed socioeconomic differences and survival outcomes in CM patients based on region of residence in the U.S.

Methods: Data on CM patients were extracted from the Surveillance, Epidemiology, and End Results U.S. database from 1975 to 2016. Patients were stratified based on geography depending on whether they resided in the Eastern, Western, or Southern U.S. Contingency table analyses followed by a post-hoc test were used to compare demographic and socioeconomic factors among CM patients. Cancer-specific relative survival (RS) and overall survival (OS) analyses were performed using the Kaplan-Meier method.

Results: A total of 664 patients were identified from the West (68.2%), the East (16.4%), and the South (15.4%). The proportion of patients presenting with a localized disease stage was comparable among all regions: 76.3% (West), 75% (East), 76.1% (South) [$p>0.05$]. The South had the largest proportion of patients who were black (4%) compared to the West (1.5%) and the East (0%) [$p<0.001$]. Mean patient income levels were significantly different across all regions: South (\$44,130), East (\$73,880), West (\$66,970) [$p<0.0001$]. The proportion of patients residing in metropolitan areas was similar in the East (94.5%) and the West (93.1%) but was statistically lowest in the South (62.7%) [$p<0.0001$]. The South had the greatest proportion of patients who were uninsured (8.5%) compared to the West (4.7%) and the East (0%) [$p<0.001$]. Five-year RS significantly differed based on region [East, 88.3%; West, 88.9%; South, 80.8%; $p=0.04$], so did the five-year OS [East, 78.4%; West, 81%; South, 70.1%; $p=0.03$].

Conclusions: The South had the greatest proportion of CM patients who were black, uninsured, had the lowest mean income level, and resided in non-metropolitan areas. Although disease stage profiles were similar among all three regions, both RS and OS were lowest for patients in the South. Clinicians should be cognizant of these geographic and socioeconomic trends while managing patients with CM.

ABSTRACT BODY:

Purpose: Hyperopia is the most common vision diagnosis in children. However, there are no evidence-based prescribing guidelines for managing hyperopia. The purpose of this study was to survey pediatric eye care providers to identify current patterns of prescribing for bilateral hyperopia when considering magnitude of hyperopia as well as other factors.

Methods: Pediatric eye care providers who were members of professional organizations or listservs were invited via email to participate in a Qualtrics survey study of current pediatric spectacle prescribing practices. Participants answered questions on "What factors influence whether or not you prescribe for bilateral hyperopia" and "At what level of bilateral hyperopia would you typically prescribe correction for a child with age-normal distance visual acuity (VA) and near visual function, and no strabismus (manifest deviation) or symptoms (select the lowest level in spherical equivalent [SE])". The distribution of responses given by ophthalmologists and optometrists was compared using Kolmogorov-Smirnov CDF test (after excluding "would not prescribe" responses).

Results: As shown in Table 1, eye care providers reported that symptoms, presence of astigmatism and/or anisometropia, reading problems, and accommodative function were most commonly considered when prescribing for hyperopia; cost and possibility of teasing by peers were least commonly considered. When considering factors for prescribing glasses for hyperopia, ophthalmologists and optometrists differed significantly for every factor except symptoms and possibility of teasing. Among factors showing the greatest differences were stereoacuity, emmetropization, and near visual acuity, where optometrists were more likely to consider these factors than ophthalmologists (Table 1). The level of hyperopia at which more than 50% of all eye care providers reported prescribing decreased with patient age from +5D at age 6 to <11 months (54.9%) to +4.5D for 1 to <2 years (53.9%) to +4D for 2 to <4 years (65.5%) to +3D for 4 to <7 years (51.1%) and for ≥7 years (59.2%). The distribution between ophthalmologists' and optometrists' responses was significantly different ($p < 0.0001$).

Conclusions: Disagreement remains among eye care providers in prescribing for children with low and moderate hyperopia.

ABSTRACT BODY:

Purpose: Despite the appeal of retinal photography in facilitating retinal screening including incentives through Medicare Benefits Schedule (MBS) items (12325 and 12326), comprehensive diabetic retinopathy (DR) screening has not been achieved in Australia. This study aimed to identify the incentives and barriers to conducting DR screening in general practices.

Methods: A qualitative study, involving in-depth interviews, was conducted between November 2019 and March 2020. Fifteen general practitioners (GPs) from urban and rural practices in Australia were recruited. Data were collected using a semi-structured interview guide. All interviews were conducted over the phone, and each interview lasted up to 45 minutes. Recorded data were transcribed verbatim. The thematic analysis was carried out using NVivo to organise data and classify recurrent themes.

Results: Thirteen male and two female GPs aged 54.7 ± 15.5 years completed the interviews. Seven participants were practising in urban areas, while eight were practising in rural areas. All participants had access to a direct ophthalmoscope, but none owned retinal cameras. None of the participants performed DR screening in their general practices. Only three participants were aware of the MBS items that allow GPs to bill for retinal photography and image reporting. Seven themes (a combination of incentives and barriers) emerged, namely (i) GPs awareness of MBS items; (ii) optometrists are perceived as ideal for DR screening; (iii) GPs are not competent in DR detection; (iv) costs; (v) time constraints; (vi) the need for dedicated staff to take the responsibility of DR screening; (vii) the use of artificial intelligence in DR detection.

Conclusions: The study identified specific strategies to enable the wider implementation of DR screening in general practice, notably investing in a nationwide awareness campaign to maximise the use of MBS items, improve GPs' competency in DR detection, subsidising equipment costs, particularly for small or rural practices, and the need for a champion ace to integrate DR screening into practice workflow. Findings can guide the current clinical guidelines and policymakers to develop a better framework of key enablers that underpin the successful implementation of DR screening. Future research is needed to identify other barriers from the patients' perspectives.

ABSTRACT BODY:

Purpose: Diabetic macular oedema (DMO) is a common cause of vision loss in the working-age population. Ozurdex is used as a first or second line treatment for DMO. The functional and structural outcomes of treatment have been reported, however its relative efficacy after anti-VEGFs have failed is yet to be determined. The purpose of our study is to present real-life data of functional and structural outcomes in patients with DMO treated with Ozurdex first line as compared to Anti-VEGF non-responders at 3 months after first Ozurdex injection.

Methods: Retrospective analysis for all patients with DMO treated with Ozurdex implant between January 2016 to October 2019, at Sunderland Eye Infirmary, UK. The full cohort was subclassified to treatment-naive eyes and anti-VEGF non-responders' eyes. The primary outcome measures were observed at 3 months post implant for the 2 groups, and included mean changes in best-corrected visual acuity (BCVA) and central macular thickness (CMT) from baseline. Secondary outcomes included proportions of patients with ≥ 10 letters gain or loss; $\geq 20\%$ of CMT gain or loss and final BCVA and CMT. Baseline characteristics of both treatment-naive eyes and Anti-VEGF non-responders were compared including age, sex, diabetes duration, DMO duration, comorbidities, baseline vision and CMT.

Results: We included 89 eyes (74 patients), with 30 treatment naïve eyes and 59 anti-VEGF non-responders. The improvement in VA in the first group was 5.7 and 5.3 letters in the second group ($p=0.85$), with the final VA of 63.9 and 58.2 letters, respectively ($p=0.13$). CMT decreased in the naïve and previous anti-VEGF groups at three months ($-83.21\mu\text{M}$ vs $-88.47\mu\text{M}$, respectively; $p=0.85$). In the treatment naïve versus previous anti-VEGF groups, we found ≥ 10 letters gain was experienced in 26.67% and 20.69% ($p=0.82$), ≥ 10 letters loss in 3.33% and 5.17% ($p=0.82$), and $\geq 20\%$ of CMT reduction in 48.28% and 44.07% ($p=0.82$), respectively.

Conclusions: Our study shows no statistically significant difference in functional or structural outcomes between treatment-naïve and previous anti-VEGF groups at three months. These results confirm that the short-term efficacy of Ozurdex implant is comparable both as a first or second line of treatment in patients with DMO.

ABSTRACT BODY:

Purpose: To report the effect of anti-interleukin-6 (IL-6) receptor monoclonal antibodies tocilizumab and sarilumab eyes with non-paraneoplastic autoimmune retinopathy (npAIR) with cystoid macular edema (CME)

Methods: Retrospective case series including 14 eyes of 8 patients with npAIR and CME treated with anti-IL-6 medications. Visual acuity (VA) and central subfield thickness (CST), total macular volume (TMV), and ellipsoid zone integrity change as measured optical coherence tomography were extracted from charts prior to and at 3, 6, 12, 18, and 24 months after anti-IL-6 therapy was initiated. Eyes that had a >20% reduction in CST were defined as treatment responders, >20% increase in CST as failures, and ≤20% change in CST as stable.

Results: Eleven eyes of six patients had failed multiple prior immunosuppressive therapies. There was a significant reduction ($P<.05$) in CST baseline ($473.1\text{ }\mu\text{m}$) after initiation of anti-IL-6 therapy that began at 3 months ($389.2\text{ }\mu\text{m}$) and continued through 24 months ($348.7\text{ }\mu\text{m}$). Similarly, there was a significant reduction ($P<.05$) in TMV baseline ($10.15\text{ }\mu\text{m}^3$) after initiation of anti-IL-6 therapy that began at 3 months ($8.91\text{ }\mu\text{m}^3$) and continued through 24 months ($7.67\text{ }\mu\text{m}^3$). VA improved from 0.84 to 0.52 at 24-month follow-up, a change that did not reach statistical significance ($P=.157$). Nine of 14 eyes (64.3%) were treatment responders, 4 eyes (28.6%) were stable, and 1 eye (7.1%) was a treatment failure. See Table 1 for full results. Prior to starting anti-IL-6 therapy, 9 of 14 eyes (64.3 %) of eyes had EZ integrity loss which was evident on macular OCT with an average loss of $30.0\text{ }\mu\text{m}$ per month. After starting IL-6 therapy, there was a significant decrease in rate of EZ change, experiencing an average restoration of $22.7\text{ }\mu\text{m}$ per month ($P=.008$). It was possible to discontinue rituximab in all 4 patients who were on this therapy for AIR, and at least one eye of all patients responded to anti-IL-6 treatment. No patient had adverse events or required discontinuation of therapy while on anti-IL-6 medication.

Conclusions: In this cohort of patients with npAIR and CME, treatment with anti-IL-6 medications tocilizumab and sarilumab, was associated with reduced CME, partial restoration of the ellipsoid zone, and a trend towards improved VA, while reducing burden of prior immunosuppressive therapies.

ABSTRACT BODY:

Purpose: Corticoids bind to glucocorticoid (GR) and mineralocorticoid receptor (MR), both expressed in the RPE but the transcriptional regulations induced by corticoids have not been fully explored.

The purposes are: - to analyzed corticoids-induced transcriptional regulations in human RPE derived from iPS (iRPE), - to measure corticoids in human ocular media, - to analyze the retinal phenotype of P1hMR mice that over express human MR.

Methods: GR and MR expression was analyzed in iRPE cells and corticoid-induced nuclear translocation was quantified. Corticoids were measured in human ocular media using a liquid chromatography-tandem mass spectrometry. iRPE cells were exposed to aldosterone, the MR-specific agonist, cortisol and cortisol + RU-486, a direct GR antagonist . Transcriptomic analysis identified genes differentially regulated at 24 hrs after stimulations. Validation was performed by RT-PCR, western-blot and immunohistochemistry. In order to evaluate the biological consequence of MR overactivation in the retina, the retinal phenotyping of mice overexpressing the human MR (P1hMR) was analyzed.

Results: iRPE cells stably express functional MR and GR. They do not produce or metabolize corticoids. In human aqueous humor and vitreous, cortisol and cortisone were measured at salivary levels but aldosterone was detected, suggesting that cortisol activates GR and MR in RPE cells. Genes regulated similarly by aldosterone and by cortisol + RU-486 represent MR activated genes. They encodes proteins involved in extracellular matrix remodeling, epithelia-mesenchymal transition (EMT) and RPE cell migration (Itgb3, Plaur and Fosl1), immune balance (Tnfsf18, Ptrx3), and in RPE phagocytosis (Mrp3, Gfra2, Ptrx3). Down-regulated genes (Cnn1, Mgp, Amtn) encodes proteins involved in extracellular matrix remodeling and choroid innervation.

P1hMR mouse showed choroidal vasodilation, elongation of photoreceptors outer segments, focal alteration of the RPE/ choroid interface, migration of RPE cells and focal choroidal excavations, mimicking human pachychoroid phenotype

Conclusions: The human RPE is a mineralo-sensitive epithelium. Activation of MR pathway in the RPE induces the regulation of genes involved in RPE differentiation, immune regulation, synaptic transmission and angiogenesis, and extracellular matrix remodeling. P1hMR mouse confirmed the pathogenic role of MR overactivation and its possible link with pachychoroid epitheliopathy.

TITLE: The impact of weather and seasons on falls and physical activity among older adults with glaucoma: a prospective cohort study

SESSION TITLE: Visual Impairment and Quality of Life

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Vongsachang, A. Mihailovic, P.Y. Ramulu, Wilmer Eye Institute, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|J. E, Johns Hopkins University Bloomberg School of Public Health, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hursuong Vongsachang: Commercial Relationship: Code N (No Commercial Relationship) | Aleksandra Mihailovic: Commercial Relationship: Code N (No Commercial Relationship) | Jian-Yu E: Commercial Relationship: Code N (No Commercial Relationship) | Pradeep Ramulu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Identifying environmental risk factors is important to prevent falls in elderly with visual impairment. We examined the relationship between weather and seasons on falls and physical activity in a prospective cohort of older patients with visual field (VF) loss.

Methods: Older patients with glaucoma were recruited from the Wilmer Eye Institute to participate in a three-year longitudinal study. Monocular VF results were combined to generate integrated VF sensitivity for each patient. Participants recorded the occurrences of falls and injurious falls using a monthly calendar over the three-year period. Steps and active minutes were recorded for 7 days consecutively at baseline and in each study year using an accelerometer. Average daily temperature and precipitation data were merged with corresponding study dates (National Centers for Environmental Information). Study dates were assigned to Northern Hemisphere astronomical seasons. Using multivariable logistic and negative binomial regression models incorporating generalized estimating equations, we analyzed the association between weather/season with 1) the odds of falling and having an injurious fall and 2) average daily steps and active minutes.

Results: Across 240 participants (Table 1), there were 406 falls recorded over 7569 person-months, of which 163 were injurious (40%). The odds of falling did not vary with temperature, precipitation, or seasons. However, every ten-degree Celsius increase in average daily temperature was associated with 24% higher odds of having an injurious fall, as opposed to non-injurious (OR=1.24, 95% CI [1.01, 1.53], p=0.04). Injuries resulting from a fall were more likely to occur outdoors, as opposed to indoors, with higher average temperatures (OR per 10 degrees C=1.46, 95% CI [1.03, 2.07], p=0.03) and summer season (OR=2.69 vs winter, 95% CI [1.12, 6.50], p=0.03). Temperature, precipitation, and seasons were not significantly associated with average daily steps or activity (Table 2).

Conclusions: Although overall falls and physical activity did not vary with weather or seasons, warmer weather may be linked with conditions that lead to injurious falls among older individuals with visual impairment. Falls should be understood as a year-round problem in the visually impaired, though the likelihood of injury and the location of fall-related injuries may change with season/temperature.

ABSTRACT BODY:

Purpose: Adaptive optics (AO) is a retinal imaging technique with potential to characterize the photoreceptor mosaic and improve current diagnostics. However, variability in acquisition protocols, instrumentation, and image quality require studies to measure and interpret pathology in AO images. This work analyzes cone density (CD) measurements in a clinical setting between healthy controls (HC) and retinitis pigmentosa (RP) patients.

Methods: AO images were acquired using the rtx1 flood-illuminated AO camera (Imagine Eyes, Orsay, France) from the right eyes of 10 RP patients and 3 HC. All subjects had five 4°x4° images acquired centered at the following locations relative to the fovea: (0°,0°), (2T°,0°), (2N°,0°), (0°,+2°), and (0°,-2°). Intrasession repeatability of CD measures was investigated using three images in four overlapping 2°x2° quadrants. Automation facilitated counting of ~190 densely sampled regions of interest using AOdetect per 4°x4° image. Comparisons of CD were made between healthy eyes and eyes with different severities of RP as determined by 24-2 Humphrey visual field mean deviations.

Results: HC had statistically higher CDs (mean 21275 ± 2890 cones/mm²) across the sampled region when compared to all RP patients (mean 12903 ± 3001 cones/ mm², p = <.0001).

There was a significant decrease in CD in all severities of RP compared to HC. Within the RP patients, the CD of severe RP patients (mean 7357 ± 1703 cones/mm²) was significantly decreased compared to mild and moderate RP patients. Within a single image of a patient, there was no statistically significant difference between CD within a 1° radius versus a 3° radius from the fovea.

Within each patient population, there was no statistically significant difference in repeated CD measurements in overlapping 2°x2° quadrants. HC showed fair intrasession repeatability (mean 21348 ± 1998 cones/ mm²), while RP patients showed good to excellent intrasession repeatability (mean 13269 ± 1146 cones/ mm²).

Conclusions: CD measurements in AO images acquired in a clinical setting reveal gradual changes that correlate with the disease severity of RP. The measured variability of the cone counting algorithms was not a substantial contributor to the changes measured due to disease. Quantitative measurements from AO imaging could help effectively measure and interpret the changes due to RP.

ABSTRACT BODY:

Purpose: To study the effects of intravitreal injection (IVI) on intraocular pressure (IOP) and to predict the patient population which may be most susceptible to acute elevations in IOP.

Methods: A three-month, prospective study of patients receiving IVI of anti-VEGF at the Acuity Eye Group. IOP was measured pre-injection as well as post-injection at 10-minute intervals up to 50 minutes. Patients with an IOP greater than 35mmHg at 30 minutes received an ACP. Patients with an IOP below 35mmHg were monitored without intervention.

Results: 617 patients were included, with a mean age of 73 years. Patients received IVI for diabetic retinopathy (n = 199), age-related macular degeneration (n= 355), and retinal vein occlusion (n = 63). Average pre-injection IOP was 16 +/-5 mmHg. Average post-injection IOP was 25, 27, 28, 27, and 29 mmHg at 10, 20, 30, 40, and 50 minutes respectively (P<.0001). The ACP group (n=17) had a pre-injection average IOP of 24 +/- 7 mmHg (p<.0001), and post-injection IOP of 47 +/- 10 and 44 +/- 9 mmHg at 10 and 20 minutes respectively (p<.0001). Overall, 33% of patients with a pre-injection IOP > 25 mmHg and 50% with a pre-injection IOP > 30 mmHg required ACP. A diagnosis of glaucoma was higher in the ACP group compared to the non-ACP, 82.3% vs 14.2% (p<0.0001), and a diagnosis of glaucoma suspect was also higher in the ACP group vs non-ACP, 17.6% vs 9.0 respectively (p>0.05). Patients with a pre-injection IOP > 25 mmHg and a history of glaucoma had a 58.3% rate of ACP. The number of IVI were similar between the ACP and non-ACP group at 22 +/- 10 vs 19 +/- 11 injections, respectively. A 31-gauge needle had a higher incidence of ACP when pre-injection IOP > 25 versus 30-gauge, 42.9% vs 29.4% respectively (p>0.05).

Conclusions: IVI of anti-VEGF medication is associated with a transient but significant increase in IOP. Patients with a pre-injection IOP of 25mmHg or greater, combined with a history of glaucoma, may be at a higher risk of prolonged IOP increases and may benefit from prophylactic ACP.

ABSTRACT BODY:

Purpose: Though chronic intraocular pressure (IOP) elevation and glymphatic disturbances have been implicated in various optic neuropathies, the relation between IOP and optic nerve (ON) cerebrospinal fluid (CSF) dynamics has not been sufficiently investigated. We employed contrast-enhanced MRI (CE-MRI) for in vivo investigation of CSF dynamics in the ON with and without chronic IOP elevation.

Methods: IOP was elevated unilaterally in adult C57BL/6J mice (n=15, Group 1) by intracameral injection of in situ cross-linking hydrogel. Chronic IOP elevation in the injected eye (Group 1a) was confirmed at 4 weeks post-injection, at 19.37 ± 3.41 mmHg (mean \pm SEM) relative to the fellow, untreated eye (Group 1b) at 11.39 ± 3.74 mmHg. Another 20 healthy naive mice received no intervention to either eye (Group 2). A polyethylene tubing was inserted intrathecally at the lumbar region (L4-L5) followed by CE-MRI using a 7-Tesla Bruker BioSpec scanner. Contrast dynamics was monitored using 3D T1-weighted FLASH sequence with an isotropic resolution of $78 \times 78 \times 78 \mu\text{m}^3$. Twelve 10-min continuous scans were acquired, beginning with 3 baseline acquisitions followed by 30 min of Gd-DTPA contrast infusion while the scanning continued till the 12 timepoint. Change in contrast intensity (CI) over time was quantified in 6 anatomical regions of interest (ROIs) viz. posterior ON subarachnoid space (ONSAS-P), anterior ON SAS (ONSAS-A), posterior ON parenchyma (ONP-P), anterior ON parenchyma (ONP-A), olfactory bulb (OB, positive control), and muscle tissue (MT, negative control).

Results: Between group ANOVAs were significant for each ROI in the ON (all p's<.001), and not significant for control regions. Post-hocs revealed that for ONSAS-A, Group 1a had lower CI than Group 1b (p<.001) and Group 2 (p<.001), while Groups 1b and 2 also differed (p=.011). For ONP-A, Group 1a had lower CI than Group 1b (p=.003) and Group 2 (p<.001), with no difference between Groups 1b and 2. For ONSAS-P, Groups 1b and 2 CI differed significantly (p=.011), and for ONP-P, Group 1a had lower CI than Group 1b (p<.001) and Group 2 (p=.003), while Groups 1b and 2 CI also differed (p=.004).

Conclusions: Chronic IOP elevation is associated with significant decrease in the CSF flow into the ON SAS and ON parenchyma. CSF dynamics is also altered in the contralateral ON projected from the fellow eye with normal IOP.

ABSTRACT BODY:

Purpose: Recent research using experimental animal models has suggested that montelukast, a leukotriene receptor antagonist, may play a role in preventing diabetic retinopathy (DR). However, few studies have investigated its potential efficacy in humans. This case-control study was conducted to investigate whether use of oral montelukast was associated with decreased odds of DR in patients with diabetes mellitus.

Methods: Medical records of subjects presenting to a tertiary eye center between November 1, 2019 and November 1, 2020 were collected using the Institutional Cohort Finder tool and analyzed. ICD codes were used to identify patients with diabetes mellitus (E08-E13) and DR (E08.31-35/E11.31-35). Control patients (with diabetes mellitus but without DR) who presented to our center during a similar time period were used to calculate crude and adjusted odds ratios for oral montelukast. Only subjects with no missing data were analyzed in this study. Using available clinical records, patients were also assessed for the presence of DR risk factors, including elevated hemoglobin (Hb)A1c levels, smoking history, end-organ damage (i.e. diabetic nephropathy and neuropathy), hypertension, hyperlipidemia, and non-Caucasian race.

Results: A total of 563 patients with DR were evaluated at our center during the study period. In our study, 14 of the 210 (6.6%) patients were identified to have used oral montelukast prior to the diagnosis of DR, compared to 60 of 353 controls (16.9%) (univariable OR: 0.38, 95% CI: 0.21-0.68, P = 0.0012). In the multivariate logistic regression analysis, use of oral montelukast was significantly associated with decreased odds of DR (adjusted OR: 0.32, 95% CI: 0.16-0.62, P = 0.0009), as well as identification as a "never smoker" (adjusted OR: 0.49, 95% CI: 0.30-0.79, P = 0.004). Several risk factors were significantly associated with increased odds of DR, including hypertension (adjusted OR: 5.81, 95% CI: 3.62-9.33, P < 0.0001), hyperlipidemia (adjusted OR: 5.51, 95% CI: 3.39-8.95, P < 0.0001), and higher HbA1c (OR 1.35, 95% CI: 1.21-1.51, P < 0.0001).

Conclusions: Use of oral montelukast is associated with decreased odds of DR in patients with diabetes mellitus; subjects with DR are less likely to have consumed oral montelukast. Given the role of chronic inflammation in the pathophysiology of DR, these protective benefits may be related to montelukast's anti-inflammatory properties.

ABSTRACT BODY:

Purpose: Intravitreal implants are routinely used for depots of sustained drug delivery. Injections of current market devices have been reported to cause retinal hemorrhages and macular holes from direct mechanical forces during injection. We provide kinematic analysis in simulated vitreous and saline to confine the range of safe injection velocities from novel intravitreal implant delivery devices.

Methods: 10 proprietary Aerie Pharmaceutical intravitreal delivery systems were recorded at 240 frames-per-second at 1024×1024 pixel resolution. 396µg implants of dimensions 265 x 265 x 4500µm were injected with fast and slow velocities into an open top chamber at room temperature and pressure. 4 implants were launched with slow velocity into normal saline. 4 implants were launched with high velocity into vitreous substitute - hyaluronic acid 1%. 2 implants were launched with high velocity into saline. Empiric initial velocity coming out of the injector barrel (v_o) was derived by launching implants straight vertically into air and assumed negligible air resistance. Adult eye retina to retina diameter is assumed to be between 19.4mm to 25.8mm (22.9mm average).

Results: Injection velocity (v_o) was 3431 ± 50 mm/s for fast injections. The 4 slow velocity injections delivered the implants exactly at the site of injection in both media. In hyaluronic acid, fast injections delivered implants to a maximum displacement (x_{max}) of 16.7 ± 3.2 mm in 25 ± 5 ms. In saline, fast injections delivered implants to x_{max} of 28.5 ± 5 mm in 50ms.

Conclusions: Slow speed injections would likely be best used for local implant placement (at site of injection) in any medium. V_o of 3431 mm/s is approximately the upper limit of injection velocity for these implants in non-vitrectomized eyes as the x_{max} range encompasses maximum retina-to-retina distance, however could be further optimized to account for injection angles that direct toward shorter paths. Smaller v_o should be used for vitrectomized eyes as modeled by saline. Empiric drag coefficients for these implants would help calculate force transmitted to the retina upon contact.

TITLE: Modified-dropless protocol (nil intraocular) for Micro-incision Vitrectomy Surgery (MIVS)

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Garcia-O'Farrill, G.T. Brown, A.A. Hunter, Oregon Eye Consultants, LLC, Eugene, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Noraliz Garcia-O'Farrill: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Brown: Commercial Relationship: Code N (No Commercial Relationship) | Allan Hunter: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Prophylactic topical eye drops to be instilled by the patient after undergoing vitreoretinal surgery can be inconvenient and expensive. We performed a retrospective clinical study to evaluate the outcomes of a novel, modified-dropless protocol for 25-gauge and 27-gauge (27G) micro-incision vitrectomy surgery (MIVS) that omits any intraocular injections of antibiotics or steroids.

Methods: The Institutional Review Board approved a database review of all patients with any surgical indication for MIVS that underwent the modified-dropless protocol performed by a single surgeon at Oregon Eye Consultants, LLC. Eighty-nine patients who had surgery between February to November 2020 were eligible from 108 total surgeries. Only patients who underwent a surgical peritomy were not candidates for the modified-dropless protocol. Instead of pre- or post-operative drops, at the time of surgery patients were given a 0.5cc subconjunctival injection of a 1:1 Cefazolin (50mg/cc):Dexamethasone (10mg/cc) in the inferior fornix and 0.5cc of posterior Sub-Tenon's Kenalog (STK). No intravitreal injections were administered. Fourteen patients who had a penicillin allergy were instead given separate subconjunctival injections of 0.25cc each of Vancomycin (10mg/cc) and Dexamethasone. Mean follow up was 69 days.

The primary endpoint was postoperative cases of endophthalmitis within 3 months. Secondary endpoints consisted of Best-Corrected Distance Visual Acuity (BCVA), intraocular pressure (IOP), and postoperative complications (retinal detachments, inflammation, need for additional surgery) within 3 months of surgery.

Results: The study comprised 89 eyes from 46 females and 43 males (mean age 69.9±9.7; range 37-93 years). Pre-operatively there were 41 phakic and 48 pseudophakic eyes. All surgeries were performed with the 27G MIVS platform.

There were no cases of postoperative endophthalmitis. Mean logMAR BCVA improved from 0.65±0.64 to 0.54±0.58 postoperatively (p=0.03). Excluding patients who had silicone oil tamponade, postoperative BCVA improved from 0.58±0.60 to 0.46±0.50 (p=0.01). Mean IOP increased from 14.3±3.7 to 15.1±4.1 postoperatively (p=0.12).

Conclusions: A modified-dropless postoperative protocol involving subconjunctival and posterior sub-Tenon's injections only may be a safe and convenient alternative to topical eye drops for patients undergoing MIVS but additional and larger studies are needed.

ABSTRACT BODY:

Purpose: Test the hypothesis that macular ganglion cell layer (GCL) measurements are able to detect early damage better than ganglion cell/inner plexiform layer (GC IPL) thickness.

Methods: First cohort included 84 glaucoma eyes with visual field (VF) mean deviation (MD) ≥ -6 dB and 129 normal eyes. 8x8 GCL and GC IPL macular grids were exported and 5 superior and inferior macular sectors were defined (Figure 1). Areas-under-ROC curves (AUC) for sectoral GCL and GC IPL measures were compared.

A second cohort of 98 glaucoma and 48 normal/glaucoma suspect (GS) eyes with GMPE macular scans had GCL/GCIPL deviation maps analyzed. Proportion of areas with abnormal ($<5\%/1\%$ cutoffs) and supernormal thickness ($>95\%/99\%$ ile cutoff) was estimated on deviation maps (Figure 2). Differences in extent of abnormal and supernormal regions were compared in glaucoma and normal/GS subjects.

Results: In the first cohort, average VF MD was -3.0 ± 1.8 dB in glaucoma eyes. Inferior sector 2 thickness performed best for detection of glaucoma with both GCL and GC IPL (AUCs=0.895; $p>0.05$). VF MD was -2.3 ± 1.7 dB in glaucoma eyes in the second cohort. In the central elliptical area, extent of GCL damage at $<5\%$ and 1% cutoffs was $27.4\% \pm 26.0\%$ and $15.2\% \pm 20.6\%$ vs. $26.7\% \pm 26.4\%$ and $14.6\% \pm 20.6\%$ for GC IPL, respectively, in glaucoma eyes ($p=0.01$ and $=0.02$, Figure 2a); the extent of GCL and GC IPL supernormal regions were similar ($p=0.87$). In normal eyes, extent of GCL abnormality at 5% and 1% cutoffs were $16.0\% \pm 18.9\%$ and $5.9\% \pm 10.7\%$ vs. $15.0\% \pm 18.4\%$ and $5.3\% \pm 10.5\%$ for GC IPL ($p=0.07$ and $=0.01$); GCL and GC IPL supernormal areas were similar ($p=0.93$). Results for the entire scan area were similar (Figure 2b). Extent of abnormality at $<1\%$ cutoff best predicted glaucoma (AUC=0.730 vs. 0.700 for GCL vs. GC IPL).

Conclusions: Macular GCL deviation maps are more likely than GC IPL to flag abnormality with acceptable specificity; however, the difference is clinically unremarkable. GCL and GC IPL sectoral thickness are equivalent for detection of glaucoma.

ABSTRACT BODY:

Purpose: This study investigated changes in higher-order wavefront aberrations (HOA) in eyes wearing Proclear multifocal soft contact lenses with two different add powers in the context of myopia management.

Methods: Using the Pathfinder II module of a Zeiss Atlas corneal topographer, HOA, up to the 6th Zernike order, were measured with and without Proclear multifocal D soft contact lenses for 6 mm pupil diameters in the right eyes of 40 subjects. Contact lenses with add powers of +1.50 D and +2.50 D were evaluated. Root-mean-square (RMS) values of combined HOA, as well as individual spherical-like (Z4,0 and Z6,0) and coma-like (Z3,-1, Z3,1, Z5-1 and Z5,1) HOA, were evaluated. In addition, Zernike coefficients of spherical aberration (Z4,0) were analyzed. Statistical analysis was carried out using repeated-measures ANOVA and Dunnett's multiple comparisons test.

Results: Mean RMS values of combined HOA increased by 0.09 μ m (SE 0.03) for 1.50D add power and 0.28 μ m (SE 0.03) for 2.50D add power. ($p < 0.0001$) Mean RMS values of spherical-like HOA increased by 0.11 μ m (SE 0.02) for 1.50D add power and 0.23 μ m (SE 0.02) for 2.50D add power. ($p < 0.0001$) Mean RMS values of coma-like HOA decreased by 0.01 μ m (SE 0.02) for 1.50D add power and increased by 0.13 μ m (SE 0.03) for 2.50D add power. ($p < 0.0001$) Mean spherical aberration coefficients were 0.26 μ m (SE 0.02) without contact lenses and further increased by 0.11 μ m (SE 0.02) for 1.50D add power and 0.22 μ m (SE 0.02) for 2.50D add power ($p < 0.0001$).

Conclusions: Proclear multifocal D contact lenses increase higher-order aberrations of the eye, especially spherical-like and coma-like aberrations. The effects are greater the higher the contact lens add power. Several studies reported significant negative associations between the RMS of total HOAs and axial eye growth and suggested that increased HOAs acted as an inhibitory signal for axial elongation and myopia progression. Especially the impact of spherical aberration on retinal image blur has been proposed to play a pivotal role in this process. Since Proclear multifocal D contact lenses demonstrated their efficacy in slowing myopia progression, it is possible that the increase in the aforementioned higher-order aberrations plays an important role in this process.

TITLE: Morphological Variants of Meibomian Glands: Correlation of Meibography Features with Histopathology Findings

SESSION TITLE: Lacrimal gland and Meibomian gland

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Singh, S. Basu, LV Prasad Eye Institute, Hyderabad, Telangana, INDIA|

Commercial Relationships Disclosure (Abstract): Swati Singh: Commercial Relationship: Code N (No Commercial Relationship) | Sayan Basu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study describes the histopathological findings of different morphologies of human meibomian glands (MG) seen on infrared imaging.

Methods: Tarsal plates dissected from 7 cadaveric upper eyelids were imaged using infrared meibography and then studied histopathologically using hematoxylin-eosin and peroxisome proliferator-activated receptor-gamma (PPAR γ) antibody (for meibocyte differentiation) staining. The different morphological characteristics of MG (varying size and shape) on meibography were correlated with histopathology using image analysis software.

Results: Of the total 127 glands, the observed morphological variants on meibography based on size were: normal (n=62), short (n=18), severely short (n=6), and dropout (n=12) glands, and on shape were hooked (n=2), tortuous (n=5), overlapping (n=1), thick (n=15) and fluffy (n=6) glands. Short, hooked, tortuous, overlapping glands had similar histological structure as seen in normal glands whereas thick, and fluffy glands had increased acinar diameter. In normal glands, the ductal epithelium was 2-3 layers thick of nucleated non-keratinized squamous cells and more multilayered in thick and fluffy glands. The areas where acini were emptying their contents into the lumen had multilayered ductal epithelium, whereas areas with no actively secreting acini had a single cell layer ductal epithelium. The mean thickness of the periacinar acellular matrix zone in normal glands was 4.21.2 microns, whereas it was 6.70.98 microns in severely shortened glands. The glands with morphology other than severely short type demonstrated strong nuclear, and weak cytoplasmic PPAR γ expression limited to the basal acinar cells similar to normal glands, whereas severely short glands showed atrophic acini with weak cytoplasmic expression of PPAR γ . Gland dropout areas showed no evidence of any glandular tissue and had normal tarsal architecture on histology.

Conclusions: Hooked, tortuous, short glands have similar acinar histology as normal glands, whereas severely short glands show atrophic acini with decreased PPAR γ expression. A larger study is warranted to validate the findings in a clinical setting with various pathologic conditions.

ABSTRACT BODY:

Purpose: To demonstrate that ganglion cell complex is the optimal outcome for detection of structural progression regardless of glaucoma severity within a Bayesian hierarchical framework.

Methods: 8×8 superpixel arrays from longitudinal macular volume scans of 112 eyes were exported. A hierarchical Bayesian random intercept and slope (RIAS) model with random superpixel variance was fit to full macular thickness (FMT), outer retinal layers (ORL), ganglion cell complex (GCC), ganglion cell/inner plexiform layer (GCIPL), and ganglion cell layer (GCL) measurements for each superpixel. We estimated population and individual superpixel slopes and intercepts. The primary outcome measure was the proportion of significant negative (worsening) and positive (improving) slopes at superpixels defined as slopes with $p < 0.1$. We compared subgroups of superpixels with mild and severe damage based on the total deviation (TD) of corresponding 10° visual field locations ($TD > -8$ and < -8 dB, respectively).

Results: Mean (SD) follow-up time and baseline 10° visual field mean deviation were 3.6 (0.4) years and -8.7 (5.8) dB, respectively. Thicker baseline measurements were associated with faster rates. A higher proportion of negative slopes was observed for FMT (54.9%), followed by GCC (36.5%), ORL (35.6%), GCIPL (30.6%), and GCL (19.8%) (Figure 1); the proportion of significant positive rates was small and comparable among various measures (Table 1). Out of 925 superpixels detected as progressing by only FMT, 79% also demonstrated significant ORL slopes. The proportion of significant negative rates was lower in the severe group for all inner macular measures; GCC identified the highest proportion of negative slopes among inner macular measures regardless of severity.

Conclusions: GCC is the optimal macular outcome measure for detection of change across the macula at all stages of glaucoma. The higher proportion of negative slopes for FMT is substantially explained by observed rates of ORL change.

ABSTRACT BODY:

Purpose: For frail patients, even low-risk procedures increase postoperative mortality risk. In a study population comprising older adults who underwent cataract surgery, we examined associations between frailty and non-vision-related health outcomes after cataract surgery, the most common procedure among Medicare beneficiaries.

Methods: We used National Health and Aging Trends Study (2010-2014) data linked to Centers for Medicare and Medicaid Services claims. Frailty (criteria: exhaustion, low physical activity, weakness, slowness, shrinking), the predictor variable, was assessed at the visit prior to cataract surgery, and participants were classified as frail (≥ 3 criteria), prefrail (1-2 criteria) or robust (0 criteria). Multivariable models, adjusted for age, gender, race, smoking, diabetes, and number of comorbidities, were used to examine associations between frailty and hospitalization rate, emergency department (ED) visits, and hospital length of stay (LOS) over the 12-months after cataract surgery.

Results: A total of 557 participants who underwent cataract surgery during the study period (2011-2014) were included in the analysis. Participants were a mean age of 76 (SE=0.3) years, and the majority were female (58%) and white (77%), and 11% were classified as frail, 49% prefrail, and 40% robust, prior to cataract surgery. In regression analysis, the odds of hospitalization in the year following cataract surgery were greater among pre-frail (OR=1.8; 95% CI=1.0, 3.2) and frail older adults (OR=3.8; 95% CI=1.8, 8.1), as compared to robust older adults. Prefrail (OR=1.5; 95% CI=0.9, 2.4) and frail (OR=2.8; 95% CI=1.5, 5.5) older adults also had greater odds of an ED visit, as compared to robust older adults. In addition, prefrail (IRR=2.4; 95% CI: 1.1, 4.8) and frail (IRR=3.8; 95% CI=1.3, 11.1) older adults had greater LOS when hospitalized, as compared to robust older adults.

Conclusions: Prefrail and frail older adults undergoing cataract surgery were more likely to be hospitalized and have an ED visit, as well as have longer LOS in the following year, suggesting that frailty may be a risk factor for these negative outcomes following cataract surgery.

ABSTRACT BODY:

Purpose: To investigate the characteristics of first-year residents in top ranked United States (US) ophthalmology residency programs over the past decade.

Methods: Data from first-year ophthalmology residents in 2009, 2013, 2016, and 2019 was obtained from institutional websites, Doximity, and LinkedIn and the Wayback Machine. For each resident, publications were obtained from Scopus and Google Scholar, research productivity was measured using the h-index, and medical school rank and region were based on 2021 US News and World Report (US News) and US Census Bureau designations, respectively. The 20 ophthalmology residency programs ranked as 'Top 13' or 'High Performing' by the 2021 US News were labeled Tier 1; the 100 unranked as Tier 2. One-way ANOVA and χ^2 tests were used to analyze trends and odds ratios (OR) were calculated using logistic regression.

Results: Data was obtained on 81% (1496/1850) of the residents; 43% (644/1492) were female; 5% graduated from medical schools outside the US or Canada; 10% (155/1492) had other graduate degrees; 21% (317/1492) attended a top 20 medical school; and 41% (616/1496) had an h-index of one or more. Over the decade, the mean h-index increased (0.87 to 1.26; $p < 0.05$) and the proportion of residents who attended top 20-ranked medical schools decreased (28 to 18%; $p < 0.05$). Independent factors associated with being a resident in a Tier 1 program were having a master's degree [OR: 2.08, 95% CI: 1.18–3.69] or PhD [OR: 2.13, 95% CI: 1.25–3.64], attending a top 20 [OR: 8.02, 95% CI: 5.12–12.55] or top 40 [OR: 2.45, 95% CI: 1.56–3.85] school, attending a school in the Northeast [OR: 1.86, 95% CI: 1.27–2.70] or having an h-index of one or more [OR: 1.84, 95% CI: 1.40–2.41].

Conclusions: Graduate degrees, attending a highly ranked medical school or a medical school in the Northeast, and research experience were key characteristics of first-year residents in top ranked US ophthalmology residency programs.

TITLE: Application of a Digital Green Filter for Improved Visualization of Retinal Breaks on Ultra-Widefield Fundus Imaging

SESSION TITLE: Imaging of posterior segment I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.M. Wai, J. Moon, M. Dahrouj, J. Miller, Massachusetts Eye and Ear Infirmary Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Karen Wai: Commercial Relationship: Code N (No Commercial Relationship) | Jade Moon: Commercial Relationship: Code N (No Commercial Relationship) | Mohammad Dahrouj: Commercial Relationship: Code N (No Commercial Relationship) | John Miller: Commercial Relationship(s);Alcon:Code C (Consultant);Allergan:Code C (Consultant);Sunovion:Code C (Consultant);Zeiss:Code C (Consultant);Genentech:Code C (Consultant)

ABSTRACT BODY:

Purpose: Ultra-widefield fundus photos have enabled eyecare professionals to better visualize and document retinal pathology. Optos (Optos P200DTx icg, Optos, Marlborough, MA, USA) is an ultra-widefield imaging system that creates pseudocolor photos by combining red (633 nm) and green (532 nm) laser sources. We hypothesize that applying an additional digital green filter overlay relative to the traditional settings of an Optos fundus photo may better highlight retinal breaks. Green light, given its shorter wavelength, will focus on the retina more superficially at the level of retinal vessels, relative to red light, which is focused on the retinal pigment epithelium and choroid.

Methods: Seventeen ophthalmology residents from a single institution were tested. Residents were presented with fundus photos of 10 eyes from 10 patients taken on the Optos system with either a retinal tear or hole. Participants were shown each fundus photo twice in a randomized order – once with traditional color settings and once with the addition of a green filter overlay. Participants were asked to identify the retinal break. Participants were scored on whether the break was correctly identified and timed on how long it took to identify the pathology, with a maximum of 20 seconds to examine each photo.

Results: On average, residents were able to identify more breaks on fundus photos with the green filter overlay compared to the standard settings (8.6/10 vs. 6.8/10, $p<0.01$). Residents were also able to correctly identify breaks on the fundus photos more quickly on images with green filter overlay relative to standard settings (7.5 seconds vs. 9.1 seconds, $p<0.05$). On a post-test survey, fifteen residents (88.2%) felt that the green filter overlay made it easier to identify retinal breaks, while two (11.8%) could not tell a difference. Fifteen residents (88.2%) felt a green filter overlay would be a useful tool in ophthalmology clinics and for telemedicine application.

Conclusions: Fundus ultra-widefield imaging has become an essential tool in identifying and documenting retinal pathology, especially in the era of teleophthalmology. Application of a green filter overlay may help in identifying retinal breaks for eyecare providers at all levels of training.

ABSTRACT BODY:

Purpose: Hyperopically defocused retinal image is thought to provide signal for the eye to grow. Multi-zone contact lenses (CL) could potentially reduce hyperopic defocus or introduce myopic defocus. This study measured the refractive states across the pupil of subjects wearing multi-zone CL designs during on-axis and off-axis accommodation.

Methods: Five young myopic subjects aged 21 to 24 years were fit bilaterally with Comfilcon A single vision (SV), center-distance (CD) multifocal with +2D add, and center-near (CN) multifocal with +2D add CLs. While subjects accommodated binocularly to electronically displayed (iWatch) letter stimuli at 0D and -4D target vergences (TV), wavefront measurements (right eye) were acquired using a custom modified COAS-HD aberrometer along the visual axis, 30⁰ nasal and 30⁰ temporal fields. Raw wavefront slope data from each lenslet of COAS were used to develop a pupil map of axial refractive error.

Results: Mean \pm SD spherical equivalent refraction was -4.77 ± 1.77 D. As stimuli approached, the distribution of refractive states across the pupil after correcting for the TV, shifted towards hyperopia for all lenses indicating accommodative lag. With the multi-zone lenses, the distributions were wider and had more myopic defocus and less hyperopic defocus. In the fovea, the mean % increase in myopically defocused pupil area (relative to SV lens) with CD and CN lenses at 0D TV was 38% and 26%, and at -4D TV was 6% and 5%, respectively. Likewise, mean % decrease in the hyperopically defocused pupil area was 5% for both CD and CN at 0D TV, and 12% and 3%, respectively, for the -4D TV. In the nasal retina (30⁰), the mean % increase in myopically defocused pupil area with CD and CN lenses at 0D TV was 28% and 8%, and at -4D TV was 5% and 1%, respectively. Mean % decrease in the hyperopically defocused pupil area was 27% and 3% for CD and CN at 0D TV, and 17% and -4%, respectively, for the -4D TV. In the temporal retina (30⁰), the mean % increase in myopically defocused pupil area with CD and CN lenses at 0D TV was 38% and 4%, and at -4D TV was 4% and -3%, respectively. Likewise, mean % decrease in the hyperopically defocused pupil area was 27% and 10% for CD and CN at 0D TV, and 12% and -15%, respectively, for the -4D TV.

Conclusions: Comfilcon A CD lens effectively reduced the hyperopic defocus and increased the myopic defocus at the pupil plane during on-axis and off-axis accommodation.

ABSTRACT BODY:

Purpose: To describe results of the United States Army Ocular Teleconsultation program from 2004 through 2018 and the current condition, benefits, barriers, and future opportunities for teleophthalmology in the clinical settings and disease areas specific to the United States military.

Methods: 653 ocular teleconsultations were reviewed; 76 concerned general policy questions and were not further analyzed while 577 were examined in more depth. The main outcome measures included diagnostic category, evacuation recommendation status by the consultant, the association of the request with trauma, the presence of photographs or advanced imaging, and which specialties participated in answering a request. The secondary outcome measures included the month and year each consult was requested, the average and median response time of consultants annually, the country from which the request originated, the military status and branch of service of each military patient, and the nationality, age, and military status of foreign patients.

Results: The average response time in 2018 was 2.27 hours compared to 9.73 hours in 2004. 60% of consults originated from Iraq and Afghanistan. U.S. Army personnel comprised the largest percentage of consults (38.6%). Non-military patients from the US accounted for 19% of consults. Non-U.S. patients including coalition forces, contractors, detainees, and non-combatants accounted for 14.4% of consults, of which 22% were children. Anterior segment consults accounted for 45.1% of all consults with corneal surface disease being the largest subset within this diagnostic category. Dermatology and neurology were the most commonly co-consulted specialties. Photographs accompanied 37.4% of consults, with the likelihood requesters included photographs being greatest in cases involving pediatric ophthalmology (77.8%) and oculoplastics (71.7%). Evacuation was recommended in 22.7% of overall cases and 41.1% of trauma cases.

Conclusions: Army teleophthalmology has been an indispensable resource in supporting and advancing military medicine, helping to optimize ophthalmic care for American military personnel, beneficiaries, allied forces, and local nationals worldwide. A dedicated ophthalmic care and coordination system which utilizes new advances in teleconsultation technology could further enhance our capability to care for the ophthalmic needs of patients abroad, with opportunity for improving domestic care as well.

TITLE: Efficacy of Netarsudil as an Additional Therapy for Glaucoma in Patients Already on Maximally Tolerated Medical Therapy

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.C. Villegas, W. Lee, Ophthalmology, Stanford University, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Natacha Villegas: Commercial Relationship: Code N (No Commercial Relationship) | Wen-Shin Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although the pivotal trials for netarsudil demonstrated that it was effective in lowering IOP as a primary monotherapy, in clinical practice it is more commonly used as an adjunctive treatment for patients on multiple topical medications. It is not clear how well netarsudil performs as an adjunctive therapy in these circumstances. This study seeks to evaluate the efficacy of netarsudil in glaucoma patients with inadequately controlled IOP on otherwise maximally tolerated medical therapy.

Methods: This is a retrospective, observational clinical study of patients started on netarsudil at Stanford University. All subtypes of glaucoma and pre-treatment IOPs were included. Exclusion criteria included glaucoma surgery or laser within 6 months of starting netarsudil and other modifications to the patient's medication regimen within 4 weeks. The primary outcome measure was treatment success, defined as IOP reduction from pre-treatment baseline below a pre-determined, patient specific target, and no further medication, laser, or surgery recommended subsequent to starting netarsudil. Other outcome measures included extent of IOP reduction and adverse effects.

Results: 62 eyes of 45 patients were included. Most patients had a diagnosis of primary open angle glaucoma (59%). Most eyes were on 3 or more drops (88%). 36 eyes (58%) achieved treatment success at first follow up. The mean change in IOP for all patients at first follow up was -3.53 mmHg (-17%). In patients who achieved treatment success, mean IOP change was -5.22 mmHg (-28.0%). Of the eyes with baseline IOP of ≤ 20 mmHg, 69% achieved treatment success, compared to only 17% of eyes with baseline IOP ≥ 21 (Figure 1). All patients that failed treatment were offered surgery. 20% of patients reported an adverse reaction to netarsudil, which led to discontinuation in 4 (6%) of the patients with initial treatment success.

Conclusions: Netarsudil is effective in lowering IOP for patients on otherwise maximally tolerated medical therapy, achieving treatment success in most patients for which glaucoma laser or surgery would be the only remaining therapeutic options, especially in eyes with baseline IOP under 20 mmHg. In addition, Netarsudil was overall well tolerated, with few patients opting to discontinue therapy due to local side effects.

TITLE: Epithelial abrasion induces distinct changes in interaction of 2 ion channel proteins Pannexin1 and P2X7 in diabetic mice

SESSION TITLE: Corneal Epithelial Repair and Corneal Neuropathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: V.E. Trinkaus-Randall, K.L. Segars, C.B. Rich, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Vickery Trinkaus-Randall: Commercial Relationship: Code N (No Commercial Relationship) | Kristen Segars: Commercial Relationship: Code N (No Commercial Relationship) | Celeste Rich: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Epithelial wound healing is essential to repair the barrier function of the cornea after injury. We found that Pannexin1 (Panx1), a channel that moves ATP into the extracellular space, is localized along cell borders in unwounded tissue and becomes concentrated near the wound margin. We propose that the region of intense localization of Panx1 is where Ca²⁺ mobilization occurs and hypothesize that the interaction of Panx1 and P2X7 is important in corneal wound healing. Our goal is to determine if the interaction is altered in moderately obese NONcNZO10/LtJ mice that model type 2 diabetes in humans.

Methods: Epithelial debridement wounds were performed on corneas from C57BL/6J and from NONcNZO10/LtJ mice. Immunohistochemical assays were performed before and after injury and imaged using confocal microscopy. Corneas were incubated in the presence or absence of inhibitors against Panx1 and P2X7 to examine Ca²⁺ mobilization and communication between cells. Proximity ligation assays (PLA) were performed to determine the interaction of the proteins before and after injury. Analyses were performed using ImageJ and CellProfiler.

Results: Panx1 was present along cell borders in unwounded tissue in both models with more diffuse staining in NONcNZO10/LtJ mice. An epithelial abrasion induced a striking difference in the localization of Panx1 and there was intense staining near the leading edge where Ca²⁺ mobilizations were detected. However, Panx1 was not intense in the epithelium of NONcNZO10/LtJ female and male mice near the wound. Inhibition caused a change in cell shape distal to the wound. It also attenuated calcium mobilizations near the leading edge that led to a fold reduction in cell-cell communication. PLA revealed a reduction in the interaction between P2X7 and Panx1 in epithelium of NONcNZO10/LtJ mice.

Conclusions: Injury induces a change in localization of Panx1 that is not detected in the epithelium from the moderately obese type 2 diabetic mice suggesting that the protein is dysregulated. The decreased interaction of the two channel proteins suggests that both are critical for the migration of epithelium and suggest that the decrease in cell-cell communication depends on this interaction. The results demonstrate that Panx1 is a critical component to the healing response, and suppression is associated with cell-cell communication and migration.

TITLE: Corneal Nerves Modulate Angiogenesis via Secreted Neuropeptides

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Yin, S. zhu, L. Liu, K. Pang, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jia Yin: Commercial Relationship(s);Alcon Research Institute:Code F (Financial Support);Kera Therapeutics:Code C (Consultant) | shuyan zhu: Commercial Relationship: Code N (No Commercial Relationship) | Lingjia Liu: Commercial Relationship: Code N (No Commercial Relationship) | Kunpeng Pang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Angiogenesis in the normally avascular cornea underlies common corneal diseases. Corneal nerves, derived from trigeminal ganglion (TG), are master regulators of ocular surface homeostasis. Here we seek to determine whether corneal nerves directly modulate angiogenesis and investigate the role of nerve-derived neuropeptides.

Methods: TG neurons were isolated from BALB/C mice and cultured in Neurobasal A medium. Conditioned media (CM) of TG neurons was collected between Day 3 and 4 of culture. A co-culture system was set up by placing TG neurons in the top chamber of a transwell and culturing vascular endothelial cells (VEC, MILE SVEN1 cell line) in the bottom chamber. VEC proliferation, migration, and tube formation were determined with and without TG neurons or their CM. *in vivo* corneal angiogenesis was induced by placing intrastromal sutures in BALB/C mouse corneas. Expression of neuropeptides were determined using immunofluorescence.

Results: Presence of TG neurons in co-culture decreased VEC proliferation by 35% ($P=0.008$) and migration by 20% ($P=0.046$). Similarly, conditioned media (CM) of TG neurons reduced VEC proliferation ($P<0.0001$), migration ($p=0.017$), and the number of junctions ($P=0.004$) and length of tubes ($P=0.001$) formed by VEC. Topical application of neuron CM led to a 76% reduction in suture induced-corneal angiogenesis *in vivo* ($P=0.025$). TG neurons and corneal nerves express neuropeptides substance P (SP) and calcitonin gene-related peptide (CGRP). In addition, more than 80% of TG neurons and 90% of subbasal corneal nerves express alpha-melanocyte-stimulating hormone (α -MSH). Exogenous SP (1 μ M) and CGRP (100nM) promoted VEC proliferation and tube formation *in vitro*, and local application of their antagonists Spantide I and CGRP837, respectively, led to decreases in corneal angiogenesis *in vivo*. In contrast, α -MSH (100nM) reduced VEC proliferation, migration, and tube formation *in vitro* and subconjunctival injection of α -MSH reduced corneal angiogenesis by 56% ($P=0.008$) *in vivo*. Antagonizing α -MSH signaling with Agouti-signaling protein or siRNA knock-down in TG neurons reversed the inhibitory effects of neuron CM on VEC proliferation, migration, and tube formation.

Conclusions: TG neurons and corneal nerves express pro-angiogenic neuropeptides SP and CGRP, and anti-angiogenic peptide α -MSH, which plays a critical role in the direction modulation of corneal angiogenesis by corneal nerves.

ABSTRACT BODY:

Purpose: Corneal tomography, such as Pentacam®, provides both corneal pachymetry and posterior corneal curvature data in addition to anterior corneal curvature data provided in corneal topography, aiding in the diagnosis and detection of keratoconus. The purpose of this study is to characterize the corneal tomography usage for keratoconus at a tertiary care center.

Methods: Single-institution retrospective study of patients treated for keratoconus from January 2012 through December 2019. Patients were categorized by age (pediatric: < 18 years, adult: ≥ 18 years) and intellectual disability status (diagnosis of Down syndrome and/or autism) at their first clinic visit. Student's t-test was used to calculate statistical differences between groups.

Results: 611 subjects were identified, 55 of which were pediatric patients. Only 11% of patients underwent corneal tomography at their first visit in 2012, which increased to 70% by 2019. Over this time period, pediatric patients were significantly more likely to have corneal tomography at their first visit compared to adult patients (42% vs. 24%, $P = 0.01$). The majority of patients had corneal topography, regardless of age ($P = 0.41$). 9 subjects with intellectual disability were identified, all of whom were adults at their first visit. 67% had corneal topography, however only one had corneal tomography, which was for the right eye only ($P = 0.22$ right eye; $P < 0.001$ left eye). Finally, patients with corneal tomography imaging at the first visit were more likely to undergo corneal collagen cross-linking (24% vs. 6%, $P < 0.001$) and less likely to require a corneal transplant (5% vs. 16%, $P < 0.001$) by their most recent visit compared to those without corneal tomography imaging.

Conclusions: Our study demonstrates greater use of corneal topography compared to corneal tomography, although tomography use is increasing. Furthermore, corneal tomography usage was more prevalent in younger populations, likely reflecting known keratoconus progression in adolescence as well as provider practice differences. We also demonstrate minimal use of corneal tomography in disabled patients, which warrants further investigation. Subjects with earlier corneal tomography imaging also had fewer corneal transplantations, suggesting the importance of obtaining earlier corneal tomography. Thus, future research may provide insight into optimal monitoring and consequences of corneal imaging in keratoconus.

ABSTRACT BODY:

Purpose: The Early Treatment Diabetic Retinopathy Study (ETDRS) severity scale has been the gold-standard for grading diabetic retinopathy (DR) in clinical research for decades. Graders determine ETDRS severity from fundus photographs by comparing lesions to standard photographs. Grading of new vessels on the disc (NVD) is based on the area involved by the new vessels compared to standard 10A (Figure 1) which has NVD equal to $\frac{1}{3}$ disc area (DA) or 0.85mm^2 . Then, an eye is categorized as $<\frac{1}{3}$ or $\geq\frac{1}{3}$ DA. However, this binary classification may be insufficient to measure regression of NVD as a potential outcome for therapeutic studies. Our goal is to use a machine learning (ML) tool to quantitatively analyze images

Methods: Fundus photographs from 66 eyes with NVD were included. Images were calibrated using disc to macula distance. Of these, 40 images were randomly selected to train a classifier with Trainable Weka Segmentation, a Fiji plugin which combines ML algorithms to perform pixel-based segmentation. The classifier was applied to the remaining images, and a segmented mask was generated for each. Artificially-segmented pixels outside the area of NVD were not excluded in the current version of our classifier. NVD area (mm^2) and vascular length (mm) were documented for each eye. All images were independently reviewed by two graders and categorized as NVD $<\frac{1}{3}$ or $\geq\frac{1}{3}$ DA.

Results: Graders categorized 31 (46.9%) eyes as $<\frac{1}{3}$ DA and 35 (53.1%) eyes as $\geq\frac{1}{3}$ DA. There was equal distribution of both categories in training and validation images. In eyes categorized as NVD $<\frac{1}{3}$ DA, the mean area of NVD with ML quantification was 0.099mm^2 (SEM=0.025), compared to 0.501mm^2 (0.159) in eyes categorized as $\geq\frac{1}{3}$ DA ($p=0.02$) Mean vascular length of NVD was 0.010mm (0.003) and 0.048mm (0.016) in both categories respectively ($p=0.026$).

Conclusions: There is strong correlation between ML quantification of NVD and subjective binary classification. Quantification of NVD using ML provides a finer measurement and ability to assess change over time. Employing this tool in longitudinal data will help describe the natural history of change in area and length of NVD over time.

TITLE: Comparison of outcomes of Ahmed Glaucoma Valve alone versus Ahmed Glaucoma Valve combined with phacoemulsification in Black and Latino patients

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.X. Chen, N. Tan, SUNY Downstate Health Sciences University College of Medicine, New York, New York, UNITED STATES|N.M. Radcliffe, New York Eye and Ear Infirmary of Mount Sinai, New York, New York, UNITED STATES|N.M. Radcliffe, New York Eye Surgery Center, The Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Shannon Chen: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Tan: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Radcliffe: Commercial Relationship(s);New World Medical:Code C (Consultant)

ABSTRACT BODY:

Purpose: Controversy exists regarding whether the Ahmed Glaucoma Valve combined with phacoemulsification (AGV-phaco) is as safe and effective as standalone AGV surgery. We sought to compare these techniques in an understudied, Black and Latino population.

Methods: We reviewed charts of eyes from Latino or Black patients followed for 12 months after AGV-phaco or AGV surgery. A single surgeon conducted all procedures in the Bronx, NY from 2014-2019. Baseline demographics, intraocular pressure (IOP), number of glaucoma medications, and visual field mean deviation were compared using Pearson's Chi-squared and Wilcoxon rank-sum tests. To evaluate postop outcomes, we used rank-sum tests or Chi-square tests on the following: 1-year change in IOP and number of medications, vision loss of 2 lines or more, slit lamp procedures, reoperation for glaucoma, shallow or flat anterior chamber, corneal complications, retinal or choroidal complications, and presence of hypertensive phase (HP). For any significant findings, we conducted linear or logistic regression and adjusted for preop IOP. HP described an IOP reading > 21 mmHg within the first 3 postop months after reduction of IOP to less than 22 in the first week, without tube malfunction. Sterling IRB deemed this study to be exempt.

Results: We studied 78 AGVs and 125 AGV-phacos from 203 eyes. At baseline, mean IOP was 7.9 mmHg higher in standalones ($p < 0.0001$). Mean change in IOP was greater for AGVs ($-15.9 \text{ mmHg} \pm 10.9$) than AGV-phacos ($-8.9 \text{ mmHg} \pm 9.6$; $p < 0.0001$). However, surgery type did not predict change in IOP after adjusting for preop IOP ($p = 0.57$). Medications decreased by approximately 1 in both groups ($p = 0.77$). Vision loss occurred in 29.5% of AGVs and in 14.4% of AGV-phacos ($p = 0.015$). HP occurred in 65.4% and 38.4%, respectively ($p = 0.00032$). After preop IOP adjustment, surgery type did not predict vision loss ($p = 0.062$), but it did predict HP. AGV-phacos were 53.6% less likely to undergo a hypertensive phase post-adjustment ($p = 0.017$). Differences in other studied events were not significant ($p > 0.05$).

Conclusions: AGV-phaco in Black and Latino patients may be as effective in treating glaucoma as standalone AGV after adjusting for preop IOP. AGV-phaco may also be slightly safer, with lower odds of HP after preop IOP adjustment. This may be due to differences in AGV pocket pathophysiology in combined surgery.

TITLE: Reliability of Intraocular Pressure Measurements in a Low Contact Drive-Through Setting

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.W. Sun, D. SALAZAR, Y. Zhou, J.D. Stein, J.S. Weizer, Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lynn Sun: Commercial Relationship: Code N (No Commercial Relationship) | DIANA SALAZAR: Commercial Relationship: Code N (No Commercial Relationship) | Yunshu Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Stein: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Weizer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has spurred innovation beyond traditional healthcare.¹ At our institution, a drive-through intraocular pressure (IOP) measurement protocol using the iCare tonometer was established to facilitate low-contact monitoring of select glaucoma patients. However, the iCare may be prone to error due to variable measurement technique and local air currents.² We endeavored to assess the reliability of drive-through IOP measurements by comparing them with recent measurements taken in clinic settings.

Methods: Inclusion criteria were all patients with drive-through IOP measurements performed from May 11-Aug. 11, 2020; exclusion criteria were any patients with IOP medication change or ophthalmic procedure between the studied IOP measurements. Drive-through IOP measurements were compared with the most recent prior in-clinic IOP measurements. Data was gathered using the Sight Outcomes Research Collaborative (SOURCE) data repository.²

Results: The study group consisted of 338 patients receiving drive-through IOP measurements. Significant differences were found between drive-through IOPs and prior in-clinic measurements. The mean drive-through vs. in-clinic IOP OD was 17.0 mmHg (SD 5.3) vs. 14.5 mmHg (SD 4.2), and OS was 17.8 mmHg (SD 5.6) vs. 15.1 mmHg (SD 4.5), a difference of 17.6% OD and 17.8% OS. Differences between individual measurements ranged from -5.5 mmHg to +12 mmHg. 71.4% of drive-through IOPs were higher than corresponding in-clinic IOPs; 22.7% were lower. 30.5% of drive-through IOPs were higher than >5 mmHg. In 18.4% of cases, drive-through IOP measurements resulted in management changes (typically, the addition of an IOP-lowering drop). In comparison, only 10.5% of in-clinic measurements resulted in management changes--the equivalent of a 75% increase in intervention.

Conclusions: Low-contact forms of IOP monitoring will continue to play a role in tele-ophthalmology. However, our data reveals potential inaccuracies in drive-through iCare IOP measurements which tend to overestimate IOP, thus triggering interventions in more drive-through cases than typically seen in clinic.

ABSTRACT BODY:

Purpose: Vision impairment associated with optic neuritis (ON) is prevalent in approximately 20% of patients with multiple sclerosis (MS). All the approved disease-modifying therapies (DMTs) available for MS function by suppressing inflammation, however, the impact on the long-term neurodegenerative phase is not completely known. Any agent with additional neuroprotective properties may offer advantages over existing therapies in reducing ultimate MS disability. The current study was undertaken to determine the neuroprotective properties of fingolimod (FTY), a sphingosine-1-phosphate receptor modulator, and its potential as a therapy for ON.

Methods: Utilizing the rat retinal neuronal cell (R28) line, an in vitro model to assess MS-induced neurodegeneration was established. Neuronal damage was induced by treatment with tumor necrosis factor (TNF α). Cell viability was quantified using Trypan blue method. Changes in signaling molecules were elucidated using Western blot and alterations in neuronal morphology were assessed by immunofluorescence studies.

Results: Treatment of R28 cells with TNF α caused significant cell death, while FTY treatment increased cell survival. Neuronal damage was induced by treating R28 cells with TNF α for 24h at a dose of 10 ng/mL. Dose-dependent studies showed that FTY concentration at 25 nM significantly reduced TNF α -induced cell death compared to the control group (N=5, p<0.01). The upregulation observed in phospho-p38 MAPK in response to TNF α treatment was significantly reduced in the presence of Fingolimod (N=3, p<0.05). Further, the level of cell survival marker, Bcl-xL was decreased, while the expression of cleaved caspase-3 (a cell death marker) was increased in TNF α -treated R28 cells. These changes were reversed significantly in response to Fingolimod treatment (N=3, p<0.05). Immunofluorescence studies using antibodies against neuronal markers, Tuj1 (neuron-specific class III beta-tubulin), and neuronal enolase demonstrated that FTY treatment protected the retinal neurons against the TNF α -induced neurodegenerative changes.

Conclusions: In conclusion, our study suggests that Fingolimod exhibited neuroprotective properties in an experimental model of optic neuritis.

TITLE: Discontinuation and Loss to Follow-Up Rates in Clinical Trials of Intravitreal Anti-Vascular Endothelial Growth Factor Injections

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Rosenblatt, N. Rayess, A. Al Moujahed, P. Mruthyunjaya, Ophthalmology, Byers Eye Institute, Stanford University School of Medicine, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tatiana Rosenblatt: Commercial Relationship: Code N (No Commercial Relationship) | Nadim Rayess: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Al Moujahed: Commercial Relationship: Code N (No Commercial Relationship) | Prithvi Mruthyunjaya: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Clinical trials are often designed to include homogenous, highly specific patient populations with many resources to reduce patient dropout. Results may not translate to real-world settings. We performed a retrospective meta-epidemiological study to evaluate discontinuation and loss to follow-up (LTFU) rates in clinical trials of intravitreal anti-vascular endothelial growth factor (anti-VEGF) injections for diabetic macular edema (DME), age-related macular degeneration (AMD), and retinal vein occlusion (RVO).

Methods: Clinicaltrials.gov was queried for all completed trials of anti-VEGF injections for DME, AMD, or RVO. Of the 658 trials identified, 582 were excluded for being non-interventional (n = 90), having fewer than 100 patients (n = 207), terminating early (n = 6), or missing study results (n = 279). The remaining 76 trials (DME n = 33, AMD n = 33, RVO n = 10) of 27,823 patients were analyzed for discontinuation and LTFU rates.

Results: Mean discontinuation rate was 12.44% (SD 8.12%, range 0 – 54.12%) (Figure 1A), with higher rates among control (18.87%) than treatment arms (10.78%, p = .006). Subject withdrawal was the most common reason for discontinuation, followed by adverse events and LTFU (Table 1). Mean LTFU rate was 1.84% (SD 1.78%, range 0 – 7.76%) (Figure 1B), with no significant differences when stratified by disease, treatment type, or treatment frequency.

Conclusions: Discontinuation rates of major intravitreal anti-VEGF clinical trials were highly variable, suggesting even trials struggle with overall patient retention. Though trial LTFU rates were low, real-world outcomes may differ due to higher reported LTFU rates, which should be considered when extrapolating trial results to clinical practice.

ABSTRACT BODY:

Purpose: To map and quantify the peripapillary retina (PPR) deformation during intraocular pressure (IOP) elevation in human donor eyes using high-frequency ultrasound elastography.

Methods: Inflation tests were performed in 10 donor globes (age: 20-74 years old, 4 male and 6 female) while IOP was raised in 0.5 mmHg steps from 5 to 30 mmHg. Each eye was inflated twice to capture 2D scans of the posterior eye centered at the optic nerve head (ONH) along the nasal-temporal (NT) and superior-inferior (SI) axis using a 50MHz ultrasound probe (Vevo2100, VisualSonics). A correlation-based speckle tracking algorithm (Tang & Liu, JBME 2012) was used to compute displacements, and strains were calculated using least squares estimation. Radial, tangential, and shear strains were obtained by coordinate transformation. Peripapillary sclera (PPS) and PPR were manually segmented for regional analysis (Fig 1A, tan and pink, respectively). Regional strain analysis was conducted at IOP = 30 mmHg using paired t-test.

Results: Localized high tangential and shear strains were present in PPR during IOP elevation (up to 5%, Fig 1B). On average, PPR had less radial compression ($-0.55 \pm 0.25\%$ vs $-2.32 \pm 0.74\%$, $p < 0.001$), greater shear ($1.49 \pm 0.65\%$ vs $1.13 \pm 0.32\%$, $p = 0.029$), and similar levels of tangential stretch ($0.29 \pm 0.19\%$ vs $0.38 \pm 0.19\%$, $p = 0.13$, Fig 2A) as compared to the PPS. Exploratory analysis showed no significant differences in strains between quadrants in either PPR or PPS (Fig 2B).

Conclusions: Peripapillary retinal damage is characteristic of glaucoma progression. Our findings showed that although PPR experienced minimal radial compression during IOP elevation, localized shear and stretch were substantial, which could contribute to mechanical damage in this region during IOP elevation. These results provide new insights into IOP-related mechanical insults to the neural tissue near the ONH, where glaucomatous damage initiates.

ABSTRACT BODY:

Purpose: Capsular pseudoexfoliation (PEX) is a heterogeneous syndrome that can present as a wide variety of clinical scenarios and early lensectomy may help to reduce comorbidity in some of them. This study aimed to assess the long-term effectiveness, predictability and safety of cataract surgery in patients presenting whether symmetric or asymmetric PEX.

Methods: A retrospective, observational clinical study was designed, including PEX patients that underwent phacoemulsification with hydrophobic acrylic intraocular lens (IOL) implantation in both eyes at one centre between 2001 and 2015. Multifocal IOL were only implanted in selected cases of asymmetric PEX. A postoperative follow-up ≥ 5 years, ≥ 3 preoperative reliable visual field (VF) tests and the presence of periodical VF tests until the analysis visit were required.

322 eyes of 161 patients were included (mean age: 71.4 ± 5.7 years), with a mean follow-up time of 8.5 ± 2.8 years (range: 6-17 years). Patients were classified in two groups: 102 patients with symmetric PEX (PEX material seen in both eyes with the slit lamp), and 118 patients with asymmetric PEX (only one eye presented clinically apparent PEX). Preoperative and postoperative visual acuity, intraocular pressure (IOP), number of hypotensive drugs and VF mean deviation (MD) were registered, as well as the appearance of intraoperative and postoperative complications. Wilcoxon test was used for statistical analysis.

Results: Before surgery, no statistical differences were found between both groups. Postoperatively, 95%, 96% and 96% of eyes were within ± 1.00 D in symmetric PEX, asymmetric PEX with monofocal IOL, and asymmetric PEX with multifocal IOL groups, respectively.

At the final follow-up visit, IOP remained stable in the main two groups ($p=0.08$; $p=0.06$) with a reduction of the number of medications ($p<0.001$). MD worsened from -8.8 dB to -11.6 dB in the symmetric group ($p<0.001$), and remained stable in the asymmetric group (from -5.0 dB to -7.1 dB; $p=0.42$). No intraoperative complications were registered in the asymmetric group, in comparison with the symmetric group: 7 (3.4%; $p=0.05$). Ten cases (4.9%) of late IOL dislocation were found, only in the symmetric group ($p=0.04$).

Conclusions: Early lensectomy with IOL implantation in patients with PEX before its symmetric presentation results effective, safe and predictable in the long term.

ABSTRACT BODY:

Purpose: QLS-101, a water-soluble phosphate ester prodrug of an ATP-sensitive potassium channel opener, is being developed by Qlaris Bio as an ocular hypotensive agent with a novel mode of action that affects distal outflow resistance and episcleral venous pressure. This summarizes the potential toxicity and pharmacokinetic (PK) profiles of QLS-101 in beagle dogs.

Methods: To assess ocular toxicity and PK, beagle dogs (age 5-7 months) were dosed topically (OU) once daily for 28 days with 2.0%, 4.0%, or 8.0% QLS-101 (n=3 males and 3 females per group). To evaluate systemic maximum tolerated dose (MTD), single escalating doses of QLS-101 (0.05-5.0 mg/kg/day) were administered by i.v. bolus to one male and one female beagle dog, with a 48h minimum observation period between doses. Plasma samples were collected at various timepoints in both studies, concentrations of QLS-101 and its active moiety QLS-100 were determined by LC/MS-MS, and data used to generate PK parameters. Mortality, clinical observations, body and organ weights, and food consumption were assessed in each study. Necropsy examinations were performed and select tissues were isolated and prepared for histopathology.

Results: QLS-101 was well-tolerated at all dose levels except 5 mg/kg/day i.v. When dosed topically, the no-observed-adverse-effect level (NOAEL) was determined to be 8.0%. At this dose, the mean C_{max} and $AUC_{T_{last}}$ values on day 28 were 147 ng/mL and 1.26 ug*h/ml, respectively, for males, with similar results in females. QLS-100 C_{max} and $AUC_{T_{last}}$ levels at NOAEL were 31 ng/ml and 166 ng*h/ml in males, with similar results in females. Using dogs administered single escalating i.v. doses, the MTD was determined to be 3 mg/kg. Side effects were limited to non-adverse skin redness at all dose levels, consistent with vasodilation. Unexpectedly, the observed skin redness initially presented peripherally in the distal limbs (fore and hindpaws) and in the pinnae rather than the trunk, neck, or face. The MTD corresponded to sex-combined C_{max} and $AUC_{T_{last}}$ values of 16.4 µg/mL and 106.55 µg*h/mL for QLS-101, and 35.5 ng/mL and 431 ng*h/mL, for QLS-100. No mortality, change in body weight or food consumption were noted. Histological examination showed no systemic toxicity as a result of QLS-101 treatment.

Conclusions: QLS-101 is well-tolerated in beagle dogs and suitable for clinical development as an IOP-lowering therapeutic.

ABSTRACT BODY:

Purpose: Ultra-widefield (UWF) fluorescein angiography (FA) is widely used in the evaluation of diabetic retinopathy (DR), but further study is necessary to explore how quantifiable biomarker areas on FA images may relate to DR treatments. This study seeks to determine if associations exist between areas of nonperfusion (NP) and neovascularization (NV) in eyes of patients with diabetes and treatment with panretinal photocoagulation (PRP) or intravitreal (IVT) injections, and if calculated areas and demographic factors are associated with DR progression.

Methods: In this retrospective, cross-sectional study, a total of 363 patients (651 eyes) who were treated at the University of Michigan Kellogg Eye Center between January 2009 and May 2018 were included. Eligible participants were 18 years or older with diagnoses of type 1 or 2 diabetes who received UWF FA. Patients with previous PRP or poor-quality images were excluded. Our main outcome measures included comparison analyses of measured surface areas (biomarkers) in millimeters squared (mm^2), number of IVT injections and PRP treatments, and DR progression.

Results: Our cohort of 363 patients (651 eyes) received a total of 3,041 IVT injections and 878 PRP treatments with a mean follow-up time of 915 days ($\text{SD} \pm 714$). IVT injections were positively associated with posterior NP (difference, 1.15 mm^2 ; 95% CI, 0.43 – 1.86; $P = 0.0017$). PRP treatments were positively associated with total NP (difference, 27.24 mm^2 ; 95% CI, 14.68 – 39.79; $P = 2.1 \times 10^{-5}$), mid-periphery NP (difference, 10.34 mm^2 ; 95% CI, 4.43 – 16.26; $P = 6.1 \times 10^{-4}$), far-periphery NP (difference, 18.67 mm^2 ; 95% CI, 10.24 – 27.09; $P = 1.4 \times 10^{-5}$), total NV (difference, 1.75 mm^2 ; 95% CI, 0.84 – 2.65; $P = 1.6 \times 10^{-4}$), mid-periphery NV (difference, 1.23 mm^2 ; 95% CI, 0.51 – 1.96; $P = 8.4 \times 10^{-4}$), and far-periphery NV (difference, 0.37 mm^2 ; 95% CI, 0.14 – 0.61; $P = 0.0019$). While DR progression was not associated with biomarker areas, it was positively associated with a pre-existing diagnosis of type 2 (147% increase; 95% CI, 7% – 473% increase; $P = 0.03$) as compared to type 1 diabetes.

Conclusions: Areas of NP and NV on UWF FA demonstrated associations with IVT injections and PRP treatments. Quantifiable biomarker areas in UWF FA may assist with patient prognostication and management.

ABSTRACT BODY:

Purpose: QLS-101, a water-soluble phosphate ester prodrug of an ATP-sensitive potassium channel opener in preclinical development, has shown potent IOP reduction in multiple normotensive and glaucomatous animal models. The purpose of this study was to determine the conversion profile and activity of QLS-101 and its active moiety (QLS-100) using human tissue.

Methods: Conversion of QLS-101 (200 μ M-5.0 mM) was examined by LC/MS-MS following incubation at pH 7.4 with either human alkaline phosphatase (ALP), acid phosphatase, or 5'-nucleotidase (2.0 nM-1.0 μ M) for up to 2h. Further dose- and time-dependent analysis of QLS-101 (0.01-40.0 mM) conversion to QLS-100 was determined following incubation with human ALP (0.0002-0.2 U/ μ l) for up to 72h. Tissue-specific conversion of QLS-101 was assessed in fresh human ocular tissues and fluids over 24h. To quantify channel activity, HEK-293 cells stably expressing human Kir6.2/SUR2B ATP-sensitive potassium channel subunits were incubated with increasing concentrations (0.003-100 μ M) of either QLS-101 or QLS-100. Pinacidil (100 μ M), a commercially-available ATP-sensitive potassium channel opener, was used as a positive control. Cell membrane potential was measured on a FLIPR fluorescence plate reader.

Results: Human ALP, but not acid phosphatase or 5'-nucleotidase, converted QLS-101 to QLS-100 in vitro, with K_m and k_{cat} values of 630 μ M and 15 min⁻¹, respectively. In a separate study at a fixed QLS-101 concentration, approximately 21% of QLS-101 was converted by ALP in a concentration-dependent manner. Similarly, ALP at a fixed concentration converted QLS-101 to QLS-100 in a QLS-101 inverse concentration-dependent manner. In human ocular tissues, 24h conversion of QLS-101 was most robust in samples of iris, ciliary body, trabecular meshwork, and sclera. Treatment of HEK-Kir6.2/SUR2B cells with QLS-100 resulted in a concentration-dependent hyperpolarization of the cell membrane, with a mean EC_{50} value of 0.53 μ M \pm 0.05, consistent with pinacidil (EC_{50} = 5.49 μ M \pm 0.99). In contrast, application of QLS-101 did not result in any significant hyperpolarization, confirming QLS-101 as an inactive prodrug.

Conclusions: QLS-101 is activated by human ALP to QLS-100, which promotes cell membrane hyperpolarization through ATP-sensitive potassium channels composed of Kir6.2/SUR2B.

ABSTRACT BODY:

Purpose: Recent clinical trials have explored the efficacy of intravitreal brolucizumab (IVB) for wet AMD in treatment-naïve patients, but little is known about its use in treatment-experienced patients. The purpose of this study is to evaluate patient response to IVB in a real-life clinical setting with a focus on successful extension of treatment interval while maintaining visual acuity (VA) and central foveal thickness (CFT).

Methods: This was a retrospective, single-center study. We included 144 patients with wet AMD who received their first treatment of IVB between 11/1/20 and 4/20/20, and these patients were followed through 12/4/20. All patients were previously treated with intravitreal anti-VEGF. Using the treat and extend regimen, patients were observed closely to ensure that they achieved optimal treatment intervals. All patients underwent eye examinations at each visit and optical coherence tomography imaging at least every other visit. Key outcome measures were VA, CFT, and treatment interval.

Results: 144 eyes that received IVB for wet AMD were included in this study (64 men and 80 women, average age 77.56 ± 11.84). Prior to the study period, patients had an average baseline logMAR VA of 0.6050 ± 0.4635 , average baseline CFT of 281.84 ± 81.63 μm , and average baseline treatment interval of 33.93 ± 9.85 days. During the study period, patients received an average of 4.37 ± 1.74 (range 1-8) treatments, with 84.0% of the population having received 3 or more treatments. Changes in VA and CFT from baseline to final treatment were of statistical nonsignificance, but average treatment interval was extended from 33.76 days to 60.37 days ($p < .001$). Average baseline treatment interval increased significantly to 43.99 ± 20.17 , 42.69 ± 15.05 , 64.60 ± 16.75 , 61.24 ± 11.83 , 62.48 ± 11.23 , and 52.70 ± 14.48 after 1, 2, 3, 4, 5, and 6 treatments, respectively ($p < 0.001$). 106 (81.54%) patients extended their treatment intervals by at least seven days, 21 (16.15%) maintained their previous interval, and 3 (2.31%) tightened their previous intervals by at least seven days. 99 (76.15%) patients achieved an interval of 56 days or longer.

Conclusions: The results of this study showed that IVB is a promising treatment option for patients with suboptimal response to other anti-VEGF agents. Our study cohort maintained VA and CFT within one standard deviation of baseline while, on average, extending their treatment intervals and therefore reducing treatment burden.

ABSTRACT BODY:

Purpose: We performed a retrospective cohort study to evaluate the temporal association between a new diagnosis of glaucoma and the subsequent onset of psychiatric disorders.

Methods: TriNetX (Cambridge, MA, USA), a federated electronic health records research network was used to identify a total of 468,480 individuals with the diagnosis of glaucoma using a series of ICD-10 codes (H40 category) and were stratified into cohorts based on age at the time of diagnosis. Each subject was then matched to a control without the diagnosis of glaucoma based on age, sex, race, BMI, and the presence or absence of essential hypertension, diabetes mellitus, cerebrovascular disease, heart failure, nicotine dependence, and alcohol related disorders. The primary endpoint of the study was the incidence of a new psychiatric disorder within 90-days of being diagnosed with glaucoma compared to matched controls. Data compilation and analysis were done through Microsoft Excel.

Results: Subjects in the 25-35 and 36-49 years of age cohorts did not show a statistically significant increase in the incidence of psychiatric disorder within 90-days of being diagnosed with glaucoma compared to matched controls. Subjects in the 50-64 years of age cohort showed a statistically significant higher risk of developing generalized anxiety disorder [RR 1.23, 95% 1.04-1.45] and adjustment disorder [RR 1.21, 95% 1.02-1.43] in the first 90-days after a new diagnosis of glaucoma compared to matched controls. Subjects in the 65 years of age and over cohort showed a statistically significant higher risk of developing generalized anxiety disorder [RR 1.550, 95% 1.41-1.7], adjustment disorder [RR 1.62, 95% 1.47-1.79], persistent mood disorders [RR 1.24, 95% 1.11-1.38], and panic disorders [RR 1.24, 95% 1.05-1.47] in the first 90-days after a new diagnosis of glaucoma compared to matched controls.

Conclusions: Patients over the age of 50 with a new diagnosis of glaucoma are at a significantly higher risk of developing new psychiatric disorders shortly after receiving a new diagnosis of glaucoma. Increased awareness of these associations can lead to improved patient care by employing an early multidisciplinary approach to address these comorbidities.

ABSTRACT BODY:

Purpose: Platelet rich plasma (PRP) is an autologous preparation that concentrates platelets in a small volume of plasma that has been used to treat ocular surface diseases. The purpose of this study was to determine if treatment with autologous PRP eye drops improved symptoms and signs of dry eye disease (DED).

Methods: A retrospective case series was conducted of patients who were prescribed autologous PRP eye drops for treatment of ocular surface disease. Subjects were excluded if they did not have a follow-up visit, underwent intraocular surgery prior to their follow-up visit, previously received nerve growth factor treatments or did not have a baseline examination with photography. Symptoms were assessed using the Ocular Surface Disease Index (OSDI) and subject report. Patients also underwent a slit lamp exam, which included ocular surface staining with fluorescein and lissamine green.

Results: The charts of 47 patients with a history of ocular surface disease were included who had been prescribed PRP drops. 64 eyes of 32 patients had evaluable photographs of lissamine green staining taken at the baseline and at follow-up. The mean age at the baseline visit was 60 years (SD 13.3) and there were 39 (83%) females. Thirteen patients (28%) had a history of ocular graft-versus-host disease. Sixteen patients (34%) had a history of Sjögren's syndrome and four patients (8.5%) had Rheumatoid arthritis. The average time of follow-up was 182.7 days, and 162.6 days for those who had follow-up photographs done. There was a statistically significant decrease in OSDI score from baseline to follow-up (39.5 vs 30.8 points, $p=0.02$). Among the 64 eyes included, 9 (14.1%) eyes had an improvement in conjunctival lissamine green staining (by ≥ 1 point) at follow-up, 49 (76.6%) eyes had stable staining and 6 (9.4%) eyes had increased staining (by ≥ 1 point) at follow-up. Among the 20 eyes with Schirmer testing, there was a borderline significant increase in score from baseline to follow-up visit (5.9 vs. 9.7, $p=0.06$).

Conclusions: We found that treatment with PRP drops was associated with a significant improvement in OSDI score for patients with ocular surface disease. The majority of eyes treated had stable or decreased lissamine green conjunctival staining at follow-up. Future larger prospective studies are needed to further evaluate the efficacy of PRP drops for treating ocular surface disease.

ABSTRACT BODY:

Purpose: Neovascular glaucoma (NVG) is a debilitating disease secondary to retinal ischemia. This study aims to examine NVG cases at Parkland Memorial Hospital and assess patient characteristics that may have impacted the types of management employed and ultimately the visual acuity (VA) and intraocular pressure (IOP) outcomes. In doing so, we hope to gain helpful insight for the management of future NVG cases.

Methods: This was a retrospective chart review of neovascular glaucoma cases at Parkland Memorial Hospital with at least 6 months of follow up. Outcome metrics included number of glaucoma medications utilized, IOP, VA, and number of surgeries performed.

Results: We found that proliferative diabetic retinopathy (PDR) was by far the most common cause of NVG in our patient population (84.62%), followed by retinal vein occlusion (RVO) (12.09%).

75% of patients with a presenting VA of 20/400 or better underwent primary tube shunt while 50% of patients with presenting VA worse than 20/400 underwent primary cyclophotocoagulation (CPC). For patients who underwent a single surgery, there was no significant difference in IOP outcomes at 1 month ($p=0.92$), 6 months ($p=0.51$), or 1 year ($p=0.70$) after surgery, or at the final follow up ($p=0.13$) between CPC vs. tube shunt. There was also no significant difference in number of surgeries required to control IOP between primary CPC vs. tube shunt cases ($p=0.31$).

Patients with presenting VA of 20/400 or better had significantly better VA at 1 month, 6 months, and 1 year post diagnosis, and at the final follow up visit than those with presenting VA worse than 20/400 ($p<0.05$).

Patients with a presenting systolic blood pressure less than 130 mm Hg had a lower IOP at 1 year post diagnosis than those with a higher systolic pressure ($p=0.02$), but otherwise there was no difference in IOP between the two groups at any of the other measured timepoints ($p>0.05$).

Conclusions: Similar to the general population, we observed that PDR and RVO are the two leading causes of NVG. Our practice pattern is consistent with commonly implemented patterns in that the majority of eyes 20/400 or better visual acuity underwent primary tube shunt while eyes with poorer presenting visual acuity underwent primary CPC. Presenting visual acuity appears to provide insight into a patient's long term visual prognosis. Blood pressure control at presentation also seems to be a modifiable risk factor for progression of NVG.

ABSTRACT BODY:

Purpose: Chronic corneal stromal changes in corneal endothelial dystrophies such as congenital hereditary endothelial dystrophy (CHED) can cause poor visual recovery despite endothelial replacement by endothelial keratoplasty (EK). The poor recovery of visual acuity has been attributed to the persistent corneal haze despite restoration of normal corneal endothelial function after EK. In this pilot study, we sought to investigate whether the persistent corneal haze in CHED is due to alterations in the protein content of the corneal stroma by comparing the proteomic profile of the corneal stroma in CHED to that of healthy corneas.

Methods: Protein profiles of archived formalin fixed paraffin embedded corneas [n=6], 3 CHED and 3 healthy age matched control corneas, age range 12-20 years, were analyzed by liquid chromatography followed by tandem mass spectrometry (LC/MS-MS). Relative protein abundances were determined by spectral counting. G test followed by post hoc Holm Sidak was used for statistical analyses to determine significance in the differential expression of proteins between CHED and the control group. Proteins were classified into functional groups using Protein ANALysis THrough Evolutionary Relationships (PANTHER) classification system.

Results: Using stringent filtering criteria, 11 and 19 proteins were detected at significantly lower and higher levels respectively in the CHED compared to control corneas ($p < 0.05$). Alpha-enolase (3.69-fold), Collagen alpha-2(I) chain (3.29-fold) and a protein similar to Mimecan (3.16-fold) were the top 3 proteins detected at lower levels, whereas the top 3 proteins detected at higher levels were Collagen alpha-2(V) chain (~4.5 fold), Heat shock protein 90kDa alpha (3.84 fold) and Thioredoxin (3.2 fold). The altered proteins are involved in the integrin signaling angiogenesis, cytoskeleton regulation in addition to inflammation and oxidative stress pathways.

Conclusions: CHED eyes using LC/MS-MS revealed significant differences in their corneal stromal protein profile compared to control. Alteration of the different collagens that are involved in the integrin signaling pathway may play a role in the corneal stromal changes and reduced cornea clarity after EK in CHED.

TITLE: Assessment of Oblique Penlight Exam to Estimate Anterior Chamber Depth

SESSION TITLE: Anterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. Garcia, Meharry Medical College School of Medicine, Nashville, Tennessee, UNITED STATES|A. Chomsky, VA Tennessee Valley Healthcare System, Nashville, Tennessee, UNITED STATES|A. Chomsky, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): John Garcia: Commercial Relationship: Code N (No Commercial Relationship) | Amy Chomsky: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to compare the estimated anterior chamber depth (ACD) by oblique penlight examination (OPE) when compared to ACD measured by partial coherence interferometry (PCI).

Methods: The study compromised a retrospective chart review of 172 eyes of 86 patients at VA Tennessee Valley Healthcare System who received an OPE and PCI as part of cataract surgery work-up. These patients had their eyes assessed with OPE by technician staff prior to dilation and received measurements that include ACD by PCI. All technicians received standardized training in performing OPE and had a standardized grading sheet available. Grading was from 1-4 (Grade 1 > ¾ Anterior chamber shadow (ACS), Grade 2 = 1/3-3/4 ACS, Grade 3 < 1/3 ACS, Grade 4 = no shadow). Patients who had prior intraocular surgery or ocular trauma were excluded from the study. One-way ANOVA and correlation analysis of the data was performed to assess statistical significance. The data was also analyzed by t-test as to whether a dichotomous OPE result showed deeper average ACD by PCI in grade 4s versus all grades 1-3.

Results: There were no grade 1s, eight grade 2s, five grade 3s and 159 grade 4s by OPE. The mean and median ACD by PCI were 3.43 and 3.28; with a range of 2.11 to 5.69.

When comparing all data, the one-way ANOVA analysis resulted in a p-value of 0.440014.

The correlation analysis resulted in a p-value of 0.496349. When comparing average ACD by PCI of all grade 4s (3.45) to all grades 1-3 (3.15), the results showed a p value of 0.203082 by t-test.

Conclusions: The results of the one-way ANOVA and correlation analysis reveal no statistical significance that the OPE properly estimates the ACD in comparison to PCI. Additionally, when looking at average ACD of grade 4s versus grades 1-3, there was also no statistical significance. Although this study is limited by its sample size, this study shows OPE does not reliably estimate ACD. Further studies of larger sample sizes are likely to reveal similar results due to the user-error associated with the OPE technique.

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) is the leading cause of dry eye disease (DED). Research over the past decade has pointed to hyperkeratinization, or the build-up and shedding of keratin protein in the Meibomian gland ducts and at the gland orifice, as the root cause of obstructive MGD. Selenium disulfide (SeS₂), a potent keratolytic agent used in dermatologic shampoos for severe dandruff and seborrheic dermatitis, may be used to target meibomian glands' hyperkeratinization and thus be useful in restoring their normal function in patients with MGD. The objective if this in-vitro study was to determine mechanism of action by which SeS₂ effect keratinization, cellular differentiation, proliferation, and adhesion.

Methods: The keratolytic effect (breakdown of disulfide bonds) of SeS₂ was investigated in an ex vivo study of human skin using concentrations of SeS₂; 0.1, 1, or 10 mM. The study measured free thiol levels, which are indicative of a decrease in the number of the disulfide bonds that determine the strength of keratin filaments. The keratostatic effect measured by cell turnover was evaluated using a keratinocyte cell line and human skin. Keratinocytes in an in vitro model were incubated with SeS₂ (500 µM, 1 mM, and 5 mM). Cell turnover was measured using the FACS propidium iodide (PI) and BrdU incorporation assay.

Results: SeS₂ was shown to cause significant keratolytic activity in human skin with a 60% increase in free thiols relative to control at 10 mM ($p < 0.05$). In vitro keratinocyte proliferation 28 hours following first exposure was reduced by up to 90%, ($p < 0.05$) at all concentrations. Similarly, the ex vivo studies, measuring BrdU incorporation at 100 µM, 1 mM, and 10 mM showed that the compound significantly reduced cell turnover by up to 35%, ($p < 0.05$), with accumulation of cells in S phase and G2/M phase during cell cycle (decreased cell division).

Conclusions: The pathogenesis of MGD is a result of accumulation of excess keratin in the gland's canal and within the lipid. The results suggest that Selenium disulfide works in multiple pathways that are involved in MGD including reduced cell turnover and activity of keratinocytes and softening of keratin through the reduction of disulfide bonds. Hence both in vitro and ex vivo models indicate that Selenium disulfide is a promising candidate for the treatment of MGD.

ABSTRACT BODY:

Purpose: To analyze whether any type of visual adaptation induced by Bangerter Filters (BF) exists, beyond changes in the blur perception, in terms of Visual Acuity (VA) measured with the Freiburg VA test.

Methods: 25 young healthy adults were enrolled in the experiment, 18 females and 7 males (mean age: 26.2 ± 2.0 years). VA was measured with the Freiburg test at 4 metres, C-Landolt optotype during 0.3 s of exposure time, 4 orientations and 30 repetitions. The BFs (density 0.6) were mounted on top of neutral spectacles. The VA was retrieved at four time points: natural viewing conditions before wearing BF (AV1); immediately after the incorporation of BF (AV2); after 40 min of vision through BF (AV3); and finally, right after returning to natural vision without BF (AV4). A control group underwent the same experimental procedure under natural vision, without filters. Objective refraction and keratometry values were also assessed before and after the use of the BFs. Regression models were used to fit the variables before and after BF use with statistical software.

Results: The Shapiro-Wilk test yielded a normal distribution for the VA values, although the parameters describing the distributions slightly changed among the 4 measurements. A statistically significant (paired T-student test) increase of 16.7% in VA was found after 40 minutes of vision through the BFs. In contrast, the average VA in the control group exhibited no change with time. The values of objective refraction and keratometry remained constant before and after the use of BFs.

Conclusions: A statistically significant increase in VA was measured after 40 min of continuous vision through BFs, with changes neither in refraction nor in ocular biometry. The results obtained from the control group showed that the VA improvement could not be credited to a learning effect. The VA improvement obtained in the experiment shows a quantitative enhancement in vision after an adaptation time.

ABSTRACT BODY:

Purpose: Meibomian Gland Dysfunction (MGD) is the leading cause of Dry Eye Disease (DED). Reduced secretion of lipids due to MGD leads to instability of the tear film and drying of the ocular surface. Meibomian glands share strong similarities with sebocytes in terms of their embryologic development, structure and holocrine mode of lipid secretion. Treatment of seborrheic dermatitis and Dandruff using Selenium disulfide (SeS₂) shampoo results in about 30% of treated patients complaining of excessive oil on their scalp and sebumeter testing indicated increased amount of sebum over the skin following treatment with SeS₂ shampoo. The objective of this work was to test the hypothesis that SeS₂ can directly induce lipid production in glands producing cells such as meibocytes and sebocytes.

Methods: The ability of SeS₂ to enhance lipid secretion was evaluated in a 3-D cultures of human sebocytes (human cell line SEBO662; BioAlternative, France). First, using a 2-D Sebocyte model, SeS₂ concentration range which did not induce apoptosis of the immortalized sebocyte cell line was determined. Following that, the lipogenic effect was tested in the 3-D culture treated with two Selenium disulfide concentrations and a carrier control. The treated cultures were incubated for 14 days. Oil-red-O stained tissue sections were evaluated to determine lipid production based on the extent of lipid accumulation which was quantified by calculating the lipid droplet surface area in the samples.

Results: When compared to control, lipid production was shown to be significantly increased by 282% (P<0.05) with 0.01 µM and by 348% (P<0.05) with 0.1 µM SeS₂.

Conclusions: Through their lipid secretion the Meibomian glands play a crucial role in maintaining a healthy ocular surface and its optical quality. Located in the upper and lower eyelids, these oil-producing glands are modified sebaceous glands and are responsible for secreting the lipid layer (meibum) that forms the outermost layer of the tear film. The in-vitro results suggest that Selenium disulfide has the potential to improve Meibomian Glands' function by increasing their lipid production. Such outcome may have significant therapeutic effects in patients with MGD

ABSTRACT BODY:

Purpose: Neuropathic ocular pain is a frequent occurrence in medium to severe dry eye syndrome (DES). Only palliative treatments, such as lubricants and anti-inflammatory drugs, are available to alleviate patients' discomfort. Anesthetic drugs are not indicated, because they may interfere with the neural feedback between the cornea and the lacrimal gland, thus impairing tear production and lacrimation. Aim of this study has been to address the analgesic and not anesthetic activity of gabapentin (GBP), given as eye drops on the ocular surface, and to show that it does not decrease lacrimation.

Methods: GBP (2%) or oxybuprocaine (BNX: 0.4%) eye drops were given to rabbits' eyes. Sensibility was estimated by a Cochet-Bonnet esthesiometer and lacrimation measured by Schirmer strips. Pharmacokinetics (PK) was studied by HPLC/MS/MS in eye tissue extracts. Expression of neurotransmitters and aquaporin-5 (AQP5) was detected in lacrimal glands in vivo, and corneal epithelial cells in vitro.

Results: Analgesic effects obtained by GBP instillation were distinct from anesthetic effects after BNX. PK analysis showed that the most part of GBT (97.7% at 30 minutes, and 96.7% at 2 hours) remains in the conjunctiva, and the cornea contains most of the remaining amount (2.1% at 30 minutes, and 2.5% at 2 hours). Schirmer test showed that BNX indeed decreased lacrimation in the first 30 minutes, whereas GBP – unexpectedly – even stimulated it, with an effect lasting 90 minutes. Correspondingly, the neuro-mediators Ach and Ne were decreased in the lacrimal glands after BNX treatment, while they were dramatically increased after GBP treatment. Similar findings were made for AQP5 expression. Notably, GBP also increased AQP5 expression in corneal epithelial cells in vitro.

Conclusions: GBP appears to be endowed with anti-inflammatory (published), analgesic and secretagogue properties. Therefore, topic administration of GBP as eye drops could be the ideal treatment for neuropathic pain caused by severe dry eye.

ABSTRACT BODY:

Purpose: Dark adaptation (DA), a functional outcome measure, is impaired early in age-related macular degeneration (AMD) prior to visual acuity loss. Metabolomics, the qualitative and quantitative analysis of metabolites, have provided insight on multifactorial diseases including AMD. In order to better understand AMD pathogenesis, we performed a study to analyze the association between plasma metabolite levels and DA in AMD.

Methods: Cross-sectional study including both eyes of 71 subjects, 53 with AMD (13 early AMD, 31 intermediate AMD, 9 late AMD) and 18 controls. Participants were imaged with color fundus photographs for AMD classification (Age-Related Eye Disease Study classification). Fasting blood samples were collected and used for metabolomic profiling with ultra-performance liquid chromatography-mass spectrometry (LC-MS). Patients were also tested with the AdaptDx (MacuLogix, Harrisburg, PA) DA 20 minutes protocol. Rod-intercept time (RIT) was assessed and area under the dark adaptation curve (AUDAC) were calculated. Associations between RIT and metabolite levels were tested using multilevel multivariate mixed-effects linear modelling. An alternative analysis was performed using AUDAC as the outcome.

Results: Prolonged RIT was significantly associated ($P < 0.01$) with lower levels of fatty acid-related lipids and higher levels amino acids related to glutamate, leucine, isoleucine, and valine metabolism. Specifically, 8 plasma metabolites were associated with RIT, including 2 amino acids (N-acetylglutamine [$P = 0.005$], +r and N-acetylleucine [$P = 0.008$], +r), 1 carbohydrate (mannitol/sorbitol [$P = 0.003$], +r), and 5 fatty acid-related lipids ([$P < 0.008$], -r). Similar results were found for 14 significant plasma metabolites when AUDAC was used as the outcome, with the addition of 2

nucleotides (beta-alanine [P= 0.002], +r, and xanthine [P= 0.008], -r).

Conclusions: To our knowledge, this is the first report to study the association of metabolites with DA. Our results suggest that reduced levels of fatty acid-related lipids and elevated levels of amino acids may be associated with worse DA (prolonged RIT or increased AUDAC), suggesting that oxidative stress and mitochondrial dysfunction may play a role in AMD and its visual impairment.

TITLE: Treatment zone characteristics in children with slower axial elongation after orthokeratology treatment

SESSION TITLE: Contact Lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Guo, S. Cheung, P. Cho, School of Optometry, The Hong Kong Polytechnic University, Hong Kong, CHINA]

Commercial Relationships Disclosure (Abstract): Biyue Guo: Commercial Relationship: Code N (No Commercial Relationship) | Sin Wan Cheung: Commercial Relationship: Code N (No Commercial Relationship) | Pauline Cho: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the treatment zone characteristics in children with slower axial elongation (AE) after orthokeratology (ortho-k) treatment and potential correlation with myopia control effect

Methods: Pertinent data was retrieved from 34 children (ROMIO: 13; TOSEE: 21) were retrieved: 18 subjects with the slowest AE (0.03 ± 0.12 mm) and 16 subjects with the fastest AE (0.70 ± 0.11 mm) after 24-month lens wear. The subtractive tangential corneal topographical map (24-month visit) was used to determine the treatment zone (TZ), defined as the central flattened area enclosed within points showing no refractive change. Measurements were taken with the cross-sectional line aligning with the horizontal axis and passing through the approximate geometric center of the TZ. The size and depth (maximum dioptric change) of the TZ were determined. Induced myopic defocus was defined as differences between the points with greatest dioptric changes for both temporal (difference between AD) and nasal (difference between BE) as shown in Figure 1. The slopes of corneal power changes (eg. AD/DC or BE/EC in Figure 1) on temporal and nasal sides (along the horizontal cross-sectional line) were estimated manually using print-outs of the graphs. Only data from the right eye were analysed and compared.

Results: Baseline data (refraction, vision, and axial length) did not differ between the fast and the slow progression subjects, but the former were younger (8.68 ± 0.82 vs 9.95 ± 1.49 years; $p = 0.004$). Smaller TZ size were noted in the slow progression group (2.98 ± 0.58 mm vs 3.56 ± 0.80 mm, $p = 0.024$), but no significant correlation between TZ size and axial elongation was found ($r = 0.317$, $p = 0.068$). No significant differences were found in TZ depth, slopes of corneal power change and induced myopic defocus between the two groups.

Conclusions: Slower progressors after ortho-k treatment has statistically smaller TZ size compared to fast progressors. However, no correlation was found between TZ size and axial elongation.

TITLE: Rasch Analysis and Validation of a Timed Instrumental Activities of Daily Living Instrument in Low Vision Patients

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.R. Gobeille, K. Fujiwara, R.W. Massof, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Micaela Gobeille: Commercial Relationship: Code N (No Commercial Relationship) | Kyoko Fujiwara: Commercial Relationship: Code N (No Commercial Relationship) | Robert Massof: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Assess internal and external validity of a Timed Instrumental Activities of Daily Living (TIADL) instrument to evaluate visual ability based on task performance time and error rate for patients with low vision when the instrument is administered in patients' homes.

Methods: Data were collected within patients' homes from patients with low vision receiving home care from an occupational therapist (n=144). Patients completed a series of ADL tasks as quickly and accurately as possible. Tasks included: 2 telephone tasks, 8 cash transaction tasks (i.e. making change), 3 search tasks (i.e. finding items on a shelf), 3 short reading tasks (i.e. reading package information), and a medication management task. Completion time and number of errors were recorded for each task. Data were then quantized and underwent Rasch analysis to estimate the latent visual ability variable based on observed time and accuracy. The Activity Inventory (AI) was also administered and data underwent Rasch analysis to estimate self-reported visual ability.

Results: At baseline, average TIADL task performance time was 26 seconds (range 1-441 seconds), and 72% of the 2561 tasks performed were completed without error.

Pseudo- R^2 was large for TIADL item measures estimated by time (0.996) and error (0.954), as well as for person measures estimated by time (0.929). Pseudo- R^2 for TIADL person measure estimated by error was small (0.16). The distribution of TIADL person measure infit mean squares approximated the expected χ^2/df distribution for both time and error. Item infit z-scores fell within 2 standard deviations of 0 except for one item corresponding to medication management. TIADL item measures estimated from time versus those from error were well correlated ($R=0.73$), while person measures estimated from time versus those from error showed a more moderate correlation ($R=0.38$). Visual ability based on TIADL time was moderately correlated ($R=0.34$) with visual ability based on the AI.

When rehabilitation outcome measures were compared between TIADL time and the AI, change scores were positive (0.65 logit for AI, 0.54 logit for TIADL time) and Cohen's effect sizes were moderate ($d=0.78$ for AI, $d=0.53$ for TIADL time). Weak agreement was seen between AI and TIADL time change scores ($R=0.16$).

Conclusions: Valid outcome measures can be estimated from TIADL performance time when observed in the patient's home environment.

TITLE: A Comparison of Short-term Efficacy and Post-operative Management of Xen Gel Stents to Glaucoma Drainage Devices in a Private Practice Setting.

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Mitchell, J. Nolan, M. Latina, Advanced Glaucoma Specialists, Massachusetts, UNITED STATES|M. Latina, Tufts University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mathew Mitchell: Commercial Relationship: Code N (No Commercial Relationship) | John Nolan: Commercial Relationship: Code N (No Commercial Relationship) | Mark Latina: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The XEN gel stent is touted as comparable to the trabeculectomy, however, many surgeons prefer glaucoma drainage devices (GDD) as a primary glaucoma surgical procedure. To our knowledge there have been no studies comparing XEN to GDD procedures. This study evaluates short-term efficacy and post-op management of the XEN compared to GDD in a real-world private practice setting.

Methods: We performed a retrospective chart review of 123 patients treated with either glaucoma shunt surgery, using Baerveldt, Molteno, or Ahmed valves, or XEN surgery with ab-interno or ab-externo implantation. The IOP, number of glaucoma medications, visits, and needling interventions were determined for the groups over 3 months. Two-tailed Mann-Whitney U Test was used for statistical analysis.

Results: A total of 123 patients were included, 35 males, 24 females with a mean age of 75 in the glaucoma shunt group (GSG)(n=59) and 24 males, 40 females with a mean age of 74 in the Xen stent group (XEN)(n=64). GSG used Baerveldt 250mm (n=4), Molteno 3 185mm (n=15), and Ahmed FP7 (n=27) or S2 (n=13) valves. XEN was inserted internally (n=36), and externally (n=27). Pre-op IOP of GSG (26.2 ± 8.95 mmHg) was not significantly different from XEN (24.0 ± 7.21 mmHg) ($p=0.3$). XEN had greater percent post-op IOP reduction at 1 month (XEN= $37.5\% \pm 28.4\%$, GSG= $23.7\% \pm 30.8\%$, $p=0.008$), however, the reduction was not significantly different at 1 day (XEN= $61.7\% \pm 37.3\%$, GSG= $45.1\% \pm 48.1\%$, $p=0.07$), 1 week (XEN= $57.9\% \pm 23.2\%$, GSG= $44.0\% \pm 35.5\%$, $p=0.06$), and 3 months (XEN= $36.2\% \pm 23.5\%$, GSG= $31.9\% \pm 26.3\%$, $p=0.3$). XEN required more post-op visits over 3 months (XEN= 11.9 ± 4.1 , GSG= 9.53 ± 3.3 , $p=0.0002$). GSG required more IOP-lowering medications at 3 months (3.12 ± 1.08 vs. 2.14 ± 1.46 , $p=0.0003$). Post-op interventions were not significantly different between GSG (1.02 ± 1.23) and XEN (1.34 ± 1.54) ($p=0.3$).

Conclusions: Both the GSG and XEN achieved similar percent reduction in IOP at 3 months of 31.9-36.2%. XEN required significantly more post-op visits, while GSG required significantly more post-op medicines to achieve the reduction in IOP. Although there were more post-op visits in the XEN group, this could be due to lack of experience with the relatively new procedure. In a private practice setting, the two procedures produced a similar IOP reduction at the end of the global period with a slight variation in post-op management.

TITLE: Sociodemographic and Economic Factors in Outcomes of Tube Shunts for Neovascular Glaucoma

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Arbabi, W.S. Shalaby, J. Myers, M. Moster, R. Razeghinejad, L. katz, A. Shukla, Ophthalmology, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amirmohsen Arbabi: Commercial Relationship: Code N (No Commercial Relationship) | Wesam Shalaby: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan S. Myers: Commercial Relationship: Code N (No Commercial Relationship) | Marlene R. Moster: Commercial Relationship: Code N (No Commercial Relationship) | Reza Razeghinejad: Commercial Relationship: Code N (No Commercial Relationship) | L. Jay katz: Commercial Relationship: Code N (No Commercial Relationship) | Aakriti Garg Shukla: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the potential impact of sociodemographic and economic factors on the neovascular glaucoma (NVG) tube shunt surgery outcomes

Methods: This retrospective, single center, comparative case series included consecutive patients who underwent tube shunt surgery for NVG and had ≥ 6 months of follow-up. Regional average adjusted gross income (AGI) was determined by cross-referencing self-reported residential zip codes with average AGI per zip code supplied by the Internal Revenue Service. Two groups were created: 1) lower income - individuals from neighborhoods with the lowest 10% of AGI (near the United States poverty line), 2) higher income – the remaining 90% of individuals. Main outcome measures were visual acuity (VA), intraocular pressure (IOP), and glaucoma medication number at 6 months and the most recent visit.

Results: Mean annual AGI in the higher income group (130 patients) was \$69,596 \pm 39,700 and the lower income group (16 patients) was \$27,487 \pm 1,600 ($P < 0.001$). Age, sex, distance to the clinic, language, and all baseline clinical variables (including VA and IOP) were comparable between groups. Lower income was associated with non-white race (81.3% vs. 52.3%; $P = 0.024$). At month 6, VA in the lower income group (median: HM, range: 20/70 – NLP) was worse than the higher income group (median: CF, range: 20/25 – NLP) (logMAR VA : 2.32 ± 0.8 vs. 1.77 ± 1.1 ; $P = 0.02$); these trends persisted through the most recent visit ($P = 0.043$) (Figure 1). Follow-up IOP and medications were similar between groups.

Conclusions: Our study analyzed a possible relationship between income and outcomes after surgery for NVG and found that despite similar preoperative characteristics in the two groups, those with lower income had significantly worse VA at postoperative month 6 and at their most recent visit. Furthermore, the lower income group had a higher proportion of non-white race, which may have affected surgical outcomes. Additional study on this potential association is warranted and may help guide clinicians in counseling patients and provide further insight regarding reasons for worse visual outcomes in the most vulnerable populations.

TITLE: Transcleral Cyclophotocoagulation Using Slow Burn Technique in Glaucoma Secondary to Vitreoretinal Surgeries: One-Year Results

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Liu, M. Khodeiry, H. Sheheitli, M. Sayed, R.K. Lee, Bascom Palmer Eye Institute, Department of Ophthalmology, University of Miami Miller School of Medicine, Miami, Florida, UNITED STATES|X. Liu, Beijing Tongren Eye Center, Beijing Tongren Hospital, Capital Medical University, Beijing, Beijing, CHINA|

Commercial Relationships Disclosure (Abstract): Xiangxiang Liu: Commercial Relationship: Code N (No Commercial Relationship) | Mohamed Khodeiry: Commercial Relationship: Code N (No Commercial Relationship) | Huda Sheheitli: Commercial Relationship: Code N (No Commercial Relationship) | Mohamed S Sayed: Commercial Relationship: Code N (No Commercial Relationship) | Richard Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The management of secondary glaucoma following vitreoretinal surgeries is challenging as postoperative conjunctival scarring and subconjunctival migration of silicone oil may limit the success of conventional filtration and tube surgeries. We report the treatment outcomes of slow burn transscleral cyclophotocoagulation (TSCPC) as a primary glaucoma surgical technique in the management of secondary glaucoma attributed to prior vitreoretinal surgeries.

Methods: A retrospective study of 18 eyes of 18 patients with medically uncontrolled glaucoma secondary to pars plana vitrectomy (PPV) with silicone oil injection (SOI) and no history of previous incisional glaucoma or cyclodestructive procedures, who underwent TSCPC using slow burn settings (1250-milliwatt power and 4-second duration). The primary outcome: surgical success at 1 year defined as intraocular pressure (IOP) 6 - 21 mmHg and reduced $\geq 20\%$ from baseline, no incisional glaucoma reoperation, and no loss of light-perception vision. Secondary outcomes included glaucoma medication use, visual acuity (VA) changes, and surgical complications.

Results: The mean age of the patients at time of surgery was 52.0 ± 17.4 years, and the mean follow-up duration was 18.1 ± 4.7 months. At 1 year, IOP decreased from 29.7 ± 9.6 mmHg to 14.6 ± 6.5 mmHg with mean IOP reduction of 45.8 % ($p < 0.001$). The baseline number of glaucoma medications was 4.2 ± 0.9 at baseline and 1.9 ± 1.3 at 1 year after TSCPC ($p < 0.001$). A non-significant change in logMAR VA from 1.36 ± 6.8 at baseline to 1.29 ± 0.79 at 1 year was reported ($p=0.722$). The success rate at 1 year was 72.2 %. Two eyes (11.1%) had TSCPC retreatment. One eye (5.6%) required incisional glaucoma reoperation. Complications included: iritis in 2 eyes (11.1%), macular edema in 1 eye (5.6%), hypotony transient in 1 eye (5.6%) and hyphema in 1 eye (5.6%).

Conclusions: Slow burn TSCPC as a primary glaucoma surgical procedure in patients with secondary glaucoma following PPV and SOI has high efficacy and minimal complications. Prospective studies with a larger number of participants are needed to confirm our encouraging results.

TITLE: The association between retinal vascular occlusions and cardiovascular disease subtypes

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Madala, M.H. Goldbaum, M. Bakhoun, The Viterbi Family Department of Ophthalmology, University of California San Diego, La Jolla, California, UNITED STATES|C. Bakhoun, Pediatric Nephrology, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Samantha Madala: Commercial Relationship: Code N (No Commercial Relationship) | Christine Bakhoun: Commercial Relationship: Code N (No Commercial Relationship) | Michael Goldbaum: Commercial Relationship: Code N (No Commercial Relationship) | Mathieu Bakhoun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal vascular occlusions are associated with cardiovascular disease. However, the association of retinal vascular occlusions with different subtypes of cardiovascular disease is not well defined. Additionally, whether retinal vascular occlusions are associated with higher risk of stroke independent of underlying cardiovascular disease is unknown.

Methods: In this cross-sectional study, we reviewed the records of 98,202 individuals who were evaluated by an ophthalmologist or an optometrist at our institution for different clinical indications from July 1, 2015 until July 1, 2020. We identified individuals with retinal vascular occlusions, stroke and cardiovascular diseases including hypertension, diabetes mellitus (DM), carotid disease, coronary heart disease (CHD) and atrial fibrillation (AF) through billing diagnosis codes. All statistical analyses were performed using IBM SPSS version 26. Logistic regression models were used to analyze odds ratios for retinal vascular occlusions and stroke with 95% confidence intervals. Differences between two and three groups were analyzed with Pearson-Chi Square and one-way ANOVA tests, respectively.

Results: The following cardiovascular diseases were significantly associated with retinal vascular occlusion: carotid disease (OR, 3.0; CI 2.5 – 3.6), hypertension (OR, 2.1; CI 1.9 – 2.4) and DM (OR, 1.5; CI 1.3 – 1.7). CHD and AF were not significantly associated with retinal vascular occlusion. Females had lower odds of retinal vascular occlusion (OR, 0.88; CI 0.79 – 0.98). After adjusting for age, sex and underlying cardiovascular co-morbidities, we found that presence of retinal vascular occlusion was associated with an odds ratio for stroke of 2.2 (CI 1.9 – 2.7). The association between retinal vascular occlusion and stroke was significantly higher in individuals younger than 40 years of age, with an odds ratio for stroke of 8.4 (CI 3.6 – 19.6, $p < 0.001$), even after adjusting for sex, hypertension, DM, carotid disease, AF and CHD.

Conclusions: Our findings demonstrate a strong association between retinal vascular occlusion and carotid artery disease, hypertension and DM. Our results also demonstrate that retinal vascular occlusion is significantly associated with stroke, and more strongly so in younger subjects. Individuals who present with retinal vascular occlusion warrant further evaluation for underlying cardiovascular disease and stroke prevention.

ABSTRACT BODY:

Purpose: Falls risk increases with glaucoma. Gait impairments occur in people with glaucoma; however, they do not fully explain why greater visual field loss results in higher fall rates (Mihailovic 2020). Harmonic ratios, which are derived based on the frequency analysis of trunk acceleration signals, quantify step-to-step gait symmetry and have been associated with falls risk in older adults (Bellanca 2013). Harmonic ratios have not been examined in glaucoma. This pilot study tested the hypothesis that gait symmetry will be reduced with worse visual field loss in glaucoma, particularly under sensory challenging conditions and increased attention demands.

Methods: Ten adults with glaucoma (6F/4M, 67±8 years), instrumented with motion capture markers (Vicon Motion Systems Ltd, UK) and accelerometers (Delsys Inc., MA), were asked to walk in 8 conditions with varying floor (hard floor, carpet), light (well-lit, dim) and concurrent information processing (IP) task conditions (no task, auditory IP choice reaction time task). Glaucoma severity was determined using the visual field mean deviation (VF MD) assessed by automated Humphrey perimetry (Zeiss, CA). The VF MD measured in the better/worse eye and averaged across the 10 participants was equal to -2.9±3.8 / -7.5±6.7 dB, respectively. The analyses used mixed linear models with the fixed effects including VF MD either in the better eye or worse eye, floor/light condition, IP condition and the first order interaction of these factors. Subject was added as a random effect. The dependent gait measure was the anteroposterior (AP) harmonic ratio (Bellanca 2013). Statistical significance was set at 0.05.

Results: Visual field MD in the better eye was associated with the AP harmonic ratio ($F(1,8)=11.9$, $p=0.009$), i.e. step-to-step gait symmetry in the anteroposterior direction was reduced with worse visual field loss in the better eye. In addition, the main effect of floor/light condition was associated with the AP harmonic ratio ($F(3,58)=8.4$, $p<0.0001$). Post-hoc analyses found this effect was driven by a change in floor condition. All other effects included in the analyses did not reach statistical significance ($p>0.1$).

Conclusions: Gait symmetry is reduced in glaucoma and thus may be an important metric. Further research is needed to determine if reduced gait symmetry is associated with increased falls risk in this population.

TITLE: Live two-photon calcium imaging in retinal ganglion cells: characterization of early changes in a mouse glaucoma model.

SESSION TITLE: Neurodegeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Shiga, L. Alarcon-Martinez, N. Belforte, H. Quintero, D. Villafranca-Baughman, F. Dotigny, A. Di Polo, Department of Neuroscience, University of Montreal Hospital Research Center (CRHUM), Montreal, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Yukihiro Shiga: Commercial Relationship: Code N (No Commercial Relationship) | Luis Alarcon-Martinez: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Belforte: Commercial Relationship: Code N (No Commercial Relationship) | Heberto Quintero: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Villafranca-Baughman: Commercial Relationship: Code N (No Commercial Relationship) | Florence Dotigny: Commercial Relationship: Code N (No Commercial Relationship) | Adriana Di Polo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Calcium plays a critical role in the regulation of neuronal activity. Our current understanding of calcium dynamics in living retinal ganglion cells (RGCs) and how they are altered in glaucoma is limited. Here, we used two-photon laser scanning microscopy (TPLSM) to investigate i) real-time light-triggered calcium responses in ON and OFF RGCs and their compartments (dendrites, soma, axons), and ii) alterations in light-evoked calcium responses during ocular hypertension damage.

Methods: Live calcium imaging in RGCs was performed by TPLSM in transgenic mice carrying the calcium indicator CGaMP6 (Thy1.GCaMP6) or after intraocular administration of an adeno-associated virus (AAV) encoding GCaMP6. Ocular hypertension was induced by intracameral injection of magnetic microbeads. The following light-evoked calcium responses were measured: i) baseline fluorescence (F_0), ii) peak fluorescence ($\Delta F/F_0$), iii) rise time (T_r : time to reach 1/3 peak $\Delta F/F_0$), and iv) decay time (T_d : time to fall to 1/3 peak $\Delta F/F_0$). Student's t-test or ANOVA were applied (significance = $p < 0.05$).

Results: TPLSM imaging demonstrated distinct light-evoked calcium dynamics among RGC subtypes, with ON cells characterized by higher peak ($\Delta F/F_0$) fluorescence and faster (low T_r) responses than OFF cells (N=8 mice/group, n=~70 cells/group, $p < 0.001$, $p < 0.01$). TPLSM also revealed distinct compartment-dependent calcium responses including lower baseline (F_0) in axons and dendrites relative to soma, and higher peak fluorescence ($\Delta F/F_0$) in axons relative to soma (N=5 mice/group, n=5-7 cells, ANOVA, $p < 0.001$, $p < 0.05$). RGC calcium responses were altered soon after induction of ocular hypertension. For example, ON RGCs transduced with AAV.GCaMP6 displayed a significant increase in T_d values relative to controls (N=4-8 mice/group, n=48-61 cells/group, $p < 0.05$) suggesting delayed calcium signal decay in glaucoma. These results were consistent with those observed in Thy1.GCaMP6 mice (N=7-8 mice/group, n=76-90 cells/group, $p < 0.05$).

Conclusions: Our data support that: i) TPLSM is a powerful tool to assess calcium dynamics in living RGCs with unprecedented spatiotemporal resolution, ii) calcium responses differ among RGC subtypes and subcellular compartments, and iii) calcium dynamics are altered in glaucoma indicating impaired calcium homeostasis in vulnerable RGCs.

ABSTRACT BODY:

Purpose: The projected prevalence of visual impairment (VI) in the USA has been estimated but has not accounted for the increasing prevalence of myopia, particularly in older individuals. We estimate the USA prevalence of VI in 2050 accounting for the changing distribution of both age and myopia.

Methods: 1. Age projections of the USA population in 2050 were taken from the USA census website.
2. Overall prevalence of myopia (−0.50 D or worse) of 49.8% was used, based on Vitale et al. (2008) and Holden et al. (2016).
3. The distribution of myopia, by severity, was calculated using the model of Brennan et al. (2020)
4. VI as a function of age and refractive error was modelled by multiple linear regression from a large data set of an advanced European population (Tideman et al. 2016). This data set is agnostic with respect to the disease condition associated with VI.
5. Finally, by convolving the distributions of myopia and age with the cumulative risk of VI, the number of individuals in the USA with VI in 2050 was calculated.

Results: Of the estimated 2050 USA population of 399.8 million, 199.1 million will be myopic and 29.5 million will have high myopia (< -5D). The cumulative odds of visual impairment (20/40 or worse) is $10^{(0.057\text{Age} - 0.122\text{Rx} - 4.03)}$ and the projected total number with VI is 19.1 million. Of these, 12.6 million will be myopes compared with 6.5 million non-myopes. Given approximately equal numbers of myopes and non-myopes, an estimated 6 million cases of VI will therefore be directly attributed to increased risk of eye disease associated with myopia (= 12.6 – 6.5). Among individuals 65 years and younger, myopes will comprise 75% of individuals with VI, while representing only half of the population. At 82 years, myopes will still account for two-thirds of VI.

Conclusions: Assuming that the data from Tideman et al. are applicable to the USA, we predict that some 30% of VI in the US population in 2050 will be attributable to myopia. Failure to account for the increasing prevalence of myopia among the aging population leads to a substantial underestimate of the prevalence of VI. Approaches that treat disease-states associated with myopia are needed to reduce the threat of VI in the USA.

ABSTRACT BODY:

Purpose: We report a case series of patients with persistent macular holes who underwent human amniotic membrane (hAM) subretinal placement to achieve successful anatomic macular hole closure.

Methods: This is a retrospective review of a non-consecutive case series conducted at New York Eye and Infirmary of Mount Sinai. There were 10 patients from March 2019 to May 2020 who presented with persistently open full-thickness macular holes. All patients underwent subretinal hAM subretinal placement to promote closure of recalcitrant, full-thickness macular holes.

Results: Ten patients, 6 females and 4 males were included in the series. The mean age was 56.7 years (range 20-77 years). Eight of the patients had already undergone pars plana vitrectomy with internal limiting membrane peeling and gas or silicone oil tamponade. One patient's previous surgical history was unknown. One patient had a chronic full-thickness macular hole for over a decade. The mean preoperative BCVA was 1.6 logMAR (20/800) ranging from 2 to 0.8 logMAR (20/2000 – 20/150). Eight patients received gas as tamponade, of which 5 patient received SF6 20-25% and 3 patients received C3F8 10-14%. Two patients received silicone oil as tamponade. Patients were examined 1 day, 1 week, 1 month, 3 months and 6 months. An optical coherence tomography scan was performed at every visit. BCVA improved from mean 1.6 logMAR preoperatively (20/800) to 1.4 logMAR (20/500) 1-month after the surgery. At the 3-month post-operative visit, the BCVA improved to 1.1 logMAR (20/250), for 9 of the 10 patient records available. In all 10 cases, the macular hole appeared closed at the 1 week post-operative visit and remained closed at their last follow-up exam. OCT showed macular hole closure in all the cases. No adverse events such as increase in intraocular pressure or intraocular inflammation were reported during the post-operative period.

Conclusions: For large, chronic, recurrent, or persistent macular holes, the use of amniotic membrane subretinal transplantation may serve as a useful surgical adjunct to promote macular hole closure.

ABSTRACT BODY:

Purpose: Since its discovery, nerve growth factor (NGF) has sparked widespread interest in possible therapeutic utility across neurologic diseases. NGF and other neurotrophic factors are upregulated in neuropathic pain, although their precise role remains to be fully understood. Herein, we assess the possible therapeutic benefit of recombinant human NGF (rhNGF) in the ciliary nerve ligation model of neuropathic corneal pain.

Methods: Adult 7- to 8-week-old male C57BL/6J mice underwent ciliary nerve ligation for the induction of NCP and were treated with six 10 µL drops/day of 0.02mg/mL rhNGF or vehicle (n=6/group). Clinical outcomes were assessed at 7-, 10-, and 14-days post-ligations. Outcomes included corneal fluorescein staining (CFS), Cochet-Bonnet esthesiometry, and challenge with 10 µL of [5M] saline, cold saline, and L-menthol for assessment of pain by the paw wipe response. At day 14, trigeminal ganglia (TG) were excised for qRT-PCR analysis of neurotrophic factors and cytokines.

Results: Ligation did not significantly alter CFS or corneal sensitivity between groups at any time point ($p>0.05$). Animals did not differ in their baseline or post-ligation responses to [5M] saline prior to treatment initiation (16.0 vs 13.0, $p>0.05$; 31.0 vs 31.6, $p>0.05$). There was a persistent decrease in response to [5M] saline in the rhNGF-treated group (Day 7: 21.7 vs 30.2, $p<0.001$; Day 10: 18.0 vs 27.4, $p<0.001$; Day 14: 16.2 vs 28.3, $p<0.0001$). Responses to cold saline were slightly, although not significantly, reduced in the NGF group (Day 7: 5 vs 8.6, Day 10: 5.2 vs 7.8, Day 14: 4.4 vs 7.2; all $p>0.05$). Similar results were obtained with responses to L-menthol (Day 7: 5.0 vs 9.0, $p<0.05$; Day 10: 5.2 vs 7.4, $p>0.05$; Day 14: 2.8 vs 5.8, $p>0.05$). rhNGF treatment reduced levels of several neurotrophic factors in the TG compared to vehicle treatment (BDNF: 0.78 vs 1.00, $p<0.05$; NT-3: 0.25 vs 1.00, $p<0.01$; NT-4/5: 0.11 vs 1.00, $p<0.05$), but did not show increase in pro-inflammatory cytokines (IL-1b: 0.50 vs 1.00, IL-6: 0.92 vs 1.00, TNF-a: 0.69 vs 1.00; all $p>0.05$).

Conclusions: These findings suggest that topical rhNGF treatment improves pain outcomes in our neuropathic corneal pain and warrant future studies in the clinic. Furthermore, qRT-PCR results indicate that topical rhNGF treatment alters expression of neurotrophic factors, but not pro-inflammatory cytokines within the TG.

Yzer, J. van meurs, Rotterdam Ophthalmic Institute, Rotterdam, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Danny Jokl: Commercial Relationship: Code N (No Commercial Relationship) | R Theodore Smith: Commercial Relationship: Code N (No Commercial Relationship) | Rando Allikmets: Commercial Relationship: Code N (No Commercial Relationship) | Sankha Amarakoon: Commercial Relationship: Code N (No Commercial Relationship) | weijia fan: Commercial Relationship: Code N (No Commercial Relationship) | mihai busuioc: Commercial Relationship: Code N (No Commercial Relationship) | Suzanne Yzer: Commercial Relationship: Code N (No Commercial Relationship) | jan van meurs: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose: Can uniocular, peripheral retinal laser influence AMD vision outcome long term?

Methods: Methods: 14 patients with AMD with IRB approval (Rotterdam, The Netherlands (ISRCTN 967546)- and baseline vision (20/20-20/40 OU), consented to uniocular, 200 argon laser 200 μ spots at 200 mV to the superior temporal retina, with the untreated eye as control. At termination, binocular changes in drusen volume and visual acuity were observed. In place of a control, AREDS AAMD long term visual outcomes were used.

11/14, patients, (5 M, 6F; ages 58-83), 3 patients had deceased, were examined a mean of 58 months (12-74 months) with digital fundus photos and drusen images. DNA of 11/14 patients was analyzed for ARMS2 and CFH with AMD-associated SNPs. Masked clinical and genetic data were correlated.

Results: At a significance level of 0.05 - a significant interaction beneficial effect between increasing time from the initial laser treatment was found.

In the treated eye, coefficient for time was 0.0013 ($p=0.0016$) - for every month increase, the average VA increases by 0.0013 units, adjusting for eyes (whether it's the right eye or the left eye).

In the control eye, coefficient for time was 0.0040 (p -value < 0.0001) - for every month increase, the average VA increases by 0.0040 units.

- 64% of the cohort displayed little visual loss after 10 years;

- 27% had uniocular visual loss;

- 9% (one case) had bilateral visual loss.

The two genetic risk alleles showed no correlation with the final visual acuity.

Uniocular retinal laser had a binocular effect on vision outcomes:

91% (10/11subjects) maintained baseline visual acuity in one or both eyes.visual acuity in one or both eyes.

A significant interaction between treatment and time ($p=0.0028$), with better VA for the treated eye was found.

Conclusions: In the presence of alleles for ARMS2 and CFH, functional long term binocular visual outcomes compared favorably to AREDS AAMD long term visual acuity findings,

The mean net change in drusen area in the treated (resp., control) eye was +1.5 resp., -1.1) mm sq, was not significant (paired t test ($p= 0.13$)).

- These serendipitous findings suggests a systemic immune system activation to inflammation induced by uniocular retinal laser.

- Despite limitations of a pilot study, confirmation from a larger controlled study is warranted.

TITLE: Transcription factors mediating the post cataract surgery response

SESSION TITLE: Posterior Capsular Opacification and Fibrosis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.G. Novo, A. Garg, A. Faranda, M.H. Shihan, Y. Wang, M.K. Duncan, Biological Sciences, University of Delaware, Newark, Delaware, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Samuel Novo: Commercial Relationship: Code N (No Commercial Relationship) | Ananya Garg: Commercial Relationship: Code N (No Commercial Relationship) | Adam Faranda: Commercial Relationship: Code N (No Commercial Relationship) | Mahbubul Shihan: Commercial Relationship: Code N (No Commercial Relationship) | Yan Wang: Commercial Relationship: Code N (No Commercial Relationship) | Melinda Duncan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cataract surgery is known to induce ocular inflammation, which if left untreated, can result in damage to other ocular tissues. We have previously reported that the lens epithelial cells (LECs) retained in the eye post cataract surgery (PCS) initiate the expression of inflammatory cytokines 1-2 days prior to their phenotypic transition into the myofibroblasts and aberrant lens fiber cells that cause posterior capsular opacification (PCO). However, the mechanism driving the initiation of inflammatory gene expression in LECs and its relationship to PCO pathogenesis is unknown.

Methods: RNA isolated from wildtype (WT) mouse LECs at 0 and 6 hours after lens fiber cells removal to simulate cataract surgery was used for RNAseq. FosB^{tm1.Nes} mice that carry a floxed FosB allele were bred to MLR10Cre mice, which express Cre recombinase in the lens, to generate a FosB lens conditional knockout (cKO) mice. RNAseq was conducted on the FosB cKO mice similarly to the wildtype (WT) mice. The transcriptomic changes observed were validated by immunostaining WT and FosB cKO mice at various times PCS.

Results: RNAseq revealed that remnant LECs upregulate numerous genes known to contribute to the inflammatory response, smooth muscle cell proliferation, and cell migration by 6 hours PCS. Further, the top most upregulated differentially expressed gene in LECs at 6 hours PCS was FosB, a member of the AP1 complex of transcription factors and an immediate early gene (IEG), which drives the inflammatory, fibrotic, and proliferation response of cells in other systems. FosB protein levels upregulate in LECs by 6 hours PCS and slowly downregulate over the next 5 days PCS. We generated a FosB lens cKO mouse to test the hypothesis that FosB upregulation PCS is important in LEC response to surgery. These lenses develop normally and are transparent into adulthood. Initial analysis of the upregulation of TNC, a classic fibrotic marker, and CXCL1 and COX2, 2 classic inflammatory markers, did not reveal any major changes, however, RNAseq is ongoing to determine globally the role of FosB PCS.

Conclusions: IEGs, including FosB upregulate robustly within 6 hours PCS. FosB is not necessary for lens development or transparency, while its roles in PCO are under active investigation.

ABSTRACT BODY:

Purpose: Chemical injury to the eye leads to ocular hypoxia and inflammation, which in turn contribute to tissue damage and decrease in vision. We have previously demonstrated that a perfluorodecalin-based supersaturated oxygen emulsion (SSOE) reduces optical opacity and tissue fibrosis after alkali burn to mouse corneas. Herein, we aim to determine the effects of SSOE on ocular hypoxia and tissue inflammation after alkali burn.

Methods: SSOE containing 25% oxygen-carrier perfluorodecalin was manufactured in hyperbaric condition. Alkali burn was induced by placing a 2-mm-diameter filter paper disc soaked with 1M sodium hydroxide solution onto the central cornea of BALB/C mouse for 20 seconds, followed by irrigation with PBS until the pH level of the ocular surface returned to 7. 50 μ l SSOE or non-oxygenated emulsion (vehicle control) was applied to the cornea immediately after burn for 30 minutes. The anterior chamber oxygen concentration was recorded using the DP-PSt7-2 oxygen sensor. Cell apoptosis was determined with TUNEL staining. The expression of inflammatory markers IL-1 β and MMP9 was determined with real-time PCR, and the infiltration of CD45⁺ cells to the cornea and conjunctiva was evaluated by immunostaining and flow cytometry, respectively.

Results: Alkali burn led to a 60% decrease (165 vs 66 μ mol/L, $P < 0.0001$) in the anterior chamber oxygen concentration, which was reversed and further increased (535 μ mol/L, almost 3 times over atmospheric level) by topical application of SSOE, but not the vehicle control. Alkali burn led to cell apoptosis in all layers of the cornea at 1 hour, whereas in SSOE-treated eyes, apoptotic cells were only seen at the superficial epithelial layer (TUNEL-positive cell 100% in control vs 45% in SSOE group, $P = 0.025$). Moreover, SSOE reduced apoptosis of lens epithelial cells (60% in control vs 17% in SSOE group, $P = 0.004$). SSOE treatment reduced the expression of IL-1 β in the cornea ($P = 0.003$) and of MMP9 in the iris/ciliary body ($P = 0.049$). In addition, SSOE treatment decreased the infiltration of CD45⁺ inflammatory cells in the cornea and conjunctiva (27.8% in control vs 19.9% in SSOE group, $P = 0.002$) at 24h after alkali burn.

Conclusions: Topical application of SSOE reduces tissue hypoxia, cell apoptosis, and inflammation after alkali burn. These are the potential mechanisms underlying the therapeutic efficacy of SSOE in treating chemical injury.

ABSTRACT BODY:

Purpose: To determine the safety and efficacy of corneal photovitrification (CPV), a new corneal laser procedure, for vision improvement in patients with late stage age-related macular degeneration (AMD) and other retinal disorders involving central vision loss.

Methods: In this retrospective observational cohort study, 60 treated (46 wet AMD - most of which continued to receive anti-VEGF injections, 8 dry AMD, 6 other) and 24 untreated eyes of 42 patients (22F, 20M, 77.7 ± 10.4y) received pre-Tx best corrected distance visual acuity (BCDVA) and potential visual acuity (PVA) examinations and post-Tx BCDVA examinations at 1 month (1m), 3m, 6m and 12m follow-up times. Analyses included descriptive statistics (mean ± SD), Wilcoxon signed rank tests (p-values for post- vs. pre-Tx) for BCDVA, and Pearson correlation coefficients (PCCs) for logMAR values of post-Tx BCDVA vs. pre-Tx PVA.

Results: Safety - No complications or adverse events occurred.

Efficacy - Mean (± SD) BCDVA of treated eyes improved significantly (p=0.0022) from 20/316 (1.20 logMAR) at baseline to 20/200 (1.00 logMAR) at 12m post-Tx, corresponding to 16.7 (± 9.3) letters gained. Mean (± SD) BCDVA of treated eyes also improved significantly with 8.4 (± 11.2), 12.7 (± 15.9) and 9.3 (± 9.3) letters gained at 1m, 3m and 6m, respectively. BCDVA changes of untreated eyes were as large as 2.9 ± 5.1 letters gained at 12m post-Tx, but were not statistically significant.

PVA - At baseline, the mean (± SD) PVA value of treated eyes was 20.8 (± 10.6) letters better than the mean (± SD) BCDVA value, indicating great potential for improvement, but actual mean BCDVA improvements were in the range of 40 to 80% of the PVA "prediction". PCCs for post-Tx BCDVA logMAR values of treated eyes vs. pre-Tx PVA logMAR values were positive and large: 0.71, 0.56, 0.80 and 0.63 at 1m, 3m, 6m and 12m, respectively.

Conclusions: The CPV corneal laser procedure provides significant vision (BCDVA) improvements in patients with late stage AMD and other retinal disorders with central vision loss. The BCDVA improvements correlate well with PVA "predictions".

ABSTRACT BODY:

Purpose: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a respiratory virus that initially appeared in Wuhan, China in December of 2019. It quickly spread around the globe with the World Health Organization declaring the outbreak a pandemic on March 11, 2020. With rapidly changing national and global guidelines researchers at Temple University (Philadelphia, PA) surveyed ophthalmologists across the United States to examine their response to the pandemic during the months of April 2020 to July 2020.

Methods: The survey is a population based, cross-sectional study. Participants were identified on April 21, 2020 with the "Find an Ophthalmologist" feature on the American Academy of Ophthalmology's website allowing for random retrieval of contact information across the 50 states, ensuring a random sampling of participants by state and general demographics. We distributed the survey via email with responses collected between April and July 2020. We sent 2,299 emails and collected 147 responses (response rate of 6%). Results were compiled and analyzed using the Google Survey Tool.

Results: Ophthalmologists of every specialty, practice type, and geographic region responded. Patient visits across the country fell with 41.8% of respondents seeing less than 25% of their usual volume. Only 20.5% of ophthalmology practices were seeing 26-50% of their patients, 12.3% of practices were seeing 51-75% of patients, and 11.6% of practices were still seeing 76-100% of their patients; 13.7% of ophthalmology practices saw no patients at all. The most common changes implemented were physicians and staff masking (97.29%), decreasing ancillary staff (96.66%), patients masking (95.24%), and cleaning rooms between patients (91.84%). In the office, 61.0% of respondents implemented telemedicine software with another 47.1% indicating they plan to use telehealth at a later date. In our survey, 42.9% of respondents indicated they were performing elective procedures with 68% of respondents stating surgical masks were appropriate for short, low risk procedures compared to 80% of respondents stating N95 was most appropriate for high risk, short cases of less than one-hour duration.

Conclusions: The majority of respondents followed national trends and adhered to CDC and AAO recommendations. Significant financial burden and unpredictable viral trends further emphasize the importance of continual monitoring and adherence to established guidelines.

ABSTRACT BODY:

Purpose: Neuroinflammatory processes and neurodegeneration are important elements of ischemic retinopathies including diabetic retinopathy (DR). There is a great need for therapies targeting earlier disease before irreversible damage. Soluble guanylate cyclase (sGC) exhibits neuroprotective effects in the central nervous system, but its expression and role in the retina remains unclear. sGC activators might be of potential benefit, especially since they can act on sGC rendered nonfunctional by oxidative stress. The purpose of this study was to evaluate the effect of a novel sGC activator, runcaciguat, in retinal ischemia-reperfusion (I/R) and DR animal models.

Methods: Expression of sGC alpha and beta subunits was evaluated in post-mortem human retina specimens by immunohistochemistry. Transient retinal ischemia-reperfusion was induced in rats by elevation of the intraocular pressure for 20-45 minutes. Streptozotocin injection was used to induce diabetes in other rats. Genome wide expression and RNA Sequencing analyses were performed following I/R. Oral runcaciguat (0.1-10 mg/kg PO QD) was evaluated in a prophylactic and/or interventional setting. Treatment effect on retinal morphology and function were evaluated by histological staining, optokinetic testing (OKT), and electroretinography (ERG).

Results: In addition to retinal blood vessels, multiple human neuronal elements expressed both sGC alpha and beta subunits, including retinal ganglion cells. I/R upregulated multiple inflammatory chemokines, including Ccl2, Cxcl10, Ccl3, Ccl4, and Timp1, at 1 hour after reperfusion and peaking by 6 hours. Runcaciguat-treated rats exhibited better visual acuity compared with vehicle (0.17 ± 0.03 cycle/degree vs. 0.02 ± 0.01 cycle/degree, p value < 0.0001) as measured by OKT, and neuroretinal function as measured by ERG. Runcaciguat-treated rats had improved morphology including increased inner plexiform layer thickness. Runcaciguat-treated diabetic rats exhibited superior neuroretinal function by ERG (312.3 ± 65.5 μ v vs 182.3 ± 60.4 μ v) and increased inner plexiform layer thickness (31.95 ± 11.94 μ m vs 27.93 ± 10.21 μ m) and ganglion cell count, compared to vehicle treatment.

Conclusions: The anti-inflammatory and neuroprotective effects of runcaciguat support sGC as a novel early therapeutic target for diabetic and other ischemic retinopathies.

ABSTRACT BODY:

Purpose: To characterize the macular ganglion cell layer plexus (GCLP) boundaries using projection-resolved optical coherence tomographic angiography (PR-OCTA) in healthy eyes.

Methods: Participants were scanned using a commercial OCTA system (RTVue-XR Avanti; Optovue Inc, Fremont CA) in a 6×6-mm area centered on the foveal avascular zone. The split spectrum amplitude decorrelation angiography algorithm (SSADA) was applied to detect flow signal. The GCLP anterior boundary was marked at the nerve fiber layer (NFL)-GCL junction. PR-OCTA algorithm was used to remove flow projection artifacts. Ganglion cell and inner plexiform layer (GCIPL) was divided into 20 equal slabs. In each slab, vessel density (VD) in each polar coordinate sector (Figure 1) were measured using a custom software with automatic shadow exclusion and reflectance compensation. Fifth-degree polynomial fit was used to analyze the correlation between VD and depth in the GCIPL and estimate the boundary between GCIPL and intermediate capillary plexus.

Results: 38 normal participants (78.9% female) were enrolled, and one eye in each participant was studied. Mean age and standard deviation was 59.6±10.7. The watershed (depth of minimum VD) between the GCLP and the intermediate capillary plexus (ICP) is located at 75% depth within the GCIPL (Figure 2) throughout the macula. GCLP VD was significantly ($p<0.0001$) correlated with GCIPL and macular ganglion cell complex (GCC) thickness ($r=0.443$, and $r=0.857$, respectively). The correlation was significantly stronger for macular GCC compared to GCIPL ($z=-3.3$, $p<0.001$).

Conclusions: Macular GCLP supplies the anterior 75% of the GCIPL. Its density is better correlated with GCC, which also contain the NFL, than with the GCIPL, suggesting that it also supplies the posterior aspect of the NFL. Mapping the macular GCLP may be useful in evaluating ganglion cell perfusion in glaucoma and optic neuropathies.

ABSTRACT BODY:

Purpose: Uncertainty exists regarding the safety of intravitreal brolucizumab (IVB) in patients with nAMD post hoc clinical trials. We performed a retrospective clinical analysis to investigate the relative risk of adverse events and adjunctive treatment costs in a year-long cohort study designed to analyze pre-treated anti-VEGF eyes that converted to IVB.

Methods: We performed a chart review of 144 patients (64 male, mean age 77.6 ± 11.8) who received treatment between 10/1/2019-12/4/2020. Qualifying criteria were: IVB initiated between 11/2019-4/2020 and previous anti-VEGF treatment. Random selection of 155 patients (mean age 82.14 ± 9.8) treated with intravitreal aflibercept (IVA) for nAMD at the same institution in this time period was used for comparison. Patients underwent eye exams aided by optical coherence tomography. Additional diagnostics were given upon clinical judgment. Adverse events were classified as Uveitis, Retinal Artery Occlusion (RAO), or Anterior chamber inflammation (ACI). Number of follow-ups and associated healthcare expenditures were used to assess costs. Key outcome measure for safety evaluation was best-corrected visual acuity (BCVA).

Results: Total of 16 eyes (11.1%) with IVB had adverse events versus 1 uveitis case in the IVA group (0.64%). Eyes that switched to IVB were significant for higher inflammatory rates ($p < 0.0001$) with relative risk of 17.2 compared to IVA. Of the IVB events, 4.9% were Uveitis, 2.8% RAO, and 4.2% ACI. Mean baseline ETDRS letters was 52.58 vs 45.37 at the last examination with an overall decreased BCVA (-7.20 ETDRS). BCVA ± 2 lines were maintained in 68.8% of patients at the last exam. Total treatment costs were \$14,128 to \$1,336 in IVA. On average, the adjunct cost was \$883 per patient on IVB.

Conclusions: Use of IVB was significant for increased risks versus IVA in eyes with prior anti-VEGF. With \$883 per event added to the marketed q12W cost, IVB is still cost efficient by \$3237 versus an q8W IVA regimen in 1 year. While lower costs make IVB an attractive alternative for nAMD treatment, increased risks compounded by higher individual treatment costs is dramatic compared to IVA. Additional follow-ups with potential irreversible vision loss increase patient burden and warrant extra caution with IVB use. Prospective study >1 year would aid this evaluation.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is the most common cause of failure of retinal reattachment surgery. There is no available pharmacologic treatment for PVR. The molecular pathways involved in the initiation and progression of PVR are poorly understood. In this study, we sought to identify the genes and transcriptional networks involved in PVR progression.

Methods: All animal procedures were conducted in accordance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research and were approved by the Johns Hopkins Animal Care and Use Committee. PVR was induced unilaterally in specific pathogen free Dutch Belted rabbits by vitrectomy, retinotomy, retinal detachment, platelet-rich plasma injection, and cryotherapy. At different time points after PVR induction, extracted retinas were dissociated into either single cells or single nuclei. Samples were processed to assess the transcriptional profile using single cell or single nucleus RNA sequencing (sc-RNAseq or sn-RNAseq). Fellow eyes were used as non-PVR controls.

Results: Retinas (N=9) were harvested at time points ranging from four hours to 30 days after PVR induction. We profiled >40,000 single cells and nuclei in this study. Retinal pigment epithelium cells, glial cells, and neural retinal cell types were identified in the sc-RNAseq and sn-RNAseq data sets using selected marker genes. The data identified several candidate genes involved in PVR progression, including inflammatory response and cellular proliferation genes. Pseudotime analysis was performed to examine progression from control conditions to early and late stage PVR.

Conclusions: Our high throughput analysis identified several genes that were differentially expressed between control and disease states. SnRNA-seq may have an advantage over scRNA-seq as it can reduce dissociation-induced cellular stress responses. These studies support snRNA-seq and sc-RNAseq as useful tools to study transcriptional networks in animal models of PVR and to identify novel molecular targets for potential pharmacologic modulation.

ABSTRACT BODY:

Purpose: To Rasch calibrate and evaluate performance of a previously developed questionnaire evaluating symptoms of childhood intermittent exotropia (IXT).

Methods: An initial 22-item questionnaire was developed based on interviews of children with IXT and their parents. The questionnaire had been previously reduced to 7 items by selecting items associated with reduced health-related quality of life (Hatt SR et al,2016). In the present study, the 7-item child IXT symptom questionnaire, with 3 response options, was completed by 386 children age 3 to 10 years old who were enrolled in an RCT comparing overminus to non-overminus glasses, with follow-up exams at 6 and 12 months on treatment and at 18 months (after overminus had been weaned). Factor analysis was performed to determine dimensionality, and Rasch analysis was performed to evaluate questionnaire performance and obtain logit values(converted to a 0 (no symptoms) to 100 scale). Overall differences between time points were assessed using the paired t-statistic. Differences between treatment groups and 95% confidence intervals (CIs) were estimated using ANCOVA, adjusted for baseline scores.

Results: The childhood IXT symptom questionnaire was unidimensional. Response ordering was appropriate. There was no notable local dependence, no significant differential item functioning for sex or age, but suboptimal targeting (mean -1.62 logits) and poor person separation (0.95). Overall, 6-, 12-, and 18-month scores were similar, and all showed significant improvement from baseline (Mean differences from baseline: -5.3 pts, 95% CI -7.2 to -3.4 at 6 months, -6.6 pts 95% CI -8.6 to -4.6 at 12 months, -5.7 pts 95% CI -8.1 to -3.4 at 18 months). There was no significant difference in the IXT symptom score between children treated with overminus and non-overminus glasses while on treatment (mean 28.8 vs 31.1 points; mean difference -3.0, 95% CI -6.2 to 0.1 at 6 months, and 28.4 s vs 28.1 points; mean difference 0.2, 95% CI -2.9 to 3.4 at 12 months).

Conclusions: The Rasch scored childhood IXT symptom questionnaire showed reasonable psychometric performance and was able to detect improvement in symptoms after 6, 12, and 18 months of either overminus or non-overminus glasses treatment. Overminus glasses treatment does not appear to reduce child-reported symptoms of IXT more than non-overminus.

ABSTRACT BODY:

Purpose: Accuracy of medication data in electronic health records (EHRs) is essential for patient care and research. Previous work has shown frequent errors in medication lists include incomplete records, duplicated prescriptions, and failed discontinuation of medications. Since medication lists are inaccurate, physicians often record medication information in progress notes, which is difficult to automatically extract since notes are written as free-text narratives. The purpose of this study is to develop a natural language processing (NLP) model for automatically extracting medication information from free-text notes for glaucoma patients. Medication is a crucial part of glaucoma treatment and is important for glaucoma research such as predicting disease progression.

Methods: We used an NLP technique called Named Entity Recognition (NER) to extract medication information from clinical notes. First, we sampled a dataset of 296 progress notes from office visits at OHSU in 2019 with ICD10 codes associated with glaucoma. Next, we manually annotated text in each note for six entities related to medication. Figure 1 displays an example of the annotation. Next, we developed and evaluated an NER model with the Python spaCy package, using the annotated dataset randomly split into 75% for training and 25% for testing. Finally, we evaluated the results of the NER model's extraction for the test set comparing the manually annotated and the NER model's extracted entities using F1 score, precision, and recall.

Results: Table 1 shows the overall and per-entity performance for the NER model on test data. The NER model had an overall F1 score = 0.949, precision = 0.944, and recall = 0.953. The F1 scores for the entities ranged from 0.97 for the "Route" and 0.91 for the "Dosage". An error analysis was performed for false negative and positive on all entities. Several causes of errors were identified, including differences in note formatting, ambiguous annotation, and misclassification when medication information was contained in multiple short sentences.

Conclusions: This study shows that NLP can be used to accurately extract glaucoma medication information from free-text EHR data; the performance of our model is similar to the best performing published NLP models for medication extraction studies. This has implications in improving the data quality and usefulness for medication data in glaucoma research.

ABSTRACT BODY:

Purpose: To investigate the characteristics of cataract surgery-related malpractice between 2000 and 2020.

Methods: All U.S. medical malpractice civil trials involving patients who suffered complications of cataract surgery were retrospectively searched in the LexisNexis legal database between January 1, 2000 and December 1, 2020. Available data was collected on each case. Monetary amounts were inflation-adjusted to 2020 dollars. Data collection and descriptive statistical analyses were conducted using the Statistical Package for the Social Sciences with $p < 0.05$ for significance.

Results: Over the past 20 years, 482 cataract surgery litigations were identified in the LexisNexis database, filed in 37 states. New York (27.5%), Florida (8.9%), and California (8.3%) were the top three states with the greatest number of cases. Of the cases where the age was known, the majority of plaintiffs were between the ages of 60-79. 48.5% of verdicts were for the defendant, 11.8% were for the plaintiff, and 30.5% were settled. The remaining cases were either dismissed, pending, discontinued, mediated, or other/unknown. The leading reasons for litigation were retinal detachment and endophthalmitis. The average amounts demanded, offered, and awarded were \$1,224,061, \$241,314, and \$1,350,600 respectively. When comparing between the decades of 2000-2010 and 2011-2020, there was a significant increase in the amounts demanded ($p = 0.039$, Mann Whitney U test) in the second decade compared to the first with no significant increase in the amounts awarded ($p = 0.118$, Mann Whitney U test).

Conclusions: Almost half of reviewed cataract-related malpractice litigation resulted in a defendant verdict.

Settlements or plaintiff verdicts were very costly with amounts awarded averaging above \$1 million. Over the past decade, while plaintiffs are demanding significantly more, there was no significant increase in awarded amounts.

Commercial Relationships Disclosure (Abstract): Ehtesham Shamsher: Commercial Relationship: Code N (No Commercial Relationship) | Li Guo: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Davis: Commercial Relationship(s);UCLB:Code P (Patent) | Vy Luong: Commercial Relationship: Code N (No Commercial Relationship) | Nivedita Ravindran: Commercial Relationship: Code N (No Commercial Relationship) | Satyanarayana Somavarapu: Commercial Relationship(s);UCLB:Code P (Patent) | M Francesca Cordeiro: Commercial Relationship(s);UCLB:Code P (Patent)

ABSTRACT BODY:

Purpose: Resveratrol is a natural polyphenol found in red wine and dark chocolate known for its antioxidant, anti-inflammatory and anti-apoptotic properties. All these properties can be used to treat neurodegenerative diseases such as glaucoma. To date, resveratrol low solubility in water and bioavailability limits its clinical use. The goal of this study was to develop a novel nanoparticle formulation of resveratrol and to assess it in an ocular hypertension (OHT) rat model of glaucoma.

Methods: Resveratrol nanoparticles (RNs) were formulated using a thin film rehydration technique. OHT rat model was induced with the injection of 1.85 M normal saline solution in two episcleral veins of the left eye of 10 Dark Agouti rats. The right eye was used as an internal control. RNs (n=5) or vehicle (n=5) were given topically as an eye drop daily for 3 weeks from induction. After 3 weeks, rats were imaged with the Detection of Apoptosing Retinal Cells (DARC) technology. DARC count was defined as the number of apoptosing retinal cells counted by a masked investigator. Next, all rats were sacrificed, and their retinas immunostained with Brn3a antibody. Retinal Ganglion Cell (RGC) density ratio was defined as the ratio between the left treated and the right untreated eye (control).

Results: RNs were formulated with an encapsulation efficiency >70% and a stability >90 days. They were well-tolerated without any sign of ocular irritation. RN treatment was found to significantly reduce RGC loss compared to the vehicle (1.02 ± 0.05 vs 0.70 ± 0.11 RGC density ratio, $p < 0.05$). RNs did not reduce the Intraocular Pressure (IOP) suggesting that their neuroprotective effect was independent of IOP, although this effect was not found to be significant in the DARC count compared to the vehicle (493 ± 83 vs 612 ± 84 DARC count, $p > 0.05$).

Conclusions: These promising results show that topical administration of RNs was neuroprotective and well-tolerated in an OHT glaucoma rat model by reducing significantly RGC loss. This effect appears to be independent of IOP, but was not seen in the DARC count. We suggest larger studies are needed to confirm these encouraging results.

ABSTRACT BODY:

Purpose: Using optical coherence tomography angiography (OCTA), this study seeks to compare intrасession repeatability and intersession reproducibility of macular vessel parameters in glaucoma and non-glaucoma subjects.

Methods: A series of 6x6mm macular optical coherence tomography angiography scans (Cirrus HD-OCT 5000) were acquired from both glaucomatous and non-glaucomatous subjects as part of an observational, longitudinal study. Next, vessel area density (VAD), vessel skeleton density (VSD), and flux were calculated using a research-based quantification software. Additionally, perfusion density (PD_Z) and vessel density (VD_Z) were calculated using commercially developed software (Cirrus 11.0, Carl Zeiss Meditec). Finally, the intrасession repeatability and intersession reproducibility of these macular parameters were determined using the following statistical parameters: within-eye standard deviation (S_W), within-eye coefficient of repeatability (CR_W), within-eye coefficient of variation (CV_W), and intraclass correlation coefficients (ICC).

Results: The intrасession CV_W from the non-glaucoma group (n=75) was 1.466 for VAD, 1.150 for VSD, 5.203 for PD_Z , and 4.836 for VD_Z while the intersession CV_W from the non-glaucoma group (n=53) was 2.245 for VAD, 1.411 for VSD, 6.971 for PD_Z , and 6.564 for VD_Z . The intrасession CV_W from the glaucoma group (n=60) was 1.294 for VAD, 1.006 for VSD, 4.910 for PD_Z , and 4.516 for VD_Z while the intersession CV_W from the glaucoma group (n=40) was 1.899 for VAD, 1.228 for VSD, 5.858 for PD_Z , and 5.532 for VD_Z . Non-glaucomatous intrасession ICC ranged from 0.561 for PD_Z to 0.795 for VAD while non-glaucomatous intersession ICC ranged from 0.334 for PD_Z to 0.740 for VSD. Glaucomatous intrасession ICC ranged from 0.728 for PD_Z to 0.894 for VAD while glaucomatous intersession ICC ranged from 0.541 for PD_Z to 0.780 for VSD.

Conclusions: Macular OCTA parameters had greater intrасession repeatability than intersession reproducibility for both glaucomatous and non-glaucomatous eyes. Additionally, the macular parameters analyzed by the research-based software demonstrated higher repeatability than the commercial parameters across both non-glaucomatous and glaucomatous eyes.

Mauger, Department of Ophthalmology and Visual Sciences, West Virginia University, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): William Bloom: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Smith: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Hendershot: Commercial Relationship: Code N (No Commercial Relationship) | Rebecca Kuennen: Commercial Relationship: Code N (No Commercial Relationship) | Tyler Oostra: Commercial Relationship: Code N (No Commercial Relationship) | William Terrell: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Mauger: Commercial Relationship: Code N (No Commercial Relationship) | Colleen Cebulla: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The ability to view the posterior segment in keratoprosthesis (Kpro) implanted patients is limited. The purpose of this retrospective, observational study was to investigate the use of ultra-wide field (UWF) scanning laser ophthalmoscopy imaging and its utility for serial evaluation of the retina and optic nerve in patients with either a Boston type I or II Kpro.

Methods: A retrospective chart review of patients with Boston type I or II Kpro seen at The Ohio State University Wexner Medical Center between 2009 and 2020 was performed under an IRB-approved protocol. Twenty-eight Kpro patients were identified. Fifteen eyes from 14 patients implanted with a Boston type I or II Kpro underwent UWF imaging (UWFI) as standard of care using the Optos imaging system and were consecutively enrolled into this study. A total of 35 patient visits included UWFI. Images were graded for quality by a single masked reader on a defined 4-point scale ("Poor", "Fair", "Good", or "Very Good") and assessed for clinical pathology of the retina and optic nerve. Clinical characteristics and examination findings were described using descriptive statistics.

Results: Fourteen of the 15 eyes (93.3%) had a type I Kpro, while one eye (6.7%) had a type II Kpro. UWFI from 35 patient visits were reviewed for quality and clinical pathology. 2.9% of images (1/35) were graded as "poor" and provided no visualization of posterior segment structures. 97.1% of images (34/35) were deemed "fair", "good", or "very good" and provided at least some clinical utility. Clinically useful images were obtained on both type I and type II Kpro implanted patients. The optic nerve and macula were both visible in 94.3% of images (33/35). Clinical pathology included glaucoma, macular degeneration, and repaired retinal detachment. In 4 eyes, UWFI was performed serially at multiple visits (range: 3-9 individual visits), allowing for longitudinal follow up (range: 3-46 months).

Conclusions: UWFI provides adequate visualization of the posterior segment in Kpro implanted patients. Importantly, this imaging modality allowed noninvasive longitudinal monitoring of retinal and optic nerve clinical pathology in this select patient population. To the best of our knowledge, this is the first study to report the use of UWFI in a patient implanted with a type II Kpro.

ABSTRACT BODY:

Purpose: Electronic cigarette (e-cig) use in young adults has increased dramatically, the long-term effects of which are largely unknown. Acute impaired microvascular function and endothelial vascular dysfunction have been observed during e-cig use but chronic vascular effects of use remain underexplored, especially in the delicate and highly metabolically active retina where such effects might present earlier. We performed a cross sectional clinical observational study to determine if there are differences at baseline in the microvasculature and central retinal thickness (CRT) between e-cig users and age matched non-user controls using OCTA.

Methods: We obtained 10x10 scan angle images of right and left maculae in 26 adult daily e-cig users and right eye maculae in 25 age matched controls using an OCTA integrated Spectralis SD-OCT tabletop system (Heidelberg Engineering, Germany). A customized MATLAB algorithm was used to calculate foveal avascular zone (FAZ), vessel area density (VAD), and vessel length density (VLD) for the superficial and deep vascular complexes (SVC and DVC). Spectralis software was used to calculate foveal, superior, inferior, nasal, and temporal CRT. Wilcoxon rank sum tests were used to assess variability of FAZ, VAD, VLD, and CRT parameters between groups and differential contribution of e-liquid concentration and years of e-sig use.

Results: Images were acquired in 52 e-cig user eyes (n= 26, mean age 27.8 ± 6.72 yrs) and 25 non-user age matched controls (n=25, mean age 28.04 ± 4.53 yrs). FAZ, VAD, VLD, and CRT were measured in all 77 eyes. No statistically significant difference was found between users and non-users for FAZ, SVC VAD, SVC VLD, or DVC VAD. A statistically significant difference was found for DVC VLD ($p=.0003$), with e-cig users having a slightly higher VLD on average. Inferior CRT was significantly thinner in users compared to non-users ($p=.012$). E-liquid concentration significantly correlated with thinner inferior CRT in e-cig users ($P > F .0408$).

Conclusions: Overall, no significant negative differences were found in the retinal microvasculature parameters between e-cig users and non-users. Decreased inferior CRT in e-cig users might not be clinically meaningful at this time but warrants further assessment of retinal effects as this population ages and continues to use e-cigs.

TITLE: An explainable AI model to predict electrode deactivation in retinal prostheses from routine clinical measures

SESSION TITLE: Retinitis pigmentosa/ retinal prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Beyeler, Psychological & Brain Sciences, University of California Santa Barbara, Santa Barbara, California, UNITED STATES|M. Beyeler, Z. Hu, Computer Science, University of California Santa Barbara, Santa Barbara, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Beyeler: Commercial Relationship: Code N (No Commercial Relationship) | Zuying Hu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To provide appropriate levels of stimulation, retinal prostheses must be calibrated to an individual's perceptual thresholds ("system fitting"). Nonfunctional electrodes may then be deactivated to reduce power consumption and improve visual outcomes. However, thresholds vary drastically not just across electrodes but also over time, thus calling for a more flexible electrode deactivation strategy. Here we present an explainable artificial intelligence (XAI) model fit on a large longitudinal dataset that can 1) predict at which point in time the manufacturer chose to deactivate an electrode as a function of routine clinical measures ("predictors") and 2) reveal which of these predictors were most important.

Methods: We analyzed a longitudinal dataset of 5496 perceptual thresholds and electrode impedances measured on 627 electrodes in 12 Argus II patients (Second Sight Medical Products). The data was collected from 2007-2018 during 285 sessions conducted at 7 different implant centers. To prepare the raw data for machine learning, we combined threshold and impedance values with clinical data crowd-sourced from the literature, and split the features into three different categories: 1) Routinely collected data (e.g., age at blindness onset, age at implant surgery), 2) System fitting (e.g., thresholds, impedances, charge density limits), and 3) Follow-up examinations (more recent threshold and impedance measurements). We then used gradient boosting (XGBoost), a powerful XAI model based on decision trees, to predict electrode deactivation as a function of these features.

Results: The model predicted electrode deactivation from routinely collected data with 60.8% accuracy. Performance increased to 75.3% with system fitting data, and to 84% when thresholds from follow-up examinations were available. The model further identified subject age and time since blindness onset as important predictors of electrode deactivation.

Conclusions: On the one hand, these findings highlight the importance of periodical threshold measurements to continuously monitor device performance. On the other hand, in the absence of such measurements, our work demonstrates that routinely collected clinical measures and a single session of system fitting might be sufficient to inform an XAI-based electrode deactivation strategy for retinal prostheses.

ABSTRACT BODY:

Purpose: Various clinical conditions may cause dilation of the conjunctival vessels, leading to ocular redness (OR), among which allergic conjunctivitis is the most common cause, followed by dry eye disease and infectious conjunctivitis. Herein, using animal models of both allergic and non-allergic OR, we evaluated the therapeutic efficacy of topical blockade of substance P (SP) in treating the red eye.

Methods: Allergic OR was induced in Guinea pigs with topical 1.5 mg/mL histamine, and non-allergic OR was induced in rabbits with topical 5% dapiprazole. Once topical histamine or dapiprazole was applied, animals immediately received topical treatment of L-703,606, a SP receptor antagonist, or vehicle. Animal eyes were thereafter examined by a slit lamp, and images were taken every 30 seconds in the first 2 minutes, and then at 6, 10, 20, 30, 40, 50, and 60 minutes post treatment. The severity of redness was analyzed using ocular redness index (ORI) which is a continuous numerical score from 0 to 100.

Results: In the vehicle control group, the ORI reached peak at 10 minutes in allergic OR and the maximal increase from baseline was 17.04. In the non-allergic OR model, maximal increase in ORI score is 13.07 at peak time of 20 minutes post-induction. Topical treatment of L-703,606 significantly reduced ORI at each time point evaluated in both allergic and non-allergic OR models. At peak time, L-703,606 treated group showed ORI reduction of 8.21 in allergic model and 5.76 in non-allergic model, respectively.

Conclusions: Topical blockade of SP is effective for treating allergic and non-allergic red eye.

ABSTRACT BODY:

Purpose: Myopia is a refractive condition that increases the risk of glaucoma. Studies have shown that the risk of developing glaucoma, especially primary open angle glaucoma (POAG), is more pronounced in high myopes. We hypothesized that excessive myopic eye growth may cause structural changes of the outflow system, leading to IOP elevation.

Methods: Myopia was induced in healthy albino guinea pigs (n=24) by form deprivation (FD). A translucent plastic diffuser goggle was attached and randomly assigned to one of the guinea pig eyes. The ocular parameters including axial length (AXL), anterior chamber depth (ACD) and vitreous chamber depth (VCD); refractive error (Rx) and IOP were monitored regularly. After 3 to 8 weeks of FD, both eyes were removed and outflow facility was measured using constant flow method with perfusion system (iPerfusion).

Results: The treated eyes became significantly more myopic ($-4.63 \pm 0.67D$, $P < 0.01$), elongated ($0.23 \pm 0.04mm$, $P < 0.01$) and with higher IOP ($0.73 \pm 0.29mmHg$, $P = 0.02$) than fellow control eyes. In general, the IOP correlated well with the outflow facility ($r = -0.40$, $P = 0.05$). Pearson correlation analysis revealed that myopic refraction was significantly correlated with axial elongation, but not with IOP and outflow facility. However, when the correlations in both eyes were studied together, intraocular change of ACD (δACD) was found to correlate moderately and significantly with δIOP ($r = 0.40$, $P < 0.01$) and outflow facility ($r = -0.39$, $P = 0.01$).

Conclusions: Axial elongation in albino guinea pigs correlated well with changes in the IOP and outflow facility. Specifically, eyes with deepened ACD showed significantly higher IOP and lower outflow facility. It indicated that ACD deepening may cause structurally changes that lead to gradual blockage of the aqueous outflow system and elevation of IOP.

TITLE: Disease mechanisms of X-linked cone dystrophy caused by missense mutations in the red and green cone opsins

SESSION TITLE: Genetics, (gen)omics, systems and computational biology in ocular health and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Deng, P. Zhu, F.M. Dyka, W.W. Hauswirth, University of Florida, Gainesville, Florida, UNITED STATES|W. Baehr, University of Utah Health, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Wen-Tao Deng: Commercial Relationship: Code N (No Commercial Relationship) | Ping Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Frank Dyka: Commercial Relationship: Code N (No Commercial Relationship) | Wolfgang Baehr: Commercial Relationship: Code N (No Commercial Relationship) | William Hauswirth: Commercial Relationship(s);AGTC:Code F (Financial Support);AGTC:Code P (Patent);AGTC:Code C (Consultant)

ABSTRACT BODY:

Purpose: Red/green cone opsin missense mutations N94K, W177R, P307L, R330Q and G338E have been identified in subjects with congenital blue cone monochromacy or color-vision deficiency. Studies on disease mechanisms due to these cone opsin mutations have been previously carried out exclusively in cell culture. Here we expressed these cone opsin mutants specifically in mouse cones via AAV in M-opsin knockout ($Opn1mw^{-/-}$) mice to investigate their subcellular localization, the pathogenic effects on cone morphology, function, and cone viability.

Methods: AAV8-733 vectors expressing the above cone opsin mutants driven by the cone-specific PR2.1 promoter were injected subretinally into one eye of 1 month old $Opn1mw^{-/-}$ mice, while the contralateral eyes remained untreated. AAV-mediated transgene expression was analyzed by western blots. L/M-opsin mediated retinal function was analyzed 6 weeks post-injection by photopic electroretinography (ERG). Subcellular localizations of each cone opsin mutant and the other cone outer segment specific proteins were examined by immunohistochemistry. Cone viability in each mutant treated eyes was examined by retinal whole mounts stained with peanut agglutinin (PNA).

Results: Expression of N94K and W177R was barely detectible while P307L, R330Q, and G338E showed expression levels comparable to that of endogenous M-opsin. N94K and W177R were misfolded and localized exclusively in cone inner segments and endoplasmic reticulum. In contrast, P307L, R330Q and G338E were detected exclusively in cone outer segments. Expression of R330Q and G338E, but not P307L, also partially restored expression and correct localization of the remaining cone outer segment proteins and resulted in partial rescue of M-cone mediated light responses. ERG amplitudes in R330Q and G338E injected eyes were $54.5 \pm 15.5 \mu V$ and $56.3 \pm 18.1 \mu V$, respectively (average \pm STD, $n=8$), significantly higher than the unrecordable M-cone ERGs from untreated contralateral control eyes ($P < 0.0001$). Expression of W177R and P307L caused severe cell toxicity resulting in rapid cone loss, while N94K, R330Q and G338E were only modestly toxic.

Conclusions: Although the underlying biochemical and cellular defects caused by these mutants are distinct, we predict they all present a gain-of-function phenotype, resembling autosomal dominant retinitis pigmentosa associated with the majority of rhodopsin missense mutations.

ABSTRACT BODY:

Purpose: Several retinal diseases show vascular pathologies in the periphery first. Although widefield fluorescein angiography (FA) fundus cameras can image these areas, they require contrast agents and a lengthy patient setup procedure. In this work, we present how MHz swept-source OCT angiography (SS-OCTA) can provide similar information non-invasively and faster.

Methods: We developed a SS-OCTA system using a frequency-domain mode locked laser operating at an A-scan rate of 1.7 MHz with a central wavelength of 1060 nm and a tuning range of 75 nm, translating to 9 μm axial resolution in tissue. The lateral resolution is 20 μm ($1/e^2$) and the imaging depth in tissue is 6 mm. To compensate for eye motion, the retina is tracked during acquisition using an additional line scanning ophthalmoscope. If motion occurs, the scan location is corrected, and the scans acquired since motion detection are rescanned. The single shot field of view (FOV) of 18 mm by 18 mm (~65 degrees) on the retina is sampled laterally with 2048x2048 A-scans and 4 repetitions per slow scanning axis position. After SS-OCTA processing using the complex signal, projections from the inner limiting membrane to the IS/OS junction are generated. In this study, we imaged 5 healthy subjects, and 20 patients with diabetic retinopathy, choroidal neovascularization, and retinal occlusion.

Results: We acquired single shot SS-OCTA images with a FOV of 65 degrees from healthy subjects and patients with retinal diseases. The acquisition time with tracking enabled was well below 30s in patients. The image quality was sufficient to resolve capillaries over the entire FOV. Figure 1 shows the widefield SS-OCTA projection of a diabetic eye. SS-OCTA's motion contrast allows for identification of areas of non-perfusion. Because the full level of detail cannot be appreciated in the widefield image as displayed in Fig. 1, Fig. 2 shows magnified views of the same acquisition at the locations indicated by the orange boxes. In Fig. 2II), even the capillaries around the foveal avascular zone can be resolved.

Conclusions: We demonstrated that SS-OCTA is approaching the FOV of widefield FA fundus cameras. This has reduced chair time and lack of need for contrast agents, which makes widefield SS-OCTA a potential replacement for many FA exams.

ABSTRACT BODY:

Purpose: Previous evidence indicates that topical oestradiol may be beneficial for patients with dry eye disease (DED), especially in post-menopausal women. The current phase II study was performed to investigate the effect of a recently developed formulation of oestradiol eye drops on signs and symptoms of DED.

Methods: In this randomized, controlled, parallel-group study, 104 post-menopausal women with moderate to severe dry eye were included. 17- β -oestradiol-3-phosphate eye drops (RP101) were administered in three different dosage groups (group 1: 0.5% twice daily, group 2: 0.1% morning and vehicle in the evening, group 3: 0.1% twice daily) and compared to control (group 4: vehicle IntelliGel, twice daily). Treatment was administered for a total period of three months. Schirmer's test II, corneal staining and SANDE symptom score were assessed at baseline and at day 14, 30, 60 and 90 after treatment start. Safety was determined via frequency of adverse events.

Results: Schirmer's test II wetting distance significantly increased in all 4 groups from baseline to day 90 without significant difference between groups (group 1: $+5.6 \pm 6.7$; group 2: $+3.7 \pm 4.2$; group 3: $+4.8 \pm 4.5$, group 4: $+4.0 \pm 5.3$ mm/5min). Statistical significance versus baseline occurred earlier in the treatment groups versus the control group. Corneal staining score was significantly reduced after the three-month treatment period with no significant difference between treatment groups ($p < 0.001$ vs baseline in all groups). Staining of the inferior cornea, however, showed a significantly more pronounced decrease in the highest dose group compared to vehicle ($p = 0.0463$). Symptoms as assessed with the SANDE test decreased at the end of the treatment period in all 4 groups (between -18.7 ± 23.5 and -26.3 ± 28.0 mm for frequency of symptoms and between -13.1 ± 26.8 and -24.1 ± 40.2 mm for severity of symptoms). Topical RP101 eye drops were well tolerated on the ocular surface and showed a favorable safety profile.

Conclusions: The results of the study indicate that topical RP101 eye drops improve signs and symptoms of DED in post-menopausal women. The results of the study showed a good safety profile of the topical ophthalmic formulation. Further adequately powered phase III studies are required to assess therapeutic efficacy of topical oestradiol in the treatment of DED.

ABSTRACT BODY:

Purpose: To quantify the therapeutic effect of pegcetacoplan (APL2) on inhibition of photoreceptor (PR) loss on conventional OCT images using deep learning in GA.

Methods: SD-OCT scans (Spectralis) in a raster of 512x49x496 voxels were obtained at monthly intervals during the phase II FILLY trial of APL2, an investigational complement C3 inhibition, in patients with geographic atrophy (GA) secondary to AMD. Patients with complete outer retinal atrophy (cRORA) were randomized into a sham group (SM), a group receiving monthly (AM) and another group receiving bimonthly (AEOM) intravitreal injections of APL2. Using expert manual annotation at an A-scan level, a deep learning segmentation algorithm was developed based on a convolutional neural network (CNN). Fully automated delineation of the area presenting with complete photoreceptor (PR) loss was performed at baseline, at 2, 6 and 12 months. The associated retinal pigment epithelial (RPE) loss was measured via a previously established algorithm.

Results: A total of 31,752 B-Scans of 648 volumes of 162 study eyes (SM:56, AM:54, AEOM:54) were evaluated from baseline to month 12. The square-root lesion area based on PR loss was 0.108, 0.111, 0.106 mm at baseline in the SM, AEOM and AM groups. While the mean PR defect size increased to 0.110, 0.112, 0.116 mm over months 2,6,12 in the SM group, the AM group presented a significantly smaller lesion extension with 0.105, 0.106, 0.110 mm, respectively over time, which was also seen as a trend for the AEOM group (Table 1). Moreover, the PR lesion sizes were found to consistently exceed the underlying borders of RPE loss by 73, 64, 61, and 60 % at the subsequent intervals.

Conclusions: Deep-learning based algorithms are able to distinctly and reliably quantify the extension and growth of photoreceptor loss and appear to represent ideal tools to evaluate disease activity as well as therapeutic efficacy of slowing GA progression. Based on standard OCT imaging, automated monitoring of RPE and PR loss and maintenance should be considered for an optimized management of patients with GA.

ABSTRACT BODY:

Purpose: Cytomegalovirus (CMV) is latently infected in more than 80% of Asian population and recurs subclinical reactivation over the life time. Virus reactivation induces clinical issues such as viremia and retinitis only in severely immunocompromised hosts. Recently, however, it has been revealed that CMV can cause various ocular inflammation such as anterior uveitis (CMV-AU) and chronic retinal necrosis (CRN) in hosts without apparent immunosuppression and with mild to moderate immunosuppression, respectively. The signal peptides (SP) of CMV UL40 protein are polymorphic and are presented on HLA-E molecules which are directly recognized by NK cells and CD8⁺T cells. The antiviral immune responses differ depending on the polymorphisms, and two SP polymorphisms (SP1 and SP2) are frequently observed in CMV viremia. We analyzed the polymorphisms of UL40 SP sequences in the intraocular fluids of the three different CMV-associated uveitis and compared them among the diseases.

Methods: gDNA was extracted from the intraocular fluids of 25 cases of CMV-AU, 7 cases of CRN, and 16 cases of CMV retinitis. The UL40 SP region was amplified by PCR and the SP sequences were determined by direct sequencing.

Results: Two UL40 SP sequences (SP1 and SP3) were detected in intraocular fluids of CMV-associated uveitis. SP1 was the dominant type in CMV retinitis (14/16 cases, 88%), whereas it was less frequent in CMV-AU (20/25 cases, 80%) and CRN (3/7 cases, 43%). In contrast, SP3 was more frequent in CMV-AU (5/25 cases, 20%) and CRN (4/7 cases, 57%, $p=0.045$) compared to that in classical CMV retinitis. SP2, which is the 2nd most frequent type in CMV viremia, was not detected in the intraocular fluids.

Conclusions: The distributions of CMV UL40 SP sequences in intraocular fluids of CMV-associated uveitis were different among the CMV-associated diseases, suggesting that polymorphisms of UL40 may be involved in the pathogenesis of intraocular inflammation and the variations of the ocular diseases.

ABSTRACT BODY:

Purpose: Choroidal neovascularization (CNV) is a frequent and sight-threatening complication in high myopia. The anti-vascular endothelial growth factor (VEGF) therapy is the current standard of treatment in newly diagnosed myopic CNV. However, after exudation is resolved, patients may experience recurrences that were demonstrated to significantly impact the long-term visual outcomes. The aim of this study is to assess the relationship of demographics, clinical characteristics and structural optical coherence tomography (OCT) findings to disease recurrence in a cohort of patients with newly diagnosed myopic CNV.

Methods: In this IRB-approved retrospective analysis, we collected data from 64 participants (64 eyes) with successfully treated myopic CNV who had obtained resolution of exudation after treatment (study baseline) and with 3 years of regular follow-ups. At baseline, several OCT qualitative features and quantitative measurements were graded by two readers and included in the analysis. Main outcome measures included incidence of disease recurrence and hazard ratio (HR) for demographics, clinical characteristics and OCT risk factors.

Results: At month 36, 40 eyes (62.5%) developed disease recurrence (active CNV). Multivariate linear regression analysis revealed that final visual acuity (at 36 months - dependent variable) was associated with visual acuity at baseline visit ($p<0.0001$), baseline size of patchy atrophy ($p=0.010$), baseline subfoveal choroidal thickness ($p=0.008$), baseline maximum CNV height and width ($p=0.011$ and $p=0.003$), and recurrence of CNV exudation ($p=0.007$). The following factors were associated with an increased risk of disease recurrence: size of patchy atrophy had an HR of 1.14 (95% CI, 1.01-1.29; $p=0.036$); maximum CNV width had an HR of 1.02 (95% CI, 1.01-1.04; $p<0.0001$).

Conclusions: We identified OCT risk factors for the disease recurrence in eyes with successfully treated myopic CNV. Assuming that disease recurrence is a sight-threatening event, our findings may help in the identification of high-risk patients and eventually ameliorate their outcome.

TITLE: Comparative study of the effects of nicotinamide on cultured iPSC-derived human RPE cells from normal and Smith-Lemli-Opitz Syndrome (SLOS) donors

SESSION TITLE: Metabolism and protein processing: retina, photoreceptors and RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. Petrie, L.A. Skelton, S. Ramachandra Rao, S.J. Fliesler, Ophthalmology and Biochemistry, University at Buffalo, Buffalo, New York, UNITED STATES|J.A. Petrie, L.A. Skelton, S. Ramachandra Rao, S.J. Fliesler, Research Service, VA Western New York Healthcare System Buffalo VA Medical Center, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): John Petrie: Commercial Relationship: Code N (No Commercial Relationship) | Lara Skelton: Commercial Relationship: Code N (No Commercial Relationship) | Sriganesh Ramachandra Rao: Commercial Relationship: Code N (No Commercial Relationship) | Steven Fliesler: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the effects of nicotinamide (Nic) on differentiation and protein expression profiles of cultured iPSC-derived RPE cells from normal human donors (Dys0100; DYS), vs. mildly (CWI) and severely (A2) affected SLOS donors.

Methods: DYS, CWI and A2 iPSC-RPE cells were derived as previously described (Ferrer M et al., 2014; Ramachandra Rao et al., 2018). Cells (passage #6) were seeded in low-Ca²⁺ medium on tissue culture plastic, grown to confluence, and switched to high-Ca²⁺ medium containing either basal (~33 mM; vehicle control (VC)) or 10 mM Nic. Cell morphology was monitored by phase-contrast and confocal fluorescence microscopy. After 1.5 mo., monolayers were harvested in RIPA buffer and processed for Western blot (WB) analysis. Blots were probed with antibodies to RPE65, CRALBP, and Best-1, normalized to b-actin levels. CWI and A2 RPE cells cultured on poly-L-ornithine-coated RINZL plastic coverslips ± Nic, were probed with anti-Occludin MAb (clone OC3F10); F-actin was detected with Alexa Fluor® 568-Phalloidin. Statistical analysis: Student's t-test, with significance threshold P<0.05.

Results: DYS and CWI cells exhibited relatively normal RPE-like morphology; however, A2 cells appeared markedly unhealthy and hypertrophic. Supplementation of culture media with 10 mM Nic improved iPSC-RPE differentiation, polygonal morphology, monolayer uniformity, phase-bright border and anti-Occludin staining continuity, and F-actin organization, relative to VC. While the effects were modest for DYS and CWI cells, A2 cells showed profound improvement. By WB analysis, RPE65 expression levels increased in all cell lines (+Nic, vs. VC): by ~2.5X (DYS) and ~2.2X (CWI), vs. ~5.8X (A2). Similarly, CRALBP expression increased (+Nic, vs. VC) by ~1.4X (DYS) and ~1.5X (CWI), vs. ~7.4X (A2). Also, Best-1 expression increased (+Nic, vs. VC) by ~2.5X (DYS) and ~3.7X (CWI), vs. ~9X (A2).

Conclusions: Culture medium supplementation with 10 mM Nic promotes up-regulation of RPE cell markers and normal RPE-like morphology and cytology of cultured iPSC-RPE cells, particularly those derived from severely-affected SLOS donors. Nic supplementation may augment therapeutic efficacy of current standard-of-care treatment for SLOS patients.

TITLE: Impact of the COVID-19 Pandemic on Diabetic Macular Edema Patient Outcomes at a Tertiary Care Veterans Affairs Hospital

SESSION TITLE: Diabetic macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Zhou, J. Gao, K. Biggerstaff, S. Orengo-Nania, R. Channa, Baylor College of Medicine, Houston, Texas, UNITED STATES|R. Channa, UW Health, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Philip Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Jie Gao: Commercial Relationship: Code N (No Commercial Relationship) | Kristin Biggerstaff: Commercial Relationship: Code N (No Commercial Relationship) | Silvia Orengo-Nania: Commercial Relationship: Code N (No Commercial Relationship) | Roomasa Channa: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retina clinic volumes declined during the COVID-19 pandemic, and there have been limited studies on how this impacted patient outcomes. Optimal management of diabetic macular edema (DME) requires adherence to regular treatment schedules. We aimed to evaluate the impact of the pandemic on visual and anatomic outcomes in patients with DME requiring anti-VEGF injections at our institution.

Methods: Data was collected from the retina clinic at the Michael E. DeBakey VA Medical Center in Houston, Texas. Patient charts from April 2020 were compared to April 2019 to determine changes in attendance. To evaluate outcomes, we reviewed DME patients with appointments scheduled from April 1 - 30, 2020. Data from the last visit prior to April 1, 2020 was compared to the first follow-up visit between April 1, 2020 to December 1, 2020. Ocular surgery or absence of injections within the 3 months prior to scheduled appointment excluded patients from this study. Central foveal thickness (CFT) was measured from optical coherence tomography images and Snellen visual acuity (VA) measurements were obtained from the medical record. Poor outcome was defined as VA decrease of one or more lines or a CFT increase of 10% or more. Analysis included the eye with the worse VA from each patient.

Results: Total visits to the retina injection clinic decreased by 54% from 533 patient visits in April 2019 to 247 visits in April 2020. Of 562 unique patients scheduled for April 2020, 185 patients were on anti-VEGF injection schedules for DME treatment. 51 patients were excluded. Of the remaining 134 patients, the mean age was 64.7 ± 8.8 years. 86% (115/134) were rescheduled, and of these, 26/115 were lost to follow-up until the end of our study period. The remaining 89/115 were seen with an average follow-up interval of 115.2 ± 50.0 days. At follow-up, 37/89 (42%) had worsened vision, 24/89 (27%) had worsened edema, and 54% (48/89) had a poor outcome of either worsened vision or worsened edema.

Conclusions: Pandemic related rescheduling of patients with DME delayed follow-up care and treatment. On average, patients were rescheduled to a visit that was 2.4 months later than their usual visit and about half the patients experienced worsening of vision or edema. Additional studies are needed to identify patients at highest risk of vision loss so that those patients can be triaged and evaluated appropriately.

TITLE: Conditional Deletion of AP-2 β in the Periocular Mesenchyme of Mice Promotes Corneal Conjunctivalization

SESSION TITLE: Corneal epithelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Walker, A. Taiyab, M. Akula, J.A. West-Mays, Pathology and Molecular Medicine, McMaster University, Hamilton, Ontario, CANADA|T. Williams, University of Colorado, Denver, Colorado, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Haydn Walker: Commercial Relationship: Code N (No Commercial Relationship) | Aftab Taiyab: Commercial Relationship: Code N (No Commercial Relationship) | Monica Akula: Commercial Relationship: Code N (No Commercial Relationship) | Trevor Williams: Commercial Relationship: Code N (No Commercial Relationship) | Judith West-Mays: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The corneal endothelium and stroma derive from the periocular mesenchyme (POM), which originates from neural crest cells (NCCs), while the corneal epithelium stems from the anterior surface ectoderm. Signalling between the POM and surface ectoderm regulates epithelial proliferation and cell fate. Activating Protein-2 beta (AP-2 β), encoded by *Tfap2b*, is a transcription factor expressed in the POM. We have previously shown that conditional knock out AP-2 β generates a unique anterior segment phenotype that includes a closed iridocorneal angle, absent corneal endothelium and reduced corneal epithelial stratification. The purpose of this investigation was to further determine the impact of AP-2 β deletion in the POM on the corneal epithelial phenotype.

Methods: To generate the AP-2 β NCC KO model, male mice heterozygous for *Tfap2b*, *Tfap2b*^{+/-}, and the *wnt1-cre* transgene, *Wnt1Cre*^{+/-}, were bred with female mice in which the *Tfap2b* gene was floxed, *Tfap2b*^{lox/lox}. AP-2 β expressing offspring from this breeding scheme were used as age-matched controls. Eyes were enucleated from euthanized 2-3-month-old mice and processed before being embedded in paraffin. Immunohistochemistry was conducted using primary antibodies specific to Keratin-12 (K12), a corneal epithelial marker, and Keratin-15 (K15), a marker of conjunctival and limbal epithelia.

Results: Mature AP-2 β NCC KO mice have a distinct corneal phenotype, with significantly reduced stratification, an absent endothelium and disorganized, vascular stroma. 2-3-month-old eye sections from wild-type mice demonstrated consistent immunostaining of K12 across the corneal epithelium, while K15 was confined to the limbal region and continued throughout the conjunctival epithelium. In contrast, AP-2 β NCC KO mice demonstrated significantly reduced expression of K12 across the corneal epithelium, while K15 was observed consistently across the entire corneal epithelium, continuous with the conjunctiva.

Conclusions: The observed phenotypic changes in keratin expression indicate a shift towards conjunctival cell fate during development as a result of AP-2 β NCC KO. This change to the epithelial phenotype is consistent with other signs of corneal conjunctivalization seen in the AP-2 β NCC KO model, including stromal neovascularization.

ABSTRACT BODY:

Purpose: Heparan- α -glucosaminide N-acetyltransferase (HGSNAT) participates in lysosomal degradation of heparan sulfate. Mutations in the gene encoding this enzyme cause mucopolysaccharidosis IIIC (MPS IIIC) or Sanfilippo disease type C. MPS IIIC patients exhibit progressive neurodegeneration, leading to dementia and death before adulthood. Although some MPS IIIC patients exhibit incidences of non-syndromic retinitis pigmentosa and early signs of night blindness, majority of ocular phenotypes are not well characterized. The goal of this study was to investigate retinal degeneration phenotype in the Hgsnat knockout (KO) mouse model and correlate this phenotype with human ocular findings to understand the effects of Hgsnat mutation on the retina.

Methods: Heterozygous mice carrying mutation in the Hgsnat were crossed and offspring were sacrificed at 6 months of age. Cone and rod photoreceptors were analyzed using cone arrestin, S-opsin and rhodopsin antibodies. Outer nuclear layer (ONL) thickness and number of nuclei in the ONL layer were measured. Retinal OCT and fundus imaging was performed on an 11 year old MPS IIIC patient as a routine ophthalmic evaluation. Retinal histology was performed on the eye from 35 year old MPS IIIC donor and compared it to the age-matched control donor-eye.

Results: Our data suggest that loss of Hgsnat severely affects rod photoreceptors while cone photoreceptors are mainly unaffected at 6 months of age. We observed more than 30% reduction in the thickness and number of nuclei in the ONL in the Hgsnat KO retinas compared to those of the controls, indicating rod photoreceptor degeneration ($P < 0.05$). We also observed thinner outer segment length in Hgsnat KO retinas indicating reduced levels of rod photopigment rhodopsin. An 11 year old patient showed intraretinal cystic macular edema with myelinated nerve fiber. Severe retinal degeneration was observed in a 35 year old eye-donor.

Conclusions: To our knowledge, these are the first reports characterizing ocular phenotypes arising from deleterious variants in the Hgsnat gene associated with MPS IIIC clinical phenotype. Together our findings indicate that retinal manifestations of MPS IIIC are present even before cerebral manifestations. Thus, ophthalmological evaluations could be used as early diagnostic indicators of disease progression as well as end-points for evaluation of future therapies for MPS IIIC patients.

ABSTRACT BODY:

Purpose: To initiate an international discourse on consensus towards optimal training environments for highly qualified personnel, including practitioners and researchers interested in vision impairment and rehabilitation. Current training options are typically incomplete, segmented or absent from many academic environments. Using the Graduate Program for Vision Science at the Université de Montréal (UdeM) as an example, we present an education model to address this need that provides both applied and research training under one roof.

Methods: In 2016, and in consultation with 1 national and 2 local vision rehabilitation centers, UdeM developed and established a bilingual Master's degree program in Vision Science to specifically train rehabilitation professionals in orientation & mobility (O&M), low vision (LV) and vision rehabilitation therapy (VRT). The hierarchical structure and development timeline of the program options are presented in Figure 1. Trainees may choose between a professional track, leading to employment as clinician-scientists, or the research track, leading towards academia, research and/or industry (Figure 2). Enrolment and graduation data were extracted from the UdeM administrative database.

Results: Since Sept. 2016, 63 students have enrolled in the professional Master's, 31 (8 O&M, 20 LV, 3 VRT) have graduated and 25 are in progress. Additionally, 1 Basic-Science Master's thesis was completed, with 1 in progress, and 3 PhD students have graduated, with 2 in progress (the first PhD on vision rehabilitation graduated in 2017). One postdoctoral fellowship has been completed, with 2 in progress. In total, 66 trainees have completed or are currently concentrating their practicum and research efforts on Vision Impairment & Rehabilitation.

Conclusions: The presented program structure has been extremely productive in generating highly qualified personnel. The parallel tracks facilitate cross-fertilization of relevant ideas, and support integrated knowledge translation through collaboration with clinic-based internship supervisors. This training structure of clinicians as potential future collaborators allows the field of vision impairment & (especially) rehabilitation to move forward where evidence-based practice is concerned.

ABSTRACT BODY:

Purpose: To report the 3-year visual and anatomic outcomes, safety, and compliance for patients undergoing endolaserless vitrectomy with intravitreal aflibercept injection (IAI) monotherapy for proliferative diabetic retinopathy (PDR)-related vitreous hemorrhage (VH).

Methods: Eyes underwent endolaserless vitrectomy and received one preoperative and intraoperative IAI followed by randomization to a q8week or q16week IAI group. Additional IAI for PDR progression or DME was administered as needed. Non-compliance was defined as missing >3 consecutive or >6 mandatory appointments. Q8week eyes were evaluated at week 104 for PDR stability and were transitioned to q16week IAI dosing for year 3 if appropriate. Q16week eyes were subject to q8week conversion at any time point if they experienced 2 episodes of recurrent VH.

Results: 31/40 eyes were randomized (14 and 17 eyes in q8week and q16week groups, respectively) with 25/31 (81%) randomized eyes completing 152 weeks. Compliance criteria was met by 10/14 (71%) and 9/17 (53%) eyes in the q8 and q16week groups, respectively. Through 104 weeks, q8 and q16week eyes received an average of 14.4 and 8.8 IAI, respectively. At week 104, 8/14 (57%) q8week eyes were converted to q16week IAI and 3/17 (18%) q16week eyes were converted to q8week IAI. Q8week eyes observed an increase in visual acuity (VA) of 34 letters from 41 to 75 letters (20/160 to 20/32) ($p=0.003$) compared to an increase of 27 letters from 48 to 75 letters (20/100 to 20/32) in the q16week group ($p=0.013$). Adverse ocular events in compliant patients included worsening VA > 30 letters at any timepoint (3 q8week eyes, 6 q16week eyes) and VH (2 q8week eyes, 6 q16week eyes). One case of neovascular glaucoma was seen in the q16week group and 1 retinal detachment occurred in both q8 and q16week groups. In addition, recurrent VH was experienced by 1 compliant q8week eye compared to 3 compliant q16weeks eyes.

Conclusions: Endolaserless vitrectomy with aflibercept monotherapy for PDR-related VH has shown to provide significant long-term visual gains. Frequent IAI is required to achieve fewer proliferative consequences. Non-compliance remains a patient-centered issue, further indicating the need for persistent and frequent postoperative anti-VEGF therapy. This data may provide a foundation for evaluating longer acting anti-VEGF treatment modalities with this approach.

ABSTRACT BODY:

Purpose: The Belin-Ambrósio Enhanced Ectasia Display "D" (BAD-D) score is a summary corneal tomographic parameter shown to be sensitive in detecting subclinical keratoconus. We explored heritability of this parameter in a largely healthy twin cohort.

Methods: Scheimpflug corneal imaging was performed using the Oculus HR (High-Resolution) Pentacam (Oculus, Wetzlar, Germany) in adult volunteers recruited from the TwinsUK registry based at St Thomas' Hospital in London. Images from the right eye were used for analysis. Only complete twin pairs were included. The BAD-D parameter was noted, and coefficients of intra-pair correlation were calculated for monozygotic (MZ) and dizygotic (DZ) twin pairs. Heritability was estimated by maximum likelihood structural equation modelling using the OpenMx package.

Results: Images from 136 twin volunteers (37 MZ and 31 DZ pairs) were included. Mean (SD) age was 61 (11) years. The majority (93%) were female, reflecting the demographics of the registry. The mean (SD) value of the BAD-D parameter was 1.27 (0.73). Tests of normality did not detect significant deviation from a normal distribution. Pearson coefficients of intra-pair correlation were 0.68 ($p = 4.1 \times 10^{-6}$) and 0.33 ($p = 0.066$) for MZ and DZ pairs respectively. The age-adjusted estimate of heritability was 66.4% (95% CI, 46.6-79.2).

Conclusions: The calculated intra-pair correlation coefficient for MZ twins was double that for DZ twins, indicating that the majority of the variance in this parameter is determined by genetic factors. We estimated that approximately two thirds of the variance was attributable to genetic factors. Further studies can seek to identify associated genes.

ABSTRACT BODY:

Purpose: Neonatal insults from systemic diseases have been implicated in the pathway of impaired neurodevelopment in preterm infants. Thinner retinal nerve fiber layer (RNFL) assessed by optical coherence tomography (OCT) has been associated with poorer neurodevelopment in preterm infants, suggesting RNFL thickness may reflect the brain as a whole in preterm infants. However, it remains unknown if RNFL thickness can serve as a noninvasive biomarker for the impact of systemic diseases on the central nervous system in preterm infants. We aimed to investigate associations between systemic health factors and RNFL thickness in preterm infants.

Methods: The STudy of Eye imaging in Preterm infantS (BabySTEPS) prospectively enrolled infants eligible for retinopathy of prematurity screening based on standard guidelines. We imaged both eyes of these infants at 36 ± 1 weeks postmenstrual age (PMA) using a handheld OCT system at the bedside in the Duke intensive care nurseries. RNFL thickness of the right and left eyes was averaged for each infant. We evaluated associations between RNFL thickness and 27 systemic health factors using multivariable regression models.

Results: We included 83 infants with RNFL thickness measures in this study. Of the 83, 16 infants had sepsis or necrotizing enterocolitis (NEC). These events occurred before the OCT imaging (time interval = 50 ± 22 days). Among 27 systemic factors, infant weight at imaging and sepsis/NEC were independently associated with RNFL thickness. RNFL was 10.4 µm thinner in infants with sepsis/NEC than without sepsis/NEC (52.7 ± 9.0 vs. 63.1 ± 10.2 µm; $P < 0.001$). This difference remained statistically significant after adjustment for confounding variables (birth weight, birth weight percentile, gestational age, infant weight at OCT imaging, and growth velocity). A 250-g increase in infant weight at OCT imaging was associated with a 3.1 µm (95%CI = 2.1 to 4.2) increase in RNFL thickness ($P < 0.001$).

Conclusions: Low infant weight and sepsis/NEC were independently associated with thinner RNFL in preterm infants at 36 weeks PMA. To our knowledge, this study is the first to suggest that sepsis/NEC may affect retinal neurodevelopment. OCT-measured RNFL may offer a noninvasive biomarker to assess the negative impact of sepsis/NEC on the central nervous system in preterm infants.

TITLE: Molecular chaperones are direct binding partners in mitochondrial targeting of SLC4A11.

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Choi, J.A. Bonanno, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Moonjung Choi: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Bonanno: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: SLC4A11 is an ammonia-sensitive mitochondrial uncoupler suppressing glutamine induced oxidative stress. Our preliminary data indicate that SLC4A11 might traffic to the mitochondria of corneal endothelium through a "chaperone-mediated carrier-pathway". The purpose of this study is to investigate direct physical interaction between molecular chaperones and SLC4A11.

Methods: In situ protein interactions between SLC4A11 and either HSP90 or HSC70 was examined and visualized using Proximity Ligation Assay (PLA), which uses a pair of oligonucleotide-labeled secondary antibodies (PLA Probes). Anti-HA was paired with either anti-HSP90 or anti-HSC70 primary antibodies in PS120 fibroblasts transfected with either HA epitope-tagged human SLC4A11 (PS120-hSLC4A11-HA) or empty vector (PS120-EV) cells. When the primary antibodies are in close proximity to each other (< 40nm), PLA-fluorescence spots are quantified using a Zeiss LSM 800 confocal microscope with Airyscan (63X objective, 1.8X zoom). In order to validate whether the chaperones guide SLC4A11 to the mitochondrial surface receptor to import the pore of the translocase of the outer membrane (TOM) complex, mitochondria of the cells were labeled with MitoTracker CMXRos prior to PLAs: 1) HA/TOM70 (outer mitochondrial membrane marker), 2) HA/HSP90, and 3) HA/HSC70. Incubation with no primary antibody and each separate primary antibody was done as negative controls for the PLAs.

Results: Significant PLA signals of SLC4A11 with HSP90 or HSC70 were observed in PS120-hSLC4A11-HA cells, but not in PS120-EV cells. Furthermore, PLA: HA/TOM70 revealed that SLC4A11 directly binds to the mitochondrial surface receptor, TOM70. The PLA: HA/TOM70 signals were colocalized with the mitochondria labeled with MitoTracker CMXRos. Like the distribution of HA/TOM70 PLA signals to the mitochondria, fewer than half of HA/HSP90 and HA/HSC70 PLA signals closely overlapped mitochondria. More than half of the PLAs signals appeared in the cytoplasm, which indicates where SLC4A11-chaperone complexes are initially recruited.

Conclusions: We found that HSP90 and/or HSC70 are the chaperones as physical binding partners with SLC4A11, which, in turn, allows SLC4A11 to traffic across the mitochondria.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of vision loss nationwide and accounts for 8.7% of blindness. Detailed GA and drusen measurements may be promising biomarkers for staging and monitoring of AMD. However, the genetic relationship between these traits and AMD is not fully understood. Here, we investigate the genetics of quantitative measures of drusen and GA in an Amish population using genetic risk scores (GRSs) derived from a previous large AMD genome-wide association study (GWAS).

Methods: We performed chip genotyping using an Illumina Multi-Ethnic Genotyping Array with custom content. GA and drusen measures were obtained from macular optical coherence tomography (OCT) volume scans. 1,117 Amish adults with a family history of AMD from Ohio, Pennsylvania, and Indiana were included in the analyses after quality control and assurance. GRS were constructed using summary statistics of genome-wide significant SNPs for AMD from Fritsche et al. (2016). We tested the impact of the GRS for both the presence/absence of GA and drusen and, for those with GA and/or drusen, the impact on the measures. Traits included geographic atrophy, drusen area, and drusen volume within 3 and 5mm circles centered on the fovea. Logistic regression models were used to test the added utility in predicting the presence each of these drusen traits beyond a basic covariate-only model including age, sex, and smoking status. Similarly, linear models were constructed to investigate prediction of the quantitative measures of each of these traits by using the same predictors on subsets of individuals with presence of each of the traits.

Results: Results indicated a small, but statistically significant ($p < 0.05$), effect of the GRS to improve model performance for presence of each of the five traits. Area under curve (AUC) for drusen area and volume in a 3mm circle improved from 0.797 and 0.831 to 0.825 and 0.864, respectively, by adding the GRS to a covariate-only model. Further, it had a significant effect in improving prediction of the quantitative measures of drusen area and volume.

Conclusions: These results suggest that drusen development and AMD share underlying risk loci, helping to elucidate the relationship between drusen and AMD, potentially allowing for future use of drusen traits as a biomarker.

ABSTRACT BODY:

Purpose: Demodex follicularis and demodex brevis are microscopic ectoparasites known to cause blepharitis. However, there is limited knowledge regarding the prevalence of Demodex in asymptomatic healthy individuals versus those with symptomatic pathologic demodicosis.

Methods: This was a prospective, cross-sectional study examining the prevalence of and risk factors for Demodex colonization in all patients 18 years and older presenting to two large, tertiary care outpatient ophthalmology clinics. Demographic information, prescription and non-prescription ocular medications, and concurrent pathologies such as pterygia, blepharitis, and dry eye disease was also recorded. Each patient underwent epilation of four eyelashes, one from each eyelid. Each eyelash was examined underneath a compound light microscope looking for the presence of Demodex species or eggs. For patients positive for Demodex, appropriate treatment was initiated with routine follow up.

Results: 199 patients were examined, with an average patient age of 59.4 ± 2.1 years. Demodicosis was newly diagnosed in 55.3%, with 61.8% and 68.3% noted to have blepharitis and dry eye, respectively. Only 1% of those with confirmed Demodex were previously diagnosed and treated. The presence of Demodex was found to be independent of sex, number of clinic visits, self-administered lid hygiene regimen, or prescription ophthalmic drops. There were statistically significant associations noted between the presence of Demodex and age ($p=0.005$), history of pterygium surgery ($p=0.01$), dermatochalasis ($p=0.001$), blepharitis ($p<0.001$), and dry eye disease ($p=0.001$). Patients using alpha-agonist eyedrops showed a decreased risk of Demodex colonization ($p<0.05$).

Conclusions: In the clinical setting, Demodex is grossly under-diagnosed and responsible for both acute and refractory blepharitis in a large subset of patients. In agreement with prior studies, we found a positive correlation between presence of Demodex and age as well as presence of blepharitis and dermatochalasis. However, in contrast to previous studies, there was little association with pterygia and a decreased incidence of demodicosis in patients using alpha-agonist drops. Over 50% of the entire study population and over 60% of patients with blepharitis were found to have Demodex. Ongoing investigations into appropriate diagnosis and treatment regimens have great potential to improve quality of life for our patients.

ABSTRACT BODY:

Purpose: To determine the degree of uniformity in mapping of uveitis clinical concepts to International Classification of Diseases, Tenth Revision (ICD-10) code across healthcare systems using the same electronic health record (EHR) system.

Methods: Researchers from five different healthcare systems (University of Washington, Harvard University, Stanford University, Yale University, University of California San Francisco), each of which employ the Epic EHR, queried 54 uveitis related diagnostic terms and recorded associated ICD-10 codes. The main outcome measure was the degree of uniformity for uveitis ICD-10 code associations.

Results: Fifty-four uveitis related diagnostic terms were queried within the Epic EHR at five different healthcare systems. There was perfect agreement among all five centers for 52 out of 54 diagnostic terms. The proportion of uveitis diagnoses with identical ICD-10 mapping on pair-wise comparison between centers was greater than 96% for all comparisons (Table). Two diagnostic terms were observed to have differences in ICD-10 coding: (1) juvenile idiopathic arthritis associated chronic uveitis and (2) intermediate uveitis. Intermediate uveitis was associated with H20.1x (ICD-10 description: 'chronic iridocyclitis') or H20.9 (ICD-10 description: 'unspecified iridocyclitis') in three centers while being associated with H30.2x (ICD-10 description: 'posterior cyclitis') at the two remaining centers. The discrepancies appear to be related to a recent update in diagnostic mapping in the Epic EHR. Further, considerable overlap was observed for multiple diagnostic terms with the same code, creating anatomic, etiologic, and infectious non-specificity in identifying diagnosis by ICD-10 code. Fifteen diagnostic terms had no ICD-10 association at any of the centers.

Conclusions: ICD-10 mapping to uveitis diagnostic terminology appears to be highly uniform at different centers with the Epic EHR. However, temporal changes in diagnosis mapping to ICD-10 code and lack of one-to-one mapping of diagnosis to ICD-10 code add additional sources of complexity to interpretation of big data studies in uveitis.

ABSTRACT BODY:

Purpose: Cystoid macular edema (CME) following cataract surgery is a well-known phenomenon. Less is known regarding the risk factors, though, of developing CME following repair of rhegmatogenous retinal detachments (RRD).

Methods: This is a subgroup analysis of the Primary Retinal Detachment Outcomes (PRO) study, a multi-institutional study of consecutive primary RRD surgeries from 1/1/2015 through 12/31/2015. The primary outcome was development of post-operative CME following RRD surgery. The analysis was limited with those with post-operative optical coherence tomography imaging and at least 3 months of follow up following RRD repair.

Results: There were 1,466 eyes that met the inclusion criteria, and 140 (9.6%) developed post-operative CME following primary RRD repair. Multivariate analyses with statistically significant associations were older patient age (OR 1.03 per year, 95% CI 1.01 to 1.05), pre-operative proliferative vitreoretinopathy (PVR, OR 1.74, 95% 1.03 to 2.95), and cataract surgery following RRD repair (OR 2.18, 95% CI 1.47 to 3.25). Of the 843 (57.7%) phakic eyes, 76 (9.0%) developed post-operative CME. Multivariate analysis showed that cataract surgery following RRD repair was an independent risk factor ($p < 0.0001$) in this subset. Of the 623 (42.3%) pseudophakic eyes, 60 (9.9%) developed post-operative CME. Older age was an independent risk factor ($p = 0.0075$). When examining only eyes that underwent successful retinal re-attachment with a single surgery, 77 of 1211 (6.4%) eyes developed CME. Post-operative cataract surgery ($p = 0.0005$) and pre-operative PVR ($p = 0.0011$) were the independent risk factors for CME based on multivariate analyses in this subgroup. Of note, vitrectomy and vitrectomy with scleral buckle resulted in higher rates of CME compared to scleral buckle alone on univariate analyses, but did not remain statistically significant on multivariate regression analysis.

Conclusions: CME occurred in nearly 10% of eyes following RRD repair. The biggest risk factors were recurrent retinal detachment, preexisting PVR, older age, and cataract surgery following RRD repair.

ABSTRACT BODY:

Purpose: An over-active alternative complement pathway (ACP) is implicated in geographic atrophy (GA) pathophysiology and ACP end products are present in the choriocapillaris (CC), drusen and Bruch's membrane of eyes with AMD. In monkeys, a systemic Factor B antisense oligonucleotide (ASO) reduced ocular factor B (FB) protein >99%. We determined clinical safety, pharmacokinetic (PK) and pharmacodynamic (PD) activity of IONIS-FB-L_{Rx}, an ASO specifically targeting human complement factor B gene (CFB) and subsequent factor B (FB) production in the liver, as a means to decrease ACP activity in the CC.

Methods: In a phase 1 masked, randomized placebo-controlled single and multiple ascending dose study, healthy volunteers (HV) were randomized to either placebo or IONIS-FB-L_{Rx} (ACTRN12616000335493). The drug was administered (8 administrations in 6 wk – twice wk for 2 wk then once wk for 4 wk) at doses of 10 mg or 20 mg in the multiple ascending dose study. Endpoints assessed throughout the study: ocular and systemic safety, pharmacokinetic (PK) and pharmacodynamic (FB and ACP activity (AH50)).

Results: 54 HV (age range 27- 65 yrs) were enrolled and all subjects completed study (wk 19). There were no safety signals or clinically-relevant changes in ocular endpoints (BCVA, IOP, comprehensive examination), blood chemistries, hematology or vital signs following IONIS-FB-L_{Rx} dosing. The maximum tolerated dose (MTD) was not reached. The systemic PD markers of plasma FB levels reduced in a dose dependent manner by approximately 56% and 72% after multiple administrations of 10 mg and 20 mg, respectively. The mean (+/- SE) % reductions of FB, ACP activity (AH50) and classical complement pathway activity (CH50) levels for the 20 mg dose on Day 43 (7d post last administration) was -72 (+/-3), -62 (+/-5) and -12 (+/-5)%, respectively.

Conclusions: IONIS-FB-L_{Rx} is a novel antisense oligonucleotide drug, administered subcutaneously with a potential for monthly dosing. This first-in-human IONIS-FB-L_{Rx} study found the antisense drug to exhibit robust lowering of systemic FB and excellent safety profile. Based on these data, a Phase 2 double-masked, randomized placebo-controlled trial (N=330), the GOLDEN study, is currently underway to determine the potential of systemic IONIS-FB-L_{Rx} in reducing progression of GA (NCT03815825).

SUBMITTER (NAME ONLY): Alicia Canalejo

TITLE: Myopic choroidal neovascularization: prognostic factors with a PRN regimen of Anti-VEGF therapy

SESSION TITLE: CNV

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Canalejo, M. Lopez-Galvez, M. Muñoz Moreno, Hospital Clinico Universitario de Valladolid, Valladolid, Castilla y León, SPAIN|M. Lopez-Galvez, Instituto de Oftalmobiología Aplicada, Valladolid, Castilla y León, SPAIN|

Commercial Relationships Disclosure (Abstract): Alicia Canalejo: Commercial Relationship: Code N (No Commercial Relationship) | Maribel Lopez-Galvez: Commercial Relationship: Code N (No Commercial Relationship) | Maria Fe Muñoz Moreno: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the short and long-term efficacy of Anti-Vascular Endothelial Growth Factor (VEGF) intravitreal therapy with a Pro Re Nata (PRN) approach in the treatment of myopic choroidal neovascularization (CNV) and to investigate the correlation of basal risk factors with treatment outcomes, in order to individualize treatment.

Methods: Observational, retrospective study of 91 patients (28 men and 63 women) treated with Anti-VEGF therapy due to neovascularization secondary to pathologic myopia for a 1 to 6 years period. Best Corrected Visual Acuity (BCVA) and Central Retinal Thickness (CRT) before and after treatment were analyzed. The mean number of injections in the first year, and during the whole treatment period was assessed. Additionally, prognostic factors for Anti-VEGF treatment were identified such as age, baseline visual acuity, localization and anatomic features of CNV studied by OCT, as well as treatment considerations.

Results: Mean (SD) age at onset was 67.9 (14.4) years. The BCVA (logMAR) improved from 0.72 at baseline to 0.53 one month after the first injection, it remained stable in 0.53 after three months. BCVA after 6 years was 0.58 ($p < 0.05$ in all cases). A reduction of 47.96 μ m ($p < 0.05$) in CRT was observed in OCT three months after treatment. The mean number of injections during the first year was 3.05, and 3.65 for the complete follow-up period. BCVA improved 3 lines in young patients, compared to 1 line in patients over 60 years ($p = 0.115$). One month after treatment, BCVA in subfoveal CNV changed from 0.85 to 0.66 ($p < 0.05$), whereas in juxtafoveal CNV it improved from 0.58 to 0.39 ($p < 0.05$). Type 2 CNV demonstrated a better response to treatment (from 0.71 to 0.56) than type 1 CNV (from 0.75 to 0.62), $p < 0.05$.

Conclusions: Anti-VEGF therapy has demonstrated efficacy in the short and long-term with a significant improvement in BCVA and in CRT. The PRN regimen or "as needed" is appropriate and includes a more individualized treatment approach. Advanced age, poor baseline visual acuity and subfoveal localization worsen prognosis. However, further studies are needed in order to identify which patients would benefit from a more intensive therapy in the long term.

SUBMITTER (NAME ONLY): George Sanchez

TITLE: Patient's age as a prognostic factor of the visual outcome after surgical repair of primary macula-off rhegmatogenous retinal detachment (RRD)

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Sanchez, A.H. Sohn, J. McGinnis, D. Mantopoulos, Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire, UNITED STATES]

Commercial Relationships Disclosure (Abstract): George Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Ashley Sohn: Commercial Relationship: Code N (No Commercial Relationship) | Jacob McGinnis: Commercial Relationship: Code N (No Commercial Relationship) | Dimosthenis Mantopoulos: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine whether the patient's age correlates with the final best corrected visual acuity (BCVA) following surgical repair of a macula-off RRD. To look for signs of accelerated retinal atrophy after RRD in elderly patients using Optical Coherence Tomography (OCT).

Methods: Retrospective, consecutive case series. The medical records of patients who presented with RRD at an academic medical center anytime between January 2012 and October 2020 were reviewed. These patients were divided into three age groups: (A) ≤ 60 years-old, (B) 61-75 years-old, and (C) ≥ 76 years-old. Differences in postoperative BCVA between these age groups were assessed. Secondary outcome was differences in the central retinal thickness (CRT) based on OCT.

Results: From the 412 patients that were screened, 106 met the inclusion criteria (Figure 1). Eighty of them were male. Thirty-four of them were in group A, 49 in group B, and 23 in group C. The mean age \pm SD was 66.7 ± 10.3 years-old. The mean follow-up period was 22.1 ± 18.1 months. The mean logMAR (Snellen) BCVA \pm SD, pre-operatively and post-operatively, were 1.5 ± 0.8 (20/630) and 0.5 ± 0.5 (20/60), respectively. At final follow-up, logMAR (Snellen) BCVA was 0.25 (20/35), 0.57 (20/74) and 0.62 (20/83) in groups A, B, and C, respectively ($p < 0.05$ between the different subgroups). The difference in final CRT on OCT between the subgroups was not statistically significant (316.9 μ m in group A, 313.2 μ m in group B, and 310.2 μ m in group C).

Conclusions: In elderly patients who undergo successful surgery for macula-off primary RRD the visual recovery might be more limited compared to that in younger patients. In the current study the difference between the CRT in different age subgroups was not statistically significant.

TITLE: The therapeutic effect of Roxadustat in a mouse model of meibomian gland dysfunction

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Liu, S. Yang, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|S. Yang, Ophthalmology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, CHINA|

Commercial Relationships Disclosure (Abstract): Yang Liu: Commercial Relationship(s);Schepens Eye Research Institute:Code P (Patent) | Shan Yang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently discovered that meibomian glands (MGs) exist in a relatively low oxygen environment in vivo, and that hypoxia inducible factor 1 α (HIF1 α) plays a very important role in the regulation of MG function. We hypothesize that Roxadustat (Roxa) could serve as a treatment for MG dysfunction (MGD) by activating the HIF1 α pathway in MGs. To test our hypothesis, we used a newly identified MGD animal model--the Apolipoprotein E-deficient (ApoE KO) mouse--in our study. The ApoE KO mice present the clinical and pathological changes seen in MGD patients, and are also characterized by a marked increase in total plasma cholesterol levels.

Methods: Sixteen adult male ApoE KO mice were used in this study. Four sex- and age-matched wild type (WT) C57BL/6J mice were used as phenotype controls. The ApoE KO mice were treated with vehicle or Roxa for 12 weeks. Ocular surface and adnexal evaluations, and tear volume and body weight measurements were made before and after Roxa treatment. Mouse eyelids were removed and processed for histology and MG area quantification. MG sections were subjected to MG area quantification, LipidTox staining, and immunostaining for HIF1 α and its associated proteins, including glucose transporter 1 (Glut1), carbonic anhydrase 9 (CA9), peroxisome proliferator-activated receptor gamma (PPAR γ), and the adhesive protein desmoglein (Dsg). Total serum cholesterol was measured at the end of the treatment. Experiments were approved by the Institutional Animal Care and Use Committee of The Schepens Eye Research Institute and adhered to the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research.

Results: Roxa significantly reduced MG dropout, decreased corneal fluorescein staining, and increased the tear volume. Roxa also enhanced HIF1 α activation, changed the expression pattern of Glut1, CA9 and PPAR γ , and significantly increased the expression of Dsg in the MGs. In addition, Roxa significantly decreased the percentage of weight gain and total serum cholesterol level in these mice.

Conclusions: Roxa may serve as a potential new therapy for the treatment of MGD.

TITLE: Saccade Latencies are Longer for Early/Intermediate AMD than Age-Matched Normal Patients.

SESSION TITLE: AMD: Clinical and translational research I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.H. Ridder, L. Centeno, Southern California College of Optometry, Marshall B Ketchum University, Fullerton, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): William Ridder: Commercial Relationship: Code N (No Commercial Relationship) | Lani May Centeno: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous literature has shown that fixation stability and reading performance is poor in patients with advanced stages of age-related macular degeneration (AMD). However, little research has been conducted to determine oculomotor characteristics in patients with early/intermediate AMD. The aim of this study was to determine saccade latency differences between early/intermediate AMD patients and age-matched controls.

Methods: Thirteen subjects with early/intermediate AMD (age 75.1 ± 10.29) and fourteen age-matched controls (age 70.5 ± 6.42 , $p = 0.18$) were enrolled in the study. All participants underwent a clinical comprehensive eye examination including refraction, best corrected visual acuity, optical coherence tomography, color fundus photography, and fundus autofluorescence photos. The logMAR visual acuities were 0.03 ± 0.105 and -0.007 ± 0.119 for the AMD and control patients, respectively ($p = 0.35$). The simplified AREDS scale was used to classify the AMD patients (2.5 ± 1.17). Saccade latency was obtained utilizing the screen-based Tobii TX300 eye tracker (Tobii Technology, Sweden) to determine eye position. Testing procedures were conducted monocularly. The stimulus for testing was an "X" subtending 2 degrees vertically and horizontally. Initially, the cross appeared in the center of the display. The cross was displayed for 30 seconds before the stimulus was removed and an identical cross was displaced 5 degrees horizontal to the right or left of the initial cross. The second cross was displayed for 30 seconds and then removed. Saccade latency was defined as the time in milliseconds between when the cross moved and the subject's first saccade to the new cross location. The average saccade latency was determined for five forward (i.e., to the right) and backward saccades (i.e., to the left).

Results: Saccade latency was statistically increased for early/intermediate AMD (326.1 ± 91.6) compared to age-matched controls (252.3 ± 80.3) for forward saccades (two-tailed t-test, $T_{25} = 2.229$, $p = 0.035$) but not backward saccades (AMD 299.2 ± 95.7 , Control 293.1 ± 164.7 , $p = 0.37$).

Conclusions: Forward saccade latency was significantly greater for early/intermediate AMD subjects compared to age-matched controls. This increase in saccade latency for early/intermediate AMD patients may account for their increase in reading complaints.

TITLE: Perioperative management of antithrombotic agents in glaucoma surgery: a survey

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.L. Cote, D. Tingey, Ophthalmology, Western University Schulich School of Medicine & Dentistry, London, Ontario, CANADA|N. Zebardast, Ophthalmology, Massachusetts Eye and Ear Infirmary Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Stephanie Cote: Commercial Relationship: Code N (No Commercial Relationship) | David Tingey: Commercial Relationship: Code N (No Commercial Relationship) | Nazlee Zebardast: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma surgery in anticoagulated patients poses unique challenges. There is currently no consensus on perioperative management of antithrombotics for glaucoma surgeries, and the new non-vitamin K antagonist oral anticoagulants (NOACs) have introduced further uncertainty. Our purpose was to survey the practice patterns of glaucoma specialists on perioperative management of antithrombotic agents in patients undergoing glaucoma surgery.

Methods: An anonymous cross-sectional survey was sent to members of the American Glaucoma Society (AGS) to investigate ophthalmologists' usual practice regarding antithrombotic therapy prior to, during and after trabeculectomies and glaucoma drainage implantations (GDI).

Results: One hundred and six surgeons responded to our survey. For trabeculectomies, majority of surgeons reported stopping P2Y12 inhibitors, NOACs, and warfarin (55%, 56% and 64% respectively) while 49 out of 104 (47%) surgeons routinely stop aspirin (ASA) before surgery (Figure 1). Similarly, for GDI, warfarin (54%) was most commonly stopped pre-operatively, followed by P2Y12 inhibitors and NOACs (both 49%), and ASA (42%). The majority of the surgeons who discontinue antithrombotic therapy reported doing so 6 days prior to surgery for aspirin, 3-5 days before surgery for P2Y12 inhibitors and warfarin, and either 48 or 72 hours before surgery for NOACs. Of those who stop warfarin and NOACs, the majority routinely liaise with patient's internist or general practitioner. Most surgeons resumed each antithrombotic within 1-day post-operatively, however almost half of those same surgeons (55% and 42% for warfarin, 46% and 53% for NOACs, for trabeculectomies and GDI respectively) said they will occasionally delay resuming greater than 1-day. The type of glaucoma surgery affects the decision to stop an antithrombotic in 53% of surgeons. Of those surgeons, 78% are more likely to stop an antithrombotic for trabeculectomies, 7% for GDI, and 15% for minimally invasive glaucoma surgeries (MIGS).

Conclusions: There is variability in the perioperative management of antithrombotic therapy among glaucoma surgeons with a considerable proportion reporting not stopping these agents pre-operatively. Further evidence-based guidelines are required to provide recommendations and address variations in practice.

Commercial Relationships Disclosure (Abstract): Sara Vaz-Pereira: Commercial Relationship(s);Alimera Sciences:Code R (Recipient);Bayer:Code R (Recipient);Novartis:Code R (Recipient);Roche:Code R (Recipient) | Tiago Morais-Sarmento: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella De Salvo: Commercial Relationship(s);Allergan:Code R (Recipient);Bayer:Code R (Recipient);Heidelberg Engineering :Code R (Recipient);Novartis:Code R (Recipient)

ABSTRACT BODY:

Purpose: To evaluate the accuracy of MultiColor imaging (MC) compared to fluorescein angiography (FA) in detecting proliferative diabetic retinopathy (PDR) and associated diabetic retinopathy features.

Methods: Fifty-nine eyes from 38 PDR patients were included. MC images were reviewed by 2 independent masked graders. A qualitative analysis based on the following features was performed: neovascular complexes (NVC), disc neovascularization (NVD), neovascularization elsewhere (NVE), microaneurysm (MA), intraretinal hemorrhage (IRH), vitreous hemorrhage (VH), preretinal hemorrhage (PRH), fibrosis, hard exudates (HE), epiretinal membrane (ERM), diabetic macular edema (DME), ischemia and laser spots (LS). Measures of diagnostic accuracy compared to FA were determined.

Results: The sensitivity for the detection of NVC using MC was 95.1%, with a specificity of 40.0%, positive predictive value (PPV) of 92.9% and negative predictive value (NPV) of 50.0%. Sensitivity and specificity were higher in detecting NVD (88.9% and 76.9%) while NVE registered higher PPV (88.9%). MC was highly sensitive in detecting IRH, HE, ERM and LS (100%), MA (98.0%) and fibrosis (95.5%). Highest specificity was found for VH (100.0%), DME (100.0%), PRH (98.1%) and LS (89.5%). The area under the receiver-operating characteristic analysis of MC was excellent in NVD (0.83, 95% confidence interval (CI), 0.71-0.95, $p<0.001$), IRH (0.89, 95% CI 0.74-1.00, $p<0.001$), VH (0.81, 95% CI 0.60-1.00, $p=0.005$) and PRH (0.89, 95% CI 0.68-1.00, $p=0.004$) and outstanding in LS detection (0.95, 95% CI 0.87-1.00, $p<0.001$). These results are likely due to the contrast and quality of the MC, since a better discrimination is enabled by the green wavelength. The intergrader agreement for the MC features assessed was almost perfect with a weighted kappa of 0.86 (standard error: 0.02, 95% confidence interval: 0.82–0.88).

Conclusions: MC detected some PDR features such as NVD, VH, PRH, IRH and laser spots, more accurately than FA. These findings make MC a useful test for the diagnosis and follow-up evaluation of PDR, complementing the noninvasive imaging of this disease.

TITLE: In vitro characterization of a novel in situ-forming semi-interpenetrating polymer network of crosslinked collagen and glycosaminoglycans for corneal defect repair

SESSION TITLE: Corneal epithelium and Corneal tissue engineering and regenerative medicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.C. Mundy, F. Chen, P. Le, D. Myung, Department of Ophthalmology, Stanford University School of Medicine, Stanford, California, UNITED STATES|F. Chen, P. Le, D. Myung, VA Palo Alto Health Care System, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): David Mundy: Commercial Relationship: Code N (No Commercial Relationship) | Fang Chen: Commercial Relationship: Code N (No Commercial Relationship) | Peter Le: Commercial Relationship: Code N (No Commercial Relationship) | David Myung: Commercial Relationship(s);Stanford University:Code P (Patent)

ABSTRACT BODY:

Purpose: In situ-forming hydrogels are promising new candidates to treat corneal injury and disease, as global corneal donor shortages leave millions at risk for or affected by corneal blindness without effective treatment. The extracellular matrix of the corneal stroma consists of collagen type I and glycosaminoglycans (GAGs) which together provide biomechanical and biochemical cues that modulate cellular behavior. We have developed and characterized a novel semi-interpenetrating polymer network (SIPN) of crosslinked collagen and GAGs that can potentially treat corneal stromal defects and promote wound healing.

Methods: The SIPN was formed by crosslinking collagen type I with succinimidyl glutamic acid ester difunctionalized polyethylene glycol (PEG) using N-hydroxysuccinimide (NHS) ester chemistry, which was then mixed with hyaluronic acid (HA), chondroitin sulfate (CS), or both. To determine gel stiffness, storage (G') and loss (G'') moduli were measured. Transparency was evaluated by UV/Vis spectroscopy as transmittance after gelation. Gel cytocompatibility was assessed by live/dead assay using human corneal epithelial cells seeded on the gels.

Results: The collagen-PEG NHS gel and its SIPNs with HA and/or CS started to form within 1 minute, reaching 50% gelation within 10 minutes under ambient conditions. Mechanical properties were tunable by changing the concentration of PEG and the ratio of collagen:GAGs. 4% PEG (v/v PEG to collagen) gels had higher storage moduli than 8% PEG gels, whereas addition of GAGs decreased gel stiffness. The collagen-PEG and SIPN gels all showed over 95% transparency from 380 to 700 nm. Transmittance remained over 95% at 48 hours, whereas transmittance of non-crosslinked collagen decreased significantly over time. All gels were cytocompatible, with the SIPN with HA and/or CS demonstrating improved cell viability over collagen-PEG NHS alone.

Conclusions: We have developed a novel, collagen-PEG SIPN with GAGs that forms quickly in situ under ambient conditions. The hydrogel displays tunable mechanical properties, maintains excellent transparency, and promotes corneal epithelial cell viability, demonstrating the potential to promote wound healing and advance the treatment of corneal injury and disease.

ABSTRACT BODY:

Purpose: To determine the antioxidant and anti-inflammatory activity of crude extracts and their two major phenolic compounds (Oleuropein – OL and Hydroxytyrosol – HT), derived from the olive oil's industry main environmentally hazardous by-product, the Olive Pomace (OP), in human corneal (HCE) and conjunctival (IM-ConjEpi) epithelial cells.

Methods: Two OP extracts were produced: extract 1 (E1) by a conventional extraction, and 2 (E2) by a Design of Experiments extraction optimization. Their anti-inflammatory and antioxidant effects were tested in vitro in HCE and IM-ConjEpi cells. Cells were pre-treated for 2h with E1 (0.05-0.80 mg/mL) and E2 (0.005-0.400 mg/mL) and then stimulated with TNF- α (25 μ g/ml) for 24h in the presence/absence of treatments. IL-1 β , IL-6, IL-8 and IP-10 secretion was analysed by an immune bead-based array. Intracellular Reactive Oxygen Species (ROS) production was determined by H2DCF-DA dye assay in ultraviolet (UV)-B radiation-exposed cells in the presence/absence of treatment for 1h (with 1h pre-treatment). The effect of OL (5–300 μ M), HT (1–100 μ M) and their mixture (5 μ M OL + 10, 25 or 50 μ M HT) was also tested. Cells not exposed to TNF- α or UV-B, and vehicle-treated cells were used as control. Data were normalized to corresponding protein content.

Results: TNF- α stimulated IP-10-secretion was significantly decreased in a dose-dependent way by E2 and HT in IM-ConjEpi and HCE cells, and by E1 and OL in IM-ConjEpi cells. IP-10 secretion was also decreased in HCE cells by 5 μ M OL + 10 μ M HT ($P < 0.001$). IL-6 secretion was inhibited dose-dependently by HT and E1, and by 0.2 and 0.4 mg/mL of E2 in HCE ($P < 0.05$). E1 (0.6 and 0.8 mg/mL), E2 (0.2 and 0.4 mg/mL) and 100 μ M of HT decreased IL-8 secretion in HCE cells. IL-1 β production in HCE was inhibited by E1 dose-dependently. UV-B stimulated ROS production was significantly inhibited in both cell lines by E1, E2, OL and HT dose-dependently and by 5 μ M OL + 10 μ M HT ($P < 0.01$).

Conclusions: Extracts from OP, an environmentally hazardous agro-industrial by-product, as well as their major phenolic compounds, HT and OL, may be used as therapeutic agent for inflammatory and oxidative-related ocular surface diseases. The results of this work consist an essential baseline for the treatment of these diseases in the future, while are paramount for the sustainable growth of related industries. Results are patent pending.

ABSTRACT BODY:

Purpose: To develop a machine learning model to detect keratoconus severity from corneal topography, elevation and pachymetry parameters and to assess the generalizability of the model using an independent dataset from a different population.

Methods: We developed a machine learning model to detect different keratoconus severity levels from corneal parameters and compared it to four other machine learning models. The base model was trained and tested using 5881 cases in Brazil We then evaluated the model using a dataset with 1351 cases. We included only 50 raw corneal parameters and excluded all parameters that were generated by Pentacam to assess keratoconus. We utilized a 5-fold cross validation of the area under the receiver operating characteristic curve (AUC) to evaluate machine learning models.

Results: A total of 1726 eyes from the Brazil dataset were diagnosed as normal and 4155 were abnormal based on the Pentacam KCN index. A total of 400 eyes from Japan dataset were normal and 951 eyes diagnosed as KCN based on the Pentacam KCN index. The Random Forest classifier achieved the best AUC of 0.96 compared to four other classifiers once tested on the eyes from the Brazil dataset (Fig. 1). This model also achieved a high AUC of 0.87 once independently tested on all eyes from the Japan dataset (Fig. 2, left panel). Most of the confusions in the model tested on Japan dataset was between normal eyes and eyes with the mild stage of keratoconus (Fig 2, right panel).

Conclusions: The proposed machine learning algorithm provided a highly specific and sensitive model that can detect normal and four stages of keratoconus, with only raw Pentacam corneal parameters, without the machine generated keratoconus indices. The proposed model was generalizable to other cohorts from different races and has the potential to be used in cornea research and clinical practice to automatically detect keratoconus severity from corneal parameters.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic further increased the lack of human donor corneas for research purposes. In this study we established a porcine cornea model for testing corneal storage media formulations.

Methods: 14 corneas were extracted from porcine eye globes obtained from local slaughterhouse after povidone-iodide 5% disinfection. The tissues were stored in standard corneal culture medium Eusol-C (AL.CHI.MI.A. SRL) at 4°C. After 0, 3, 7, and 14 days the tissues were analyzed in quintuplicate at T0 and in triplicate for the other timepoints with Optical coherence tomography (OCT) for central corneal thickness (CCT). The corneal transparency was evaluated by measurement of optical density using a homemade instrument. At each timepoint corneal endothelium was stained with trypan blue and alizarin red and evaluated with an inverted microscope with 100 X magnification (Nikon) for endothelial cell density (ECD) and morphology in both whole cornea and in dissected corneal lamellas consisting of Descemet's membrane (DM) and endothelial cells (EC).

Results: The corneal transparency diminished along storage time of approximately 10%. Corneal thickness increased of approximately 100 µm at day 14. ECD decreased of approximately 10% from T0 to the final T14 timepoint leading to an average of 2800 cells/mm² at T14. The dissected DM corneal lamellas allowed good EC morphology evaluation which was well preserved after 14 days at 4°C. The flaccidity of porcine corneas made OCT measurements difficult and CCT showed slight variability.

Conclusions: We established a porcine cornea model that allowed reproducible corneal evaluation of ECD, endothelial morphology CCT and transparency in whole porcine corneas and dissected DM corneal lamellas. In conclusion, the evaluation of porcine corneal tissues allowed to compensate to the lack of human donor tissues for research use, providing a reliable tool for testing corneal storage media formulations.

ABSTRACT BODY:

Purpose: Amblyopia is a developmental disorder caused by disruption of symmetric binocular visual input early in life. Most amblyopic individuals suffer from impairments in stereopsis and motion perception, especially in the central visual field. We studied the impact of amblyopia on the functional organization of fine-scale stereo- and motion-selective clusters across human extrastriate visual cortex.

Methods: We localized stereo- and motion-selective clusters across areas V2, V3, V3A and MT in 5 amblyopic (3 strabismic and 2 anisometropic) subjects and 14 controls using high-resolution (1 mm isotropic) fMRI in a 7T scanner. In separate scan sessions, we also measured speed, direction, and coherence sensitivity of the response in the motion-selective clusters. We also localized color-selective clusters in the same subjects as an internal control.

Results: Controls (≈ 50 arc sec randot stereoacuity) showed stereo-selective clusters across extrastriate visual areas (Fig. 1A), while amblyopic individuals (>250 arc sec) showed no significant stereo-selective response (Fig. 1B). Nevertheless, interdigitated clusters of motion- and color-selective responses were still found in areas V2/V3 of amblyopic individuals, as detected in controls. In both groups we also detected motion-selective responses within areas V3A and MT.

Despite the overall similarity in the distribution of motion-selective clusters between the two groups, the level of motion-selective response, especially to higher speeds and lower coherency levels, was weaker in amblyopic compared to control subjects. In V2 and V3, this between-groups difference: (i) was confined to those regions that represented the central (0° - 3°) visual field and (ii) accompanied a weaker direction-selectivity in amblyopic compared to control subjects.

Conclusions: Amblyopia affects the functional organization and the response selectivity of stereo- and motion-selective clusters across human extrastriate visual cortex. The spatial distribution of this effect is consistent with behavioral reports of a stronger amblyopia impact on central compared to peripheral vision.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) plays an essential role in maintenance of photoreceptors. RPE dysfunction may cause several diseases including retinitis pigmentosa, age-related macular degeneration, and pathologic myopia. Strategies for regenerative medicine are divided into autologous and allogeneic, somatic and stem cell-derived, an epithelial cell sheet and cell suspension. Iris pigment epithelium (IPE) is an alternative candidate because of relatively easy access for sampling. The purpose of this study is to prepare an IPE cell sheet for autologous implantation and evaluate neuroprotective effects in vivo.

Methods: Using our own technology to produce an RPE cell sheet with Bruch's membrane, a cell sheet of IPE cells, which were isolated from the iris and cultured, was prepared and implanted into the subretinal space of the right eye in 10 nude rats to evaluate possible adverse events histologically and in 13 royal college surgeons (RCS) rats under immunosuppression to assess neuroprotective efficacy. As the control group, only the sham surgery was performed in 10 nude rats and 10 RCS rats. At week 2, all of the right eyes of nude rats were enucleated to evaluate any adverse events histologically. In months 1 and 3, the right eyes of RCS rats were enucleated to assess both neuroprotective effects and any adverse events. To evaluate neuroprotective effects, the remaining outer nuclear layer (ONL) was graded from 1 to 5 (1: totally missing, 2: very slightly remaining, 3: slightly remaining, 4: moderately remaining, 5: largely remaining).

Results: There were no adverse events both in and outside of the implanted site in nude rats and RCS rats. In the control group of RCS rats, 3 of 5 eyes in month 1 and all of 5 eyes in month 3 showed the totally missing ONL (grade 1). In contrast, the ONL was somewhat remaining in all of 8 eyes (in grades 2-4) in month 1 and 4 of 5 eyes (in grades 2 and 3) in month 3 in the group with the IPE cell sheet implantation.

Conclusions: An IPE cell sheet implantation showed neuroprotective efficacy, suggesting the potential for regenerative medicine. We will plan to perform a phase I/IIa clinical study for regenerative medicine for diseases related to RPE dysfunction.

ABSTRACT BODY:

Purpose: EMA is a novel imaging technique permitting direct erythrocytes visualization. With EMA, erythrocytes can be observed in motion or in stasis. One cause of the transient stasis is hypothesized to be a manifestation of status of vasomotion. Erythrocytes in stasis could serve for characterizing hemodynamics status of retinal/choroidal vasculature in systemic and ocular diseases including primary open-angle glaucoma (POAG). This research has two main goals 1) developing a network model to quantify paused erythrocyte densities in EMA; 2) studying differences of relative paused erythrocyte densities for the control and POAG/POAG suspects.

Methods: 1) To train a network, we labelled 3752 cells in 24 temporally averaged (TA) images from 6 eyes (4 POAG/POAG suspects, 2 controls) which can visualize erythrocytes in stasis. Two trained researchers labelled pausing erythrocytes, and consensual labellings were used for network training. A regressional network was designed and trained in the manner of leave-one-eye-out cross validation to count pausing erythrocytes. 2) The trained model was applied to 22 eyes (16 POAG/POAG suspects, 6 controls) from 15 subjects. For each eye, EMA imaged both its peripapillary and macula area with duration of 5-15 seconds. The detected paused erythrocyte densities are 106.6 ± 159.27 cells/TA image and 191.25 ± 98.08 /TA images in the peripapillary and macula area. We defined peripapillary to macular ratio (PMR) as the paused cell count ratio between peripapillary and macula area. Generalized estimating equation (GEE) was used to compare PMR between controls and POAG/POAG suspects.

Results: 1) The cross validated f1-score of trained network is 0.938, which showed no significant difference compared to two trained researchers ($p < 0.05$). 2) The PMR value was 0.94 ± 0.23 in controls and 0.49 ± 0.18 in POAG/POAG suspects. POAG is statistically significant related to the PMR value ($p < 0.001$).

Conclusions: 1) Regression based neural network is a reliable model to quantify paused erythrocytes in EMA videos. 2) Our results showed differing PMR values between control and POAG/POAG suspects. This new finding manifests PMR can be potentially considered as a pathophysiological biomarker of early stage glaucomatous damage. Further studies are needed to determine the axial location of paused erythrocytes to better explain the phenomenon.

ABSTRACT BODY:

Purpose: To develop a method of estimating pulsatile ocular blood volume (POBV) from measurements taken during an ophthalmic exam with a tonometer capable of measuring intraocular pressure (IOP) and ocular pulse amplitude (OPA).

Methods: A data set compiled from a previous accuracy study (Boehm 2008) on the PASCAL dynamic contour tonometer (DCT) provided central corneal thickness (CCT) and axial length (AL), as well as IOP and OPA using DCT and intracameral (ICM) measurements for 60 cataract patients. Briefly, once supine intracameral pressure was set to 15, 20, and 35 mmHg (randomized sequence) using a fluid-filled manometer, the system was closed by a stopcock, and IOP and OPA measurements were acquired at each manometric set-point (DCT and ICM simultaneously). The statistically significant correlation of ocular rigidity (OR) to the natural log of AL from a previously published study invasively measuring ocular rigidity through fluid injection was applied to the data set to estimate OR from AL. Friedenwald's original pressure volume relationship was used to derive the estimated blood volume delivered to the choroid with each heartbeat (POBV) as a function of OR, IOP, and OPA, according to the equation $POBV = \log((OPA+IOP)/IOP) / OR$. Linear regression analyses were performed comparing OPA to OR and calculated POBV at each of the three manometric set-points. POBV was also compared to the factor OPA/IOP with all data points combined. Significant threshold was $p < 0.05$.

Results: OR estimated from AL showed a significant positive correlation to OPA for both DCT ($p < 0.011$) and ICM ($p < 0.006$) at all three manometric pressure set-points, with a greater slope for lower IOP. Calculated POBV also showed a significant positive correlation to OPA ($p < 0.001$) with greater slope at lower IOP. In the combined analysis, POBV showed a significant positive correlation to OPA/IOP ($p < 0.001$) in both ICM and DCT measurements with $R^2 = 0.9685$, and $R^2 = 0.9589$, respectively (see Figure).

Conclusions: POBV provides a straight-forward method to estimate pulsatile ocular blood volume noninvasively. Higher IOP with lower OPA results in the lowest values of POBV. The OPA/IOP factor may provide a useful clinical tool for evaluating changes in ocular blood flow in diseases with a vascular component, such as diabetic retinopathy and normal tension glaucoma. Future studies are warranted.

Commercial Relationships Disclosure (Abstract): Jonathan Ibinson: Commercial Relationship: Code N (No Commercial Relationship) | Atieh Yousefi Koupaei: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Roberts: Commercial Relationship(s);Oculus Opitgerate GmbH:Code C (Consultant);Ziemer Ophthalmic Systems AG:Code C (Consultant) | Matthew Reilly: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the performance of a static air quality monitor to measure aerosolization of a dynamic air puff from a noncontact tonometer (NCT) using cornea phantoms.

Methods: Three rubber corneal phantoms of different stiffnesses were used to represent intraocular pressure (IOP) values of 6, 13, and 43 mmHg. No liquid components and therefore no aerosol-generating potential was present. Reported concentrations of particulate matter (PM) less than 2.5 and 10 μ m, respectively PM_{2.5} and PM₁₀, were recorded using a static air quality indicator (AQI; LKC 1000S+) during an air puff generated using an Ocular Response Analyzer G3. The phantoms were mounted in a styrofoam head with eye socket locations. The AQI was set in four locations around the phantom. Depending on indicator position with respect to the phantom, the locations were defined as "upper/lower" and "same/opposite." Tests were performed in an isolated room. Baseline AQI values were recorded prior to each test with a one-minute delay between tests to allow the device to recalibrate. An ANOVA was performed to assess the effect of covariates IOP and location on changes to AQI measurements from the baseline, Δ PM_{2.5} and Δ PM₁₀. A Monte Carlo simulation with 10,000 replicates was undertaken to determine the likelihood of observing published trends by chance. The statistical significance threshold was $p < 0.05$.

Results: No correlations were found between PM_{2.5} and IOP ($p = 0.3943$) or location ($p = 0.3049$). Reported concentrations of PM₁₀ depended significantly on both IOP ($p = 0.0241$) and location ($p = 0.0167$), specifically the lower opposite location ($p = 0.0031$). Monte Carlo simulations using these results suggest that the likelihood of finding a spurious positive correlation between IOP and PM at the upper same location are 53% and 92% for PM_{2.5} and PM₁₀, respectively.

Conclusions: While a statistically significant correlation was found between reported PM₁₀ and IOP/location, even the highest reported PM values were far below the AQI sensitivity of ± 10 and $\pm 15 \mu\text{g}/\text{m}^3$ for PM_{2.5} and PM₁₀, respectively. The AQI updates every 3 seconds, yet the NCT puff is approximately 30 ms in duration. Since these experiments were conducted in the absence of any aerosol source (i.e., tear film), published IOP-PM correlations are likely a result of air pressure magnitude. (Tang 2020) Therefore, the AQI is not capable of quantifying aerosolization with an NCT air puff.

ABSTRACT BODY:

Purpose: Various carriers for the Boston Keratoprosthesis (KPro) have been proposed including xenografts, autografts, collagen constructs, as well as fresh, frozen, dehydrated and γ -irradiated allografts. One potential limiting factor in the use of these carriers is the discrepancy in thickness. We examine the impact of corneal thickness on aqueous leak after KPro implantation.

Methods: Using a femtosecond laser, ethanol-preserved corneal donor buttons were mounted on an artificial anterior chamber and cut to various thicknesses. Anterior segment OCT was used to measure the thickness before and after the cut creation. A dermatologic punch was used to make a central hole and the KPro was assembled in the standard fashion. The assembled corneal construct was mounted onto the anterior chamber which was attached to a phacoemulsification machine with the intraocular pressure (IOP) set at the lowest setting of 20 mmHg. The IOP was gradually increased and a fluorescein strip was used to check Seidel positivity.

Results: Three corneas were cut with resulting post-cut thicknesses of 168 μm , 346 μm , and 413 μm , and a fourth cornea was left uncut with a thickness of 858 μm . When connected to the phacoemulsification machine, the three cut corneas were Seidel positive at 20 mmHg, while the fourth remained Seidel negative even at maximal IOP (80 mmHg).

Conclusions: A minimal corneal carrier graft thicknesses between 413 μm and 858 μm is required to avoid intraoperative leak during KPro implantation. Additional experiments are needed to further narrow down this range.

ABSTRACT BODY:

Purpose: To measure acute lamina cribrosa (LC) deformations induced by elevated intraocular pressure (IOP) when healthy and at onset of experimental glaucoma (EG).

Methods: The optic nerve heads (ONHs) of four eyes of four rhesus macaque monkeys were imaged using optical coherence tomography (OCT, Spectralis) in three imaging sessions before (baselines 1 and 2) and at the onset of laser-induced EG. Onset was defined as confirmed peripapillary RNFL loss from OCT. In each session, the ONHs were scanned after IOP was set for 10 minutes to 10 mmHg and to 40 mmHg. Digital volume correlation (DVC) analysis was then used to determine the LC changes between scans. LC changes represent either acute (between IOP levels) or chronic deformations (between sessions at the same IOP, Fig. 1).

Results: LC deformations between baseline 1 and baseline 2 at low IOP (10 mmHg) were the smallest (compression 2-3%) in all four eyes, indicating good repeatability (Fig. 2, Step 4). During baseline, acute IOP-induced LC deformations were substantially larger (8-12%) and consistent in all four eyes at both tests (Fig. 2, Steps 1 and 2), indicating stable LC compliance. Compared with the acute IOP effects at baseline, the acute IOP effects at onset (Fig. 2, Step 3) were larger in three monkeys (up to 17%) and smaller in one monkey (5%). Interestingly, chronic changes induced by onset of EG (Fig. 2, Step 5, 8-15%) were larger than the acute IOP-induced LC deformations at baseline.

Conclusions: Acute and chronic IOP-induced LC changes can be reliably measured using OCT and DVC. At EG onset, three of four monkeys exhibited substantial changes in the LC and increased LC compliance, suggesting that the damage and remodeling processes are already advanced.

TITLE: Pathogenesis of Space Associated Neuro-Ocular Syndrome examined using the Ex-Vivo Human Translaminar Autonomous System

SESSION TITLE: Optic Neuropathies - Pathophysiology and Therapies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T.P. Sharma, Ophthalmology, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tasneem Sharma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The chronic dysregulation between intracranial pressure (ICP) and intraocular pressure (IOP) in space may restructure the posterior eye to a condition that is maladaptive to Earth and can cause Space Associated Neuro-ocular Syndrome (SANS). We will employ our novel ex-vivo translaminar autonomous system (TAS) to effectively recreate the ex-vivo mechanical and pathological IOP/ICP microenvironment to study SANS pathogenesis.

Methods: To recapitulate SANS conditions, dissected human posterior cups (PCs) (N=3) were cultured in the TAS model for various translaminar differentials (IOP: ICP chambers; 16:12; 16:15, 21:12, 21:15 mmHg) and maintained over 14 days. In addition, the ONs were placed in 6- and 10-degree tilts with IOP: ICP at 16:15 mmHg. Posterior globe changes were determined via photomicrographs. We identified retinal, inflammatory and apoptotic markers through TAQMAN arrays. The FN and COLIV expression were examined from conditioned medium of various groups by Western analysis. Degeneration of ON axons from various experimental conditions was assessed by paraphenylenediamine staining. The morphological reorganization and gliosis of optic nerve head (ONH) was studied by expression of LAM and GFAP. TUNEL staining was used to assess apoptosis. Transport and functional analyses were performed by Cholera-toxin B and electroretinograms respectively.

Results: We successfully maintained all translaminar differentials (N=3) over 14 days. Post culture, visual micrograph depicted a general bulging at the ONH for all groups. The 6-degree tilts with IOP: ICP at 16:15 mmHg had elevated expression of all retinal markers compared to control. The tilting of the ON caused highest increase in GFAP, BAX and TLR4 expression. Compared to control, all groups displayed elevated FN and COLIV. Experimental conditions depicted greater degenerated axons. Extensive glial scarring and cupping was also observed due to ON tilting. Increased TUNEL positive cells were identified within experimental groups. Minimal expression of CTB was detected within control and certain experimental groups. Compared to control, ERGs from experimental groups showed varying amplitudes at 1000mcd.s/m².

Conclusions: Our novel TAS model characterized the SANS pathogenesis. This model can be utilized for future preclinical studies and a unique tool to test new therapeutics that can target SANS pathogenesis in astronauts.

ABSTRACT BODY:

Purpose: To quantify and analyze regional variations of mechanical strains within the corneal stroma in human donor globes during intraocular pressure (IOP) elevation using high-frequency ultrasound speckle tracking.

Methods: Ten globes from 9 human donors were obtained (age: 41-76 years old, 5 male and 4 female). Treatment with poloxamer 188 (3.5-4.25%) was used to return corneas to their physiological hydration as described previously (Clayson et al, EER, 2019). The globes were inflated from 5 to 30 mmHg in intervals of 0.5 mmHg. At each IOP level, an ultrasound scan was acquired using a 50 MHz probe (MS700, FujiFilm VisualSonics) from the central 9.73 mm of the cornea along the nasal-temporal meridian. Tissue displacements were calculated using ultrasound speckle tracking and strains were calculated using least squares estimation (Tang and Liu, JBME, 2012). The corneal stroma was divided into two regions, central and paracentral as shown in Fig 1a. The deformation of these two regions was compared using paired t-tests.

Results: Strains measured at 30 mmHg were recorded for all 10 globes. Tangential strain in the corneal stroma was significantly larger in the paracentral ($1.8 \pm 1.5\%$) than the central ($0.40 \pm 1.1\%$) zone ($p = 0.0022$, Fig 1b, Fig 2a). Radial strain was not significantly different between these two zones ($-2.1 \pm 1.9\%$ vs $-1.9 \pm 1.0\%$, $p = 0.73$, Fig 1c, Fig 2b). Shear strain magnitude was also not significantly different between zones ($2.7 \pm 1.2\%$ vs $3.1 \pm 2.2\%$, $p = 0.49$, Fig 1d, Fig 2c).

Conclusions: High-frequency ultrasound elastography enabled quantification of the different types of deformation through corneal stroma, showing tangential stretch, radial compression, and shear during IOP elevation. The central cornea was subject to lower tangential stretch but similar radial compression and shear as compared to the paracentral cornea. The finding of lower tangential strain in the central cornea was consistent with previous reports of corneal surface deformation using optical methods.

ABSTRACT BODY:

Purpose: To evaluate long term in vivo functionality of corneas regenerated using a cell-free, liquid hydrogel sealant/filler (LiQD Cornea; McTiernan et al., Sci. Adv. 2020) following deep corneal ablation with or without perforation in the feline model.

Methods: Two healthy cats underwent 3 and 1,5 mm diameter x stepwise 250/450 μ m deep surgical corneal ablation with and without needle perforation of the wound bed. The filler, made of 10% (w/w) CLP-PEG mixed with 1% fibrinogen and crosslinked with 2% (w/w) DMTMM, was applied to the wound bed that had been pre-coated with thrombin (250 U/ml). In situ gelation occurred within 5 min and a temporary tarsorrhaphy was performed. Examinations were performed weekly for 1 month and then monthly for 12 months. In vivo Outcome parameters included: slit-lamp assessment, Scheimpflug tomography, optical coherence tomography (OCT), confocal microscopy (CM), and endothelial cell morphometry, and ex vivo: transmission electron microscopy (TEM) and immunohistochemistry, including study of extracellular vesicles and exosomes.

Results: A smooth epithelial layer re-grew over the filled defects. The gelled filler remained stably integrated through the entire 12 months, without swelling, neovascularization, inflammation, infection, or rejection. Slit lamp, OCT (Fig.1), and CM showed progressive replacement of the filler by a more reflective tissue smoothly filling the wound bed, while keratocytes and nerves began to be seen, suggesting remodeling of the gel. The mild haze, maximum at 2-3 months, seen at the wound interface and within the remodeling tissue, disappeared with time. Host stroma and endothelium remained normal at all times. Tomography confirmed restoration of smooth and normal corneal surface curvature (Fig.2).

Conclusions: Biointegration of this hydrogel filler allowed stable restoration of normal corneal shape and transparency in the feline model, with less inflammation and no neovascularization compared to previous reports in the minipig and rabbit models. It offers a promising alternative to cyanoacrylate glue and corneal transplantation for ulcerated and traumatized corneas in human patients.

ABSTRACT BODY:

Purpose: Recurrence is a major complication of pterygium surgery. There is limited data on how much the surgeon's experience contributes to recurrence rates, specifically as it pertains to trainee ophthalmology residents. We performed a retrospective, cohort study to compare recurrence rates after pterygium surgery performed by attending physicians and trainee residents in our institution.

Methods: We analyzed data of pterygium surgeries performed by trainee residents and attending physicians in an academic institution in South Texas in the years 2008-2019. All residents' surgeries were performed under direct supervision of an attending physician. Only primary pterygium cases with a minimum postoperative follow-up of six months were included. Patients' demographics, primary surgeon, use of conjunctival autograft (CAU) or amniotic membrane graft (AMG), recurrence of pterygium, follow-up length, and complications were recorded.

Results: This study included 240 eyes of 229 patients with a mean age of 55.6 ± 12.3 years (range, 28-91 years). Of these eyes, 100 surgeries were performed by attending physicians (including 87 with CAU and 13 with AMG) and 140 surgeries by trainee residents (including 119 with CAU and 21 with AMG). There were no significant differences between the attending and resident groups regarding age, sex, and surgical technique (CAU versus AMG). Patients were followed for an average of 19.8 ± 15.2 months. No statistically significant differences were found between attending physicians and residents when comparing the rate of pterygium recurrence for either CAU (6.8% vs 10.0%, respectively, $p=0.42$) or AMG (69.2% vs 47.6%, respectively, $p=0.22$). Moreover, there were no significant differences in other postoperative complications between the groups.

Conclusions: Our results suggest that pterygium recurrence rates are similar between attending physicians and supervised trainee residents. Thus, acceptable outcomes can be expected when pterygium surgery is performed by a supervised ophthalmology resident.

ABSTRACT BODY:

Purpose: Rho-kinase (ROCK) inhibitors is a novel class of anti-glaucoma agents, which act by increasing the aqueous humor outflow through conventional trabecular meshwork (TM) pathway. The downstream signaling consequences of ROCK inhibition in the TM are not fully understood. In this study, we evaluated the role of thrombospondin-1 (TSP-1) in triggering ROCK inhibitor-mediated increase in outflow facility.

Methods: Primary cultures of human TM (hTM) cells were used. Cell migration assay was conducted with or without Y39983 (1 μ M, a selective ROCK inhibitor), LSKL (a TSP-1 antagonist), and TSP-1 siRNA knockdown. Differential protein expression was quantified by LC-MS/MS using SWATHMS technologies. Expression of TSP-1 protein and mRNA was confirmed by Western blot analysis and qPCR, respectively. Conventional outflow facility was measured in ex vivo mouse eyes.

Results: Proteomic analyses identified 20 proteins whose expression were significantly altered after hTM cells were treated with Y39983 for 2 days. Of these, thrombospondin-1 (TSP-1) was downregulated 5-fold following Y39983 treatment. In addition, Y39983 elicited a dose-dependent inhibition of hTM cell migration. Similarly, LSKL and TSP-1 siRNA knockdown significantly reduced TSP-1 gene expression (~50% reduction and ~80% reduction, respectively) and hTM cell migration, respectively. In the presence of Y39983, no further inhibition of cell migration was observed after LSKL treatment and TSP-1 gene silencing. Likewise, LSKL increased the outflow facility in mouse eyes by 74%, similar to that of Y39983 (increase by 82%). There were no additive effects with simultaneous treatment with LSKL and Y39983.

Conclusions: Y39983 down-regulated the TSP-1 expression in hTM and silencing TSP-1 gene expression improved the outflow facility. Since there was no additive effect with combined treatment of Y39983 and TSP-1 blockade, the results suggests that TSP-1 is a downstream effector of ROCK inhibition that regulates outflow facility.

TITLE: Low frequency ultrasound-mediated transcorneal delivery of riboflavin for corneal collagen crosslinking in treating keratoconus

SESSION TITLE: Keratoconus and Corneal Biomechanics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. SUN, M. Aresdhayana, Z. LU, J. Chung, L. Lau, Y. Chau, Department of Chemical and Biological Engineering, The Hong Kong University of Science and Technology, Kowloon, HONG KONG|

Commercial Relationships Disclosure (Abstract): Zhe SUN: Commercial Relationship: Code N (No Commercial Relationship) | Mika Aresdhayana: Commercial Relationship: Code N (No Commercial Relationship) | ZhiWei LU: Commercial Relationship: Code N (No Commercial Relationship) | JinTeng Chung: Commercial Relationship: Code N (No Commercial Relationship) | Laurence Chi Ming Lau: Commercial Relationship: Code N (No Commercial Relationship) | Ying Chau: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the feasibility of using low-frequency US to break through the epithelial barrier for the delivery of riboflavin to corneal stroma. To determine the effect of US-mediated delivery of riboflavin in ultraviolet A collagen crosslinking (UVA-CXL) on the biomechanical property of ex-vivo porcine cornea.

Methods: Riboflavin solution (0.5%) was applied to the fresh porcine corneal surface for 30 min as shown in Fig 1. In US-treated group (n=10), fresh porcine eyes with intact epithelium were treated with low-frequency US continuously. Temperature increase was maintained to be less than 1°C. In Epi-on control group (n=10), no US was applied while epithelium remains intact. In the Epi-off control group (n=10), epithelium was removed to mimic the conventional practice for corneal riboflavin delivery. Fluorophotometer(OcuMetrics) was used to quantify the amount of stromal riboflavin by the detection of fluorescence intensity. Half of each group received UVA irradiation (365nm, 3mW/cm², 30min) for CXL. Young's modulus of the corneal strip was measured by rheometer (TA, G2) to determine the change in corneal stiffness post CXL.

Results: The fluorescence intensity in the cornea of US-treated group was at least two orders of magnitude higher than Epi-on group. Fig.2A and 2B indicate that the amount of riboflavin transported to the cornea by US treatment is similar to that attained by scarping off the corneal epithelium in Epi-off group. The values of Young's modulus of US-treated and Epi-off samples were increased by UVA-CXL by 1.40 and 1.44 fold, respectively, which was in contrast to the negligible difference observed in the Epi-on samples (Fig.2C).

Conclusions: Low frequency US enhanced the absorption of riboflavin in corneal stroma via transcorneal route in the absence of thermal effect. US-mediated delivery of riboflavin to the cornea is sufficient to enable effective CXL by UVA for increasing the stiffness of porcine cornea. The study supports that low-frequency US may provide a less invasive alternative to modulate transcorneal barrier for delivering riboflavin into corneal stroma, potentially benefiting the treatment of keratoconus.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) provides high resolution cross-sectional two dimensional retinal images, with the ability to reconstruct local retinal shape from these sections in three dimensions. OCT is capable of sampling a limited area of retina in a single image. Wider field images have become available with developing technologies including swept source (SS) OCT, as well as through the merging in series of individual B scans in two dimensions. Merging SS OCT images in three dimensions (3D) has not previously been reported. Here, overlapping SS OCT cubes were reconstructed in 3D and merged via two different methods to explore the utility and limitations of composite images for retinal shape analysis.

Methods: From three eyes of three human participants, overlapping pairs of 9 x 9 mm SS OCT cubes were taken. Twenty five B scans were sampled from each cube, and used to reconstruct local retinal shape within the area covered by the scanning laser ophthalmoscope (SLO). For each eye, three pairs of corresponding points were identified in the SLO images from each cube. The reconstructed 3D images were merged via two different methods, using a rigid transformation to preserve shape features:

[1] sequential rotations using the axis-angle method

[2] via calculation of, then rotation with a quaternion.

Results: Composite images from one eye are shown in Figure 1. The two methods produced similar images, with no overall difference in alignment (mean (standard deviation) axial difference within en face overlapping area was 30.8 (23) pixels (quaternion rotation) versus 30.9 (23) pixels (axis angle rotation), where 1536 pixels = 3 mm, two sample t-test, $p < 0.005$).

Conclusions: Merged OCT images provided a good qualitative description of wide field retinal shape in three dimensions. Each rotation induced small errors, although the single rotation quaternion method performed no better than the sequential rotation required for the axis angle method. Although the magnitude of induced error was low with both rotation methods, care should be taken in performing quantitative analyses of composite images.

ABSTRACT BODY:

Purpose: To study the effect of plasma rich in growth factors (PRGF) under blue light conditions in an in vivo model of retinal degeneration after a medium-long term light exposure.

Methods: Male Wistar rats were exposed to dark/blue light conditions for 30 days. At day 7, right eyes were injected with saline and left eyes with PRGF. Electroretinography (ERG) and intraocular pressure (IoP) measurements were performed before and after the experiment. After sacrifice, retinal samples were collected. Haematoxylin-eosin staining was performed to analyse the structure of retinal sections. Immunofluorescence for Brain-specific homeobox/POU domain protein 3A (Brn3a), Choline acetyltransferase (ChAT), Rhodopsin, Heme oxygenase-1 (HO-1) and Glial fibrillary acidic protein (GFAP) was performed to study the retinal conditions.

Results: The results obtained by ERG showed that blue light reduced the retinal functionality. The use of PRGF at day 7 decreased the harmful effect of blue light after 30 days of light exposure. IoP measurements did not show significant differences among treatments. The immunohistological analysis performed showed that blue light changed the retinal structure and markers expression, which was counteracted by the treatment with PRGF.

Conclusions: Blue light causes retinal degeneration. PRGF blunted the injury, restoring the functionality of these cells and maintaining the tissue integrity.

ABSTRACT BODY:

Purpose: The cornea is a transparent, avascular tissue that covers the front portion of the eye. In pathologic and highly inflammatory conditions, the entire ocular surface is at risk for persistent scarring and visual loss. Despite all the treatment strategies, no effective solution has been found for patients with severe corneal injuries. Mesenchymal stem cells (MSCs) are of particular interest for the treatment of immune-related diseases owing to their immunosuppressive properties. Priming with proinflammatory cytokines improve the immunosuppressive function of MSCs. The purpose of our study is to identify the immunosuppressive effect of interferon (IFN)- γ and Interleukin (IL)17A primed Limbal-MSCs (LMSCs) on lymphocyte response.

Methods: LMSCs were isolated from cadaveric corneoscleral rims and cultured in DMEM with penicillin-streptomycin and fetal bovine serum. LMSCs were characterized and differentiated in passage 3. The lymphocytes were isolated from peripheral venous blood of healthy controls (n=10). LMSCs were stimulated with IFN- γ or IL-17A for 48 hours. At the end of this period, peripheral blood mononuclear cells of healthy individuals were isolated and cultured with or without stimulated LMSCs for 72 hours. The cultures were stimulated with anti-CD3 and anti-CD28 antibodies. After 72 hours, lymphocytes were collected and analyzed for proliferation assay, cell viability assay with AnnexinV/PI, Fas, FasL and CD4⁺CD25⁺FoxP3⁺T regulatory cell ratio via flow cytometry.

Results: Our results demonstrated that IFN- γ or IL-17A stimulated LMSCs suppressed the proliferation of T lymphocytes compared to unstimulated LMSCs cultures and it was statistically significant (P<0.05, P<0.05, respectively). IFN- γ stimulated LMSCs suppressed the Annexin V and Fas expression compared to unstimulated LMSCs cultures (P<0.05) but IL-17A stimulated LMSCs did not reduce the AnnexinV and Fas expression significantly compared to unstimulated LMSCs cultures (P>0.05). IFN- γ stimulated LMSCs increased T regulatory cell frequency compared to unstimulated LMSCs cultures (P<0.05).

Conclusions: Our data showed that stimulated LMSCs especially IFN- γ decreased lymphocyte proliferation and apoptosis while increased the T regulatory cell ratio. We believe that LMSCs could potentially be a source for future treatment strategies of inflammatory conditions particularly corneal disease.

Commercial Relationships Disclosure (Abstract): Gabriella Acosta: Commercial Relationship: Code N (No Commercial Relationship) | Finny Monickaraj: Commercial Relationship: Code N (No Commercial Relationship) | Arup Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Alteration of the blood-retinal barrier is the hallmark of diabetic retinopathy that results in damage to cell junctional proteins ultimately leading to vision loss. Current anti-VEGF treatments are effective only in 33-45% patients with diabetic macular edema (DME). To overcome challenges associated with existing therapies, we used a previously approved, small molecule drug library to check the efficacy on the functionally promising candidate molecules.

Methods: We used the Prestwick chemical library (PCL) consisting of off-patent compounds approved by FDA with diverse chemical and pharmacological characters, and well characterized bioavailability and safety information in humans. We performed a high throughput screening (HTS) assay platform to check the in vitro monolayer permeability in human retinal endothelial cells (HRECs) with the electrical cell substrate impedance sensing (ECIS) system. HRECs (approx. 8000 cells/well) were plated into fibronectin-coated 96-well plates and grown for 16 hours until maximum resistance was attained (1200 V). Human recombinant VEGF (50 ng/ml) was added to the wells along with each of 250 drug library compounds (10 uM). Changes in trans-endothelial electrical resistance were monitored for 24 hours. We used a cutoff range of > 75% viability using MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay with concentration of 10 uM. Resistance values were normalized to the identical starting resistance value at time 0 and presented as normalized resistance versus time.

Results: Several compounds showed toxicity and were eliminated from the trial. The ECIS assay identified 5 drugs that decreased in vitro permeability in VEGF treated HRECs. Five drugs, namely rufinamide, etofenamate, mexenone, melengestrol acetate, and sulfaquinoxaline sodium salt showed significantly increased resistance after the addition of VEGF compared to controls without drugs, while other drugs resulted in no change to mild change in resistance.

Conclusions: In this study we have identified several drugs that can decrease in vitro permeability in human retinal endothelial cells. The identified chemical probes can be directly used for anti-diabetic retinopathy drug development or serve to discover novel disease targets for future drug discovery.

ABSTRACT BODY:

Purpose: To quantitatively evaluate progression rate and the baseline predictors of progression of complete retinal pigment epithelium and outer retinal atrophy (cRORA) in cases of dry age-related macular degeneration (AMD).

Methods: Two ophthalmologists retrospectively annotated cRORA. Two-thirds of the scans were annotated by one grader and validated by a second-grader. A third of the scans were independently annotated by both graders. Primary outcomes: 1) cRORA area progression (mm^2/year); 2) cRORA square root area progression (mm/year); and 3) radial progression towards the fovea (mm/year).

The effects of the different baseline predictors on the primary outcomes were analyzed, including 1) the total area; 2) area at a diameter of 1 mm around the center; 3) focality; 4) circularity; 5) total lesion perimeter; 6) minimal feret (Feret_{\min}); 7) maximal Feret (Feret_{\max}); 8) minimal distance from the center at baseline; 9) sex; 10) age; 11) hypertension and 12) lens status.

Results: cRORA was annotated on a dataset of 37 baseline and follow up pairs of OCT scans 16 patients with dry AMD. Inter-grader variability was tested on 1989 standalone OCT B-scans and resulted in a DICE coefficient of 0.75 ± 0.16 .

Mean area progression was $1.34 \pm 0.80 \text{ mm}^2/\text{year}$ ($p < 0.0001$). Mean square root area progression was $0.32 \pm 0.18 \text{ mm}/\text{year}$ ($p < 0.0001$). Mean radial progression towards the fovea was $0.06 \pm 0.12 \text{ mm}/\text{year}$.

A multiple linear regression model (adjusted $r^2 = 0.665$) showed baseline focality (estimated $\beta = 0.101$; $p = 0.0008$) and baseline circularity (estimated $\beta = -1.789$; $p = 0.0076$) were significant factors associated with cRORA area progression. The lesions' baseline minimal distance from the center correlated with radial growth rate towards the center on univariate linear regression analysis ($p < 0.0001$; $r = 0.686$).

Conclusions: This study quantitatively measured cRORA area progression rate in dry AMD patients, as compared to traditional fundus autofluorescence measurements. cRORA area progression varied with respect to baseline focality and circularity indices. Radial progression correlated with the lesion's baseline minimal distance from the center. These results may be used in the research of treatments for retinal atrophy secondary to dry AMD.

ABSTRACT BODY:

Purpose: There exists no ideal screening tool for glaucoma. We developed and assessed the performance of a novel automated screening tool using DL on monoscopic fundus images. It is deployed on-the-edge on a portable smartphone-based fundus camera, and assesses presence of referable glaucoma.

Methods: We trained a binary classifier for referable glaucoma (glaucoma suspect and likely glaucoma) using DL with a diverse dataset of 5716 images from Asian and Caucasian populations. This included 58% images of referable glaucoma. Five glaucoma specialists were involved in grading. The ground truth came from both the images themselves as well as from a comprehensive glaucoma evaluation. The resulting algorithm was validated on two datasets. Validation set A comprised of 626 images (63% referable glaucoma) captured on the target device on Asian eyes. The reference standard was optic disc assessment on these images. An independent Test set B comprised of 389 images (62% referable glaucoma) captured on Caucasian eyes. The reference standard was the diagnosis of glaucoma made following a complete glaucoma evaluation. The ground truth for both datasets was the interpretation made by glaucoma specialists. The activation maps generated by the algorithm highlight the regions of the input images which contributed most to the automated diagnosis.

Results: The DL algorithm had a sensitivity of 97% (CI 96%-99%), a specificity of 92% (CI 88%-95%) and an AUC of 0.97 in detecting referable glaucoma on validation set A. Sensitivity in detecting likely glaucoma was 0.97. On test set B, the sensitivity for detecting referable glaucoma was 96% (CI 93%-98%) the specificity was 82% (CI 76%-88%) and the AUC 0.93. Sensitivity in detecting likely glaucoma was 0.98. Activation maps showed that the AI relied on key glaucoma features like vertical cup-to-disc ratio, neuroretinal rim abnormalities, disc hemorrhages and retinal nerve fibre layer (RNFL) defects to make a diagnosis.

Conclusions: The DL algorithm based on monoscopic fundus images deployed 'offline' on a portable fundus camera has high sensitivity and specificity in screening for referable glaucoma. Further work includes validation in prospective clinical trials.

ABSTRACT BODY:

Purpose: To determine if there are any characteristic changes in treatment-naïve nonexudative macular neovascularization (MNV) in age-related macular degeneration (AMD) when imaged using swept source optical coherence tomography angiography (SS-OCTA) that may be predictive of near-term exudation.

Methods: AMD patients with treatment-naïve, nonexudative MNV were identified and underwent SS-OCTA imaging (PLEX® Elite 9000; Carl Zeiss Meditec, Inc, Dublin, CA) using 6X6mm and 12X12mm scans by the same technician at all visits. The patients were divided into two groups based on whether the nonexudative MNV developed exudation. If the nonexudative MNV developed exudation, then the last two visits before the visit when exudation was documented were selected for analysis. If the MNV did not develop exudation, then the two consecutive visits 6 months before their last follow-up visits were used for analysis to be sure no near-term exudation developed. MNV area, choriocapillaris (CC) flow deficits (FDs), MNV vessel area density (VAD), MNV vessel skeleton density (VSD), retinal pigment epithelial detachment (PED) volume, mean choroidal thickness (MCT), and choroid vascularity index (CVI) measurements were measured at the two visits prior to exudation. The en face area measurements of the MNV were obtained by using a previously described validated automated algorithm that detected angiographic flow within the outer retina to CC slab.

Results: Twenty-one eyes with nonexudative MNV were identified and followed. Twelve eyes did not develop exudation, while nine eyes developed exudation. There were no significant differences between the two groups in the MNV area, the percentages of surrounding CC FDs, or the rate of change in any of the measurements (all P values ≥ 0.052). The eyes that did develop exudation had smaller MNV-VAD ($P=0.002$), MNV-VSD ($P=0.005$), and MNV-PED volume ($P=0.04$) measurements at the visit prior to exudation. The CT and CVI measurements over the final two visits were not significantly different between the two groups (all P values >0.19).

Conclusions: The onset of exudation was associated with lesions with less vascularity and smaller PED volume measurements, but measurements of MNV area, CC FDs, CT, and CVI or the change in any measurements did not show statistically significant differences between the two groups over the final two visits.

ABSTRACT BODY:

Purpose: To investigate the relationship between the rate of retinal nerve fiber layer (RNFL) loss during initial follow-up and the magnitude of associated visual field loss during an extended follow-up period.

Methods: This was a retrospective cohort study. A total of 1,150 eyes of 839 glaucoma patients extracted from the Duke Glaucoma Registry. Rates of RNFL loss were obtained from global RNFL thickness values of the first 5 optical coherence tomography (OCT) scans. Rates of visual field loss were assessed using standard automated perimetry mean deviation (SAP MD) during the entire follow-up period. Joint longitudinal mixed effects models were used to estimate rates of change. Eyes were categorized as fast, moderate or slow progressors based on rates of RNFL loss, with cutoffs of $\leq -2\mu\text{m}/\text{y}$, -2 to $-1\mu\text{m}/\text{y}$ and $\geq -1\mu\text{m}/\text{y}$, respectively. Univariable and multivariable regressions were completed to identify significant predictors of SAP MD loss.

Results: The rate of RNFL change was $-0.76 \pm 0.85\mu\text{m}/\text{y}$ during initial follow-up, which occurred over 3.7 ± 1.5 years. 765 (66%) eyes were slow, 328 (29%) moderate, and 57 (5%) fast progressors, with corresponding rates of SAP MD loss of $-0.16 \pm 0.35\text{dB}/\text{y}$, $-0.32 \pm 0.43\text{dB}/\text{y}$, and $-0.71 \pm 0.65\text{dB}/\text{y}$ over the extended follow-up period of 6.1 ± 1.9 years ($P < 0.001$). Age, OCT progressor group, and baseline SAP MD were all significantly associated with the rate of SAP MD loss ($P < 0.001$).

Conclusions: Rapid RNFL thinning during an initial follow-up period was predictive of concurrent and subsequent rates of visual field decline over an extended period. Patients with fast OCT thinning may be at high risk for developing functional disability.

ABSTRACT BODY:

Purpose: To report the visual, refractive and keratometric changes after INTACS implantation for keratoconus.

Methods: Retrospective chart review of records between March 2016 and September 2019 at the Cleveland Clinic Abu Dhabi. All INTACS SK rings were inserted using a femtosecond laser according to the manufacturer's recommendations. Visual, refractive and keratometric changes, along with surgical complications, were analyzed.

Results: Sixty seven eyes of 67 keratoconus patients aged 18 to 47 (average 29) years were included. Thirty-eight were male and 38 had their right eyes operated on. Seventeen had prior collagen cross-linking and 2 had previous PRK. The mean follow-up duration was 7.5 months. Statistically significant improvement was noted in uncorrected visual acuity (preop LogMAR 1.00 to postop 0.55), best-corrected acuity (0.30 to 0.20), spherical equivalent (8.29D to 5.43D), sphere (-6.59D to -3.94D), and cylinder (3.52D to 3.16D). On keratometry, SimK improved from 49.08D to 46.58D ($p<0.001$) and Kmax from 55.19D to 52.30D ($p,0.001$), however corneal astigmatism improved from 4.15D to 3.85D which was not significant ($p=0.27$). No complications were noted.

Conclusions: INTACS implantation resulted in significant improvement in visual, refractive, and keratometric outcomes in our patients.

ABSTRACT BODY:

Purpose: Ischemia-induced hypoxia is a common complication associated with numerous diseases including retinal vein occlusions. No effective solution exists to evaluate extravascular tissue oxygen tension. This report demonstrates a novel lipid-polymer hybrid organic room-temperature phosphorescence (RTP) nanoparticle (NP) platform that optically detects tissue hypoxia in real-time with high signal-to-noise ratio.

Methods: A lipid-polymer hybrid, core-shell RTP NP was fabricated with Br6A metal-free organic phosphor embedded within the polymer matrix core coated with an amphiphilic lipid shell. Poly(4-bromostyrene) (PS4Br) was chosen as the host polymer for intravitreal injection (Br6A-LPS4Br) and polystyrene-b-poly(4-vinylpyridine) (PS4VP) for intravenous injection. This was injected into 11 rabbits with a Rose Bengal dye-enhanced thrombosis retinal vein occlusion model, laser photocoagulation, or controls and evaluated with multimodal imaging post NP administration via intravenous and intravitreal administration.

Results: The fabricated RTP NPs exhibit bright RTP and high sensitivity toward oxygen quenching with desirable colloidal and optical stability. The RTP NPs were tested as a hypoxia imaging probe in vivo using rabbit RVO and photocoagulation models via intravitreal and intravenous injection respectively. The RTP NP signal is exclusively generated where tissue hypoxia is present with a signal-to-noise ratio of 12.5. Longitudinal phosphorescence imaging in Rose-Bengal RVO and control rabbits demonstrated significant phosphorescent signal peaking at 2h post-intravitreal injection of NP that persisted for at least 7 days (Figure). No ocular or systemic complications are observed with either administration route.

Conclusions: This organic RTP NPs allows for biocompatible, non-destructive, sensitive detection of tissue hypoxia longitudinally and has potential to evaluate hypoxia-driven retinal vascular diseases.

ABSTRACT BODY:

Purpose: Fabry disease (FD) is a rare X-linked lysosomal storage disorder characterized by the accumulation of globotriaosylceramide in various tissues, leading to renal, vascular, and neurological complications. Although structural changes in central and peripheral nervous system have been previously reported in FD, little is known on the alterations of retinal layers. This study aims to evaluate macular inner retinal layer changes in patients with FD using spectral domain optical coherence tomography (SD-OCT).

Methods: Twelve consecutive patients with FD and 12 age- and sex-matched healthy control participants were included in this cross-sectional study. The Mainz Severity Score Index (MSSI) was used to measure the severity of FD. All participants underwent SD-OCT (Heidelberg, Germany) imaging, and retinal layer segmentation was performed automatically. Total macular volume (TMV) and central macular thickness (CMT) were recorded, and the average thicknesses of nerve fiber layer (NFL), ganglion cell layer (GCL), inner plexiform layer (IPL), inner nuclear layer (INL) and total inner retinal layers (IRL) were measured at the central fovea (1 mm) and four quadrants (superior, inferior, nasal, temporal) of the parafoveal region (1-3 mm).

Results: Intraretinal hyperreflective dots and increased retinal vessel tortuosity were observed in the OCT images of patients with FD (Figure 1). Compared to healthy control subjects, patients with FD had significantly reduced total IRL thickness at superior ($P=0.005$), inferior ($P=0.016$), temporal ($P=0.005$), and nasal ($P=0.011$) quadrants. Additionally, INL thickness was reduced at superior ($P=0.038$), temporal ($P=0.006$), and nasal ($P=0.022$) parafoveal regions. No significant differences were observed in TMV, CMT, NFL, GCL, and IPL thickness between patient and control groups. The MSSI inversely correlated with the thickness of INL at central ($\rho=-0.666$; $P=0.018$) and inferior ($r=-0.627$; $P=0.029$) regions.

Conclusions: This study demonstrates significant structural alterations in the macular inner retinal layers in patients with FD. Further studies are required to identify potential pathophysiological mechanisms of inner retinal changes in FD.

ABSTRACT BODY:

Purpose: Plasmacytoid dendritic cells (pDCs), are specialized immune cells residing in the cornea and play a key role in linking innate and adaptive immunity. In this study, we investigated the dynamic changes of pDCs-T cell interactions in draining lymph nodes (dLNs) that define the T responses in acute herpes simplex virus (HSV)-1 keratitis

Methods: Intravital multiphoton microscopy (IV-MPM) was performed in living mice to image dLNs in bone marrow chimera mice from Tred (T cells are red) x pDC-GFP (pDCs are green) mice during steady state and after corneal inoculation with TLR-9 agonist or HSV-1 to study the kinetics of pDC/T cell interactions. Number of contacts (N), short (<5min) and long contact time (>5min or >30min) were analyzed. Local pDCs were depleted by subconjunctival injections of diphtheria toxin or PBS (sham) in BDCA-2-DTR Tg mice. dLN were excised and assessed for T cell phenotype by flow cytometry with CD45 (pan-leukocytes marker), CD3 (T cells), CD8, and CD4, and production of IL-6 and TGF- β 1

Results: IV-MPM imaging in dLNs showed pDC-T cells interactions after corneal inoculation of TLR-9 agonist compared to steady state with a high percentage having long contact time >5min (53.8% vs. 19.2%) and >30min (23.1% vs. 0%)($P<0.01$). Interestingly, we identified dLNs areas with T cell clusters after HSV-1 keratitis, where pDCs interacted with high number of T cells ($N=3.0$) compared to steady state ($N=1.5$, $p<0.01$); and a high percentage having long contact time >5min (50.0%) and >30min (15.4%) compared to areas without T cell clusters (15.4% and 0%, respectively; $P<0.01$) or during steady state (20.0% and 0% respectively; $P<0.01$). dLNs from corneal pDC-depleted mice showed an increased density of CD4 and CD8 T cells (2.1-fold and 2.3-fold) compared to sham group ($P<0.001$), as well as increased IL-6 secreting T cells (3.4-fold) and reduced TGF- β 1 secreting T cells (0.58-fold) during HSV-1 keratitis

Conclusions: Intravital imaging of dLNs demonstrates distinct pDCs-T cell interaction patterns, predominantly in areas with T cell clusters during acute HSV-1 keratitis. Moreover, pDC limit IL-6, but enhance TGF- β expression by T cells in concordance to the increase in Th17 over Tregs response previously observed by our group. Together, our data suggests that pDCs are involved in the T cell fate through direct interaction with T cells in HSV-1 keratitis

CONTROL ID: 3534505

TITLE: Pediatric Ocular Injury as a Result of Toy Gun Injury 2010-2019: An Observational Study

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Singer, A. Uppuluri, M.A. Zarbin, N. Bhagat, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Omar Singer: Commercial Relationship: Code N (No Commercial Relationship) | Aditya Uppuluri: Commercial Relationship: Code N (No Commercial Relationship) | Marco Zarbin: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to report demographic data and outcomes among pediatric patients with ocular trauma due to toy guns with projectiles. Toy guns with projectiles include toys such as BB guns, airsoft guns, pellet guns, dart guns, etc. There have been studies in the past which have reported demographic data specific to one of these categories of toy guns, this study has been conducted to assess the safety of all projectile toy guns.

Methods: Data were computed from the National Electronic Injury Surveillance System (NEISS), maintained by the Consumer Product Safety Commission (CPSC). Using product code 1399 (toy guns with projectiles) we were able to analyze injury data from 2010-2019 weighted to represent the US population. We restricted our analysis to include children aged 0-20 and analyzed eye injuries specifically. Our analysis included diagnosis of injury, location of injury, race, sex, month, day of the week, as well as disposition. We further subdivided our data by age (0-9 and 10-20) as well as analyzed the data by gender.

Results: There were a total of 6,617 cases included in the NEISS database for ocular trauma between 2010 and 2019. The more common age group was aged 0-9, making up 61.1% of those included in the study. Males were also more commonly injured, making up 79.3% of those in the study. By far the most common diagnosis was ocular contusion (51.5%), other diagnoses included hematomas, laceration, sprain, hemorrhage, conjunctival trauma, and other (encompassing all other diagnoses). The most serious cases resulted in an open globe injury, in 1.5% of all cases, and all were in the 10-20 age subgroup. 92.1% of cases were treated and released within the same visit. Of the remaining 7.9% of patients, 7% were triaged and transferred to another facility. The most common time of the year for ocular injury with toy guns was December, with 18.7% of cases occurring during this month, followed by November with 9.7% of cases. Saturday and Sunday had the highest number of eye injuries to the ED with toy guns, together the weekend accounted for 46.3% of all injuries.

Conclusions: Toy gun injuries were more common among young male patients. Injuries in the last decade were more commonly seen in the month of December and presented to the ED more frequently during the weekend (Saturday and Sunday). Only 1.5% of injuries were severe with OGIs and were seen among older children (10-20).

TITLE: iLids: Virtual oculoplastics in the COVID-19 pandemic

SESSION TITLE: Impacts of Covid on patients and practice

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Miller, D. Pennipede, Ophthalmology, University of Kansas Medical Center, Kansas City, Kansas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jordan Miller: Commercial Relationship: Code N (No Commercial Relationship) | Dante Pennipede: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During COVID-19 many adjustments have occurred within medicine. Notably, telehealth has become a ubiquitous tool for providing safe care. Past studies have looked at integration of telehealth into oculoplastics (Elishai, 2020). However, no literature exists regarding the best use of this modality; this study aims to fill that gap.

Methods: 395 men and women, aged 3-95, seen April to September 2020 in the oculoplastic department at KU Eye were included. Via chart review, subjects were categorized based on age, gender, encounter type, appointment format, whether the patient presented for their appointment, and complications experienced. The data were then analyzed using chi-square testing and linear regression models.

Results: Most patients seen were females over 60 years old (Image 1) . The most common encounter types were new patient and follow up (Image 2). There was statistical significance between encounter type and appointment format, with most telehealth visits being post-ops or follow ups ($X^2=22.94$, $df=4$, $p=0.00013$). Expectedly, there was a significant difference in the number of appointment related complications and appointment format ($X^2=60.448$, $df=2$, $p=7.481e-14$). Telehealth visits had a higher association with complications including: delay in appointment time due to connectivity issues, and having to resort to a different appointment format (i.e. rescheduling for a different day in-person, or resorting to phone due to issues with the telehealth interface). There was a positive correlation with age and complications, however this was not found to be significant ($p=0.747$). There was also no significant difference in "no-shows" among telehealth versus in-person visits ($X^2=2.6769$, $df=1$, $p=0.1018$).

Conclusions: Tried during the COVID-19 pandemic at KU Eye, and supported by Elishai et al., telehealth has proven to be a safe and effective way to provide care to patients in an oculoplastic practice. It useful for post-operative visits, pre-operative evaluation, new patient visits, and routine follow up. Patients of various ages can utilize the technology to attend a telehealth visit with minimal complications. To reduce the frequency of these complications, it may be prudent to implement an interactive tutorial for patients prior to their appointment time. Further research investigating outcomes of patients seen via telehealth versus in-person is warranted.

TITLE: Glaucoma in Guyanese patients seen in Montefiore ophthalmology clinics in the Bronx, New York

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.K. Dackowski, V. Hawn, J. Moon, Yeshiva University Albert Einstein College of Medicine, Bronx, New York, UNITED STATES|S. Patel, Edward S Harkness Eye Institute, New York, New York, UNITED STATES|W. Yao, Montefiore Medical Center, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Evan Dackowski: Commercial Relationship: Code N (No Commercial Relationship) | Vivian Hawn: Commercial Relationship: Code N (No Commercial Relationship) | Jee-Young Moon: Commercial Relationship: Code N (No Commercial Relationship) | Sejal Patel: Commercial Relationship: Code N (No Commercial Relationship) | Wen-Jeng (Melissa) Yao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The majority of Guyanese Americans live in the metropolitan New York City area. Prompted by anecdotal evidence of a higher rate of primary open-angle glaucoma (POAG), we set out to determine the risk of POAG and closed-angle glaucoma (CAG) among Guyanese patients compared to other racial and ethnic groups seen at a major hospital system in the Bronx.

Methods: Unique medical record numbers of patients (age ≥ 40) across all comprehensive and subspecialties at the Montefiore ophthalmology department were obtained for patients whose country of origin was Guyana as well as self-identified White, Black, and Hispanic patients from 2018-2020. Glaucoma-related ICD-10 diagnostic codes associated with each unique MRN were fitted to a logistic regression and the odds ratios of POAG and CAG for Guyanese patients, adjusting for age and sex, were calculated.

Results: A total of 409 Guyanese, 2787 White, 13,655 Black, and 13,713 Hispanic patients were included in this study. The mean \pm SD ages for each population were: 64.1 \pm 11.1 years in Guyanese, 67.8 \pm 12.9 years in Whites, 64.4 \pm 12.3 years in Hispanics, and 64.9 \pm 12.2 years in Blacks. For POAG, there were 37 (9.0%) cases in Guyanese patients, 145 (5.2%) cases in Whites, 910 (6.6%) cases in Hispanics, and 1725 (12.6%) cases in Blacks. After adjusting for age and sex, POAG was more common in Guyanese than in Whites (OR=2.38, 95% CI=1.62-3.50, $p<0.01$) and Hispanics (OR=1.39, 95% CI=0.98-1.98, $p=0.07$), but less common than in Blacks (OR=0.67, 95% CI=0.47-0.95, $p=0.02$). For CAG, there were 5 (1.2%) cases in Guyanese patients, 14 (0.5%) cases in Whites, 113 (0.8%) cases in Hispanics, and 116 (0.8%) cases in Blacks. Adjusting for age and sex, CAG was more common in Guyanese patients than in Whites (OR=3.07, 95% CI=0.99-8.12, $p=0.03$), while the odds ratios were not significantly different compared to the Hispanic and Black populations. Although males had significantly higher odds of both POAG and CAG, there was no heterogeneity by sex on the association between race and these glaucoma types.

Conclusions: Patients from Guyana had higher odds of POAG versus the White and Hispanic groups as well as higher odds of developing CAG compared to the White patients in our sample. These results may suggest that Guyanese patients should be referred for full eye exams to screen for glaucoma.

ABSTRACT BODY:

Purpose: Minimizing healthcare-related exposures for patients and providers are paramount during the coronavirus (COVID-19) pandemic. We performed a retrospective cohort study to compare visual outcomes and patient satisfaction in senior resident-performed immediate sequential bilateral cataract surgery (ISBCS) versus delayed sequential bilateral cataract surgery (DSBCS).

Methods: All ISBCS and DSBCS patients who underwent senior resident-performed cataract surgery in the Comprehensive Ophthalmology division of a single academic institution from May to September 2020 were included. Outcome measures were final corrected distance visual acuity (CDVA), final manifest refraction (MRx), incidence of intraoperative and postoperative complications, total number of clinical and surgical visits, and patient satisfaction, assessed postoperatively by telephone questionnaire.

Results: Fourteen (22 eyes) and 28 (56 eyes) patients underwent senior resident-performed ISBCS and DSBCS, respectively. Final CDVA was 20/25 or better in 21 (95%) ISBCS eyes and 51 (91%) DSBCS eyes ($p=0.670$). The deviation of final MRx from target refraction was within 0.50 D in 17 (77%) ISBCS eyes and 47 (84%) DSBCS eyes ($p=0.522$). There was no significant difference in intraoperative ($p=1.000$) or postoperative ($p=1.000$) complications. ISBCS patients averaged 3.5 fewer visits than DSBCS patients (5.9 vs 9.5, $p<0.001$). All ISBCS and 20 DSBCS patients (87%) reported they were overall "very satisfied" or "satisfied" with their experience ($p=0.701$), and there was no significant difference in the overall visual function 7 score, where 0 indicates the worst possible functional impairment and 100 indicates no disability ($p=0.561$). Finally, five of the six senior residents who performed the ISBCS cases included in this study reported that they preferred performing ISBCS over DSBCS.

Conclusions: This early experience demonstrates that senior resident-performed ISBCS is as safe and effective as DSBCS, with the added benefit of averaging fewer in-person visits for patients. Residency programs should consider offering senior resident-performed ISBCS to select patients during the COVID-19 pandemic.

Commercial Relationships Disclosure (Abstract): Samuel Lee: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Avallone: Commercial Relationship: Code N (No Commercial Relationship) | Fei Yu: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Caprioli: Commercial Relationship: Code N (No Commercial Relationship) | Anne Coleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine associations between niacin intake and glaucoma in the National Health and Nutrition Examination Survey (NHANES).

Methods: The study population included adults in the 2005-2008 NHANES. Dietary intake of niacin was analyzed both as a continuous variable and at a cutoff point of 16 mg per day, the recommended daily value for adult males. Glaucoma was defined as 2+ abnormal points on visual fields and cup-to-disc ratio or asymmetry $\geq 97.5\%$ of the NHANES population. Covariates included age, gender, ethnicity, level of education, income, body mass index, smoking status, alcohol intake, steroid intake, diabetes mellitus, cataract surgery, macular degeneration, and myocardial infarction. Logistic regression modeling was used to examine the associations between niacin intake and glaucoma in the study population, adjusting for all study covariates. Analyses were weighted using NHANES multistage sampling design.

Results: The weighted study population included 82,415,936 individuals, of whom 3,021,541 (3.7%) had glaucoma. There were no statistically significant associations between continuous levels of dietary niacin intake and glaucoma in any models: unadjusted odds ratio [OR] = 0.99, 95% confidence interval [CI] = 0.97, 1.01 per 1 mg increase in niacin intake; adjusted (aOR) = 1.01, 95% CI = 0.98, 1.03 per 1 mg increase. When comparing dietary niacin intake was greater versus less than 16 mg, there was a statistically significant association between niacin intake and glaucoma in the unadjusted model (OR = 0.69, 95% CI = 0.49, 0.96 for >16 mg vs ≤ 16 mg), but not in the adjusted model aOR = 0.75, 95% CI = 0.48, 1.18 for >16 mg vs ≤ 16 mg.

Conclusions: In the 2005-2008 NHANES population, there was no association between continuous levels of dietary niacin intake and glaucoma, but a possible association at a cut point of 16mg intake per day. These findings suggest the need for further study of associations between niacin and glaucoma.

TITLE: Inducible Slc4a11 knock out in adult mice produces corneal edema through alteration of pump and barrier functions

SESSION TITLE: Corneal endothelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D.G. Ogando, R. Shyam, E.T. Kim, Y. Wang, C. Liu, J.A. Bonanno, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Diego Ogando: Commercial Relationship: Code N (No Commercial Relationship) | Raji Shyam: Commercial Relationship: Code N (No Commercial Relationship) | Edward Kim: Commercial Relationship: Code N (No Commercial Relationship) | Yen-Chiao Wang: Commercial Relationship: Code N (No Commercial Relationship) | Chia-Yang Liu: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Bonanno: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The conventional Slc4a11 knock out (KO) shows significant corneal edema at eye opening; a fact that complicates the study of the initial events leading to edema. We have reported that Slc4a11 is a NH_3 -activated mitochondrial uncoupler that facilitates glutamine catabolism and suppresses mitochondrial superoxide production. Here we tested the hypothesis that inducible Slc4a11 KO in the adult mouse leads to progressive corneal edema characterized by oxidative stress and alterations of pump and barrier functions of the corneal endothelium (CE).

Methods: Slc4a11 Flox (SF) mice were crossed with mice expressing the estrogen receptor–Cre Recombinase fusion protein and at 8 weeks of age were fed Tamoxifen (Tx) enriched chow (0.4 g/Kg) for 2 weeks, followed by normal chow; and controls were fed normal chow. Corneal thickness (CT) was measured by OCT. Oxidative damage was detected by nitrotyrosine staining, tight junctions by ZO-1 and adherens junctions by F-actin staining. Pump function was tested by stromal lactate concentration and barrier function by paracellular permeability to fluorescein. To generate inducible Slc4a11 KO mice strictly in keratocytes, SF mice were crossed with Kera-rtTA;tetO-Cre driver mice (IOVS 2017, 58: 4800–4808) and were fed DOX since embryonic day 0 until test at 3 months of age.

Results: Tx induced a 98% decrease in Slc4a11 expression in corneal tissue. Tx produced gradual corneal edema with an increase in CT of 34% at 2 weeks and 49% at 8 weeks of treatment. Cell density was not changed but morphology was significantly altered. Oxidative stress was evident as nitrotyrosine abundance increased. Tx induced a decrease in the CE pump function evidenced by an increased stromal lactate accumulation (Ctrl: 4.24 ± 1.19 nmol/mg tissue vs Tx: 9.71 ± 1.36 , $p=0.02$, $n=5$), and down regulation of MCT2 and Atp1b2. However, Tx increased CE ATP levels by 12%. Tx increased paracellular permeability (decreased barrier function) by 16% and altered tight and adherens junctions. No significant differences in CT were found between WT mice and Slc4a11 KO in keratocytes only.

Conclusions: These data confirm that oxidative stress and perturbation of pump and barrier functions of the CE are early events following diminution of Slc4a11 expression. Slc4a11 expression is also high in keratocytes, however specific KO did not lead to corneal edema.

TITLE: Reference Standards for Assessment of Fluid in Neovascular Age-Related Macular Degeneration (nAMD)

SESSION TITLE: AI in the retina/ AMD imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Malik, M. Lanser, J.W. Pak, M. Banghart, B. Blodi, A. Domalpally, Department of Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kunal Malik: Commercial Relationship: Code N (No Commercial Relationship) | Melissa Lanser: Commercial Relationship: Code N (No Commercial Relationship) | Jeong Pak: Commercial Relationship: Code N (No Commercial Relationship) | Mark Banghart: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Blodi: Commercial Relationship: Code N (No Commercial Relationship) | Amitha Domalpally: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In nAMD, intraretinal (IRF) and subretinal fluid (SRF) on spectral domain optical coherence tomography (SDOCT) are used to tailor anti-VEGF treatment. Automated quantification of fluid on SDOCT using artificial intelligence (AI) may allow clinicians to identify patients requiring treatment. However, studies have shown poor agreement between assessment of fluid between AI and retina specialist. This study is designed to develop better reference standards to train AI algorithms with a robust qualitative and quantitative assessment of fluid related to nAMD.

Methods: SD OCT cube scans of 20 patients with nAMD undergoing anti-VEGF treatment were included. Experienced reading center graders assessed the following qualitative fluid variables: presence, grid location, center subfield (CSF) involvement, and type of IRF (cystoid vs non-cystoid) and SRF (presence of sub-retinal hyperreflective material or SHRM). Both IRF and SRF were categorized as mild or more than mild (mtmIRF/mtmSRF) based on subjective assessment. For quantitative assessment, volumes of IRF (internal limiting membrane to inner segment/outer segment (IS/OS)) and SRF (IS/OS to retinal pigment epithelium) were documented using custom segmentation software. All images were independently reviewed by two expert graders.

Results: IRF was evaluated in 10 (50%) eyes and categorized as mtmIRF in 6 (60%) eyes. IRF was located within CSF in 8 (80%) eyes and was associated with cysts in 10 (100%) eyes. SRF was evaluated in 14 (70%) eyes and categorized as mtmSRF in 9 (64.2%) eyes. SRF was located within CSF in 13 (92.8%) eyes and associated with SHRM in 14 (100%) eyes. The mean IRF volume was 6.3 (SD=0.27) in eyes with mild IRF and 7.9 (SD=1.2) in eyes with mtmIRF ($p=0.03$). The mean SRF volume was 0.7 (SD=0.1) in eyes with mild SRF and 1.3 (SD=0.85) in eyes with mtmSRF ($p=0.07$). Agreement on fluid severity between the two graders was 93% ($k=0.85$ SE= 0.14; 95% CI=0.57-1) for SRF and 89% ($k= 0.73$ SE= 0.25; 95% CI= 0.24-1) for IRF.

Conclusions: Detailed and reproducible evaluation of fluid on SDOCT in nAMD can be performed to provide qualitative and quantitative evaluation of SRF and IRF. Employing these methods in a dataset to correlate with physician decision to treat and patients' visual outcomes will further refine the reference standards and help train clinically useful AI algorithms.

TITLE: Digital eye strain symptoms during online university learning in Israel and the USA during the COVID-19 pandemic

SESSION TITLE: Impacts of Covid on patients and practice

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Gantz, Department of Optometry and Vision Science, Hadassah Academic College, Jerusalem, Jerusalem, ISRAEL|M. Rosenfield, College of Optometry, SUNY The State University of New York, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Liat Gantz: Commercial Relationship: Code N (No Commercial Relationship) | Mark Rosenfield: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Due to the COVID-19 pandemic, online university studies resulted in extended hours spent by students in front of digital displays. These displays differ significantly from printed materials and often result in symptoms known as “digital eye strain” (DES). This study examined the symptoms of DES in university students in Israel and in the USA during online learning.

Methods: The English and Hebrew translated DES and Ocular Surface Disease Index (OSDI) dry eye questionnaires were inserted into Google Forms and sent to university students by email and social media. The OSDI determined if the symptoms were due to pre-existing dry eye disease. Non- university students, participants with self-reported ocular infections or prior ocular surgery, and those not attending online studies were excluded. Results were analyzed using descriptive statistics, with DES survey scores above 5 considered symptomatic. Mann Whitney U-test was applied to compare the samples.

Results: The Israeli and USA cohorts comprised 160 (38 optometry students, 24 male, mean age: 26±8) and 163 State University of New York optometry students (34 male, mean age: 24±2), respectively. Respondents spent 18±9 and 15±5 weekly hours in online studies, with 7±7 and 9±3 daily hours on the computer, and 6±9 and 4±3 daily hours on cell phones in the Israeli and USA cohorts, respectively. 98% and 96% of the cohorts reported mainly using computer monitors for studying. The most frequently reported symptoms during or immediately after online studies in the Israeli and USA cohorts included eye fatigue (60% and 48%), eye strain (58% and 31%), ocular discomfort (44% and 31%), headaches (43% and 26%), dry eyes (39% and 34%), and burning eyes (40% and 22%). The prevalence of ocular eye strain, burning eyes, headaches, ocular discomfort and photophobia was significantly higher in the Israeli cohort ($p<0.05$). The prevalence of DES symptoms far surpasses the typical prevalence of mild to severe dry eye (15% in the Israeli cohort, 7% in the USA cohort).

Conclusions: Results demonstrate a high prevalence of DES symptoms in university students. In the future, a causative relationship with digital displays can be established by comparing responses to symptoms reported during live learning. Healthcare providers should educate patients about ways to reduce DES.

ABSTRACT BODY:

Purpose: Intravitreal (IVT) injections of anti-vascular endothelial growth factor drugs are currently a mainstay of pharmacological treatment for many retinal diseases but have shown relatively low patient compliance in previous studies, reducing treatment efficacy. New developments in small molecule anti-angiogenic drugs provide the future possibility of alternative drug delivery routes such as eye drops or oral tablets. This survey study aimed to determine what factors influence patient views of IVT injections and how future treatments might be administered to increase patient compliance and satisfaction with treatment.

Methods: An IRB-approved patient survey was designed to explore patient preferences, demographics, and perspectives on treatment compliance. Inclusion criteria consisted of any patient who received IVT injections for a retinal disease at the Glick Eye Institute from 2016 through July 2020. Respondent demographics and diagnosis were collected from medical records. Participants were stratified by number of IVT injections received (≤ 4 vs. ≥ 4) and by sex. Survey responses were evaluated on a five level Likert scale and differences between groups assessed using the Student's t-test.

Results: Respondents (n=54; response rate 5%) ranged in age from 27 to 91 and came from a diverse pool of education and income levels. Retinal disease diagnoses included macular degeneration, diabetic retinopathy, ocular histoplasmosis, and central serous retinopathy. Responses revealed that 83.3% of participants agreed or strongly agreed that they were apprehensive prior to receiving their first IVT injection, but that 79.6% were willing to receive injections indefinitely to preserve their vision. However, when questioned about future alternative treatment routes, 75.5% of participants preferred eye drops over IVT injections and 65.4% preferred oral tablets over IVT injections. Despite this, a majority of patients still preferred ophthalmologist visits spaced every 1–3 months. Responses did not differ between sex or between number of IVT injections received.

Conclusions: A majority of retinal disease patients are willing to receive IVT injections indefinitely in order to preserve their vision. However, if new treatments were available, most participants would prefer eye drops or oral tablets over IVT injections. This finding underscores the value of developing new therapeutics with alternative delivery routes.

ABSTRACT BODY:

Purpose: To characterize and quantify intraretinal cystoid spaces in patients with macular hole (MH).

Methods: We conducted a retrospective, observational study which included consecutive, MH patients who underwent successful MH closure after a primary surgery with 12-month follow-up postoperatively. We obtained 3×3-mm macular optical coherence tomography scans with a commercial device preoperatively and processed with a custom software. The software detected the intraretinal cystoid spaces in each of B-scan images and quantified as fluid volume (FV) (Figure). We defined inner FV as cystoid spaces in the inner nuclear layer and outer FV as cystoid spaces between the outer plexiform layer and the Henle's fiber layer. MH was classified with the International Vitreomacular Traction Study (IVTS) classification. Spearman's correlation coefficient was used for univariate analysis. In multivariate analyses, variables that were a P value less than 0.10 in the univariate analysis were selected by forward stepwise selection for linear regression models.

Results: Forty-two eyes of 39 patients were included. Eleven eyes (26%) were small MH, 12 eyes (29%) were medium MH, and 19 eyes (45%) were large MH. Sixteen eyes (38%) had vitreomacular traction (VMT). Of 42 eyes, 39 eyes (93%) underwent combined phacovitrectomy and all eyes were pseudophakia postoperatively. Large MH was associated with increased inner FV compared to small MH ($P = 0.0026$), while there were no differences in the outer FV between MH size. Inner and outer FV was similar in eyes with and without VMT. Postoperative VA was significantly associated with the inner FV ($p = 0.39$, $P = 0.0097$), while minimum MH size ($p = 0.29$, $P = 0.063$), basal MH size ($p = 0.20$, $P = 0.21$), and outer FV ($p = -0.053$, $P = 0.74$) were not. In multivariate analysis, the inner FV was the only significant factor for postoperative 12-month VA ($\beta = 0.44$, $P = 0.0033$).

Conclusions: Inner FV is associated with larger MH size based on IVTS classification and worse postoperative VA. These suggest inner FV represents retinal degenerative change associated with more advanced MH.

TITLE: Dendrimer-based nanoparticles for early detection and therapeutic targeting of microglia in a rat glaucoma model

SESSION TITLE: Pharmacological intervention or cellular mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: I.F. Pitha, S. Kambhampati, A. sharma, R. Sharma, L. McCrea, K. Rangaramanujam, Center for Nanomedicine/Ophthalmology, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ian Pitha: Commercial Relationship: Code N (No Commercial Relationship) | Siva Kambhampati: Commercial Relationship: Code N (No Commercial Relationship) | anjali sharma: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Liam McCrea: Commercial Relationship: Code N (No Commercial Relationship) | Kannan Rangaramanujam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal and optic nerve (ON) microglia were identified previously as early indicators of damage and therapeutic targets in glaucoma models. Hydroxyl dendrimer nanoparticles selectively target activated microglia in the brain and retina. Here, we assess dendrimer-based nanoparticles for their ability to label activated microglia and therapeutically target microglia in laser-induced experimental rat glaucoma.

Methods: Unilateral, translimbal laser treatment was performed to induce glaucoma in Wistar rats and IOP was monitored serially by rebound tonometry. Cy5-labelled dendrimer (D-Cy5) was administered either intravitreally or systemically at 3, 7, or 28 days following laser treatment. Retinal biodistribution and microglial uptake was determined by immunofluorescence microscopy and Iba-1 labelling at 3-28 days following dendrimer treatment. N-acetylcysteine-conjugated dendrimer (D-NAC) or free NAC (20µg/eye) was injected intravitreally 7 days after translimbal laser and retinal transcription of TNFα, IL-1b, MCP-1, ICAM-1, iNOS, and NRF2 was determined by RT-PCR (n=6 per group) on day 28.

Results: In the laser induced glaucoma eyes, activated microglia were increased in the retina and ON compared to contralateral control eyes. Intravitreally administered D-Cy5 was selectively localized and retained in activated microglia of laser-treated eyes for up to 28 days. D-Cy5 colocalization with Iba-1 positive retinal microglia was 90% at 7 days after injection and 55% after 28 days. Retinal cross sections demonstrated nerve fiber layer and inner plexiform layer dendrimer uptake in laser-treated eyes, with minimal dendrimer uptake in healthy eyes. Following laser treatment and systemic D-Cy5 administration, dendrimer uptake was not seen in retina, however, was present in the ON. A single dose of intravitreal D-NAC reduced significantly retinal transcription of inflammatory markers TNFα, IL-1b, MCP-1, ICAM-1, and iNOS compared to untreated ($p < 0.01, 0.01, 0.01, 0.05,$ and 0.01 respectively) and NAC-treated eyes ($p < 0.05, 0.05, 0.01, NS,$ and NS respectively).

Conclusions: Hydroxyl dendrimer nanoparticles labeled activated microglia at early timepoints and reduced transcription of inflammatory genes in laser-induced glaucoma. These results highlight the potential of dendrimers for early glaucoma detection and as targeted therapeutics for glaucoma treatment.

ABSTRACT BODY:

Purpose: Several neurodegenerative diseases involve accumulation of misfolded tau, which leads to neurofibrillary tangle formation. Also, tau hyperacetylation promotes tau accumulation and aggregation. Here, we examined the levels and distribution of acetylated (Ac) and total tau in rat retinas following acoustic blast overpressure (ABO) exposure, relative to unexposed controls.

Methods: Anesthetized adult male Long-Evans rats were subjected to ABO exposure, twice, with 1-mo. recovery between exposures. Eyes/retinas were harvested at 48 h post-2nd ABO exposure; non-exposed, age/sex-matched rats served as controls. Immunohistochemistry (IHC) was performed on cryosections of PFA-fixed eyes, probing with polyclonal antibodies (Abs) against Ac-tau (9AB or AC312) or a pan-tau rabbit mAb (EP2456Y). Average % IPL area occupied by pan-tau-labelling was calculated in thresholded z-stack images using ImageJ. Ab specificity was tested by Western blot (WB) analysis, using in vitro-acetylated recombinant rat tau (Ac-rat-tau) as a standard. Statistical analysis: Student's t-test, with significance threshold $P < 0.05$ ($N = 7/\text{group}$).

Results: IHC with Ac-tau Abs showed immunolabelling of nuclei within the GCL INL, ONL and RPE-choroid, and diffuse-to-punctate IPL labelling. A filamentous labelling pattern in the IPL and INL was evident using Ab AC312. However, pan-tau mAb EP2456Y labelled the inner retina, with a diffuse-to-punctate pattern in the GCL, IPL, and perinuclear labeling in the INL, consistent with prior studies. Tau puncta in the IPL varied in size and density. Thresholded image analysis of the IPL region revealed a ~2.8 fold increase in %Area occupied by pan-tau- labelled puncta in ABO-exposed retinas compared to controls. WB analysis revealed that both anti-Ac-tau Abs detected Ac-rat-tau, but not non-Ac-rat-tau. However, both Abs exhibited cross-reactivity with the catalytic domain of p300 acetyltransferase, required for tau acetylation in vitro. EP2456Y detected both Ac and non-Ac forms of tau, but not p300, and was tau-specific.

Conclusions: Visual dysfunction following ABO exposure may be due, in part, to retinal tauopathy caused by tau accumulation, aggregation, and inclusion body formation. However, IHC results obtained using 9AB and AC312 anti-Ac-tau Abs should be interpreted with caution, due to potential cross-reactivity with p300.

ABSTRACT BODY:

Purpose: This retrospective study aimed to compare single surgery anatomic success (SSAS) between pars plana vitrectomy (PPV) and vitrectomy with scleral buckle (PPV/SB) for primary retinal detachment repair.

Methods: Charts of patients who presented to Texas Retina Associates between August 2010 to February 2020 for retinal detachment were reviewed. An initial cohort was randomly generated for preliminary analysis. The primary outcome measure was single surgery anatomic success (SSAS), defined as attachment at 3 months after primary surgery without any additional surgeries during that interval. Patients with <90 days of follow-up data were excluded. Other collected data included pre-operative and final visual acuity, detachment morphology, macular status, lens status, demographic information, and length of follow-up. Group comparison of categorical data was performed with Pearson's chi-square and Fisher's exact test.

Results: 2,103 eyes were identified in our cohort, which were treated with PPV (n = 1791) or PPV/SB (n = 312). Overall, PPV/SB had significantly higher single surgery success rate (94.2%) compared to PPV (87.8%, p = 0.001). In 909 phakic eyes, the SSAS was significantly higher with PPV/SB (94.9%, 187/197) compared to PPV alone (87.2%, 621/712, p = 0.002). In contrast, there was no statistically significant difference in SSAS between PPV/SB and PPV among the 1,167 pseudophakic eyes (92.9% vs 88.8%, p = 0.18). In phakic eyes with inferior pathology, those undergoing PPV/SB reported significantly greater SSAS than PPV (96.9% vs 79.7%, p < 0.001), however the difference was not significant in superior pathology (p = 0.53). Mean change in visual acuity was similar for PPV/SB and PPV (logMAR Snellen 0.48 and 0.44 respectively, p = 0.73).

Conclusions: The addition of scleral buckle to vitrectomy may improve surgical outcomes in patients with primary retinal detachments, particularly in phakic eyes and in those with inferior detachments. We report higher single surgery anatomic success rates than previously described in literature. Despite the differences observed in surgical outcomes, visual recovery was similar for PPV and PPV/SB in our cohort.

ABSTRACT BODY:

Purpose: Fuchs endothelial corneal dystrophy (FECD) is the most common trinucleotide repeat (TNR) expansion disorder, involving a CTG repeat in the widely expressed transcription factor 4 gene. It is unknown whether patients with FECD are at variable risk of systemic disease, but several other TNR expansion disorders such as myotonic dystrophy type 1 are associated with increased cancer risk. We sought to quantify the risk of malignancy in patients with FECD.

Methods: Using the Medicare Limited 5% Data Sets, U.S. Medicare fee-for-service beneficiaries (age ≥ 65 years old) with FECD and cancer were identified via International Classification of Diseases (ICD), 9th and 10th Revision diagnostic codes from January 1, 2014 to December 31, 2016. Odds ratios (OR) and 95% confidence intervals (95% CI) were calculated to compare risk of various cancers in Medicare beneficiaries with FECD compared to those without FECD. The main outcome measure was OR of cancer at various anatomic locations in patients with and without FECD. In order to evaluate the potentially confounding variable of intensity of medical care between groups, the Charlson comorbidity index for systemic diseases, such as diabetes and cardiovascular disease, was applied.

Results: Of the 1,462,740 beneficiaries in the Medicare Limited 5% Data Set, 15,534 (1.1%) patients had an ICD code for FECD. Compared to U.S. Medicare beneficiaries without FECD, FECD patients were at increased risk for the following malignancies after adjustment for age, sex, race, tobacco use, and Charlson comorbidity index: breast (OR: 1.32; 95% CI: 1.22 to 1.43; $p < 0.001$), cutaneous basal cell (OR: 1.42; 95% CI: 1.35 to 1.49; $p < 0.001$), cutaneous squamous cell (OR: 1.45; 95% CI: 1.38 to 1.53; $p < 0.001$), and ovarian (OR: 1.84; 95% CI: 1.48 to 2.30; $p < 0.001$). Conversely, FECD cases were at decreased risk for lung (OR: 0.81, 95% CI: 0.71 to 0.93, $p = 0.003$) and prostate cancer (OR: 0.88; 95% CI: 0.81 to 0.96; $p = 0.002$).

Conclusions: Patients with FECD ≥ 65 years old may be at increased risk for cancer at several anatomic locations. Further studies are needed to confirm this association, elucidate potential disease mechanisms, and identify genetic and/or environmental risk factors.

TITLE: Influence of optical blur on light and dark perimetric stimuli scaled for changes in eccentricity

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Williger, M.W. Dul, V. Moore-Stoll, H. Rahimi, J. Jin, J. Alonso, SUNY College of Optometry, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Max Williger: Commercial Relationship: Code N (No Commercial Relationship) | Mitchell Dul: Commercial Relationship: Code N (No Commercial Relationship) | Veronica Moore-Stoll: Commercial Relationship: Code N (No Commercial Relationship) | Hamed Rahimi: Commercial Relationship: Code N (No Commercial Relationship) | Jianzhong Jin: Commercial Relationship: Code N (No Commercial Relationship) | Jose-Manuel Alonso: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Standard clinical perimetry uses 0.43 degree stimuli which are influenced by optical blur and retinal eccentricity. We assessed the influence of optical blur on light and dark perimetric stimuli scaled for changes in eccentricity.

Methods: Three eyes of 3 control subjects were tested using full optical correction followed by 3 levels of optical blur (+1, +3, +5) at the corneal plane with contact lenses. To mitigate the effects of learning, 3 tests preceded the introduction of optical blur. Each test was comprised of 579 trials, including 51 catch trials at 90 different positions in the visual field, each position was repeated 3 times for each the light and dark trials with 6 repeats in each of two blind spot positions.

Hardware consisted of a head mounted display equipped with an eye tracker (HTC VIVE embedded Tobii) with a refresh rate of 90 Hz, a max luminance of 200 cd/m² and a horizontal field of view of 100 degrees. Unity (version 2017) software was used to generate the stimuli and a library provided by Tobii Pro was used to measure eye movements at 120 Hz. Eye movement was restricted within a central 2.5 degree radius circle. Stimuli were light or dark squares superimposed on a spherical binary noise background. Stimulus size was increased as a function of eccentricity using a power law relationship: $\text{stimulus size} = \text{minimum scale} * (\text{eccentricity}/5)^\alpha$, where the minimum scale is the size in degrees of the stimulus 5 degrees from the fovea, eccentricity is the distance from the fovea in degrees, and alpha is the exponential scale in which the size of the stimulus increases as a function of eccentricity. The minimum scale was set at 2.5 with an alpha of 0.26.

Results: Response accuracy was recorded as a percentage for each visual field location and intrasubjective comparisons were made between light and dark stimuli as well as between magnitudes of optical blur. Consistent with previous work, subjects were more accurate for darks (~10% error rate) vs. light (~20% error rate) stimuli. There was no change in percentage accuracy with the introduction of optical blur for either lights ($p = 0.17$) or darks ($p = 0.15$) (Figure 1).

Conclusions: Both light and dark perimetric stimuli scaled in size for retinal eccentricity are resistant to blur up to +5 diopters. Scaling perimetric stimuli may be useful in clinical practice.

ABSTRACT BODY:

Purpose: Treating healthy and diabetic mice with dopamine receptor agonists selectively enhanced visual function; the D1R agonist increased spatial frequency thresholds, while the D4R agonist increased contrast sensitivity thresholds (Jackson et al., J Neurosci 2012; Aung et al., J Neurosci 2014). Here we investigated the benefits of three dopamine receptor agonists (D1R, D2R, D4R) on visual function at various stages of diabetic retinopathy (DR) in rats.

Methods: Hyperglycemia was induced in 2-month-old male Long-Evans rats using streptozotocin (STZ; blood glucose > 250 mg/dL). Optomotor responses (OMR) were measured in diabetic and control rats before and 30 minutes after a single intraperitoneal injection of SKF38393 hydrobromide, a dopamine D1R agonist (1 mg/kg); Bromocriptine mesylate, a dopamine D2R agonist (5 mg/kg); or PD168077 maleate, a dopamine D4R agonist (1 mg/kg). Each agonist was injected 2-3 days apart. OMR was assessed at 8 weeks post-STZ (n=10-11/group) and at 16 and 20 weeks post-STZ in a subset of rats (n=4-6/group). OMR thresholds were compared pre- and post-agonist between diabetic and control rats at 8 weeks post-STZ and then all agonists compared across time using three-way repeated ANOVAs.

Results: At all timepoints, spatial frequency and contrast sensitivity thresholds were significantly decreased in diabetic rats ($p < 0.0001$; Figure). At 8 weeks post-STZ, the D1R agonist selectively increased spatial frequency thresholds in diabetic rats ($p < 0.0001$), but not in control rats. Additionally, the D4R agonist selectively increased contrast sensitivity thresholds in diabetic rats ($p = 0.0003$) but not in control rats. These differences were not detectable at 16 or 20 weeks post-STZ. The D2R agonist did not show significant effects at any timepoint.

Conclusions: These results show that acute dosing of the D1R agonist selectively benefits visual acuity, while D4R selectively benefits contrast sensitivity at early stages of DR. Therefore, dopamine receptor agonists may benefit visual deficits associated with diabetes if they are administered early in disease progression.

ABSTRACT BODY:

Purpose: Accuracy of automated retinal layer segmentation is dependent on image quality. The purpose of this study is to assess the feasibility of an automated quality SD-OCT assessment tool through a “segmentation confidence score” as a predictor of image quality and segmentation accuracy.

Methods: Eighty-six SD-OCT scans (Cirrus, Zeiss) were included in this study. Following review of each of the 128 slices, two expert readers assigned each scan a quality grade based on manual segmentation feasibility: good - gradable with minimal defects, fair - gradable despite notable defects, or poor - ungradable. Using an automated image feature assessment platform, traditional image quality parameters related to signal intensity including signal intensity mean, median, variance, skew, kurtosis, and homogeneity were calculated for each slice and averaged for each scan.

Utilizing an automated machine learning (ML) enhanced retinal layer segmentation platform, the following layers were segmented: internal limiting membrane, outer nuclear layer, ellipsoid zone, retinal pigment epithelium, and Bruch’s membrane. A segmentation confidence score for each layer of each slice was obtained, ranging from 0-100 based on the percentage of x-axis pixels where the ML platform was able to detect a layer. Confidence scores for all layers and slices were averaged to obtain a mean confidence score for each scan. The performance of a random forest ML classifier was assessed with traditional image quality parameters and also with the segmentation confidence scores. AUC values were obtained from 10 iterations of 5-fold cross-validation [reported: mean (variance)].

Results: Using the image parameters related to signal intensity measures alone, the AUCs for classifying good, fair, and poor quality scans were 0.951 (0.001), 0.874 (0.005), and 0.931 (0.007), respectively. The addition of the ML-derived segmentation confidence scores to the ML scan quality classifier increased the AUCs for good, fair, and poor quality scans to 0.975 (0.0005), 0.929 (0.003), and 0.992 (0.0001), respectively.

Conclusions: The ML-based segmentation confidence score enabled a highly discriminating tool for assessing OCT quality. Automated quality assessment could enable rapid feedback for optimizing automated image analysis, clinical trial inclusion, and clinical feedback for photographers.

TITLE: Acquired vitelliform macular degeneration, characteristics and challenges of managing subretinal fluid

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Juliano, S. Patel, H. Ameri, Department of Ophthalmology, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joseph Juliano: Commercial Relationship: Code N (No Commercial Relationship) | Sagar Patel: Commercial Relationship: Code N (No Commercial Relationship) | Hossein Ameri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the characteristics of sub-retinal fluid (SRF) in acquired vitelliform macular degeneration (AVMD) and highlight diagnostic challenges in this entity given the similarity to age-related macular degeneration. We examined the spectrum of image findings in patients with AVMD and provide a treatment approach in cases that are difficult to differentiate from wet age-related macular degeneration (AMD) when SRF occurs.

Methods: A retrospective review of electronic medical record and clinical imaging of 22 eyes of 16 patients with AVMD at a single institution from 2015 - 2020. The rates of SRF, drusen, pigment epithelial detachment (PED), and patient clinical information such as age, length of follow-up, and BCVA was determined.

Results: The mean age at diagnosis with AVMD was 72 years old with a mean follow-up time of 29 months. Median best corrected visual acuity (BCVA) was 20/29 at presentation and 20/29 at final follow-up. Drusen was a prevalent clinical feature, found in 13 of 22 eyes (59.1%) in our study. Four of 22 eyes (18.2%) had the presence of PEDs. SRF was found in 10 of 22 eyes (45.5%) at some point during their follow-up. Of these 10 eyes, in 7 eyes the SRF was located underneath the fovea (70%), recurrence occurred in 4 of 10 eyes. All recurrences of SRF were in the same location as the initial presentation of sub-retinal fluid. The average time of the occurrence of SRF in AVMD was 2.4 ± 3.6 months, and the average time of SRF disappearance was 7.6 ± 5.6 months. Three eyes received an anti-vascular endothelial growth factor injection for SRF. In 66% of cases receiving an injection the fluid later relapsed and remitted without further injections during the course of follow-up.

Conclusions: AVMD remains a diagnostic challenge in the context of SRF, particularly when associated with drusen. In our case series, SRF tended to be central involving and recurred with or without the use of anti-VEGF injections. Proper differentiation of AVMD may prevent unnecessary long-term treatment with intravitreal anti-VEGF injections.

ABSTRACT BODY:

Purpose: Appointment compliance (AC) has a significant impact on physician-patient relationship and overall patient care. However, determinants of AC in Ophthalmology and its subspecialties remains elusive.

Methods: We performed a five-year, January 2014 to December 31, 2018, retrospective analysis across Kresge Eye Institute (KEI) and its affiliated 24 outpatient Michigan locations. A total of 597,364 appointments across >13 subspecialties were included, in which cancellations, testing, pediatric, and spontaneous emergency appointments were excluded. AC was the primary outcome of interest. Compliant (CO) and non-compliant (NC) groups were compared to the following variables: patient characteristics (gender, race, age, insurance), appointment rank (relative to patient history), scheduling location, month, and ophthalmic specialty, in regard to arrival and no-show.

Results: Among all appointments, 59.77% were associated with a female patient and 79.16% of the total number of appointments were compliant. The mean patient age across all appointments was 58.01 years (SD: 20.07 years) with a range of <1 year to 118 years (IQR: 48.09-71.52 years) and depicted a CO of 59.61%. AC differed concerning specialty, with retina representing the highest compliance across all appointments at 23.84%. Among 200+ insurance providers, Medicare was most frequently used and represented the greatest CO at 44.41%. African Americans were the primary ethnicity served by KEI at 61.02% and had the highest number of NC appointments at 73.36%. Appointment month depicted significant compliance in the month of March at 9.02% ($p < 0.0001$). Among appointment locations, KEI General, which had the highest frequency of appointments represented the least compliance with an NC of 36.06%.

Conclusions: Our study demonstrates the impact of patient demographics, appointment characteristics, and ophthalmic subspecialty on AC. A better understanding of these determinants could allow for an increased CO for Ophthalmology practices.

ABSTRACT BODY:

Purpose: Canine corneal endothelial dystrophy (CED) represents a spontaneous model for Fuchs endothelial corneal dystrophy (FECD). Current therapies for CED are palliative, warranting investigation of new therapeutics addressing the underlying endothelial degeneration. This study evaluates the tolerability and efficacy of the topical rho-kinase inhibitor, ripasudil, in the treatment of a canine model of FECD through a prospective, single-arm clinical trial.

Methods: Twenty-four eyes of 14 client-owned CED-affected dogs received topical ripasudil 4 times daily. Ophthalmic examination, intraocular pressure (IOP) measurement, ultrasonic pachymetry, in-vivo confocal microscopy, and Fourier-domain optical coherence tomography were performed at baseline and at 1, 3, and 6 months after enrollment. Central corneal thickness, percentage of cornea affected by edema, and corneal endothelial cell density at each time point were determined by a masked analyst. One-way repeated measures analysis of variance or Friedman's test were used to evaluate the effect of treatment on disease progression. Due to high variability in disease severity and response to therapy, individual eyes were also classified as improved, progressed, or stable at the 6-month time point based on defined clinical response criteria (Table 1).

Results: During the treatment period, all 14 dogs developed some degree of conjunctival hyperemia, 4 dogs demonstrated reticulated intraepithelial bullae, and 2 dogs developed corneal stromal hemorrhage. These adverse events did not necessitate permanent cessation of ripasudil treatment in any dog. No significant differences were found in corneal endothelial cell density, corneal thickness, extent of corneal edema, or IOP between baseline, 3-month, and 6-month measurements. When considered individually, 5 eyes improved, 14 eyes remained stable, and 5 eyes progressed during the treatment period.

Conclusions: Topical ripasudil was well-tolerated in the eyes of dogs with CED. As previously reported, conjunctival hyperemia and reticulated intraepithelial bullae were the most common adverse events encountered. Variable response to therapy was observed, with some eyes, particularly those with early disease, showing a favorable response while others progressed during the treatment period. Further studies are needed to investigate factors that influence the response to ripasudil therapy in a canine model of FECD.

ABSTRACT BODY:

Purpose: There are currently no dependable ways to predict visual outcomes in patients with diabetic macular edema (DME) who are being treated with anti-vascular endothelial growth factor (VEGF) injections. Identification of biomarkers that are predictive of visual outcomes is crucial for the clinical management of DME. The purpose of this study was to test the hypothesis that patients with greater retinal thickness fluctuations have worse visual outcomes.

Methods: This retrospective cohort study analyzed 270 DME patients seen at the Cleveland Clinic Cole Eye Institute from 2012 to 2019 based on the following inclusion criteria: initiation of anti-VEGF therapy during the study period without prior anti-VEGF treatment, follow-up for at least 12 months after first injection, no concomitant maculopathies, and no concurrent steroid injections or focal laser photocoagulation treatment received. Visual acuity (VA) and central subfield thickness (CST) were collected at 0, 3, 6, 9, and 12 months for each patient. Retinal thickness fluctuation was quantified by the standard deviation (SD) of CST across 12 months. Eyes were stratified into quartiles based on CST SD, and 12-month VA was compared. A mixed effects regression model was also used to evaluate the relationship between CST SD and VA at 12 months.

Results: Mean baseline and 12-month VAs were 63.3 ± 15.7 and 68 ± 13.8 ETDRS letters ($p < 0.001$). Mean baseline and 12-month CST were 401.8 ± 124.9 and 337.1 ± 101.0 μm ($p < 0.001$). Mean CST SD was 61.8 ± 52.5 μm . CST SD was a significant negative predictor of 12-month VA ($p < 0.001$) when adjusting for baseline factors, demographics, injections, DR stage, HbA1c, and insulin dependence.

Conclusions: Larger retinal thickness fluctuations are associated with poorer visual outcomes in eyes with DME treated with anti-VEGF injections. Retinal thickness variability may be an important prognostic biomarker for DME patients and may aid in the evaluation of these patients' progress in clinical practice.

ABSTRACT BODY:

Purpose: The main outcome results of the SCORE2 trial demonstrated that, among patients with macular edema due to central (CRVO) or hemi-retinal vein occlusion (HRVO), intravitreal bevacizumab was non-inferior to aflibercept with respect to visual acuity after 6 months of monthly injections. The current study evaluates the cost-effectiveness of treatment initiation with bevacizumab versus aflibercept.

Methods: We modeled two algorithms: 1) initiate bevacizumab, switching to aflibercept if a patient does not respond to treatment; 2) initiate treatment with aflibercept,. A microsimulation model was constructed simulating 10,000 participants in TreeAge Pro using SCORE 2 data. Parameter estimates were drawn from an a priori distribution creating 100 independent simulations to be pooled. Cost of treatment with bevacizumab and aflibercept was taken from the literature. Patient-centered effectiveness was measured using quality adjusted life years (QALYs) estimated in a two-stage process. First, baseline utility scores were estimated for all participants from NEI-VFQ scores applying a mapping algorithm by Payakachat. Next, utility scores were mapped to visual acuity and other factors using a mixed model method (SAS PROC MIXED). ETDRS best-corrected visual acuity (BCVA) in the best-seeing eye and asymmetry in ETDRS BCVA between eyes had the best fit. The incremental cost-effectiveness ratio for the simulation is reported.

Results: In the simulation, participants initiated with aflibercept gained 1.7 more letters in the treated eye at 6 months than patients initiated with bevacizumab and 3.9 more letters at 12 months. Approximately 20% of simulants who initiated treatment on bevacizumab switched to aflibercept within six months. The difference in QALYs (a person-based measure) was 0.001 QALY favoring those initiated with bevacizumab due to modest differences in the untreated eye. Treatment of those initiated with aflibercept was \$20,029 more after 12 months than those initiated with bevacizumab.

Conclusions: Initiating treatment with bevacizumab in patients with CRVO- or HRVO-associated macular edema, and reserving treatment with aflibercept for those who do not respond to initial treatment, is likely to be a preferred strategy from the perspective of payors considering benefits in the broader health sector.

ABSTRACT BODY:

Purpose: Bardet-Biedl Syndrome (BBS) is a syndromic disease characterized by obesity, hypogonadotropic hypogonadism, polydactyly, developmental delay, genitourinary abnormalities, renal disease, and retinal degeneration. Despite syndromic findings, patients often are misdiagnosed with nonsyndromic retinitis pigmentosa (RP). Fundus autofluorescence (FAF) imaging can be especially helpful in diagnosing inherited retinal degenerations (IRDs) by detecting outer retinal degeneration. Here we analyze wide-field FAF in adult patients with BBS to determine if unique patterns exist.

Methods: Nine patients with genetically-confirmed BBS (6 females, 3 males; age range 18-65) were identified. Electronic medical records were reviewed for medical and ocular history, ocular clinical exam findings, and ocular imaging.

Results: Past medical history revealed syndromic findings in all patients and suspicious family history elements in several patients. Prior to their BBS diagnosis, 4 of 9 patients had been diagnosed with nonsyndromic RP and one with Leber congenital amaurosis (LCA). Three patients had mutations in BBS1, one in BBS2, one in BBS4, one in MKKS, one in TTC8, and two in BBS10. Visual acuity varied from 20/50 to no light perception (NLP), but generally decreased with increasing age. Advanced cataracts prevented fundus visualization in one patient. Macular atrophy was present in 8 patients. Optical coherence tomography (OCT) showed macular loss of outer retinal structure in 8 patients. Seven patients displayed foveal hypoautofluorescence with concentric hyper- and hypoautofluorescence in a bullseye pattern. Six of 8 patients had few to no peripheral pigmentary changes/bone spicules on clinical exam, however wide-field FAF of these patients revealed extensive speckled or diffuse peripheral hypoautofluorescence.

Conclusions: Despite other syndromic findings (which can be life-threatening), patients with BBS are often misdiagnosed with nonsyndromic RP. We conclude that, along with detailed medical and family history, specific imaging findings on wide-field FAF can aid in the diagnosis of BBS in adult patients with suspected IRDs by better delineating macular degeneration patterns and unearthing extensive peripheral hypoautofluorescence not always evident on clinical exam.

ABSTRACT BODY:

Purpose: To investigate if intraoperative retinal changes during epiretinal membrane (ERM) peeling affect anatomic or functional outcomes after surgery.

Methods: We measured retinal thickness using an intraoperative optical coherence tomography (iOCT) device in patients undergoing pars plana vitrectomy with membrane peeling for idiopathic ERM. Changes in intraoperative central macular thickness (iCMT) were compared with postoperative improvements in CMT and best-corrected visual acuity (VA).

Results: 27 eyes from 27 patients (mean age 68 years) underwent iOCT-assisted ERM peeling surgery. Before surgery, mean VA was logMAR 0.50±0.36 (Snellen 20/63) and mean baseline CMT was 489±82 µm. Mean iCMT before peeling was 477±87 µm, which correlated well with preoperative CMT (P<0.001). Mean change in iCMT was -39.6±37µm (range -116 to +77µm). After surgery, VA improved to logMAR 0.40±0.38 (Snellen 20/50) at month 1 and logMAR 0.27±0.23 (Snellen 20/37) at month 3, while CMT decreased to 397±44µm and 396±51µm at months 1 and 3. Eyes that underwent greater amount of iCMT change (absolute value of iCMT change) were associated with greater CMT reduction at month 1 (P<0.001) and month 3 (P=0.010), while those with greater intraoperative thinning (actual iCMT change) showed a trend toward better VA outcomes at months 1 (P=0.054) and 3 (P=0.036).

Conclusions: Intraoperative changes in retinal thickness may predict anatomic and visual outcomes after idiopathic ERM peeling surgery.

ABSTRACT BODY:

Purpose: Real-world physical activity patterns in monocular persons have not been previously characterized. This study uses a nationally representative sample to compare the physical activity levels of functionally monocular to binocularly sighted persons in the United States.

Methods: This cross-sectional study uses data from the 2003-2004 and 2005-2006 National Health and Nutrition Examination Survey (NHANES) to compare differences in physical activity between functionally monocular and binocular participants. Functionally monocular is defined as visual acuity of better than 20/200 in one eye and 20/200 or worse in the other eye after auto-refraction. The main outcome measures were accelerometer-measured mean steps per day and mean daily minutes of moderate or vigorous physical activity (MVPA). Statistical analysis was conducted using multivariable negative binomial regression models, which included age, gender, race/ethnicity, better-eye visual acuity, educational attainment, and obesity as covariates. Sample weights were used according to guidelines from the National Center from Health Statistics.

Results: 7,967 NHANES participants had complete visual acuity and accelerometer data. The mean age at baseline was 44.5 years, and a majority were Caucasian (73%) and female (52%). In unadjusted analysis, functionally monocular participants (n=102) took fewer steps (7,254 vs 10,012, $p<0.01$) and engaged in fewer minutes of MVPA (13.6 vs 26.8, $p<0.01$) per day compared to binocularly-sighted participants (n=7,846). When adjusted for age and better-eye visual acuity, however, these between-group differences were not statistically significant. These results may be explained by the age disparity between groups: the mean age of the monocular group was 65.5 (CI 50.8-70.2) compared to the binocular group, which was 44.2 (CI 43.2-45.3). In our final model, monocular participants took 17% fewer steps per day ($p=0.15$) and engaged in 26% fewer minutes per day of MVPA ($p=0.12$).

Conclusions: Functionally monocular persons have similar physical activity levels compared to those with binocular eyesight in the United States. Additional work is needed to determine if particular types of activity are impacted by monocular status, and if the timing of vision loss has an impact on activity levels.

Commercial Relationships Disclosure (Abstract): Yayu Chen: Commercial Relationship: Code N (No Commercial Relationship) | Chi-Fong Lin: Commercial Relationship: Code N (No Commercial Relationship) | Cheng-Jan Yang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: With the rapid development of technology, the frequency and duration of using digital devices have increasing in daily life, including mobile phone, tablet and computer. Near work for prolonged time can have negative effects for binocular vision. Therefore, this study evaluated the visual symptoms and binocular vision functions after wearing progressive addition lenses (PALs) in Taiwanese non-presbyopia adults.

Methods: 51 healthy non-presbyopia adults aged from 20 to 30 years old were recruited in this study. All participants were measured visual symptoms and binocular vision functions before and after wearing PALs (+0.85 D) for 6 months. Convergence insufficiency symptom survey (CISS) was to use for quantifying the visual symptoms. Near point of convergence (NPC), amplitude of accommodation (AA) and near positive fusional vergence (NPFV) were measured for evaluating binocular vision functions.

Results: After wearing PALs for 6 months, the scores of CISS were statistically significantly reduced (before: 16.86 ± 6.69 ; after: 12.35 ± 7.18 , $p < 0.001$). There was no significant difference before and after wearing PALs for 6 months in the results of NPC, AA and NPFV. However, the mean values of NPC (before: 4.94 ± 4.56 cm; after: 4.40 ± 3.51 cm, $p = 0.285$), AA_{OD} (before: 10.38 ± 3.75 D; after: 10.52 ± 2.80 D, $p = 0.710$), AA_{OS} (before: 10.22 ± 3.75 D; after: 10.43 ± 2.98 cm, $p = 0.588$) and NPFV (before: $7.10 \pm 9.34^\Delta$; after: $7.78 \pm 9.96^\Delta$, $p = 0.597$) were slightly improved.

Conclusions: Our results showed that PALs could significantly ameliorate visual symptoms and slightly improved the binocular vision functions for Taiwanese non-presbyopia adults.

ABSTRACT BODY:

Purpose: Antibiotic resistance is a global crisis. Antimicrobial peptides are being developed to provide new therapeutic options to reduce resistance. Some of these antimicrobial peptides have broad-spectrum antimicrobial activity and act rapidly on bacteria reducing its resistance. However, the half-life of peptides in the body is compromised due to proteolysis. In order to overcome this degradation, peptide mimics are developed to retain the benefits of the antimicrobial activity. This study investigated whether an antimicrobial peptide mimic could work in synergy with quinolones and cephalosporins against a multidrug-resistant strain of Staphylococcus aureus.

Methods: The antimicrobial peptide mimic 758 was used together with the first line antibiotics ciprofloxacin and ceftazidime. The minimum inhibitory concentration (MIC) of each drug was determined by the microtitre broth dilution method. Subsequently, a checkerboard assay was performed to examine the interaction between antibiotics and peptide mimic. The results were expressed as the fractional inhibitory concentration index (FICI). FICIs of ≤ 0.5 indicate synergism; 0.6-1 indicates additive effect; 1-4 - no interaction and ≥ 4 - antagonism.

Results: Peptide mimic 758 had a MIC of 2.5µg/ml for multidrug-resistant S. aureus strain. Compound 758 produced synergism with both ciprofloxacin and ceftazidime with a FICI of < 0.2 and 0.3 respectively. The MIC of ciprofloxacin was reduced from 2.5µg/ml to 0.15µg/ml and of the peptide mimic from 2.5µg/ml to 0.03µg/ml. The MIC of ceftazidime was reduced from 32µg/ml to 10µg/ml and of the peptide mimic from 2.5µg/ml to 0.03µg/ml.

Conclusions: The peptide mimic was able to significantly enhance the antimicrobial activity of the first-line antibiotic ciprofloxacin and third-generation cephalosporin ceftazidime. Future research will examine other strains and bacteria, as well as the mechanism of the synergy.

ABSTRACT BODY:

Purpose: Retinal nerve fibre layer (RNFL) thinning is an important early marker of glaucoma. It is known that RNFL thickness is associated with birth weight and head circumference at birth, both markers of intrauterine growth. We explored relationships between patterns of fetal anthropometric growth, as reflective of early life influences on fetal wellbeing, and global RNFL thickness measured in young adulthood.

Methods: A subset of Caucasian participants (n = 485) from the Raine Study, a pregnancy cohort study based in Western Australia, were included in the analysis. Participants underwent serial ultrasound scans at 18, 24, 28, 34 and 38 weeks' gestation, with fetal biometry measured at each scan. An eye examination including measurement of optic disc parameters via spectral-domain optical coherence tomography imaging was undertaken at a 20-year follow-up. Growth trajectories based on measurements of fetal head circumference (FHC), abdominal circumference (FAC), femur length (FFL) and estimated fetal weight (EFW) were explored via group-based trajectory modelling. Generalised estimating equations (GEEs) were used to evaluate differences between groups of participants with similar growth trajectories with respect to global RNFL thickness.

Results: Participants with consistently large FHCs throughout gestation had thicker RNFLs than those with small, moderately small or moderately large FHCs, after adjusting for fetal sex, maternal smoking during pregnancy, gestational age at birth, and intraocular pressure and axial length at the 20-year follow-up ($p = 0.005$, 0.005 and 0.003 , respectively). This model showed better fit according to the quasi-information criterion when compared to similarly adjusted GEE models analysing associations between RNFL thickness and either birth weight or head circumference at birth. There were no significant differences in RNFL thickness between trajectory groups in the FAC, FFL or EFW models, although similar trends to those in the FHC model were demonstrated.

Conclusions: FHC growth is strongly correlated with RNFL thickness in young adulthood and is moreover a better predictor than birth weight or head circumference at birth. This indicates that adverse early life conditions may predispose towards thinning of the RNFL in child and adult life. There may therefore be implications for the long-term risk of glaucoma in individuals with restricted FHC growth.

ABSTRACT BODY:

Purpose: The quantity and quality of blinking are key determinants of homeostasis at the ocular surface. However, few epidemiological studies have examined the characteristics of blinking. We therefore determined the number of blinks (BN) and incomplete blink rate (IBR) according to sex and age in a population-based study (Hirado-Takushima study). We also investigated factors related to the ocular surface or lifestyle that might influence these parameters.

Methods: The study subjects were residents of Takushima Island, Nagasaki Prefecture, Japan, who gave informed consent and for whom BN and IBR were measurable with a LipiView interferometer (Johnson&Johnson). Generalized additive model (GAM) analysis was performed separately according to age and sex. Systemic illness (hypertension, diabetes, dyslipidemia, collagen disease, depression), lifestyle-related factors (BMI, visual display terminal [VDT] time, TV time, time spent outside, use of eye makeup or contact lenses, having a pet, sleep time), ocular symptoms, and tear film– and meibomian gland–related parameters (15 items) were evaluated, and factors potentially affecting BN and IBR were examined with a mixed-effects model.

Results: A total of 356 subjects (133 men and 223 women; mean age \pm SD, 55.5 ± 22.4 years) and 701 eyes were enrolled in the study. BN was 3.17 ± 1.72 over 20 s and decreased with age in both men and women ($p=0.017$). Individuals with dyslipidemia had a reduced BN ($p=0.015$). The fluorescein staining score ($p=0.044$) and meiboscore ($p=0.027$) were positively and the thickness of the lipid layer of the tear film ($p<0.0001$) was negatively related to BN. Mean IBR was 41.1% for all ages. IBR decreased with age ($p=0.015$). VDT time ($p=0.017$) and eye makeup use ($p=0.006$) were positively and time spent outside ($p=0.036$) and TV time ($p=0.022$) were negatively related to IBR.

Conclusions: BN may increase to compensate for disturbance of the ocular surface, including when the lipid layer of the tear film is deficient as a result of meibomian gland dysfunction, whereas IBR may be susceptible to lifestyle factors such as eye makeup use and VDT time.

ABSTRACT BODY:

Purpose: To determine the association of age, presence of optic nerve head drusen (ONHD) and number of previous intravitreal anti-VEGF injections with inner retinal layer thicknesses in patients with pseudoxanthoma elasticum (PXE).

Methods: In this retrospective study, longitudinal spectral domain optical coherence tomography (OCT) imaging data from patients with PXE were compared to controls. A custom deep-learning-based segmentation algorithm was trained and validated to quantify the retinal nerve fiber layer (RNFL), ganglion cell layer (GCL), inner plexiform layer (IPL) and the inner nuclear layer (INL) for each ETDRS-subfield. The association of age, number of anti-VEGF injections and ONH drusen with the RNFL/GCL/IPL/INL thickness as dependent variable were investigated using mixed model regression. The model was applied for a macular ring including all outer ETDRS subfields with an ETDRS grid centered to the fovea.

Results: Fifty-three eyes of 30 patients with PXE were compared to 100 eyes of 100 controls. The mean age was (median [IQR]) 54.0 [46.3, 61.7] years for patients vs. 58.1 [36.6, 37.8] years for controls. In patients, ONHD were visible in 15 eyes from 13 patients and the number of anti-VEGF injections ranged from 0 to 55. In the multivariable analysis, age ($-0.09 \mu\text{m}/\text{year}$, $p < 0.001$), the diagnosis of PXE ($-1.80 \mu\text{m}$, $p = 0.022$) and an interaction term between age and the presence of ONHD ($-0.22 \mu\text{m}/\text{year}$, $p = 0.002$) were significantly associated with the GCL thickness in the ring of all outer ETDRS subfields. Including the number of intravitreal injections did not improve the model fit. The RNFL was solely dependent on age without any influence of other parameters. The IPL showed significantly decreased thickness in patients ($-4.79 \mu\text{m}$) compared to controls ($P = 0.015$), but with a significant interaction of group and age ($+0.11 \mu\text{m}/\text{year}$, $P = 0.003$) compatible with gliotic remodeling in older patients with concurrent atrophic changes.

Conclusions: This study demonstrates a significant association of ageing and ONHD with GCL thinning in patients with PXE. Given the severity of postreceptor neuronal degeneration in a subset of patients, neuroprotective therapy once available would warrant consideration. Further, emerging anti-VEGF agents, which allow for less frequent intravitreal injections and/or smaller injections volumes, may be considered to minimize transient intraocular pressure elevations with potential adverse effects on the GCL.

TITLE: Follow-up for in-person eye care after teleophthalmology diabetic eye screening in a U.S. academic medical center

SESSION TITLE: Diabetic Retinopathy Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Luo, M. Wingelaar, B. Xing, B. Burckhard, Y. Liu, Ophthalmology & Visual Sciences, University of Wisconsin-Madison School of Medicine and Public Health, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Susan Luo: Commercial Relationship: Code N (No Commercial Relationship) | Maxwell Wingelaar: Commercial Relationship: Code N (No Commercial Relationship) | Bohan Xing: Commercial Relationship: Code N (No Commercial Relationship) | Braden Burckhard: Commercial Relationship: Code N (No Commercial Relationship) | Yao Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Teleophthalmology provides evidence-based diabetic eye screening in primary care, but U.S. studies have reported low follow-up rates (e.g. 30%) for in-person eye care among screen positives. In this study, we evaluated follow-up outcomes after teleophthalmology in an academic U.S. medical center.

Methods: We retrospectively reviewed medical records of adults with diabetes who had teleophthalmology performed using a Topcon NW400 retinal camera (Topcon Medical Systems, Inc., Oakland, NJ, USA) at 2 primary care clinics in Madison, WI between Jan 2018 and Oct 2020. Single-field 45° images of the fundus and anterior photos of each eye were reviewed by eye care providers. Patients needing further in-person eye care were contacted by letter and by phone from schedulers to make an eye appointment. The primary outcome was chart documentation of a completed follow-up eye appointment within 1 year of imaging.

Results: Among 361 patients, the average age was 58.4 years, 54% were men, and 98% had health insurance. 332 patients (92%) had gradable images, including 15% with diabetic retinopathy that was severe or worse in 0.6%. A total of 74 patients (21%) were referred for follow-up eye care due to either abnormal findings (13%) or ungradable images (8%). Patients referred for follow-up eye care were more likely to be insured by Medicare or Medicaid ($p<0.001$) than Commercial insurance. Pathologic findings were identified among 58% ($n=19$) of patients with ungradable images. No uninsured patients were referred for follow-up. There was a 65.5% follow-up rate ($n=58$) among patients imaged between Jan 2018 and Dec 2019, with 48.3% following up within the recommended timeframe. Patients with higher hemoglobin A1c ($p=0.04$) were less likely to follow-up. Among those that did not follow-up ($n=20$), 75% had made an eye appointment, but either cancelled (45%) or no-showed (30%). A total of 8 patients (21%) among those who followed up underwent treatment (e.g. laser, intravitreal injection, and/or cataract surgery).

Conclusions: We found higher follow-up rates (65.5%) for in-person eye care compared to prior reports. While lack of insurance has been cited as a major barrier, follow-up rates remain limited even among patients with insurance. Interventions to further increase follow-up are needed to more effectively improve visual outcomes after screening.

ABSTRACT BODY:

Purpose: To describe the clinical features of patients with pterygium and analyze the recurrence rate of conjunctival autografting alone, conjunctival autografting combined with intraoperative mitomycin C, and amniotic membrane grafting.

Methods: A retrospective study of primary pterygium was conducted between January 2017 and February 2020. The number of patients who presented with pterygium was 292, while the number of operated cases was 94 (32.19%). The main outcome measured was recurrence over an average follow-up period of 29.3 ± 11.9 months.

Results: Pterygium involving the cornea was observed in 55% of the cases. In the multivariate regression analysis, female gender was the only independent risk factor for a pterygium to encroach on the cornea. The overall rate of recurrence for the three procedures was 17% over an average time of 14.19 ± 11.9 months, with 37% of the recurrences occurring after the first year. The only factor associated with a significant risk of recurrence was dry eye disease. The recurrence rates following conjunctival autografting with and without mitomycin C were 15.6% and 15.8%, respectively. The recurrence rate following the amniotic membrane graft was almost double (27%) that following the conjunctival autograft (15.6%); however, this difference was not statistically significant. For conjunctival autografts, adding fibrin glue to sutures did not result in a lower recurrence rate ($p=0.747$).

Conclusions: The only factor associated with the recurrence of pterygium was dry eye disease. More than one-third of recurrences developed after the first year, which stresses the importance of a long follow-up.

ABSTRACT BODY:

Purpose: Primary open angle glaucoma (POAG) and periodontitis have both been shown to be inflammatory-driven processes, with several previous studies suggesting that there may be a link between periodontal disease and an increased risk of glaucoma. The purpose of our study was to explore further the association between chronic periodontitis and glaucoma in a retrospective case-control study design. Our null hypotheses stated that POAG did not affect the prevalence of periodontitis, prevalence of tooth extraction, or average number of tooth extractions as compared with healthy, age-matched patients without POAG.

Methods: Patient information was extracted from charts in the BigMouth Dental Data Repository for UTHealth School of Dentistry from 2006-2019 among patients between ages 18-80 years old. Patients that had identified as having a diagnosis of glaucoma on a medical questionnaire were selected for the glaucoma case group and randomly selected, age-matched patients who had reported as having no diagnosis of glaucoma on the same medical questionnaire were selected for the controls. There were 330 patient charts in the BigMouth database that met the inclusion criteria for the glaucoma group. For the controls, 330 age-matched healthy patients were selected. The three main outcome measures that we identified during data extraction were periodontal disease, history of tooth extraction, and number of teeth extracted. Chi-square, Student's t-test, and one-way ANOVA calculations were performed for statistical analysis purposes, as appropriate.

Results: There was a statistically significant increased prevalence of patients with periodontal disease among older glaucoma patients aged 70-79 years vs. controls ($p=0.035$). This was the only age range in which we found a statistically significant difference in the prevalence of periodontal disease between test and control groups. There was no statistically significant difference in the prevalence ($p=0.800$) or average number ($p=0.653$) of tooth extractions between the two groups.

Conclusions: Our study found a statistically significant increased prevalence of periodontal disease among older glaucoma patients aged 70-79 years old compared to controls, although this association was not found to be similarly significant within the other age ranges. This finding corroborates previous studies that concluded that there is in fact an association between periodontal disease and an increased risk of glaucoma.

Commercial Relationships Disclosure (Abstract): Yi Hua: Commercial Relationship: Code N (No Commercial Relationship) | Jason Walker: Commercial Relationship: Code N (No Commercial Relationship) | Po-Yi Lee: Commercial Relationship: Code N (No Commercial Relationship) | Bryn Brazile: Commercial Relationship: Code N (No Commercial Relationship) | Ian Sigal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxygen in the lamina cribrosa (LC) is essential for maintaining functioning retinal ganglion cell axons and vision. Measuring LC oxygen experimentally is not yet possible and thus it is usually studied using numerical models. LC oxygen models have been highly simplified and generic (Chuangsuwanich et al., 2016), or eye-specific but 2D (Hua et al., 2020). Our goal was to leverage new 3D eye-specific models of the LC vessel network to identify the factors with the largest influence on LC oxygen.

Methods: We reconstructed a detailed 3D model of the monkey LC vessel network based on histological sections (Fig. 1). Hemodynamics boundary conditions were defined to simulate blood flow from the circle of Zinn-Haller, drainage through the central retinal vein, and interactions with the pre and retrolaminar regions. Using a Monte Carlo approach, 500 models were generated with varying (baseline \pm 20%) microvessel diameter, pressures (arteriole, venule, prelaminar, and retrolaminar), inflow hematocrit, and oxygen consumption rate. Models were simulated to estimate LC neural tissue oxygen concentration. Regression analysis was used to determine factor influences on the minimum (10th percentile) oxygen concentration in the LC.

Results: The factors influencing the minimum oxygen concentration the most were: the microvessel diameter, oxygen consumption rate, and arteriole pressure; and to a less extent: the venule, retrolaminar, and prelaminar pressures, and the inflow hematocrit (Fig. 2).

Conclusions: Our models predict that the microvessel diameter, oxygen consumption rate, and arteriole pressure have the largest influence on the oxygen concentration in the LC. To understand the susceptibility to ischemia in retinal ganglion cell axon damage and vision loss, the influential factors should be better characterized.

TITLE: Sex Differences in Scholarly Productivity, Academic Promotion, and NIH Funding of Academic Glaucoma Specialists

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Chiam, M.L. Camacci, S. Pantanelli, Department of Ophthalmology, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|E. Lehman, Department of Public Health Sciences, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mckenzee Chiam: Commercial Relationship: Code N (No Commercial Relationship) | Mona Camacci: Commercial Relationship: Code N (No Commercial Relationship) | Erik Lehman: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s);Carl Zeiss Meditec :Code C (Consultant);Bausch & Lomb:Code C (Consultant)

ABSTRACT BODY:

Purpose: Glaucoma specialists represent the fourth largest subspecialty within academia. To our knowledge, this is the first study to investigate sex differences in scholarly productivity, academic promotion, and NIH funding within this sub-group.

Methods: This was a cross-sectional study of glaucoma specialists employed across 113 US academic institutions. Using institutional websites, data on gender, residency graduation year, and academic rank were collected between January-March 2019. The Scopus database was used to obtain each faculty member's h-index, which is a measurement of publication productivity, and m-quotient, which adjusts for an individual's career length. The NIH Research Portfolio Online Reporting Tool database was queried for data on NIH funding. Chi-square testing was used to analyze categorical values and Wilcoxon Rank Sum testing was used for continuous variables.

Results: A total of 431 glaucoma specialists were identified, of whom 157 (36.4%) were female and 274 (63.6%) were male. A greater proportion of females vs. males were assistant professors [101 (64.3%) vs. 126 (46.0%); $p=0.003$] and a smaller proportion of females were full professors [20 (12.7%) vs. 80 (29.2%); $p=0.001$]. No difference was found among associate professor positions [female: 36 (22.9%) vs. male: 66 (24.1%); $p=1.000$] and department chair positions [3 (1.9%) vs. 22 (8.2%); $p=0.103$]. Females had lower median h-indices compared to their male counterparts (4.0 vs. 8.0; $p<0.001$), but similar median m-quotients (0.4 vs 0.5; $p=1.000$). Females had a shorter median career length based on their residency graduation year compared to males (13.0 vs 21.0 years; $p<0.001$). Among NIH-funded investigators, females had a median grant funding of \$1.1M compared to \$1.4M for males ($p=1.000$).

Conclusions: Shorter career length among female glaucoma specialists likely contributes to the difference seen in scholarly productivity and composition of senior academic ranks between sexes. Career length should be considered when comparing scholarly productivity between sexes.

ABSTRACT BODY:

Purpose: To evaluate ganglion cell complex (GCC) and retinal nerve fiber layer (RNFL) with optical coherence tomography (OCT) and functional tests as visual acuity (VA) and Hardy Rand and Rittler (HRR) Standard Pseudoisochromatic Test in patients with Autosomal Dominant Optic Atrophy (ADOA).

Methods: Prospectively defined, cross-sectional study of 38 eyes of 19 patients with diagnosis of ADOA. All patients underwent a complete functional examination with VA and colour test, and a structural examination with OCT (Cirrus®, Zeiss).

Results: Analysis of OCT results was done and correlated with functional tests. Results show that temporal sectors of GCC and inferior and superior RNFL sectors were directly correlated with VA measured with ETDRS and with HRR in eyes with ADOA.

Conclusions: Functional and morphologic changes observed in ADOA eyes are helpful to understand the physiology of the disease. Analyzing OCT, VA and colour test could be a future tool to select patients who can take benefit of receiving future treatments.

ABSTRACT BODY:

Purpose: Assessment of corneal sensitivity (CS) allows to identify alterations of ocular surface sensory innervation associated with several conditions including neurotrophic keratopathy (NK) and dry eye disease (DED). Currently, Cochet-Bonnet (CB) esthesiometer represents the standard for measuring CS. A novel, single-use corneal esthesiometer (KeraSenseTM) has been developed. The aim of this study is to evaluate the accuracy, reproducibility, and repeatability of the KeraSenseTM in comparison to CB.

Methods: 26 healthy subjects (60±13 years of age) and 41 patients (60±17 years of age) with NK (N=16), diabetes (N=14) and dry eye (N=11) were included. CS was assessed in all subjects with KeraSenseTM (Dompé Farmaceutici SPA, Milan, Italy) and CB. KeraSenseTM assesses CS by disposable devices of fixed nylon thread lengths: 15, 35 and 55 mm. Repeatability and reproducibility of KeraSenseTM were assessed by comparing results of 3 different measurements by the same masked investigator and by two different physicians, respectively. Sensibility, specificity, and accuracy for the diagnosis of NK have also been evaluated.

Results: CB evaluation showed that patients with NK had significant ($P<0.001$) decrease of CS (30±23 mm) when compared with healthy subjects (59±1 mm), and with patients with DM (57±5 mm) and dry eye (58±2 mm). KeraSenseTM showed repeatability and reproducibility, respectively with 100% agreement between different measurements and 99.6% concordance between different operators (Kappa index interrater agreement $P<0.001$). Corneal sensitivity values assessed by KeraSenseTM were significantly associated with CB values (ANOVA $P<0.001$). A 55mm KeraSenseTM value was adequate to exclude an NK diagnosis, while all patients with a KeraSenseTM value of 0 or 15mm had NK. KeraSenseTM response at 35mm showed good sensitivity and specificity to discriminate the presence of NK.

Conclusions: KeraSenseTM showed significant association with CB assessment and represents an expeditious and accurate device to assess CS without need of calibration, and being single-use, ensuring better safety also in the context of SARS-Cov2 outbreak.

Commercial Relationships Disclosure (Abstract): Zia Chaudhuri: Commercial Relationship: Code N (No Commercial Relationship) | Pratibha Kataria: Commercial Relationship: Code N (No Commercial Relationship) | Umesh Garga: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cross-sectional assessment of connective tissue changes by high-resolution surface coil orbital MRI was performed in Indian subjects to establish age specific normative data in this group and aid trans-ethnic comparison with Caucasian subjects, where these changes have now been found to be causal for the genesis of the “sagging eye syndrome” (SES), a small-angle mechanical strabismus associated with symptomatic diplopia.

Methods: 52 orbits of 27 adult non-strabismic subjects in the age group between 18-40 years (Group A, n=18 subjects (36 orbits), average age=25±5.6 years, M:F::10:8), 41-60 years (Group B, n=05 subjects (10 orbits), average age=46.4±4.7 years, M:F::2:3) and >60 years (Group C, n=04 subjects (08 orbits), average age=74±6.3 years, M:F::3:1) were imaged by high-resolution fast spin echo T2 weighted (T2FSE) surface coil MRI sequences with the subject fixating at a central target (1.5T, Siemens Symphony). 2 mm thick quasi-coronal image planes perpendicular to the orbital axis were analysed for extra-ocular muscle (EOM) pulley locations, EOM cross-sections and LR-SR band length while quasi-sagittal and axial planes were used to analyse rectus EOM length, all by Image J software as per published norms.

Results: The average LR-SR band length was 8.6±2.2 mm in Group A, 10.5±2.7 mm in Group B and 15.5±2.4 mm in Group C. The inter-group differences were significant at p≤0.05 with the Group A versus Group B difference being 0.03, Group B versus Group C difference being 0.001 and the Group C versus Group A being 2.65785E-09 (Figure 1).

Conclusions: Age-related connective tissue changes in non-strabismic Indian subjects were similar to those observed in Caucasian subjects. This may translate as the basis of strabismus due to SES in this ethnic group.

TITLE: Reduced WNT10A in keratoconus corneal epithelium and Bowman's layer and upregulation of collagen I suggest Wnt signaling as a therapeutic target

SESSION TITLE: Keratoconus and Corneal Biomechanics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: U. Soiberman, J.W. Foster, M. Lu, A.S. Jun, C. Eberhart, Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|S. Chakravarti, Ophthalmology, NYU Langone Health, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Uri Soiberman: Commercial Relationship: Code N (No Commercial Relationship) | James Foster: Commercial Relationship: Code N (No Commercial Relationship) | Michelle Lu: Commercial Relationship: Code N (No Commercial Relationship) | Shukti Chakravarti: Commercial Relationship: Code N (No Commercial Relationship) | Albert Jun: Commercial Relationship: Code N (No Commercial Relationship) | Charles Eberhart: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The hallmark of keratoconus (KC) is biomechanical failure of the cornea, with fragmentation of Bowman's layer (BL) contributing to reduced corneal strength. Proteomic studies of collagen I in the KC corneal epithelium have shown underexpression of this major structural component of the extracellular matrix. Collagen I spatially localizes to BL and is produced in part by corneal epithelium. Wnt signaling, which regulates extracellular matrix production, has been shown to be dysregulated in KC, and our transcriptomic study of progressive KC corneal epithelium demonstrates underexpression of WNT10A mRNA. However, it is unclear whether WNT10A regulates collagen I expression in the corneal epithelium.

Methods: RNA-sequencing was performed on corneal epithelium samples of five progressive KC and five myopic control eyes. WNT10A underexpression was validated using TaqMan qPCR on 31 additional independent samples; protein level validation with Western blot analysis. Immunohistochemistry was performed on tissue microarrays containing cores from over 100 KC and control cases. Additionally, WNT10A was overexpressed in vitro in immortalized corneal epithelial cells.

Results: WNT10A was underexpressed in KC corneal epithelium as compared to myopic controls (transcript ratio KC/control=0.59, $p=0.02$ per RNA-sequencing study; transcript ratio=0.66, $p=0.03$ per qPCR; protein ratio=0.07, $p=0.06$ per Western blot). Immunohistochemical analysis demonstrated WNT10A absence or marked decrease in BL of KC corneas ($p<0.0001$). Finally, WNT10A positively regulated COL1A1 expression in corneal epithelial cells (protein ratio=11, $p=0.02$).

Conclusions: Though long suggested historically, our results provide for the first time a potential molecular mechanism supporting the hypothesis that alterations of the epithelium contribute to stromal pathogenesis in KC. Specifically, we find that WNT10A promotes COL1A1 expression, and hypothesize that when WNT10A levels are low, reduced deposition of collagen I in BL may compromise biomechanical strength and potentiate breaks typical of KC. These studies also suggest that the Wnt pathway represents a therapeutic target, as its manipulation in the corneal epithelium may induce collagen I production and increase tensile strength in KC.

TITLE: Reliability of successive corneal tomography and biomechanical measurements by Pentacam® and Corvis ST® in keratoconus patients without treatment and after corneal crosslinking

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Xanthopoulou, C. Munteanu, B. Seitz, E. Flockerzi, Ophthalmology, Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg/Saar, Saarland, GERMANY|M.W. Belin, Ophthalmology & Vision Science, The University of Arizona James C Wyant College of Optical Sciences, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kassandra Xanthopoulou: Commercial Relationship: Code N (No Commercial Relationship) | Cristian Munteanu: Commercial Relationship: Code N (No Commercial Relationship) | Berthold Seitz: Commercial Relationship: Code N (No Commercial Relationship) | Michael Belin: Commercial Relationship(s);Oculus:Code C (Consultant) | Elias Flockerzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the reliability of successive measurements of corneal tomography and biomechanics measured by Pentacam® and Corvis ST® (CST, Oculus, Wetzlar, Germany) in keratoconus (KC) patients at least two years after corneal crosslinking (CXL) compared to untreated KC cornea.

Methods: Three successive corneal tomography (n=28 eyes of 21 patients) and biomechanic measurements (n=23 eyes of 16 patients) per eye were performed in the two years after CXL group (CXLG) including mild to advanced KC stages. Two control groups were formed consisting of non-operated and stage-matched KC corneas according to Belin's ABCD classification, the first including KC cornea with three successive Pentacam measurements (n=26 of 24 patients, Pentacam controls, PC) and the second including KC cornea with three successive CST measurements (n=26 of 26 patients, CST controls, CSTC). Main outcome measures included K1, K2, Kmean, astigmatism for anterior and posterior corneal curvature, Kmax, thinnest pachymetry and the KC indices (tomography) and the biomechanical parameters that are included within the Corvis Biomechanical Index (CBI: A1 velocity, DA ratio 2mm, ARTh, integrated radius and SP-A1).

Results: All tomographic parameters in the CXLG and PC group showed excellent reliability (Cronbach's $\alpha > 0.95$) as well as good intra-class correlation coefficients (ICC: CXLG > 0.92 , PC: > 0.709), except for the Index of Height Asymmetry (Cronbach's α : CXLG 0.855, PC: 0.605; ICC: CXLG: > 0.782 , PC: > 0.585). The CST measurements showed better reliability in the CXLG than in the CSTC (Cronbach's α , CXLG|CSTC: A1 velocity: 0.943|0.912, DA ratio 2mm: 0.931|0.906, ARTh: 0.976|0.433, SP-A1: 0.839|0.524). Only the integrated radius showed a better reliability in the CSTC (0.974) than the CXLG (0.857).

Conclusions: Corneal tomography parameters showed excellent reliability independent of preceding CXL with the exception of the KC Index of Height Asymmetry (IHA). The biomechanical parameters turned out to show a better reliability two years or longer after CXL than in untreated cornea with the exception of integrated radius. Despite an overall high reliability of both devices, repeated CST measurements could be useful in the precise evaluation of progression using corneal biomechanics in untreated KC.

ABSTRACT BODY:

Purpose: In patients with geographic atrophy, subretinal photovoltaic implants with 100µm pixels provided prosthetic acuity of 1.1-1.3 pixels (20/460 – 20/560). Rats with implants of 75 and 55µm pixels also demonstrated grating acuity matching the pixel pitch. However, stimulation threshold increases for smaller pixels in the current design and exceeds the charge injection limit with pixels below 40µm. To decrease the stimulation threshold and decouple it from the pixel width, we added honeycomb-shaped vertical walls surrounding each pixel. This approach relies on migration of the retinal cells into the honeycomb wells. Here, we investigate the structural integration of the inner retinal cells with the wells and its effect on retinal stimulation.

Methods: To evaluate the effect of honeycombs on retinal stimulation, 25µm tall walls were polymerized on flat photovoltaic arrays with 40µm and 20µm pixels. Visually evoked potentials (VEP) were recorded weekly for 9 weeks after implantation of the arrays beneath the degenerate rat retina. Retinal anatomy was examined by confocal imaging of immunolabelled whole mounts.

Results: With both, flat and honeycomb implants, VEP amplitude decreased after the day of implantation and then gradually increased back to the original level during 6-9 weeks post-op. However, stimulation thresholds with honeycombs and flat implants of both pixel sizes remained the same: $0.057 \pm 0.029 \text{ mW/mm}^2$. Majority of cells populating the wells were cone and rod bipolar cells, and much fewer horizontal cells. The macro- and micro-glial response to the honeycomb implants were comparable to that with flat implants and to the degenerate retina controls. The deep capillary plexus (DCP) and amacrine cells, as well as the inner plexiform layer remained entirely above the honeycomb walls.

Conclusions: Retinal migration into the honeycombs does not negatively affect its electrical excitability. Lack of cell death indicates that DCP above the wells provides oxygenation and nutrients to cells within the wells. Comparable glial response to flat implants suggests that migration and separation of the retinal cells by the walls does not cause additional stress. The 25µm deep wells accept majority of the INL, while leaving the tertiary neurons, such as amacrine and ganglion cells, outside. This is important for selective stimulation of the secondary neurons and preservation of the inner retinal signal processing in prosthetic vision.

ABSTRACT BODY:

Purpose: Electric scooters (e-scooters) and hoverboards are novel personal motorized vehicles. Herein, we comparatively evaluated eye and orbit injuries in non-electric, e-scooter, and hoverboard riders in the United States between 2014-2019.

Methods: We queried the National Electronic Injury Surveillance System (NEISS) for head and neck injuries by body part codes related to non-powered scooters and powered scooters/hoverboards from 2014-2019. We used NEISS complex sampling design to obtain US population projections of injuries and hospital admissions. We queried keywords in case narratives to capture eye and orbit injuries and analyze trends in location, type, and mechanism of ophthalmologic injuries.

Results: A total of 92368 (95% CI, 65633-119107) and 22217 (95% CI, 9761-34673) non-powered and e-scooter injuries occurred. Since its introduction in 2015, 19227 (95% CI, 11308-27148) hoverboard injuries occurred. In contrast to a 24% ($p=0.002$) decrease in non-powered scooters injuries from 2014 to 2019, e-scooter injuries increased 586% ($p=0.01$) and hoverboard injuries increased 866% ($p<0.001$). Increased hospital admissions were associated with non-powered scooters (55.88%, $p=0.03$) and e-scooters (1093%, $p=0.47$). Among all age groups, young adults (18-34) were most injured accounting for 43% of e-scooter injuries in 2019, while specifically experiencing a 5980% ($p=0.002$) uptick in e-scooter injuries. Urban e-scooter cases increased by 830%. (Figure 1)

Descriptive narratives noted eye injuries in 242 unweighted NEISS cases, yet only 30 cases were documented under body part code 77: eyeball. Eye injuries increased 96.9% during the study period ($p=0.23$). The most common ophthalmologic injuries reported included eyebrow (40.9%) and eyelid (11.3%) lacerations, periorbital contusions (18.7%), orbit fractures (6.6%), and corneal abrasions (5.1%). E-scooter riders sustained 5 times more orbit fractures compared to no-powered scooter riders. Ejection and riding while intoxicated increased over the study period as mechanisms of injury with e-scooters (Figure 2).

Conclusions: From 2014-2019, there were significant increases in both head and neck injury cases and hospital admissions related to e-scooters. Eye injuries similarly increased but were under-reported by body part code compared to the injury narratives.

SUBMITTER (NAME ONLY): Mia Sheindlin

TITLE: Color Contrast Threshold Testing- Novel Method to Evaluate Acquired Color Vision Deficits in Patients with Macular Edema

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.G. Sheindlin, J. Sheindlin, M. Harooni, N. Ragusa, The Bronx Eye Center, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Mia Sheindlin: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Sheindlin: Commercial Relationship: Code N (No Commercial Relationship) | Mark Harooni: Commercial Relationship: Code N (No Commercial Relationship) | Nikola Ragusa: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Color contrast threshold testing is not typically explored in the clinical setting to test for worsening visual health. We developed a novel approach to test color contrast threshold testing to evaluate subtle color vision deficits. This feasibility study utilized a retrospective chart review from a clinical retina practice where color contrast threshold testing results from patients with and without macular edema were compared.

Methods: Color contrast threshold testing was performed on all patients. Patients with Snellen visual acuity less than 20/70 were excluded. Patients with retinal vascular disease were divided into two cohorts: patients with macular edema and without macular edema. Macular edema was based on clinical findings including cystic changes on OCT testing and clinical evaluation which was documented on patients' charts from that visit. In this study, macular edema was either from diabetic retinopathy, central retinal vein occlusion, or branch retinal vein occlusion. Additional data collection included age, gender, lens status, OCT central macular thickness (Heidelberg Spectralis), and results were compared to age matched controls. T-tests with bonferroni corrections were used to test for significance in quantitative variables.

Results: 108 eyes from 54 patients were identified and included in this study. 3 eyes from 2 patients were excluded for not meeting visual acuity requirements, and 20 eyes from 10 patients were excluded for having incomplete data sets. Across all colors, average color vision threshold values were significantly greater in patients with macular edema as compared to patients without (1420.60 vs. 669.05) (52.90%). Green showed the highest difference (202 vs. 92) (80.77%), while red showed the least difference (360 vs. 197) (45.28%).

Conclusions: This study showed the feasibility of our diagnostic tool to evaluate worsening acuity in patients with relatively healthy vision measurements and coexisting macular edema. Our examination detected worsening color vision, while Snellen visual acuity and OCT thickness measurements remained relatively equal between the two cohorts. Further work is required to define the application of this new technology across various ophthalmic conditions.

TITLE: ONSET-2 Phase 3 Study of OC-01 Nasal Spray for the Treatment of Dry Eye Disease

SESSION TITLE: Dry eye clinical treatments

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Raizman, New England Eye Center, Boston, Massachusetts, UNITED STATES|J.

Nau, A. Gibson, P. Shah, Oyster Point Pharma, Inc., Princeton, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Raizman: Commercial Relationship(s);Oyster Point:Code C (Consultant) | Jeffrey Nau: Commercial Relationship(s);Oyster Point Pharma:Code E (Employment) | Andrea Gibson: Commercial Relationship(s);Oyster Point Pharma:Code E (Employment) | Puja Shah: Commercial Relationship(s);Oyster Point Pharma:Code E (Employment)

ABSTRACT BODY:

Purpose: Tear film instability leads to symptoms of ocular discomfort and signs of decreased tear production. OC-01 (varenicline), a novel compound delivered via nasal spray, is a nicotinic acetylcholine receptor agonist that activates the trigeminal parasympathetic pathway to stimulate the lacrimal functional unit to reestablish the natural tear film. This Phase 3 study (ONSET-2) evaluated the efficacy and safety of OC-01 in treating the signs and symptoms of dry eye disease (DED).

Methods: The study randomized 758 subjects at a 1:1:1 ratio to receive 0.6 mg/mL OC-01 nasal spray (N=260), 1.2 mg/mL OC-01 nasal spray (N=246), or placebo (vehicle) nasal spray (N=252) twice daily for 28 days. Outcome measures included anesthetized Schirmer's Test Score (STS) and Eye Dryness Score (EDS, 0-100 scale) at Day 28.

Results: Subjects treated with OC-01 nasal spray showed statistically significant improvement compared with placebo as indicated by a gain in STS of ≥ 10 mm from baseline by Day 28. The percentage of eyes showing improvement in the 0.6 mg/mL, 1.2 mg/mL, and placebo groups were: 47.3% ($p < 0.0001$ compared to placebo), 49.2% ($p < 0.0001$) and 27.8%, respectively. Mean change in STS was 11.3 mm ($p < 0.0001$), 11.5 mm ($p < 0.0001$), and 6.3 mm, respectively (Fig.1). A robust and (nominally) significant reduction in EDS from baseline was demonstrated with 0.6 mg/mL and 1.2 mg/mL compared to placebo at Week 2 of -16.5 mm ($p < 0.05$), -17.9 mm ($p = 0.0078$) and -12.7 mm; and at Week 4 of -19.8 mm ($p < 0.05$), -22.2 mm ($p = 0.0014$), and -15.4 mm, respectively (Fig.2). The improvement in EDS at Day 28 was evident, regardless of baseline EDS categorization, indicating that OC-01 would benefit a broad population of DED patients. The most common adverse event in the 0.6 mg/mL and 1.2 mg/mL groups was sneezing (95.0% and 96.7%, respectively).

Conclusions: Compared to placebo, OC-01 nasal spray demonstrated improvement in both signs and symptoms of DED by Day 28 despite baseline EDS and has an excellent safety and tolerability profile under conditions of the study.

ABSTRACT BODY:

Purpose: The management of rhegmatogenous retinal detachment (RRD) involves the use of intraocular tamponades. The most common types of vitreous substitutes include intraocular gas and silicone oil (SO). Retinal displacement, also described as a low integrity retinal attachment (LIRA), is a common complication that occurs after RRD repair, particularly following pars plana vitrectomy (PPV). Here, we developed a theoretical computer model to investigate the physical factors that contribute to retinal displacement.

Methods: We developed a computer simulation model on MATLAB to calculate the contact angle and pressure between the endotamponade and the retina using interfacial tension and the densities of gas, SO, and the vitreous. A second simulation was used to determine the dynamics of fluid motion in the subretinal space and to calculate any deformations of the retina.

Results: We demonstrated that the larger the volume of a gas tamponade, the greater the contact pressure on the retina over a greater area of contact. A gas tamponade that filled 93% of the ocular cavity, as in PPV, exerted a pressure that was four times higher than a tamponade that filled 14% of the ocular cavity, as in pneumatic retinopathy. Moreover, for the same fill ratio, gas had a larger contact angle and contact pressure than SO. At 93% fill, gas exerted a contact pressure of 1.5 mmHg on the retina at a contact angle of 125° , while SO exerted 0.024 mmHg at a contact angle of 100° .

Furthermore, endotamponades stretch the retina by displacing subretinal fluid to non-contact areas, causing retinal displacement. A gas tamponade that filled 14% of the ocular cavity stretched the retina an order of magnitude lower than one that filled 93%, suggesting a greater risk of retinal displacement in PPV. In addition, at the same fill volume, a SO tamponade stretched the retina significantly less than a gas tamponade, indicating that a SO tamponade may confer less risk of retinal displacement.

Conclusions: Our findings suggest that endotamponades stretched the retina by displacing the remaining subretinal fluid after RRD repair. This retinal stretch may be an important mechanism underlying retinal displacement. The degree of gas filling and the type of endotamponade may be modulated to reduce the risk of retinal displacement.

ABSTRACT BODY:

Purpose: Endothelial cell (EC) loss is the most frequent cause of corneal transplant failure, thus making endothelial preservation critical for good surgical outcomes. Current corneal storage vials (VC) differ greatly from how the cornea exists naturally, where ECs are isolated and physically separated from the epithelium. Our group developed a novel dual-chamber corneal storage vial (DCV) comprised of two compartments that become isolated by the corneal graft and prevent epithelial and endothelial interaction. We hypothesize that the DCV will improve EC viability and better preserve corneal structure during cold storage.

Methods: Donor human cornea pairs (N=9) were recovered by the Florida Lions Eye Bank, with one cornea from each pair stored in the VC and the other in the DCV. All cornea pairs were preserved in Optisol-GS media and stored at 2–8°C for 2 weeks. Corneal thickness and EC density were evaluated at days 1, 7, and 14. Osmolarity was measured in preservation media after 2 weeks. Lactate dehydrogenase and annexin V levels were measured in the media and corneal tissue respectively, to assess for cytotoxicity and apoptosis.

Results: Preliminary results revealed increased corneal thickness in grafts stored in the VC compared to the DCV at days 1, 7, and 14 ($p=0.036$, $p=0.077$, and $p=0.19$, respectively). Osmolarity was significantly increased in both the epithelial ($p=0.0015$) and endothelial ($p=0.0035$) compartments of the DCV compared to the VC, suggesting that smaller volumes in DCV compartments may lead to hyperosmolar conditions that preserve corneal stromal hydration. There was no significant difference in EC density between vials. Despite a small sample size, cytotoxicity was lower in the DCV endothelial media than the VC media in 6 of 8 samples ($p=0.16$), and annexin V concentrations were lower in the DCV endothelium than the VC endothelium in 5 of 6 samples ($p=0.10$).

Conclusions: Use of the DCV decreases corneal swelling, increases osmolarity, and potentially reduces endothelial apoptosis during corneal cold storage by physically separating the corneal epithelium and endothelium. The DCV has the potential to transform the way corneal grafts are preserved and will provide scientists with a platform to develop customized preservation solutions.

TITLE: Systemic Disease Associations with Angioid Streaks using a U.S. National Healthcare Database

SESSION TITLE: AMD and Retinal Disease Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Li, J.B. Nadelmann, B. McGeehan, B.L. VanderBeek, Ophthalmology, Scheie Eye Institute, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yafeng Li: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Nadelmann: Commercial Relationship: Code N (No Commercial Relationship) | Brendan McGeehan: Commercial Relationship: Code N (No Commercial Relationship) | Brian VanderBeek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the systemic associations of angioid streaks (AS) using a large U.S. healthcare database.

Methods: This is a retrospective cross-sectional study of all patients diagnosed with AS, identified by ICD9 and ICD10 coding, in a large, national U.S. insurer from 2000 - 2019. All patients were 18 years or older and had at least one active year of enrollment within the plan. Any patient with a diagnosis of choroidal rupture or pathologic myopia were excluded. The literature was reviewed for all published associations with AS, as well as those in the standard mnemonic for AS (PEPSI). The rates of each disease state in those with AS were then calculated.

Results: After applying exclusion criteria, 2,072 patients were eligible for the study. The mean and standard deviation of age for this group is 63.4 (18.5) years, respectively, with 817 (39.4%) males and 1,255 (60.6%) females. The number of patients and rates of association between AS and the well characterized conditions of the PEPSI mnemonic are as follows: Pseudoxanthoma elasticum (PXE) - 258 patients (12.5%), Ehlers-Danlos syndrome - 21 patients (1.0%), Paget's disease - 7 patients (0.3%), hemoglobinopathies (i.e. sickle cell disease) - 33 patients (1.6%), and idiopathic, the largest group -1,756 patients (84.7%). To enumerate the less commonly described but previously reported diseases associated with AS, 514 patients (24.8%) were diagnosed with diabetes, 319 patients (15.4%) familial adenomatous polyposis, 222 patients (10.7%) had lead poisoning, 524 (25.3%) had senile elastosis, and 697 (33.6%) had non-exudative AMD.

Conclusions: AS, pathologically characterized as breaks in Bruch's membrane, has a known significant association with PXE. Concurrently, the association of AS with other less reported diseases lends support to a new mnemonic and new mechanistic understanding of AS formation.

ABSTRACT BODY:

Purpose: The national underutilization of eyecare services warrants study of the correlation between geographic market saturation and realized access

Methods: Observational cohort study using datasets from Centers for Medicare & Medicaid Services, U.S. Census Bureau, U.S. Department of Agriculture, and Housing and Urban Development, to calculate county- and state-level ophthalmologic service usage, market saturation, and demographic characteristics. Negative binomial regression models were used to evaluate the association between results and demographic or population-specific variables.

Results: Ophthalmologic service usage ranged from 58.200% to 15.170%, while saturation ranged from 21763.00 to 91.40 FFS beneficiaries per registered ophthalmologist. Usage was statistically significantly associated with several demographic characteristics in each geography: lower proportion of African American ($b = -0.091$, 95% CI: $(-0.159, -0.022)$, $p = 0.009$), Hispanic ($b = -0.226$, 95% CI: $(-0.318, -0.133)$, $p < .001$), and other race beneficiaries ($b = -0.408$, 95% CI: $(-0.520, -0.294)$, $p < .001$), relative to the proportion of white beneficiaries; a higher proportion of female ($b = 2.709$, 95% CI: $(2.347, 3.072)$), $p < .001$ relative to male; a higher proportion of adults having completed an associate degree or some college ($b = 0.255$, 95% CI: $(0.098, 0.412)$), $p = 0.001$, or holding a bachelor's degree or higher ($b = 0.405$, 95% CI: $(0.301, 0.508)$), $p < .001$, relative to the proportion of adults with only a highschool diploma; a lower proportion of adults in each geography experiencing poverty ($b = -0.236$, 95% CI: $(-0.413, -0.060)$, $p = .009$), geographies with lower Multidimensional Deprivation Index ($b = -0.234$, 95% CI: $(-0.358, -0.109)$, $p < .001$); a higher urban-influence code ($b = 0.008$, 95% CI: $(0.006, 0.010)$, $p < .001$).

There was no significant correlation between the usage of ophthalmologic services and the geographic market saturation of ophthalmologists (Spearman's $\rho = -0.030$, $p = 0.227$).

Conclusions: Ophthalmologic service usage is significantly influenced by population demographics and contextual factors. The presence of more ophthalmologists may benefit local population health; however, increased provider density alone appears insufficient to promote the usage of eye care services. As ophthalmologists try to meet the needs of their local population, focus on individual and contextual barriers may help increase realized access and improve population health.

TITLE: Highly-enriched retinal pigment epithelium and photoreceptor genes without circadian variability

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Milićević, S. Nymark, Faculty of Medicine and Health Technology, Tampere University, Tampere, Pirkanmaa, FINLAND|C. Sandu, M. Felder-Schmittbuhl, Institut des neurosciences cellulaires et integratives, Strasbourg, Alsace, FRANCE|J.B. ten Brink, A. Jongejan, P. Moerland, A.A. Bergen, Amsterdam UMC Locatie AMC, Amsterdam, North Holland, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Nemanja Milićević: Commercial Relationship: Code N (No Commercial Relationship) | Cristina Sandu: Commercial Relationship: Code N (No Commercial Relationship) | Jacoline ten Brink: Commercial Relationship: Code N (No Commercial Relationship) | Aldo Jongejan: Commercial Relationship: Code N (No Commercial Relationship) | Perry Moerland: Commercial Relationship: Code N (No Commercial Relationship) | Soile Nymark: Commercial Relationship: Code N (No Commercial Relationship) | Marie-Paule Felder-Schmittbuhl: Commercial Relationship: Code N (No Commercial Relationship) | Arthur Bergen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A number of physiological processes in retinal pigment epithelium (RPE) and photoreceptors (PR) are regulated by the circadian clock. In this study, we tested the hypothesis that circadian clock-regulated genes in RPE and PR overlap with the current lists of known “signature” RPE and PR genes. We defined new lists of highly-enriched RPE and PR genes by using arrhythmic clock gene mutant $Per1^{-/-} Per2^{Brdm1}$ mice.

Methods: We performed RNA-sequencing on laser-capture microdissected (LCM) RPE and PR from WT and $Per1^{-/-} Per2^{Brdm1}$ mouse eyes obtained under constant darkness at 4 time-points over 24h. We compared time-affected genes from WT RPE and PR with current “signature” RPE and PR gene lists. To define the new list of non-rhythmic highly-enriched RPE and PR genes, we first averaged gene expression levels obtained at all time points from RPE and PR genes obtained from $Per1^{-/-} Per2^{Brdm1}$ mice. We ranked the top 10% genes based on expression levels, subtracted overlapping and time-affected genes. Functional annotation was performed using g:Profiler.

Results: RNA sequencing of LCM samples revealed that 594 genes (~3% total) in the RPE and 2,372 genes (~10% total) in PR showed temporal variations in WT mice. In contrast, only 2 genes were time-affected in $Per1^{-/-} Per2^{Brdm1}$ PR and none in RPE. We found that 2 (out of 64) RPE and 12 (out of 65) PR “signature” genes were time-affected. Unexpectedly, we found overlap between “signature” genes of PR and time-affected RPE genes (and vice versa) suggesting that sampling time affected the compiling of current “signature” genes. By using transcriptomes obtained from $Per1^{-/-} Per2^{Brdm1}$ mice, we defined 828 non-rhythmic highly-enriched RPE and 641 PR genes. We found that highly-enriched RPE genes are enriched in MAPK signaling, focal adhesion and oxidative phosphorylation, whereas PR genes are enriched in mTOR signaling and GTPase activity, among others. Finally, we found that 37 RPE and 9 PR genes overlap between “signature” and our new highly-enriched gene lists.

Conclusions: Our findings indicate that sampling time substantially affected the compiling of “signature” RPE and PR genes. Our new lists will be useful in a number of applications such as extrapolating RPE and PR data from whole eye transcriptomics and for assessing the molecular characteristics of stem-cell derived RPE and PR.

TITLE: Comparison of various statistical methods for calculating laser flare photometry values in patients with uveitis

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.L. Chen, G.N. Holland, E. Tsui, Ophthalmology, UCLA Stein Eye Institute, Los Angeles, California, UNITED STATES|C. Vatanatham, G.N. Holland, E. Tsui, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|N.J. Jackson, Division of General Internal Medicine and Health Services Research, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chaipayorn Vatanatham: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Jackson: Commercial Relationship: Code N (No Commercial Relationship) | Judy Chen: Commercial Relationship: Code N (No Commercial Relationship) | Gary Holland: Commercial Relationship: Code N (No Commercial Relationship) | Edmund Tsui: Commercial Relationship(s);Kowa:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To evaluate various statistical methods of calculating laser flare photometry (LFP) values in patients with uveitis. The currently accepted approach to calculating LFP values is to obtain 7 measurements, delete the highest and lowest values, and use the mean of the 5 remaining values to reflect the level of anterior chamber (AC) flare.

Methods: Patients with a history of uveitis were prospectively enrolled and underwent comprehensive eye examinations and grading of AC flare with a modified Standardization of Uveitis Nomenclature (SUN) grading system, which included Grade 0.5+. Seven repeat LFP measurements were obtained on both the Kowa FM-500 (used originally to establish the current approach) and FM-700 laser flare meters during a single visit. Eight statistical methods were utilized to compare LFP measurements, including: 1) comparison of raw data; 2) mean of raw data; 3) mean after removal of highest and lowest values; 4) median of raw data; 5) Median Absolute Deviation (MAD) outlier detection with mean (high threshold of 2.24); 6) MAD outlier detection with mean (low threshold of 1.28); 7) boxplot outlier detection (Carling method) with mean; and 8) boxplot outlier detection (Tukey method) with mean. LFP values were also compared with the SUN grading system. Agreement between the FM-500 and FM-700 was characterized using intraclass correlation coefficients (ICC).

Results: LFP was performed on 126 eyes (64 patients, mean age 42.3±22.7 years, 45/64 [70.3%] female). Distribution of AC flare SUN grades were Grade 0 (n=48 eyes), 0.5+ (6), 1+ (28), 2+ (16), 3+ (6), 4+ (2). Mean LFP values for each grade were: Grade 0 (mean=10.2, range [0, 98]), 0.5+ (19.5, [0, 41.9]), 1+ (16.4, [1.8, 359]), 2+ (24.6, [0, 100.9]), 3+ (135.0, [5.7, 325.5]), 4+ (166.4, [69.3, 377.5]). Mean LFP values (photon units/msec) on the FM-700 across the 8 methods were 23.33, 23.71, 21.08, 22.88, 22.90, 22.81, 22.83, 22.92, respectively. Across all 8 methods, the ICC for LFP values between the two flare meters did not vary substantially, with a range of ICC from 0.81 to 0.84. LFP values correlated with SUN grades (correlation coefficients 0.68-0.72 across all 8 methods, all p<0.001).

Conclusions: All eight statistical methods for calculating LFP values resulted in similar flare values compared to the current standard, suggesting that alternative, simpler methods of calculating LFP values may be suitable.

ABSTRACT BODY:

Purpose: The anti-inflammatory efficacy of corticosteroids in ocular inflammatory conditions is well-established. However, risks of long-term steroid use include steroid-induced ocular glaucoma, which is thought to develop as extracellular matrix proteins accumulate and impair proper function of the trabecular meshwork (TM). Rho kinase inhibition (ROCKi) has been shown to attenuate steroid-induced collagen and fibronectin deposition in cultured TM cells. Furthermore, ROCKi has been shown to lower IOP by increasing aqueous outflow through the TM. Inhibition of ROCK during steroid use for ocular inflammatory conditions may provide a strategy to decrease the risk for steroid-induced glaucoma. Here we demonstrate the in-vitro stability and corneal metabolism of a new class of corticosteroids with ROCKi activity. We also show the ocular tissue distribution of lead candidates, and their metabolites, following topical instillation.

Methods: Multiple compounds were synthesized to contain a steroid covalently linked to the active metabolite of netarsudil, AR-13503. The in vitro stability and ex vivo corneal metabolism of the compounds were determined. Ocular tissue distribution in mice was measured post-tissue harvest by HPLC-mass spectrometry following topical administration of these compounds.

Results: Lead compounds demonstrated good stability profiles in vitro. The corticosteroid and ROCKi metabolites were detected in corneal explants. Following topical dosing with the ROCK-steroids, physiologically relevant levels of both corticosteroid and the ROCKi were found in the cornea, conjunctiva, and meibomian glands of mice.

Conclusions: We have developed a novel corticosteroid with inhibitory activity against ROCK and, thus, strong potential to reduce risks associated with conventional corticosteroids. Our data demonstrate the favorable pharmacokinetic profile of ROCK-steroid compounds for topical anti-inflammatory applications.

ABSTRACT BODY:

Purpose: To investigate home visual field monitoring with the Toronto Portable Perimeter (TPP) by glaucoma patients in a prospective cohort study.

Methods: Patients with reliable visual fields on the Humphrey Field Analyzer (HFA) were recruited from the Glaucoma Clinic at Toronto Western Hospital. Each participant was instructed in a 20-min session on using the TPP and performed a bilateral TPP-Standard 24-2 protocol. Then, participants were instructed to perform bilateral tests at least twice monthly at home with a personal TPP. Mean deviation (MD), pattern standard deviation (PSD) and test duration of reliable visual fields on the TPP were compared with the most recent reliable HFA SITA-Standard results. A reliable test was defined as: false positive < 20%, false negative < 20%, fixation loss < 33%. Inter-test variability was measured by calculating the root mean squared error (RMSE) of MDs and PSDs in consecutive visual field tests of the same eye.

Results: To date 148 reliable home TPP visual field tests were performed by 8 patients (mean age: 70 years; range: 53 to 81) on 16 eyes (mean HFA MD: -6.05 dB; -13.19 to +0.54). Patients completed home TPP visual field tests at an average rate of 2.8 tests per 30 days (0.9 to 4.3). Compared to HFA there were no significant differences in MD (mean±std: +0.61±1.74 dB, p=0.18); PSD (-0.79±1.43 dB, p=0.04) were significantly lower and test durations (-30.11±46.11 seconds, p=0.02) shorter with TPP. Inter-test variability of MD was similar between the TPP and HFA (1.23 vs. 1.47 dB, p=0.50) while inter-test variability of PSD (0.59 vs. 1.64 dB, p<0.01) was better (lower RMSE) with TPP. In 14 eyes with 5 reliable home tests, the standard error of the mean estimates of MD and PSD in each eye was reduced to 0.32 dB and 0.22 dB, respectively.

Conclusions: Our preliminary results showed that glaucoma patients can perform TPP visual fields reliably at home. Results from the TPP were similar to the HFA. Consecutive tests at home exhibited less variability than consecutive tests on the HFA. Testing on the TPP took less time than HFA (on average 5.6 min on the TPP vs. 6.0 min on the HFA, and no requirement to visit a testing center). Patients also found home tests to be more convenient and relaxing. Frequent testing over short periods of time appears to improve MD and PSD precision and thus may potentially enable earlier detection of change.

TITLE: Keratoconus: Trends in Management and Adherence to Preferred Treatment Patterns

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Mgboji, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|V. Varadaraj, U. Soiberman, D. Srikumaran, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Glory Mgboji: Commercial Relationship: Code N (No Commercial Relationship) | Varshini Varadaraj: Commercial Relationship: Code N (No Commercial Relationship) | Uri Soiberman: Commercial Relationship: Code N (No Commercial Relationship) | Divya Srikumaran: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The treatment of keratoconus has evolved over the past decades to include advanced contact lenses, intrastromal implants, and corneal crosslinking in addition to keratoplasty— all of which are most appropriate at different stages of disease. We performed a retrospective review to elucidate current trends and identify potential disparities in keratoconus treatment.

Methods: We extracted data from electronic medical records of 1,135 patients with keratoconus seen at the Wilmer Eye Institute from January 2017 to September 2020. We used t-tests and chi square tests to detect associations between patient characteristics and various treatment modalities, including corneal crosslinking and keratoplasty. Logistic regression models adjusted for age, sex, race, insurance, and family history of allergies were constructed to calculate odds ratios (OR) describing these associations.

Results: A total of 1,135 patients with a mean age of 40.5 (SD 16.5), were included, about half of whom were white (51.5%). In unadjusted analysis, patients who were younger (25.0 vs. 42.3 years), male (73.9% vs. 26.1% for females), white (52.3% vs. 25.2% for black patients) and who had private insurance (94.6% vs. 5.4% for government insurance) were significantly ($p < 0.05$ for all) more likely to have had corneal crosslinking. No factor was associated with keratoplasty during this period. In a multivariable logistic regression model, black patients had lower odds of receiving corneal crosslinking compared to white patients (OR 0.58 95% CI 0.34-0.98). Increasing age was also associated with lower odds of corneal crosslinking (OR 0.91 95% CI 0.89-0.93).

Conclusions: This study identifies racial disparities in keratoconus management with corneal crosslinking. These results are of interest as most health care payors have only recently started to endorse CXL as a covered benefit. Further analyses are needed to determine whether these disparities are related to socioeconomic barriers, disease severity, insurance coverage or other factors.

ABSTRACT BODY:

Purpose: The US 21st Century Cures Act promoted Healthcare Level Seven's (HL7's) FHIR API utilization to facilitate real-time health data interoperability. FHIR standards have the potential to mobilize siloed digital clinical data to improve healthcare quality, outcomes and value. Although many FHIR resources have been validated, their applicability to ophthalmology remains limited, presenting challenges to practical specialty adoption and clinical utility.

Methods: To counter this problem, a multidisciplinary collaboration of ophthalmologists, technologists, HL7 representatives, and industry stakeholders compiled an implementation guide (IG) driven by a series of real-world interoperability ophthalmic 'use cases.' FHIR IG development is a semi-structured process defining the technical artifacts and contextual content required to solve such problems.

Manual assembly of FHIR base resources referencing existing terminologies (e.g. SNOMED-CT, LOINC, ICD) has aided the foundational codification of clinical, administrative, and workflow elements. Where resource limitations deemed essential to meet use-case defined requirements were identified, FHIR's flexibility enabled the creation of appropriate extensions, constraints and new value sets. This IG will undergo testing at FHIR connectathons prior to formal submission for H7 international balloting.

Results: We developed 15 use cases to inform IG compilation and published a live, web-accessible IG (based on FHIR v4.0.1), enabling collaborative refinement of FHIR profiles and accompanying content. This provides clinical and implementation guidance, incorporating numerous ophthalmology-specific modifications, such as a uniquely structured laterality definition and novel representations of diagnostic device derivations.

This project has obtained unanimous project support from required HL7 voting procedures, gained formal sponsorship from HL7's Patient Care and EHR Working Groups and approval from the FHIR Management Group, and Clinical Steering Division approval.

Conclusions: Mapping ophthalmology's entire clinical lexicon into FHIR format enables unprecedented healthcare data exchange possibilities. Our framework facilitates iterative IG expansion and validation for clinical accuracy and technical functionality. Drawing broad specialty stakeholder engagement to advance adoption, this serves to improve clinical care quality and patient outcomes.

ABSTRACT BODY:

Purpose: To contribute the largest retrospective study to date on the efficacy of PTK as a treatment for RCES in patients with symptoms refractory to conventional treatments

Methods: A retrospective chart review and telephone survey were conducted in Vancouver, Canada at the Pacific Laser Eye Centre. Inclusion criteria were patients who received PTK for RCES between 2010 and 2020. Exclusion criteria were patients with comorbidities potentially affecting treatment efficacy including band keratopathy, secondary scarring of the cornea from previous ulceration, Salzmann's nodular dystrophy, granular dystrophy, and Reis-Bückler's corneal dystrophy.

555 patients' sex, age, past ocular history, etiology of RCES, symptoms, visual acuity, interventions trialled prior to PTK, need for retreatment, and time to retreatment were collected in a chart review. 112 patients answered the following in a 10-minute telephone survey: symptoms that led them to seek treatment, the presumed cause of their RCES, efficacy of PTK, therapies trialled prior to and following PTK, and overall satisfaction level.

Results: This study included 593 eyes of 555 patients (46.2% male; 50.9 ± 14.2 years old) who underwent PTK for RCES. The leading identified causes of RCES were trauma (45.7%) and anterior basement membrane dystrophy (44.2%). The most common pre-PTK interventions were ocular lubricants (90.9%), hypertonic solutions (77.9%), and bandage contact lenses (50.9%). 36 eyes had undergone surgical interventions such as stromal puncture, epithelial debridement, or diamond burr polishing.

Post-PTK, 78% of patients did not require any subsequent therapies, 20% required ongoing drops and 6 patients (1.1%) reported no symptom improvement. All 6 eyes were successfully retreated with PTK between 11.3 ± 14.9 months from initial PTK. All study patients showed no significant differences in best corrected visual acuity pre- vs. post-operatively.

Conclusions: When compared to other surgical options, PTK is costly but frequently more effective. Most surgical alternatives present cheaper options than PTK for the management of refractive-neutral RCES. Nonetheless, the third-party public health vetted nature of this study, the high patient satisfaction, and the low recurrence rate of RCES suggest that a re-evaluation of the role of PTK as an earlier part of standard management of RCES should be conducted.

ABSTRACT BODY:

Purpose: Current treatments for neovascular eye diseases based on anti-vascular endothelial growth factor therapy are ineffective in a significant fraction of patients. In seeking alternative therapeutic targets, ferrochelatase (FECH) has been identified as a promising protein. We set out to develop an injectable, long-acting microparticle (MP) formulation for sustained delivery of griseofulvin (GRF), which is metabolized into a FECH inhibitor.

Methods: GRF was loaded in poly(lactic-co-glycolic acid) (PLGA) MPs by the double emulsion (W1/O/W2) method. GRF and PLGA were added to the organic (O) phase, and magnesium hydroxide ($\text{Mg}(\text{OH})_2$) (0-20 wt%) was added to the internal aqueous (W1) phase. The effects of $\text{Mg}(\text{OH})_2$ content on particle size (laser diffraction), morphology (scanning electron microscopy), and in vitro release were evaluated. The sustained antiproliferative effect of MPs was evaluated on human retinal endothelial cells (HRECs) using an AlamarBlue assay.

Results: The mean particle size (D50) of MPs was measured to be in the range of 15-22 μm (Figure 1a). MPs were spherical with sizes consistent with the laser diffraction measurement. MPs prepared without $\text{Mg}(\text{OH})_2$ had a solid surface, whereas those with $\text{Mg}(\text{OH})_2$ showed porous surfaces. The porosity increased with the amount of $\text{Mg}(\text{OH})_2$ added to the MPs (Figure 1b). MPs without $\text{Mg}(\text{OH})_2$ released ~15% of loaded drug in phosphate-buffered saline (pH 7.4) with 0.2% Tween 80 at 37 °C in 1 day and slowly released the remainder (up to ~80%) in 60 days (Figure 2a). The inclusion of $\text{Mg}(\text{OH})_2$ dramatically changed the GRF release profile. MPs with 20% $\text{Mg}(\text{OH})_2$ showed a high burst release of GRF (~70%), followed by a complete release in 5 days. MPs with 10% and 5% $\text{Mg}(\text{OH})_2$ showed >90% and >75% drug release in 5 days. The MPs containing 2% $\text{Mg}(\text{OH})_2$ showed a minimal burst release (~18% in 1 day) followed by continuous release (~100% in 38 days) and were considered the most suitable for 1 month GRF delivery. GRF released from the MPs throughout the release period remained active and inhibited the proliferation of HRECs (Figure 2b).

Conclusions: GRF-loaded PLGA MP were developed for long-term ocular delivery. The optimized MP formulation provided a sustained release of bioactive GRF over a month and effectively inhibited proliferation of HRECs. These results warrant further evaluation in animal models to test the feasibility of neovascular eye disease treatment.

ABSTRACT BODY:

Purpose: Vitreous hemorrhage is approximated to resolve 1% per day through the trabecular meshwork, but the factors that affect this rate remain unexplored. We performed a retrospective clinical case study to learn how lens status and other factors can affect vitreous hemorrhage (VH) resolution time in proliferative diabetic retinopathy (PDR).

Methods: This is a retrospective analysis of eyes with PDR presenting with acute VH at an academic medical center between May 1, 2015 and December 31, 2019. We gathered information on lens status (phakic and pseudophakic) and other variables including visual acuity, medications, and glaucoma. In the survival analysis, the primary outcome measure was the number of weeks from diagnosis to either 'resolution' or 'progression to surgery', whichever came first. Kaplan-Meier univariate analysis method was used to estimate resolution time, and log-rank test determined significance. Cox proportional hazard regression modeling was used to determine adjusted hazard ratios and predictor variables.

Results: Among 157 total eyes (100 phakic, 57 pseudophakic), the groups were similar in age (57 v. 64 years), visual acuity at presentation (LogMAR 1.33 v. 1.38), past history of VH (41% v. 43%), and progression to surgery (Log-rank=1.422, df=1, p=.23). The mean resolution time was 33.0±4.1 weeks (95%CI: 25.0-41.0) for pseudophakic eyes compared to 63.4±9.1 weeks (95%CI: 45.7-81.2) for phakic ones, with a significant difference in the survival of VH (Log-rank = 7.78, df=1, p=.007). Multivariate cox regression showed pseudophakic eyes were 2.4 times (95%CI: 1.3-4.6, p=.008) more likely to resolve than phakic eyes. Vision at presentation (p=0.51), blood-thinning medication (p=0.63), age (p=0.50), and glaucoma (p=0.28) were not found to be associated with resolution time.

Conclusions: VH secondary to PDR resolves at twice the rate in pseudophakic eyes compared with phakic ones. VH is removed from the eye through the trabecular meshwork, so it is possible that being pseudophakic offers an enhanced pathway around the zonules for red blood cells to travel the posterior segment to the anterior chamber. Being able to account for factors that affect VH resolution better guides patient expectations and decisions on surgery.

ABSTRACT BODY:

Purpose: Globally, the need for cost-effective delivery of corrective lenses for pediatric refractive error is great. The present study aims to assess the global incidence and financial burden of pediatric refractive error via literature review and to design glasses that provide an accessible and affordable avenue to reduce the burden of refractive errors in pediatric patients.

Methods: The present study involved an investigation into the global need for corrective lenses for astigmatism in resource-poor regions via an extensive literature review. Global prevalence data of refractive error from 1990-2016 WHO regions were extracted and reported as Estimated Pooled Prevalence (EPP). Data on the financial burden of astigmatism was investigated and reported as the United States Dollar (USD) per patient per year. Following the literature review, preliminary designs of cheap, customizable glasses were developed.

Results: In children, the EPP of myopia, hyperopia, and astigmatism was 11.7% (95% CI: 10.5–13.0), 4.6% (95% CI: 3.9–5.2), and 14.9% (95% CI: 12.7–17.1), respectively. (Hashemi 2018) The highest incidence of refractive errors occurs in Southeast Asia and the Americas. The US average financial burden of uncorrected refractive errors (amblyopia, astigmatism) is approximately \$145.92 per patient per year beginning at age 5. Studies have shown that costs tend to increase with time as the severity of the defect increases (Malvankar-Mehta 2018)

The design of the working model is easy to assemble, highly customizable, and affordable. Adjustable straps make the design-friendly to use for those with variable head circumference and anopia. Rotatable lens facilitates adjustment for varied astigmatism axis.

Conclusions: Childhood visual impairment is a global public health problem associated with significant financial strain, especially in low and middle-income countries. Its most common causes are avoidable with comprehensive vision screening and treatment of common refractive errors. The need for a financially feasible and easily accessible solution warrants further research and design of gadgets such as the Adjustable Eyeglasses.

ABSTRACT BODY:

Purpose: Possible retinal involvement by COVID-19 has been a topic of recent debate. We performed a prospective study to determine whether retinal abnormalities can be identified on OCT in convalescent fully recovered patients following COVID-19 infection.

Methods: This is a prospective, case-controlled study that recruited COVID19 patients who were admitted to the United Christian Hospital Hong Kong, China. At 2 months post-recovery, patients' visual acuity, refraction were measured. Spectral-domain OCT of the macula and retinal nerve fiber layer and enhanced depth imaging were performed. Age-matched and refraction-matched healthy individuals that were not infected with COVID-19 were enrolled as controls. Qualitative and quantitative assessment of retinal abnormalities on structural OCT and retinal and choroidal layer thickness are the main outcomes. Principal component analysis (PCA), partial least squares discriminant analysis (PLS-DA), and volcano plot were applied to data analysis.

Results: 20 subjects (40 eyes) with COVID-19 and 25 (50 eyes) age-matched asymptomatic healthy controls were enrolled. Structural OCT abnormalities could be observed in 24% of control eyes and in 25% of COVID-19 subjects. No differences were observed between the post-COVID-19 cohort and the healthy controls for any qualitative retinal abnormalities. PCA and the PLS-DA demonstrated a substantial overlap in the 95% confidence region between the two groups. Further analysis showed there are no significant differences in any quantitative feature including retinal volume, choroidal thickness, retinal layer thicknesses in various macular regions, and peripapillary nerve fiber layer thickness with the exception of the retinal outer temporal quadrant region. However, the impact this quantitative feature has on the dataset is miniscule given that its fold change impact was below 1.0.

Conclusions: Following full recovery from symptomatic COVID 19 infection no significant abnormalities were evident on structural OCT. Although long-term damage to the retina appears to be uncommon after COVID-19 infection, this study provides valuable insight into the recovery process after COVID-19 and provides potential retinal features that should be considered in the larger population to separate between these groups.

ABSTRACT BODY:

Purpose: To characterize retinal vascular density and reactivity in the human retina in the macula, temporal macula and peripapillary retina using optical coherence tomography angiography (OCTA).

Methods: OCTA 3*3mm² images were acquired from the macula (M), temporal macula (TM) and peripapillary retina (PP) in 8 healthy subjects. Images from the superficial, deep and choriocapillaris layers of the M and TM were extracted and the vessel skeleton densities (VSD) computed. In addition, the mean flow deficit sizes (MFDS) of the choriocapillaris and mean PP VSD was calculated. Choriocapillaris reactivity (CR) and retinal vascular reactivity (RVR) in each region and layer were assessed under three gas non-rebreathing conditions – room air (RA), 5%CO₂ and 100%O₂. RVR is the percent change in VSD between RA-CO₂ and RA-O₂. CR is computed in a similar manner with MFDS. ANOVA was used to compare the VSD measurements with significance at p=0.05.

Results: Under RA conditions, the mean VSD of the superficial layer was significantly different across regions [M=0.16, TM=0.13, RPV=0.15; F(1,7)=15.6, p=0.006] and a similar trend occurred in the deep layer [M=0.14, TM=0.12; F(1,7)=5.0, p=0.06, Fig 1A]. RVR differed among regions of the superficial layer [M=8%, TM=15%, and PP=7%; F(2,7)=28.22, p<0.001, Fig 1B] and the deep layer [M=19%, TM=37%; F(1,7)=8.7, p=0.02, Fig 1B]. There was a significant heterogeneity in the layer specific vascular reactivities [superficial =12.8%, deep =28.2% and CR =2.8%; F(2,7)=58.03, p<0.001]. However, CR and MFDS did not differ between regions.

Conclusions: There are significant differences in the regional retinal capillary density and vascular reactivity in the macula, temporal macula and peripapillary retina. These regional differences may help explain the spatial distribution of pathology in retinal vascular diseases. Similar regional difference are not present in the choriocapillaris.

ABSTRACT BODY:

Purpose: Protein aggregation has been one of the leading triggers of various disease conditions, such as Alzheimer's, Parkinson's and other amyloidosis. TGFB1-associated corneal dystrophies are protein aggregation disorders in which the mutant TGFB1p aggregates and accumulates in the cornea, leading to a reduction in visual acuity and blindness in severe cases. Currently, the only therapy available is invasive and there is a known recurrence after surgery. In this study, we tested the inhibitory and amyloid dissociation properties of four osmolytes in an in-vitro TGFB1p peptide aggregation model. We also tested the toxicity of the disaggregated fibrils on human corneal fibroblasts.

Methods: The 23-amino acid long peptide (TGFB1p 611-633 with the mutation c.623 G>R) from the 4th FAS-1 domain of TGFB1p that rapidly forms amyloid fibrils was used in the study. Several biophysical methods like Thioflavin T (ThT) fluorescence, Circular Dichroism (CD), fluorescence microscopy, and Transmission electron microscopy (TEM) were used to study the inhibitory and amyloid disaggregation properties of four osmolytes (Betaine, Raffinose, Sarcosine, and Taurine). The toxicity of the disaggregated amyloid fibrils on corneal fibroblasts was studied using xCELLigence and Incucyte assays.

Results: The osmolytes were effective in both inhibition and disaggregation amyloid fibrils derived from TGFB1p 611-633 c.623 G>R peptide. The osmolytes did not have an adverse toxic effect on cultured human corneal fibroblast cells and could potentially be a useful therapeutic strategy for patients with TGFB1p corneal dystrophies. The disaggregated amyloid fibrils after treatment with osmolytes did not have any toxic effect on the human corneal fibroblasts.

Conclusions: The osmolytes were not toxic to the human corneal fibroblast cells. The osmolytes were effective to disaggregate the in-vitro amyloid fibrils. The osmolytes were also effective to delay or inhibit amyloid fibril formation in these peptides with G623R mutation. The disaggregated amyloid fibrils after osmolyte treatment added to the human corneal fibroblast cell did not show any toxicity.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor (VEGF) receptor inhibitors can be used to fabricate a rat model that presents with a retinopathy of prematurity (ROP)-like fundus (Nakano et al., 2016). This model of ROP is developed using oxygen-induced retinopathy (OIR). The aim of the present study was to determine the association between the ROP-like fundus and the fundus blood flow.

Methods: This study enrolled a control group of 33 rats and an experimental group of 31 rats, which were subcutaneously administered with a VEGF receptor inhibitor (KRN633; anti-VEGF group) at seven and eight (postnatal) days of age. Subsequently, at two and three weeks of age, the ocular blood flow was measured with Laser Speckle Flowgraphy-Micro and compared between the two groups. After the measurement at three weeks of age, flat-mounted retina specimens were prepared and used to examine the correlations of retinal arterial tortuosity and the avascular region with the blood flow.

Results: At three weeks of age, the mean blur rate (MBR) of the anti-VEGF group was significantly higher than that of the control group ($p = 0.03$). Moreover, the rate of increase in MBR from two to three weeks of age positively correlated with the retinal arterial tortuosity ($r=0.50$ $p=0.0039$).

Conclusions: The MBR of the anti-VEGF group at three weeks of age was significantly higher than that of the control group, identical to a previous experiment that measured the blood flow in OIR. Moreover, higher rates of increase in MBR from two to three weeks of age were associated with greater retinal arterial tortuosity, suggesting that blood flow was higher in the anti-VEGF group than in the control group. Although the reproducibility of this study's results need to be confirmed, they indicate that the pathology of rats with anti-VEGF drug-induced ROP-like fundi correlates with the fundus blood flow. Therefore, in terms of the ocular blood flow, the rat model in the present study can be used as a new model of ROP.

ABSTRACT BODY:

Purpose: To use magnetic resonance imaging (MRI) to noninvasively measure changes in steady-state free and total water gradients in human lenses in vivo with advancing age.

Methods: 57 subjects aged 18 to 86 years were recruited under approval from the University of Auckland Human Subjects Ethics Committee (#017162), fitted with a 32-channel head receiver coil and placed in a 3 Tesla clinical MR scanner. MRI scans of the crystalline lens were obtained using a volumetric interpolated breath-hold examination (VIBE) sequence with dual flip angles, then corrected for field inhomogeneity post-acquisition with a B_1 -map obtained using a TurboFLASH sequence. Corrected lens free water (T_1) and total water (PD) maps were then calculated using an established MRI signal equation (Blüml et al., 1993; Deoni et al., 2003). PD values were normalised to an external water reference included in the scanner. Free and total water profiles along the lens optical axis were extracted using MATLAB custom-written software and the age-dependent changes in parameters determined by linear regression.

Results: No significant changes to either the profile shape or amount of total water in different regions of the lens was observed with age (all $p > 0.05$). Unlike total water, which was linearly distributed across the lens, a gradient in free water that was highest in the periphery and lowest in the central region was observed in all lenses. However, with advancing age, this free water gradient collapsed from an initial parabolic shape in young lenses to one with an enhanced central plateau in older lenses, as indicated by significant increases in the values of the profile shape parameter with age (anterior: 0.067/year, $p = 0.004$; posterior: 0.050/year, $p = 0.020$). Furthermore, with advancing age a significant increase in central free water content was also observed (1.932 ms/year, $p = 0.022$).

Conclusions: MRI can successfully map free and total water distributions of in vivo human lenses. The observation that the steady-state free, but not total, water gradient of the lens collapses with age raises the possibility that age-dependent changes to the way lens proteins bind water is an underlying cause of changes to lens optics and therefore overall vision that is observed as we age.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is an important cause of irreversible vision loss for which no treatment other than surgery is available. Large animal models of induced PVR have been used to study disease mechanisms and to test novel pharmacologic treatments. Photography-based staging scales in these models classify lesion severity by macroscopic features but do not provide data regarding microscopic retinal structure. Here we aimed to study the use of optical coherence tomography (OCT) imaging in characterizing the microscopic in vivo features of retinal lesions in a rabbit model of induced PVR.

Methods: All animal procedures were conducted in accordance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research and were approved by the Johns Hopkins Animal Care and Use Committee. PVR was induced unilaterally in specific pathogen free Dutch Belted rabbits by vitrectomy, retinotomy, retinal detachment, platelet-rich plasma injection, and cryotherapy. At baseline and different time points after PVR induction, in vivo lesion severity was documented by color fundus photography and staged according to the Fastenberg scale. OCT imaging (EnFocus OCT, Leica Microsystems) was performed at each time point. Qualitative and quantitative features were extracted from OCT images by a masked observer.

Results: The retinas (N=9) of lesioned rabbits were imaged at baseline and at time points ranging from 4 hours to 30 days after PVR induction. PVR lesion severity ranged from Fastenberg stages 3 to 5. Qualitative OCT features that were analyzed included retinal thickening, epiretinal membrane, vitreoretinal traction, media opacity, and retinal detachment. OCT features that could be quantified included retinal thickness and retinal detachment height. Cataract formation impeded OCT imaging in several eyes.

Conclusions: OCT imaging may provide detailed information regarding in vivo retinal structure in rabbit eyes with PVR across the severity spectrum. Qualitative OCT lesion descriptors could reveal abnormalities in the epiretinal, retinal, and subretinal locations. The development of objective and quantifiable OCT-based biomarkers in animal models of PVR might facilitate further preclinical research on developing novel treatment modalities.

ABSTRACT BODY:

Purpose: Various magnetic resonance imaging (MRI) findings have been identified in patients with idiopathic intracranial hypertension (IIH), including optic disc protrusion, globe flattening, empty sella, vertical optic nerve tortuosity, nerve sheath expansion, slit ventricles, transverse venous sinus stenosis, and tonsillar prolapse. We aimed to innumerate these findings in a Bronx cohort and establish clinico-radiological correlations.

Methods: A retrospective chart review of 45 consecutive patients with confirmed IIH and 47 controls who had MRIs for other reasons, was conducted. Demographic, clinical and brain MRI/MRV details were analyzed with Pearson correlation, student's t-test, and Mann Whitney calculations using STATA-14 software. Sensitivity, specificity, positive predictive value (PPV), and likelihood ratios (LR) were calculated, for each MRI sign. Significance was set at $p < 0.05$.

Results: IIH patients were predominately female (91% vs 68%; $p = 0.006$), younger (28.3 vs 45.2yrs; $p < 0.001$) and obese (BMI=34.8 vs 30.7; $p < 0.015$) compared to controls. Mean (SD) number of MRI findings was 2.8(2.1) in IIH and 1.4(1.7) in the controls; ($p < 0.001$). In the IIH group, mean (SD) lumbar puncture opening pressure (LPOP) was 32.2(11.8) cm H₂O. LPOP correlated with the number of MRI/MRV signs ($Rho = 0.31$; $p = 0.04$); BMI had minimal correlation ($Rho = 0.21$; $p = 0.16$). Vertical nerve tortuosity ($p = 0.003$), slit ventricles ($p < 0.001$) and transverse sinus stenosis ($p < 0.001$) occurred more in IIH than controls. Other MRI findings were not significantly different. Optic disc protrusion had low sensitivity, 13.3%; CI 5.9-27.0% but high specificity, 95.7%; CI 84.0-98.9%, PPV, 75.0% and +LR, 3.1 while vertical nerve tortuosity had intermediate sensitivity 52.1%; CI 36.4-65.5% and specificity 78.7%; CI 64.3-88.3% and lower PPV 69.7%, and +LR 2.4. Slit ventricles (sensitivity 53.3%; CI 38.5-67.5%, specificity 93.6%; CI 81.5-97.9%, PPV 88.9%, +LR 8.3), and transverse venous sinus stenosis (sensitivity 40.0%; CI 26.5-55.1%, specificity 93.6%; CI 81.5-97.9%, PPV 85.7%, +LR 6.2) had the highest predictive values.

Conclusions: The results affirm that IIH occurs in young females with high BMI. Opening pressures positively correlated with the number of MRI signs. Ventricular slits and transverse sinus stenosis were the brain MRI/MRV signs that were most predictive of IIH diagnosis.

ABSTRACT BODY:

Purpose: To evaluate the association between retinal thickness variability and visual outcome at 2 years in eyes receiving anti-vascular endothelial growth factor (anti-VEGF) therapy for neovascular age-related macular degeneration (nAMD).

Methods: Sixty-four eyes receiving anti-VEGF therapy for nAMD were analyzed. Variability in spectral-domain optical coherence tomography central subfield thickness (CST) was calculated from the standard deviation of all visits after 3 loading doses from month 3 to 24. Eyes were divided into quartiles (Q) based on the CST variability values and the visual acuity at 2 years were compared.

Results: The mean \pm standard deviation (SD) age of the patients at the first anti-VEGF injection was 75.3 ± 9.4 years. The mean \pm SD baseline visual acuity and CST were 0.59 ± 0.39 and 364 ± 113 μm respectively. A significant correlation was found between CST variability and visual acuity at 2 years (Spearman's $\rho = 0.54$, $P < 0.0001$), indicating eyes with lower CST variability having better visual acuity at 2 years. Eyes with the lowest CST variability was associated with the best mean visual improvement at 2 years (Q1: +9.7 letters, Q2: +1.1 letters, Q3: -2.5 letters, Q4: -9.5 letters; $P = 0.018$). No significant difference in the number of anti-VEGF injections was found between the 4 groups ($P = 0.21$).

Conclusions: In patients undergoing anti-VEGF therapy for nAMD, eyes with more stable CST were associated with better visual acuity outcome.

TITLE: Predictive value of retinal venous oxygen saturation for the visual prognosis after twelve months in branch retinal vein occlusion

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.K. Jeppesen, T. Bek, Ophthalmology, Aarhus Universitetshospital, Aarhus, DENMARK|S.K. Jeppesen, Aarhus Universitet Health, Aarhus, Midtjylland, DENMARK|

Commercial Relationships Disclosure (Abstract): Signe Jeppesen: Commercial Relationship: Code N (No Commercial Relationship) | Toke Bek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have shown that the retinal oxygen saturation at referral has no predictive value for visual outcome after twelve months in patients with central retinal vein occlusion treated with anti-VEGF compound. It is of interest to evaluate whether this conclusion is similar in patients with venous occlusions only involving a part of the retina in whom the epidemiological background, complication pattern and visual prognosis is different.

Methods: The association between oxygen saturation, visual acuity and central retinal thickness was studied at the time of referral and after six and twelve months in 111 patients successively referred to the Department of Ophthalmology, Aarhus University Hospital, between February 2017 and August 2019 with a newly diagnosed venous occlusion affecting branches peripheral from the central retinal venule.

Results: Sixty-seven patients with a visual acuity between 35 and 60 ETDRS letters at referral were treated with intravitreal injection of anti-VEGF compound. The venous oxygen saturation improved in parallel central retinal thickness and visual acuity over twelve months but had no predictive value for visual acuity after twelve months. In twelve untreated patients with better visual acuity, low age and high oxygen saturation at the time of referral were positive predictors for the visual outcome after twelve months.

Conclusions: Oxygen saturation, visual acuity and central retinal thickness improves in parallel during treatment of branch retinal vein occlusion with intravitreal injection of anti-VEGF compound. Retinal oximetry has no value for predicting visual acuity after twelve months in treated patients but may potentially become a tool for predicting the visual prognosis in untreated patients with a high visual acuity at referral.

TITLE: Relationship between temporal L-cone flicker sensitivity and established clinical parameters in Stargardt's disease

SESSION TITLE: Assessing human vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C.R. Huchzermeyer, J. Fars, J.J. Kremers, Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Bayern, GERMANY|C.R. Huchzermeyer, J. Fars, J.J. Kremers, Department of Ophthalmology, University Hospital Erlangen, Erlangen, GERMANY|

Commercial Relationships Disclosure (Abstract): Cord Huchzermeyer: Commercial Relationship: Code N (No Commercial Relationship) | Julien Fars: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the relationship between L-cone-specific temporal contrast sensitivity (L-cone tCS) and established functional and structural outcome parameters in Stargardt's disease (STGD).

Methods: Twelve patients (5F, 24±14yrs) with confirmed STGD were included. L-cone-isolating temporal modulation was created in a 12° test field using a four-primary LED stimulator using triple silent substitution. L-cone tCS was defined as 1 / L-cone contrast at threshold. Mean deviation of tCS was calculated by 1) subtracting the logarithm of the observed tCS from age-correlated normal values, 2) converting to decibel and 3) averaging the 12, 16, and 20Hz results.

Clinical parameters were: mean deviation of static white-on-white perimetry in the central 12° (MD12), area of hyporeflexivity (AoH) in infrared scanning-laser-ophthalmoscopy scans, and best corrected visual acuity (logMAR). Principal component analysis (PCA) was performed to identify associations between outcome parameters and to subdivide patients into different clusters. Pearson correlation coefficients were calculated for confirming associations found in PCA.

Results: In the PCA 2D plot, three clinically meaningful clusters were identified: 1) fundus flavimaculatus without central defect (FF; good logMAR, good MD12), 2) bull's-eye maculopathy (BEM; good logMAR and reduced MD12), and 3) central defect and eccentric fixation (CD; both logMAR and MD12 reduced). Interestingly, one patient, who was located between the CD cluster and the BEM clusters, showed signs of BEM in the OCT but seemed to have lost central fixation recently. In our cohort, L-cone tCS deviation was inversely correlated to AoH ($R=-0.63$; $p=0.03$) and positively correlated to MD12deg ($R=0.74$; $p=0.01$).

Conclusions: PCA can be useful to explore phenotypes, when clinical outcomes are intercorrelated. Close association between MD and L-cone tCS is not surprising, because stimulus detection in white-on-white perimetry is also dominated by L-cones. As a consequence, tCS did not provide additional information that might change clustering. However, tCS can be measured faster than perimetric MD and might be used as a surrogate in patients who cannot perform static perimetry.

ABSTRACT BODY:

Purpose: ADOA is the most common inherited neuro-ophthalmic disorder which starts in the first decade of life and leads to progressive, irreversible vision loss from degeneration of retinal ganglion cells (RGCs). More than 400 mutations have been reported in ADOA and most patients harbor mutations in the OPA1 gene that lead to haploinsufficiency. Reduced OPA1 levels are associated with impaired mitochondrial function in RGCs leading to apoptosis. Currently, there is no approved disease-modifying treatment for ADOA. Targeted Augmentation of Nuclear Gene Output (TANGO) uses antisense oligonucleotides (ASOs) to reduce inclusion of a non-productive, alternatively spliced exon in OPA1. We previously demonstrated that TANGO ASOs can be utilized to increase OPA1 expression in cultured human cells and in the rabbit retina. In this study, we use fibroblasts from patients with ADOA as an in vitro model to evaluate efficacy of our approach.

Methods: Skin fibroblasts were obtained from 3 unrelated patients with ADOA, each with different heterozygous OPA1 mutations. ASOs were delivered by lipid-based transfection. RNA and protein were isolated to assess changes in OPA1 mRNA splicing and OPA1 protein levels. Mitochondrial respiration was evaluated by measuring the oxygen consumption rate (OCR) using the XFe96 Extracellular Flux Analyzer from Seahorse Biosciences. Flow cytometry with DCFDA dye was used to detect intracellular reactive oxygen species (ROS).

Results: All 3 fibroblast samples showed decreased expression of OPA1 mRNA and OPA1 protein when compared to wild-type fibroblasts. Patient fibroblasts exhibited impairment in mitochondrial respiration as seen by decreased basal OCR, ATP-linked respiration, and spare respiratory capacity. Intracellular ROS levels also increased. TANGO ASOs reduced the non-productive exon inclusion, increased total OPA1 protein levels, and improved mitochondrial function in patient fibroblasts.

Conclusions: We validated the use of patient fibroblasts as an in vitro model of ADOA pathophysiology. Improvement in mitochondrial function suggests that ASO-mediated increase in OPA1 can potentially modify disease progression in ADOA in a mutation-independent manner.

ABSTRACT BODY:

Purpose: The intrachoroidal cavitation (ICC) is a peripapillary pathological lesion usually associated with high myopia, which may cause serious clinical consequences such as visual field defect. However, due to the challenges in existing imaging devices to visualize three-dimensional (3D) morphology of the ICC, details in structural characteristics and their influence on visual function, remain poorly understood. Using deep learning (DL)-based image enhancement and 3D rendering of volumetric swept-source optical coherence tomography (SSOCT) images, we evaluated the 3D anatomic characteristics of the ICC in comparison with the existing 2D parameters.

Methods: Thirteen eyes of 12 consecutive patients with peripapillary ICC were enrolled (age: 52.5 ± 6.3 years, refractive error: -8.4 ± 3.2 D, and axial length: 27.1 ± 1.4 mm). DL-based image enhancement, automatic segmentation of the ICC, and 3D rendering was applied to parapapillary 6 x 6 mm volumetric SSOCT scans. We evaluated the anatomical relationship between the ICC and the Bruch membrane opening (BMO). The 3D volume, as well as the 2D maximum width and length of the ICC, were calculated as morphologic parameters. Associations between the ICC parameters and visual field mean deviation (VFMD) of standard automated perimetry were investigated.

Results: The ICC was successfully segmented, and 3D visualized in all eyes. The ICC was located inferior to the optic disc in all eyes and observed bilaterally in 1 patient and unilaterally in 11 patients. The ICC was detected with fundus photographs in 12 eyes out of the 13 eyes. VFMD ranged from -11.1 to 0.12 dB (mean -2.61 ± 3.16 dB). All the ICCs showed direct contact with the BMOs and two cases showed the overlap. The ICC volume ranged from 55.3 to $975.4 \times 10^{-3} \text{ mm}^3$ ($358.4 \pm 283.3 \times 10^{-3} \text{ mm}^3$), the ICC width from 118.5 to 512.4 μm ($248.5 \pm 108.9 \mu\text{m}$), and the ICC length from 0.19 to 2.00 mm (1.10 ± 0.47 mm). The ICC volume ($P=0.02$, regression coefficient=-0.007) was significantly associated with VFMD while the ICC width and length were not.

Conclusions: 3D images of the ICC were successfully generated using DL-based enhancement of SSOCT volumetric scans. 3D volume parameter seems to reflect the pathological influence of the ICC on visual function better than the existing 2D metrics, which potentially leads to an improved pathological understanding of the ICC.

ABSTRACT BODY:

Purpose: Laguna ONhE automatically analyzes hemoglobin distribution in optic disc retinographies (1-9). Its main index, called GDF (Globin Distribution Factor) involves a classifier based on Deep Learning that tends to produce extreme values: (1=normal, 0=glaucoma). The consequence is a good detection performance, outweighed by certain variability in the limit range between normality and glaucoma. Therefore, its influence has been reduced in a new index, called Globin Individual Pointer (GIP). It may be useful in the follow-up of cases.

Methods: Two retinographies of 78 normal eyes and 59 confirmed or suspected glaucomas were obtained using a simple manual fundus camera (DEC-200, MiiS, Taiwan). The reproducibility and diagnostic capability of both indices were compared.

Results: Analyzing the average of both GDF series, a ROC area of 0.937 (CI=0.882-0.971) and a sensitivity of 67.8%% for 99% specificity were obtained. Its intra-class correlation coefficient was 0.970 (CI 0.958-0.978). GIP achieved a smaller ROC area (0.902, CI=0.839-0.946, $p<0.01$), sensitivity of 50.85% for 99% specificity, and a higher intra-class correlation coefficient (0.990, CI=0.985-0.993, $p<0.0001$).

Conclusions: Both indices are complementary: GDF useful for diagnostic classification, especially considering that not all glaucomas were confirmed cases but only with signs of suspicion, and GIP for individual progression assessment.

Figures: Test-retest scatter plots of GDF (Fig1) and GIP (Fig2) indexes. The 0 and -15 value are at 5% and 1% percentile of the normal population.

ABSTRACT BODY:

Purpose: To determine the properties of primary optic nerve head astrocyte (ONHA)-derived extracellular vesicles (exosomes), their uptake into primary neurons, and to identify the functional effects of exosomes on neuronal survival and neurite outgrowth.

Methods: Exosomes were prepared by ultracentrifugation from primary rat ONHAs. To determine the functional effects of lysyl oxidase like-1 (Loxl1) knockdown, we transduced ONHA with lentivirus harboring either control or Loxl1-targeting small hairpin RNA. A stable line with ~50% Loxl1 knockdown was generated. Exosomes were characterized by nanoparticle tracking analysis and immunoblotting. Uptake of exosomes into primary cortical neurons was quantified by quantitative microscopy using RNA-based labeling. Functional effects of exosomes were determined by testing their antioxidative properties in primary cortical neuronal culture. To quantify effects on neuronal differentiation, exosomes were added to neuronal cultures on days 3 and 5 in vitro and neurite outgrowth was quantified on day 7.

Results: Exosomes derived from wildtype, control- and Loxl1 shRNA-transduced ONHAs were of similar size (119.8 ± 4.3 , 121.9 ± 2.8 and 121.1 ± 2.5 nm, respectively, $n=3$, $P=0.89$). ONHA exosomes expressed the prototypical markers Alix and CD63, but were deficient of CD81. Exosomes were taken up by primary neurons, and this uptake was time-dependent and peaked at 4 h after addition ($n=3$, $P<0.05$). Viability of rat primary cortical neuronal cultures in response to oxidative stress insult did not change in the presence of exosomes derived from wild-type, control- or Loxl1 shRNA-transduced ONHA cultures, suggesting lack of antioxidative properties. Wild-type ONHA exosomes increased neurite outgrowth of primary rat cortical neurons by $20.1 \pm 3.3\%$ (from 57.6 ± 4.4 to 77.6 ± 6.5 μm , $n=5$, $P<0.05$); similarly, exosomes from control shRNA-transduced ONHAs increased neurite outgrowth by $18.7 \pm 2.0\%$ (to 76.3 ± 4.6 μm , $n=5$, $P<0.05$). In contrast, exosomes from Loxl1 shRNA-transduced ONHAs prevented any increase in neurite outgrowth ($2.2 \pm 4.0\%$ change; 59.8 ± 3.3 μm , $n=5$, $P=0.98$).

Conclusions: Our data provide evidence that ONHA-derived exosomes can exert functional effects on neurons and identify Loxl1 as a putative mediator of these effects. Altered exosome-mediated neuron-glia signaling in exfoliation

glaucoma, where LOXL1 expression is chronically reduced, may be of pathological importance.

ABSTRACT BODY:

Purpose: Though raised intraocular pressure (IOP) is the main risk factor, about a third of patients with glaucoma have IOP within the normal range (Normal Tension Glaucoma - NTG). Whilst reducing IOP can slow progression, glaucoma may deteriorate despite IOP lowering, suggesting that other factors confer susceptibility. Mitochondrial dysfunction is an important factor contributing to a number of age-related neurodegenerative diseases and mounting evidence suggests that it contributes to glaucoma pathogenesis. Nicotinamide adenine dinucleotide (NAD⁺) is a central coenzyme involved in mitochondrial function and fundamental biological processes in health, ageing and disease. NAD⁺ depletion has been observed in other neurodegenerations

Methods: NAD⁺ and NADH levels (Promega NAD/NADH-Glo™ Assay; two technical repeats) and mitochondrial function (XFe24 Analyzer), expressed as oxygen consumption rate (OCR) pmol/min, were measured in the same fibroblast lines from 5 NTG patients and 5 non-glaucomatous Controls. NAD⁺ and NADH concentrations were normalised to protein content and expressed as nM/μg. NTG inclusion criteria: minimum 5 years follow up with at least 8 reliable visual fields, IOP ≤ 21mmHg. Controls were age matched with an absence of glaucoma and IOP ≤ 21mmHg. Both groups had absence of active haematological malignancy/recent infection/chemotherapy/radiotherapy or drugs known to affect mitochondrial function

Results: Median (IQR) NAD⁺ (p<0.01) and NADH⁺ (p<0.05) concentrations (average of two runs) were significantly reduced in the NTG group: 374 (372 - 400), 56 (42 - 57), compared to the Control group: 656 (613 - 1164), 121 (80 - 171) respectively (Fig. B, D). Median Basal (p<0.01), ATP-linked (p<0.01), and Maximal Respiration (p<0.05), were significantly lower in the NTG group compared to the Control group (Fig. A, C, D). The estimation of NAD⁺ concentration was relatively imprecise with a mean difference of 29% and SD of differences of 19% between the two runs

Conclusions: Our data show evidence of relative NAD⁺ and NADH depletion in NTG patients, which may contribute to a reduction of various components of systemic mitochondrial function, supporting NAD⁺ levels as a potential therapeutic target

TITLE: Subretinal choroidal neovascularization in central serous chorioretinopathy resistant to mineralocorticoid receptor antagonists

SESSION TITLE: CNV

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Kassotis, Ophthalmology, Columbia University Vagelos College of Physicians and Surgeons, New York, New York, UNITED STATES|V. Diaconita, T.H. Tezel, Ophthalmology, Edward S Harkness Eye Institute, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alexis Kassotis: Commercial Relationship: Code N (No Commercial Relationship) | Vlad Diaconita: Commercial Relationship: Code N (No Commercial Relationship) | Tongalp Tezel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Choroidal neovascular membranes (CNV) are an infrequently explored complication of central serous chorioretinopathy (CSCR) that can substantially impact recovery. This retrospective case analysis aims to better characterize the role of CNV in patients with CSCR who failed treatment with the mineralocorticoid receptor antagonist eplerenone.

Methods: Those included in this study were diagnosed with CSCR without CNV at presentation in one physician's practice between January 2012 and August 2019. All subjects had imaging with Spectral Domain Optical Coherence Tomography (SD-OCT) and angiography. Chart review was used to extract subjects' age, gender, risk factors, treatment, vision at the time of diagnosis and resolution, and date of resolution if applicable. Central macular thickness (CMT), subfoveal choroidal thickness (SFCT) and choroidal vascularity index (CVI) were determined from SD-OCT images. Binary logistic regression analyses were conducted to identify clinical features associated with CNV development.

Results: This study includes 35 eyes of 31 patients. Twenty-four eyes (68.6%) demonstrated complete resolution of subretinal fluid within 8.5 ± 1.9 months. Eleven eyes (31.4%) developed CNV. CNV incidence doubled after 5 months at which time 50% of the patients had complete resolution of subretinal fluid with eplerenone (Figure 1). Of eyes that did not resolve with eplerenone, a significantly higher proportion had CNV than did not (66.7% vs 20%, $p=0.02$). Binomial regression analyses indicate that the persistence of subretinal fluid (RR 5.99; CI: 1.21-29.41; $p=0.028$) and duration of eplerenone use (RR 1.06; CI: 1.00-1.13; $p=0.042$) were the only clinical features significantly associated with the presence of CNV in CSCR (Figure 2).

Conclusions: Individuals without CNV at presentation who fail to respond to eplerenone treatment within 5 months may have developed an underlying CNV and thus, could benefit from investigatory imaging.

ABSTRACT BODY:

Purpose: To investigate the correlation of viral load at baseline and over 21 days with severity of signs, symptoms, and viral clearance in participants with adenoviral conjunctivitis.

Methods: Of 212 participants screened for adenoviral conjunctivitis (Ad-Cs), 56 met the following criteria and were randomized: ≥ 18 years of age, symptoms ≤ 4 days, a positive point-of-care immunoassay via AdenoPlusTM (Quidel, San Diego CA). One eye of each participant was randomized to a single, in-office administration of either 5% povidone-iodine (PVP-I) or artificial tears (AT). Examinations at baseline, days 1-2, 4, 7, 14, and 21 included assessment of participant symptoms, clinician graded signs, and conjunctival swabs for qPCR analysis. Repeated measures generalized estimating equations were used for calculating the correlation (r) of viral load with signs and symptoms over 21 days. Severity of signs and symptoms is reported for 3 equal size tertiles of baseline viral load: low ($\log qPCR < 6.13$), middle ($\log qPCR 6.13-6.78$) and high ($\log qPCR > 6.78$).

Results: Twenty-five participants were qPCR positive for adenovirus and had sufficient follow-up visits. Viral load was not correlated with participant symptoms or clinician graded signs at baseline. However, higher viral load over 21 days had correlations with increased severity of participant symptoms of tearing, matting and redness ($r \geq 0.70$; $p < 0.02$) and with clinician graded signs of bulbar redness and serous discharge ($r \geq 0.60$; $p < 0.01$). Higher baseline titers were correlated with longer time to viral clearance ($r = 0.59$, $p = 0.0075$). Days to viral clearance in low, middle and high baseline viral titer tertiles were 10.3 ± 5.6 , 9.5 ± 3.5 , and 19.8 ± 3.8 , respectively. The incidence of subepithelial infiltrates or pseudomembranes was higher in the highest tertile of viral load (75%, 6 of 8) compared to the lowest tertile (40%, 4 of 10, $p = 0.43$).

Conclusions: High correlations were found between viral load with more severe signs and symptoms over 21 days. Higher baseline viral load was associated with longer time to viral clearance.

TITLE: AMD Drusenoid deposits “L”, Lipid type: Density, Structural, Volume analysis, and their evolution study with Morphology-Structural software. 5 years follow-up

SESSION TITLE: AMD: Clinical and translational research I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Gonzalez, SELARL CABINET DR C GONZALEZ, TOULOUSE, FRANCE|

Commercial Relationships Disclosure (Abstract): Corinne Gonzalez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study AMD drusenoid deposits “L”, with regard to their density, structure volume and evolution with morphology-structural software to enhance drusenoid deposits “L” knowledge, evolving potential and etiopathogenesis

Methods: 124 eyes of 64 patients, 22 men, 42 women, with AMD drusenoid deposits “L”, Lipid Type (soft Drusen, Drusenoid PED “L”). Deposits were evaluated by Autofluorescence, IR imaging, OCT, notably OCT en Face (Spectralis HRA-OCT, spectral domain OCT), and Morphology-Structural software (M-S software). ETDRS visual acuity (VA), complete ophthalmic examination with Fundus exam were added. M-S software let analyze drusenoid deposit volume and contours, 3D deposit reconstruction, display in 3D space, let drusenoid deposit contents analyze, discrimination, differentiation, let grading (volume and contours analyze), let measurements: density (grey levels of deposits), structure (structural measures, texture parameters), volume (in μm^3), evaluation and characterization of those “L” type deposits. Evaluation, comparison for each eye, for each patient, between all studied patients, was done every 6 months, so evolution assessment of those drusenoid deposit parameters too. 5 years follow-up.

Results: AMD Drusenoid Deposits “L” are: dark grey, optical empty, fatty, equal and the same in all cross-section (OCT/OCT en face). From M-S software, “L” have rather Low density, each density parameter having not only its own profile, curve modulation and up and down during evolution, but difference in between, and likeness between both eyes. Structural and Volume parameters have also their own profile and similarity between both eyes. Cycle evolution was seen for all parameters curve, specific for each curve, with also similarity between both eyes. So this allow better AMD Drusenoid Deposits “L” knowledge, physiopathology understanding, evolution assessment, evolving potential, particularly to atrophy.

Conclusions: AMD Drusenoid deposits “L”, study and knowledge, especially regarding their contents, in particular through Morphology-Structural Software contribute to and improve AMD physiopathology, etiopathogenesis understanding and hypothesis formulations.

ABSTRACT BODY:

Purpose: Normal axial length growth (ALG) in infancy is modulated by hyperopic defocus on the retina and accommodation. Childhood cataract (CC) and CC surgery disrupt both mechanisms with potential for altered ALG. We compared axial length (AL) in children with CC before and after surgery to typical children (norms) to determine whether CC and surgery affect ALG.

Methods: 110 eyes of 55 children (age 2 weeks - 7 years) with CC were included: 30 eyes, 15 children with unilateral CC and 80 eyes, 40 children with bilateral CC. Eyes with structural abnormalities were excluded. AL data for cataracts was retrospective. AL norms were derived from a cross-sectional prospective study of 332 typical children (age 8 weeks - 7 years) at the same center. AL was measured pre- and postoperatively. Surgical procedures were performed by a single surgeon (AC). Bilateral CC data was combined, as there was no significant difference between eyes. Preoperative ALG curves were calculated for each population and best described by the function $AL = a + b \cdot \ln(t)$, where t is age in weeks. 95% confidence intervals were calculated via the bootstrap method. We then found the difference in AL between age-matched norms and pre- and postoperative AL 13 months after surgery (range 9-18 months), again via the bootstrap method.

Results: For healthy eyes, a was 16.62 (16.21, 17.01, 95% CI) and b was 1.01 (0.92, 1.09). Between groups, b did not differ significantly. For bilateral CC, a was 15.65 (14.80, 16.48). The trend was towards shorter AL but was not significant. For unilateral CC, the a value for affected eyes was 14.37 (12.33, 16.12) and for fellow eyes 16.47 (15.29, 17.41). The affected eye was significantly shorter than norms. The unaffected eye was no different than controls. 13 months postoperatively, eyes with bilateral CC did not approximate normal ALG; change in difference was only 0.1% (-3.3%, 3.7% 95% CI), but affected eyes of unilateral CC did approximate normal ALG, changing by 5.9% (3.4%, 8.7%) and no longer differing significantly from fellow eyes or norms.

Conclusions: In CC there is altered ALG, and the affected eye(s) at presentation is shorter. This indicates a disease process beyond a structural abnormality alone; the presence of cataract itself is enough to cause a difference in ALG. Additionally, there are likely different mechanisms of visual deprivation between unilateral and bilateral CC and altered ALG mechanisms following surgery.

SUBMITTER (NAME ONLY): Rachel Fortner

TITLE: Impact of the COVID19 pandemic on glaucoma patients: did delay in elective care lead to progression of disease?

SESSION TITLE: Healthcare Delivery during Covid Pandemic

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Fortner, Vanderbilt University School of Medicine, Nashville, Tennessee, UNITED STATES|J. Lindsey, Ophthalmology, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|J. Lindsey, Ophthalmology, VA Tennessee Valley Healthcare System, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rachel Fortner: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Lindsey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic provided unique insight into delayed glaucoma care, as one of the first events in living memory during which in-person health care services, such as eye care, were abruptly curtailed. In this retrospective cohort study, we tested the hypothesis that among patients with glaucoma, delayed care was associated with increased risk of disease progression necessitating change in clinical management.

Methods: Manual chart review was performed for 172 patients with glaucoma at the Veterans Affairs (VA) Tennessee Valley Healthcare System (TVHS) Eye Clinic. The exposure cohort was a random sample of 78 patients who were already established at the VA and had a scheduled outpatient clinic visit during the closure of the clinic between 3/20/2020 and 6/1/2020. The comparator group involved 94 patients with glaucoma who had at least two appointments before COVID (1/1/2018-2/28/2020). Left eyes were analyzed, and demographics, time between recommended and actual follow-up visits, stage of glaucoma, and change in treatment regimen were compared between the 2 cohorts. Fisher's exact test and Pearson's chi-squared test were used to determine whether there were significant differences in disease progression between the groups.

Results: In the exposure cohort, 56.4% of patients had postponed appointments, 28.2% never returned to clinic, and 15.4% had no delay compared to 13.8%, 0%, and 86.2% respectively in the comparator cohort with a statistically significant difference in all three categories ($p < 0.0001$). In addition, 37.5% of all patients had disease progression during the pandemic compared to 17.0% in pre-pandemic times. There is evidence to suggest that there is a significant difference in disease progression in the exposure group compared to the comparator group ($p < 0.0190$). A larger sample size is needed to determine significance in progression of disease between the cohorts when stratified by delayed/not delayed.

Conclusions: Our results are consistent with our hypothesis that delayed care during the pandemic resulted in a change of clinical management due to an increased risk of disease progression. Moreover, many patients were lost to follow up and did not return for their visit. Further research is needed to determine if disease progression is sustained after multiple appointments.

ABSTRACT BODY:

Purpose: To describe the ocular features and characteristics of retinal detachment in high myopia associated with mutations in LEPREL1 gene.

Methods: Retrospective chart review including details of ocular history, ophthalmic examination, multimodal imaging and surgical interventions were obtained during a mean duration of 9.1 ± 4.8 years.

Results: 20 eyes of 10 patients were included. 2 patients were males and 8 patients were females. Mean age of the patients was 18.6 ± 5.5 years followed up for 9.1 ± 4.8 years. Mean axial length was 28.9 ± 1.9 mm and mean refraction was -13.9 ± 2.8 diopters. BCVA on presentation was 0.62 ± 0.65 (Snellen = 20/80) and on last follow up was 0.45 ± 0.69 (Snellen = 20/50). Anterior segment examination revealed posterior subcapsular cataract in 16 eyes (80%) and associated with temporal lens subluxation in 5 eyes (25%). 6 eyes of 5 patients (50%) developed retinal detachments (RD) at age of 11 ± 3.2 years. All eyes (100%) with retinal detachment had giant retinal tears (GRT). Anatomical reattachment was achieved in 5 out of 6 eyes. No significant difference was found in axial length or cycloplegic refraction between eyes with and without RD ($P=0.897$ and 0.861 respectively). Previous lensectomy with PCIOL was not associated with higher risk of RD ($P=0.550$).

Conclusions: LEPREL1-related high myopia confers a high risk of early-onset RD associated with giant retinal tears. Surgical interventions can achieve good anatomical and visual outcomes in these patients. This phenotype mimics the ocular features of Stickler syndrome.

ABSTRACT BODY:

Purpose: Determine demographics and clinical characteristics of low vision patients at Cole Eye Institute (Cleveland, Ohio) from 2014-2019.

Methods: This was a single center, retrospective cross-sectional analysis of all adult patients (age>18) seen at Cole Eye Institute between 2014-2019 with best corrected visual acuity (BCVA) of 20/400 or worse in at least one eye. Demographic and clinical data were collected from clinical visits in Oct, 2014-Oct, 2019. One International Classification of Diseases diagnosis code (ICD-9 or ICD-10) was associated to each patient as the most likely cause of low vision. Correctable causes of blindness were excluded.

Results: Out of 500,093 patients seen in 2014-2019, 17,995 eyes from 15,610 patients (3.1%) had vision of 20/400 or worse. Bilateral low vision accounted for 2,384 patients (15.3%). The average age was 69.3 (range: 18-114) with 58.0% being female and 68.4% being Caucasian. The most frequently associated diagnoses in patients with at least one low-vision eye were age-related macular degeneration (AMD, 24.6%), glaucoma (16.9%), retinal detachment (10.6%), and diabetic retinopathy (8.8%). In bilateral low vision, glaucoma (25.9%), retinal detachment (12.1%), and diabetic retinopathy (10.3%) were the most common diagnoses. Glaucoma (34.0%) was more prevalent than AMD (7.4%) in eyes with no light perception (NLP) (Figure 1). Whereas, in eyes with vision between 20/400 and count fingers (CF), AMD and glaucoma accounted for 25.8% and 12.2% of eyes respectively (Figure 1). When stratified by age, the proportion of low-vision patients associated with glaucoma stayed stable at 12-19% whereas low-vision associated with AMD becomes apparent above age 65 accounting for 23% of low-vision patients in age 65-80 and 50% in patients aged >80 (Figure 2).

Conclusions: The most common diagnoses accounting for uncorrectable low vision are AMD and glaucoma. Glaucoma is associated with more profound vision loss, and consistently accounts for 12-19% of low-vision patients irrespective of age. AMD is associated with less profound vision loss compared to glaucoma and is seen in elderly population with 50% of those over 80 having visual acuity of 20/400 or worse in at least one eye.

ABSTRACT BODY:

Purpose: Uncertainty exists regarding the natural history of vitreomacular adhesion (VMA) and vitreomacular traction (VMT) and patient or ocular characteristics that predispose toward release versus complications. We aim to evaluate the characteristics and outcomes of VMA and VMT at a tertiary care center.

Methods: This retrospective longitudinal cohort study includes eyes from 2008 to 2020 with VMA or VMT with ≥ 6 months of follow-up. Eyes with ocular comorbidities were excluded. The visual acuity (VA), optical coherence tomography characteristics, outcomes and interventions were recorded.

Results: One hundred ten eyes of 93 patients were identified. Of 58 eyes with VMA, 22 were focal ($\leq 1500 \mu\text{m}$ in length) and 36 were broad ($> 1500 \mu\text{m}$). The average age was 63.0 ± 8.6 years. Eighteen (31.0%) spontaneously released, 9 focal and 9 broad. Average time to release was 31.4 ± 27.8 months. A smaller proportion of patients ≥ 65 years old had spontaneous release (4/25) compared to patients < 65 years old (11/25, $p=0.03$). Average VA was 20/23 at presentation, 20/24 at 12 months and 20/24 at release. Six eyes progressed to VMT.

Of 52 eyes with VMT, 45 were focal and 7 were broad. A higher proportion of VMT were focal compared to VMA ($p<0.00001$). The average age was 67.3 ± 10.9 years. Seventeen (32.7%) spontaneously released, similar to proportions of spontaneously released VMA ($p=0.85$). Fifteen were focal and 2 were broad ($p=0.80$). Average time to release was 20.1 ± 19.3 months. The proportion of patients with spontaneous VMT release ≥ 65 years old (5/15) versus < 65 years old (8/28) were similar ($p=0.75$). Average VA was 20/35 at presentation, 20/34 at 12 months and 20/34 at release. Complications include lamellar holes ($n=2$) and full thickness macular hole ($n=1$). Seven eyes were treated. Three eyes received intravitreal ocriplasmin; 2 successfully released and the remaining patient opted for observation thereafter. Four eyes received pars plana vitrectomy. Proportions of patients who were male, pseudophakic or had epiretinal membranes (ERM) were not different between those who had spontaneous release of VMA or VMT versus those who did not.

Conclusions: VMA may spontaneously release after years of observation, particularly in patients < 65 years old. Rates of spontaneous VMA and VMT release are comparable. Sex, lens status, focal versus broad attachment, and presence of ERM do not affect spontaneous release of VMA or VMT.

Commercial Relationships Disclosure (Abstract): Jinmiao Li: Commercial Relationship: Code N (No Commercial Relationship) | Yun Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Pflugfelder: Commercial Relationship: Code N (No Commercial Relationship) | De-Quan Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore novel role and molecular mechanism of a natural osmoprotectant ectoine in protecting corneal barrier function through promoting anti-inflammatory cytokine IL-37 in human corneal epithelial cells (HCECs) under hyperosmolarity stress, an in vitro dry eye model.

Methods: Primary HCECs were established from donor limbal tissue. The confluent cultures in iso-osmolar medium were switched to hyperosmotic media (400-500 mOsm), without or with prior incubation of ectoine at different concentrations (1-40 mM) for 2-48 hours. Cell viability and proliferation were evaluated by WST assay. The integrity of apical barrier junction proteins and the expression of cytokines and cathepsin S were evaluated by RT-qPCR, ELISA, immunostaining and confocal microscopy.

Results: HCECs were survived well in 450mOsm but partially damaged in 500mOsm media. Ectoine well protected HCEC survival and proliferation in 450 and 500mOsm media. The integrity of corneal epithelial barrier was largely disrupted in HCECs exposed to 450 mOsm, as shown by 3D confocal images of immunofluorescent staining of tight junction proteins ZO-1 and occludin. Ectoine at 10-20mM well protected the barrier proteins under hyperosmotic stress. The expression of pro-inflammatory cytokines (TNF- α , IL-1 β and IL-6) were dramatically stimulated by hyperosmolarity but significantly suppressed by Ectoine at 5-40 mM as quantified by RT-qPCR and ELISA. The protease cathepsin S, which was stimulated by hyperosmolarity and TNF- α , directly disrupted epithelial barrier while its inhibitor LY3000328 restored the barrier integrity. Interestingly, IL-37 decreased significantly in HCECs by hyperosmolarity, but prior-incubation of ectoine increased IL-37 at mRNA and protein levels, suppressed TNF- α and cathepsin S activity, and protected cells from barrier disruption under hyperosmolarity. Furthermore, rhIL-37 was observed to suppress pro-inflammatory cytokines and TNF- α -induced cathepsin S in HCECs exposed to hyperosmolarity.

Conclusions: Our findings demonstrate that the hyperosmotic stress disrupts corneal epithelial barrier through stimulating pro-inflammatory cytokines and cathepsin S while suppressing IL-37. Ectoine inhibited the pathological course to protect the corneal epithelium. It provides new insight into pathogenesis and therapeutic potential for dry eye disease.

TITLE: Age, race and sex influence utilization of care for the inflammatory and infectious eye diseases in the United States

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Chauhan, Southern Illinois University- School of Medicine, Springfield, Illinois, UNITED STATES|J.T. Rosenbaum, Oregon Health & Science University School of Medicine, Portland, Oregon, UNITED STATES|J.T. Rosenbaum, Legacy Health System, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Krati Chauhan: Commercial Relationship: Code N (No Commercial Relationship) | James Rosenbaum: Commercial Relationship(s);Abbvie:Code C (Consultant);Novartis:Code C (Consultant);Gilead:Code C (Consultant);Roche:Code C (Consultant);Affibody:Code C (Consultant);Immune Response:Code C (Consultant);Kyverna:Code C (Consultant);Santen:Code C (Consultant);Corvus:Code C (Consultant);Horizon:Code C (Consultant);Horizon:Code F (Financial Support);Prizer:Code F (Financial Support);UpToDate:Code R (Recipient)

ABSTRACT BODY:

Purpose: Utilization of the eye care in the United States is influenced by health care disparities, which are defined as care affected by patient's age, race or sex. There is a lack of national level data regarding trend of utilization for inflammatory and infectious eye diseases in the United States, and whether this trend is influenced by health care disparities. We have conducted a retrospective, observational study based on the intelligent research in sight (IRIS) data to study this trend and how this trend is affected by age, race and sex of the patient.

Methods: We have used intelligent research in sight (IRIS) registry data available through National Vision and Eye Health Surveillance System (VEHSS). IRIS, is the United States' first comprehensive eye disease clinical registry. VEHSS uses ICD-10 codes to identify ocular disorders. Each code is categorized in one subgroup and multiple subgroups are combined to form a category. Inflammatory and infectious eye disease category includes subgroups of ocular inflammatory conditions, lacrimal system and orbital inflammation, keratitis, conjunctivitis, eyelid inflammation and infection, and endophthalmitis.

Utilization for the inflammatory and infectious eye disease category is stratified by age, sex and race. We have measured trends of utilization for the years 2016-2018. We have identified the effect of stratification on utilization; by race, sex, age alone; combining race and sex; age and sex; and the combination of race, sex and age.

Results: There is a decrease in utilization for the inflammatory and infectious eye diseases from the years, 2016 to 2018. This trend remains, when utilization is stratified by sex, race and age. Asians and Native American have higher utilization for all the three years for both males and females. (Figure 1). Utilization is low for the younger age groups (0-17, 18-39) and then steadily increases for age > 40 years for 2016-2018 for both males and females and for all the races (Figure 2). Females have higher utilization for all the races from 2016-2018. This remains when utilization is stratified by race; a black female has higher utilization than a black male.

Conclusions: Utilization of care for inflammatory and infectious eye diseases is influenced by age, race and sex. Asian, Native Americans, females and older age groups have higher utilization.

TITLE: Multiplatform Input for Intraocular Lens Implant Calculation after Myopic Corneal Refractive Surgery

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Lu, J. Ho, H. Jung, Ophthalmology, University of Washington School of Medicine, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Randy Lu: Commercial Relationship: Code N (No Commercial Relationship) | Joanne Ho: Commercial Relationship: Code N (No Commercial Relationship) | Hoon Jung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Calculating intraocular lens (IOL) power for cataract surgery is more complex in patients with prior corneal refractive surgery. We performed a retrospective, comparative analysis of patients who had surgically treated cataracts with a history of corneal refractive surgery, assessing the accuracy of IOL outcome predictions generated by the ASCRS calculator separately and in conjunction with other devices in multiple combinations.

Methods: The study was performed at a single site. Data from all patients with a history of uncomplicated cataract surgery, prior myopic corneal refractive surgery, and multi-platform analysis was included. Biometric measurements included Zeiss IOLMaster® 700, Zeiss ATLAS® 9000, and Oculus Pentacam®. Eyes with significant additional ophthalmic pathology affecting vision or without one-month post-operative checks were excluded. Outcomes included manifest refraction at post-operative month one, power of implanted IOL, and predicted IOL power from each group. IOL prediction error was found by subtracting the power of implanted IOL from the power of the predicted IOL. A one sample t-test to identify prediction errors significantly different from zero, an ANOVA to determine differences in IOL prediction error between groups, an F test to determine variance of IOL prediction error for each group, and a chi-square test to analyze the difference in percentage of eyes within +0.50D and +1.00D error between groups. A p-value of ≤ 0.05 was considered statistically significant.

Results: Twenty-eight eyes met inclusion criteria. Biometry alone (IOLMaster® 700) predicted significantly higher IOL power as compared to implanted IOL power (mean=0.45D). No significant difference in IOL power prediction performance, variance of IOL prediction error, or percentage of eyes within +0.50D and +1.00D of refractive prediction error was found between groups.

Conclusions: IOLMaster® 700 and Atlas® 9000 group yielded prediction error closest to zero with the highest percentage of eyes within 0.50D and 1.00D, though this result was not statistically significant. Adding parametric data achieved only 36-56% accuracy to within +0.50D.

Commercial Relationships Disclosure (Abstract): Yingna Liu: Commercial Relationship: Code N (No Commercial Relationship) | Yanyan Wu: Commercial Relationship: Code N (No Commercial Relationship) | Ping Ma: Commercial Relationship: Code N (No Commercial Relationship) | Jian Wu: Commercial Relationship: Code N (No Commercial Relationship) | Murtaza Saifee: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Arnold: Commercial Relationship: Code N (No Commercial Relationship) | Junyi Chen: Commercial Relationship: Code N (No Commercial Relationship) | Mingguang He: Commercial Relationship: Code N (No Commercial Relationship) | Yangfan Yang: Commercial Relationship: Code N (No Commercial Relationship) | Ying Han: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies showed that certain quantitative SS-OCT measurements were correlated with increased intraocular pressure, suggesting a possible association between anatomic anterior chamber configurations with glaucomatous changes. This study aims to evaluate the diagnostic performance of SS-OCT in distinguishing primary angle closure disease from control eyes, as well as primary angle closure (PAC) and primary angle closure glaucoma (PACG) from primary angle closure suspect (PACS) eyes.

Methods: In this cross-sectional study, consecutive adult patients who were diagnosed with PACS, PAC or PACG, and control patients who presented to the Zhongshan Ophthalmic Center from June 2018 to June 2019 were enrolled. A total of 385 eligible eyes from 241 participants underwent a complete ocular examination, including Goldmann applanation, gonioscopy, and SS-OCT. Eight SS-OCT images 45 degrees a part, starting from 0° were analyzed per eye. Anterior segment dimension and angle parameters were measured. The probabilities of PACD vs control, and PACS vs PAC/PACG eyes were modeled as functions of patient demographics and SS-OCT parameters using a gradient boosting machine learning approach, either using all measurements across all 8 images or using individual meridional scans only: (0°, 180°), (45°, 225°), (90°, 270°), and (135°, 315°).

Cross-validated area under the receiver operating characteristic curve (cvAUC) of the prediction models were calculated.

Results: SS-OCT showed a strong ability to identify PACD from control subjects with a cvAUC value of 0.94 (0.91, 0.96), with ACD measurement at 180° being the most predictive measurement (Figure 1). Individual meridional scans demonstrated similar diagnostic performance. SS-OCT had a moderate ability in distinguishing PAC and PACG from PACS with a cvAUC value of 0.79 (0.73, 0.85), with lens vault at 270° being the most predictive measurement (Figure 2). The vertical meridional scan (90°-270°) demonstrated the highest cvAUC values of 0.76 (0.70, 0.82).

Conclusions: SS-OCT had excellent diagnostic performance in distinguishing PACD vs control eyes but only moderate performance in distinguishing PAC/PACG eyes vs PACS eyes. As a diagnostic tool, SS-OCT holds potential in associating anterior segment anatomy with its physiologic consequences in understanding the pathway of glaucoma pathogenesis.

TITLE: Telehealth Appointments Increase the Likelihood that Patients with Diabetes and Diabetic Retinopathy Return for Recommended In-person Care

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.C. Lasalle, S. Anjum, J.L. Marx, S. Roh, D.J. Ramsey, Department of Ophthalmology, Lahey Hospital and Medical Center, Burlington, Massachusetts, UNITED STATES|C.C. Lasalle, S. Anjum, J.L. Marx, S. Roh, D.J. Ramsey, Tufts University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Claudia Lasalle: Commercial Relationship: Code N (No Commercial Relationship) | Sidrah Anjum: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Marx: Commercial Relationship: Code N (No Commercial Relationship) | Shiyong Roh: Commercial Relationship: Code N (No Commercial Relationship) | David Ramsey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this study is to determine whether telehealth (TH) appointments improve the rate of return for in-person diabetic eye exams.

Methods: A retrospective chart review was conducted to determine the rate of return for in-person diabetic eye examinations for patients with diabetes who had been seen in the Department of Ophthalmology at the Lahey Hospital & Medical Center in 2019. Since TH appointments were not initiated at the Lahey Hospital & Medical Center until March 16, 2020 in response to the COVID-19 pandemic, this study looked at only patients who were seen after this date. The main outcome was the number of in-person diabetic eye exams completed by patients who had a prior TH encounter compared with those that did not have a TH encounter. Patient demographic (age, gender, ethnicity, and race) and clinical characteristics (A1c, type of diabetes, and severity of retinopathy) were abstracted from the medical record.

Results: Of the 7,796 patients with a diagnosis of diabetes who were seen in 2019, 1,723 (22.1%) completed TH appointments in 2020. The rate of return for in-person diabetic eye examinations was significantly greater for the cohort of patients who completed a TH appointment compared with those who did not (44.6% compared with 36.5%, OR: 1.71 95% CI: 1.54 - 1.90, $p < 0.0001$). Patients with diabetic retinopathy were more likely to complete a TH visit. Of the 1,202 patients with diabetic retinopathy, 365 patients (30.4%) completed a TH appointment. In contrast, only 1,294 of the 5,999 patients (21.6%) without a history of retinopathy completed a TH appointment ($\chi^2 = 43.693$, $p < 0.0001$). For both groups the likelihood that a patient would subsequently complete an in-person diabetic eye exam increased after the completion of a TH encounter: 74% of patients with diabetic retinopathy completed an in-person visit after a TH appointment, compared with 49.6% of patients who returned for in-person care without a prior TH appointment (OR: 2.89; 95% CI: 2.20 - 3.79, $p < 0.0001$). Similarly, 44.6% of patients without retinopathy who completed a TH visit returned for in-person care, compared with only 36.5% who did not complete a TH visit (OR: 1.40; 95% CI: 1.24 - 1.59, $p < 0.0001$).

Conclusions: TH appointments are an effective method to improve the likelihood that patients with diabetes and diabetic retinopathy will return for recommended in-person care.

TITLE: Substrate stiffness modulates gene expression and phagocytosis in segmental human trabecular meshwork cells

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Nartey, K. Dhamodaran, V. Raghunathan, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|J. Staverosky, J.A. Vranka, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrews Nartey: Commercial Relationship: Code N (No Commercial Relationship) | Kamesh Dhamodaran: Commercial Relationship: Code N (No Commercial Relationship) | Julia Staverosky: Commercial Relationship: Code N (No Commercial Relationship) | Janice Vranka: Commercial Relationship: Code N (No Commercial Relationship) | VijayKrishna Raghunathan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aqueous humor outflow in the trabecular meshwork (TM) is segmental with regions of high- (HF) or low-flow (LF) that vary in their molecular signature, biomechanics, and response to pressure. Whether these changes are driven by cells or their microenvironment is unclear. Recently, we isolated HF and LF TM cells and found differences in gene expression and extracellular matrix (ECM) stiffness. We hypothesize that cells from these regions are intrinsically different and exhibit phenotypes that vary as a function of substrate stiffness and differ in phagocytic function.

Methods: Using whole human globe perfusion, HF and LF TM were delineated using cell mask orange, a plasma membrane stain. Primary human TM (hTM) cells [n=3 non-glaucomatous donors] were isolated and primary cultures established. Cells were seeded on substrates of relevant stiffness: soft hydrogel (3kPa to mimic normal HF), stiff hydrogel (80kPa to mimic glaucomatous LF) or glass (>1GPa). RT-qPCR was used to determine relative expression levels of COLIV, TIMP1, SPARC, CTGF, and MMP1 genes. HF and LF hTM cells were cultured on these substrates with or without dexamethasone (DEX) for 72 h. Phagocytic ability was measured using quantitative phagocytosis assay.

Results: CTGF mRNA levels were upregulated in HF compared to LF cells (3-fold change) seeded on stiffer substrates. MMP1 and TIMP1 were overexpressed in LF relative to HF cells (1.5-fold change) and expression levels of both were higher on soft substrates. SPARC was upregulated in HF compared to LF cells on soft substrates (2.3-fold change). Phagocytic ability of HF and LF hTM cells was higher on soft substrates and attenuated on stiffer substrates (1.5-2.5-fold change). DEX impaired phagocytosis in both HF and LF cells on soft and stiff substrates (2-fold mean decrease), but not on glass. Following DEX treatment, LF cells seeded on soft and stiff substrates showed a decline in phagocytic uptake by 18-40% compared to their HF counterparts.

Conclusions: Our data demonstrate that HF and LF hTM cells have intrinsic phagocytic differences, a critical property in facilitating aqueous humor outflow and maintaining intraocular pressure homeostasis in TM tissues. That substratum stiffness can differentially mediate phagocytosis and expression of ECM genes in these cells highlights an intricate dynamic relationship between biophysical and biochemical cues in segmental TM cells.

ABSTRACT BODY:

Purpose: Anti-VEGF injections are essential to maintaining and/or improving ocular conditions including neovascular age-related macular degeneration (nAMD) and diabetic retinopathy. This study aims to assess the effect of unintended delays in anti-VEGF treatment during the first wave of the COVID-19 pandemic.

Methods: This retrospective case series identified patients receiving regularly scheduled anti-VEGF injections from two practices in Minnesota. Diagnoses were limited to nAMD, DME, proliferative diabetic retinopathy, and RVO. Patients were grouped based on whether they maintained or delayed their 'post-lockdown follow-up visit' by more than two weeks during the COVID-19 lockdown. The COVID-19 lockdown was declared on March, 28th, 2020 in Minnesota. Visual acuity and structural changes to the retina using ocular coherence tomography (OCT) were assessed to determine whether delayed treatment resulted in worse visual outcomes.

Results: A total of 167 eyes from 117 patients met criteria for inclusion in this study. In the delayed group, the average BCVA at the pre- and post-lockdown visits were 0.614 and 0.715 (logMAR) respectively ($p=0.007$). Treatment intervals were shortened in 21% of patients delayed by 2-4 weeks, 68% of patients delayed by 5-8 weeks, and 42% of patients delayed greater than 9 weeks. Central subfield thickness (CST) increased from 341 to 447 in the DME delayed group ($p=0.03$) and from 301 to 314 ($p=0.4$) in the nAMD delayed group.

Conclusions: These results suggest that treatment delays may negatively impact the visual and anatomic outcomes of patients with nAMD and DME. Further investigation with a larger sample size is ongoing.

TITLE: Temporal Trends in Prevalence of Diabetic Retinopathy Screening Amongst Patients with Diabetes in an Urban Setting: A Canadian population-based study over a decade

SESSION TITLE: DR: Epidemiology and service provision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Felfeli, M.H. Brent, D. Wong, Department of Ophthalmology and Vision Sciences, University of Toronto, Toronto, Ontario, CANADA|T. Felfeli, Institute of Health Policy, Management and Evaluation, University of Toronto Dalla Lana School of Public Health, Toronto, Ontario, CANADA|D. Wong, Department of Ophthalmology, Unity Health Toronto, Toronto, Ontario, CANADA|M.H. Brent, Department of Ophthalmology, Toronto Western Hospital, Toronto, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Tina Felfeli: Commercial Relationship: Code N (No Commercial Relationship) | Michael Brent: Commercial Relationship: Code N (No Commercial Relationship) | David Wong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Early identification of diabetic retinopathy (DR) with screening eye examinations allows for secondary prevention of acquired vision impairment. This study aimed to determine the temporal change in prevalence of DR screening based on patient profiles in a representative Canadian population in an urban setting over ten years.

Methods: This is an analysis of a nationally representative sample of patients with diabetes from the Ontario Diabetes health claims database for 2011-2015 and 2016-2020. The cohort was created using algorithms with ICD diagnosis codes applied to physician billing claims for adults aged 19 years and greater. Prevalence estimates, odds ratio (OR) and 95% confidence intervals (CI) for DR screening based on baseline clinical characteristics and sociodemographic factors were calculated.

Results: Of 1,346,578 patients with diabetes, 455,027 (34%) had not been screened for DR in 2016-2020, which was higher than the number of unscreened patients in 2011-2015 (OR=0.93; 95% CI=0.92-0.93; $p<0.001$). The mean duration of diabetes amongst patients unscreened for DR increased between 2011-2015 to 2016-2020 (9.15 ± 6.80 vs 10.67 ± 7.02 ; $p<0.001$). Although DR screening amongst young adults of 20-39 years old increased from 2011-2015 to 2016-2020 (OR=1.17; 95% CI=1.14-1.20; $p<0.001$), this age group persistently had the highest proportion of unscreened patients than other age groups (58% for 20-39 years old vs 42% for 40-64 years old and 24% for 65 years and older). Immigrants were less likely to have been screened for DR compared to non-immigrants (OR=0.67; 95% CI=0.66-0.68; $p<0.001$). When patients were stratified by access to primary healthcare, those who had a family physician were more likely to be screened for DR (OR=2.31; 95% CI=2.26-2.36; $p<0.001$).

Conclusions: Approximately a third of patients with diabetes in an urban setting in Canada have not been screened for DR. The proportion of unscreened patients has increased over the past decade with the population growth and chronicity of diabetes. Of all patients with diabetes, young adults, immigrants and those not under the care of family physicians are at highest risk of not being screened for DR. These findings guide resource allotment aimed at improving the rates of screening eye examinations for DR.

TITLE: Using Intraoperative Triamcinolone Acetonide Irrigation to Reduce Post-Operative Pain from Scleral Buckle Surgery

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Vaidya, V. John, Virginia Tech Carilion School of Medicine, Roanoke, Virginia, UNITED STATES|R. Albuquerque, M. McClintock Jr, V. John, Retina, Vistar Eye Center, Roanoke, Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Parth Vaidya: Commercial Relationship: Code N (No Commercial Relationship) | Romulo Albuquerque: Commercial Relationship: Code N (No Commercial Relationship) | Micheal McClintock Jr: Commercial Relationship: Code N (No Commercial Relationship) | Vishak John: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Scleral buckle surgery is a widely used ophthalmic surgery for the correction of rhegmatogenous retinal detachment. Studies suggest that eye pain is a common and underestimated occurrence after scleral buckle surgery, but as of yet, there is no definitive management method for reducing pain following scleral buckle surgery. We aim to control pain following scleral buckle surgery with sub-tenon irrigation with triamcinolone acetonide at the time of surgery. Using a randomized prospective clinical study, we test if this technique will reduce the pain, nausea/vomiting, and analgesic use caused by scleral buckle surgery.

Methods: Forty-eight patients undergoing scleral buckle surgery will be randomized into two groups. The experimental group receives a sub-tenon irrigation of 1 cc 40mg/mL triamcinolone acetonide around the base of the scleral buckle (0.25 cc in each quadrant) at time of operation. The control group does not receive any triamcinolone irrigation. Pain scores are measured 1 day post-operatively via 11-pt numerical rating scale as the primary outcome. The nausea/vomiting score is measured 1 day post-operatively via standard 6-pt scale. Patients track pain medication use via pill count. Values will be measured again at 1-2-week and 6 months post-op.

Results: With 13 patients enrolled, pain was reduced in the experimental group at one day ($x = 2.2$ vs 1.1) and one week post-operatively ($x = 0.8$ vs 0.0), though the difference is not statistically significant ($p = 0.23$ and 0.099 respectively). Acetaminophen use was not significantly different between the groups ($x = 3125, 2750$ mg, $p = 0.85$), nor was ibuprofen use ($x = 600, 683$ mg, $p = 0.9$). The nausea/vomiting score was not significantly different between the groups ($x = 0.2, 0.11$, $p = 0.6$). Not enough patients have reached the 6-month time point for statistical analysis.

Conclusions: Though it is not statistically significant at this time, there is a measurable decrease in median pain score between the control and experimental group at both 1 day and 1 week post-op. We are optimistic this will trend towards significance as we continue to enroll patients. No significant differences or trends could be established with the nausea/vomiting score or analgesic use. This study shows that sub-tenon irrigation of triamcinolone acetonide at the time of scleral buckle surgery may be a promising method for reducing post-operative pain.

ABSTRACT BODY:

Purpose: Despite growing literature looking at factors that contribute to the closure of full-thickness macular holes, there are still gaps in our knowledge. This study sought to examine the role of preoperative and intraoperative factors in predicting anatomic and visual success of vitrectomy for full-thickness macular holes.

Methods: A retrospective chart review of cases in calendar 2019 was conducted at the University of Wisconsin. Inclusion criteria included vitrectomy for macular hole and pre- and post-operative imaging. Successful closure was defined as the absence of a full-thickness disruption by imaging. Data was summarized using the median and inter quartile range (IQR; span from 25th to 75th percentile capturing central 50% of the sample) for continuous features or with frequencies and percentages for categorical factors. Risk factors associated with hole closure were compared between groups using either rank-sum procedures or Fisher's exact tests. Odds ratios and supporting 95th confidence intervals (CI₉₅) were computed for categorical factors by inverting Fisher's exact test or using logistic regression with Firth's correction in cases where the explanatory factor had more than two levels and data especially sparse. Analyses were performed using R (ver. 4.0.3).

Results: There were 64 subjects who met inclusion criteria and had vitrectomy for macular hole (Table 1). One had a traumatic injury and was especially young (< 15 years old) at the time of repair; all others were between 48.8–87.4 years at time of surgery. Internal limiting membrane was peeled in all cases (1 in a prior surgery). Hole closure was successful for 57 subjects (89%); 55 (86%) had single surgery success. Age, lens status, prior hole repair, and chronicity (present > 1 year) were not associated with the outcome ($p > 0.10$ for each). Pathologic myopia or staphyloma ($n=8$, 12.5%) was associated with lower odds of success (OR=0.14; CI₉₅: 0.02-0.86, $p = 0.036$). Median minimum hole diameter (MHD) was 335.2 μ m. Larger MHD was greater among those who had an unsuccessful repair, but not significantly ($p = 0.071$). Data suggest an estimated 71% (CI₉₅: 42-100%) chance a subject with an unsuccessful outcome would have a larger MHD.

Conclusions: The study suggests that the factors that portend a decreased likelihood of a successful macular hole surgery include pathologic myopia/staphyloma and larger MHD.

ABSTRACT BODY:

Purpose: Scleral microstructural and mechanical properties can be affected by myopia. Second harmonic generation (SHG) microscopy can glean information about collagen microstructure whereas scanning acoustic microscopy (SAM) is sensitive to bulk mechanical tissue properties. This study used SHG and SAM to investigate the relationship between tissue microstructure and mechanical properties in myopic guinea pig (GP) eyes.

Methods: One week of form-deprivation myopia was induced in the right eyes of four 1-week-old GPs. Left eyes were untreated controls. GPs were euthanized at 14-days of age; both eyes were enucleated, slowly fresh frozen, and stored at -80°C . Whole unfixed globes were vertically cryosectioned every $12\mu\text{m}$. Posterior regions of adjacent tissue sections were scanned with SAM (250-MHz transducer) or SHG (860nm excitation wavelength). Maps of bulk modulus (K), mass density (ρ), sound speed (c), and acoustic attenuation (α) were estimated from SAM data using a Fourier-domain, model-based inverse method. A curvelet-based analysis method operated on SHG images to estimate collagen fiber length (L), straightness (S), orientation (O), and width.

Results: Differences in mean material properties between control and myopic (-5.54 , -3.21 , -9.29 , and -7.13 D) eyes were $\Delta c = -17.55 \pm 5.81$ m/s, $\Delta K = -0.11 \pm 0.2$ GPa, $\Delta \rho = -0.01 \pm 0.002$ g/cm³, and $\Delta \alpha = -0.37 \pm 0.19$ dB/MHz/cm (all $p < 0.05$). Comparing estimated collagen fiber characteristics to material parameters, the standard deviation of O (σ_O) most strongly correlated with ρ and α ($r = 0.79, p < 0.0001$ and $r = -0.75, p < 0.0001$) while S was most strongly correlated with c and K ($r = -0.63, p = 0.001$ and $r = -0.52, p = 0.01$). Associations were weak between control eye L and σ_O with distance from the optic nerve head (ONH, $r = -0.64, p = 0.05$ and $r = -0.43, p = 0.22$) whereas myopic eye L and σ_O were positively correlated with distance ($r = 0.86, p = 0.001$ and $r = 0.83, p = 0.003$). Similarly, K, c, and α did not vary with distance in control eyes (all $p > 0.5$) but increased further from the ONH in myopic eyes ($r = 0.83, 0.9, 0.72, p < 0.001$).

Conclusions: Bulk mechanical parameters measured with SAM correlated with collagen fiber microstructure, particularly fiber orientation. Results of this study demonstrate the effect of myopia on scleral tissue microstructure and subsequent changes in bulk tissue mechanical properties. SAM may be effective for assessing microstructural and mechanical changes associated with myopia.

TITLE: Vascular Endothelial Growth Factor-A (VEGF-A) and High Myopia in Marmosets

SESSION TITLE: Refractive control: Molecular and Anatomical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: X. Zhu, A. Nour, A. Benavente-Perez, Biological and Vision Sciences, SUNY College of Optometry, New York, New York, UNITED STATES|S. Dellostritto, SUNY College of Optometry, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Xiaoying Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Dellostritto: Commercial Relationship: Code N (No Commercial Relationship) | Ana Nour: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Benavente-Perez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The exact mechanisms leading to myopic ocular complications are unclear. VEGF has been suggested to play a key role in myopic choroidal neovascularization (CNV), which can lead to irreversible vision loss. VEGF signals endothelial cells to proliferate and migrate causing neovascularization, and is upregulated during ischemia-related myopic axial elongation. This suggests that VEGF may be a direct trigger of myopic CNV. This study investigates the associations between retinal and choroidal VEGF-A concentrations with myopia development and RPE thickness.

Methods: Two-month old marmosets ($n = 10$) wore -5.00 or -10.00 D soft contact lenses for 18 to 38 weeks to induce myopia and axial elongation of various degrees. Refractive error (RE) and axial length (AL) were measured using a Nidek autorefractor and A-scan biometer, respectively, before and after lens treatment. Foveal and parafoveal RPE thickness were measured using optical coherence tomography (OCT) at the end of lens treatment, after which retinal and choroidal VEGF-A concentrations were quantified using ELISA.

Results: Eyes exhibiting myopia had greater axial elongation ($R^2 = 0.50$, $p < 0.001$). The degree of eye growth and myopia developed correlated with retinal VEGF-A concentration, such that larger and more myopic eyes exhibited lower retinal VEGF-A concentrations ($R^2 = 0.27$, $p = 0.037$ and $R^2 = 0.34$, $p = 0.009$, respectively). There was also a trend towards increased choroidal VEGF-A concentrations in myopic eyes that exhibited thicker nasal parafoveal RPE, but it did not reach significance ($R^2 = 0.40$, $p = 0.07$).

Conclusions: VEGF-A concentration changed in marmoset eyes with different degrees of myopia and axial elongation. Low myopic eyes had higher VEGF-A concentrations than high myopic eyes. These differences could be due to a diluting effect caused by increased eye size/volume with a higher turnover rate, or represent an altered physiological production due to sustained RPE cellular stretch.

TITLE: In vivo optoretinography reveals photoreceptor inner segment ellipsoid as the signal source of the second hyperreflective OCT band of outer retina

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Ma, T. Son, T. Kim, X. Yao, Bioengineering, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|X. Yao, Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Guangying Ma: Commercial Relationship: Code N (No Commercial Relationship) | Taeyoon Son: Commercial Relationship: Code N (No Commercial Relationship) | Tae-Hoon Kim: Commercial Relationship: Code N (No Commercial Relationship) | Xincheng Yao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study is to verify anatomic and physiological correlates of the second (2^{nd}) hyper-reflective band in optical coherence tomography (OCT) of the outer retina.

Methods: Wild type mice (C57BL/6J) were used for this study. A custom-designed OCT was employed for dynamic near-infrared (NIR) imaging of the retina activated by a visible light flicker stimulation. Stimulus-evoked intrinsic optical signal (IOS) changes at individual retina layers were measured. Spatiotemporal properties of the IOS changes at the photoreceptor outer segment (OS) and inner segment (IS) were investigated. Comparative analysis of structural OCT reflectance and functional IOS change at the photoreceptor intersegment ellipsoid (ISe) was implemented to evaluate the signal source of the 2^{nd} hyper-reflective OCT band of the outer retina.

Results: Rapid IOS change was observed at the OS right away after the stimulation (Fig. 1), and the early OS-IOS was predominantly distributed at the boundaries connected to the IS and RPE. On contrary, the IS-IOS showed a time delay and a relatively slow time course. The IS-IOS distribution perfectly matched the location of the 2^{nd} OCT band of the outer retina. High-speed OCT recording disclosed robust OS-IOS within 2 ms, and the IS-IOS showed a time delay of ~ 12 ms relative to the stimulus onset. The average OCT intensity of IS showed a gradual increase after the retinal stimulation, while the intensity of OS remained the same.

Conclusions: The consistency of the spatial distribution of the stimulus-evoked IS-IOS and the 2^{nd} OCT band supports the ISe, which has abundant mitochondria, as the signal source of the 2^{nd} OCT band of the outer retina.

TITLE: Optimizing transfection and transduction-based gene delivery in primary and immortalized RPE cells

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Shaw, Cell Biology, Neurobiology, Anatomy, Medical College of Wisconsin, Milwaukee, Wisconsin, UNITED STATES|D.M. Lipinski, Department of Ophthalmology and Visual Sciences, Medical College of Wisconsin, Milwaukee, Wisconsin, UNITED STATES|D.M. Lipinski, Nuffield Laboratory of Ophthalmology, University of Oxford, Oxford, Oxfordshire, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Erika Shaw: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Lipinski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dry age-related macular degeneration (AMD) is the leading cause of blindness in the elderly and is characterized by the formation of deposits, termed drusen, between the retinal pigment epithelium (RPE) and Bruch's membrane, a selectively permeable barrier that separates the RPE from the choroid. As such, a therapeutic approach capable of breaking down drusen would be beneficial for the treatment of the early stage AMD. A dichotomy exists, however, wherein the delivery of new genetic material to immortalized or primary RPE cells in vitro is highly inefficient, yet the same approaches applied in vivo results in highly efficient gene delivery. As a consequence, the aim of this study is to evaluate methodologies to increase transgene delivery efficiency in vitro using immortalized ARPE19 and primary bovine RPE cells.

Methods: ARPE19 cells (N=5 wells/reagent) were seeded in 6-well plates at passages 23 through 30; primary bovine RPE cells were seeded at 50,000 cells per well without being passaged. At 70% confluency a GFP reporter construct was delivered either by transfection using 1) Lipofectamine, 2) LTX, 3) P3000 or 4) PEI (polyethylenimine) reagents, or through transduction by addition of 1.2×10^{11} vector genomes (vg) of rAAV2/1 directly into media. After 72 hours cells were fixed and gene delivery efficiency quantified by fluorescence microscopy and flow cytometry.

Results: Lipofectamine LTX and P3000 were the most effective transfection reagents with 20.0% transfection and 32.4% transfection at P26, respectively. Transfection efficiency was found to be dependent on cell passage number among all transfection reagents (Figure 1). Specifically, Lipofectamine LTX and P3000 both demonstrated statistically significant decreases in transfection efficiency between passage number P27 and P28, which persisted through P30 ($p < 0.0001$, one way ANOVA with Tukey's multiple comparisons).

Conclusions: Through this study, we identified the most effective method of transfection for transgene delivery into ARPE19 cells in vitro, which we expect to help facilitate the screening of novel therapies to prevent dry AMD.

Rosenberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Chief residents (CRs) must develop specific leadership competencies. A defined curriculum for this training has not yet been established. We developed an innovative training program for the incoming July 2020 CRs and performed a prospective study to evaluate the effectiveness of the curriculum.

Methods: Twenty incoming 2020-2021 CRs participated in a training program prepared and housed by the Department of Ophthalmology at Montefiore Medical Center (Bronx, NY, USA). Self-assessment surveys were distributed to the participants to evaluate their personal leadership qualities prior to, and six months following their participation in the training program. Additionally, Program Directors (PDs) evaluated the leadership competencies of their 2020-2021 CRs six months following their participation in the program, the results of which were compared to PD evaluations of the prior year's CRs. All surveys were anonymous. Scores ranged from 1 (unsatisfactory) to 5 (mastery), and the statistical difference in average scores was examined using a nonparametric Mann-Whitney U-test.

Results: Participating specialties included Ophthalmology, Anesthesiology, Dermatology, Nuclear Medicine, Obstetrics/Gynecology, Pathology, Physical Medicine and Rehabilitation, Radiation Oncology, and Radiology. CRs felt that the program's stated objectives were met with mean scores of 4.55/5. CR's self-assessment scores showed improvement ($p=.0004$). While no statistically significant improvement was seen in the PD evaluations, the mean scores of several key questions were higher for the 2020-2021 residents than the 2019-2020 residents: addressing conflict diplomatically (4.17 vs. 4.12), maintaining one's emotions (4.25 vs 4), and organizing well (4.42 vs. 4.06).

Conclusions: This study confirms that the training program was beneficial, especially by self-report of the participants. Changes in PD evaluation scores were not statistically significant, but this may be due to the 2020-2021 participants having served six months as CR while the 2019-2020 comparative group was evaluated after a full year. A formal program including multiple specialties allows for ophthalmology CRs to learn from their colleagues and facilitates a more organized approach to the acquisition of leadership qualities.

ABSTRACT BODY:

Purpose: Early detection and treatment of diabetic retinopathy (DR) is important for preventing vision loss. We conducted a cross-sectional clinical study to assess the effectiveness of a teleophthalmology screening program that used non-mydriatic fundus photography (nFP) in a low-risk, well-insured suburban population of patients with diabetes.

Methods: 214 patients due for annual diabetic eye screening with no prior history of DR were recruited to undergo nFP through their primary care providers at eight Beth Israel Lahey Health locations. Two 40° color fundus images centered on the disc and macula were obtained of both eyes and transmitted to a retinal specialist for remote review. The characteristics of these patients were compared to those of the total patient population eligible for nFP, as well as a 1:10 age-, sex-, and race-matched cohort. Income was estimated by the average household income based upon patients' zip code. Patients in the teleophthalmology group who were diagnosed with DR through the program were compared with those who screened negative. Chi-square analyses and z-tests were performed for significance and odds ratios were computed for effect size.

Results: The teleophthalmology program enrolled patients of lower income ($p = 0.010$) and with worse diabetes control as measured by HbA1c (7.39 ± 1.65 versus 7.05 ± 1.46 , $p = 0.004$), when compared with the matched cohort. These patients were also less racially diverse, younger, and more likely to be male. Interestingly, these patients had lower blood pressures ($<140/90$ mmHg) and had had more recent eye exams, microalbumin tests, and HbA1c measurements than the matched cohort. A total of six patients (2.8%) were diagnosed with DR as a result of screening by nFP. This rate of new DR was within the expected range in such a low-risk population comprising mainly patients who had recently had a negative eye examination ($\chi^2 = 0.148$, $p = 0.701$; $\chi^2 = 1.678$, $p = 0.195$). Prior diabetic renal disease was predictive of new DR (OR 7.50 95% CI 1.25 – 44.82, $p = 0.010$).

Conclusions: The teleophthalmology program successfully reached a more medically-vulnerable patient population and found a rate of DR consistent with the expected rate of new DR in a low-risk population. Expanding nFP as a component of health maintenance outreach to patients from underserved cohorts will be potentially effective for proactively preventing complications from diabetes.

ABSTRACT BODY:

Purpose: TrkB is a receptor for the neurotrophin BDNF and activation of TrkB upon ligand binding exerts neuroprotective effects on retinal ganglion cells (RGCs). In this study, to strengthen the efficiency of gene therapy, we developed a membrane-targeted form of mutant TrkB that contains only the intracellular region of TrkB (iTrkB) as an AAV vector. We then examined the therapeutic effects of AAV-iTrkB on neuroprotection and optic nerve regeneration.

Methods: GLAST KO mice, a mouse model of normal tension glaucoma, and the optic nerve crush (ONC) model were used for examining the effects of AAV-iTrkB. AAV-iTrkB or AAV-control was injected intravitreally into GLAST KO mice (3 weeks old) and WT mice (6 weeks old) for ONC. The number of RGCs was determined by immunostaining of the wholemount retina with an anti-RBPMS antibody and multifocal electroretinogram (mfERG) was measured for assessment of retinal function. ONC was performed 2 weeks after intravitreal administration of AAV-iTrkB or AAV-control. Regenerating axons were detected by injecting Cholera toxin B with alexa 647. Visual function was analyzed electrophysiologically by visual evoked potentials and behaviorally by the optokinetic response test and pupillary light reflex test.

Results: AAV-iTrkB treatment, without BDNF, increased the survival rate of RGCs in GLAST KO mice. Moreover, visual responses measured by mfERG were higher in AAV-iTrkB-treated mice than AAV-control-treated mice. In the ONC model, AAV-iTrkB treatment alone promoted RGC survival and induced robust axon regeneration compared with AAV-control. Regenerated axons reached their brain targets, resulting in partial recovery of visual function and behavior in some mice.

Conclusions: AAV-iTrkB is a potential candidate for treatment of glaucoma and other neurodegenerative diseases.

ABSTRACT BODY:

Purpose: To 1) determine the feasibility of remotely administering and training subjects at home on how to use Vivid Vision Perimetry (VVP-10), a portable virtual reality-based visual field test during COVID-19 shelter-in-place; 2) assess the correlation between VVP-10 and standard automated perimetry (SAP) and the test-retest variability of VVP-10.

Methods: Inclusion criteria included subjects 21 or older with glaucomatous visual field defects, and exclusion criteria included those with retinal diseases or significant cataracts. Virtual reality devices were given to subjects during clinic visits or mailed to them. Subjects were remotely trained using training software and coaching via Zoom and proceeded to take 10 tests at home over 14 days. Subject age and sex, test duration, response rate at each of the test points (fraction correct), and SAP results including mean deviation and individual test point sensitivities were recorded. The Pearson correlation coefficients of SAP mean sensitivity versus VVP-10 fraction correct for all eyes together and fraction correct of tests 6-10 versus tests 1-5 for individual eyes were calculated. A bootstrap analysis that resampled eyes with replacement was done to calculate the 95% confidence interval of the Spearman correlation coefficient between SAP sensitivity versus VVP-10 fraction correct for each point of the 54 test locations.

Results: Of the 20 subjects enrolled, 11 (55%) were male and the average (SD) age was 62.9 (10.5) years. Eight (40%) subjects were Asian and 12 (60%) were Caucasian. In total, 37 glaucomatous eyes with an average (SD) mean deviation of -6.1 (6.1) dB were analyzed. The Pearson correlation coefficient of SAP mean sensitivity versus VVP-10 fraction correct for 37 eyes was 0.68. The Pearson correlation coefficient between fraction correct in tests 6-10 versus tests 1-5 for individual eyes ranged from 0.78-0.99 (median = 0.94). Spearman correlation coefficients of SAP sensitivity versus VVP-10 fraction correct at each point ranged from 0.008-0.85 (median = 0.58).

Conclusions: We demonstrate good test-retest variability of VVP-10 and a strong correlation with SAP, both globally and in a pointwise manner. VVP-10 is portable, inexpensive, and can be used entirely remotely while producing results that are similar to the current gold standard for assessing glaucomatous visual fields.

ABSTRACT BODY:

Purpose: The Centers for Disease Control reports 28.2% of surveyed US adults had reduced access to medical care (June/August 2020) due to the COVID-19 pandemic, with 8.9% reporting reduced access to vision care. A non-mydratic digital retinal camera was piloted for deployment to the Emergency Department (ED) to help address this gap in vision care. Referrals for clinical follow-up in vision threatening diseases (VTDs) such as age-related macular degeneration, cataracts, diabetic retinopathy (DR), and glaucoma were assessed with human readers. Artificial Intelligence (AI) deep learning software was evaluated in known DR cases.

Methods: 33 patients with known VTDs (48.48% male, avg 59.33 years) and 36 control subjects (41.67% male, avg 31.33 years) were included in tele-ophthalmology screening. A Canon CR-2 Plus AF non-mydratic retinal camera captured 45-degree angle color and auto-fluorescence images of the eyes. Images (136 eyes) were graded by a certified telemedicine reader on site and an off-site clinical ophthalmologist following International Clinical Diabetic Retinopathy Disease Severity Scale (ICDRSS). Intergrader agreement between readers was evaluated with Cohen's kappa. An automated deep learning screening software optimized for DR (SELENA+, EyRIS Pte Ltd, Singapore) performed independent validation of readable color fundus images (17 eyes).

Results: 5.07% of images were deemed unreadable by graders due to poor quality. Intergrader agreement for subject referral was $\kappa = 0.710$ (95% CI 0.545-0.875, $p < .0005$), with the clinical ophthalmologist generating more referrals than the telemedicine reader. Readers had 96.97% sensitivity (95% CI 91.12-1.028) and 72.22% specificity (95% CI 57.59-86.85) in detecting referable disease. Positive predictive value was 76.19% (CI 63.31%- 89.07%) and negative predictive value was 96.30% (CI 89.17%- 1.034%). Of the 10 false positives, 6 were referred for rule out of glaucoma. Four had early stage cataracts that were deemed nonurgent. SELENA+ referred 100% of the known 9 DR patients.

Conclusions: Tele-ophthalmology deployment in the ED helps limit patient and staff exposure to SARS-CoV-2 without sacrificing evaluation for VTDs. Tele-ophthalmology readers err on the side of caution to avoid missing VTD in a given patient. Use of AI can help keep strict adherence to referral guidelines.

ABSTRACT BODY:

Purpose: To train and characterize the effectiveness of a hybrid deep learning system that combines Optical Coherence Tomography Angiography (OCTA), OCT structural data, and foveal OCT b-scans to distinguish between normal eyes, eyes with non-neovascular age-related macular degeneration (AMD), and eyes with neovascular AMD. To also determine retinal pathology features most predictive of neovascular AMD diagnosis.

Methods: We used 346 retrospective OCTA scans from patients 18 years and older; 97 were diagnosed with no significant vascular pathology (non-AMD), 169 with non-neovascular AMD, and 80 with neovascular AMD with actionable choroidal neovascularization (CNV). For each patient, an OCTA volume and an OCT structural volume were created using deep retinal, avascular, outer retina and choriocapillaris, choriocapillaris, and choroid layers as input for a 3D convolutional neural network (CNN); foveal OCT b-scans were used as input for a 2D CNN. Hybrid CNNs were constructed and trained respectively on: (1) OCTA, (2) OCTA and OCT structure, (3) foveal OCT b-scans, and (4) OCTA, OCT structure, and foveal OCT b-scans combined (Figure [1]). Each CNN's performance was evaluated via accuracy, precision, recall, and F-1 score. In addition, multinomial logistic regression analysis was conducted to determine the predictive importance of 5 retinal features (adjudicated for presence by OCTA experts) for final AMD diagnosis by experts and by CNNs: (1) intra/sub-retinal fluid (IRF/SRF), (2) scarring, (3) geographic atrophy, (4) CNV, and (5) pigment epithelial detachment.

Results: The CNN achieving highest test accuracy of 77.8% for this 3-class detection task combined OCTA and OCT structure. Next came the CNN combining OCTA, OCT structure, and foveal OCT b-scans at 75.2% accuracy. The model combining all 3 modalities had slightly higher precision, recall, and F-1 score for the neovascular AMD class. For CNNs, IRF/SRF was an important predictor for neovascular AMD vs. non-AMD eyes; the CNN was able to predict IRF/SRF presence with up to 82.4% accuracy.

Conclusions: Just as experts rely on both OCTA and OCT structure to diagnose AMD, CNNs also performed best when trained on OCTA and OCT structure combined. IRF/SRF, known to be an important predictor for neovascular AMD diagnosis by experts, was found to be important by CNNs as well and was detected with high accuracy. [1] Thakoor et al., ISBI 2021

TITLE: Spatially-Resolved Quantitative Proteomic Analysis of Proteins Involved in the Formation of the Lens Extracellular Diffusion Barrier

SESSION TITLE: Lens Biochemistry/Cataract

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Wang, K.L. Schey, Biochemistry, Vanderbilt University, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Zhen Wang: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Schey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The presence of a physical barrier to extracellular space molecular diffusion in the lens has been confirmed in multiple species including rat, bovine and human. This extracellular diffusion barrier has been proposed to restrict the movement of solutes into the lens and act to direct nutrients into the lens core via the sutures at both poles. The purpose of this study is to characterize the molecular components that could contribute to the formation of this barrier.

Methods: Three distinct regions of the lens cortex of bovine lenses were captured by laser capture microdissection guided by dye penetration. Mass spectrometry-based quantitative proteomic analysis was performed to determine protein changes. Imaging mass spectrometry was also employed to visualize protein distribution differences in the barrier region. Gene ontology enrichment analysis and protein-protein interaction network analysis were also carried out.

Results: Dye penetration showed that lens fiber cells shrink the extracellular spaces of the broad sides of fiber cells first followed by closing the extracellular spaces at the short sides at normalized lens distance (r/a) of 0.9 in the bovine lens. Accompanying the closing of the extracellular spaces and fiber cell morphologic changes, dramatic proteomic changes were detected. Label free quantification, gene ontology enrichment analysis, and protein-protein interaction network analysis revealed potential proteins that could be involved in formation of the extracellular diffusion barrier include some junction proteins and cytoskeletal proteins. Imaging mass spectrometry also revealed a sharp intermediate filament transition from vimentin to lens-specific beaded filament proteins at this normalized lens distance. AQP0 and its interacting partners, ERM proteins, were among a few proteins that were upregulated in the barrier regions suggesting a particularly important role of the major lens membrane protein AQP0 in controlling the narrowing of the extracellular spaces in lens fiber cells.

Conclusions: The formation of lens extracellular diffusion barrier is accompanied by significant membrane and cytoskeletal protein remodeling.

ABSTRACT BODY:

Purpose: To demonstrate the utility of incorporation of intraoperative Swept Source-Microscope Integrated OCT (SS-MIOCT) into the 3D heads-up surgery system (NGENUITY®) during ocular surgery.

Methods: This is a retrospective study on the use of the assimilated NGENUITY® with the SS-MIOCT during anterior and posterior segment surgeries. Eight patients were enrolled. Five patients underwent pars plana vitrectomy for retinal detachment (3 cases), macular hole (1 case) and epiretinal membrane (1 case). The other 3 patients underwent Descemet Stripping Automated Endothelial Keratoplasty (DSAEK).

Images obtained with the NGENUITY® and the SS-MIOCT (B-scan and live 3D OCT images) were displayed concurrently on the same 3D 4K screen. Surgeon feedback was documented intraoperatively. Feedback included comments on image quality, visualization benefits and challenges. Postoperative analysis included evaluation of surgical and OCT image quality and review of intraoperatively documented surgeon's feedback.

Results: The SS-MIOCT was successfully integrated into the NGENUITY® in all 8 cases. The concurrent B-scan and 3D OCT view was useful for detecting residual subretinal fluid, edges of macular holes during ILM peeling, confirming graft attachment in DSAEK (Fig.1) and for live volumetric OCT visualization of instrument-tissue interaction (Fig.2).

Conclusions: The integration of the 3D heads-up surgery with SS-MIOCT could be an ideal interface for both surgical view and OCT view for tissue microanatomy. The display of the OCT data along with the surgical view on the large 4K monitor can provide excellent visualization of OCT images while maintaining the surgeon's attention on the surgical field.

ABSTRACT BODY:

Purpose: We previously reported that rearing infant monkeys under narrowband, long-wavelength lighting (630 nm) prevented the development of form deprivation myopia (FDM). The purpose of this study was to determine the effects of narrowband, short-wavelength lighting on the phenomenon of FDM in infant monkeys.

Methods: Starting at 26.4 ± 2.2 days of age, infant monkeys (*Macaca mulatta*) were reared under short-wavelength blue LED lighting (465 nm; illuminance = 183 ± 28 lux) with a diffuser lens in front of one eye and a plano lens in front of the fellow eye (FD-BL, n = 7). Refractive development, corneal power, and vitreous chamber depth were measured every two weeks by retinoscopy, keratometry, and ultrasonography, respectively. Comparison data were available from previous studies for similar diffuser rearing groups housed under white fluorescent lighting (FD-WL, n = 16) or narrowband, equal-energy, long-wavelength red lighting (630 nm; FD-RL, n = 7).

Results: All seven monkeys in FD-BL group developed at least -0.5 D of relative myopia in the form-deprived eyes during the four month treatment period. At the end of the treatment period, the mean (\pm SD) degree of anisometropia (treated eye refraction – fellow eye refraction) for the FD-BL monkeys was -2.73 ± 3.40 D and comparable to that for the FD-WL monkeys (-4.48 ± 3.73 D; T = 1.06, p = 0.30). Moreover, the developmental time course for the longitudinal interocular differences in refractive error for the FD-BL group was not significantly different from that of the FD-WL monkeys (mixed design, repeated measures ANOVA, F = 1.01, p = 0.36). In contrast, the longitudinal changes in anisometropia for the FD-RL monkeys was statistically different from that of the FD-WL monkeys (F = 4.49, p = 0.03). All the between eye and between group refractive-error differences were correlated with differences in vitreous chamber depth.

Conclusions: Unlike narrowband, long-wavelength red lighting, narrowband blue lighting did not suppress FDM, nor did it enhance the degree of myopia. These results suggest that under open-loop viewing conditions, short-wavelength lighting does not alter the eye's intrinsic axial elongation rate. However, as observed in other species, the effects of quasi-monochromatic ambient lighting on vision-dependent refractive development varies with wavelength.

ABSTRACT BODY:

Purpose: Although some investigations have examined the pathologic effects of proliferative diabetic retinopathy (PDR) on the pupillary light reflex (PLR), effects on both the direct and consensual reflex have not been fully explored. This prospective clinical study examines the effects of PDR on the direct and consensual PLR using a clinically marketed objective pupillometer not previously studied in this population. We hypothesize that diabetic retinal changes will decrease constriction amplitude absolute value and change (Ac and Ac%), velocity of constriction (Vc), and velocity of re-dilation (Vr), while prolonging latency of onset of constriction (Loc) and maximal constriction (Lmaxc).

Methods: PLR metrics of 28 right eyes (15 healthy control, 13 with PDR) were measured with the EyeKinetix Objective Pupillometer (Konan Medical, Irvine, California USA) during normal course of care in a retina clinic. Patients diagnosed with PDR were included in the experimental group. Patients with glaucoma or suspect at examination were excluded. Statistical analysis was completed using independent samples t-test.

Results: Ac, Ac%, Vc, and Vr were significantly decreased compared to the control group. Loc and Lmaxc were increased but the change was statistically non-significant.

Conclusions: This data further reinforces that pathologic changes in PDR affect pathways in the PLR. Therefore, complete quantitative characterization of PLR with pupillography metrics may be a valuable biomarker for evaluating ophthalmic disease activity in diabetic patients.

TITLE:

Efficacy of Hydrogel Carried Drug in Ocular Disease

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Hu, The Forsyth Institute, Cambridge, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Arthur Hu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

Retinal vascular diseases are the leading cause of blindness, with the most challenging aspect in their treatment being the lack of non-invasive treatment. The purpose of the present study is to investigate the therapeutic potential of a biodegradable hydrogel as a vector in delivering fenofibrate, a clinically proven oral drug, in treating retinal diseases.

Methods:

FB was packaged with PLGA, β CD, and CS - HA. The release kinetics, tissue bioavailability, and stability of each were compared and determined. FB-CS-HA hydrogel was incubated in a solution with various pH to mimic tear conditions nighttime to daytime, respectively. In vitro enzymatic degradation behavior of hydrogel was investigated at 0, 12, 24, 48, 96, 120, and 144 hours, and the bioavailability of FB was measured by HPLC-MS. The anti-inflammatory effect was examined in ARPE 19 cells exposed to LPS in either the presence or absence of FB loading hydrogel. The releasing speed and total releasing amount of FB in ARPE 19 cells were measured by flow cytometry. NF- κ B activation and the levels of inflammatory factors of monocyte chemoattractant protein-1 (MCP-1), intercellular adhesion molecule-1 (ICAM-1), and tumor necrosis factor-alpha (TNF α) were measured.

Results:

FB was released at a therapeutic dose up to 144 hours in all three hydrogels with a 1% (w/v) loading dose. The degradation of hydrogel was slightly faster in an alkaline condition and is likely pH-sensitive. FB was released at a rather stable speed up to 96 hours in the hydrogel. Exposure of ARPE19 cell in the hydrogel to LPS increased the levels of MCP-1, ICAM-1, and TNF α in the absence of FB, whereas their levels decreased in the presence of FB. Exposure of ARPE19 cells to LPS in the hydrogel in the absence of FB elevated NF- κ B phosphorylation and induced NF- κ B nuclear translocation, both of which were inhibited in the presence of FB.

Conclusions: Hydrogel contact lenses are a viable biodegradable and biocompatible tool in the delivery of clinically-proven drugs in the treatment of retinal diseases.

ABSTRACT BODY:

Purpose: Optic Nerve Head Drusen (ONHD) are calcified deposits of axonal debris that lie within the optic nerve head. Incidentally found in 2-3% of the population, there are three types of ONHD described: superficial, buried, and pearl. Over time, ONHD progress toward the surface of the optic nerve, causing severe damage and visual field (VF) loss. There are no established treatment modalities for ONHD associated VF defects. We hypothesize that TimololTM and natural supplements may play a role in reducing the development of VF defects.

Methods: Three ONHD patients were evaluated. Visual acuity, non-contact puff tonometry, color and fundus autofluorescence (FAF) photography using a non-mydratic retinal camera were captured. VF was assessed via 60-4 and 10-2 threshold tests on a Zeiss Humphrey Field Analyzer. Ganglion cell complex (GCC) and retinal nerve fiber layer (RNFL) thickness were assessed using Ocular Coherence Tomography (OCT) on an OptoVue RTVue XR Avanti. Subject 1 is a 52 y/o female with long standing OU pearl ONHD. FAF demonstrated hyperfluorescent signals encircling the optic nerve head (Figure 1) and VF testing demonstrated significant peripheral losses OU with visual field index of 8% OD and 21% OS. A daily regimen of 1000mg Citrus Bioflavonoid Complex, AREDS2 supplements and 1053mg turmeric, which have been found to have anti-inflammatory and antioxidant effects on the retina, was started. TimololTM 0.01%, once nightly, was initiated to prevent nocturnal IOP elevation.

Results: After 10 months, IOP decreased from 18mmHg to 14mmHg OU, and VF stabilization was observed. OCT showed a 4.3% increase in RNFL, no change in GCC OS, and a 32% decrease in RNFL with a 14% increase in GCC OD (Figure 2). Subject 2 is a 24 y/o female with pearl ONHD of comparable volume to subject 1 and has no observable VF, RNFL, or GCC changes due to her young age. Subject 3 is a 24 y/o female with buried ONHD OS and peripheral VF loss, RNFL thinning, and GCC loss.

Conclusions: Our findings suggest that early intervention directed at lowering IOP along with neuroprotective supplements may have a role in delaying VF loss, observed through stability on structural testing, albeit over a short period. Lower IOP may slow damage in ONHD patients, especially by preventing nocturnal IOP elevation. These findings suggest that a prospective clinical trial should be considered for patients with advanced ONHD.

ABSTRACT BODY:

Purpose: To investigate the spectrum and frequencies of genetic mutations in a cohort of patients with known or suspected retinal dystrophies and correlate them with phenotypical characteristics. Advances in next generation sequencing allow for patients to be tested in a cost-effective and rapid manner with identification of pathogenic mutations becoming more clinically relevant.

Methods: A cohort of 29 patients seen in a general retina clinic with known or suspected retinal dystrophies were evaluated with a broad genetic testing panel comprising at least 248 genes (some patients had an updated panel of 293 genes) associated with the development of retinal dystrophies. Phenotypical characteristics were analyzed and related back to their associated genetic mutations to link disease features with genotypes.

Results: Twenty-seven of 29 patients (93.1%) tested positive for a variant(s) in one or more of the genes tested. Fourteen of these patients (48.3%) tested positive for a pathogenic variant(s) in one or more of the genes tested. Thirteen patients (44.8%) were positive for genetic variants not yet associated with any particular retinal disorder (variants of unknown significance). Both patient groups had similar disease characteristics including reduced visual acuity, legal blindness, and dyschromatopsia. Two patients did not exhibit any specific genetic variants in the genes tested, but one of the two patients was discovered to have Klinefelter Syndrome (XXY).

Mutations were discovered in 69 of the 293 genes with ABCA4 and CA4 the most frequently mutated genes harboring pathogenic variants. GRM6 was the most frequently mutated gene of the variants of unknown significance.

Conclusions: This study supports the utility of genetic testing with a broad screening panel in a cohort of patients who carry a clinical diagnosis of retinal dystrophy. In this cohort, a significant number of patients had a pathogenic genetic mutation or a variant identified.

ABSTRACT BODY:

Purpose: To quantitatively characterize macrophage-like cells (MLC) at the vitreoretinal interface using optical coherence tomography angiography (OCTA) in different severity stages of diabetic retinopathy (DR).

Methods: 72 eyes of 72 subjects (age 46.0 ± 13.6 years)—18 healthy controls, 22 diabetics without DR (DM no DR), 17 with non-proliferative DR (NPDR), and 15 with proliferative DR (PDR)—were included. Repeated (average 6.5; range 3-10) OCTA scans were obtained for each eye. We segmented, registered and averaged the 3- μ m OCT slab above the vitreoretinal interface to visualize MLC distribution, and the OCTA slab of the underlying superficial capillary plexus to compare MLC distribution to vascularity. MLCs were binarized using a semi-automated method and quantified. We compared MLC density in the area overlying blood vessels, within the perivascular 30- μ m watershed region, and within ischemic areas ($> 30 \mu\text{m}$ from nearest vessel).

Results: MLC density was 6.4 ± 7.0 cells/ mm^2 in healthy controls, 7.8 ± 6.5 cells/ mm^2 in DM no DR, 5.8 ± 4.1 cells/ mm^2 in NPDR, and 21.9 ± 19.4 cells/ mm^2 in PDR. MLC density was higher in PDR compared to all other groups (2.8 to 3.8-fold; $p < 0.01$ for all). We next investigated the location of increased MLC density in PDR. MLC density was most increased in perivascular areas (4.9 to 10.2-fold, $p < 0.002$ vs. all groups), up-regulated on blood vessels (3.1 to 3.9-fold, $p < 0.012$ vs. all groups), and marginally elevated in ischemic areas (2.1 to 3.4-fold, $p < 0.033$ vs. all groups).

Conclusions: MLC density is significantly increased in PDR and was more pronounced in the perivascular region and on blood vessels compared to ischemic areas, suggesting a potential role of MLCs in retinal inflammation or damage. As the noninvasive nature of OCT precludes definitive identification of MLCs in this study, further study is needed to confirm their identity and function.

ABSTRACT BODY:

Purpose: To map the choroidal vascularity index and compare two eyes in patients with unilateral central serous chorioretinopathy (CSCR).

Methods: This was a retrospective, observational study performed in patients with unilateral CSCR. Choroidal thickness (CT) and Choroidal vascularity index (CVI) were measured and mapped in various zones according to the early treatment diabetic retinopathy (ETDRS) grid. The choroidal characteristics in each zone were compared with each other and also with the fellow eyes.

Results: A total of 20 CSCR patients (20 study and 20 fellow eyes) were included in the study. On repeated measures analysis of variance, outer nasal region CT was seen to be significantly lower than central CT ($p=0.042$) and inner nasal CT ($p=0.007$); outer ring CT was significantly less than central ($p=0.04$) and inner ring ($p=0.01$) CT in CSCR eyes. In fellow eyes, outer nasal CT was significantly lower than inner nasal ($p=0.02$), inner temporal ($p=0.02$) and outer temporal CT ($p=0.01$); outer ring CT was found to be significantly lower than inner ring CT; and nasal quadrant CT was significantly lower than superior quadrant CT ($p=0.01$) and temporal quadrant CT ($p=0.02$). CVI values were not significantly different between the different zones (Figure 1). In CSCR eyes, a positive correlation was seen between CT and CVI values ($r=0.58$, $p=0.1$). There was a weak negative correlation between CT and CVI in fellow eyes ($r=-0.183$, $p=0.64$) (Figure 2-A). The correlations were not statistically significant. On plotting all the CVI values against the corresponding CT values, a positive correlation was seen in CSCR eyes ($r=0.54$, $p<0.01$), while it was slightly weaker in fellow eyes ($r=0.3$, $p<0.01$) (Figure 2-B).

Conclusions: Correlation between CVI and CT was altered in CSCR eyes as compared to fellow eyes with increasing CVI towards the center of the macula and superiorly in CSCR eyes. This correlation could be used as a guide to detect sub-clinical activity, although future studies with higher sample size are required to validate the association.

ABSTRACT BODY:

Purpose: Purpose: To compare Haller vessel patterns between two eyes of patients with unilateral central serous chorioretinopathy (CSCR) using enface swept-source OCT scans

Methods: Methods: This was a retrospective, observational study done in patients with unilateral CSCR. We examined reconstructed, pre-treatment en-face SS-OCT images of the patients and compared the frequencies of different Haller vessel patterns between the two eyes. Two masked observers assigned pattern designations with a third observer finalizing designation in non-consensus. Continuous variables were expressed as mean \pm standard deviation. Comparisons were done using Chi-square test.

Results: Results: A total of 202 eyes of 101 patients with unilateral CSCR were included. Of the 101 patients, 29 of them (28%) were female. The mean age was 48 ± 11 years. In study eyes, the reticular was the most common pattern at a prevalence of 46%. In fellow eyes, the herringbone was the most common at 52%. The number of eyes with "herringbone" pattern ($p < 0.001$, $OR = 0.3$) was significantly higher in fellow eyes while "reticular" pattern ($p < 0.001$, $OR = 3$) was significantly higher in CSCR eyes. Other patterns such as branched from below, branched from above, double arcuate and laterally diagonal were not significantly different. A negative trend was observed when comparing herringbone pattern to age, but statistical significance was not reached. Acute CSCR had a larger number (14/49) of herringbone patterns whereas chronic CSCR had the greatest numbers (14/21) of reticular patterns, however, there was no statistically significant difference.

Conclusions: Conclusions: Reticular pattern was more common in CSCR eyes, while herringbone was more in fellow eyes. This is a similar trend to studies comparing CSCR to healthy eyes. Since we are comparing eyes within the same patient, this trend also demonstrates that eyes develop these perturbed vascular patterns in conjunction with disease progression.

TITLE: Characterization of Phospholipid Transfer Protein (PLTP) and Cholesterol Ester Transfer Protein (CETP) expression and activity levels in human Retinal Pigment Epithelium (RPE) cells

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Pivovar, L. Ibrahim, A. Yazdanyar, Ophthalmology, State University of New York Upstate Medical University, Syracuse, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrew Pivovar: Commercial Relationship: Code N (No Commercial Relationship) | Leina Ibrahim: Commercial Relationship: Code N (No Commercial Relationship) | Amirfarbod Yazdanyar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Drusen seen in Age Related Macular Degeneration (AMD) are filled with lipid particles. Phospholipid Transfer Protein (PLTP) and Cholesterol Ester Transfer Protein (CETP) are main players of lipid homeostasis systemically, however their role in lipid metabolism and drusen formation remains unknown. In this pilot study, we aim to characterize PLTP and CETP expression and activity levels in human retinal pigment epithelium (RPE) cells.

Methods: Immortalized human ARPE-19 cells were grown at 37°C to 70-80% confluence in Dulbecco's Modified Eagle Medium/Nutrient Mixture F-12 (DMEM:F12) with 5% Fetal Bovine Serum (FBS) and 1% Penicillin/Streptomycin in culture flasks before conducting experiments. PLTP and CETP protein expression levels and activity were measured on RPE cell lysate and media via western blot analysis and activity assay kits. Monolayers of cultured ARPE-19 cells were fixed and immunostained with anti-PLTP and anti-CETP antibodies to examine cellular localization of these proteins.

Results: The presence of PLTP in ARPE-19 cells was confirmed via western blot. PLTP activity in ARPE-19 cell lysate was found to be similar to its activity in WT mouse plasma. Activity assays also detected CETP activity in ARPE-19 cell lysate. Immunohistochemistry (IHC) analysis of PLTP and CETP in ARPE-19 cells was successful in visualizing both proteins but insufficient to determine possible protein localization to a cellular compartment.

Conclusions: Our findings showed that PLTP and CETP are both expressed in RPE cells. PLTP activity is measurable in RPE cells and is comparable to its activity in plasma when adjusted for protein concentration. CETP activity is present but it is low. Our data suggest that RPE cells possess the machinery for lipid production and that the study of these proteins in RPE physiology and their role in AMD pathogenesis is prudent.

ABSTRACT BODY:

Purpose: Recent studies have found that female ophthalmologist trainees and cataract surgeons perform fewer procedures than their male counterparts even after controlling for clinical productivity and parental leave. However, little is known about gender differences in practice patterns among retina specialists. Thus, we compared procedure volume among practicing male and female retina specialists in the United States.

Methods: We used the Medicare Provider Utilization and Payment Data: Physician and Other Supplier Dataset and the Physician Compare National Downloadable File to identify procedures billed in 2017. Retina specialists were defined as those who performed intravitreal injection or posterior segment photocoagulation while not billing for neodymium-doped yttrium aluminum garnet laser capsulotomy. Common retina procedures were categorized into 3 groups: intravitreal injections, posterior segment laser and surgical retinal detachment repair. We examined associations between gender and procedural volume using linear regression while controlling for providers' clinical volume, years since medical school graduation, and group practice size.

Results: In our cohort, 2,413 (82.4%) male and 516 (17.6%) female retina specialists billed Medicare for a retina procedure in 2017. Female retina specialists billed for significantly fewer clinical visits in 2017 (1,229 vs 1,807 per provider per year; $p < 0.001$) and had significantly more members in their group practice (434 vs 237 per provider; $p < 0.001$) than males. In multiple regression analysis, male gender was associated with greater annual laser volume (β , 12.2; 95% confidence interval [CI], 5.5 to 18.9; $p < 0.001$) as well as surgical retinal detachment repair volume (β , 9.61; 95% CI, 6.5 to 12.7; $p < 0.001$) after controlling for clinical volume, group practice size and years in practice. There was no significant difference in yearly intravitreal injection volume by gender (β , 171.6; 95% confidence interval [CI], -83.5 to 426.6; $p = 0.19$).

Conclusions: Female retina specialists performed fewer clinic visits and procedures than male retina specialists in 2017. After controlling for provider experience, group practice size and clinical volume, male retina specialists performed significantly greater numbers of posterior segment laser and retinal detachment procedures, however, there was a non-significant difference in intravitreal injection volume.

TITLE: Baseline choriocapillaris flow deficits in treatment-naïve neovascular AMD correlate with number of subsequent anti-VEGF injections

SESSION TITLE: AI in the retina/ AMD imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.L. Nesper, N. Konopek, J.X. Ong, A.A. Fawzi, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Peter Nesper: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Konopek: Commercial Relationship: Code N (No Commercial Relationship) | Janice Ong: Commercial Relationship: Code N (No Commercial Relationship) | Amani Fawzi: Commercial Relationship(s);NIH grant R01 EY31815:Code F (Financial Support);Research instrument support by Optovue, Inc., Fremont, California, USA:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Using optical coherence tomography angiography (OCTA), we tested the hypothesis that baseline choriocapillaris flow deficits surrounding treatment-naïve choroidal neovascular membranes (CNV) correlate with the number of subsequent anti-vascular endothelial growth factor (VEGF) injections during the course of treatment for age-related macular degeneration (AMD).

Methods: We used a semi-automated method to compensate for focal and global signal attenuation of the treatment-naïve choriocapillaris. We then binarized the choriocapillaris using the local Phansalkar and global MinError(I) methods. We quantified flow deficit density (FDD) in the 200 µm annulus surrounding the dark halo of the CNV and the entire area outside the dark halo of the CNV. We used Pearson r and t-tests to compare FDD at baseline with number of anti-VEGF injections received from 6 to 12 months and 12 to 24 months after starting therapy

Results: Our initial analysis included 9 eyes of 9 patients (6 females; age 69.9 ± 5.7 years). The number of anti-VEGF injections, which ranged from 1 to 6 over the subsequent 6 to 12 months, was significantly correlated with greater baseline FDD in the annulus (Phansalkar, $r=0.797$, $p=0.005$; MinError(I), $r=0.690$, $p=0.020$). When assessing injections received between 6 and 12 months, eyes that received higher number of injections ($n=5$, 4-6 injections) had higher FDD in the annulus and entire area around the dark halo (Phansalkar, $p<0.05$) compared to the low injection group ($n=4$, 1-2 injections). These relationships showed a trend using MinError(I) (both $p>0.05$). No tests were significant for number of injections between 12 and 24 months.

Conclusions: The study highlights the importance of the choriocapillaris during the pathogenesis of neovascular AMD. Our results suggest an early influence for choriocapillaris deficiency on treatment response between 6 and 12 months, but more subjects are needed to confirm these results.

ABSTRACT BODY:

Purpose: Tissue transglutaminase 2 (TGM2), a protein cross-linker associated with scar tissue development following wound healing, is integral for epithelial cell migration and adhesion and involved in the transformation of keratocytes to fibroblasts and myofibroblasts ("KFM" transformation). We hypothesized that TGM2 inhibition with cysteamine hydrochloride (CH), the active compound in Cystaran[®], would not impair epithelial migration in vitro, would be safe for application to epithelial and stromal wounds, and would result in decreased corneal haze formation following stromal wound healing.

Methods: CH was applied to corneal epithelial cells in vitro and migration assays were performed. 3 New Zealand white rabbits received bilateral corneal epithelial wounds, and 8 rabbits received bilateral stromal wounds by PTK. In each trial, one eye received CH and the contralateral eye received vehicle control, QID (until healed or until euthanasia, respectively). Rabbits received daily ophthalmic examinations, inflammation scoring, and fluorescein photography. SD-OCT was also performed at fixed time-points in the stromal wound trial. Corneas from the stromal trial were collected following euthanasia at day 28 or 42, and H&E, IHC, qPCR, and Western blots were performed to assess healing and KFM transformation.

Results: Epithelial cell migration was unaffected by CH in vitro. Topical application of CH to experimentally wounded rabbit corneas was safe following both epithelial wounding and stromal wounding, with no difference in healing found between treated versus control eyes regardless of depth of wound. There was no difference in KFM transformation in vitro or in stromal haze development in vivo between CH treated and control tissues with comparable haze areas on OCT and α -smooth muscle actin expression in corneal tissue.

Conclusions: Despite previous reports highlighting the importance of TGM2 in epithelial cell processes, no effect on corneal epithelial cell migration or epithelial or stromal wound healing was found in this study. These results support the safe use of this compound in patients, including when corneal wounds are present. There was no effect on corneal scar tissue formation in this study, highlighting the need for future studies investigating additional inhibitors.

ABSTRACT BODY:

Purpose: Prompt repair of post-traumatic scleral lacerations (SLs) is suggested to restore globe integrity. When a zone 3 SL extends posteriorly, repairs can be challenging (Fig. 1). We reviewed the visual outcomes of patients with and without complete repair of zone 3 posterior SLs treated with pars plana vitrectomy (PPV).

Methods: We reviewed 110 patients with ruptured globes who underwent globe exploration and/or repair, followed by PPV for the management of traumatic vitreoretinal sequelae (i.e., non-resolving vitreous hemorrhage, retinal detachment, lens rupture, intraocular foreign body) between 2008 and 2020. Demographic, surgical, perioperative, and visual acuity (VA) data were recorded. Patients whose SL could not be entirely closed, or with signs of posterior globe rupture based on examination, CT, or ultrasonography, were included in the study. At least 6-months follow-up post-PPV was required. Bivariate analysis between the incomplete closure and the complete closure group was used to identify differences between VA. Analysis was reported as mean \pm SD. Two-tailed tests were evaluated with an $\alpha = 0.05$.

Results: Of the 110 patients identified with ruptured globes, 14 had an incompletely repaired zone 3 SL and met our follow-up criteria. The average age of patients with incomplete repair of a zone 3 SL was 43.28 ± 17.83 years. Most of these patients were men (85.71%). The average number of surgical interventions post-initial repair that these patients underwent was 2.92 ± 1.32 . Mean VA at presentation in patients with an incomplete closure was logMAR 2.47 ± 0.28 , compared to 2.36 ± 0.33 in the complete closure group ($n=7$). However, no significant difference in the mean initial VA between these two groups was detected ($p=0.46$). In addition, final VA measured on the most recent follow-up visit showed no significant difference between mean best corrected VA in the incomplete closure (2.03 ± 0.82) and complete closure (2.25 ± 0.32) groups ($p=0.49$). There were no documented cases of endophthalmitis, and one eye was enucleated. The mean final IOP in patients in the incomplete closure group was within normal limits (10.58 ± 5.93 mmHg).

Conclusions: Our study indicates that incomplete closure of posterior SLs can be compatible with good outcomes, provided early vitreoretinal intervention. Therefore, aggressive attempts at closing posterior SLs should be avoided.

ABSTRACT BODY:

Purpose: Intravital imaging approaches have emerged as a powerful technique to study cellular behaviors in the natural environment. Various intravital microscopy strategies have been used to characterize cell dynamics in live mice; however, an optical modality for large-scale imaging of ophthalmology with the subcellular resolution is still a great challenge. Here, we demonstrate a new lightsheet microscopy that enables live imaging of the anterior segment in fluorescent transgenic mice. Furthermore, we highlight the imaging of the corneal endothelium whose detailed healing process remains unclear.

Methods: The excitation source, equipped with 488, 561, and 640nm lasers, is collimated and expanded to the desired beam diameter at $1/e^2$ width of 3mm. The expanded laser beam uses an acousto-optic tunable filter to control the exposure time and wavelength selection. Two water-immersion objective lenses, 10x NA0.3 and 16x NA0.8, are used for excitation and detection respectively. During imaging, the customized eye holder is designed to stabilize the eyeball as well as minimize motion artifacts. The large-scale 3-dimensional (3D) images can be stitched by 5 sub-stacks of which dimensions are $400 \times 512 \times 250 \mu\text{m}^3$.

Results: Large-scale 3D images of ocular surfaces, including the full thickness of corneas and limbus, and the intraocular lens can be visualized. We create wounds with the precise, controllable size of $50 \mu\text{m} \times 50 \mu\text{m}$ by multiphoton femtosecond laser ablation in corneal endothelium to characterize the 4-dimensional wound healing dynamics. During homeostatic status, corneal endothelial cells were outlined in hexagonal shape without proliferation. After wounding, cells on the wound edge exhibited a latent period for about 9 hours before they started migrating as a sheet toward the wound center. This migratory phase lasted from 10 hours to about 40 hours after wounding and closed the wound. Large-scale imaging showed that endothelial cells across the entire cornea remained arrested in G1-phase during the entire healing process without division. Without replenishment of new cells, the healed wound had reduced cell density with compensatory cell enlargement.

Conclusions: This study not only broadens the application of lightsheet microscopy on intravital imaging in ophthalmology but also provides key insights into the spatiotemporal cell dynamics of corneal endothelium during wound healing.

ABSTRACT BODY:

Purpose: The Notal OCT Analyzer (NOA) is a Deep learning-based algorithm developed for Notal's Home OCT System. This study evaluated the performance of the NOA in segmentation of intraretinal fluid (IRF) and subretinal fluid (SRF) regions, and quantification of fluid volumes, in cube scans from self-imaging of subjects with neovascular age-related macular degeneration at home with the Home OCT System

Methods: The data comprised a total of 2024 B-scans, with 8 eyes contributing 3 volume scans each. Each B-scan was segmented independently by 3 human expert graders to identify and quantify IRF and SRF. Intra-group and inter-group agreement were compared (i.e., agreement between the NOA and human graders, versus within the human graders). The outcome was the Dice coefficient for segmentation comparisons (pixel-wise and compared by Bonferroni-adjusted Kruskal-Wallis test), and the Pearson correlation coefficient and absolute mean difference for volume comparisons.

Results: Of the 2024 B-scans, the number identified with fluid by Grader 1 was 449 (356 with SRF and 96 with IRF). For the segmentation, the Dice coefficient of the NOA was not statistically different from that of the human graders. For the fluid quantification, the correlation coefficient between the NOA and the human graders (mean of three) was . The absolute mean difference between the NOA and the human graders (mean of three) was 1.2 nL. This was lower than the difference between Graders 1 and 2 (1.5 nL) and Graders 1 and 3 (1.8 nL), and similar to the difference between Graders 2 vs 3 (1.2 nL).

Conclusions: The NOA performs robustly in automatically segmenting and quantifying retinal fluid from cube scans acquired by patient self-imaging using the Home OCT System. In sample of eyes, the agreement with human expert grading was very high, and was similar or superior to the level of agreement between different human experts. Automated analysis of OCT images is a prerequisite for efficient remote patient monitoring with a Home OCT System that generates data at scale over time and may be useful for patient care.

ABSTRACT BODY:

Purpose: Children with bilateral retinoblastoma (RB) receive similar treatments for each eye, however, there is often a variable therapeutic response between the eyes. Independent genomic events may occur during tumorigenesis in each eye, but these alterations are not fully understood. In this case report, we use the aqueous humor (AH) liquid biopsy to evaluate the cell-free tumor DNA (ctDNA) from each eye in a single patient with bilateral RB.

Methods: One patient with bilateral RB was included. Multiple samples of AH were obtained from each eye during routine intravitreal melphalan therapy and following enucleation of the left eye. Routine clinical blood testing was performed to determine germline RB1 status. CtDNA was isolated from the AH and sequenced on an Illumina platform to assess genome-wide somatic copy number alterations (SCNAs). The same sequencing libraries were used to identify somatic RB1 pathogenic variants using a custom hybridization and next generation sequencing panel targeting RB1. Tumor fraction (TFx) was estimated using ichorCNA software.

Results: Five AH samples from both eyes (3 from the right eye and 2 from the left eye) were included. Peripheral blood RB1 testing detected germline 13q and 16p deletions. Analysis of AH ctDNA identified a different somatic RB1 mutation and distinct SCNA profiles in each eye. Three SCNAs were consistently identified in all AH samples from the

right eye; two SCNAs were detected in each AH sample derived from the left eye. The right eye was salvaged and TFX values in this eye decreased over the course of treatment. The left eye required enucleation due to tumor recurrence and demonstrated higher TFX values.

Conclusions: We present distinct inter-eye genomic profiles in a case of bilateral RB using the AH liquid biopsy. In addition, the longitudinal alterations in TFX corresponded to therapeutic response in each eye. Identifying inter-eye genomic heterogeneity without the need for enucleated tumor tissue may help direct active management of RB, with particular usefulness in bilateral cases.

ABSTRACT BODY:

Purpose: Corneal transplants performed in inflamed high-risk(HR) host beds result in markedly higher immune graft rejection compared to low-risk(LR) setting, primarily due to maturation of host antigen-presenting cells(APCs) & their ability to allosensitize host Thelper1(Th1) cells. We examined the immunomodulatory function of regulatory T-cells(Tregs) in suppressing graft-site APC maturation in the early stages post-transplantation.

Methods: HR & LR allogeneic corneal transplantations were performed with C57BL/6 mice as donors & BALB/c as hosts. On days 3&7, post-transplantation CD4⁺CD25⁺FoxP3⁺ Tregs & phenotypic maturation markers on CD11b⁺MHC-II^{hi} APCs were assessed by flow cytometry in graft recipient mice. Tregs from graft sites were FACS sorted from HR or LR recipient mice & co-cultured to precondition bone marrow GM-CSF-generated CD11b⁺APC(1:20) in the presence of LPS(100ng/ml) & IL-2(10ng/ml) for 48 h. APC maturation markers were evaluated by flow cytometry & proinflammatory cytokine production was assessed by ELISA. Also, sorted Tregs were co-cultured with syngeneic bone marrow GM-CSF-generated CD11b⁺ APC & sonicated allogenic splenocytes(1:20:21) as above in the presence of anti-TGF β 1 blocking Ab. Subsequently, Tregs were removed, CD4⁺CD25⁻ naïve T cells were added for 5 days, IFN γ production was assessed by ELISA.

Results: Tregs frequencies & their functional phenotype (measured by FoxP3 expression) were significantly higher in LR compared to HR(p<0.01). Frequencies of MHC-II^{hi},CD80,CD86,CCR7 in CD11b⁺APC were found significantly lower in LR compared to HR(p<0.001). Expression of MHC-II, CD80, CD86, CCR7, production of IL-1 β ,IL-12 was significantly reduced in LPS-stimulated APC co-cultured with LR Tregs compared to HR (p<0.001). Blocking with TGF- β 1 antibodies abolished the suppressive effect of LR Tregs. IFN- γ production was significantly lower in the supernatant of CD4⁺CD25⁻ naïve T cells co-cultured with LPS-stimulated APC-preconditioned with LR Tregs, this effect was abolished when anti-TGF β 1 Ab was added to the preconditioned media.

Conclusions: These results provide a novel insight into the role of Tregs in suppressing APC maturation at graft-site in the early stages after corneal transplantation and, consequently, suppresses Th1 alloimmunity. These results suggest the therapeutic potential of Tregss in improving graft survival in HR corneal transplantation.

TITLE: The effect of anti-VEGF injection loading dose in diabetic macular edema as measured by hand-held ERG system

SESSION TITLE: Central Vision and ERG

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Kozak, J. Centeno, Moorfields Eye Hospital Abu Dhabi, Abu Dhabi, UNITED ARAB EMIRATES|

Commercial Relationships Disclosure (Abstract): Igor Kozak: Commercial Relationship: Code N (No Commercial Relationship) | John Centeno: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Anti-vascular endothelial growth factor (VEGF) is the first line of treatment for diabetic macula edema (DME). Previous retinal function studies using full-field or multifocal electroretinography have investigated late effects of anti-VEGF treatment on retina. The aim of this study is to follow full-field electroretinography (ffERG) changes for the first 6 months of anti-VEGF treatment using portable ffERG system.

Methods: In this prospective pilot study, eyes with diabetic macula edema and either severe NPDR or PDR have been included. Inclusion criteria were treatment naïve patients with no prior ocular surgery willing to participate in study. All patients received 3 injections in the initial loading phase with 3 months follow up and injection if needed. The retinal function has been assessed at baseline and months 1, 2, and at the last follow up - 6 months after the first injection with the full Field Flash ERG (RETeval® ERG). We measured 16Td and 32Td flash stimulus for both a- and b-wave amplitudes and implicit times. Other collected data included best-corrected visual acuity (BCVA) and spectral-domain optical coherence tomography (OCT) at every visit.

Results: Eleven eyes of 7 patients with a mean age of 54 years (range 42-67) have been included in the analysis. Patients have received on average 4 injections in the study period. The mean BCVA improved significantly from 0.41 ± 0.34 to 0.27 ± 0.29 logMar ($p=0.014$). The central retinal thickness improved from 415 ± 151 microns to 333 ± 105 microns, which was not statistically significant ($p=0.1$). The implicit time at 32Td flash intensity significantly prolonged from 32.08 ± 3.68 ms to 33.48 ± 3.05 ms ($p=0.04$) (Figure 1). There was a moderate correlation between the BCVA gain and the implicit time at baseline of $r=0.63$. The amplitudes remained unchanged and stable during the observation. In the majority of patients, the implicit time prolonged after the first injection and then slightly recovered or remained stable at the new level over the course of the following 5 months.

Conclusions: The best corrected visual acuity improved significantly as a result of the anti-VEGF intravitreal treatment. The implicit time significantly prolonged after the first injection followed by stabilization with time. This might be a manifestation of an increased cell stress after the initiation of treatment to which the eye adapts over the course of the treatment.

ABSTRACT BODY:

Purpose: Despite anatomically successful surgery for fovea-on rhegmatogenous retinal detachment (RD), unexplainable loss of vision is regularly observed in these patients. We hypothesize that the retinal function loss induced by the RD extends beyond the detached area, towards the fovea. Thus, the aim of this study is to investigate the retinal sensitivity loss in relation to the distance to the RD border in patients with fovea-on rhegmatogenous RD.

Methods: We prospectively evaluated 15 patients with fovea-on RD and healthy fellow eye. Preoperatively, OCT-scans of the RD border were obtained (Spectralis-OCT2, Heidelberg Engineering). The RD border was located on the B-scans and highlighted on the SLO-image.

Microperimetry (MAIA, Centervue) was performed using a custom grid of 52 points covering the RD border and the retina on both sides. The macular area was investigated using the standard foveal centered grid of 37 points covering a circular area of 10° in diameter (Figure 1). At 6 weeks postoperatively, microperimetry was performed in the fellow eye, covering the same areas as in the study eye.

Microperimetry data was overlaid on the SLO-image and the RD border was indicated; for each sensitivity measurement, the shortest distance to the RD border was calculated. Loss of retinal sensitivity was calculated as the difference in sensitivity between the study and the control eye at each corresponding location (study-control). The relation between retinal sensitivity loss and the distance to the RD border was assessed using a locally weighted scatterplot smoothing (LOWESS) curve.

Results: Retinal sensitivity loss was 22 dB at 3° inside the RD and decreased approximately linearly to 4 dB at 2° outside the RD. The loss further decreased outside the RD until it reached a plateau of 2 dB at 6° (Figure 2).

Conclusions: Retinal sensitivity loss extends beyond the RD border towards the fovea. These results may explain the loss of vision in patients in whom the fovea has not been detached.

TITLE: Unintentional retinal displacement in eyes treated for rhegmatogenous retinal detachment with pars plana vitrectomy and silicone oil.

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. dell'Omo, M. Filippelli, P. Napolitano, I. Paiano, C. Costagliola, Department of Medicine and Health Sciences "V. Tiberio", Universita degli Studi del Molise, Campobasso, Molise, ITALY|

Commercial Relationships Disclosure (Abstract): Roberto dell'Omo: Commercial Relationship: Code N (No Commercial Relationship) | Mariaelena Filippelli: Commercial Relationship: Code N (No Commercial Relationship) | Pasquale Napolitano: Commercial Relationship: Code N (No Commercial Relationship) | Ilaria Paiano: Commercial Relationship: Code N (No Commercial Relationship) | Ciro Costagliola: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the clinical characteristics, outcomes and rate of unintentional displacement in eyes treated for rhegmatogenous retinal detachment (RRD) with pars plana vitrectomy (PPV) and silicone oil (SO).

Methods: This was a retrospective observational study. Overall, 50 eyes of 50 patients who underwent surgical repair by 23-gauge PPV and SO injection for primary RRD complicated by proliferative vitreoretinopathy (PVR) between December 01, 2018 and June 30, 2020, at a single Institutional Center, were followed. One thousand centistokes SO was used in all eyes. The patients postured face-down immediately after surgery. Blue-fundus autofluorescence (B-FAF) pictures were obtained at 1 month after surgical procedures using the Spectralis HRA+OCT (Heidelberg Engineering, Heidelberg, Germany)

Results: Primary success rate was obtained in 44 eyes (88%) on which the final analysis was conducted.

Preoperative PVR was grade A in 7 (15.9%), grade B in 28 (63.6) and grade C in 9 (20.5) eyes. Fovea was off and the detachment involved both the superior and inferior hemispheres of the retina in all cases. Breaks were located in the upper quadrants in 21 (47.7%) eyes, in the lower quadrants in 12 eyes (27.3%), and in both upper and lower quadrants in 11 (25%) eyes. Mean number of breaks was (2.4 ± 1.9) . Intraoperative PFCL was used in 30 (68.2%) eyes. Peeling of epiretinal membrane/internal limiting membrane in the macula area was performed in 13 (29.5%) of eyes during the first operation and carried out in all other eyes in occasion of SO removal. Preoperative BCVA was 2.1 ± 1.0 logMAR and improved to 0.8 ± 0.7 logMAR at the last follow-up ($P < 0.0001$). An upward unintentional retinal displacement was observed in 2 cases (4.5%).

Conclusions: Pars plana vitrectomy and SO tamponade for complicated RRD are associated with good anatomical and functional outcomes and with a very low rate of unintentional retinal displacement. Of the factors potentially implicated in favoring displacement that were studied, none was found significant.

SUBMITTER (NAME ONLY): Oi Man Mandy Wong

TITLE: Comparison of trabeculectomy and oral valganciclovir in treating cytomegalovirus anterior uveitis(CMV AU) with uncontrolled intraocular pressure(IOP)

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Wong, A.H. Yu, C.K. Chan, Hong Kong Eye Hospital, Hong Kong, HONG KONG|O. Wong, A.H. Yu, C.K. Chan, Ophthalmology and Visual Sciences, The Chinese University of Hong Kong Faculty of Medicine, Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): Oi Man Mandy Wong: Commercial Relationship: Code N (No Commercial Relationship) | Amy Yu: Commercial Relationship: Code N (No Commercial Relationship) | Carmen Chan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There has been no consensus on the treatment of CMV AU with uncontrolled IOP despite maximal topical medications. This retrospective case series described the efficacy and safety of trabeculectomy with mitomycin-C(MMC) in these patients, and compared it with previously published efficacy data on oral valganciclovir.

Methods: Forty-one eyes of 41 CMV AU patients received either trabeculectomy with MMC(n=30) or a single course(20-148 days) of oral valganciclovir (n=17) for uncontrolled IOP, with 6 in the latter requiring subsequent trabeculectomy. Clinical information, IOP and use of IOP-lowering medication/steroid at baseline and every 3 months over 2 years post intervention were recorded. Survival endpoint was defined as further intervention for uncontrolled IOP(glaucoma surgery or another course of valganciclovir). Treatment success was defined as IOP \leq 21 mmHg with same or less IOP-lowering medications compared to baseline, without systemic acetazolamide or reaching survival endpoint.

Results: For those receiving trabeculectomy, median IOP significantly dropped from 24.1(IQR: 20.5, 32.0)mmHg at baseline to 13.0(10.3, 16.2)mmHg at 24 months, while on 5.0(5.0, 5.0) and 0.0(0.0, 0.8) IOP-lowering medications, respectively, with up to 72.2% IOP reduction(Wilcoxon sign-rank test, $p < 0.01$ at all time points). Treatment success was 80% at 24 months. Those with history of/concomitant intraocular operation had shorter survival(18.8 months versus 23.5 months, log-rank test, $p = 0.041$, Fig.1). 53.5% and 30.0% had hypotony and wound leak, respectively, with no serious sequelae.

In the first interventions for IOP control (n=38, either trabeculectomy or valganciclovir), female, history of endophthalmitis and systemic acetazolamide use at baseline were associated with longer survival compared to their counterparts($p = 0.035$, 0.046 , 0.034 , respectively). After excluding one eye with prolonged valganciclovir use post-trabeculectomy, trabeculectomy group(n=22) had higher chance for treatment success at 24 months than valganciclovir group(n=15)(OR: 6.8, 95% C.I.:1.5 to 30.2), longer survival(21.9 months versus 13.6 months, $p = 0.003$, Fig 2), but less %reduction in steroid use(Fisher's exact test: $p = 0.018$).

Conclusions: Trabeculectomy with MMC is efficacious and safe for IOP control in CMV AU, with higher success than oral valganciclovir but less %reduction in steroid.

ABSTRACT BODY:

Purpose: This cross-sectional study evaluates the association of time outdoors and light exposure patterns with myopia in children from the Singapore Growing Up Towards Healthy Outcomes (GUSTO) birth cohort

Methods: We performed cycloplegic spherical equivalent (SE), myopia ($SE \leq -0.5D$) and axial length (AL) measurements in 422 multi-ethnic children (41.2% myopic; 47.6% girls; 59.5% Chinese) who attended the 9-year GUSTO visit and were not on myopia treatment (atropine and orthokeratology). Time outdoors in the past month (physical or leisure activities) was assessed with a questionnaire and outdoor activity types with an activity diary filled over 7 days. Light exposure patterns: light levels (lux), duration, timing (morning: 7-11 AM; afternoon: 11 AM-3 PM; evening: 3-7 PM) and frequency of light exposure (number of outdoor episodes ≥ 1000 lux continuously ≥ 5 mins) were measured with a wrist-worn watch (FitSight) over 14 days. Paired eyes ($n=844$) were analyzed using Generalized Estimating Equations with multivariable linear or logistic regression model

Results: Time outdoors (Mean \pm SD: 1.65 ± 1.42 hours/day) and average light levels (467 ± 231 lux) were low, with 76.0% of the daily duration of light exposure < 5000 lux. Light levels were highest during mid-day, compared to the morning or evening ($P < 0.001$). Children exhibited 1.7 ± 1.0 daily outdoor episodes. Time outdoors, the duration and frequency of light exposure were higher on weekends than weekdays ($P < 0.05$). Boys exhibited higher light levels, duration and frequency of light exposure than girls ($P < 0.05$). While outdoors, children spent the longest duration on walks, neighborhood play and swimming. In multivariable analyses, time outdoors was associated with lower odds of myopia (OR=0.79; 95% confidence interval (CI): 0.67 to 0.93; $P=0.005$) and less myopic SE ($\beta=0.15D$; 95% CI: 0.01 to 0.29; $P=0.034$) but not associated with AL ($P=0.15$). Light levels were not associated with myopia and SE but were marginally associated with AL ($\beta=-0.31mm$; 95%CI: -0.62 to -0.003; $P=0.048$). The duration, timing or frequency of light exposure were not associated with myopia, SE or AL ($P > 0.05$)

Conclusions: Increasing time outdoors was protective against myopia and myopic SE. Light levels or specific outdoor light patterns were not associated with myopia. Longitudinal studies are needed to confirm these findings

ABSTRACT BODY:

Purpose: Lengthy and unreliable visual field (VF) testing presents a burden to both glaucoma patient and clinician. We retrospectively evaluated the ability to predict VF loss from unsegmented optical coherence tomography (OCT) scans using deep learning (DL) technology.

Methods: Data used in this study consist of 1643 matched OCT-VF pairs encompassing 998 eyes of 542 patients that visited the glaucoma clinic of the University Hospitals Leuven between 2015-2019. Inclusion criteria were defined as having had a SPECTRALIS® OCT scan with the Glaucoma Module Premium Edition (scanning laser ophthalmoscopy (SLO), 24 radial scans and three circumpapillary rings), as well as a reliable Humphrey Field Analyzer (HFA) 3 exam with the strategy 24-2 SITA Standard (52 test points), performed on the same day. Data was split into train/validation/test sets on patient level, following a 60/20/20 key.

The convolutional neural network used across all experiments was an Xception model pretrained on ImageNet. The 52 output nodes feature a linear activation function to allow for regression. The model was trained using mean squared error loss and Adam optimizer. Four models were trained (using the 3.5mm, 4.1mm, 4.7mm circumpapillary scans and SLO images), which were also compared with a combined model. Analysis on the 24 radial scans was beyond the scope of this study. Performance was evaluated using Pearson's r and mean absolute error (MAE). 95% confidence intervals were obtained through bootstrap sampling.

Results: The circumpapillary scan with the largest radius (4.7mm) achieved the best performance among all individual models ($r=0.77$ [0.72-0.82], $MAE=5.08$ [4.68-5.50]). Models trained on circumpapillary OCT scans significantly outperformed the model trained using SLO images ($r=0.65$ [0.58-0.71], $MAE=5.79$ [5.23-6.38]). Model combination resulted in an $r=0.78$ [0.74-0.83] and $MAE=4.86$ [4.43-5.29]. Performance was comparable on the test set ($r=0.79$ [0.75-0.82], $MAE=4.76$ [4.40-5.15]).

Conclusions: This study is the first to report on a DL system that predicts individual VF threshold values from unsegmented OCT scans. The average correlation of 0.79 exceeds the performance of prior work that leveraged retinal layer thickness info using non-DL techniques. Fast, consistent VF prediction from OCT could become an ersatz solution for visual function estimation in patients that are unable to complete HFA exams.

ABSTRACT BODY:

Purpose: With the increasing application of funduscopically invisible retinal laser treatments, a sensitive method enabling the detection of small structural and metabolic changes is desired. Aim of this study was to apply the fluorescence lifetime imaging ophthalmoscopy (FLIO) to monitor the sites of laser irradiation to identify its potential in the evaluation of laser-induced tissue changes.

Methods: Seven eyes of Chinchilla bastard rabbits were treated in vivo using a diode laser with a wavelength of 514 nm, spot diameter of 85 µm and single pulses with duration of 5.2 or 50 µs with different power settings. FLIO (excitation at 473 nm, detection with short spectral channel (SSC, 498-560 nm) and long spectral channel (LSC, 560-720 nm) was conducted directly and one week after irradiation. Structural changes were examined by optical coherence tomography (OCT).

Results: Selective damage of retinal pigment epithelium (RPE) was induced with the shorter pulse duration with the power up to 5.6 W, while visible photocoagulation was achieved with the longer pulses and maximum power of 11 W. Directly after irradiation the FLT at laser spots was highly extended (SSC: 1142±109 ps; LSC: 461±47 ps) compared to the one in the non-irradiated periphery (SSC: 705±35 ps; LSC: 211±20, p<0.01). The FLT around photocoagulation was also significantly longer (SSC: 738±45 ps; LSC: 229±22 ps), whereas it was rather shorter at the further surrounding (SSC: 637±55 ps; LSC: 182±28 ps) (p<0.01). At the sites of selective RPE damage, the FLT was slightly longer in the nearby surroundings directly after irradiation, whereas, after one week, shortened over wider region, up to about 1000 µm from the spots. The longer FLT in the nearby surroundings directly after irradiation corresponded to the hypofluorescent area in fundus autofluorescence (FAF), and also to the disruption of ellipsoid zone and external limiting membrane in OCT. These changes in FAF and OCT were no more visible after one week.

Conclusions: Extension of FLT at laser spots is considered due to RPE damage, whereas the longer FLT in their surroundings directly after irradiation might be a result of temporary change of photoreceptor, and the later shortening due to tissue metabolic alterations. FLIO may therefore be a sensitive tool to monitor subtle structural as well as metabolic changes following laser treatment.

ABSTRACT BODY:

Purpose: To create an exhaustively optimized single cell retina single cell transcriptome dataset created from all publicly available retina single cell transcriptomes. We use this dataset to provide the basis for a highly responsive reactive web app for querying gene expression across retina cell type, study, species, developmental stage, and other factors. Second, we demonstrate how research groups can project their private single cell experiments onto our reference retina single cell atlas with minimal compute resources.

Methods: We re-quantified over 1 million single cell transcriptomes across three species, 30 studies, and 7 single cell technologies. After quality control we retain over 700,000 high quality transcriptomes. To optimize the batch correction, we tested 12 independent tools methods and benchmarked them with an un-biased algorithm to identify the optimal method and parameters. After batch correction we create a 2 dimensional UMAP projection, run thousands of differential gene expression tests across cell types, and calculate developmental trajectories for the major retinal cell types. We then hand-curated over 300,000 published retina cell type labels to create an xgboost-based machine learning tool to label all cells in our dataset.

Results: After batch correction the 2D UMAP places the retina cell types in distinct spaces with the progenitor populations in the center. The photoreceptor progenitors flow from the center into the differentiated rods and cones. Likewise, the amacrine / horizontal precursors lead into the terminally differentiated amacrine and horizontals. The retinal ganglion and muller glia are also in distinct clusters. Importantly these cell type positions are generally consistent across species and studies. Our differential testing confirms that our machine learning cell type tool correctly labels the cells based on the community knowledge.

Conclusions: Despite a high amount of technical variation between published single cell transcriptome atlases, we confirm that we can create a coherent, high-quality meta-atlas. Furthermore, we demonstrate how our meta-atlas is a community resource by illustrating projection of independent and outside single cell transcriptome data onto our meta-atlas with minimal compute and disk resources. Our dataset is made available for powerful user-led analysis at plae.nei.nih.gov.

TITLE: Outcomes of simultaneous Descemet Stripping Automated Endothelial Keratoplasty (DSAEK) and intraocular lens exchange surgery

SESSION TITLE: Corneal transplantation and surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Awidi, Y. Daoud, Cornea, Cataract and External Disease, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Abdelhalim Awidi: Commercial Relationship: Code N (No Commercial Relationship) | Yassine Daoud: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the outcome of performing simultaneous Descemet Stripping Automated Endothelial Keratoplasty (DSAEK) and Intraocular Lens (IOL) exchange surgery.

Methods: A non-randomized retrospective chart review was conducted on 41 patients. The studied outcomes included status of the intraocular lens, status of the cornea transplant, as well as best corrected distance visual acuity (BCDVA), spherical equivalent (SEQ), and intraocular pressure (IOP) pre-operatively, as well as post-operative 1 day, 1 week, 1 month, 3 months, 6 months, 12 months, and 24 months.

Results: 41 patients, of which, 49% male, and 51% female were included. At the time of pre-operative assessment, 14 patients had an ACIOL implant (34.1%), 11 had a PCIOL implant (26.8%), 8 were aphakic (19.5%), with the 8 remaining patients (19.5%) having either a sulcus or capsular bag IOL implants.

Positioning of the IOL after exchange was 19 iris-sutured (46.3%), 9 scleral-fixated/sutured (22%), 4 ACIOL (9.8%), 4 PCIOL (9.8%), 3 sulcus placements (7.3%), and 2 in the capsular bag (4.9%).

At 1 year follow up, 57% of the patients' corneal grafts were clear, 23% had corneal haze that did not require further surgery, while 23% had either corneal edema, or folds in the Descemet's membrane and stroma, that were managed medically. At the same time period, only one eye had subluxation that necessitated an IOL repositioning surgery.

Mean IOP remained consistent during the follow up periods (14.25 ± 5.85 at baseline and 15.43 ± 7.99 at one year).

Mean BCDVA improved from 1.33 ± 0.66 at baseline to 0.82 ± 0.70 at two years follow up.

Conclusions: Simultaneous DSAEK and IOL exchange surgery may offer a sustained improvement in visual acuity in patients with complex ocular history and may decrease the risk associated with increased trips to the operating room.

ABSTRACT BODY:

Purpose: The prevalence of endogenous fungal endophthalmitis varies between studies and the risk factors are poorly defined. This study aims to define prevalence in a large population and identify risk factors warranting ophthalmic evaluation.

Methods: Retrospective review of 291 inpatients with fungemia and a documented ophthalmic evaluation (January 2015-September 2019) was performed. We reviewed the presence of visual complaint, number and duration of positive blood cultures, history of gastrointestinal (GI) surgery in preceding 6 months, solid organ transplant, human immunodeficiency virus (HIV) infection, diabetes mellitus (DM), intravenous (IV) drug use, and central venous access. Student's t-test and chi-squared statistical analysis were performed.

Results: 291 patients were included; 6 had vitreoretinal involvement and 2 required intravitreal antifungal injection. Those with vitreoretinal involvement had an average of 3 positive cultures over 0.69 weeks, while those with normal findings averaged 2.85 positive cultures over 0.59 weeks ($p=0.89$, and 0.80 , respectively). History of GI surgery, organ transplant, immunocompromised state, DM, IV drug use, and central venous catheter were not found to be significant. However, 33.3% of the endophthalmitis group had a visual complaint compared to 4.20% of the non-endophthalmitis group ($p<0.001$). When grouped together, visual complaints, positive blood cultures for 3 or more days, and history of recent GI surgery were significant predictors of ocular involvement. For patients without any of these 3 major risk factors, the negative predictive value was 98.7%.

Conclusions: Patients who have visual complaints at the time of positive fungal blood culture are significantly more likely to have a positive screening examination. No other individual variables were found to be predictive of a positive screening examination. A positive examination is exceedingly rare in patients not meeting risk criteria (major factors) for screening. Serious consideration of replacing the current practice of uniform ophthalmic screening among fungemic patients with examination limited to those meeting major criteria is recommended.

ABSTRACT BODY:

Purpose: To validate a novel automated swept source optical coherence tomography (SS-OCT) algorithm to measure elevations of the retinal pigment epithelium (RPE) in eyes with non-exudative age-related macular degeneration (neAMD).

Methods: Patients with drusen were enrolled in a prospective OCT study and underwent imaging with both spectral domain OCT (SD-OCT, Cirrus HD-OCT, Carl Zeiss Meditec Inc, Dublin, CA, USA) and SS-OCTA (PLEX Elite, Carl Zeiss Meditec Inc, Dublin, CA, USA) at the same visit using the 6X6mm scan patterns. The RPE elevation measurements (square root area and cube root volume) from the SS-OCTA algorithm were compared with the corresponding measurement produces by the fully automated, validated algorithm on the SD-OCT instrument. Standard deviations of drusen measurements from 4 repeated scans were also calculated to evaluate the reproducibility of the SS-OCTA algorithm.

Results: A total of 53 eyes from 28 patients were scanned on both instruments. A very strong correlation was found between the measurements from the two algorithms (all $r > 0.95$), although the measurements of drusen area and volume were all larger on the SS-OCTA instrument (Figure 1). This systematic increase in area and volume measurements was due to a more accurate segmentation of Bruch's membrane in the SS-OCT algorithm. The reproducibility of the new SS-OCTA algorithm was analyzed using a sample of 66 eyes from 43 patients. The standard deviations were small in comparison to the means over the entire range of measurements. There were no significant correlations between the standard deviations and mean measurements of the square root of area and cube root of volume measurements between repeated scans using the SS-OCTA algorithm (Figure 2). The intraclass correlation coefficient was greater than 99% from different macular regions for both the square root area and cube root volume measurements.

Conclusions: A novel automated SS-OCTA algorithm for the quantitative assessment of drusen was validated against the SD-OCT algorithm and was shown to be highly reproducible.

ABSTRACT BODY:

Purpose: We applied an artificial intelligence algorithm to new-onset visual field (VF) loss encountered in 3 US prospective cohorts followed for primary open-angle glaucoma (POAG). The algorithm objectively quantified VF loss into archetypal patterns. We examined self-reported race in relation to the specific archetypes (ATs) of VF loss.

Methods: Participants aged ≥ 40 years who without glaucoma and reported eye examinations in the Nurses Health Study (NHS) ($n=75,767$; 1980 to 2018), NHS2 ($n=80,857$ women; 1989-2019), and the Health Professionals Follow-up Study ($n=36,838$ men; 1986-2018) were followed. Information on demographics including race, medical conditions and lifestyle were assessed with biennial questionnaires. Incident POAG cases with reproducible VF loss were confirmed by medical record review. The earliest reliable VF for the worse eye was identified, and archetypal analysis was used to identify the optimal number of VF loss patterns. Each case was classified according to the most dominant VF loss archetype. Multivariable-adjusted relative risks (RRs) for each archetype and 95% confidence intervals (CIs) were estimated using Cox proportional hazards regression on pooled data. Major covariates included cohort, age, family history of glaucoma, census-tract based socioeconomic index, number of eye exams during follow-up, and medical history such as diabetes and hypertension. False discovery rate was used to account for multiple comparisons.

Results: Mean age was 57 ± 10 years and 81% were women. Of the 1377 POAG cases, 1301 were Caucasian, 36 were of African descent, 21 were Asian, and 19 were Hispanic white. We observed 14 ATs (see Figure), of which 13 reflected function loss. We observed that having African descent compared to being non-Hispanic White was associated with ATs consistent with advanced glaucomatous loss: AT5 \rightarrow RR=2.84 (95%CI=1.26, 6.41); AT8 \rightarrow RR=5.35 (95%CI=1.79,16.0); AT10 \rightarrow RR=3.80 (95%CI=1.27,11.4); AT11 \rightarrow RR=3.79 (95%CI=1.32,10.9); and AT12 \rightarrow RR=11.43 (95%CI=3.77, 34.6). Being Asian compared to being non-Hispanic White was not significantly associated with any AT. Being Hispanic White compared to being non-Hispanic White was significantly associated with AT10 (RR=4.97; 95%CI=1.48,16.7) and AT11 (RR=6.58; 95%CI=2.56,16.9).

Conclusions: African and Hispanic Americans with POAG were more likely to present with central or advanced VF loss.

ABSTRACT BODY:

Purpose: Drivers with glaucomatous field loss are at greater risk for driving errors and motor vehicle crashes compared to age matched controls. This pilot study evaluated relationships between visual field loss and real-world driving in an instrumented vehicle (IV).

Methods: In a prospective pilot study, 11 Glaucoma subjects with visual acuity $\geq 20/40$ in both eyes and 6 controls with normal visual acuity and no history of ocular disease were tested on a standardized drive across commercial, rural, and highway road sections in Omaha NE in the IV, VENUS (Vehicle for Ergonomics, Neuroscience, and Safety). The IV drive video was evaluated by a certified occupational therapist and driving errors were annotated. Drivers in the IV performed a sign identification task (IT) including 73 restaurant and road signs along a 1.4 mile section of the route. Binocular visual field index (OU-VFI) and binocular superior VFI (S-VFI) and binocular inferior VFI (I-VFI) were calculated from monocular Humphrey visual fields (HVF) using previously described techniques. Cognitive ability was assessed using Montreal Cognitive Assessment [MoCA]. Spearman's rank order correlation was used to determine association between variables.

Results: 11 Glaucoma subjects (6 males, age: 57 ± 15 years, MoCA score 26 ± 3) were age matched with 6 controls (4 males, age: 69 ± 5 years, MoCA score 27 ± 2). The mean OU VFI for the glaucoma subjects was $85 \pm 14\%$ (range 61 to 99%). The mean S-VFI was $80 \pm 23\%$ and I-VFI was $89 \pm 11\%$. Driving errors in IV are enumerated in table 1. Glaucoma subjects made more driving errors than controls. Age and MoCA were not significantly associated with driving errors or performance on the LT task.

For the glaucoma subjects, driving errors were associated with OU-VFI ($r = -0.6$, $p = 0.07$). I-VFI correlated better with number of driving errors ($r = -0.7$, $p = 0.03$) than did S-VFI ($r = -0.5$, $p = 0.1$) (Figure 1).

Glaucoma subjects identified fewer street signs than controls (table 1). The percentage of signs identified correlated with worsening OU-VFI ($r = 0.8$, $p = 0.002$), S-VFI ($r = 0.8$, $p = 0.003$) and I-VFI ($r = 0.8$, $p = 0.007$).

Conclusions: Glaucoma subjects make more driving errors, particularly in lane maintenance, and have trouble identifying road signs compared to controls. Inferior field loss has greater influence on driving performance than superior field loss. Glaucoma subjects may benefit from customized driving rehabilitation therapy based on the region of their field loss.

TITLE: Predictors of Inadequate Health Literacy Among Comprehensive Ophthalmology Patients

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Hamdan, Vanderbilt University School of Medicine, Nashville, Tennessee, UNITED STATES|E. Brown, Ophthalmology and Visual Sciences, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|S. Gangaputra, Ophthalmology and Visual Sciences, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Saif Hamdan: Commercial Relationship: Code N (No Commercial Relationship) | Sapna Gangaputra: Commercial Relationship: Code N (No Commercial Relationship) | Eric Brown: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Health literacy (HL), defined as the ability to get, understand, and use basic health information and services, is essential for effective care delivery. Yet, over quarter of US adults are estimated to have inadequate HL, which is associated with poorer health outcomes and higher health care costs. This study aims to characterize the HL profile among comprehensive ophthalmology patients and to identify the associations with inadequate HL.

Methods: In January 2020, routine HL assessment was integrated into the clinic intake performed by ophthalmic technicians in all comprehensive ophthalmology clinics at an academic eye institute as part of a quality improvement initiative. HL was assessed using the Brief Health Literacy Screening (BHLS), an orally-administered, validated 3-item survey with each question scored on a five-point Likert scale. A retrospective chart review of adult patients seen at all comprehensive ophthalmology clinic sites of an academic eye institute from January 2020 to October 2020 was performed. Information collected included basic demographic factors, education level, neighborhood area deprivation index, HL score, comorbid systemic diseases, and visual acuity. Patients younger than 18 years old or those with a preferred language other than English were excluded.

Results: A total of 5313 patients met the inclusion criteria. The median age was 69 years; the majority of patients were White (85%) and Female (60%) with 51% (2,710) of the study cohort more deprived than the national median. The average best-corrected visual acuity of the best eye was 20/25. Overall, 291 (5.5%) patients had inadequate HL and 313 (5.9%) had not completed high school. Age (both younger and older age), male gender, Black race, higher deprivation index, lower education level, comorbid diabetes, and worse visual acuity were all observed to be associated with a greater likelihood of inadequate HL.

Conclusions: Many comprehensive ophthalmology patients may still have inadequate HL despite generally higher levels of education and socioeconomic status. As many ophthalmic disease processes require chronic management, further studies should review the impact of limited HL and appropriate targeted interventions on visual outcomes.

ABSTRACT BODY:

Purpose: Calcium alginate (CA) swabs are recommended for culturing corneal ulcers, but cotton tip applicators (CTA) are less expensive and more readily available. Whether one is absolutely better than the other is unknown. We compared the efficacy of each swab in recovering ocular surface bacteria using a novel in vitro model under moistened and dry swabbing conditions.

Methods: Ex vivo pig eyes were de-epithelialized and incubated at room temperature to allow for growth of bacteria on the ocular surface over time. The corneas were swabbed at 4 hour increments from 0 to 24 hours and plated on blood agarose plates. Colonies were counted to create a growth curve. It was determined that swabbing the corneas after six hours of incubation allowed for enough growth of colonies that could be easily counted and was reproducible. Next, 40 pig eyes incubated together were evenly divided into two groups; 20 eyes were swabbed with thioglycolate-moistened or dry CA swabs, and the remaining were swabbed similarly with CTA. The colonies on each blood agarose plate were counted, groups were averaged and a 2-tail T-test was used for statistical analysis.

Results: Overall, there is a statistically significant difference in number of colonies obtained after swabbing the ocular surface with moistened versus dry swabs (51.9 +/- 13.2 vs 28.5 +/- 13.8, respectively; p-value <0.0001). Moreover, swabbing with a moistened CTA yielded more bacteria than dry CTA (56.1 +/- 11.5 vs 29.9 +/- 14.8, respectively; p-value <0.0001); this held true for wet versus dry CA as well (47.6 +/- 13.7 vs 27.2 +/-13.0, respectively; p-value <0.0001). Furthermore, there was a statistically higher number of colonies obtained using moistened CTA over moistened CA (56.1 +/- 11.5 vs. 47.6 +/- 13.7, respectively; p-value 0.0399).

Conclusions: Moistened CTA swabs are superior to moistened CA in isolating bacteria from the ocular surface, but a moistened CA is better than swabbing with a dry CA swab or dry CTA. Regardless of which is used, it is important that all swabs be moistened with a medium such as thioglycolate to increase the recovery of bacteria from the ocular surface.

TITLE: Short-term videogaming involving multiple-element tracking enhances attentive motion tracking in the periphery

SESSION TITLE: Peripheral optics and vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Curtis, O. Iteghie, A. Chakraborty, Chicago College of Optometry, Midwestern University - Downers Grove Campus, Downers Grove, Illinois, UNITED STATES|A. Chakraborty, School of Optometry and Vision Science, University of Waterloo, Waterloo, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Madeline Curtis: Commercial Relationship: Code N (No Commercial Relationship) | Oshiobughie Iteghie: Commercial Relationship: Code N (No Commercial Relationship) | Arijit Chakraborty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Attentive motion tracking is critical to daily living activities, such as navigation and team sports. Previously, we have used perceptual learning to train attentive motion tracking in the periphery for adults with central vision loss and normal vision. Here we investigated if short-term videogaming on FIFA20 that involves tracking multiple elements (players), enhances peripheral multiple objects tracking (MOT), considered a marker of attentive motion tracking. In addition, we also tested whether performance enhancement from such videogame transfers to two related tasks: global motion perception (GMP) and static numerosity judgment (SNJ, static attention), and one unrelated task: global form perception (GFP). Finally, we used two other video games, Need for Speed (involves fast visual motion) and SIMS 4 (involves feature recognition) were used as control games to test any non-specific effect of videogames.

Methods: 15 adults (26.53 ± 4.5 y) with normal binocular vision played each video game on PlayStation-4 for 30 mins, across separate sessions, with a 5d wash-out period. Psychophysical thresholds were measured for a random hemifield, pre- and post- videogame in each session. Speed threshold of MOT (8 elements, starting speed $4^\circ/\text{s}$), motion coherence threshold (GMP; 2AFC direction discrimination for random-dot-kinematograms [100 dots, 6deg/s speed]), form coherence threshold (GFP; 2AFC Glass pattern discrimination), and presentation time threshold for the SNJ task (static frames from the MOT task with 8 ± 1 element presented temporally in 2AFC) were measured. The participants filled a questionnaire to report their videogaming experience.

Results: Only the FIFA 20 significantly improved performance on MOT ($15 \pm 4.5\%$, $t_{14} = 9.7$, $p = 0.009$) and SNJ ($10.5 \pm 3\%$, $t_{14} = -7.4$, $p = 0.02$) tasks, but not on GMP and GFP. Furthermore, linear regressions were conducted using the percentage change in MOT and SNJ as the dependent variables, and the type of video game, age, gender, and past gaming experience, as predictor variables. Other than FIFA20, no other variable independently predicted task improvement.

Conclusions: Videogaming involving tracking multiple elements significantly improved peripheral attentive motion tracking. Such improvement transferred to one related task. Our results suggest that videogaming could be considered as a medium to train peripheral attention in patients with central vision loss.

Commercial Relationships Disclosure (Abstract): Johannes Kirchner: Commercial Relationship: Code N (No Commercial Relationship) | Tamara Watson: Commercial Relationship: Code N (No Commercial Relationship) | Markus Lappe: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Video-based eye tracking devices cannot measure translational eye motion and require a calibration process that relies on the participant's self-report of accurate fixation. To circumvent these limitations, we developed an eye tracking method based on real-time MRI data. We tested this novel method by measuring the participant's horizontal gaze using real-time MRI and a conventional video-based eye tracker (Eyelink 1000) simultaneously.

Methods: In order to study the human eye in motion we used a balanced steady-state free precession (bSSFP) MRI sequence, collecting data of a single slice with a temporal resolution of 35ms. We start our analysis with a geometric model of the human eyeball, assuming that the sclera, the outer curvature of the cornea and the inner curvature of the lens take the shape of an ellipsoid. The geometric model is fitted to MRI data by matching the normal vectors of the model to the gradient flow field of the MRI data. We used a high-resolution 3D T2-weighted MRI scan to optimise the model for each eye and then collected dynamical single-slice data of the eye in motion for 2 participants. In particular, we collected binocular horizontal eye movements between targets at -7° and 7° and some blink-related eye movements. The eye movement was estimated as the best projection of the 3D model.

Results: A linear regression analysis of the horizontal gaze between Eyelink and MRI yielded highly significant results ($P < 0.001$) for both participants and both eyes. The correlation coefficients were 0.99, 0.97, 0.99 and 0.97. Apart from rotation, we also measured translations of up to 1.7mm during blinks.

Conclusions: We demonstrated a proof of principle that MRI can be used to track the human eye with high temporal resolution using a fully-automated algorithm. We anticipate that our work will lead to a deeper understanding of oculomotor mechanics and will be in particular useful for studying eye movement disorders like nystagmus and strabismus.

ABSTRACT BODY:

Purpose: Anti-VEGF therapy is the gold standard for treatment of wet age-related macular degeneration (wet AMD). Currently, the choice of anti-VEGF drugs, number of injections, and their intervals vary among retina providers. This study investigates the difference in intravitreal injection practice patterns between retina providers in visual outcomes of wet AMD in a single hospital-based setting.

Methods: Data from chart reviews of four retina practitioners between 2010-2020 at the University of Texas Medical Branch hospital were collected. Qualified subjects included a diagnosis of wet AMD (18-100 years) who received Bevacizumab, Ranibizumab, or Aflibercept eye injections. Each eye was counted separately, and eyes that switched providers were excluded. Patient demographics, ophthalmic clinical findings (visual acuity, IOP, macular thickness), and number and intervals of anti-VEGF injections were analyzed using Chi-squared and Kruskal-Wallis tests for quantitative variables.

Results: The study included 182 eyes from 145 patients (80.5 yrs.), predominantly Caucasians (93.1%) and females (66.2%). A significant number of eyes received Bevacizumab (78%) over Ranibizumab (8%), with no significant difference in Aflibercept use ($p=0.77$) amongst all retina providers. Additionally, all providers had statistically significant differences in intravitreal injection regimens with respect to number of injections per eye ($p=0.0001$) and average intervals between injections (min 28 and max 45 days, $p=0.002$). However, there was no statistical difference in the number of injections needed to first achieve 20/30 or better visual acuity ($p=0.80$). Of note, 15.4% patients of Providers 1 & 2, 11% patients of Provider 3, and 7.1% patients of Provider 4 achieved 20/30 after a median number of injections of 9, 6, 2, and 2 at an average interval of 28, 30, 45, and 34 days respectively. Provider 1 had significantly better results compared to others, but when examining the overall effect, the providers were not significantly associated with visual acuity improvement after adjusting for all other clinical variables ($p=0.13$).

Conclusions: Because significantly different intravitreal injection patterns resulted in similar visual outcomes, adopting a "best practice" recommendation may decrease treatment and financial burden in wet AMD patients.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a sight-threatening disease that requires strict, scheduled screening and timely treatment for Type 1 ROP. Examining infants in the neonatal intensive care unit (NICU) confers an added burden for ophthalmologists whose practices are predominantly outpatient. We sought to evaluate the time required to provide ROP services and approximate compensation to better understand incentives for this crucial service.

Methods: The ROP coordinator tracked time ophthalmologists spent providing ROP services at two NICUs (2018-2020). Estimated revenue was calculated using appropriate Current Procedural Terminology (CPT) codes for Medicaid reimbursement (2020 Medicare Physician Fee Schedule; Baltimore, MD; CMS.gov). A level 2 inpatient consultation code was used for examinations. Three pediatric ophthalmologists performed screening only (OS), while four retina specialists screened and treated (ST). Total time comprised examination, photography, and administrative duties; travel time at our institution was estimated as 45 minutes. Extrapolation of the time distributions of various ROP services to 100% estimated the physician reimbursement for a hypothetical full-time ROP service.

Results: The ophthalmologists cumulatively spent an average of 108 hours (h.) yearly providing ROP services (8.24% of an annual practice based on a 47-week schedule of 4 days/week, 7 h./day); this increased to 181 h. yearly (13.76% of annual practice) if travel time was included. Estimated annual Medicaid physician reimbursements for OS and ST were \$14,655 and \$18,182 (\$150/h. and \$168/h.), respectively; with travel time they decreased to \$89/h. and \$100/h., respectively. A hypothetical full-time ROP practice would generate annual physician salaries of \$196,801 for OS and \$220,652 for ST. With travel time, this decreases to \$73,655 and \$82,631, respectively.

Conclusions: At this institution, performing ROP services requires substantial time, especially if travel among facilities is necessary. This highlights the extensive and costly requirements for the critical task of decreasing ROP blindness. As few ophthalmologists prefer to perform ROP services after training, it is important for hospitals to make this highly litigious field more appealing.

ABSTRACT BODY:

Purpose: Limitations in the technical designs of commercially available eLVES may cause some users to experience visual discomfort for a number of reasons including binocular vision and vestibulo-ocular deficits. One possible reason for reported symptoms of visual discomfort using such devices is the decentration of the pupils within the optical viewing systems of these head-mounted displays (HMDs). Thus, we aimed to investigate the impact of pupil decentration (including heterophoria measures) on reported symptoms of visual discomfort in the IrisVision eLVES.

Methods: Fifty low vision patients ($BCVA \leq 20/60$ and at least 70° of visual field) completed phoria testing with Maddox Rod. Interpupillary distances were obtained with a pupillometer and through the IrisVision eLVES in order to derive heterophoria (eso vs exo) measures through the HMD using Prentice's Rule. All subjects took the device home for a 2-4 week trial period. A revised version of the simulator sickness questionnaire (SSQ) was administered twice during the trial period by telephone. Person measures and item measures, for responses to SSQ items relating to visual discomfort, were estimated by Rasch analysis. Deming regression normalized by standard deviation was used to compare 1) distance phoria measurement methods (Maddox Rod vs HMD) 2) phoria vs SSQ person measures (symptoms).

Results: Twenty-one of the 50 subjects were able to complete horizontal phoria testing using the HMD and with the Maddox Rod (mean age = 65.3 years). Deming regression comparing measured Maddox Rod values to predicted HMD phoria values shows the data (prism diopters) are centered around zero (mean = -0.6, stdev = 3.77). When person measures are anchored to item measures, only one participant showed significant symptoms. Pseudo R^2 was 0.490 between SSQ person measure and Maddox Rod phoria, and 0.435 between SSQ person measure and HMD-derived phoria.

Conclusions: To our knowledge, this is the first study to investigate the impact of heterophoria testing and visual discomfort using a head-mounted eLVES among low vision patients. There was no significant correlation to phoria measures on either the HMD test or Maddox Rod to suggest higher simulator sickness symptoms with higher measures of esophoria or exophoria. In addition, predicted phoria measures using the HMD correlates well to Maddox Rod findings.

TITLE: Fluorescence lifetime imaging ophthalmoscopy (FLIO) follow-up analysis in patients with age-related macular degeneration

SESSION TITLE: Imaging of posterior segment I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Buxton, The University of Utah School of Medicine, Salt Lake City, Utah, UNITED STATES|L. Sauer, A.S. Vitale, N.K. Modersitzki, P.S. Bernstein, John A. Moran Eye Center, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jace Buxton: Commercial Relationship: Code N (No Commercial Relationship) | Lydia Sauer: Commercial Relationship(s);Tesseract Health:Code C (Consultant) | Alexandra Vitale: Commercial Relationship(s);Tesseract Health:Code C (Consultant) | Natalie Modersitzki: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bernstein: Commercial Relationship(s);Tesseract Health:Code C (Consultant)

ABSTRACT BODY:

Purpose: In eyes with age-related macular degeneration (AMD), fluorescence lifetime imaging ophthalmoscopy (FLIO) shows a characteristic pattern of prolonged mean autofluorescence lifetimes. This study investigates changes in autofluorescence lifetimes over time in patients with AMD to better understand disease progression.

Methods: 26 patients with AMD (mean age 75 ± 9 years) were followed at the Moran Eye Center with a prototype Heidelberg Engineering FLIO. The mean follow-up time was 16 ± 8 months (range 6 - 34 months). Fundus autofluorescence was excited at 473 nm, and FLIO lifetimes were recorded in short (SSC, 498 - 560 nm) and long (LSC, 560 - 720 nm) spectral channels. Mean autofluorescence lifetimes were investigated.

Results: At baseline, FLIO lifetimes in the outer ring (OR) of a standardized early treatment diabetic retinopathy study (ETDRS) grid were 297 ± 54 ps (SSC) and 405 ± 58 ps (LSC). At follow up, the same area showed FLIO lifetimes of 306 ± 59 ps (SSC) and 411 ± 57 ps (LSC), $p < 0.01$ for both spectral channels. The central area (C) did not show any significant changes ($P = 0.67$ and 0.18). The average 12-months prolongation of FLIO lifetimes in the OR was 7 ± 20 ps (SSC) and 7 ± 13 ps (LSC).

Conclusions: In eyes with AMD, prolonged FLIO lifetimes further increase over time, particularly in the OR of the LSC, as eyes progress to more advanced stages of AMD. The rate of progression is variable amongst patients and even between eyes of the same patient. FLIO may be useful to monitor the progression of AMD.

ABSTRACT BODY:

Purpose: Older adults with combined vision and hearing loss (dual sensory loss/DSL) are often sidelined in vision and hearing research, and evidence suggests that they are at a high risk of cognitive impairment, functional decline, social isolation, falls, depression, and mortality. These consequences get exacerbated during the COVID-19 pandemic due to physical distancing restrictions on mobility and social interactions. Around one million older adults in Canada experience DSL; yet, there is very limited evidence in the Canadian context that could inform pandemic preparedness for this population. Hence, the present study identifies and describes the barriers to health information and health services access for older adults with DSL during the COVID-19 pandemic.

Methods: We conducted semi-structured qualitative interviews with 11 community-dwelling older adults with DSL (age 62-85 years; 7 female) in Montreal between September and December 2020. Diverse remote communication modes and accessible formats were used to obtain consent and interview participants. Interviews were audio-recorded and transcribed verbatim. Data were managed using NVivo software and analyzed using a thematic analysis approach.

Results: Findings indicate that the central barriers to healthcare information and access are linked to communication breakdown between older adults with DSL and healthcare providers, in addition to the presentation of information through inaccessible formats. Furthermore, healthcare staff rarely have the additional time available that is necessary to interact with the DSL clientele or have the necessary training to accommodate their communication needs. In terms of barriers to accessibility, participants reported that they have difficulty following the 2-meter distance requirements and coloured lines painted on the floor to ensure physical distancing in the healthcare setting.

Conclusions: Our results highlight that the pandemic heightened the risk for older adults with DSL because of the systemic and physical barriers to healthcare access for this population. There is a dire need for training of healthcare professionals to accommodate the communication and accessibility needs of older adults living with DSL. Healthcare administrators and policymakers should consider the distinct accessibility and communication needs of this vulnerable population in order to help them age well.

ABSTRACT BODY:

Purpose: Uveitis is a rare chronic condition, "orphan disease" in the paediatric population. The incidence is 4.3 per 100,000 and prevalence 27.9 per 100,000. It is sight threatening due to disease progression and treatment failure. The mainstay of uveitis treatment is steroids. Steroid induced cataract and glaucoma is well documented and has been found to account for a quarter of all acquired glaucoma in children. Steroid sparing agents and biologic therapy (genetically engineered proteins targeting specific parts of the immune system that cause inflammation) are increasingly being used. The purpose of this study is to investigate rates, timing and visual outcomes of paediatric uveitic cataract and glaucoma surgery in relation to the treatment of the uveitis with biologic therapy and steroid sparing immunosuppression.

Methods: Retrospective chart review of demographic data and treatment outcomes of all paediatric uveitis patients presenting to the Children's Hospital Westmead, Sydney Eye Hospital and Save Sight Institute from 2005- 2020.

Results: Pilot data highlights that there were 115 patients (207 eyes) diagnosed with paediatric uveitis during this period. The majority had bilateral uveitis (n = 100, 80%). 64 patients were female and 51 patients male. The most common aetiological diagnosis was JIA-U (n = 77, 67%), followed by idiopathic uveitis (n = 34, 29.6%). Anatomical diagnosis was 84% anterior uveitis and 16% non-anterior uveitis. Cataract surgery was required in 46 patients / 40% (61 eyes / 29.4%); glaucoma surgery - trabeculectomy or tube surgery in 40 patients / 34.7% (49 eyes / 23.7%). A number of patients underwent multiple surgeries. The mean duration of inflammation prior to commencement of a biological agent was 22.0 months (range: 1-48 months). Baseline age at commencement of biologic therapy was 9.12 years (3.42 SD). Of those patients on biologic therapy, the baseline VA was logMAR 0.24 (0.34 SD) and final VA was logMAR 0.18 (0.28 SD) with a mean change in VA from baseline of logMAR -0.07 (0.23 SD).

Conclusions: Paediatric uveitis is a complex disease. The advent of biologic therapy and other steroid sparing agents, in this real world data, are having beneficial effects on visual outcome, uveitic cataract and glaucoma surgery in these patients.

ABSTRACT BODY:

Purpose: To determine how water and solute fluxes are affected in a bovine hyperbaric oxygen (HBO) model of lens ageing that has previously been shown to induce an age-dependent hyperopic shift in lens power clinically observed in human lens.

Methods: All experiments were performed on bovine lenses that had been first exposed to either 100% nitrogen (HBN) (pressure control group) or 100% oxygen (HBO) at a pressure of 100atm for 15hr in a Cell Disruption Vessel. A pico-injector/microelectrode based pressure measurement system was utilised to measure the intracellular hydrostatic pressure gradient that drives water efflux. T1 based MRI imaging was used to map free water content and to visualise the delivery of the MRI contrast agent FeraSpin XS to the lens core. Western blotting of dissected lens fractions with Cx46 antibodies was used to assess gap junction protein degradation in the different areas of the lens.

Results: HBO exposure significantly increased the free water content in the inner cortex and core of the bovine lens and this change was associated with an increase in the hydrostatic pressure gradient relative to the HBN control. These effects of HBO were deemed to be associated with an inhibition of microcirculation system as the delivery of the FeraSpin XS to the core of the lens was abolished following HBO exposure but was unaffected by incubation in HBN. HBO also induced the degradation of Cx46 in the outer and inner cortex.

Conclusions: Our results show that acute oxidative damage to the lens gap junctions traps water in the lens core causing an elevation of the hydrostatic pressure gradient and an inhibition of solute delivery to the lens core that is driven by the microcirculation system. We envisage that the age-related accumulation of oxidative damage to gap junctions may trigger similar changes in older human lenses, which may eventually contribute to the onset of lens cataract.

ABSTRACT BODY:

Purpose: Neuroinflammation is increasingly implicated in glaucoma pathogenesis. We previously showed that decreasing macrophage/microglia activation and astrogliosis rescued retinal ganglion cells (RGCs) following intraocular pressure (IOP) elevation in mice (PMID33147455). Our findings also suggest monocyte infiltration may drive astrogliosis. Using the microbead occlusion model of glaucoma, we examined the association between RGC death and the distribution of retinal myeloid cells following IOP elevation.

Methods: Microbead injections were used to elevate IOP as previously described (PMID32045598). Briefly, 4-month-old C57BL/6J mice received injections of magnetic microbeads in the anterior chamber of one eye while the contralateral eye received sterile balanced salt solution (BSS). Mice were injected on days 0 and 16. IOP was measured immediately prior to the first injection, 4 days post-injection, and then weekly thereafter. After 6 weeks, immunolabeling of retina flat-mounts for RBPMS and Iba1 was used to quantify cellular density [cells per 63x high-power field (HPF)] of RGCs and myeloid cells, respectively, in the central and peripheral retina.

Results: IOP remained elevated for 6 weeks following microbead injections (Mean \pm SEM 15.4 \pm 0.3mmHg vs. BSS 11.9 \pm 0.2, $p<0.0001$). After 6 weeks, RGC density was lower in microbead vs. BSS eyes (107.1 \pm 2.9 vs. 124.3 \pm 2.5, $p<0.05$). In contrast, myeloid cell (Iba1+) density was higher in microbead vs. BSS eyes (4.0 \pm 0.1 vs. 2.8 \pm 0.1, $p<0.001$; Fig. 1). Interestingly, in microbead eyes, higher central myeloid cell density was correlated with lower RGC density, particularly in the periphery ($R=0.14$, $p<0.0001$). The same correlation was not observed in BSS eyes.

Conclusions: Results support increased macrophage/microglia activation in response to ocular hypertension. The correlation between higher central macrophage/microglia density and greater RGC loss suggests that increased central activation and/or monocyte extravasation from the optic nerve are important drivers of RGC death. Examining for evidence of monocyte infiltration immediately after IOP elevation will expand upon this finding.

ABSTRACT BODY:

Purpose: Since the start of the COVID-19 pandemic, numerous authors have published data demonstrating retinal changes found in patients with COVID-19. These include differences in retinal vascular anatomy, hyper-reflective changes on optical coherence tomography (OCT), and signs of microvascular disease such as cotton wool spots and retinal hemorrhages. However, other authors have debated the validity of these findings and the effects of COVID-19 on the retina remain uncertain. Herein, we aim to retrospectively assess for retinal changes in patients infected by COVID-19 who were seen at a tertiary eye care center.

Methods: A retrospective review of patients who presented to Massachusetts Eye and Ear (Boston, MA, USA) between March 1st and October 31st, 2020 with a history of a positive COVID-19 polymerase chain reaction test was performed. Patients were included if they presented within 90 days of their first positive COVID-19 test and underwent color fundus photography and/or OCT of the macula.

Results: A total of 119 eyes from 61 patients with mean age of 63 years and mean presentation of 60.4 days after first positive COVID-19 test (range 4 to 90 days) were included. Among 83 eyes which underwent OCT of the macula, inner retinal hyper-reflective changes were seen in 16.9% (n=14), outer retinal hyper-reflective changes in 18.1% (n=15), intra-retinal fluid in 28.9% (n=24), and sub-retinal fluid in 14.5% (n=12). Among 48 eyes which underwent color fundus photography, retinal hemorrhage was seen in 27.1% (n=13), optic disc edema in 2.1% (n=1), and cotton wool spots in none of the eyes. Among 109 eyes which underwent a documented exam of the posterior segment, retinal hemorrhage was seen in 23.9% (n=26), optic disc edema in 2.75% (n=3), and cotton wool spots in 3.7% (n=4). Sub-analysis of 70 eyes from 41 patients with no alternative retinal pathology (diabetic retinopathy, retinal vein occlusion, etc.) to potentially cause the above findings revealed that none of the eyes demonstrated any of the above exam findings on OCT macula (n=35), fundus photography (n=28), or documented exam (n=66).

Conclusions: While a number of patients seen after COVID-19 infection demonstrated retinal findings, all could be explained by pre-existing retinal conditions. In a sub-group of eyes without pre-existing retinal disease, we did not identify any retinal findings that could be attributed to COVID-19.

ABSTRACT BODY:

Purpose: To compare the acute and chronic manifestations of Stevens-Johnson Syndrome(SJS) and Toxic Epidermal Necrolysis (TEN) in an HIV-positive and HIV-negative population of patients.

Methods: This retrospective review evaluated all SJS/TEN patients within the Research Patient Data Registry of the Mass General Brigham healthcare system with and without HIV-infection. Patients were required to have relevant documentation of acute ocular manifestations as well as at least one chronic follow up visit ≥ 3 months post-discharge. Main outcome measures for acute ocular outcomes were acute ocular Sotozono score (AOSS), and for chronic ocular outcomes were severe ocular complications (SOC), chronic ocular Sotozono score (COSS), and best corrected visual acuity (BCVA) as measured using LogMAR VA.

Results: Seventeen patients were reported in the HIV-positive (HIV+) group and 181 patients reported in the HIV-negative (HIV-) group. HIV+ patients had a higher frequency of TEN in comparison to the HIV- patients ($P = 0.003$). However, HIV- patients had a higher AOSS compared to those who were HIV+ ($P = 0.010$). Zero of 17 HIV+ patients required AMT therapy whereas 50 of 181 HIV- patients required AMT therapy ($P = 0.008$). Chronic ocular data was present for only 6 of the 34 eyes of HIV+ patients. Severe ocular complications (SOC) occurred more frequently in the HIV+ group than the HIV- group before and after controlling for AOSS ($P < 0.0001$). LogMAR VA was better in the HIV+ group relative to the HIV- group before controlling for AOSS ($P = 0.004$) and was equivalent after controlling for AOSS ($P = 0.383$). Cornea, conjunctiva, eyelid margin, and total COSS were not significantly different between groups before and after controlling for AOSS.

Conclusions: Despite having more severe systemic presentation of SJS/TEN, HIV-positive patients had less severe acute ocular disease than HIV-negative patients and required less AMT therapy. However, chronic ocular disease was worse in those who were HIV positive. This finding may be due to a different and/or suppressed immune mechanism of disease in those with HIV positivity, or a smoldering and longer acute or subacute disease phase and requires further study. Future studies are indicated to determine the pathophysiology of acute disease in HIV positive SJS/TEN patients and whether there should be a lower threshold to perform AMT.

TITLE: Temporary disruption of binocular vision by monocular noise-adaptation induces a naso-temporal asymmetry in global motion perception

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Thompson, A. Chakraborty, School of Optometry and Vision Science, University of Waterloo, Waterloo, Ontario, CANADA|K. Hall, A. Chakraborty, Chicago College of Optometry, Midwestern University - Downers Grove Campus, Downers Grove, Illinois, UNITED STATES|B. Thompson, Centre for Eye and Vision Research Limited, Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): Kennedy Hall: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Thompson: Commercial Relationship: Code N (No Commercial Relationship) | Arijit Chakraborty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A nasalward bias in motion coherence thresholds has been reported in individuals with a history of monocular deprivation. However, the mechanism behind this bias is unclear. Here we investigated whether the locus of such asymmetry lies within the early visual areas, such as V1, or further downstream within the extrastriate cortex.

Methods: In individuals with normal vision ($n = 14$), we measured motion coherence (MT+/V5) and contrast-detection (V1) thresholds for random dot kinematograms (100 dots, 6 deg/sec) in one eye after adaptation of the fellow eye to visual noise. To measure the motion coherence threshold, the contrast of the dots was maintained at 100% and coherence was varied. To measure detection thresholds, coherence was fixed at 100% and contrast was varied. Within separate sessions, thresholds were measured monocularly with and without adaptation of the fellow eye. Adaptation involved 60s viewing a random-dot-kinematogram with an equal number of black and white dots with varying speed and contrast, followed by 15 s periods of top up adaptation after every 10 trials.

Results: Only motion coherence thresholds following noise adaptation exhibited a robust naso-temporal asymmetry in favor of nasalward motion (mean nasal MCT: $8 \pm 2.25\%$ vs mean temporal MCT: $14 \pm 2\%$). When compared to the non-adapted condition, noise-adapted motion coherence thresholds were significantly worse only for temporalward motion post adaptation (noise-adapted $14 \pm 2\%$ vs. non-adapted $8 \pm 1.92\%$). Contrast detection thresholds did not show any naso-temporal asymmetry for any condition.

Conclusions: We were able to simulate the monocular nasal temporal MCT asymmetry we have previously observed in individuals with monocular deprivation using monocular noise adaptation of one eye. The presence of such asymmetry only in the global motion, but not in the contrast-detection task, suggests that MT+/V5 could be a potential site for this asymmetry.

Commercial Relationships Disclosure (Abstract): Brian Krawitz: Commercial Relationship: Code N (No Commercial Relationship) | C Gustavo De Moraes: Commercial Relationship: Code N (No Commercial Relationship) | George Cioffi: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Girkin: Commercial Relationship: Code N (No Commercial Relationship) | Massimo Fazio: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Bowd: Commercial Relationship: Code N (No Commercial Relationship) | Robert Weinreb: Commercial Relationship: Code N (No Commercial Relationship) | Linda Zangwill: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Liebmann: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the effect of trabeculectomy on the rates of functional (visual field, VF) vs. structural (optical coherence tomography, OCT) glaucoma progression.

Methods: Participants were recruited from the African Descent and Glaucoma Evaluation Study (ADAGES). Eyes that underwent trabeculectomy and had at least 3 good quality Humphrey 24-2 VFs and spectral-domain OCT scans of the retinal nerve fiber layer (RNFL) performed before or after surgery were included for analysis. Rates of mean deviation (MD) and global RNFL thickness change were calculated using a linear mixed effects model.

Results: For VF analysis, 86 eyes before trabeculectomy and 134 eyes after trabeculectomy were included. The mean (95% CI) global rate of progression decreased from -0.41 (-0.52 to -0.30) before surgery to -0.25 (-0.33 to -0.17) dB/year after surgery (39% reduction, $p=0.003$). For OCT analysis, 20 eyes before trabeculectomy and 90 eyes after trabeculectomy were included. The mean rate of RNFL thinning decreased from -0.65 (-1.78 to 0.47) before surgery to -0.25 (-0.46 to -0.03) $\mu\text{m}/\text{year}$ after surgery (61% reduction, $p=0.008$).

Conclusions: Trabeculectomy decreases the rate of progression of VF and OCT global parameters. Despite the smaller sample size, the effect was more evident on OCT and may help better understand the effect of IOP reduction on rates of change of structural and functional parameters in glaucoma.

ABSTRACT BODY:

Purpose: The human retina is composed of different neuronal and non-neuronal cell types. Significant cell heterogeneity is observed within many neural retina cell types, with their composition in the tissue ranging anywhere, from 75% to less than 0.05%. However, the number of retinal cell subtypes and their gene expression signature remains largely undiscovered, especially for rarer cell types. Additionally, open chromatin profiles for the human retina at the single-cell level has not yet been reported. Therefore, we are generating the first version of human neural retinal cell atlas reference by characterizing both the transcriptome and open chromatin profile for all cell types in the human retina.

Methods: Single-nuclei RNA-seq and single-nuclei ATAC-seq were carried out to profile well-characterized normal human retina from over twenty donors (average age over 70). Each donor retina was dissected into three geographic regions: the fovea, macula, and peripheral retina and flash-frozen afterward. A fractionation protocol was developed to enrich nuclei from rare neuron cell types, including bipolar cells, amacrine cells, and retinal ganglion cells. Integrative data analysis was performed to identify cell subtypes, marker genes, chromatin signature, and transcription factors and modules. Experimental approaches including immunofluorescence staining and RNA in situ hybridization are performed to validate novel cell populations.

Results: A transcriptome profile was generated for over 250K nuclei, leading to the identification of over 60 cell types in the human retina. Through comparison among the human, and previously reported monkey/mouse datasets, we have identified conserved and primate-specific subtypes. In parallel, single-cell open chromatin profiles were generated using single-nuclei ATAC-seq from 160k nuclei. The integration of the single-nuclei RNA-seq and single-nuclei ATAC-seq data allows us to obtain the open chromatin profiles of each subtype. Key transcription factors and transcription modules were identified at both major- and sub- cell-type levels.

Conclusions: This study represents the most comprehensive single-cell transcriptome and chromatin accessibility profiling for the human neural retina to date. Over 400K single nuclei were profiled for their transcriptome or chromatin accessibility, with over 60 cell types. This well-characterized dataset serves as the first version of a human retina cell atlas reference.

MacLaren, Oxford University Eye Hospital, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Hend Ahmed: Commercial Relationship: Code N (No Commercial Relationship) | Jasleen Jolly: Commercial Relationship: Code N (No Commercial Relationship) | Lyndon Da Cruz: Commercial Relationship: Code N (No Commercial Relationship) | Adam Dubis: Commercial Relationship: Code N (No Commercial Relationship) | Robert MacLaren: Commercial Relationship(s);Biogen:Code C (Consultant)

ABSTRACT BODY:

Purpose: Choroideremia is an X-linked retinal degeneration which causes a circumferentially constricting degeneration of the retinal pigment epithelium and choroid, leading to rod function loss. Current dark adaptation protocols test the full field sensitivity and seek the absolute dark-adapted threshold. Alternatively, single point testing and sub-absolute threshold endpoints may provide the opportunity for quicker, more reliable testing in this disease.

Methods: Choroideremia patients underwent dark adaptation testing using the AdaptDx (Maculogix, Hummelstown, PA, USA) dark adaptometer and autofluorescence imaging. Following 80% rod bleaching, testing was performed at 9-degree superior to fixation. Rod recovery time was defined as the time needed to achieve a sensitivity improvement of 3 AU. The sensitivity at 18min was also recorded. Autofluorescence images were reviewed to assess whether the testing location lay within the preserved retina.

Results: Fifty-six eyes from 28 patients were included in this analysis. Twenty-one eyes had a detectable rod recovery time (mean \pm SD, 15.0 \pm 4.3 minutes), with 3 of them \leq 10 min which was deemed normal. Three patients had a detectable recovery in only 1 eye. At 18 minutes, the average threshold for all eyes was 2.30 \pm 0.82. A strong correlation in 18-minute sensitivity was observed between right and left eyes ($R^2 = 0.70$). Eyes with detectable rod recovery had significantly higher sensitivity (mean \pm SD, 3.12 \pm 0.56) compared with eyes with undetectable recovery (1.81 \pm 0.25, $p < 0.001$). Thirty-two eyes had residual retina at the targeted region. The average threshold at 18 minutes for these eyes was 2.62 \pm 0.77 dB. Of these, only 15 eyes had a detectable rod recovery. Meanwhile, 6 eyes with no remaining retina at the targeted point had a detectable, yet prolonged, rod recovery. Interestingly, no significant association was observed between the undetectable rod recovery and presence/absence of remaining retina the testing location ($p = 0.09$).

Conclusions: The dark adaptation testing maybe useful for assessment of choroideremia. AdaptDX testing provided several key findings. The mean threshold at 18 min was greater for the eyes with detectable rod recovery time. However, the lack of relationship between presence of residual retina and testing threshold suggest eye movement may have played a role and would need to be controlled in future use.

TITLE: Mechanical properties of scleral collagen fibers obtained using a new fiber-based specimen-specific model of sclera microstructure.

SESSION TITLE: Glaucoma: molecular, biochemical and biomechanical disease mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F. Ji, I.A. Sigal, Bioengineering, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|F. Ji, M. Bansal, Y. Hua, I.A. Sigal, Ophthalmology, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|B. Wang, Mechanical Engineering, Southwest Jiaotong University, Chengdu, Sichuan, CHINA|

Commercial Relationships Disclosure (Abstract): Fengting Ji: Commercial Relationship: Code N (No Commercial Relationship) | Manik Bansal: Commercial Relationship: Code N (No Commercial Relationship) | Bingrui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Yi Hua: Commercial Relationship: Code N (No Commercial Relationship) | Ian Sigal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Scleral collagen fiber mechanical properties are central to overall eye mechanics, and thus multiple techniques have been used to determine them using modeling. Most models, however, use continuum approaches that do not consider critical characteristics of the fibers. Our goal was to determine the fiber mechanical properties using a newly developed specimen-specific fiber-based model of sclera.

Methods: Two optic nerve heads (ONHs) were sectioned at 30 μm thickness, one coronally and the other sagittally. The sections were imaged using polarized light microscopy (PLM) to obtain local collagen fiber density and orientations in the section planes. Images of 17 serial coronal sections were registered to form a volume. A square region of sclera was selected and the fibers were traced in all images accordant to local fiber orientations (Fig 1). Fiber overlaps were resolved by an iterative algorithm. The out-of-plane fiber orientations were adjusted to match the sagittal PLM data. The fibers were then embedded in a matrix and the assembly was used in an inverse modeling process to derive fiber mechanical properties by matching published experimental biaxial extension data assuming a hyperelastic Mooney-Rivlin behavior.

Results: A model with 1016 fibers was constructed. Wilcoxon rank sum tests showed that fiber orientations were not significantly different between the model and histology for both coronal ($p>0.7$) and sagittal ($p>0.6$) directions. The estimated fiber stiffness was 1488.7MPa (Fig 2).

Conclusions: Our fiber-based sclera model incorporated detailed specimen-specific architecture, and previously ignored fiber-level mechanics, such as fiber-fiber interactions and long-distance load transfer. Although the model predicts higher fiber stiffness than previous studies (e.g. Grytz et al. 2013), the biomechanical behavior was in excellent agreement with experiments.

TITLE: Laser Prophylaxis in Stickler Syndrome

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Khanna, S.H. Rodriguez, M. Blair, Ophthalmology and Visual Sciences, University of Chicago Division of the Biological Sciences, Chicago, Illinois, UNITED STATES|M.A. Blair, M.J. Shapiro, M. Blair, Retina Consultants, Ltd., Des Plaines, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Saira Khanna: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Rodriguez: Commercial Relationship: Code N (No Commercial Relationship) | Mateo Blair: Commercial Relationship: Code N (No Commercial Relationship) | Michael Shapiro: Commercial Relationship: Code N (No Commercial Relationship) | Michael Blair: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Stickler syndrome (SS) is an inherited, progressive collagenopathy first described in 1965 that is the leading cause of pediatric retinal tears and detachments. Retinal tears or detachments in SS have been shown to occur as early as 8 months, and SS patients require frequent examinations to detect retinal detachments (RD) and prevent development of proliferative vitreoretinopathy which can result in severe vision loss. The purpose of this study is to compare the visual acuity (VA) and odds of RD among patients with SS who received prophylactic laser to those who did not.

Methods: Retrospective chart review included patients with SS at University of Chicago Medical Center or Retina Consultants, Ltd. between 1/1/2006 and 10/6/2020. Patients older than 3 years of age underwent laser indirect ophthalmoscopy and received a pattern of about 10 rows of 360 degrees of laser prophylaxis from the ora serrata to the equator (complete laser). The association between RD and laser was investigated using Pearson chi-square / Fisher's exact test. Frequency weighting to control for 2 eyes of the same patient was used to calculate median logmar visual acuity (VA) and interquartile range (IQR). To compare logmar visual acuity by laser treatment groups, a mixed effects logistic regression controlling for 2 eyes of the same patient; nonverbal patients were excluded from visual acuity regression analysis.

Results: A total of 230 eyes of 124 patients were included. Of those, 90 (39%) eyes had no laser, 7 (3%) received inadequate laser elsewhere, and 133 (58%) received complete laser. Of the eyes who received complete laser, only 5 eyes (4%) had an RD, compared to the 69 eyes (71%) which had inadequate or no laser ($p < 0.001$). Among 204 eyes of 103 patients, patients with complete laser had about 6 lines better vision compared to patients without laser or with inadequate laser (-0.55 logmar, CI -0.79 - -0.30 , $p < 0.001$). The odds of low vision were 2.1 (CI 1.1-3.0, $p < 0.001$) times lower for eyes with complete laser.

Conclusions: Complete laser prophylaxis seems to reduce the chance of retinal detachment and improve visual outcomes in patients with SS. Laser prophylaxis should be considered in all patients with confirmed SS after the age of 3.

ABSTRACT BODY:

Purpose: Routine use of face masks for both patients and physicians during intravitreal anti-vascular endothelial growth factor (VEGF) injections has increased with the emergence of the COVID-19 pandemic. This study evaluates the impact of physician, ancillary staff, and patient face mask use on rates and outcomes of post-injection endophthalmitis.

Methods: In this retrospective comparative cohort study, all eye receiving intravitreal anti-VEGF factor injections from 10/1/2019 to 7/31/2020 were included from twelve centers. Cases were divided into a “no face mask” group if no face masks were worn by the physician or patient during intravitreal injections or a “universal face mask” group if face masks were worn by the physician, ancillary staff, and patient during intravitreal injections. The main outcome measures were rate of endophthalmitis, visual acuity, and microbial spectrum.

Results: Of 505,968 intravitreal injections administered, 85 of 294,514 (0.0289%; 1 in 3,464 injections) cases of endophthalmitis occurred in the “no face mask” group, and 45 of 211,454 (0.0213%; 1 in 4,699 injections) cases occurred in the “universal face mask” group (odds ratio, 0.74; 95%CI, 0.51–1.18; p=0.097; Table 1). In the “no face mask” group, there were 27 cases (0.0092%; 1 in 10,908 injections) of culture-positive endophthalmitis compared to 9 cases (0.004%; 1 in 23,494 injections) in the “universal face mask” group (OR, 0.46; 95%CI, 0.22–0.99; p=0.041). Three cases of oral flora-associated endophthalmitis occurred in the “no face mask” group (0.001%; 1 in 98,171 injections) compared to one (0.0005%; 1 in 211,454) in the “universal face mask” group (p=0.645). At endophthalmitis presentation, mean logMAR visual acuity was 2.04 for “no face mask” group compared to 1.65 for the “universal face mask” group (p=0.022), although no difference was observed three months after treatment (p=0.764; Table 2).

Conclusions: Universal face mask use during intravitreal anti-VEGF injections did not show a statistically significant reduction in presumed endophthalmitis, but there was a reduced rate of culture-positive endophthalmitis. Future studies are warranted to assess the role of face mask use to reduce endophthalmitis risk, particularly that due to oral flora.

TITLE: Dark Adaptation Survey as a Screening Tool for Age Related Macular Degeneration

SESSION TITLE: AMD: clinical research - biomarkers and outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Shaikh, M. Bhardwaj, A.M. Alwreikat, S. Anjum, D. Hagan, D. Ramsey, Ophthalmology, Beth Israel Lahey Health, Cambridge, Massachusetts, UNITED STATES|D. Hagan, Boston University, Boston, Massachusetts, UNITED STATES|S. Bowen, Press Ganey, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Noreen Shaikh: Commercial Relationship: Code N (No Commercial Relationship) | Mahesh Bhardwaj: Commercial Relationship: Code N (No Commercial Relationship) | Amer Alwreikat: Commercial Relationship: Code N (No Commercial Relationship) | Sidrah Anjum: Commercial Relationship: Code N (No Commercial Relationship) | Dan Hagan: Commercial Relationship: Code N (No Commercial Relationship) | Shane Bowen: Commercial Relationship: Code N (No Commercial Relationship) | David Ramsey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Nearly 200 million people have age-related macular degeneration (AMD), yet effective screening methods to identify these individuals in the general population are quite limited. Although signs of AMD can readily be identified by means of a comprehensive eye examination or confirmed by special testing, many individuals with AMD remain undiagnosed, representing a significant unmet public health need. The goal of this study is to develop a survey capable of identifying patients with AMD based upon visual symptoms.

Methods: A pilot study was conducted in patients with and without AMD presenting at an eye clinic. Participants were recruited to complete the (DA) Survey instrument at the time of a comprehensive eye evaluation which included optical coherence tomography. Patients were staged according to the Age-Related Eye Disease Study classification system. The 10-item survey utilized asked questions related to DA and night vision using the Likert-type response format (severe, moderate, mild, or no difficulty). Linear regression and multivariate analysis were performed using SPSS® (Version 22.0, IBM Corp.).

Results: A total of 31 patients with AMD and 51 controls were recruited for the pilot study. Cronbach's α showed a high degree of internal consistency reliability ($\alpha = 0.92$). Average DA Survey score in AMD was 3.2 ± 0.8 compared with 2.0 ± 0.9 among controls ($P < 0.001$). For every question, the average response score was significantly higher among patients with AMD compared with controls. Logistic regression analysis was performed to predict AMD among 31 patients with AMD and 51 controls using age, sex, average visual acuity, and DA Survey score. Based on this model, association of AMD with age and DA Survey score was statistically significant ($R^2 = 0.442$, $P < 0.001$), whereas it was not significant for sex or visual acuity.

Conclusions: Night vision problems are common in patients with AMD., and symptom severity correlates with severity of the disease. Screening for DA symptoms may help identify subjects with AMD. Future work will seek to validate the survey in a larger population and determine the extent to which other diseases with and without diminished night vision impact symptom severity. Low-cost and easily administered screening tools such as our DA Survey may aid in identifying individuals in need of referral for evaluation and treatment for undiagnosed eye disease thereby preventing vision loss.

TITLE: Validation of an autonomous AI-based diagnostic system for holistic maculopathy screening in a routine occupational health checkup context

SESSION TITLE: AI in the retina/ AMD imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Zapata, D. Royo, A. Bures, C. Salinas, O. Font, Optretina, Barcelona, SPAIN|M. Zapata, S. Banderas, Vall d'Hebron Hospital Universitari, Barcelona, Catalunya, SPAIN|A. Bures, C. Salinas, Instituto de Microcirugia Ocular, Barcelona, Catalunya, SPAIN|

Commercial Relationships Disclosure (Abstract): Miguel Zapata: Commercial Relationship(s);Optretina:Code I (Personal Financial Interest) | Sandra Banderas: Commercial Relationship: Code N (No Commercial Relationship) | Didac Royo: Commercial Relationship(s);Optretina:Code I (Personal Financial Interest) | Anniken Bures: Commercial Relationship(s);Optretina:Code E (Employment) | Cecilia Salinas: Commercial Relationship(s);Optretina:Code E (Employment) | Octavi Font: Commercial Relationship(s);Optretina:Code E (Employment)

ABSTRACT BODY:

Purpose: evaluate the accuracy of an autonomous artificial intelligence (AI) system for holistic maculopathy screening during occupational checkups

Methods: A retrospective study on an unclean and unprepared dataset of 5,918 images from a population of 2,839 people evaluated with non-mydriatic cameras during routine occupational health checkups. The images were obtained by a trained technician using handheld non-mydriatic cameras on the participant's office premises. The camera models employed were Optomed Aurora (field of view (FOV) 50 degrees, 88% of the dataset), Zeiss Visuscout 100 (FOV 40 degrees, 9 % of the dataset), and Optomed SmartScope M5 (FOV 40 degrees, 3% of the dataset). Image acquisition took around two minutes per patient. The ground truth of the dataset was evaluated per eye; 2 retina specialists graded each image; if the grading did not match, a 3rd one reviewed the image to break the tie. The specific pathologies considered for evaluation were diabetic retinopathy (DR) (more than mild DR. Age-related macular degeneration (AMD) (mild or worse, suspected glaucomatous optic neuropathy (GON), and Nevus. Images with possible signs of maculopathy that didn't match the described taxonomy were classified as Other.

Results: the assembly of algorithms for evaluating abnormalities had an area under the curve (AUC) of 0.963 with a sensitivity of 0.929 and a specificity of 0.868. The algorithms individually obtained: AMD: AUC 0.98; Sensitivity 0.938; specificity 0.957. DR AUC 0.95; Sensitivity 0.811; specificity 0.948. GON AUC 0.8892; Sensitivity 0.536 specificity 0.957. Nevus AUC 0.931; Sensitivity 0.867; specificity 0.907.

Conclusions: The holistic IA approach is comparable to human experts at simultaneous detection of DR, AMD, GON, and Nevus. The integration of pathology-specific algorithms allows for obtaining high sensitivities without sacrificing specificity. Deep learning may facilitate wider screenings of eye diseases and become quick and reliable support for ophthalmological experts.

SUBMITTER (NAME ONLY): Nate Goergen

TITLE: Pragmatic usage of Netarsudil: A retrospective chart review from a tertiary care center

SESSION TITLE: Glaucoma Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Goergen, M. Gagrani, V. Gulati, D.A. Ghate, Ophthalmology, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nate Goergen: Commercial Relationship: Code N (No Commercial Relationship) | Meghal Gagrani: Commercial Relationship: Code N (No Commercial Relationship) | Vikas Gulati: Commercial Relationship: Code N (No Commercial Relationship) | Deepta Ghate: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Netarsudil (NL), a rho kinase inhibitor, lowers intraocular pressure (IOP) by increasing outflow facility. There is limited literature on the efficacy of NL in secondary glaucomas and as combination therapy. This retrospective study aims to evaluate the prescription patterns, compliance, and efficacy of NL in an academic glaucoma clinic.

Methods: A retrospective chart review was conducted at a tertiary glaucoma clinic for patients prescribed NL from 01/17 to 5/20. Patient demographics, diagnosis, medication history were noted. Baseline IOP was defined as mean IOP of all visits before starting NL while on stable medication regimen. IOP lowering efficacy was calculated as the difference between IOP at the first visit after starting NL and baseline IOP.

Results: 133 patients were prescribed NL during the study period with a mean age of 69 ± 20 years. 59% were females and 74% were white. The indications for NL prescription were IOP over target and/or drug regimen simplification. Of the study subjects, 67 had a diagnosis of a primary glaucoma (84%). NL was always used as part of a combination glaucoma medication regimen (average medication usage 3 ± 1). NL prescription was not filled by 17% (n=22) subjects mainly due to cost of medication (n=15). 101 eyes of 76 patients were used for IOP analysis. The mean change in IOP was -1 ± 6 mmHg. IOP decreased in 67% and increased/did not change in 33% patients (Table 1). None of the demographic or ocular factors were statistically associated with the prescription fill status or IOP lowering efficacy. NL was discontinued in 52% (50/96) patients after a mean duration of 78 ± 99 days due to a) surgery due to inability to achieve target IOP (42%) b) allergies or intolerance (30%) c) cost (14%) d) paradoxical rise in IOP (12%).

Conclusions: NL was used as an adjunct 2nd-4th line medication in a tertiary glaucoma practice in Midwestern USA. Of patients prescribed NL, 17% of prescriptions medications went unfilled and NL was discontinued in 52% of patients due to poor efficacy, allergies, and expense. IOP response to NL may be variable in this population with severe complex glaucoma.

ABSTRACT BODY:

Purpose: Schlemm canal (SC) is characterized by high local variations in morphology. Previously, we reported characteristics of SC using SC area measurements by optical coherence tomography (OCT) in healthy eyes. Herein, we examine the interobserver variability of SC height, width, and area in glaucomatous and healthy eyes.

Methods: The anterior segment of six eyes from three subjects (1 female, 2 male) were imaged using OCT (Cirrus HD-OCT, Zeiss, Dublin, California, USA). A 4x4mm volumetric image of the limbus (depth of 2mm) was acquired with the Anterior Segment Cube scan protocol, comprised of 128 horizontal B-scans composed of 512 A-scans. SC was positioned to the side of the image to maximize visualization of aqueous humor vessel crossings. Scans were processed to maximize visualization of SC; image volumes were averaged (3x3x3 kernel) and contrast was enhanced with the local histogram algorithm using Fiji (version 2.10/1.53c). A cross-sectional B-scan and the two B-scans +/- 5 frames were identified as three reference frames, based on best visualized SC location (Fig. 1). Three independent observers performed manual segmentation to measure SC width, height, and cross-sectional area for these three reference frames per volume. Width was defined as the longest measure of SC and height as perpendicular to the line used for width measurement. The observers performed these measurements on 15 volumes for a total of 45 analyzed frames each. The coefficient of variation was calculated based on standard deviations estimated using hierarchical multi-level random-effects models. Interobserver variability was quantified with a two-way ANOVA to calculate the intraclass correlation coefficient (ICC).

Results: Participants had a mean age of 72.0 ± 7.47 years (range: 66 to 82) and consisted of one healthy subject and two with primary open angle glaucoma. Measurement means and variation are presented in Table 1. The ICCs for interobserver variability are excellent for width measurements and low to moderate for height and area (Table 2).

Conclusions: Excellent ICC for interobserver variability of SC width suggests it is suitable for use in clinical trials.

ABSTRACT BODY:

Purpose: Several pieces of legislation have been put in place in Canada to ensure employment equity for individuals with disabilities. Yet, there is not much known about the employment experiences of people with seeing disabilities. These estimates are important to ascertain the effectiveness of employment policies for people with sensory disabilities in an equitable way. Our study aimed to provide an employment profile of people with seeing disabilities in Canada.

Methods: We used the 2017 Canadian Survey on Disability (CSD), a national survey of individuals 15 years of age and above with a functional limitation, representing more than 6 million (n = 6,246,640) Canadians. A subset of the larger dataset was created with individuals with seeing disability (25-64 years) and weighted descriptive analyses were performed using SPSS.

Results: Out of the estimated 892,220 adults with seeing disability who were represented on the survey, 54% were employed, 6% were unemployed and 40% were not in the labour force. Of those who reported being employed, 80% were in full-time employment while 20% were in part-time employment; and 85% had a permanent job while 15% reported having a temporary job. The top three employment accommodations that were needed and were made available included: modified work hours (45%); work from home (38.5%) and modified workstation (37%). The top three needed, but least available accommodations were technical aids (14%), communication aids (22%) and computers with specialized software or adaptation (27%). Overall, 26% reported that accommodation was required but was not made available by the employer. While 75% of individuals with seeing disabilities, who were out of the labour force, were so because of their condition, the remaining identified barriers that prevented them from working, which included (top 3): (i) too few jobs available (20%); (ii) inadequate training/experience (19%), (iii) past attempts unsuccessful (19%).

Conclusions: Adults with seeing disability in Canada experience low labour force participation in comparison to general population. Rigorous programs are required that assist them with job search, job retraining and workplace accommodations. Although accessibility legislation has been put in place, programs should be established that provide accessibility solutions to various employers, enabling them to hire individuals with different abilities.

ABSTRACT BODY:

Purpose: The first line treatment for center-involved diabetic macular edema (CI-DME) utilizes anti-vascular endothelial growth factor (VEGF) drugs. The ophthalmologic community remains disputed regarding an optimized approach as to the choice, number, and frequency intervals of intravitreal injections for best visual outcome. This retrospective study investigates the clinical practice patterns of retinal providers using anti-VEGF therapy on visual outcome in DME patients.

Methods: EPIC EMR was used to identify 185 clinically diagnosed DME eyes of 131 subjects (18-100 years) that were seen between 2010-2020 by any of the four retina specialists practicing in a single hospital-based center at University of Texas Medical Branch. The subjects received either Bevacizumab, Aflibercept, or Ranibizumab for DME treatment. The number, interval, and total length of injection treatment were recorded for each provider. Eyes treated by only the same provider were included. First achieved visual acuity (VA) of 20/30 was used to quantify efficacious treatment, and all data was assessed using Chi-square and Kruskal-Wallis tests.

Results: Identified DME patients (age 61.6 yrs), primarily in Caucasians (67%) with no gender difference, had increased propensity of hyperlipidemia and chronic kidney disease (75% and 51% respectively). Among providers, there was a significant difference in the median number of injections (3-8, $p=0.0002$) and in the time interval between the first and last injections (83-296 days; $p=0.0015$) per eye. However, providers were similar in the average intervals between injections (30-40 days; $p=0.38$). Although VA improved pre- and post-treatment amongst providers, there was no significant difference in improvement when comparing the providers. Bevacizumab was the most common choice of anti-VEGF for all four providers ($p=0.23$) followed by Aflibercept ($p=0.27$). When compared to other anti-VEGF drugs, Aflibercept resulted in significantly better visual outcome ($p=0.001$).

Conclusions: Our results show a consensus of monthly use of injections for improved vision despite differences among providers in the frequency and total length of injections. Aflibercept has better visual outcome among all the providers. Further studies are needed to establish an algorithm to institute a "benchmark" protocol for retina physicians in managing DME.

ABSTRACT BODY:

Purpose: To demonstrate optimal strategies for structural imaging of the human retina with an adaptive optics optical coherence tomography (AOOCT) system guided with real-time eye tracking signals from an adaptive optics scanning laser ophthalmoscope (AOSLO).

Methods: A 1040 nm swept source OCT system was coaligned with an AOSLO system via a dichroic mirror placed prior the deformable mirror such that the OCT 7.2 mm beam size would benefit from the adaptive optics correction. Independent AOOCT focus-adjustment was implemented with a set of fold mirrors on a motorized stage to adjust the distance between one of the telescopes in the sample arm of the OCT path. A second motorized stage was used in the reference arm to match the path length and maintain the interference signal. Eye position reported from the AOSLO with cellular resolution and at a frequency of 960 Hz was used to drive a 2D scanner in the AOOCT path to compensate for eye motion in real time. The purpose for independent focus control was to allow the AOOCT to be optimally focused on a retinal layer of interest while the AOSLO maintained focus on the photoreceptor layer, which offers rich texture and high signal-to-noise for accurate, high-speed tracking. AOSLO and AOOCT videos were recorded in sync such that each AOSLO frame corresponded to four AOOCT B-scans acquired at 120Hz. Volumes were acquired from two subjects, in which the AOOCT focus was adjusted through the retinal layers.

Results: We successfully implemented actively stabilized AOOCT with independent focus adjustment to image different layers in the retina while maintaining high fidelity active eye motion tracking using the AOSLO locked onto the photoreceptor mosaic. Since the eye motion was corrected in real time using the same spatial reference, the volumes required minimal processing and could be averaged within the entire imaging session over multiple acquisitions with no lateral registration.

Conclusions: We have implemented an AOOCT system with active eye tracking that has full control for focus-optimized targeted imaging in 3 dimensions. The AOOCT offers high throughput as individual volume images require no distortion correction or lateral registration between separate imaging sessions. This is the first step in building a platform technology that will be used for a range of applications including visual psychophysics, clinical applications and measuring the optoretinogram.

ABSTRACT BODY:

Purpose: To study the racial differences in outcomes of full thickness macular hole (FTMH) repair following pars plana vitrectomy (PPV) between white and black patient population groups.

Methods: A retrospective cohort study was performed using TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising multiple health organizations in the United States. Patients who underwent PPV for FTMH repair were identified and categorized into white and black cohorts. The primary outcomes were retinal tear (RT), retinal detachment (RD) with retinal break, serous RD, epiretinal membrane (ERM), macular hole (MH), macular edema (ME), macular degeneration (MD), glaucoma, cataracts, retinal vein occlusion (RVO), retinal artery occlusion (RAO) and endophthalmitis. Outcomes were compared 90-days postoperative between the groups after propensity score matching using logistic regression and greedy nearest-neighbor matching algorithm.

Results: A total of 2,974 patients were included in the analysis with 1,487 patients in each of the white and black cohorts after propensity matching. At the 90-day postoperative period, black patients had a significantly greater risk of developing macular hole (RR 1.35; 95% CI 1.23,1.49) while white patients had a significantly greater risk of developing RD with retinal break (RR 1.62; 95% CI 1.19,2.21), glaucoma (RR 0.75; 95% CI 0.62,0.9), ERM (RR 2.52; 95% CI 2.07,3.07), ME (RR 2.83; 95% CI 1.79,4.49), and MD (RR 3.30; 95% CI 1.63,6.67). No significant difference was noted in the development of RT, serous RD, cataracts, RVO, RAO and endophthalmitis. The incidence of a second vitrectomy for FTMH repair within the 90-day period was similar in both cohorts (4.8% vs 4.0%).

Conclusions: Racial differences are apparent when evaluating outcomes after FTMH repair. While white patients have a greater risk of post-operative complications when compared to black patients, black patients were noted to have a greater risk of post-operative MH suggesting that the post-operative recovery time period for black patients may be longer compared to white patients.

ABSTRACT BODY:

Purpose: COVID-19, a highly contagious respiratory virus, presents unique challenges to the practice of ophthalmology as a high-volume, office-based specialty. In response to the COVID-19 pandemic, many operational changes were adopted in our ophthalmology clinic to enhance patient and provider safety, while maintaining necessary clinical operations. The aims of this study were two-fold: to evaluate how measures adopted during the pandemic period affected the performance of the retina clinic and patient satisfaction; and to build a model from lessons learned for regulating future clinic operational performance, when the number of patients and providers returns to pre-pandemic levels.

Methods: Timestamps were extracted from the electronic medical records of in-person retina encounters from March 15 to May 15, 2020 and compared with the same period in 2019 to assess patient flow through the clinical encounter. Patient satisfaction was evaluated by Press Ganey patient experience surveys returned by randomly selected outpatients. A discrete-events simulation was designed to model the clinic with COVID-era restrictions to assess operational performance under conditions of increasing patient and provider volumes.

Results: Retina clinic volume declined by 62% during the COVID-19 health emergency. Average check-in-to-technician time declined by 79%, total visit length declined by 46%, and time in the provider phase of care declined by 53%. Interestingly, patient satisfaction with access nearly doubled during the COVID-period compared with the prior year ($p < 0.0001$), while satisfaction with overall care and safety remained high during both periods. A model incorporating COVID-related changes demonstrated that wait time before rooming reached levels similar to the pre-COVID era by 30 patients per provider in a 1-provider model and 25 patients-per-provider in a 2-provider model ($p < 0.001$). Capacity to maintain distancing between patients was exceeded only in the two 2-provider model above 25 patients-per-provider.

Conclusions: Clinic throughput was optimized in response to the COVID-19 health emergency. Modeling these clinic changes can help plan for eventual volume increases in the setting of limits imposed in the COVID- era. The changes implemented enhanced the delivery of eye care and improved patients' sense of wellbeing, thus potentially becoming a new standard of care.

TITLE: Effectiveness of a novel eyelid retractor and irrigation device in simulated chemical ocular injury

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Kondapalli, Everett and Hurite Ophthalmic Association, Pittsburgh, Pennsylvania, UNITED STATES|W.R. Bloom, Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Srinivas Sai Kondapalli: Commercial Relationship(s);Rinsada:Code P (Patent) | William Bloom: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intervention after chemical ocular injury includes prompt irrigation to restore physiologic pH. The purpose of this laboratory study was to assess the effectiveness of a novel eyelid retractor and irrigation device after simulated chemical injury in a porcine model.

Methods: A total of 18 porcine eyes were included in this study. The alkali chemical injury group included eyes receiving 1.0mL of 10.0% sodium hypochlorite solution with a pH of 13.0 (n=10). The acid injury group included eyes receiving 1.0mL of 10.0% acetic acid solution with a pH of 2.5 (n=8). The solution was left in each eye for one minute and the periocular tissue was moved in a blinking motion ten times. To assess standard chemical injury management, eyes in the acid (n=4) and alkali (n=5) injury groups were directly rinsed with saline via 10cc syringe. This process was performed three times total. To assess experimental chemical injury management, eyes in the acid (n=4) and alkali (n=5) injury groups were rinsed with saline using a novel eyelid retractor with irrigation ports connected to a 10cc syringe. Using the device to retract the eyelid, the syringe plunger was depressed to allow simultaneous irrigation. This process was performed three times total. One minute after each rinse, pH was measured using a digital pH meter. Statistical significance of post-rinse mean pH between management conditions was compared using unpaired t-tests ($p < .05$).

Results: A single pH measurement of 7.2 was collected from one porcine eye to establish an approximate physiologic surface pH prior to chemical exposure. In eyes exposed to sodium hypochlorite, there was a significant difference in mean post-rinse pH ($p = .02$) using the novel device (9.0 ± 0.19) compared with using a syringe alone (9.5 ± 0.23). In eyes exposed to acetic acid, there was also a significant difference in mean post-rinse pH ($p < .001$) using the novel device (4.4 ± 0.14) compared with using a syringe alone (3.8 ± 0.10).

Conclusions: A syringe is often the only available frontline irrigation device after chemical exposure and does not facilitate eyelid retraction to irrigate the ocular fornix and palpebral conjunctiva resulting in residual chemicals on the ocular surface. The results of this study suggest use of a modified eyelid retractor and irrigation device more effectively neutralized pH after simulated chemical injuries compared to current irrigation practices.

ABSTRACT BODY:

Purpose: To identify imaging biomarkers and patient characteristics that predict future need for anti-VEGF therapy in diabetic retinopathy (DR) using an integrative machine learning predictive model.

Methods: Retrospective image analysis study of anti-VEGF naive eyes with DR who underwent ultra-widefield fluorescein angiography (UWFA) and optical coherence tomography (OCT). Quantitative UWFA analysis was performed using a custom semi-automated platform for leakage index (LI), ischemic index, microaneurysm (MA) count and vascular density (VD) parameters (skewness, kurtosis, variance, and zero VD index). OCT scans were reviewed for mean central subfield thickness (CST) and the presence of diabetic macular edema (DME). Two random forest classifiers grown with 1000 trees using 3 randomly sampled features as candidates at each split were created to differentiate eyes that required anti-VEGF within 3 months (including on the day of UWFA) and after 3 months of the imaging visit from the eyes that did not require any anti-VEGF during the follow-up period. Features including age, gender, follow-up time, visual acuity (VA), panretinal LI, macular LI, ischemic index MA count, CST, presence of DME and VD parameters were selected for model testing.

Results: Eyes requiring anti-VEGF within 3 months (n=38) of the UWFA imaging session and eyes requiring anti-VEGF after 3 months (n=34) following the imaging visit were compared to the eyes that did not require any anti-VEGF treatment (n=101), independently. The mean follow-up time was 22 (11- 43) months. The area under the curve (AUC) for the anti-VEGF initiation within 3 months model was 0.93 ± 0.03 with the most important features being VA, CST, macular LI, and total LI (importance: 0.211, 0.197, 0.100 and 0.069 respectively). The AUC for differentiating eyes that required anti-VEGF treatment after 3 months vs eyes that did not require any anti-VEGF treatment was 0.77 ± 0.04 with the four most important features being VA, macular leakage index, total leakage index, and follow-up time (importance: 0.112, 0.112, 0.102 and 0.100 respectively).

Conclusions: A ML predictive model was successful identifying eyes requiring immediate and future anti-VEGF therapy. The most important predictive features in both models included VA and macular LI.

ABSTRACT BODY:

Purpose: Retina is the largest subspecialty within academic ophthalmology, comprising 22.0% of all academic ophthalmologists. This study sought to investigate differences in publication productivity between medical and surgical retina specialists.

Methods: The Penn State College of Medicine Institutional Review Board reviewed the study protocol and determined the study was exempt from further review. This was a cross-sectional study of academic retina specialists identified through review of institutional websites of all 113 US ophthalmology residency training programs accredited by the ACGME. Faculty members were categorized as medical or surgical retina specialists based on academic institutional websites regarding the retina fellowship training they completed. Faculty data on residency graduation year were collected between January-March 2019. The h-index measures a published author's publication productivity and citation impact, and was obtained for each retina specialist from the Scopus database. The m-quotient adjusts for career duration and was calculated by dividing the h-index by the total number of years between the author's residency graduation year and 2019. Wilcoxon Rank Sum tests were used to analyze for differences in h-indices and m-quotients between medical and surgical retina specialists.

Results: Among 623 retina specialists identified, 117 (18.8%) were medical specialists and 506 (81.2%) were surgical specialists. Medical and surgical specialists had median career durations of 23.0 (interquartile range (IQR) 20.0) and 19.0 years (IQR 20.0), respectively. Medical specialists had a higher median h-index [14.0 (IQR 28.0) vs. 11.0 (IQR 19.0); $P = 0.023$] and m-quotient [0.83 (IQR 0.90) vs. 0.64 (IQR 0.75); $P = 0.019$] than surgical specialists.

Conclusions: There are fewer medical than surgical retina specialists in academia. Medical retina specialists had a higher median publication productivity than their surgical counterparts, even after accounting for career duration.

ABSTRACT BODY:

Purpose: The underrepresentation of women has been observed in several medical societies but has not been examined yet in ophthalmology research.

This retrospective, observational study examined the gender of awardees of the Association for Research in Vision and Ophthalmology (ARVO) over the past 70 years. More specifically, we determined trends in gender distribution of awards by award category (achievement, public service, research) and awardees' individual characteristics (country of affiliated institution, level of education).

Methods: Award data were compiled from lists displayed on the official ARVO society website. Award details were collected, including: name, society, specialty/subspecialty, description, category (designated based on the award name and description), year(s), and demographic type. Professional websites (ex. LinkedIn, Twitter, ResearchGate, university pages, conference pages, private practice pages, newspapers) were searched to extract a gender-specific pronoun and photograph of each awardee.

Results: This study analyzed 13 different awards given to 299 awardees. 43 (14.4%) awardees were women and 254 awardees (85.6%) were men.

Of 248 achievement awards recognizing an individual's overall contribution, 32 (12.9%) awards were given to women and 216 (87.1%) were given to men. Of 43 research awards recognizing scientific advancement, including the best abstract or publication, 11 (25.6%) were given to women and 32 (74.4%) were given to men. Of 8 public service awards, recognizing humanitarianism or volunteer efforts, none were given to women.

In years with relevant sample size ($n > 2$), the smallest gender gap was in 2010 (37.5% women, 62.5% men).

Most awardees were affiliated with a US institution. Amongst 250 domestic awardees, 36 (14.4%) were women. In the case of 49 international awardees, 7 (14.3%) were women.

Awardees with only an MD degree ($n=96$, 32.3% of total) were mostly men (93.8%), as were awardees with only a PhD or equivalent degree ($n=91$, 30.6% of total, 84.6% men). Finally, awardees with both degrees ($n=44$, 14.8% of total) were also often men (86.4%).

Conclusions: Overall, women were underrepresented in awards given ($<50\%$), even when stratified by category ($<25.6\%$ women) or individual characteristics ($<15.4\%$ by degree, $<14.4\%$ by country of affiliated institutions). These findings suggest a need for greater and more conscious representation in ophthalmology.

ABSTRACT BODY:

Purpose: Anti-vascular endothelial growth factor (anti-VEGF) therapy improves visual acuity (VA) in neovascular age-related macular degeneration (nAMD) patients but the impact of baseline macular atrophy (MA) on long-term visual outcomes is not well understood. This study examines how baseline MA affects long-term visual outcomes in nAMD patients treated with anti-VEGF injections.

Methods: A single eye of patients treated with anti-VEGF injections for nAMD over a 7-year time period at the Cole Eye Institute, Cleveland Clinic were included in this study. Eyes were imaged at baseline using Cirrus SD-OCT and retinal pigment epithelium (RPE) sub-illumination analysis (Cirrus High-Definition Spectral Domain-OCT Review V9.5.1; Carl Zeiss Meditec, Dublin, CA) was used to automate identification of atrophy and measure the total area of RPE sub-illumination within 5mm of the fovea. MA was determined by the presence of atrophy within 5 mm of the fovea. Segmentation errors were manually corrected. Clinical outcomes including VA, number of injections and number of appointments were collected.

Results: 68 patients (60.3% female) with mean age 81.8 ± 9.1 years and baseline VA 68.9 ± 13.7 ETDRS letters were included. 53 eyes (77.9%; mean age 82.1 ± 8.6 years and baseline VA 68.7 ± 15.0 ETDRS letters) had MA at baseline. The mean sub-RPE illumination was $2.9 \pm 2.6 \text{ mm}^2$ in this cohort. 15 eyes did not have MA at baseline had an average age of 80.7 ± 11.1 years and a baseline acuity of 69.7 ± 8.4 ETDRS letters. No differences in baseline characteristics existed between the 2 cohorts (all $p > 0.05$). At 7 years, eyes with baseline MA lost a mean 7.4 ETDRS letters (95% CI, 0.7 to 14.1) from baseline and had received a mean 38.3 ± 16.0 injections over 52.7 ± 16.5 appointments. At 7 years, patients (n=15) without baseline MA lost a mean 10.4 ETDRS letters (95% CI, -2.7 to 23.5) from baseline and had received a mean 40.0 ± 14.4 injections over mean 54.3 ± 11.3 appointments. There were no significant differences in vision loss from baseline, injections, or appointments between the 2 cohorts (all $p > 0.05$).

Conclusions: The results of this study suggest that nAMD eyes with baseline MA treated with anti-VEGF injections were associated with progressive vision loss at 7 years. Further research is needed to examine how the progression of MA affects VA outcomes in nAMD patients treated with anti-VEGF therapy.

ABSTRACT BODY:

Purpose: Intravitreal dexamethasone implants (Ozurdex) are not currently indicated for cystoid macular edema (CME), although they are currently being used as therapy for this condition. Additionally, little data exists on the effects of an intravitreal dexamethasone implant as a treatment for CME. We conducted a retrospective chart review to determine changes in visual function and macular thickness following treatment with an intravitreal dexamethasone implant in patients with CME.

Methods: This chart review included 31 eyes in 28 patients who received at least one intravitreal dexamethasone injection for treatment of CME. Visual acuity (VA) and optical coherence tomography central subfield thickness (CST) were compared before and after the first intravitreal dexamethasone implant. P value was calculated from a 2-tailed paired T-test with a statistical significance value of $P < 0.05$.

Results: In 27 out of 31 eyes, after 1 intravitreal dexamethasone implant, there was significant improvement in peak ETDRS VA (mean +15.5 letters, $p = 0.00001$). The peak ETDRS VA change ranged from -12 to +65 letters. There was a significant decrease in CST in 30 out of 31 eyes after 1 intravitreal dexamethasone implant (mean -168.6 μm , $p = 0.0004$). The CST ranged from a peak decrease of 1204 μm to an increase of 22 μm . Intraocular pressure increased in 27 out of 31 eyes. 8 eyes reached an intraocular pressure of ≥ 25 mmHg with 4 of these reaching an intraocular pressure of ≥ 30 mmHg.

Conclusions: Treatment with an intravitreal dexamethasone implant may significantly benefit VA and CST in patients with CME.

TITLE: Spatiotemporal dynamics of photoreceptor outer segment phagosome ingestion by the retinal pigment epithelium

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Umapathy, J. Chung, M. Tomlinson, C. Lim, D.S. Williams, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|D.S. Williams, Neurobiology, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ankita Umapathy: Commercial Relationship: Code N (No Commercial Relationship) | Julie Chung: Commercial Relationship: Code N (No Commercial Relationship) | Madeline Tomlinson: Commercial Relationship: Code N (No Commercial Relationship) | Caleb Lim: Commercial Relationship: Code N (No Commercial Relationship) | David Williams: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) performs several functions crucial to the maintenance of vision, including the daily phagocytosis of the distal tips of the photoreceptor outer segments (OS). Previous visualization of the phagocytic cup formed by the RPE has been limited to electron microscopy. These static images, though informative, do not accurately capture an inherently transient and dynamic process. We used live imaging, for the first time, to visualize the dynamics of OS ingestion and the transient localization of proteins involved in phagocytosis.

Methods: Primary mouse RPE cells were transfected with proteins of interest (Tractin-RFP/GFP, GFP-FBP17, AMPH1-BAR-mCherry, mRFP-RAB5, GFP-RAB7, or LAMP1-YFP), fed labeled isolated OS, and imaged using spinning disk confocal microscopy. Phagosome diameter was measured in cells pre-treated with cytochalasin D (to disrupt actin dynamics) or DMSO vehicle.

Results: Live imaging of RPE cells transfected with Tractin-RFP (actin) and fed labeled OS showed ingestion of OS by apical actin-rich phagocytic cups that bit phagosome-sized pieces. Cytochalasin D pre-treatment provided greater temporal resolution of actin involvement in phagosome scission such as localized increases in actin intensity coinciding with the site and time of scission events, and concentrated bursts of actin polymerization within the cup pushing phagosomes further into the cell. Furthermore, inhibitor-treated cells tended to produce phagosomes with smaller diameters. Membrane curvature-sensing proteins and regulators of actin dynamics, FBP17 and AMPH1-BAR, also localized to the phagocytic cup. Both coincided with highly curved membranes; AMPH1 was found at the rim and base of the cup, and FBP17 was restricted to the rim of the growing (but not regressing) cup. Early and late endosomal markers, RAB5 and RAB7 (but not the lysosomal marker, LAMP1), entered the phagocytic cup, before closure, to interact with incoming phagosomes.

Conclusions: By visualizing actin dynamics during phagocytosis, we show a role for actin in driving phagosome scission, size, and movement into the cell. The spatiotemporal localization of FBP17 and AMPH1-BAR highlight the transient nature of phagocytosis, whereas that of endosomal markers suggests that phagosome maturation may begin earlier than expected. These data provide unprecedented insight into the process of OS phagocytosis.

TITLE: Outcomes of corneal crosslinking for keratoconus in children and young adults

SESSION TITLE: Corneal Biomechanics, Keratoconus and Collagen Crosslinking

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Saleh, E.B. Koo, S.R. Lambert, E.E. Manche, Ophthalmology, Stanford University School of Medicine, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Solin Saleh: Commercial Relationship: Code N (No Commercial Relationship) | Euna Koo: Commercial Relationship: Code N (No Commercial Relationship) | Scott Lambert: Commercial Relationship: Code N (No Commercial Relationship) | Edward Manche: Commercial Relationship(s);Avedro, Inc.:Code C (Consultant);Johnson and Johnson Vision, Inc.:Code C (Consultant);Placid0, Inc.:Code I (Personal Financial Interest);RxSight, Inc.:Code I (Personal Financial Interest);VacuSite, Inc.:Code I (Personal Financial Interest);Alcon, Inc.:Code F (Financial Support);Allergan, Inc.:Code F (Financial Support);Avedro, Inc.:Code F (Financial Support);Carl Zeiss Meditec:Code F (Financial Support);Johnson and Johnson Vision, Inc.:Code F (Financial Support);Presbia:Code F (Financial Support)

ABSTRACT BODY:

Purpose: There is limited North American data on the efficacy of corneal crosslinking for pediatric keratoconus, which is often severe at diagnosis and progresses rapidly. We performed a retrospective medical record review to assess the effect of corneal crosslinking on vision, keratometry and wavefront aberration in children and young adults with progressive keratoconus.

Methods: We included patients aged ≤ 22 years with keratoconus who underwent corneal crosslinking between January 2013 and November 2019 at Byers Eye Institute at Stanford University. Outcome measures included logMAR corrected distance visual acuity (CDVA), keratometry and total wavefront aberration. Measurements were taken at baseline and 12 and 24 months postoperatively.

Results: A total of 57 eyes of 49 patients aged 12-22 years were included. The mean preoperative CDVA was logMAR 0.38 ± 0.32 (20/48) and postoperative CDVAs were logMAR 0.29 ± 0.31 (20/39) and 0.31 ± 0.31 (20/41) at 12 and 24 months postoperatively. Compared to preoperative mean Kmax, there was an improvement of -0.8 D to a mean postoperative Kmax of 59.1 ± 9.1 D at 12 months and -1.3 D to 59.7 ± 8.8 D at 24 months. Linear mixed modelling showed significant improvements in Kmax at 12 and 24 months ($p=0.013$, $p=0.001$, respectively). In a sub-analysis of available wavefront aberration data, there were no significant changes in root mean square, defocus, astigmatism, coma, trefoil, tetrafoil, spherical aberration or second order astigmatism at 12 months postoperatively.

Conclusions: Corneal crosslinking stabilized, and in some cases improved the visual, topographic and wavefront aberration parameters in pediatric and young adult patients with keratoconus. The procedure may prevent disease progression in this population.

TITLE: Retinal OFF pathway activation leads to greater accommodation-induced choroidal thinning

SESSION TITLE: Molecular and Structural

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Hoseini-Yazdi, S.A. Read, D. Alonso-Caneiro, M.J. Collins, School of Optometry and Vision Science, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Hosein Hoseini-Yazdi: Commercial Relationship: Code N (No Commercial Relationship) | Scott Read: Commercial Relationship: Code N (No Commercial Relationship) | David Alonso-Caneiro: Commercial Relationship: Code N (No Commercial Relationship) | Michael Collins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Both near work and retinal OFF pathway activation have been implicated in the development of myopia. This study examined the interaction between accommodation and retinal ON and OFF pathway activation, and their association with changes in choroidal thickness in healthy young adults.

Methods: Nineteen subjects with a mean age of 25 ± 5 years and refractive error of -1.6 ± 2.2 D (range -5.5 to $+0.75$ D) participated. The left eye's sub-foveal choroidal thickness (SFCT) was assessed with Spectralis optical coherence tomography before and after a series of 30-min long binocular viewing tasks, including reading a passage of bright text on a dark background (ON pathway activation) and dark text on a bright background (OFF activation), and a control condition of viewing a movie with no bias towards ON or OFF pathways. Each task was preceded by a 20-min adaptation period of watching a movie at distance. The tasks were performed with 0 D and 5 D (induced by soft contact lenses) accommodation demands. Repeated measures ANOVA was conducted to examine the change in SFCT associated with contrast polarity (3 levels) and accommodation (2 levels).

Results: Significant main effects of accommodation and polarity were observed (both $p < 0.001$), with the SFCT reducing significantly by $-7 \pm 1 \mu\text{m}$ with 5 D accommodation compared to 0 D accommodation ($-3 \pm 1 \mu\text{m}$, $p < 0.001$), and by $-9 \pm 1 \mu\text{m}$ with OFF pathway compared to ON pathway activation ($-4 \pm 1 \mu\text{m}$, $p = 0.002$) and the control condition ($-2 \pm 1 \mu\text{m}$, $p < 0.001$). The change in SFCT with ON pathway activation was not significantly different from that observed with the control condition, both at 0 D ($-2 \pm 2 \mu\text{m}$ vs $+1 \pm 1 \mu\text{m}$, $p = 0.52$) and 5 D ($-6 \pm 1 \mu\text{m}$ vs $-5 \pm 1 \mu\text{m}$, $p = 0.99$) accommodation. However, selective activation of the retinal OFF pathway resulted in a significantly greater thinning of the choroid compared to the control condition, both at 0 D ($-7 \pm 1 \mu\text{m}$, $p = 0.003$) and 5 D ($-11 \pm 1 \mu\text{m}$, $p = 0.005$) accommodation demands.

Conclusions: The choroidal thinning associated with accommodation was approximately doubled with selective activation of the retinal OFF pathway through reading standard dark on light background text, providing a potential mechanism that involves accommodation and the OFF signalling pathway, linking near work and myopia.

TITLE: Ophthalmology Resident Surgical Aptitude and Performance of ACGME-Identified Core Oculofacial Procedures

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Patel, I.U. Scott, C. Weller, Ophthalmology, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|I.U. Scott, Public Health Sciences, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Saagar Patel: Commercial Relationship: Code N (No Commercial Relationship) | Ingrid Scott: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Weller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate qualitative and quantitative measures of ophthalmology resident perceptions and ability to perform ACGME-identified core oculofacial procedures at a single institution.

Methods: Prospective case series. Anonymous questionnaires analyzed residents' perceptions of their knowledge and ability to perform steps of the ACGME-identified oculofacial procedures identified in Table 1. These were graded on a 1 to 5 scale. During an introductory suturing laboratory, an oculoplastics attending evaluated each resident's ability to oppose wounds on a suturing pad with the following surgical knots: simple interrupted, simple running, horizontal mattress, vertical mattress, deep dermal. Scores were based on successful apposition of the wound, appropriate spacing of suture, appropriate knot formation, and efficiency.

Results: Nine residents completed the survey and seven residents completed the introductory suturing lab. The mean score of all residents for the suturing lab was 56.1/100. The mean scores for residents' perceived knowledge and perceived performance of each procedure are listed in Table 1. Scores trended upwards for each postgraduate year (PGY) in both knowledge and performance. No resident felt comfortable with independent performance of the following procedures: levator advancement, ectropion repair, entropion repair. All residents reported that "primary" surgical cases contributed to their skill set and believed that additional "primary" surgical cases and surgical wet labs would improve their surgical skills.

Conclusions: Residents' perceived knowledge correlated with their perceived ability to perform ACGME-identified core oculofacial procedures ($r = 0.96$). Residents believed that additional "primary" surgeries and wet labs would improve their surgical skills. Residents' perceived knowledge and perceived ability to perform the procedures increased with PGY level. Additional objective data via cadaver courses are upcoming.

ABSTRACT BODY:

Purpose: Clustered regularly interspaced short palindromic repeats (CRISPR)-based genome editing technology has significant potential as a novel mode of gene therapy for retinal disorders. We previously identified single guide RNAs (gRNAs) targeting conserved regions in exon 1 of the vascular endothelial growth factor-a (VEGFA) gene in mice, rhesus macaques, and humans, and demonstrated efficient genomic ablation in human cell lines in vitro and mouse eyes in vivo using *S. pyogenes* Cas9 (SpCas9). Here, we evaluate the effectiveness of these gRNAs to target VEGFA in the rhesus macaque genome using SpCas9 ribonucleoproteins (RNPs) in a cell-free system.

Methods: We identified 2 target sequences (V1 and V2) in exon 1 of mouse, rhesus macaque, and human VEGFA gene in silico, then synthesized functional gRNAs by combining these target sequences with trans-activating crisper RNA (tracrRNA) and assembled with SpCas9 protein to generate VEGFA-targeting RNPs. The 1.4kb target VEGFA gene was amplified from rhesus macaque and human genomic DNA separately, then incubated with V1, V2, or both V1+V2 RNPs to compare genome editing efficiency in vitro.

Results: The in silico predictions for on-target activity of V1 and V2 target sequences were 60.5 and 49.5 for rhesus VEGFa, and 60.0 and 54.0 for human VEGFa, respectively. The off-target scores were 43.5 and 45.5 for rhesus VEGFa and 43.0 and 45.0 for human VEGFa. RNPs targeting the V1 and V2 loci of VEGFA demonstrated successful genomic ablation of the target gene sequence of rhesus macaques in vitro, with a genome editing efficiency of 46.39% using V1 gRNAs, 20.95% using V2 gRNAs, and 44.60% using V1+V2 gRNAs. In comparison, genome editing efficiencies using human VEGFA, which has similar on- and off-target scores to those of rhesus macaque, were 84.72% using V1 gRNAs, 37.10% using V2 gRNAs, and 68.54% using V1+V2 gRNAs.

Conclusions: CRISPR-based genomic ablation of the VEGFA gene using SpCas9 RNPs can be achieved with nonhuman primate and human genomes in vitro, although genome editing efficiencies do not reflect in silico predictions. In vitro assays may better indicate in vivo effectiveness of VEGFA ablation than in silico predictions, and may help facilitate clinical translation of CRISPR-based anti-angiogenesis therapies.

TITLE: Vitreomacular separation on OCT in eyes with central retinal vein occlusions

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Zheng, X. Zhang, S. Fekrat, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|A. Thomas, Tennessee Retina, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yuxi Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Xinxin Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Akshay Thomas: Commercial Relationship(s);Alimera:Code C (Consultant);Avisis:Code C (Consultant);Bausch + Lomb:Code C (Consultant);Genentech:Code C (Consultant);Zeiss:Code C (Consultant) | Sharon Fekrat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the impact of complete vitreomacular separation on presenting characteristics, treatment patterns, and clinical outcomes of central retinal vein occlusions (CRVO).

Methods: We performed a retrospective longitudinal cohort study of patients seen at our institution for treatment-naïve CRVO between 2009-2017 and who had at least 12 months of follow-up. Presenting OCTs were individually reviewed for vitreomacular status at the presenting visit. Presenting clinical characteristics, treatment patterns, and outcomes were tabulated and analyzed between eyes with complete vitreomacular separation and those without.

Results: Of the 141 treatment-naïve eyes with CRVOs identified, 54 (38.3%) had complete vitreomacular separation on OCT at presentation, while 87 (61.7%) did not. Eyes with vitreomacular separation had baseline central subfield thickness (CST) of $490.0 \pm 296.1 \mu\text{m}$, while those with attached posterior hyaloid (including partially attached) had baseline CST of $548.7 \pm 286.0 \mu\text{m}$ ($p=0.15$). CST on final visit was significantly lower for eyes that presented with vitreomacular separation ($280.5 \pm 139.9 \mu\text{m}$ vs $345.0 \pm 172 \mu\text{m}$, $p=0.02$). 12-month injection burden was lower for eyes that presented with complete vitreomacular separation (3.3 ± 3.6 injections vs 4.8 ± 4.1 injections, $p=0.02$). Presence of cystoid macular edema (CME) at presentation and final visit did not differ between groups. On presentation, 38/54 (70.4%) eyes with vitreomacular separation had CME, while 61/87 (70.4%) of those without had CME ($p=0.97$). At final visit, 15/54 eyes (27.8%) of eyes with vitreomacular separation had CME while 27/87 (31%) did not ($p=0.68$).

Conclusions: Assessment of the vitreomacular relationship on OCT at presentation in eyes with CRVO may serve as a prognostic imaging biomarker. Eyes with complete vitreomacular separation have a significantly lower injection burden and CST at final visit compared to eyes without.

ABSTRACT BODY:

Purpose: The introduction of whole genome sequencing (WGS) within the UK National Health Service (NHS) represents a global shift from targeted panel testing to genomic analysis. We performed a retrospective analysis of patients with a range of genetic eye disorders who had WGS to evaluate its utility.

Methods: Data was gathered from 1669 families from the ocular genetics service at Moorfields Eye Hospital, who underwent WGS through the UK Genomics England 100,000 Genomes Project. Patients were grouped into 4 categories based on their primary diagnosis: posterior segment disorders (including retinal dystrophies and optic neuropathies); anterior segment abnormalities (including bilateral congenital cataract, primary congenital glaucoma, and corneal dystrophies); ocular malformations (including microphthalmia, anophthalmia and coloboma); and albinism/nystagmus. A targeted virtual gene panel was applied to the WGS data in the first instance, followed by re-analysis incorporating off-panel variant interrogation and expert review with a multidisciplinary team (consisting of bioinformaticians, ophthalmologists specialising in genetic eye disease, clinical geneticist, and genetic counsellors) for unsolved cases.

Results: Overall, WGS yielded a molecular diagnosis in 55.8% of cases (931/1669). Solve rates grouped by diagnosis, family history, ethnicity and prior testing can be found in Table 1.

In 183 families (11.0% of all families; 19.6% of solved families), the genetic diagnosis was missed by initial laboratory analysis, but found through re-analysis by our multidisciplinary team. This was achieved by having expertise in ocular phenotypes, relaxing variant filtering, applying additional gene panels and interrogating copy number variation and non-coding variants.

Conclusions: A multidisciplinary, case-specific approach to genetic testing utilizing unbiased genome sequencing technology has yielded an overall molecular solve rate of 55.8% of patients in this large mixed cohort. It is uniquely possible to further scrutinise WGS data as new discoveries are made enabling additional molecular diagnoses without the need for additional expensive molecular investigations.

ABSTRACT BODY:

Purpose: To evaluate outcomes of eyes with neovascular age-related macular degeneration (nAMD) with moderate to very large retinal pigment epithelial detachments (PEDs) in the OSPREY trial.

Methods: This was a post hoc analysis of the OSPREY phase II, randomized, multicenter, double-masked trial comparing brolucizumab 6mg and aflibercept (AFL) 2mg in nAMD. Treatment-naïve nAMD eyes presenting PEDs were evaluated in the following groups as determined at baseline: (1) all PEDs with a maximum height 150µm (brolucizumab n=20, AFL n=21); (2) very large PEDs with a maximum height 250µm (brolucizumab n=12, AFL n=10). SD-OCT scans were analyzed in a machine-learning enhanced novel software platform for multi-layer volumetric assessment to categorize PED size and provide volumetric measures, including sub-RPE volume and intraretinal fluid (IRF) and subretinal fluid (SRF) volumes. No adjustment was made for multiple comparisons.

Results: A total of 41 eyes were included in this analysis. When considering all PEDs 150µm, the mean change in BCVA was +7.3 letters in the brolucizumab group (p=0.02) and +6.6 letters in the AFL group (p=0.05). In the very large PED cohort, mean change in BCVA was +5.6 letters (p=0.26) and -0.4 letters (p=0.94) in the brolucizumab and AFL groups, respectively. In both cohorts, brolucizumab and AFL demonstrated significant reductions in PED maximum height (p<0.05). In very large PEDs, the mean reduction at Week 4 was -122.7µm with brolucizumab compared to -84.1µm with AFL. At Week 56, the mean reduction was -167.0µm with brolucizumab compared to -153.2µm with AFL. Significant reductions in sub-RPE volume were noted with both treatment regimens across all PED cohorts (p<0.05; all but two time points with AFL). In both cohorts at Week 56, there was a reduction in mean IRF volume (0.11 and 0.12mm³ with brolucizumab, 0.08 and 0.10mm³ with AFL) and SRF volume (0.45 and 0.74mm³ with brolucizumab and 0.40 and 0.78mm³ with AFL).

Conclusions: Both brolucizumab and AFL demonstrated significant improvement in PED features. In very large PEDs, functional response was more limited. Although exploratory in nature, this analysis suggests a possibly more rapid improvement in exudative parameters and possibly greater functional response in the very large PED group with

brolocizumab.

TITLE: Normative Distribution of Optical Coherence Tomography Retinal Features and Associations with Visual Function in Older Adults (from the Eye Determinants of Cognition Study)

SESSION TITLE: Aging, social and environmental determinants and the eye

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Dong, R.A. Sharrett, Epidemiology, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|X. Guo, L.T. Arsiwala, P.Y. Ramulu, A. Mihailovic, Wilmer Eye Institute, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|A. Abraham, Ophthalmology, University of Colorado, Denver, Colorado, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Yanan Dong: Commercial Relationship: Code N (No Commercial Relationship) | Xinxing Guo: Commercial Relationship: Code N (No Commercial Relationship) | Alison Abraham: Commercial Relationship: Code N (No Commercial Relationship) | Richey Sharrett: Commercial Relationship: Code N (No Commercial Relationship) | Lubaina Arsiwala: Commercial Relationship: Code N (No Commercial Relationship) | Pradeep Ramulu: Commercial Relationship: Code N (No Commercial Relationship) | Aleksandra Mihailovic: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Structural and angiography measures of retinal optical coherence tomography (OCT) imaging are often employed clinically to evaluate retinal health in individual patients. However, the normative distribution of these measures across older populations has not been well characterized. Here we describe the distribution of retinal features and its associations with visual function in a population-based bi-community sample from the Eye Determinants of Cognition (EyeDOC) study.

Methods: OCT structural and angiographic images were obtained in EyeDOC participants from two communities: Jackson, MS (all Black) and Washington County, MD (all White). Retinal measurements included retinal nerve fiber layer (RNFL) thickness, macular ganglion cell complex (GCC) thickness, macular vessel density (VD, % of area covered by vessels) in the superficial and deep capillary plexus (SCP and DCP), and the area of the foveal avascular zone (FAZ). Aspects of visual function including corrected distance visual acuity (VA) and contrast sensitivity (CS) were assessed. Differences in means for each retinal feature by age and community were tested using t-test and one-way ANOVA. Associations of visual function with retinal features were estimated from adjusted linear regression models.

Results: Retinal measures were available in 759 participants (46% black; 63% female; mean age 80 years[range: 73-94 years]). Mean GCC thickness was lower for Jackson vs. Washington County participants (89.2 μ m, 92.3 μ m, $p < 0.001$). Mean VD in DCP were statistically lower for participants ≤ 80 years old (44.67%, 43.69%, $p < 0.001$). Mean FAZ differed by community (Jackson: 0.36 mm², Washington: 0.26 mm², $p < 0.001$; Table 1). Each 10 μ m increase in RNFL thickness was related to 0.016 logCS better (95% confidence interval[CI]: 0.005-0.027, $p = 0.004$) among all participants and 0.012 logMAR VA better (95% CI: 0.001-0.023, $p = 0.049$) among Jackson participants (Table 2). Each 10 μ m increase in GCC thickness was associated with 0.016 logCS better (95% CI: 0.003-0.029, $p = 0.017$) overall, with a larger effect among Jackson participants ($\beta = 0.022$, 95% CI: 0.006-0.040, $p = 0.009$).

Conclusions: Results from this aging bi-community population suggested that different references should be used for different age and community groups for structural and functional retinal evaluations.

SUBMITTER (NAME ONLY): Christie Hang I Lam

TITLE: High Glucose Induces Mitochondrial Dysfunction in Photoreceptor cells

SESSION TITLE: Retinal diseases: molecular and biochemical mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Lam, H.H. Chan, D. Tse, School of Optometry, The Hong Kong Polytechnic University, Kowloon, HONG KONG

Commercial Relationships Disclosure (Abstract): Christie Hang I Lam: Commercial Relationship: Code N (No Commercial Relationship) | Henry Chan: Commercial Relationship: Code N (No Commercial Relationship) | Dennis Yan-yin Tse: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Photoreceptors have high metabolic activity, yet limited reserve capacity for mitochondrial oxidative phosphorylation. While mitochondrial dysfunction has been implicated in the cell death of various retinal cell types, including retinal endothelial cells, pericytes, and Müller cells, under simulated hyperglycemic stress, its effect on photoreceptor cells remains unclear. Here we investigated the effects of high glucose on mitochondrial membrane potential ($\Delta\Psi_M$), morphology, bioenergetics, and cell apoptosis of 661w photoreceptor-like cells.

Methods: The effect of high glucose (55mM) on $\Delta\Psi_M$ of 661w cells over time was evaluated with tetramethylrhodamine ethyl ester (TRME) fluorescein intensity level relative to normal glucose condition (5.5mM). Mitochondrial network of 661w cells incubated in these two conditions for 48 hours was identified using MitoTracker Green staining. Mitochondrial images were captured in live cells with confocal microscopy and analyzed for mitochondrial morphology changes based on form factor (FF) and aspect ratio (AR) values. Mitochondrial bioenergetics was assessed by measuring oxygen consumption rate (OCR) using the Seahorse XFe24 Extracellular Flux Analyzer. Cell apoptosis was evaluated by annexin V assay.

Results: 661w cells incubated in high glucose condition exhibited a multiphasic change in $\Delta\Psi_M$ over time (Fig 1). Significant increase in mitochondrial fragmentation was also observed when compared to normal glucose condition (FF= 2.95 ± 0.40 vs 4.82 ± 0.42 , $p<0.01$; AR= 1.96 ± 0.10 vs 2.44 ± 0.08 , $p<0.001$). OCRs were significantly reduced in cells grown in high glucose condition compared to those in normal glucose condition (ATP production: 7.62 ± 0.84 vs 9.86 ± 0.40 ; Maximal respiration: 10.52 ± 0.86 vs 14.33 ± 0.89 , $p<0.05$). Cell apoptosis was also increased by approximately 1.4-fold in high glucose condition compared to normal glucose condition ($p<0.001$).

Conclusions: High glucose affects the mitochondria of 661w cells by disrupting the homeostasis of $\Delta\Psi_M$, changing mitochondrial morphology, and increasing mitochondrial fragmentation. Impaired mitochondrial function and increased cell apoptosis were also observed. The detrimental effects of glucose on mitochondrial function and cellular metabolism may lead to photoreceptor cells apoptosis, contributing to the pathogenesis of diabetic retinopathy.

TITLE: Western Blot Total Protein versus a Housekeeping Gene Normalization in the DBA2/J Mouse Retina

SESSION TITLE: Glaucoma: biochemistry, molecular biology, biomechanics, genomics and proteomics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.N. Nwabueze, R. Prasad, K.M. Joos, Ophthalmology, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nkechi Nwabueze: Commercial Relationship: Code N (No Commercial Relationship) | Ratna Prasad: Commercial Relationship: Code N (No Commercial Relationship) | Karen Joos: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma carries a huge disease burden and understanding it is critical. Quantitative Western Blot (WB) analysis requires comparison of the target protein normalized to an internal control. However, the housekeeping proteins can be susceptible to oxidative stress, mechanical changes, and aging in the retina. Normalization to total protein was recently reported. We compared B-actin and total protein as internal controls in mice with increasing age and with elevated intraocular pressure (IOP).

Methods: Mouse tissues were acquired following protocols that were ethically reviewed and approved by the Vanderbilt University Medical Center Institutional Animal Care and Use Committee, and adhered to the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research. We divided the eyes of 10-month old DBA/2J mice into two groups based upon: 1) normal IOP (NIOP; $<10\text{mmHg}$) and 2) High IOP (HIOP; $>10\text{mmHg}$) measured by tonometer (TONOLAB, Icare). A third group consisted of eyes from 10-week DBA/2J mice. Samples consisted of three retinas. 7 WBs comparing relative quantities among the 3 groups using B-actin, and 7 WBs using total protein levels (REVERT Total Protein Stain, LICOR Biosciences, Lincoln) were run. Comparison of expression among the 3 groups was performed with one-way ANOVA (SigmaPlot 12.5, Systat).

Results: A significant difference in B-actin levels was present among the 3 groups ($P<0.001$) with a significant increase in the HIOP group compared to the other 2 groups (Bonferroni Multiple Comparison, HIOP vs NLIOP $P=0.006$; HIOP vs 10-week old $P<0.001$). No significant difference in total protein staining was present among the 3 groups ($P=0.274$).

Conclusions: Total protein staining may be the superior method for normalization of WB proteins in the mouse retina. There was an increase in B-actin levels in the DBA/2J HIOP retinas compared to B-actin levels in the other groups, suggesting an influence of IOP. Whereas, there was no significant difference in total protein staining among the 3 groups.

TITLE: The close link between hypoxia and autoinduction of placental growth factor in galectin-1 expression in retinal pigment epithelium cells

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Yamamoto, A. Kanda, S. Kase, S. Ishida, Laboratory of Ocular Cell Biology and Visual Science, Department of Ophthalmology, Hokkaido University Faculty of Medicine and Graduate School of Medicine, Sapporo, Hokkaido, JAPAN|

Commercial Relationships Disclosure (Abstract): Taku Yamamoto: Commercial Relationship: Code N (No Commercial Relationship) | Atsuhiko Kanda: Commercial Relationship(s);Bayer Yakuhin Ltd:Code F (Financial Support);Bayer AG:Code F (Financial Support) | Satoru Kase: Commercial Relationship: Code N (No Commercial Relationship) | Susumu Ishida: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Galectin-1/LGALS1, a member of β -galactoside-binding lectin family, contributes to angiogenesis and fibrosis in various ocular diseases. Hypoxia-dependent and -independent pathways increase galectin-1/LGALS1 expression in Müller glial cells. Here, we show new findings on the galectin-1/LGALS1 regulatory system in human retinal pigment epithelium (RPE) cells, the major cellular participant in the pathogenesis of neovascular age-related macular degeneration (nAMD).

Methods: Human RPE cells were used to evaluate changes in gene and protein expression with real-time quantitative PCR and immunoblot analyses, respectively. The promoter and enhancer region of LGALS1 was analyzed by reporter assay and chromatin immunoprecipitation. nAMD patient specimens were examined by immunofluorescence analysis.

Results: Hypoxia induced galectin-1/LGALS1 expression (fold change = 1.7, $p < 0.05$) via binding of hypoxia-inducible factor-1 α to hypoxia-responsive elements in the LGALS1 promoter region. Blockade of vascular endothelial growth factor receptor (VEGFR)1 partially decreased hypoxia-induced galectin-1/LGALS1 expression (fold change = 1.2, $p < 0.01$). Among several VEGFR1 ligands induced by hypoxia, placental growth factor (PIGF)/PGF alone upregulated galectin-1/LGALS1 expression (fold change = 2.2, $p < 0.05$) via phosphorylation of activator protein (AP)-1 subunits following AKT and p38 mitogen-activated protein kinase (MAPK) activation. AP-1 site in the LGALS1 enhancer region was required for PIGF-induced galectin-1/LGALS1 expression in RPE cells. PIGF application upregulated PGF expression (fold change = 1.8, $p < 0.01$) via extracellular signal-regulated kinase 1/2, AKT, and p38 MAPK pathways. nAMD patient specimens demonstrated co-localization of galectin-1 with HIF-1 α , PIGF, and VEGFR1 in RPE cells.

Conclusions: Our present findings implicate the significance of hypoxia as a key inducer of galectin-1/LGALS1 in RPE cells and autoinduction of hypoxia-induced PIGF as a vicious cycle to amplify the pathogenesis of nAMD.

TITLE: Anterior Segment Biometric Measurements Explain Misclassifications by a Deep Learning Classifier for Detecting Gonioscopic Angle Closure

SESSION TITLE: Data science, machine learning, and artificial intelligence

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Shen, M.F. Chiang, A. Pardeshi, R. McKean-Cowdin, B. Xu, University of Southern California Keck School of Medicine, Los Angeles, California, UNITED STATES|R. Varma, Southern California Eye Institute, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alice Shen: Commercial Relationship: Code N (No Commercial Relationship) | Michael Chiang: Commercial Relationship: Code N (No Commercial Relationship) | Anmol Pardeshi: Commercial Relationship: Code N (No Commercial Relationship) | Rohit Varma: Commercial Relationship: Code N (No Commercial Relationship) | Roberta McKean-Cowdin: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Xu: Commercial Relationship(s); Heidelberg Engineering: Code F (Financial Support)

ABSTRACT BODY:

Purpose: To identify biometric parameters that explain misclassifications by a deep learning classifier to detect gonioscopic angle closure based on anterior segment OCT (AS-OCT) images.

Methods: Subjects of the Chinese American Eye Study underwent a complete ocular examination with gonioscopy and AS-OCT imaging of each quadrant of the anterior chamber angle. A previously described deep learning algorithm was applied to one AS-OCT per quadrant to predict a gonioscopy grade based on the modified Shaffer grading scale (grades 0/1 = closed; grades 2/3/4 = open). Median biometric measurements were calculated and compared between prediction classes using the Kruskal-Wallis test due to non-normal distributions. Pairwise comparisons of median biometric measurements between prediction classes were performed using the post-hoc Dunn's test, adjusted for multiple comparisons.

Results: Among 584 total images, 271 images with angle closure (true positive, TP) and 224 images with open angle (true negative, TN) were correctly predicted by the classifier. 77 images with open angle were overcalled as closed (false positive, FP). 12 images with angle closure were undercalled as open (false negative, FN).

There were significant differences ($p < 0.001$) in median parameter measurements between prediction classes among anterior chamber angle (ACA) parameters (angle opening distance, trabecular iris space area, scleral spur angle). The order of median ACA parameter measurements from smallest to largest was: TP, FN, FP, TN.

There were significant differences ($p < 0.036$) in median parameter measurements between prediction classes among anterior segment (AS) parameters. For some AS parameters (iris area, anterior chamber depth), the order of median parameter measurements from smallest to largest differed from the ACA parameters: TP, FP, FN, TN. This order was the same for other AS parameters (iris curvature, lens vault) when median parameter measurements were ordered from largest to smallest.

Conclusions: Overall, there were more FP than FN by the deep learning classifier. Our findings suggest that when there is disagreement between ACA and AS parameters, the classifier preferentially makes predictions based on AS over ACA parameters. A second layer of quantitative analysis may help identify initially misclassified images and improve classifier accuracy in detecting gonioscopic angle closure.

ABSTRACT BODY:

Purpose: Visual acuity (VA) remains the primary functional endpoint for quantifying treatment effectiveness. To enrich VA information collected in retina trials, we apply a novel quantitative VA (qVA) framework to estimate VA thresholds from different testing paradigms (1). We propose that novel Bayesian analytics can reduce the uncertainty of VA estimates in patients with retinal disease.

Methods: Prospective, observational study performed at Mass Eye and Ear. We recruited patients with vision ranging from 20/15 to 20/100 during regular retina clinic visits. ETDRS testing, in the right and then left eye, was followed by qVA testing, which consisted of 15 sequential rows of 3 optotypes. Patients were retested in the opposite order after at least 30 minutes. We generate a qVA profile using a Bayesian model of VA that defines the probabilities for correctly reporting the different numbers of optotypes presented in ETDRS/qVA tasks. To quantify the evolution of a qVA profile, we calculate the half-width of 68.2% credible intervals (HWCI) for VA threshold estimates (2), as a function of 1-14 rows completed during ETDRS/qVA testing.

Results: 53 eyes of 31 patients, with mean age of 65.1 ± 13.3 and 21 females (68%) were included in the study. Repeat testing generated a total of 106 ETDRS/qVA tests. Figure 1 presents the Bayesian priors for VA threshold, and final posteriors for two patients. Figure 2a demonstrates the rapid reduction in average HWCI during VA testing. Figure 2b presents HWCIs for an aggregate analysis concatenating two ETDRS/qVA runs for each patient (N=53). Paired t-tests revealed statistically significant HCWI reductions for qVA: 22% for single and 20% for double runs ($p < 10^{-6}$).

Conclusions: We demonstrate that the novel application of a qVA analysis reduces uncertainty in VA estimates from ETDRS/qVA testing. The qVA advantage most likely emerges from its intelligent sampling and fine-grain resolution, relative to coarse, static sampling of ETDRS. These results support the feasibility for qVA testing and analysis to improve the signal-noise features of VA data in clinical trials.

ABSTRACT BODY:

Purpose: To review the complication of anterior chamber migration of Ozurdex implant in patients with sutured intraocular lenses (IOL).

Methods: Institutional review board approval was obtained for this retrospective study. The practice management database of a single retinal speciality group was searched by current procedural terminology (CPT) for all patients with sutured IOLs and Ozurdex intravitreal implants over a five year period from 2016 through 2020. Patients matching these parameters had their charts reviewed individually. Data collected includes age, sex, eye, date of sutured IOL, number and dates of intravitreal ozurdex injections, pre and post injection visual acuity, pre and post injection intraocular pressure, occurrence of anterior chamber (AC) migration of ozurdex, further surgical procedures, corneal transplation, and most recent visual acuity and intraocular pressure.

Results: Database search revealed seven patients that fit the criteria of having an Ozurdex implant and sutured IOL. Four of the seven patients experienced AC migration of Ozurdex implant. This resulted in three additional surgical procedures to remove the AC foreign body. One patient was treated with positioning. Three of the four patients who experienced AC migration of the Ozurdex implant required corneal transplant. Of the patients with AC migration, final visual acuity ranged from 20/300 to 20/400. Of the patients without AC migration, final visual acuity values were 20/40, 20/50, and 20/200. There was no significant difference in intraocular pressure in all seven patients.

Conclusions: Patients with Ozurdex implants seem to be at a higher risk of AC chamber migration in sutured IOLs. This appears to lead to corneal failure and poor visual outcomes.

TITLE: Short term visual outcomes with extended anti-VEGF therapy intervals for macular edema as a result of the COVID-19 pandemic

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Clark, Ophthalmology, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrew Clark: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has placed an unprecedented strain on the modern healthcare system with outpatient providers needing to make significant adjustments in practice patterns in response. Ophthalmologists face unique challenges with limited ability to practice remotely, need for close quarters contact to facilitate routine examination and lack of validated personal protection equipment compatible with standard ophthalmic examination equipment. Macular edema is one common retinal condition necessitating frequent examination and in-office intervention. In this single institution retrospective case series, visual outcomes were reviewed for patients with macular edema previously stabilized by regular intravitreal bevacizumab (IVA) injections that were extended as result of limitations imposed by the pandemic.

Methods: Patients with stable macular edema from diabetic disease (DME) or retinal vein occlusion (RVO) were identified. A total of 11 patients (10 DME and 1 RVO, 11 eyes) underwent extended therapeutic interval. Patients were monitored using Snellen visual acuity, clinical examination and macular OCT.

Results: The median injection frequency was increased from 42d (range 28-84d) to 84d (range 42-252d) with an average percentage increase in duration between injections of 45%. The number of treatment cycles under extended therapy was between 1-3 cycles. The length of extension was based on a combination of patient preference, logistical limitations and provider clinical judgment. Only one of eleven patients demonstrated recurrence of center-involving edema with extended injection interval. The visual decline in Snellen visual acuity for the affected patient was one line (20/40 to 20/50) without subjective appreciation of decreased vision. The remaining ten patients demonstrated no visual decline with extended therapy.

Conclusions: These results suggest that temporary extension of IVA treatment interval leads to neither immediate nor significant visual decline in patients with previously well controlled edema. Long term follow-up is necessary to determine if these patients will remain clinically stable with extended therapy or if there is increased risk of recurrent or recalcitrant edema.

ABSTRACT BODY:

Purpose: Ocular injuries can result in permanent remodeling of the neuroglia system. This has been associated with increased susceptibility to neuroinflammation and subsequent glaucoma. Here, we employed a high throughput in-drop single-cell RNAseq to assess the dynamic changes in the transcriptional profile of myeloid cells of the retina after ocular injury.

Methods: C57BL/6J mice received corneal alkali burn to induce sterile retinal inflammation. Retinal tissues were collected 1, 4, and 7 days after the injury, CD45⁺CD11b⁺ cells were isolated using FACS sorting and processed for high-throughput microfluidic-based single cell sequencing. Bioinformatic analysis was performed with the Seurat V2 program and key findings were further assessed using a CX3CR1^{+/EGFP} bone marrow chimera model.

Results: One day post injury, we identified two distinct clusters of myeloid cells, representing the resident microglia (Siglec1-) and the peripheral monocytes (Siglec1+) that infiltrate into the parenchyma after injury. Acetylation genes Eif5a, Eif3k, Naa38 were highly upregulated in microglial cells as compared to peripherally engrafted monocytes. However, 4 days post injury, the signatures of the two populations started to overlap, with peripheral monocytes expressing a subset of microglia genes, such as P2ry12, Tmem119, Aif1, Fcrls. At 7 days post injury, the signatures of the two populations appeared to converge further. Further validation in bone marrow chimeras revealed a morphometric convergence between infiltrated and resident CX3CR1⁺ cells, further corroborating the RNAseq findings. The transition of peripheral monocytes to microglia was supported by gradual change from CD45^{hi}CX3CR1^{lo} monocyte to CD45^{lo}CX3CR1^{hi} microglia phenotype. Further, 4 days after injury, P2ry12 was found to be expressed on infiltrated monocytes.

Conclusions: Our results suggested that infiltrated monocytes in the retina undergo in situ phenotypical changes that allow them to adapt to the new environment. This is associated with de novo expression of P2ry12 and Tmem119 "microglia specific genes" and phenotypical changes that promote their long-term engraftment into the tissue.

ABSTRACT BODY:

Purpose: Age related-macular degeneration (AMD) is a disease that often presents bilaterally, although there have been limited studies in long term progression of Spectral Domain Optical Coherence Tomography (SD-OCT) biomarkers comparing two eyes in the same patient. The aim of the study was to compare progressive OCT changes between two eyes among subjects with dry AMD over a period of 5.7 years.

Methods: We performed a retrospective imaging study on the volumetric SD-OCT of 33 patients (66 eyes) with bilateral dry AMD with a minimum follow-up of at-least 4 years. Yearly OCT scans were evaluated for emergence and progress of four late dry AMD characteristics: iRORA, cRORA, drusen ooze and drusen collapse. Statistical analysis was done using Microsoft Excel. Univariate analysis was done for the various characteristics at baseline.

Results: Patients with a mean age of 77.2 ± 10 years were followed up for a total of 68.7 ± 21.5 months. At baseline, iRORA, cRORA, drusen ooze was present in 12.1%, 15.2% and 21.2% of the patients, respectively. At the final follow up iRORA, cRORA, drusen ooze was present in 27.3%, 48.5% and 57.6% of the patients, respectively. Bilateral drusen ooze was present in 9.1% of the patients at baseline. 15.2% of the patients had bilateral drusen ooze at the final follow up with mean interval of 5.0 ± 1.4 years between the two eyes. Bilateral iRORA was present in none of the patients at baseline. 9.1% of the patients had bilateral iRORA at the final follow up with a mean interval of 4.7 ± 2.1 years between the two eyes. Bilateral cRORA was present in 9.1% of the patients at baseline. 18.2% of the patients had bilateral cRORA at the final follow up with mean interval of 1.7 ± 0.6 years between the two eyes. By the final follow-up 9/33 (27.2%) and 6/33 (18.1%) of the patients had evidence of drusen collapse in unilateral and bilateral eyes, respectively. For patients with observed drusen collapse bilaterally, the mean interval was 2.2 years.

Conclusions: Any single OCT biomarker such as cRORA, iRORA, drusen ooze and drusen collapse is seen bilaterally in a minority (less than 22%) of the patients with dry AMD at presentation. Even over a long-term follow-up, only 36.4% of the patients showed at-least one bilateral biomarker over a period of 5.7 years. In patients with bilateral OCT biomarkers, cRORA had the shortest mean interval in appearance between the two eyes.

ABSTRACT BODY:

Purpose: Regular ophthalmology follow-up is essential for patients with diabetic retinopathy (DR), the leading cause of vision loss in working-age people in the US. Research is needed to better understand factors influencing follow-up and to find ways to encourage appropriate attendance. We sought to delineate patient-perceived barriers to ophthalmic follow-up in our mostly rural population. We anticipated patients with poor follow-up would report more barriers, and financial barriers related to transportation, parking, and childcare would be prominent.

Methods: Semi-structured interviews were conducted with adult patients with diabetes mellitus seen at least once in our clinics for diabetic eye care. Participants were randomly selected from a previous retrospective study based on whether they had good (n=10) or poor (n=10) attendance at follow-up appointments. Questions explored factors that supported or prevented their attainment of the prescribed interval, the management and progression of their diabetes, and their knowledge about DR. Results between the two groups were compared with descriptive statistics.

Results: Both groups of patients reported similar barriers to attendance, and 85% of patients reported at least 1 barrier. The most stated barriers for both groups were financial cost, having someone accompany them, and parking. The poor follow-up group also reported taking time off work as a barrier. More patients in the good follow-up group reported regularly checking their blood sugar (90% vs. 70%) and following up with their primary care physician (100% vs. 90%). They also responded more accurately to 3 knowledge questions about DR (77% vs. 57% correct responses).

Conclusions: The interviews challenged the notion that our patients with poor follow-up faced more barriers than those with good follow-up. When patients with good follow-up were asked an open-ended question of what factors allowed them to make it to their appointments, 50% of them responded by describing barriers instead; demonstrating how these patients also overcame challenges. Patients expressed a wide variety of factors that affected their ability to attend appointments, so any specific incentive, such as a parking voucher, ride service, or scheduling assistance may not meet the needs of all patients. It may be more effective to offer a financial incentive to utilize tools of behavioral economics to encourage patients to attend follow-up visits.

ABSTRACT BODY:

Purpose: To evaluate the antiviral potential of five multipurpose disinfecting solutions against coronavirus (murine hepatitis virus a surrogate for SARS-CoV-2 human corona virus).

Methods: Murine hepatitis virus ATCC/VR261 stock was prepared prior to testing by growing in A9 ATCC/CCL 1.4 cells in Dulbecco's minimum essential medium (DMEM) containing 5% fetal bovine serum (FBS) and antibiotics (streptomycin sulphate and penicillin G). Test solutions (BioTrue, ReNu Advanced [Bausch and Lomb], ACUVUE RevitaLens [Johnson and Johnson Vision], cleadew [Ophtecs corp.] or AOSept Plus [Alcon]) were mixed with viruses at 10^4 plaque forming units (PFU)/mL as the final concentration and incubated at room temperature for the specified disinfection time as recommended by each manufacturer. Phosphate buffer saline (PBS) was used as a negative control. Surviving virus from each sample was then quantified by standard plaque forming unit assay and the reduction of PFU for each disinfectant was compared to the negative control.

Results: The three multipurpose disinfecting solutions BioTrue (containing PHMB and polyquaternium-1), ReNu Advanced (PHMB, polyquaternium-1 and alexidine) and ACUVUE RevitaLens (polyquaternium-1 and alexidine) did not kill the coronavirus at the manufacturers recommended disinfection time. After treatment, the virus's titer ($3.8 \pm 0.2 \log_{10}$ for BioTrue, $3.7 \pm 0.1 \log_{10}$ for ReNu and $3.7 \pm 0.2 \log_{10}$ for Revitalens) was similar to the negative control ($3.7 \pm 0.1 \log_{10}$). AOSept Plus (hydrogen peroxide) and cleadew (povidone iodine) reduced the numbers of coronaviruses to below the detection limit (i.e. killed $3.7 \pm 0.1 \log_{10}$ viruses compared to control).

Conclusions: This study shows that oxidative contact lens disinfecting solutions (i.e. those containing povidone-iodine or hydrogen peroxide) provide superior antiviral activity against a coronavirus surrogate of SARS-CoV-2.

ABSTRACT BODY:

Purpose: Evidence exists that cigarette smoking may be associated with glaucoma; however, the relationship between intraocular pressure (IOP) and smoking is unclear. In this study, relationship between smoking status and IOP in civilian, non-institutionalized participants in the Korea National Health and Nutritional Examination Survey (KNHANES) was investigated.

Methods: Subjects from 2008-2011 KNHANES who were ≥ 40 years of age, who had visual fields and optic disc photographs, and had IOP measured were included. Diagnosis of glaucoma was based on the Rotterdam criteria. Subjects were divided into current smokers, past smokers, and never smoker categories. Mean IOP was compared between the three categories among those with glaucoma and without glaucoma. Multivariate linear regression modeling was used to assess the relationship between IOP and clinical and behavior characteristics.

Results: 14416 subjects in 2008-2011 KNHANES were included. 8510 subjects (59.0%) never smoked, 1733 (12.0%) were past smokers, and 4173 (29.0%) were current smokers.

A greater proportion of male Korean subjects were smokers (84.2% past smokers or current smokers) compared to female subjects (8.1%, $p < 0.0001$).

Past smokers were statistically significantly older than never smokers and current smokers (60.0 ± 11.3 , 57.6 ± 11.3 , 56.7 ± 11.5 years, respectively, $p < 0.0001$).

A greater proportion of current smokers (18.1%) had glaucoma compared to never smokers (11.6%) and past smokers (9.7%, $p < 0.00001$).

The mean IOP of all subjects was 14.0 ± 2.7 mmHg.

Never smokers had statistically significantly lower IOP (13.9 ± 2.7 mmHg) compared to past smokers (14.1 ± 2.7 mmHg, $p = 0.005$) and current smokers (14.0 ± 2.8 mmHg, $p = 0.031$, Tukey post hoc test), while there was no statistically significant difference between past smokers and current smokers ($p = 0.438$).

In multivariable linear regression analysis, IOP did not correlate with smoking status, but varied statistically significantly with age, gender, glaucoma, cataract, and diabetic retinopathy (DR).

Male, glaucoma, cataract and DR were associated with IOP increase of 0.058, 0.068, 0.045, and 0.025 mmHg, respectively ($p < 0.0001$ for male, glaucoma, and cataract, $p = 0.030$ for DR). IOP decreased by 0.087 mmHg per year of age ($p < 0.0001$).

Conclusions: Smoking was more prevalent among Korean males than females. IOP in Koreans was higher with diagnosis of glaucoma, cataract and DR, and lower in female and older subjects.

ABSTRACT BODY:

Purpose: Pancreatic islet transplantation into the anterior chamber of the eye (ACE) has been shown to improve the glycaemic control and metabolic parameters in both Type-1 and Type-2 diabetic non-human primates (NHPs). This novel transplantation site also allows the delivery of therapeutic agents, such as immunosuppressive drugs, locally to circumvent unwanted systemic side effects.

Methods: Local anti-inflammatory or immunosuppression treatment using micronized dexamethasone (DEX) implant was done intravitreally. Allogeneic transplantation of pancreatic islets was done into the ACEs of non-human primates (allogeneic grafts without immunosuppression, CTL, n=2 eyes; allogeneic grafts with local immunosuppression treatment, DEX, n=8 eyes). Survival of the transplanted islet grafts and DEX concentration in the ACE were assessed in parallel for 24 weeks.

Results: DEX was detected in the aqueous humour of the ACE with a peak at week 8 and started to taper off by week 15. Islet grafts with local DEX treatment showed significantly better survival than the non-treated CTL islets (median survival time- 12 weeks vs 3 weeks, log-rank test $p < 0.0001$). Islet grafts showed a good functional response to high glucose stimulation even though a high dose of DEX showed a transient suppression of islet graft function at week 8 to 12.

Conclusions: The ACE may turn out to be a novel and superior site for pancreatic islet transplantation to treat diabetes and local dexamethasone treatment is a potential therapeutic approach to maintain long-term function and survival of allogeneic islet grafts.

TITLE: Binocular properties of fixational eye movements as assessed using a high-resolution binocular scanning laser ophthalmoscope

SESSION TITLE: Eye Movements and Binocular Vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.T. Chung, R.W. Li, M.N. Agaoglu, P.K. Tiruveedhula, A.J. Roorda, School of Optometry, University of California Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Susana Chung: Commercial Relationship: Code N (No Commercial Relationship) | Roger Li: Commercial Relationship: Code N (No Commercial Relationship) | Mehmet Agaoglu: Commercial Relationship: Code N (No Commercial Relationship) | Pavan Tiruveedhula: Commercial Relationship(s);University of California, Berkeley:Code P (Patent);C. Light Technologies:Code C (Consultant) | Austin Roorda: Commercial Relationship(s);University of Rochester:Code P (Patent);University of Houston:Code P (Patent);University of California, Berkeley:Code P (Patent);C. Light Technologies:Code I (Personal Financial Interest)

ABSTRACT BODY:

Purpose: Previous studies have established that fixational eye movements (FEMs), especially microsaccades and at least the vertical component of slow-drifts, are mostly conjugate in the two eyes. However, specifics of the properties of FEMs during binocular vs. monocular fixation are less well documented. The purpose of this study was to determine how the presence of visual input of a fixation target affects the properties of binocular fixation.

Methods: We used a custom-built, high-resolution two-channel confocal scanning laser ophthalmoscope (bino-TSLO) in this study. The bino-TSLO allows us to deliver visual targets and to record movies of the retina of the two eyes simultaneously and independently. When aligned properly, subjects perceived a single 6°x6° red imaging field. Five adults with normal binocular vision were instructed to fixate at the center of a 1° cross presented at the primary gaze position while we captured videos of the retina of both eyes for trials of 10s each. Three conditions, each with multiple trials, were tested in random order: the cross was presented in both eyes (“both”) or in only one of the two eyes (“left” or “right”). Eye positions were extracted from the videos using a brute-force cross-correlation algorithm at a sampling rate of 540 Hz. Characteristics of FEMs, including (1) fixation stability, (2) rate, amplitude and direction of microsaccades; and (3) direction and amplitude of drifts, were determined for each trial and for each eye.

Results: The two eyes demonstrated a high degree of conjugacy in terms of the occurrence, amplitude and direction of microsaccades, regardless of whether the fixation cross was presented in one or both eyes. Drift direction and amplitude were mostly similar between the two eyes only in the “both” condition; else, the eye that did not receive the cross demonstrated larger drift amplitudes with directions different from that of the fellow eye. Further, for the “left” or “right” conditions, fixation stability of the eye that received the cross was similar to that for the “both” condition; but fixation stability of the fellow eye worsened by ~1.6x.

Conclusions: Despite the high degree of conjugacy of the two eyes during fixation, the lack of visual input to one eye affects the characteristics of drifts and stability in that eye, emphasizing the importance of the presence of visual input in fine oculomotor control.

TITLE: Anti-VEGF switch therapy from bevacizumab to aflibercept in radiation retinopathy secondary to uveal melanoma

SESSION TITLE: Recent Advances in Uveal Melanoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Srivastava, University of Alberta Faculty of Medicine & Dentistry, Edmonton, Alberta, CANADA|E. Weis, Ophthalmology, University of Alberta Faculty of Medicine & Dentistry, Edmonton, Alberta, CANADA|

Commercial Relationships Disclosure (Abstract): Ojas Srivastava: Commercial Relationship: Code N (No Commercial Relationship) | Ezekiel Weis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Radiation-induced injury to ocular structures is a common iatrogenic consequence of radiotherapy for uveal melanoma. Radiation retinopathy is a dose-dependent complication of the retina following exposure to ionizing radiation. To the best of our knowledge, this is the first series describing the outcomes of patients treated with monthly aflibercept for radiation maculopathy who have failed monthly bevacizumab. Failure is defined as incomplete resolution of fluid despite monthly injections for 6 months or complete resolution of fluid with monthly injections, but an inability to extend beyond a 1-month interval between treatment. Clinically significant improvement is defined as an improvement of 1 line of visual acuity on an Early Treatment Diabetic Retinopathy Study chart or reduction in sub-retinal fluid of 100 microns. It is hypothesized that a portion of patients who failed bevacizumab will respond with a clinically significant difference with aflibercept.

Methods: A prospective case-series of patients with clinically significant radiation maculopathy were enrolled. The currently utilized clinical treatment algorithm of primary bevacizumab followed by aflibercept for failed cases was employed. Standardized testing, as part of the Alberta Ocular Brachytherapy program, was performed on all patients at two sites in Alberta, Canada. Visual and retinal response to therapy was assessed with regression analyses.

Results: Thirty patients, 17 female and 13 male, with a mean age of 57 years (± 15) underwent the switch from monthly intravitreal bevacizumab treatment to intravitreal aflibercept. The primary endpoints were central foveal thickness (CFT) and visual acuity (VA) at one month, three months, and six months following the switch to aflibercept. Regression analysis showed statistically significant differences between bevacizumab and treatment by aflibercept at one month ($P=0.003$, $P=0.02$), three months ($P=0.004$, $P=0.004$), and six months ($P=0.003$, $P=0.013$) in both CFT and BCVA, respectively. Fourteen patients showed a clinically significant improvement in CFT and seven patients showed a clinically significant VA improvement following six months of aflibercept.

Conclusions: This pilot study suggests that a portion of patients who have failed monthly bevacizumab may respond to aflibercept. A larger series would be beneficial in quantifying this response.

ABSTRACT BODY:

Purpose: A broad range of complications may present following mechanical vitrectomy (MV), including vitreous hemorrhage (VH), cataract formation, and endophthalmitis. Using a large sample population database, we investigated the impact of MV along with other clinical and non-clinical factors on the risk of developing VH.

Methods: Cases of MV were obtained from the National Inpatient Sample (NIS) database between 2002 and 2013 using ICD-9 codes. Associated morbidities and procedures were assessed in cases labelled with a principal procedure of MV and a non-primary diagnosis of VH. Perioperative complications occurring during the same operative admission were abstracted using secondary ICD-9 diagnosis codes. Univariate and multivariate logistic regression analyses were carried out in MV cases to determine risk factors for the development of VH. The data was weighted using the NIS-provided discharge-level weights in order to generate nationally representative estimates. The Bonferroni correction method was applied to decrease risk of type II errors.

Results: There were 3,927 MV cases identified in the dataset. These were divided into vitreous hemorrhage (n=610, median age = 55, 52% male) and non-vitreous hemorrhage (n=3,317, median age = 57, 51% male) cohorts. Factors associated with increased risk of vitreous hemorrhage included diabetes with chronic complications (OR=2.02), renal failure (OR=1.60), congestive heart failure (OR=1.56), and obesity (OR=1.58). Demographic factors were analyzed and showed that, relative to white cases, there was an increased risk of VH in Black (OR=1.52), Hispanic (OR=1.43), and Asian (OR=1.80) cases. Confidence intervals can be seen in Figure 1.

Conclusions: Retrospective analysis of a large patient population showed that the risk of VH following MV is increased in cases with complicated diabetes, renal failure, congestive heart failure, and obesity. Black, Hispanic, and Asian cases were also independently associated with an increased risk of VH. Limitations of this study include its inability to demonstrate temporal relationships due to its retrospective nature, a database that records cases rather than individual patients, and the limited cases of MV that occur in inpatient settings.

ABSTRACT BODY:

Purpose: To report a phenomenon observed in a series of patients who underwent subretinal injection of voretigene neparvovec-rzyl (VN) for RPE65-mediated Leber congenital amaurosis.

Methods: Multi-center retrospective chart review of patients who underwent subretinal VN injection at four participating institutions. Patients were identified as having perifoveal chorioretinal atrophy if: i) the areas of atrophy were not directly related to the touch-down site of the subretinal cannula; and ii) the areas of atrophy enlarged over time. Demographic data, visual acuity, refractive error, fundus photos, optical coherence tomography, visual fields, and full-field stimulus threshold (FST) were analyzed.

Results: 18 eyes of 10 patients who underwent subretinal injection of VN developed perifoveal chorioretinal atrophy. 8/10 patients (80%) had bilateral atrophy. Mean age was 11.6 years (range: 5-19), and 6 patients (60%) were male. Baseline mean logMAR visual acuity and FST were 0.82 (standard deviation (SD): 0.51) and -1.3 log cd.s/m² (SD: 0.44), respectively. The mean spherical equivalent was -5.7 diopters (range: -11.50 to +1.75). Atrophy was identifiable at an average of 4.7 months (SD: 4.3) following surgery, and progressively enlarged in all cases up to a mean follow-up period of 11.3 months (range: 4-18). The atrophy developed within and outside the area of the subretinal bleb in 10 (55.5%) eyes, exclusively within the area of the bleb in 7 (38.9%) eyes, and exclusively outside the bleb in 1 (5.5%) eye. There was no significant change in visual acuity (p=0.45). There was a consistent improvement in FST with a mean improvement of -3.21 log cd.s/m² (p<0.0001). Additionally, all 13 eyes with reliable pre- and post-operative visual fields demonstrated improvement (expansion or gain of isopters) following surgery, but 3 (23.1%) eyes demonstrated paracentral scotomas related to the atrophy.

Conclusions: A subset of patients undergoing subretinal VN injection developed progressive perifoveal chorioretinal atrophy following surgery. Further study is necessary to determine what ocular, surgical delivery, and vector-related factors predispose to this complication.

ABSTRACT BODY:

Purpose: Ocular adverse events have been reported in association with dupilumab, a monoclonal antibody therapy to treat allergic diseases including atopic dermatitis (AD). We sought to describe clinical findings and treatment for dupilumab-related ocular complications.

Methods: Retrospective case series of 20 dupilumab-treated AD patients seen for a new ocular complaint in an academic ophthalmology practice. Primary outcomes were specific ocular exam findings (conjunctival injection, eyelid dermatitis, corneal fluorescein staining, blepharitis, or meibomian gland dysfunction (MGD)) and treatments prescribed at the initial visit and follow-up visits.

Results: A total of 20 dupilumab-treated AD patients were included. The mean age was 47 years (range 18-73), with over half being women (55%) and the majority Caucasian (70%). Symptom onset occurred at a mean of 101 days (SD=109, 95% CI: 49.91 to 151.79) from the first dupilumab dose. The most common ocular findings were conjunctival injection (75%) and corneal staining (60%). Blepharitis was seen in about a third (30%) of patients and 25% had MGD. After the initial visit, 10% were observed without treatment, while 15% patients were treated with artificial tears (AT) alone. Other treatments included antihistamine drops (20%) and steroid drops alone (15%). In 40% of patients, a combination of steroids and various other topical eye drops were prescribed. Out of the 20 patients, 17 were seen in follow-up. Steroid drops were required at follow-up in 3 out of 4 patients initially treated with antihistamines alone and in two-thirds of patients initially treated with AT only. Mean follow-up period was 89 days (range 5-369). Dupilumab was discontinued in 7 out of 20 patients; of those who discontinued, 3 were able to restart it later.

Conclusions: Conjunctival injection was the most frequent dupilumab-related ocular complication observed followed by corneal staining. The majority of patients initially treated with antihistamines or AT alone subsequently required steroid drops to control symptoms. Some patients who discontinued dupilumab were able to restart the medication after achieving adequate control of their ocular symptoms. Future larger studies are needed to confirm the incidence of dupilumab-related ocular complications, identify risk factors, and compare treatment outcomes.

ABSTRACT BODY:

Purpose: To investigate pre- and intra-operative metrics associated with good visual acuity (VA) following retinal detachment (RD) repair for proliferative vitreoretinopathy (PVR) that included relaxing retinectomy at time of surgery.

Methods: This was a single-institution, retrospective study evaluating all patients (pts) undergoing retinectomy during repair of RD with PVR from 1/1/2015-12/31/2019 with a final VA of 20/70 or better.

Results: Of 3,789 pts undergoing RD surgery during the study period, only 57 underwent retinectomy at time of RD surgery and had a final VA of 20/70 or better. 16 pts were female (28%) and the mean age was 61.8 ± 10.5 years. The mean time from diagnosis to initial surgery was 2.1 ± 1.1 days. The mean initial RD size was 160 ± 60 degrees. 22 eyes (39%) were macula on at time of initial diagnosis. Only 7 eyes' (12%) macula never detached during the study period. The mean pre- and post-operative logMAR VA was 0.93 ± 0.85 and 0.33 ± 0.16 respectively. The mean number of surgeries was 2.4 ± 0.9 . The average retinectomy size was 151 ± 12.1 degrees. 14 eyes (25%) had a scleral buckle (SB) placed at initial surgery (Table 1). There was no difference in mean number of surgeries in eyes with a SB placed at initial surgery compared to those that did not (2.1 ± 0.6 vs 2.4 ± 1.0 , $p = 0.28$), or in mean final VA (0.28 ± 0.16 vs 0.34 ± 0.17 , $p = 0.20$). 16 eyes (28%) had primary PVR, of which 7 eyes (44%) had primary retinectomy (Table 2). Significantly fewer surgeries were required in these 7 eyes compared to the 9 eyes not undergoing primary retinectomy for initial RD with baseline PVR (1 ± 0.0 vs 2.3 ± 0.7 , $p = 0.0002$), but no difference in final VA was seen (0.33 ± 0.16 vs 0.39 ± 0.11 , $p = 0.52$). The mean time from recurrent RD diagnosis to surgery was 2.5 ± 1.2 days, with no difference in time to surgery for recurrent RDs in eyes with macula on versus off RDs (3.1 ± 2.4 vs 2.3 ± 1.4 days, $p=0.12$, Table 2). 2 eyes (3.5%) had silicone oil tamponade at the final visit.

Conclusions: Eyes undergoing primary or secondary retinectomy during repair of RD with PVR can still achieve good VA. Macula status and time to surgery may be important factors in determining visual outcomes.

Commercial Relationships Disclosure (Abstract): Ying Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Bogdan Tanasa: Commercial Relationship: Code N (No Commercial Relationship) | Michael Nahmou: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goldberg: Commercial Relationship: Code N (No Commercial Relationship) | Michael Kapiloff: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Enhanced cyclic-AMP (cAMP) signaling promotes neuronal survival after injury. cAMP signaling is highly compartmentalized in cells, and distinct compartments regulate different cellular processes. We recently showed that elevation of cAMP in a perinuclear compartment organized by the scaffold protein muscle A-kinase anchoring protein α (mAKAP α) is sufficient to protect retinal ganglion cells (RGCs) in the mouse optic nerve crush model. However, the underlying mechanisms remain unclear. In this study, we aim to identify neuroprotective gene expression regulated by perinuclear cAMP in RGCs.

Methods: We intravitreally injected 4-week-old C57BL/6J mice with the adeno-associated virus gene therapy vector AAV2.4D3(E)-mCherry to express in RGCs the type 4D3 phosphodiesterase anchoring disruptor peptide 4D3(E)-mCherry, which displaces PDE4D3 from mAKAP α signalosomes in neurons and elevates cAMP in that compartment. Control mice were injected with AAV2.mCherry. Two weeks later the mice were subjected to right-sided optic nerve crush. RGCs pooled from 8 eyes for each cohort were isolated by immunopanning with Thy-1 antibody one day after crush. Cell suspensions were submitted to the Stanford Genome Sequencing Service Center (GSSC) for 10X Chromium Single Cell 3' library preparation and HiSeq 4000 sequencing. scRNA-seq analysis was carried out with Seurat using R.

Results: 3800-6000 cells were sequenced for each condition, among which 15%-25% expressed RBPMS and were identified as RGCs. About half of the RGCs in each group expressed the mCherry reporter gene. Analysis of differentially expressed genes showed that expression of the 4D3-mCherry anchoring disruptor reversed many of the changes in gene expression induced by crush injury ($p=1e-16$). In particular, Npy, Mmp12, Ucn and Timp2 were differentially regulated by elevation of cAMP in the perinuclear compartment.

Conclusions: Our study shows that elevation of perinuclear cAMP can reverse changes in gene expression following acute optic nerve crush injury, providing an explanation for the pro-survival effects of PDE4D3 anchoring disruption. In addition, our results provide candidate therapeutic targets for subsequent testing. In the future, we will apply this approach to derive further insight into the diversity of gene expression programs relevant to RGC neuroprotection and axon regeneration therapies.

ABSTRACT BODY:

Purpose: The relationship between glaucoma, a leading cause of irreversible blindness globally, and smoking, a major modifiable health hazard, is uncertain. In this cross-sectional study, association between cigarette smoking and glaucoma in the civilian, non-institutional participants of the U.S. National Health and Nutritional Examination Survey (NHANES) and the Korea NHANES (KNHANES) was investigated.

Methods: U.S. participants from 2005-2008 NHANES and Korean participants from 2008-2011 KNHANES who were ≥ 40 years of age and had visual fields and optic disc photographs were included. Participants with non-glaucomatous reason for either abnormal cup/disc ratio or visual fields were excluded. Glaucoma diagnosis was based on the Rotterdam criteria. Logistic regression modeling was performed to assess the association between glaucoma and smoking history, while controlling for age, sex, household income, alcohol consumption, refractive errors, body mass index, diabetes, and hypertension.

Results: Glaucoma prevalence in the US sample was 5.5% (212/3864 subjects) and 7.8% in the Korean sample (1143/14608 subjects). In both populations, subjects with glaucoma compared to those without were older, likely to be male, and to have diabetes and hypertension. Korean subjects with glaucoma were also more likely to have less education, lower income, and greater alcohol consumption.

In the U.S., 54.7% glaucoma subjects were smokers while 50.7% non-glaucoma subjects were smokers ($p=0.25$). In Korea, 51.4% glaucoma subjects were smokers while 45.4% non-glaucoma subjects were smokers ($p<0.001$). Among smokers, 34.2% Korean glaucoma subjects were current smokers while 32.2% non-glaucoma Korean subjects were current smokers ($p<0.001$). In the U.S., 30.2% glaucoma subjects were current smokers and 42.1% non-glaucoma subjects were current smokers ($p=0.01$).

The effect estimations of both non-smoker/smoker and current/ex-smoker comparisons were similar in adjusted models but neither had statistically significant differences.

Among smokers, greater pack/day of smoking history was associated with statistically significantly higher odds of glaucoma in the U.S. population ($OR=1.70$, $95\%CI=1.08-2.67$, $p=0.002$), but not among Koreans.

Conclusions: Smoking habit and exposure differ across populations and cultures. Cigarette smoking may be associated with higher odds of glaucoma in both the U.S. and in South Korea.

ABSTRACT BODY:

Purpose: The COVID-19 Pandemic resulted in a substantial decrease in outpatient ophthalmology clinic visits due to stay-at-home orders. Retinal vascular diseases and wet age-related macular degeneration require adherence to treatment regimens with anti-vascular endothelial growth factor (anti-VEGF) injections. The purpose of this study was to assess how the COVID-19 pandemic affected the number of injections compared to pre-pandemic values.

Methods: This retrospective, observational clinical study assessed all anti-VEGF injections of aflibercept and ranibizumab for both 2019 (Jan-Dec) and 2020 (Jan-Nov) at an academic center. The total number of injections for each year was compared, as well as the number of injections for each month in 2020 compared to the average number of monthly injections in 2019. Both 1-sample and 2-sample t-tests were conducted, and a p-value less than 0.05 was considered significant.

Results: The total number of aflibercept and ranibizumab injections in 2019 (Jan-Nov) were 4989 and 522 respectively, compared to 4855 and 515 in 2020 (Jan-Nov). No significant difference in injections was noted between 2019 and 2020 for either aflibercept ($p=0.31$) or ranibizumab ($p=0.80$). When analyzing each month in 2020 compared to the average number of aflibercept injections per month in 2019, there were significantly fewer aflibercept injections administered in February ($p<0.01$), August ($p=0.03$), and November ($p<0.01$), but significantly higher injections administered in July ($p<0.01$) and October ($p<0.01$). For ranibizumab, significantly fewer injections were administered in March ($p=0.02$), April ($p=0.02$), and May ($p<0.01$), but a higher number of injections were administered in September ($p<0.01$) and November ($p<0.01$).

Conclusions: Despite stay-at-home orders, there was no significant decrease in the overall number of aflibercept or ranibizumab injections during the COVID pandemic compared to the prior year. Although further information is needed to determine if these injections represent both new and return patients, these data suggest that in this specific population, patients still returned to their retina specialist for care despite the ongoing pandemic.

ABSTRACT BODY:

Purpose: To investigate how inhibition of the lens microcirculation system differentially affects water transport, water content, lens geometry, GRIN, and power of the bovine lens.

Methods: Bovine lenses were incubated in either artificial aqueous humour (AAH), high extracellular K^+ (AAH-High K^+), or ouabain (AAH+ouabain) for 4 hours. A microelectrode/pico-injector based pressure measurement system was utilised to measure the intracellular hydrostatic pressure gradient that drives water efflux. MRI was used to measure free and total water content. A custom-built Laser Ray Tracing (LRT) system that scanned lenses with 151 parallel rays delivered at 4 different angles was used to extract changes in lens geometry, gradient refractive index (GRIN) and power over time. Lens geometry and GRIN were inputted into ZEMAX optical modelling software to assess changes in overall vision quality.

Results: Like smaller rodent lenses, the larger bovine lens exhibited an intracellular hydrostatic pressure gradient that varied from approximately 0 mmHg at the lens surface to 326 mmHg in the core. Inhibiting the microcirculation system by depolarization of the lens membrane potential with AAH-High K^+ , reduced the lens central hydrostatic pressure by 16%, increased the water content across the whole lens, caused a slight rounding of the lens geometry and a decrease in GRIN, which manifested as a slight increase in power in the lens core over time. Inhibiting the microcirculation by blockade of the Na^+/K^+ -ATPase with AAH+ouabain, reduced the lens central hydrostatic pressure by 24%, increased the water content specifically in the lens core, caused a substantial rounding up of the lens geometry, but increased the central GRIN. Taken together these changes induced a significant increase in lens power and resulted in a marked myopic shift in overall vision quality.

Conclusions: While inhibition of the microcirculation system by depolarizing the lens, or blocking the Na^+/K^+ -ATPase both decreased lens pressure, increased lens water content and increased power, ouabain counter-intuitively increased central GRIN. This suggests that blockade of Na^+/K^+ -ATPase has altered the refractive index increment (dn/dc) of crystallins in the lens core, presumably by changing the ionic environment in this lens region.

ABSTRACT BODY:

Purpose: To study the retinal peri-papillary and macular vascular structures in eyes of primary angle closure suspects (PACS)

Methods: Control and PACS subjects were recruited from a community screening. Only one eye per subject was used for analysis. All participants underwent a questionnaire survey, physical and ophthalmic examinations, ocular biometry measurements, and optical coherence tomography angiography (OCTA). We compared basic demographics and vessel structure parameters between control and PACS eyes. Univariate and multivariate linear regression analysis were performed to investigate factors associated with vascular parameters in both groups.

Results: Data from 254 subjects including 155 PACS and 99 controls were analyzed. In the peri-papillary region, PACS eyes showed similar retina nerve fiber layer (RNFL) and vessel densities (VDs) including and excluding large vessels compared to control eyes. Compared to control eyes, all macular OCTA parameters showed significant differences in PACS eyes, including decreased superficial VD (mean=17.23 vs 13.80, $p=0.006$) and deep VD (mean=31.33 vs 27.92, $p=0.004$), larger fovea avascular zone (FAZ) area (mean=0.35 vs 0.39, $p=0.006$) and longer FAZ perimeter (mean=2.29 vs 2.45, $p=0.004$). Gender ($p=0.039$), age ($p<0.001$), and Garway Heath (GH) superior hemisphere RNFL ($p<0.001$) were risk factors influencing optic disc VD excluding large vessels (Table 1). Axial length (AL) was the major factor affecting macula superficial and deep vessel densities ($p=0.004$ and 0.001 respectively), while PACS was independent factors associated with larger FAZ perimeter ($p=0.046$) (Table 2).

Conclusions: While PACS and control eyes have comparable RNFL and vascular structure around the optic nerve head, macular vascular structures are significantly different, which could precede clinical functional and structural abnormalities.

ABSTRACT BODY:

Purpose: Low vision Rehabilitation (LVR) has a significant benefit in improving the quality of life of visually impaired patients. However, such services are highly underutilized, depriving patients of essential care. This study investigates the barriers to LVR services in a hospital-based setting for patients with impaired vision.

Methods: A retrospective chart review of low vision patients seen at the University of Texas Medical Branch from 2010-2020 identified 487 subjects that were eligible for low vision referral. Low vision was defined as having a best corrected visual acuity of 20/70 or worse in the better eye, or a visual field of less than 20 degrees. The number of patients referred to LVR services were identified from the EPIC EMR database and were interviewed over the phone regarding their referral experience to the LVR services. Another questionnaire was sent to 9 practicing ophthalmologists to capture their referral patterns. Responses were analyzed and tabulated in percentages.

Results: Patients with low vision referrals (n=48) were primarily Caucasians (60%), retired (60%), and females (60.4%), with a mean age of 70.7 years. Only 32 patients utilized LVR services, of which 11 agreed to take the questionnaire. About half of the patients (45.5%) did not know if they had been referred to LVR. Qualitative analysis revealed several barriers to accessing LVR services including: poor physical health (81.8%), denial of need for low vision aid (72.7%), lack of transportation (36.3%), and lack of referrals (33.3%). 88.9% of vision care providers reported referring eligible patients to LVR services in their practices. Common factors for not referring low vision patients included: patient's overall health (66%), older age (33.3%), lack of social support (33.3%), poor cognitive function (33.3%), and less likelihood of following up with LVR services (33.3%). However, all the providers reported familiarity with the available LVR services at the practicing clinic.

Conclusions: This study identified several addressable barriers that can be eliminated to provide LVR services to patients with low vision. Changing the current provider referral pattern and increasing patient awareness of available LVR resources may tremendously improve the quality of life of low vision patients.

TITLE: Long-pulsed ultrasound enhances the cytotoxic effect of doxorubicin on cultured human retinal pigment epithelium cells

SESSION TITLE: Diabetic retinopathy/retinal pharmacology/physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. LaRocca, S. Mohammadi, C. Kenney, K. Lin, Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Meg LaRocca: Commercial Relationship: Code N (No Commercial Relationship) | Seyed Omid Mohammadi: Commercial Relationship: Code N (No Commercial Relationship) | Cristina Kenney: Commercial Relationship: Code N (No Commercial Relationship) | Ken Lin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the effects of long-pulsed, 1 MHz ultrasonic application on human retinal pigment epithelium (ARPE-19) cell viability at various doxorubicin concentrations.

Methods: In this in vitro study, ARPE-19 cells were plated in 96-well plates and treated with 360 μ L of solution containing 0.01, 0.1, 1, 10, or 100 μ g/mL of doxorubicin. 5.5 mg of doxorubicin (Fisher Scientific) was first dissolved in 550 μ L of DMSO to form a stock solution. The stock solution was then transferred to 54.45 mL of media and serially diluted to create the various titrated concentrations. Cell plates were sealed with MicroAmpTM Optical Adhesive Film, inverted, and placed in a water bath at room temperature. Cell plates were then treated with 1 MHz of ultrasound (US) at a power of 4.93 W/cm² and pulse repetition frequency (PRF) of 30 Hz for five minutes (Olympus EPOCH 650 Ultrasound). Media were removed from the wells and replaced with 100 μ L of media with the corresponding doxorubicin concentration. The control mimicked all parameters including the 1% DMSO but cells did not receive US application. As an additional control group, US was applied to cells without doxorubicin to analyze the effects of US on cell viability. MTT assays were performed at both 24 and 48 hours to quantify cellular metabolism, which had been used in literature as a marker for cell viability.

Results: At 24 hours after US was applied, there was a significant decrease in viability in cells treated with doxorubicin 0.1 μ g/mL to 100 μ g/mL (Figure 1). The same trend was observed at 48 hours (Figure 2). At both 24 and 48 hours, the untreated group without doxorubicin showed that ultrasound alone did not have a significant effect on cell viability (rightmost two columns in Figures 1 and 2).

Conclusions: US has played a pivotal diagnostic role in ophthalmology, but its therapeutic potential has been largely unexplored. This study demonstrated that long-pulsed US enhanced the cytotoxic effect of doxorubicin at physiologically relevant concentrations. This observation suggests a potential adjunctive role of ultrasound in treating tumors. Further studies using other cell types are underway to further explore the therapeutic role of ultrasound.

ABSTRACT BODY:

Purpose: Inherited retinal degenerative disorders (IRD) such as Retinitis Pigmentosa (RP) and Leber Congenital Amaurosis (LCA) can be caused by mutations in the RPE65 gene. These mutations cause visual function impairments which have significant impacts on patients' vision-dependent activities of daily living (ADL) and broader health-related quality of life (HRQoL). There is limited evidence on the patient experience of RP more broadly and no known genotype-specific experiences. This study aimed to explore the experience of RPE65-related RP/LCA from patient and caregiver perspectives.

Methods: Semi-structured qualitative concept elicitation interviews were conducted with 11 patients (7 adults, 1 adolescent, 3 children aged 6-11 years) and 5 caregivers of children aged 3-11 years in the US, Germany and France. Patients had a clinical and genetic diagnosis of RPE65-related RP/LCA. Thematic analysis of verbatim interview transcripts was performed.

Results: Night blindness, reduced peripheral vision and problems with color vision were the most frequently reported visual function symptoms of RPE65-related RP/LCA. Proximal vision-dependent impacts included limitations to mobility and ADLs. White cane and low vision assistive devices were visual aids used by adults, adolescents and children. Participants reported impacts on HRQoL domains including emotional well-being, social, financial, and work/school functioning. Severity of limitations varied based on lighting conditions and familiarity of environment. Overall, similar concepts were reported across all participant groups.

Conclusions: These findings provide in-depth insight into the visual function symptoms and impacts on vision-dependent ADLs and broader HRQoL associated with RPE65-related RP/LCA. Findings are largely consistent with evidence generated thus far in other RP genotypes, and suggest that the visual function symptoms and impacts relevant to measure in clinical studies are consistent across RP/LCA genotypes. Interview findings contributed to the

development of patient- and observer-reported outcome measures specific to RP (including RPE65-related RP/LCA) designed for use in clinical trials and to track disease severity in clinical practice.

SUBMITTER (NAME ONLY): Tyler Dowd-Schoeman

TITLE: Characterizing Intergroup Variation of Fundus Autofluorescence between Multiple Subtypes of Retinitis Pigmentosa

SESSION TITLE: Retinitis pigmentosa/ retinal prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Dowd-Schoeman, H. Ameri, USC Roski Eye Institute, University of Southern California Keck School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Tyler Dowd-Schoeman: Commercial Relationship: Code N (No Commercial Relationship) | Hossein Ameri: Commercial Relationship(s);Spark Therapeutics :Code C (Consultant)

ABSTRACT BODY:

Purpose: There are currently over 90 genes associated with the development of retinitis pigmentosa (RP), an inherited retinal disorder affecting approximately 1 in 3000-5000 people worldwide. Previous research has demonstrated variability in disease severity and rates of disease progression between separate subtypes of RP, but research concerning possible imaging biomarkers that can differentiate between distinct genotypes of RP is limited. Our aim was to use fundus autofluorescence (FAF) imaging in order to examine whether patterns of autofluorescence (AF) differed in a heterogenous group of RP patients.

Methods: We used the NIH EyeGene database to compile FAF images of 31 patients with RP that met our exclusionary criteria. These patients had pathogenic mutations spanning 11 RP-associated genes, including HK1, IMPDH1, KLHL7, NR2E3, PRPF31, RP1, RP2, USH2A, RPGR, RHO, and PRPH2. The FAF images were reviewed for patterns of autofluorescence and qualitative observations were recorded.

Results: Eight patterns of fundus autofluorescence were identified in the RP patients included in the study. Four of these patterns were found within the macula, including a bull's eye pattern of AF, central foveal hyper AF, a perifoveal hyper AF ring, and a macular hyper AF ring. The remaining four patterns were extramacular and included a mid-peripheral hyper AF ring, extramacular spots of hyper AF, patches of hypo AF and diffuse hypo AF in the periphery. A double concentric hyper AF ring was present in 4 of the 11 RP-subtypes studied (RHO, RPGR, USH2A, NR2E3). To our knowledge this is the first report of a double concentric ring of hyper AF in RPGR-linked RP

Conclusions: Of the genes studied, there were no highly-penetrant patterns that were unique to a single subtype of RP, suggesting there may be significant phenotypic overlapping between RP subtypes on FAF imaging. The double concentric hyper AF ring is less specific than previously thought.

ABSTRACT BODY:

Purpose: Treatment of diabetic macular edema (DME) with anti-vascular endothelial growth factor (Anti-VEGF) injections can improve the severity of diabetic retinopathy (DR). However, little is known about the effect and durability of these agents on DR grading outside of clinical trials. This study aims to explore the development of proliferative DR (PDR) during and after treatment of DME with anti-VEGF injections from a large multi-centre database.

Methods: Data from 27 UK centres using the same electronic medical record system were remotely extracted. The analysis was restricted to eyes that received anti-VEGF agents for DME between February 2013 and December 2018. The primary outcome was the time from first DME treatment (DR grade prior to first treatment) until progression to PDR. Time-to-event analysis was done to demonstrate the rate of progression to PDR stratified by baseline DR grade.

Results: A total of 4 922 patients (58.2% male) were included. Mean age (standard deviation [SD]) was 66.41 (11.90) years and mean(SD) follow-up was 13.07 (15.29) months. On average, each patient received 6.29 (SD 6.3) anti-VEGF injections during this period. More severe DR grades required a higher number of injections; 5.81 injections for grade 1 (Mild non-proliferative DR[NPDR]), 6.56 and 6.84 injections for grade 2 (moderate NPDR) and grade 3 (severe NPDR), respectively. Kaplan-Meier survival curves showed that progression to PDR was strongly influenced by the baseline DR grade (Fig. 1). Controlling for the baseline DR grade, a higher number of injections (>6 compared to 6 injections or less) didn't confer a lower risk of PDR development.

Conclusions: This is the largest cohort of DME patients who received anti-VEGF injections and were evaluated for PDR development. Baseline DR grade is an important influential factor for PDR development during DME treatment. Moreover, DR improvement in clinical trials may not be reproduced in routine care settings where patients receive fewer treatments and could have less rigorous diabetes mellitus control. This will help inform clinicians about the importance of carefully following these patients and adjusting their follow-up intervals accordingly.

ABSTRACT BODY:

Purpose: To demonstrate a fully integrated Home OCT System used by subjects with neovascular age-related macular degeneration and to propose novel reporting parameters of self-imaging performance and retinal fluid volume dynamics.

Methods: Pilot study of 8 eyes from 4 subjects with mean (SD) age of 74 (4) years (mean baseline VA 20/50). Subjects self-imaged at home daily for 1 month. Automatic secure data transmission to the Cloud was followed by volume scan reconstruction and deep learning-based analysis (Notal OCT Analyzer; NOA). Outcomes included subjects' ability to self-image daily, comparison of fluid status with human expert grading, and temporal dynamics of intraretinal (IRF) and subretinal fluid (SRF) volumes

Results: During 232 cumulative study eye-days, the subjects self-imaged 212 times (91%). The mean (SD) self-image acquisition time was 41 (15) seconds. In 100 of the 212 (47%) scans, retinal fluid was identified by the NOA (46% IRF, 46% SRF, 8% both). In 197 of the 212 (93%) scans, there was agreement of fluid status between NOA and human grading. In 5 eyes with a change in fluid status, the mean (maximum) interval between human grading and NOA identifying the change was 1.5 (3) days. In 4 eyes, the change was from fluid absence to presence, and the mean (maximum) fluid volume at detection of recurrence was 1.6 (3) nL. The temporal fluid dynamics over 1 month will be presented, including: identification of fluid status change, interval of fluid increase or decrease in relation to treatment, maximum fluid volume, fluid volume cumulated over time, and spatial distribution of fluid thickness over time.

Conclusions: To the best of our knowledge, this represents the first longitudinal pilot study of a home OCT system. It fulfils the relevant requirements: self-imaging with a device designed for low cost at large quantities, automatic data transmission, volume scan reconstruction, AI-based image analysis, and fluid volume tracking over time. The biomarker of fluid volume, and its related parameters, may present useful information in the management of retinal diseases.

ABSTRACT BODY:

Purpose: Patient-reported difficulties caused by the characteristic functional impact of AMD, in particular in its early and intermediate stages, are only captured in selected patient-reported outcomes (PROs), none of which currently meet the FDA criteria for PRO development. The Vision Impairment in Low Luminance (VILL) questionnaire was designed to meet these criteria as well as to capture the characteristic impact of all AMD stages on patients' lives. Here we report its psychometric functioning and test-retest reliability in the European multi-center study MACUSTAR.

Methods: Using the baseline VILL data from participants of the MACUSTAR study (intermediate, early, late or no AMD) psychometric characteristics including model fit, person reliability (PR), person separation index (PSI), targeting and dimensionality of the existing VILL subscales (reading, VILL-R; mobility, VILL-M; emotional, VILL-E) were investigated using Rasch analysis (Winsteps, Chicago, IL). In a subset with repeated data test-retest reliability was assessed using mean deviation (MD), intra-class correlation coefficients (ICC) and Bland-Altman analysis.

Results: A baseline dataset including 716 participants was available for analysis. The VILL subscales were unidimensional. Dropping five misfitting items in an iterative process (VILL-R, 3 items; VILL-M, 1 item; VILL-E, 1 item) improved model fit. After removal of a total of 39 single misfitting responses from three additional misfitting items, 32 items could be retained and no item showed misfit. PR and PSI were 0.91 and 3.27 (VILL-R), 0.87 and 2.58 (VILL-M) and 0.73 and 1.65 (VILL-E), respectively. The mean person measure-item measure differences were 2.0 (VILL-R), 2.1 (VILL-M) and 1.6 (VILL-E). 289 participants were included in the evaluation of test-retest reliability of the VILL-32. MD and ICC (95% confidence interval) were 0.30 and 0.92 (0.90-0.94, VILL-R), 0.07 and 0.93 (0.91-0.94, VILL-M) and 0.30 and 0.85 (0.81-0.88, VILL-E).

Conclusions: Our results support internal consistency and test-retest reliability of the VILL in AMD in a large sample. The reading and mobility subscales are reliable measures while the emotional subscale is noticeably less precise. Thus, the emotional subscale was dropped, resulting in 29 items overall. The validation process of the instrument using functional data is ongoing.

TITLE: Identification of the final time point for a successful therapeutic intervention and arrest of retinal remodeling in a mouse model of retinitis pigmentosa

SESSION TITLE: Models to study retinal degeneration and remodeling

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Kajtna, S. Koch, Department of Pharmacy, Ludwig-Maximilians-Universität München, München, Bayern, GERMANY|J. Kajtna, S. Koch, Physiological Genomics, Biomedical Center, Ludwig-Maximilians-Universität München, GERMANY|

Commercial Relationships Disclosure (Abstract): Jacqueline Kajtna: Commercial Relationship: Code N (No Commercial Relationship) | Susanne Koch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A typical feature of retinitis pigmentosa (RP) is the initial loss of photoreceptors, followed by remodeling of the inner retina and blood vessels. How these changes may ultimately limit therapy outcome remains unknown. In this study we investigate if gene therapy at different RP disease stages can halt or even reverse retinal remodeling.

Methods: We use a novel genetically engineered RP mouse model ($Pde6b^{STOP/STOP}$, $Pde6g::CreERT2/+$), which carries a floxed STOP cassette on both alleles and expresses a rod specific tamoxifen inducible Cre. Mice were treated at 4, 12, 16 and 24 week of age by tamoxifen-induced Cre activation; at the time point of treatment the outer nuclear layer thickness had decreased by 37%, 67%, 82% and 88%, respectively (relative to the 40 weeks old wild-type). The remodeling and rescue of vision were evaluated by ERG recordings, water maze test and immunohistochemistry. The retinal vasculature was analyzed by immunohistochemistry and trypsin digests stained with H&E.

Results: In our RP mouse model, we observed progressive loss of rod bipolar processes, delocalized rod bipolar cell bodies, and dramatic reductions of horizontal cell neurites. Remodeling of inner retinal cells is halted and the function rescued after treatment at 16 weeks or earlier, but not by treatment at 24 weeks. The successful restoration of vision was preserved at least until age of 40 weeks. The retinal degeneration in our RP model is accompanied by blood vessel remodeling, which can be quantified as the reduced area of the vasculature and increased number of acellular capillaries. Mice treated at 16 weeks of age or earlier had significantly less acellular capillaries at 40 weeks of age than the untreated RP mice.

Conclusions: The results show that inner retinal remodeling can be halted in the long term after treatment at 16 weeks of age or earlier; however, inner retinal plasticity remains limited. In addition, we observed a positive effect of our treatment on the retinal vasculature remodeling.

ABSTRACT BODY:

Purpose: To evaluate the short-term effect of dexamethylphenidate (D-MPH) on visual acuity, pupil size, anterior chamber depth (ACD), and accommodation-convergence reflex in children treated with D-MPH XR for attention-deficit/hyperactivity disorder (ADHD).

Methods: Prospective cohort study including 15 patients aged 8-16 (11.58 ± 2.39) treated with D-MPH for ADHD. Patients were questioned for subjective complains such as blurred vision and photosensitivity. Ophthalmic evaluation was performed twice; prior to and 1.5 hours following D-MPH administration. The exam included evaluation of best corrected visual acuity at distance and near, accommodation range, convergence range, 3-D vision test and anterior chamber optical coherence tomography (OCT).

Results: A significant association between pupil diameter and D-MPH treatment dose was demonstrated ($p=0.001$). Additionally, a positive correlation between complains about blurred vision and D-MPH daily dosage was found. There were no significant changes in visual acuity, convergence range, stereo vision, accommodation range, or anterior chamber measures.

Conclusions: Our findings provide further support to the effect of stimulants on pupil diameter, as well as on subjective complains about blurred vision in a dose dependent manner. Additionally, future research is required to further investigate a potential role for pupil diameter as a marker of response to D-MPH.

TITLE: Linking ERG recordings to psychophysical data in human subjects

SESSION TITLE: Ganglion cells and beyond

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.J. Kremers, A.J. Aher, K. Stüwe, Section for Retinal Physiology, University Hospital Erlangen, Erlangen, GERMANY|

Commercial Relationships Disclosure (Abstract): Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship) | Avinash Aher: Commercial Relationship: Code N (No Commercial Relationship) | Karin Stüwe: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The ERG originates in the activity of retinal neurons and therefore can be considered to be an epiphenomenon of the neuronal visual responses. It was found previously that ERG responses to continuous stimulation are correlated with activity of major retinal pathways and with visual perception. In the present study, we tried to find a method to link psychophysical thresholds to ERG recordings.

Methods: Psychophysical flicker detection thresholds were measured foveally (3° diameter) in three normal subjects to luminance stimulation with three temporal profiles: sine-wave, rapid-on sawteeth and rapid-off sawteeth. The temporal frequency was varied between 1 and 39 Hz. We measured full field ERGs to the same waveforms and temporal frequencies at 0, 3, 5, 10, 15 and 20% contrast in four normal subjects (total recording time for each condition: 80 sec). The ERG responses were averaged for all subjects and for a 1 sec episode. Then the ERGs were analyzed with a peak-to-trough detector (PTD) that integrated the ERG responses in two time windows that were shifted in time relative to each other. The two time windows were slid over the whole recording episode and subtracted to obtain the PDT output at each time instant. A root mean square (RMS) calculation was performed on the PTD output for the whole recording period to obtain the cumulative PDT response. Several time windows and shifts (difference between the two time windows) were used.

Results: The response strength of the PTD increased with increasing contrast. Contrasts for a threshold PTD response could be defined. The thresholds strongly depended on the chosen PTD characteristics. With well-chosen PTD characteristics, the PTD thresholds for all stimuli resembled the psychophysical thresholds.

Conclusions: Although the ERG is not the neuronal visual response that is transferred to the brain, it is assumed that it is uniquely related to the neuronal response (if the neuronal response is altered, the ERG is also altered; if the neuronal response is not changed, the ERG is not changed). With the PTD algorithm, the ERG can possibly be used as an objective tool to link retinal activity, elicited by continuous luminance waveforms, with psychophysical data.

ABSTRACT BODY:

Purpose: Behcet's disease (BD) is a chronic, multisystem vasculitis that may result in a blinding uveitis. The introduction of TNF- α inhibitors has substantially changed the treatment of this condition, however there remains a paucity of data regarding long term visual outcomes, particularly compared with conventional immunosuppression, and ocular vs non-ocular manifestations of BD.

Methods: Retrospective case series of patients who met the revised International Criteria for Behcet's Disease (ICBD) and presented between 1990–2018 to the Royal Victorian Eye and Ear Hospital, Melbourne, Australia, were reviewed. Demographic, ophthalmic examination, systemic manifestations, medication use and complications were noted.

Results: Forty-two patients (33 males, median age 30.1 years (IQR 25.7–35.5)) were observed for a median of 6.4 years (IQR 2.8–12.9). At first ocular presentation, 25 patients met the ICBD diagnostic criteria. A further 16 (98%) met the criteria during follow-up. The most common presenting BD manifestations were ocular (N=39), oral ulcers (N=25), genital ulcers (N=8), joint involvement (N=5), skin lesions (N=4) and vascular manifestations (N=1). The majority (N=28) developed ocular disease prior to non-ocular symptoms, with ocular involvement split evenly between unilateral (N=22) vs bilateral disease. Median best corrected logMAR visual acuity at presentation was 0.301 in 54 uveitic eyes; 15 of which were anterior uveitis, 11 intermediate, 2 posterior and 26 were panuveitis. During follow-up, 41 (98%) patients were treated with corticosteroids (CS), 36 (86%) with conventional disease-modifying anti-rheumatic drugs (DMARDs) and 10 (24%) were treated with biologic DMARDs. Despite treatment, visual impairment (logMAR >0.3), legal blindness (logMAR >1) and near total blindness (light or no light perception) persisted in 23, 12 and 5 eyes, respectively. Vision threatening complications included cataract (N=28), hypopyon (N=11), glaucoma (N=7), retinal vasculitis (N=28) and cystoid macula oedema (N=24).

Conclusions: Preliminary data suggests that ocular manifestations typically occur prior to systemic disease in our cohort of patients with BD. As expected, men of working age are most commonly affected, often with sight threatening disease at initial presentation. Despite treatment with CS and CS-sparing agents, including TNF- α inhibitors, visually significant complications with permanent vision loss still occur.

ABSTRACT BODY:

Purpose: The long-established use of xenon flashes in full-field electroretinography (ERG) is being superseded by LED-based stimuli typically involving different recording systems, with potential consequences for studies that involve longitudinal or legacy data. This study compares retrospective recordings from xenon- and LED- based ERG systems in patients with confirmed ABCA4-related macular dystrophy (patients with Stargardt disease and normal full-field ERGs), with the aim of examining potential differences in response components.

Methods: Patients who attended Moorfields Eye Hospital with at least one molecularly confirmed mutation of the ABCA4 gene, a clinical presentation consistent with Stargardt Disease, and with macular dystrophy (full-field ERGs that fall within “normal” reference limits) were ascertained. Full-field ERGs incorporated the International Society for Clinical Electrophysiology of Vision (ISCEV) standard and were elicited using either LED- (Group A; “Diagnosys ColorDome™” system) or xenon-flash (Group B; “CH electronics” system) stimuli, each obtained using a different recording system. The dark-adapted strong flash (DA 10.0) ERG, light-adapted single flash cone (LA 3.0) ERG and 30Hz flicker (LA 30Hz) ERG were compared between the two groups.

Results: A total of 344 patients were analysed. There were 122 subjects in Group A (Mean age 37.5 years, SD: 14.0. Mean pupil size: 8.4; SD: 0.8) and 222 subjects in Group B (Mean age 36.8 years, SD: 14.7. Mean pupil size: 8.2; SD: 1.1). Amplitudes for the DA 10.0, LA 3.0 and LA 30Hz flicker ERGs did not show statistically significant differences (Table 1) between the 2 Groups. Peak times for the three tests showed small but statistically significant differences ($p<0.001$) between Group A and Group B.

Conclusions: The use of xenon- or LED- based flash stimuli and recording methods are important considerations when evaluating ISCEV-standard ERGs in patients with ABCA4-related macular dystrophy. The findings are relevant not only to studies that aim to monitor retinal function longitudinally using different equipment, but also those seeking to establish ERG reference ranges, pool data or interrogate legacy ERG data sets with novel methods, such as artificial intelligence.

ABSTRACT BODY:

Purpose: To assess the outcomes of home monitoring of distortion caused by macular diseases using a smartphone-based application (app), and to examine them with hospital-based assessments of visual acuity (VA), Optical Coherence Tomography (OCT) derived central macular thickness (CMT) and the requirement of intravitreal injection therapy.

Methods: Participants were trained in the correct use of the app (Alleye, Oculocare Ltd) in person or by using video and telephone consultations. Automated threshold-based alerts were communicated based on a traffic light system. A "threshold alarm" was defined as three consecutive "red" scores, and turned into a "persistent alarm" if present for greater than a 7-day period. Changes of VA and CMT, and the requirement for intravitreal therapy after an alarm were examined. We conducted an observational study with a retrospective analysis of data.

Results: 245 patients performing a total of 11,592 tests (mean 46.9 tests per user) were included and 84 eyes (164 alarms) examined. The mean drop in VA from baseline was -4.23 letters (95%CI: -6.24 to -2.22; $p < 0.001$) and mean increase in CMT was 29.5 μm (95%CI: -0.08-59.13; $p = 0.051$). Sixty-six eyes (78.5%) producing alarms either had a drop in VA, increase in CMT or both and 60.7% received an injection. Eyes with persistent alarms had a greater loss of VA, -4.79 letters (95%CI: -6.73 to -2.85; $p < 0.001$) or greater increase in CMT, +87.8 μm (95%CI: 5.2-170.4; $p = 0.038$).

Conclusions: Smartphone-based self-tests for macular disease may serve as reliable indicators for the worsening of pathology and the need for treatment.

ABSTRACT BODY:

Purpose: To compare the visual performance of a bifocal intraocular lens (IOL) (ZMB00) and a rotationally asymmetric multifocal with +1.5 diopters near addition intraocular lens (IOL) (Lentis Comfort LS-313 MF15 [Oculentis GmbH]).

Methods: We evaluated postoperative parameters 10 weeks after the last surgery in cataract patients who underwent bilateral ZMB00 or LS-313 MF15 implantation from August 11, 2011, to March 26, 2020, with the right and left lenses implanted within 3 months of each other.

Results: The study enrolled 1774 eyes of 887 patients. The bifocal group comprised 1326 eyes of 663 patients (67.0 ± 7.8 years; females/males, 518/145), and the rotationally asymmetric multifocal group comprised 448 eyes of 224 patients (73.6 ± 7.0 years; females/males, 125/99). Uncorrected near visual acuity was significantly better and the higher-order aberrations (ocular/internal, scaled to a pupil size of 4 mm)

(WF_4_post_O_TotalHOA/Third/Fourth/Trefoil/Coma/Tetrafoil/Spherical,

WF_4_post_I_TotalHOA/Third/Trefoil/Coma/Tetrafoil/Spherical) were significantly smaller, and distance/near spectacle independence were significantly better in the bifocal group ($p < 0.00068$, Wald test). Contrast sensitivity ($6.3/4.0/2.5/1.6/1.0/0.7$ degrees), and contrast sensitivity with glare ($4.0/2.5/1.6/1.0/0.7$ degrees) were significantly better in the rotationally asymmetric multifocal group ($p < 0.00068$, Wald test).

Conclusions: The two IOL groups had different characteristics in terms of uncorrected near visual acuity, the higher-order aberrations, distance/near spectacle independence, and contrast sensitivity with/without glare.

ABSTRACT BODY:

Purpose: Binocular indirect ophthalmoscopy (BIO) is the gold standard for retinopathy of prematurity (ROP) screening, however associated use of an eyelid speculum and scleral depression results in significant infant stress. Handheld optical coherence tomography (OCT) may identify ROP severity biomarkers and is non-contact. We performed a prospective, observational study to compare vital signs measured during BIO and OCT to identify whether OCT has an advantage in lowering cardiorespiratory impact of screening.

Methods: This study included 16 premature infants screened for ROP, recruited between April 2019 and February 2020. Each infant underwent BIO and OCT (using an investigational handheld swept source OCT) at least 30 minutes apart, alternating the order at each consecutive screening session. Infants who were too unstable were excluded from the study. Vital signs were obtained 1 minute before, 1 and 2 minutes into, and 15 minutes after the examination. Vital sign deviations from baseline were compared for each infant between the two imaging modalities using a paired linear mixed model to adjust for multiple imaging sessions.

Results: This study included 26 examinations among 16 infants (62.5% female, mean gestational age 285.86 ± 2.82 weeks, mean birth weight 1058.25 ± 289.00 grams) with 9 infants at ROP stage 1, 4 at ROP stage 2, and 1 at ROP stage 3. BIO duration was significantly shorter than OCT (4.4 vs. 10.8 minutes, $P < 0.001$). Vital signs increase from baseline were significantly greater for BIO compared to OCT for heart rate at 1 minute (18.81 ± 20.75 vs. 0.00 ± 22.82 beats per minute, $P = 0.04$), diastolic blood pressure at 2 minutes (41.22 ± 31.69 vs. 28.19 ± 25.84 mmHg, $P = 0.04$), mean arterial pressure at 2 minutes (46.83 ± 34.83 vs. 36.99 ± 20.08 mmHg, $P = 0.04$), and systolic blood pressure at 15 minutes (10.85 ± 10.55 vs. -5.12 ± 13.53 mmHg, $P = 0.04$).

Conclusions: OCT resulted in significantly lower impact on heart rate and blood pressure compared to BIO. The ability to screen for ROP using OCT may benefit overall health for these vulnerable premature infants. Further studies should explore the potential utility of OCT as an ROP screening tool.

ABSTRACT BODY:

Purpose: We investigated the efficacy of the low-power, high-frequency electrical current treatment administered by Rexion-Eye[®] in a cohort of 18 patients affected by mixed-type dry eye disease (DED) of medium to severe level.

Methods: 18 mixed type DED patients (17 female and 1 male; age range 42-81 years) were randomly recruited and treated. Therapy was administered with the Rexion-Eye[®] device (Resono Ophthalmic, Sandrigo, Italy), which applies, via an electrode mask worn over closed eyes, a weak alternate electrical current with a specific spectrum of frequencies (4-64 MHz, Quantum Molecular Resonance, QMR[®]). The treatment protocol provides for one 20-min session per week, for 4 weeks. Patients were examined at baseline and one month after the last treatment, by measuring: tear meniscus height (TMH), non-invasive tear break-up time (NIBUT), measured with IDRA (SBM Sistemi, Turin, Italy); Meibomian gland number (in lower eyelid) and quality of secretion; Ocular Surface Disease Index (OSDI) score; Schirmer's II test; ocular inflammation, by Oxford staining and by MMP9 (with InflammDry by Quidel, San Diego (CA), USA).

Results: Results are reported in Table 1 and 2. In this cohort of patients, all clinical endpoints markedly improved, with a limited improvement only in the Schirmer's II test. Clinical parameters related to inflammation especially showed a remarkable benefit, as evidenced by the reduction of MMP9 and Oxford staining and normalization of TMH. Subjective benefit (OSDI) was reported by patients and no adverse event was observed in any of them.

Conclusions: In accordance with previous studies, Rexion-Eye[®] proved to be very effective in improving subjective and objective ocular parameters. Of particular interest in this mixed-type DED patients cohort is the capability of Rexion-Eye[®] to normalize the clinical parameters affected by inflammation.

ABSTRACT BODY:

Purpose: Glaucoma is one of the leading causes of irreversible vision loss. Several studies have shown a link between vascular damage and glaucoma on optical coherence tomography angiography (OCTA) images. These studies were mostly conducted in the region of the optic nerve head (ONH) or on larger 6x6 mm macula scans. Moreover, all these studies use handcrafted features for the glaucoma classification. We therefore propose a fully automatic classification algorithm on 3x3 mm macula scans based on convolutional neural networks (CNN) that are able to learn features from the images themselves.

Methods: Whole retina projection OCTA images (Spectralis OCT II, Heidelberg Engineering, Heidelberg) of 75 eyes of 75 healthy persons (h) and 184 eyes of 125 glaucoma patients (g) were retrospectively identified from the Erlangen glaucoma registry. They were divided into training set (h: 45 eyes/45 patients, g: 110 eyes/76 patients), validation set (h: 15 eyes/15 patients, g: 37 eyes/24 patients) and test set (h: 15 eyes/15 patients, g: 37 eyes/25 patients). Eyes of one person only belong to a single set. Different CNNs were trained and the one performing best (according to the AUROC) on the validation set was chosen for evaluation. For comparison, handcrafted features that were compatible with the available data (only a single enface OCTA image available) were selected. We chose the commonly used vessel density (VD) and a combination of global and local features proposed by Ong et al. (Ong). We then trained a support vector machine (SVM) on each of these traditional feature sets and again chose the best performing one on the validation set.

Results: The ROC curves, AUROC values and confusion matrices can be found in Figure 1 and the accuracies in Figure 2 for the different methods on the test set.

Conclusions: We were able to outperform other handcrafted features on 3x3 mm macula scans and achieved results on par with other algorithms proposed for different ocular regions. These other studies often have shown that their features work better on projections of a single vascular plexus than on a whole retina projection. Therefore, the next step would be to apply the deep learning pipeline presented in this paper to the different retinal plexuses separately.

ABSTRACT BODY:

Purpose: Sarcoidosis is a granulomatous inflammatory disease that can affect any organ including the central nervous system (CNS) and the eyes. This cross-sectional study aimed to investigate retinal neural structure in patients with different clinical manifestations of sarcoidosis.

Methods: A total of 200 eyes of 103 biopsy-verified sarcoidosis patients without diabetes mellitus were included and categorized into four groups according to their phenotype: 1) sarcoidosis without ocular or CNS affection (non-ocular/no-CNS), 2) ocular sarcoidosis, 3) CNS sarcoidosis, and 4) combined ocular and CNS sarcoidosis (ocular/CNS).

Best corrected visual acuity (BCVA) was assessed. Swept source optical coherence tomography (SS-OCT) was obtained (Topcon Swept Source DRI OCT Triton), with measurements of central macular thickness (CMT), retinal thickness (RT), retinal nerve fiber layer (RNFL), and ganglion cell layer (GCL) thickness. Differences in retinal neural structures between groups were evaluated by Kruskal-Wallis Test and pairwise by Wilcoxon Rank Sum Test.

Results: The mean age of participants was 50.4 years (SD13.4 years), 52% were males, and 54.5% of patients had a duration of sarcoidosis above five years. Median BCVA was above 80 Early Treatment Diabetic Retinopathy Study letters in all groups.

Eyes of the non-ocular/no-CNS group had a lower CMT and RNFL than the ocular sarcoidosis group ($p=0.003$ and $p=0.011$). Likewise, the RNFL was thinner in non-ocular/no-CNS eyes compared to ocular/CNS ($p=0.002$) and in those with ocular sarcoidosis compared to the CNS group ($p=0.029$).

In subgroup analyses of patients with a duration of sarcoidosis above five years, the CMT in eyes of the non-ocular/no-CNS group was thinner than all other groups: ocular ($p=0.0001$), CNS ($p=0.0002$) and ocular/CNS ($p=0.029$). Moreover, there was a thickening of CMT in the ocular group compared to the CNS group ($p=0.002$). Similarly, RT and RNFL were thinner in the non-ocular/no-CNS group compared to both the ocular ($p<0.0001$ and $p=0.13$) and the ocular/CNS group ($p<0.0001$ and $p=0.03$). Finally, a thickening in those variables was also observed in the ocular compared to CNS group ($p=0.01$ and $p=0.0004$).

Conclusions: In particular for patients with a long duration of sarcoidosis, these results indicate increasing retinal thickening in patients with ocular involvement of sarcoidosis.

ABSTRACT BODY:

Purpose: To study if the contrast range of uncertainty around a flicker detection thresholds was enlarged in patients with retinitis pigmentosa (RP).

Methods: We used a psychophysical procedure based on a temporal contrast sensitivity procedure combined with the silent substitution paradigm in a group of RP patients and in a normal control group. We examined 17 normal subjects (27±8 years, 7 females, 10 males) and 21 RP subjects with different genetic backgrounds (45±15 years, 6 females, 15 males). The subjects had to indicate the presence or absence of perceived flicker. The stimuli were created with a dedicated LED stimulator. Parafoveal L-cone, M-cone, S-cone and Rod-isolating stimuli at different temporal frequencies, between 1 and 4 Hz (low frequencies) and 12 and 20 Hz (high frequencies), were generated using triple silent substitution. Two randomly interleaved staircase procedures were used to determine psychometric curves. The thresholds and slope values of the psychometric curves were extracted. The slope values correspond to the range of uncertainty towards the tested condition. The shallower the slope value (i.e. smaller value), the larger is the range of uncertainty. These slope values were compared between normal subjects and RP patients using Wilcoxon-signed-rank tests.

Results: At high frequencies, the slope values were not significantly different between the two groups and a large slope variability was found especially at high frequencies for M-cone isolating stimuli. At low temporal frequencies, there were significantly shallower slopes for the L-cone, M-cone and for Rod isolating stimuli in RP patients compared to the normal subjects ($p < 0.05$).

Conclusions: RP patients display a larger range of uncertain flicker perception at low temporal frequency for Rod isolating stimuli and at low temporal frequencies for L- and M-cone isolating stimuli where the parvocellular pathway mediates flicker detection. The larger uncertainties in RP patients are possibly related to the area of retinal degeneration and can possibly be used to diagnose and monitor the disease.

ABSTRACT BODY:

Purpose: To facilitate the diagnosis and quantification of fibrotic tissue in the human retina by analyzing polarization-sensitive (PS) OCT data using an automated process.

Methods: 59 eyes of 59 patients (77 ± 6 years) with neovascular age-related macular degeneration (nAMD) were imaged using a custom-built spectral domain PS-OCT system operating at 860nm with an A-scan rate of 70kHz and an integrated retinal tracker. Raster scans consisting of 250 B-scans \times 1024 A-scans were recorded at the macula, covering an area of $8 \times 6 \text{ mm}^2$. After standard SD-OCT data processing, PS data (retardation, optic axis orientation, degree of polarization uniformity) were extracted. The PS data were compensated for the birefringence of cornea and Henle's fiber layer. The double-compensated axis orientation was projected onto an enface map, fibrosis was separated from healthy tissue based on axis uniformity and using a region growing algorithm, and finally the area of the segmented fibrosis was obtained. A sub-set of 16 patients were measured three times to assess the repeatability of the method.

In addition, color fundus photography (CFP) was performed on all eyes.

Results: Fig. 1(a–c) shows an example of measurements in a patient with fibrosis. Patches of well-defined axis orientation (Fig. 1a) are an indicator of fibrosis and are segmented (blue areas in Fig. 1b). The CFP in Fig. 1c shows a yellow-whitish discoloration at the same location, indicating the presence of fibrosis. In 31 of the 59 eyes, fibrosis was diagnosed on CFP. Of the 28 eyes diagnosed as non-fibrotic based on CFP, our algorithm confirmed the absence of fibrosis in 23 cases (82%). Manual inspection of the data of the remaining 5 cases suggests the occurrence of false positives in the PS method. Of the 31 eyes diagnosed with fibrosis based on CFP, our algorithm confirmed fibrosis in 21 cases (68%). After manual inspection of the disagreeing cases, 9 out of 10 cases were assessed to likely be non-fibrotic and the remaining case might have a weak fibrotic lesion.

Fig. 1d shows the results of the repeatability measurements (mean and SD (error bars)). The mean repeatability of the fibrotic lesions $> 0.5 \text{ mm}^2$ was 17%. Patients who have been diagnosed as fibrotic based on CFP are marked with an orange background.

Conclusions: PS-OCT can be used to detect and quantify fibrotic lesions in nAMD with good repeatability. Some discrepancies to CFP require further analysis.

ABSTRACT BODY:

Purpose: The lack of molecular diagnoses in rare genetic diseases can be explained by limitations of current standard genomic technologies. Upcoming long-read (sequencing) techniques have complementary strengths to overcome these limitations. By using optical mapping and long-read sequencing, we aimed to identify the pathogenic variant in a large family with X-linked choroideremia. In this family, aberrant splicing of exon 12 of the choroideremia gene CHM was detected in 2003, but the underlying genomic defect remained elusive.

Methods: We performed optical imaging followed by long-read whole genome sequencing to enable identification of a hidden structural variant in affected cases and carrier females in the studied family. This was followed by Sanger sequencing validation and segregation analysis. In silico analysis was performed to evaluate putative hair-pin formation as an underlying mechanism to exon 12 skipping in the mRNA.

Results: Optical mapping and long-read sequencing approaches now revealed an intragenic 1,752 bp inverted duplication including exon 12 and surrounding regions, located downstream of the wild-type copy of exon 12. Both breakpoint junctions were confirmed with Sanger sequencing, segregate with the X-linked inheritance in the family. The breakpoint junctions displayed sequence microhomology suggestive for an erroneous replication mechanism as the origin of the structural variant. The inverted duplication is predicted to result in hairpin-formation with the wild-type exon 12, which leads to skipping of this exon in the mature mRNA.

Conclusions: The identified inverted duplication is deemed the pathogenic cause of disease in this family. Our study shows that long-read sequencing and optical genome imaging techniques has significant potential for identification of structural variants in genetic diseases.

Commercial Relationships Disclosure (Abstract): Jian Sun: Commercial Relationship: Code N (No Commercial Relationship) | xiaoqin Huang: Commercial Relationship: Code N (No Commercial Relationship) | Siamak Yousefi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop a deep learning construct to detect Uveitis from retinal fundus photographs of Experimental Autoimmune Uveitis (EAU) mice and to propose a framework for consistent and reproducible characterization of images related to animal research studies.

Methods: Accuracy, consistency, and reproducibility are critical for animal model characterization. We developed a deep learning model (DLUveitis) based on the VGG16 architecture to grade uveitis from retinal fundus photographs of EAU mice (Fig. 1). We utilized 1800 fundus photographs to train and test the models for detecting five levels of disease severity and used 300 images to independently validate the findings. We further developed a method to calculate the detailed clinical score of EAU and visualize the outcome of different models (Fig. 2)

Results: We analyzed 2100 fundus photographs that corresponded to normal, trace, moderate, advanced and severe stages of the uveitis disease. Three human expert readers annotated the training images based on evaluations from both fundus photographs and optical coherence tomography (OCT) images. Based on the initial dataset of 1800 fundus images, the AUC of the model in distinguishing five levels of severity was 0.98 (95%CI, 0.97-0.99). Based on the additional independent validation subset of 300 images, the AUC of the model in distinguishing five levels of severity was 0.96 (95%CI, 0.93-0.99). Our model outperforms human graders.

Conclusions: Animal models are invaluable tools for studying human diseases and drug testing. The proposed deep learning construct accurately detects uveitis and five severity levels from fundus photographs of EAU mice. In addition, the clinical score generated by DLUveitis provides more details about the disease severity, compared to human experts, thus providing a highly consistent and reproducible pilot model for subsequent animal research studies.

TITLE: Macular pigment response to carotenoid supplementation in patients with open angle glaucoma: the ENIGMA trial.

SESSION TITLE: Retina/RPE: Biochemistry and molecular biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Loughman, J.S. Butler, I. Flitcroft, E. Loskutova, Centre for Eye Research Ireland, Technological University Dublin, Dublin, Dublin, IRELAND|C.J. O'Brien, Mater Misericordiae University Hospital, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): James Loughman: Commercial Relationship: Code N (No Commercial Relationship) | Colm O'Brien: Commercial Relationship: Code N (No Commercial Relationship) | John Butler: Commercial Relationship: Code N (No Commercial Relationship) | Ian Flitcroft: Commercial Relationship: Code N (No Commercial Relationship) | Ekaterina Loskutova: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent investigations have demonstrated that macular pigment (MP) is lower in glaucomatous eyes. MP exhibits specific biological qualities which may confer neuro-protective and functional benefits in glaucoma. The European Nutrition In Glaucoma Management (ENIGMA) trial was designed to evaluate, for the first time, the MP response to supplementation in glaucoma.

Methods: ENIGMA (NCT04460365) comprised a randomized, placebo controlled, double masked trial. Individuals with open angle glaucoma, VA < 0.3, no other ocular disease, and no history of dementia were eligible for inclusion. Participants were randomized in a 2:1 ratio to receive a dietary carotenoid supplement [10mg lutein (L), 10mg meso-zeaxanthin (meso-Z) and 2mg zeaxanthin (Z)], or placebo for 18 months. MPOD was measured at baseline, 6, 12 and 18 months by dual-wavelength autofluorescence using Heidelberg Spectralis.

Results: 62 participants were enrolled, 44 assigned to treatment and 18 to placebo. No baseline differences between groups were observed ($P > 0.05$ for all -Table 1). Repeated measures ANOVA showed that sqrt MPOD volume differed significantly for the interaction between treatment and time [$F(3,111) = 31.718690$, $p < 0.001$] with a significant effect of time [$F(3,111) = 71.277135$, $p < 0.001$] and no significant effect of treatment [$F(1,37) = 2.642403$, $p = 0.112$]. Post hoc tests with Bonferroni correction revealed a significant difference between baseline MPOD and MPOD at each timepoint (6, 12 and 18 months) in the treatment group only (Fig 1). There was a significant difference in MPOD volume between the treatment and placebo group at 12 and 18 months.

Conclusions: ENIGMA is the first study to demonstrate that MP levels can be augmented in glaucomatous eyes by carotenoid supplementation, which represents an important pre-cursor to any functional or health-related benefits that may accrue. From a neuro-protective perspective, oxidative stress and chronic inflammation are key pathways of tissue damage involved in glaucoma. As potent antioxidant and anti-inflammatory nutrients, L, Z and meso-Z supplementation to increase MPOD might support retinal ganglion cells and confer protection by preventing the pathophysiological cascades of oxidative stress and inflammation in glaucoma.

ABSTRACT BODY:

Purpose: To analyze the concentration of tear cytokines and substance P (SP) in patients suffering from chronic pain and/or dry eye (DE) who either had previous LASIK-type refractive surgery (RS) or did not have it.

Methods: 180 subjects were recruited and divided into 5 groups: 52 patients with pain and/or DE post-RS (P/DE-RS); 31 non-RS patients with pain and DE (P/DE-nonRS); 35 non-RS patients with only DE (DE-nonRS); 30 asymptomatic post-RS control subjects (C-RS); and 32 asymptomatic non-RS control subjects (C-nonRS). Inclusion criteria for DE were: Ocular Surface Disease Index score ≥ 13 and abnormal results in both eyes of at least 2 of the following tests: tear break-up time ≤ 7 sec, Schirmer ≤ 5 mm and corneal or conjunctival staining ≥ 1 (Oxford scale). Chronic ocular pain was considered when lasting ≥ 3 months and the Numerical Rating Scale score was ≥ 2 (range 0-10). Concentration of EGF, fractalkine, IL-1b, IL-1Ra, IL-2, IL-4, IL-6, IL-8, IL-9, IL-10, IL-17A, MCP-1, MCP-3, TNF-a, IFN-g, GRO, MIP-1a, MIP-1b, NGF and RANTES in tear samples was analyzed by multiplex immunobead-based assay and SP concentration by enzyme-linked immunosorbent assay. The relationship between markers and groups were evaluated by ANCOVA using propensity score to control age and sex effect. Molecules with percentage of detection $< 50\%$ (IL-17A, IL-2, IL-9, IFN-g and MIP-1a) were analyzed using contingency tables.

Results: IL-10 tear concentration was significantly higher in the groups who had LASIK RS (P/DE-RS and C-RS) than in DE-nonRS ($p < 0.02$) or C-nonRS ($p < 0.03$). SP was significantly elevated in both LASIK groups (P/DE-RS and C-RS) compared to the two non-RS symptomatic groups (P/DE-nonRS and DE-nonRS) ($p < 0.03$ and $p < 0.02$ respectively). SP concentration was also higher in controls who had RS (C-RS) than in controls who did not have it (C-nonRS) ($p = 0.018$). IL-9 showed the highest percentage of detection in groups with pain (P/DE-RS and P/DE-nonRS) ($p = 0.0001$). LASIK groups followed by P/DE-nonRS group had the highest percentage of detection of MIP-1a ($p = 0.0003$). IL-17A was only detected in the C-RS group.

Conclusions: IL-10, SP, MIP-1a and IL-9 might be involved in the development of chronic pain in patients who had RS and in DE patients. These results add further insight into the molecular mechanisms involved in the development of chronic pain and DE and might be helpful in the design of new therapeutic approaches.

ABSTRACT BODY:

Purpose: The putative presence of the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) in ocular specimen put ophthalmologists and co-workers at risk. So far, few results are available from small sample size studies. The aim of our study is to evaluate the presence of viral RNA of SARS-CoV-2 in conjunctival swabs of a large cohort coronavirus disease 2019 (COVID-19) patients in the Netherlands.

Methods: A total of 243 symptomatic laboratory-confirmed COVID-19 patients were included in this observational multicenter study. Sample collection took place during the 'second wave' of the pandemic (from August to November 2020) in two medical centers in the Netherlands. From a subset of subjects (healthcare workers), consecutive conjunctival samples were available from follow-up visits. Tear/conjunctival samples were obtained by gently sweeping the inferior conjunctival fornices of both eyes with a disposable swab. Samples were analyzed by reverse transcription (RT) PCR for detection of SARS-CoV-2 viral RNA.

Results: Viral RNA was detectable in conjunctival swabs from 17 out of 243 (7.0%) COVID-19 patients. The mean age of those 17 subjects was 46.7 ± 16.2 years (range 26-80 years) and the male-to-female ratio was 4/13. One subject reported increased tearing as ocular symptom. Conjunctival samples were positive for viral RNA as long as 12 days after disease onset. Cycle threshold (Ct) values for conjunctival swabs (mean 34.5 ± 5.1 , range 22.6 – 42.0) were significantly higher than of nasopharyngeal swabs (mean 16.7 ± 3.6 , range 12.1 - 24.3) ($p < 0.0001$). No correlation ($r = -0.10$, $p = 0.70$) between Ct values of conjunctival and nasopharyngeal swabs was observed. The majority of positive conjunctival samples were detected during the first visit, while three subjects became positive during the second visit and one subject during the fourth visit. None of the subjects tested positive in the conjunctival sample more than once.

Conclusions: Ocular transmission of SARS-CoV-2 remains a crucial issue that requires vigilance of protecting the ocular surface by wearing protective equipment. Particularly for ophthalmologists, protective measures are warranted during the ophthalmic examination and ocular surgery.

ABSTRACT BODY:

Purpose: The temperature and blood flow of the ocular surface and peripheral tissue increase when conventional warm compresses are applied. We investigated the effect of thermal pulsation treatment (LipiFlow) on the temperature and blood flow in those areas in patients with meibomian gland dysfunction (MGD).

Methods: We recruited 13 eyes of 13 patients with MGD (mean age, 64.9±18.1 years) and measured the non-invasive tear break-up time (NIBUT), blood flow, and temperature before and 5 minutes after LipiFlow. The blood flow and temperature were measured in the anterior ocular segment, i.e., upper and lower eyelid skin and palpebral and bulbar conjunctiva. The blood flow was measured as the mean blur rate using laser speckle flowgraphy (LSFG-OAS, Soft Care). The temperature was measured using ocular surface thermography (TG-1000, Tomey). The NIBUT was determined using tear film interferometry (DR-1 Alpha, Kowa).

Results: The NIBUT of before and after 5 minutes after LipiFlow was 4.9±2.6 and 7.1±4.8 seconds. The NIBUT was significantly longer 5 minutes after LipiFlow compared to before (paired t-test, P<0.05). The temperature of the upper (34.29±0.52 and 35.49±0.26°C) and lower (33.93±0.60 and 35.13±0.48°C) eyelid skin and palpebral (34.51±0.37 and 35.63±0.41°C) and bulbar (34.61±0.43 and 35.82±0.47°C) conjunctiva increased significantly 5 minutes after LipiFlow compared with before LipiFlow (P<0.01 for both comparisons). The temperature differences of the upper and lower eyelid skin and palpebral and bulbar conjunctiva between before and after LipiFlow were 1.20°C, 1.21°C, 1.13°C, and 1.21°C, respectively. The blood flow in those areas (927.8±354.6 and 1104.8±352.6, 870.6±325.7 and 1273.3±610.9, 1840.7±676.6 and 2424.2±565.7, 287.5±78.1 and 358.9±105.1) also increased significantly 5 minutes after LipiFlow (P<0.05 for all comparisons). The rate changes in those areas between before and after LipiFlow were 124.5%, 144.5%, 188.1%, and 139.5%, respectively.

Conclusions: LipiFlow resulted in significant increases in temperature and blood flow in the ocular anterior segment compared to before its use.

ABSTRACT BODY:

Purpose: The uncertainty quantification of segmentation results is critical for understanding the reliability of the segmentation model. The purpose of this study is to investigate the effect of deep learning-based segmentation with uncertainty measurement in the relationship between RNFL thickness and visual field mean deviation (MD).

Methods: Optical coherence tomography (OCT) scans were acquired from both eyes on 634 glaucoma patients, 404 glaucoma suspects, and 49 healthy controls using commercial OCT device (Cirrus HD-OCT, 200x200 Optic Disc Cubes; Zeiss, Dublin, CA). All subjects had visual field (VF) tests at each visit (Humphrey VF, SITA 24-2 test; Zeiss). A segmentation model was trained using Bayesian deep learning for voxel-wise segmentation of RNFL layer in OCT volume and compute the voxel-wise uncertainty of the segmentation output. The higher uncertainty denotes the unreliability of the segmentation and vice versa and it allows the determination of erroneous segmentation at test time. Uncertainty-guided global mean of the RNFL thickness ($RNFL-U_{mean}$) was then computed by discarding the voxels with erroneous segmentation labels with higher uncertainty during the thickness computation. Also, the global mean of the RNFL thickness ($RNFL_{mean}$) was computed without taking uncertainty into account. Pearson correlation coefficient between $RNFL-U_{mean}$ and MD was computed and compared with the Pearson correlation coefficient between $RNFL_{mean}$ and MD.

Results: The proposed $RNFL-U_{mean}$ gave stronger correlation with MD than $RNFL_{mean}$. The Pearson correlation coefficients were (0.67 ($RNFL-U_{mean}$) vs 0.63 ($RNFL_{mean}$); $p < 0.001$) for glaucoma subjects, (0.56 vs 0.53 ; $p = 0.01$) for glaucoma suspects and (0.08 vs 0.01; $p = 0.21$) for normal subjects.

Conclusions: The proposed uncertainty-guided computation of RNFL thickness showed improved correlation with the visual field MD. This demonstrates that segmentation uncertainty can be used to reduce the effect of inaccurate segmentation in computing the RNFL thickness. This also shows that uncertainty-guided computation of RNFL thickness is a better predictor of visual function than the normal RNFL thickness computed without using uncertainty.

ABSTRACT BODY:

Purpose: Drainage tube or trabeculectomy surgeries in late-stage glaucoma remains beset by unacceptably high 1-year failure rates due to post-operative inflammation and fibrosis. Fibrosis is known to follow a two-stage process with inflammation over the first 1-7 days followed by collagen deposition. Current approaches to remedy this rely on administration of anti-metabolites (mitomycin C) and an intensive course of patient-administered corticosteroid drops. These present their own issues, particularly adverse side-effects and poor patient compliance. Therefore, we describe a proteoglycan (PG)-modified hyaluronic acid (HyA) drug-device that aims to address post-surgical inflammation and remove patient compliance issues.

Methods: PG-Hyaluronic acid hydrogels were chemically crosslinked and assessed for percentage crosslinking, swelling, degradation and ease of insertion into cadaveric rabbit eyes. The innate ability of the modified gels to reduce collagen deposition in the absence of drugs was tested using primary human conjunctival fibroblasts stimulated with Transforming Growth Factor-Beta (TGF- β). The device was further enhanced using prednisolone drug loading with release assessed over 28 days in PBS and efficacy evaluated in a chick embryo model.

Results: It was found that HyA hydrogels were capable of rapid swelling in <30 min, stability up to 4 weeks minimum and enzymatic degradation related to cross-linking efficacy. The device was easily implanted using standard surgical tools (Figure 1A). In vitro analysis using drug-free, PG-HyA gels in TGF- β stimulated conjunctival fibroblasts demonstrated a reduction to normal collagen levels at 24 hours (Figure 1 B+C).

Release of prednisolone from gel composites were found to exhibit a biphasic release with an initial burst release over 72 hours and a more gradual release for up to 28 days. Furthermore, this was found to effectively inhibit angiogenesis up to 5 days ex-vivo.

Conclusions: This work demonstrates a strong proof of concept validation for a straightforward solution to a long running issue in glaucoma surgery. Future work now focuses on an in-depth pre-clinical study.

ABSTRACT BODY:

Purpose: Deformation of the lamina cribrosa (LC) is a defining characteristic of glaucomatous optic neuropathy and is a potential diagnostic tool. However, due to the limitations in existing imaging modalities, it has not been widely used for glaucoma diagnosis. We propose a new strategy for diagnosing glaucoma by combining multiple LC morphometric parameters obtained from deep learning (DL)-enhanced three dimensional (3D) optical coherence tomography (OCT) imaging.

Methods: Seventy-Four eyes of 74 glaucoma patients and 86 eyes of 86 control subjects without glaucoma who underwent parapapillary swept source OCT were investigated. Mean \pm standard deviation age and axial length in glaucoma and control eyes were 57.7 ± 11.7 and 46.4 ± 8.8 , and 25.7 ± 1.6 and 24.4 ± 1.2 mm, respectively. The 3D OCT images of the LC were obtained through a series of procedures that consists of DL-based noise reduction, projection artifact reduction, adaptive compensation, automatic segmentation, and 3D volume rendering. Multiple morphologic parameters of the LC were measured from 3D images. The performance of the individual LC parameters as well as the extreme gradient boosting (XGBoost) machine learning model integrating multiple parameters for discriminating glaucoma from healthy were assessed by the area under the curve (AUC) values. The performance of retinal nerve fiber layer (RNFL) thickness based on normative database was also evaluated for reference.

Results: The LC was significantly deeper in glaucoma patients (0.53 ± 0.14 mm) than control subjects (0.47 ± 0.09 mm, $P=0.002$). The best performing single LC parameter in discriminating glaucoma from control was the LC depth (AUC 0.64). The optimized XGBoost analyses yielded excellent discriminating performance (AUC 0.90), which was better than the AUC value of the total RNFL thickness (0.85).

Conclusions: Multiple morphologic parameters of the LC were successfully obtained from 3D DL-enhanced OCT images. Integrating multiple LC parameters by machine learning yielded excellent performance that was comparable to existing RNFL parameters. Results of the current study demonstrated the clinical relevance of 3D LC imaging.

ABSTRACT BODY:

Purpose: With a population incidence varying between 0.20% for severe cases and 25% for mild to moderate ones, negative dysphotopsia (ND) is associated with the perception of dark crescent shadows in the peripheral field of view (PFOV) of pseudophakic patients. As contributing factors, literature reviews enumerate biometry (pupil size in photopic conditions, angle kappa, hyperopia etc) and intraocular lens characteristics (IOL, tilt and decentration, optic body size etc). Building on our previously communicated results, the current study evaluates the predictive ability of personalized theoretical eye models to localize the ND in PFOV.

Methods: In a prospective study conducted at Hanusch Hospital, Vienna, Austria, post-operative biometrical data sets (pupil size, ACD and AL, anterior corneal topography, IOL tilt and decentration and refractive errors) were acquired from six patients implanted with monofocal IOLs and with ND complaints. A Harms tangent screen subjective method was used to localize in PFOV the perceived shadow (HvF). Following a previously presented methodology (M. State et al., IOVS, Vol.60, 3703, 2019), personalized Liou-Brennan (non)-sequential eye models were generated using the acquired biometrical data. Irradiance maps were computed using a polar coordinates detector and compared with the HvF data.

Results: Mean axial length was 22.83 (21.05 – 24.80) mm, mean IOL power 24.4 (20.5 – 30.0) D, mean IOL tilt -1.86 (-6.21 – 2.96) degrees and mean decentration 0.16 (-0.27 – 0.44) mm. Average residual astigmatism difference between theoretical and measured data was 0.49 (0.02 – 0.97) D. Aligned with HvF data, the irradiance maps localized ND in the peripheral visual field up to 85 degrees.

Conclusions: Previously presented theoretical results evidenced that in identical biometrical conditions, IOLs from different manufacturers with similar mechanical platforms but different optic edge designs are characterized by comparable ND profiles with the peripheral location of the shadows between 69 and 76 degrees. Further expanding the utilization of these eye models, the current results demonstrate their clinical relevance in terms of PFOV localization of ND.

ABSTRACT BODY:

Purpose: Peripapillary OCT-A scans are a challenge for analysis as VD is dependent on demarcation of the optic disc. Longitudinal VD analysis require that each pixel of the OCT-A scan has to be at the exact same location during follow-up scans in order to see inter-visit differences. Aim of the present study was to investigate BMO-based peripapillary OCT-A analysis with and without implementation of the Anatomical Positioning System (APS; Glaucoma Module Premium Edition [GMPE], Heidelberg Engineering, Germany) compared to manual analysis in healthy eyes.

Methods: Thirty-seven eyes of 37 controls were measured twice by en-face OCT-A (Heidelberg OCT II Spectralis). OCT-A data were analyzed by the Erlangen Angio-Tool (EA-Tool, version 3.0), implementing an APS-based analysis of the peripapillary region in addition to implementation of BMO landmarks. The APS function allows alignment of OCT-A scans according to each individual FoBMOC (Fovea-to-Bruch's Membrane Opening-Center) axis. APS and BMO coordinates were exported by SP-X1902 software (Heidelberg Engineering, Germany). Peripapillary OCT-A scans were analyzed: (I) manually (circle fitted on the shortest distance of the vertical or horizontal diameter of the optic disc), (II) BMO-based, and (III) BMO-based with APS information. II and III allowed an equidistant measurement of VD from BMO. The study was approved by the local ethics committee and was done in accordance with the tenets of the Declaration of Helsinki. Informed consent was obtained from each participant. Data were presented as mean \pm standard deviation. Coefficients of variation (CV) were calculated. T-tests for paired samples were done.

Results: Peripapillary mean VD was 42.7 ± 16 and 41.1 ± 19 (manually), 50.5 ± 15 and 48.8 ± 16 (BMO-based), and 44.7 ± 11 and 44.4 ± 15 (BMO-based and APSified) for 1st scan and 2nd scan, respectively. Peripapillary mean VD yielded a significant difference between the 1st and 2nd scan for manual ($p=0.02$) and BMO-based ($p=0.04$), yet not for BMO-based and APSified analysis ($p>0.05$). CV were 10.0 (manually), 8.0 (BMO-based), and 8.0 (BMO-based and APSified).

Conclusions: The novel integration of BMO landmarks into the EA-Tool allows a BMO-based peripapillary VD analysis, taking into account individual optic disc anatomy. Additional implementation of APS information increases reproducibility for longterm OCT-A studies of the peripapillary region.

Commercial Relationships Disclosure (Abstract): Ivan Fernandez-Bueno: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Puertas-Neyra: Commercial Relationship: Code N (No Commercial Relationship) | Leticia Hernández-Rodríguez: Commercial Relationship: Code N (No Commercial Relationship) | Nadia Regina Galindo-Cabello: Commercial Relationship: Code N (No Commercial Relationship) | Jose-Carlos Pastor: Commercial Relationship: Code N (No Commercial Relationship) | Ricardo Usategui-Martin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Neuroretina (NR) cultures are useful tools for cellular and molecular research into neuroretinal degeneration that bridges the gap between cell cultures and in vivo models. Although the degeneration of retinal cells is perfectly described at the micro and ultramicroscopic level in organotypic cultures, cell death rates have not been previously characterized. The purpose of this study was to determine if there are differences in cell apoptosis rates over time in the organotypic culture of pig NR.

Methods: NR explants (n=25) were obtained from porcine eyes (n=5; local slaughterhouse) and cultured over Transwell membranes. Cultures were maintained under standard culture conditions for 1, 3, 6, and 9 days (n=5 each). NR explants were fixed in paraformaldehyde and embedded in Tissue-Tek OCT compound. Furthermore, fresh NR explants (n=5) were processed in parallel before culturing. NR sections were immunostained for TUNEL (In Situ Cell Death Detection Kit, Roche). The apoptosis rate was calculated by counting the number of TUNEL positive elements according to the total number of nuclei (in arbitrary units; AU) and evaluated in the total NR tissue and by layers. Statistical analyses were performed using SPSS software. After confirming homogeneity of variance and normal distribution, ANOVA with Bonferroni adjustment was applied. P-values <0.05 were considered statistically significant.

Results: Total NR apoptosis rate was statistically higher in days 3, 6, and 9 of culture (all $p < 0.001$) in comparison with fresh NR (fresh NR: 0.4 ± 0.6 AU; day 1: 3.9 ± 0.6 AU; day 3: 6.2 ± 0.7 AU; day 6: 12.5 ± 2.0 AU, and day 9: 15.1 ± 1.1 AU). Besides, the apoptosis rate was statistically higher on days 6 and 9 in comparison with days 1 and 3, respectively (all $p < 0.001$). Apoptosis in the NR layers peak at day 6 in the ganglion cells layer (GCL), and day 9 in the outer and inner nuclear layers (ONL and INL), showing significant differences comparing to fresh NR and culture days 1 and 3 (all $p < 0.001$).

Conclusions: Statistically significant differences in apoptosis rates are distinguishable in the organotypic culture of pig NR over time. Early apoptosis in the GCL, in comparison with ONL and INL, could be due to the axotomy produced in this type of culture. These findings enable future research to characterize in-depth the processes of cell death by apoptosis, as well as by autophagy and necroptosis, in NR degeneration in vitro.

ABSTRACT BODY:

Purpose: To assess the effects of intraocular pressure (IOP) and duration of the ex-vivo experiment on the correlation between the parameters of the gamma distribution, used to model corneal optical coherence tomography (OCT) speckle, in porcine intact eyes.

Methods: Twenty three eyeballs were subjected to IOP from 10 to 40 mmHg with a step of 5 mmHg (Experiment 1), where a computer-controlled syringe pump allowed maintaining a stable IOP level in the anterior chamber. At each IOP level, horizontal OCT B-scans of the central 5 mm of the cornea were acquired using spectral-domain OCT (SOCT REVO). To evaluate the potential influence of duration of the experiment on the OCT speckle statistics, 10 eyeballs were maintained at the constant IOP of 15 mmHg (Experiment 2) and imaged in the same manner as in Experiment 1, to match the overall duration of the experiments (seven time-points). Spatial maps of the gamma distribution parameters, shape (v) and scale (a), were calculated from OCT scans of size 592x1592 pixels by dividing them into 21x21-pixel segments and assigning the estimated parameters to the segments' central points. For each spatial map, the Pearson's correlation coefficients ($\rho_{v,a}$) were calculated between the gamma parameters, separately for two regions of corneal stroma: central (2 mm) and non-central (the remaining part of the scan).

Results: The group mean values of $\rho_{v,a}$ (see Figure) differed statistically significantly in Experiment 1 (effect of IOP) for both central and non-central regions (rmANOVA, both $p < 0.001$) and in Experiment 2 (effect of duration) for the central region only ($p = 0.034$). Post-hoc analysis with Bonferroni correction in Experiment 2 showed no statistically significant results for any of the time-points.

Conclusions: This study shows that variation in IOP causes significant changes in the correlation between the parameters of the gamma distribution, pointing to the potential of OCT imaging technology for visualising IOP-induced changes in corneal stroma, particularly in its central part.

ABSTRACT BODY:

Purpose: Stargardt disease (STGD), the most common form of inherited macular disease, is caused by mutations in the ABCA4 gene. Due to its large size, studies focusing only on exonic regions have resulted in a proportion of genetically unresolved cases. This underscores the necessity for effective sequencing and variant analysis to interrogate the entire 128-kb gene.

Methods: Single-molecule molecular inversion probe (smMIP) based sequencing of the entire ABCA4 gene and 40-kb of flanking sequence was employed for 1054 probands with STGD/STGD-like phenotypes. Most probands (833/1054) were prescreened for exonic variants but remained unresolved. Potentially splice-altering variants were assessed in vitro. 36 Irish probands were included in this cohort, with an additional 126 Irish samples having undergone smMIP sequencing of ABCA4 in a subsequent group. Analysis of the entire recruited Irish STGD cohort was carried out to detect known pathogenic deep intronic variants (DIVs). Detailed clinical examination of all individuals carrying c.4539+2028C>T was performed.

Results: 27 DIVs were identified in 448/1054 probands, 13 of which were novel. Two pathogenic variants were identified in 97/162 Irish cases. 22/97 harboured a pathogenic intronic variant, of which 12/22 carried a DIV. c.4539+2028C>T, resulting in a retina specific pseudoexon inclusion, was detected in 7/12 cases. Analysis of the entire Irish STGD cohort identified 25 individuals who carry this DIV, including two homozygotes who exhibit profound macular hypofluorescence and are the only homozygotes reported to date. In contrast, 15 other heterozygous incidences have been reported globally in STGD patients, indicating significant enrichment in Ireland. One heterozygous incidence has been found in >800 control alleles in Ireland.

Conclusions: The study highlights the importance of interrogating non-coding regions of disease genes. Unique insights into the genetic architecture of STGD in individual populations can be achieved by sequencing large numbers of international cases. Identification of individuals homozygous for intronic variants is paramount in assessing

phenotypic outcome and variant severity. Studies such as this are particularly relevant given recent advances in splice modulating therapeutics, appropriate access to which will only be possible given an accurate genetic diagnosis.

Commercial Relationships Disclosure (Abstract): Lynn Ebner: Commercial Relationship: Code N (No Commercial Relationship) | Marijana Samardzija: Commercial Relationship: Code N (No Commercial Relationship) | Federica Storti: Commercial Relationship: Code N (No Commercial Relationship) | Vyara Todorova: Commercial Relationship: Code N (No Commercial Relationship) | Duygu Karademir: Commercial Relationship: Code N (No Commercial Relationship) | Julian Behr: Commercial Relationship: Code N (No Commercial Relationship) | Fraser Simpson: Commercial Relationship: Code N (No Commercial Relationship) | Markus Thiersch: Commercial Relationship: Code N (No Commercial Relationship) | Christian Grimm: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxygen delivery to the outer retina through a continuous choroidal blood flow is crucial for cell metabolism, function, and survival. Mild but chronic conditions of reduced oxygen (hypoxia) can lead to retinal pathologies in patients, and a chronic hypoxic response in rods causes age-dependent retinal degeneration in mice. Apart from a decrease in inspired oxygen (normobaric hypoxia), hypoxia can be caused by exposure to reduced barometric pressure (hypobaric hypoxia). Since the cellular response to such chronic conditions is mostly unknown, we investigated the retinal transcriptome of mice kept for up to 11weeks in normobaric hypoxia and up to 7weeks in hypobaric hypoxia.

Methods: Wild type mice were exposed to normobaric hypoxia in a hypoxic chamber at 400m above sea level (asl) or to hypobaric hypoxia at the high-altitude research station on the Jungfrauoch (3450 masl). Bulk sequencing of retinal RNA was performed for 7 different conditions, ultimately (a) comparing acute and chronic hypoxia to normoxia, (b) investigating the adaptation to hypoxia over a timeframe of 6h, 48h and 11weeks, and (c) identifying differences between hypobaric and normobaric hypoxia. Additionally, length of photoreceptor segments was investigated.

Results: Retinas exposed to acute hypoxic conditions up-regulated gene sets involved in the response to oxygen levels, angiogenesis, ion transport, and programmed cell death. Differentially expressed genes in the hypoxic groups indicated a cellular adaptation process to chronic normobaric hypoxia. Based on their time-dependent response, we identified 23 genes which adapted within 48h and 40 genes which adapted after 11weeks of normobaric hypoxia. 7 genes however, showed an increased foldchange with prolonged exposure, suggesting that they might be key factors for phenotypic changes evoked by chronic hypoxia. A subset of 17 genes was regulated in hypobaric but not normobaric hypoxia. Shorter cone and rod segments were detected in some, but not all, hypoxic conditions.

Conclusions: This study identified differences in the genomic response to different levels and nature of hypoxia and presents data that (I) implies a high adaptability of mouse retina to chronic changes in inspired oxygen, (II) reveals differences in the retinal response to normobaric and hypobaric hypoxia, and (III) suggests that hypoxia may lead to a reduction in the length of photoreceptor segments.

TITLE: Assessing the risk of hypopyon formation following mechanical vitrectomy

SESSION TITLE: Vitreoretinal interface diseases / PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I.S. Shaikh, M. Oydanich, A.S. Khouri, Rutgers New Jersey Medical School Institute of Ophthalmology and Visual Science, Newark, New Jersey, UNITED STATES|M.S. Shaikh, New Jersey Institute of Technology, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ibraheem Shaikh: Commercial Relationship: Code N (No Commercial Relationship) | Marko Oydanich: Commercial Relationship: Code N (No Commercial Relationship) | Musa Shaikh: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The formation of a hypopyon, a white blood cell exudate in the anterior chamber of the eye, is a previously reported but uncommon complication of mechanical vitrectomy (MV). Using a large sample population database, we investigated the impact of various clinical and non-clinical factors on the risk of developing hypopyon after MV.

Methods: Cases of MV were obtained from the National Inpatient Sample (NIS) database between 2002 and 2013. ICD-9 diagnosis and procedural codes were used to assess associated morbidities in cases with a principal procedure of MV. Perioperative complications occurring during the same operative admission were abstracted using ICD-9 codes, and secondary diagnoses of hypopyon were identified. Univariate and multivariate logistic regression analyses were carried out in cases that underwent MV to determine risk factors for the development of a hypopyon. The dataset was weighted using the NIS-provided discharge-level weights in order to achieve nationally representative estimates. The Bonferroni correction method was applied.

Results: There were 3,927 MV cases that were grouped into hypopyon (n=50, median age=76, 58% female) and non-hypopyon (n=3,877, median age=61, 49% female) cohorts. Co-morbid factors associated with increased risk of hypopyon formation included retinal vasculitis (OR=18.23), rheumatoid arthritis (OR=4.87), and tobacco use (OR=1.98). Younger age was strongly protective against hypopyon formation in the age groups 0-19 (OR=0.08), 20-39 (OR=0.10), 40-59 (OR=0.34), and 60-79 (OR=0.47) in comparison to the reference group of ≥80 years of age (Figure 1). Race, sex, and insurance status did not show statistically significant associations.

Conclusions: A large patient population was utilized to examine this rare complication following MV. We found an increased risk of hypopyon formation in cases that underwent MV with comorbidities associated with inflammatory states, including retinal vasculitis, rheumatoid arthritis, and tobacco use. Younger age was a protective factor, with an exponential increase in risk of hypopyon development associated with advancing age. Limitations of this study include the limited cases of MV in the inpatient setting, the use of a database that records cases rather than individual patients, and the limited ability to demonstrate casual relationships in a retrospective analysis.

ABSTRACT BODY:

Purpose: The relative ellipsoid zone reflectivity (rEZR) on spectral-domain optical coherence tomography (SD-OCT) imaging is a potential indicator for photoreceptor's health. The purpose of this study was to investigate the natural history of the rEZR in subjects with intermediate age-related macular degeneration (iAMD) and its association with high-risk factors of disease progression including reticular pseudodrusen (RPD) and pigmentary abnormalities (PA).

Methods: SD-OCT volume scans (49 B-scans, field size 20°x20°, collected every 6 months for 3 years) from an existing natural history cohort of AMD patients with bilateral large drusen (>125 μm) were used in this study. Using an automatic rEZR determination approach, the average rEZR of each raw SD-OCT volume was determined as the mean ratio of the ellipsoid zone (EZ) to the external limiting membrane (ELM) reflectivity (linear range of grey values: 0-1). The change in rEZR over 3 years was determined using linear regression models, adjusting for baseline age and the presence of RPD and PA.

Results: A total of 145 eyes of 145 iAMD patients (mean age: 69.8 ± 8.1 years) were included, with RPD and PA being present in 30 (21%) and 37 (26%) eyes, respectively. At baseline, the average rEZR was lower in eyes with RPD (28.9 ± 15.5, arbitrary units, AU) compared to eyes without RPD (38.7 ± 17.2 AU, p = 0.005), however, there was no significant difference in rEZR between eyes with (33.6 ± 14.2) and without PA (37.8 ± 18.2, p = 0.208). Longitudinal analysis showed that rEZR was associated with age, the presence of RPD and PA. The rEZR linearly decreased over time and that the rate of change was significantly greater in eyes with RPD (-6.66 ± 2.2 AU per 6 months) compared to eyes without RPD (-0.73 ± 0.06 AU per 6 months, p<0.001), adjusted for age and the presence of PA at baseline.

Conclusions: The rEZR decreases over time and the rate of reduction is greater in eyes with RPD, a high-risk phenotype of progression, compared to eyes without. These findings warrant further studies evaluating the rEZR as a prognostic biomarker for progression to advanced AMD.

TITLE: The effectiveness of the ILUVIEN[®] (0.2 µg per day of mg fluocinolone acetonide) implant in the treatment of non-infectious posterior uveitis – 12-month outcomes from UAE

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Gurbaxani, I. Kozak, Moorfields Eye Hospital Dubai, Dubai, Dubai, UNITED ARAB EMIRATES|

Commercial Relationships Disclosure (Abstract): Avinash Gurbaxani: Commercial Relationship(s);Alimera:Code C (Consultant) | Igor Kozak: Commercial Relationship(s);Alimera:Code C (Consultant)

ABSTRACT BODY:

Purpose: The objective of this study was to evaluate the effectiveness and safety of the ILUVIEN (0.2 µg per day of mg fluocinolone acetonide [FAc]) implant (Alimera Sciences Inc., Georgia, USA) for the treatment of non-infectious posterior uveitis and to focus on the 12-month outcomes in seven patients (10 eyes) in clinical practice in the United Arab Emirates..

Methods: This prospective interventional case review surveyed consecutive patients. Ten eyes from seven patients were treated with the FAc implant for posterior uveitis at the Moorfields Eye Hospital in Abu Dhabi and Dubai, UAE between December 2018 and October 2020 . Patients were monitored for between 3 and 12 months (median, 9.0 months; 25th and 75th quartiles, 6.0 and 12.0) with best-corrected visual acuity (BCVA), central retinal thickness (CRT), vitritis and anterior chamber (AC) cell scores and intraocular pressure (IOP) being recorded.

Results: Diagnoses included panuveitis, retinal vasculitis , vitritis, pseudophakic CME / panuveitis, multifocal choroiditis, vasculitis. Prior treatment with a dexamethasone implant was done in 5 of the 10 eyes (median, 2.0 implants; 25th and 75th quartiles, 1.0 and 2.0 implants). No systemic steroids were being given at the time of FAc therapy or during the 12 months of follow-up. At Month 12, BCVA increased by 16.1±5.5 ETDRS letters (mean±SD) from a baseline of 64.5±15.8 letters (P=0.0029); CRT improved by 79.0±96.0 microns from a baseline of 370.4±101.1 microns (P>0.05); and, mean IOP was unchanged from baseline (P>0.05), remaining below a mean value of 21 mmHg at all time points upto the 12 months. Baseline vitritis score was 1.4±1.2 and improved at months 3 (-0.8±0.8), 6 (-1.0±1.0) and 12 (-2.0±0.7). At Month 12, a vitritis score of zero was observed in four of the five treated eyes. A similar response was also seen for AC cells with the mean baseline value (0.5±0.8) improving at months 3 (-0.4±0.8), 6 (-0.6±0.9) and 12 (-1.0±1.0). Adverse events included posterior capsule opacification in one eye which was managed with YAG laser. Another eye had an epiretinal membrane, but this was not related to treatment.

Conclusions: Results gained from treating patients in clinical practice in the UAE show the FA implant to be effective in the treatment of non-infectious posterior uveitis affecting the posterior segment of the eye.

ABSTRACT BODY:

Purpose: Existing automated retinal image quality assessment (RIQA) models, commonly trained on diabetic retinopathy (DR) images, have limited applicability to neuro-ophthalmic conditions (e.g., papilledema, ischemic optic neuropathy (ION), etc.). Their inconsistent performance is due to the appearance of the abnormal optic disc (swelling, atrophy, etc). Hence, our aim was to develop a new automated RIQA system that can predict, without human intervention, if a fundus image has an acceptable image quality for subsequent evaluation of the optic nerve head (ONH).

Methods: A total of 2,082 fundus images obtained from the EyeQ, a publicly available DR data set, and 5,208 images collected within the Brain and Optic Nerve Study with Artificial Intelligence (BONSAI) Consortium data set (total of 486 ION, 1,644 papilledema, 832 optic atrophy, 559 DR, and 3,769 normal fundoscopic images) were segmented for their ONH region and given quality-labels by a trained human classifier. The data set was divided proportionally into images used for training (80%) or testing (20%). A dedicated deep-learning system (EfficientNet-B5 CNN), was trained to automatically perform a binary quality classification of retinal images (i.e. "Acceptable" or "Rejected"). The classification performance of our RIQA was evaluated by calculating the area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity.

Results: Using 5-fold cross-validation on the training data set, our model classified ONH segmented fundus images into "Acceptable" vs "Rejected", yielding an average AUC of 0.982, accuracy of 94.2%, sensitivity of 93.3%, and specificity of 94.6%. When tested against the testing data set for external validation, our model achieved an average AUC of 0.982, accuracy of 92.6%, sensitivity of 93.9%, and of specificity 92%.

Conclusions: An automated deep learning system trained on digital color images of normal and abnormal optic discs due to various optic neuropathies can discriminate between acceptable and poor image quality. Further developments will aim to provide instantaneous image quality evaluation coupled to fundus cameras and/or independent deep learning-based diagnostic algorithms.

ABSTRACT BODY:

Purpose: Patients of higher age or with reduced acuity exhibit increased involuntary eye motion during fixation. This causes distortion and gaps in optical coherence tomography (OCT) and OCT angiography (OCTA), which can substantially complicate qualitative and quantitative image analysis. We evaluated whether motion correction in late-stage age-related macular degeneration (AMD) can be improved by advanced motion modeling.

While a multitude of correction approaches exist, their accuracy and reliability in pathology is insufficient for the high resolution of OCT due to (1) toleration of implausible displacement estimates that limit distortion correction, (2) independent displacement estimation of A- or B-scans that is unreliable in areas with few features, sequential correction procedures where (3) initial steps lack correction of following ones and require (4) superfluous resamplings that cause interpolation artifacts, and (5) use of inaccurate features.

Methods: Our from-scratch redesigned motion model estimates (1) plausible, (2) closed motion trajectories throughout each volume-scan that map A-scans to their correct position in a single mapping (3, 4) based on the similarity of the OCT data itself (5). 3-D displacements and tilt along the transverse directions were parameterized with a Hermite B-spline along acquisition time. Further key features include regularization for continuity, gradient descent optimization, OCTA white line removal, and preliminary illumination normalization.

Evaluation is ongoing. To date, we evaluated on data of 14 eyes (Table 1) that covers a 3x3 mm (1) or 6x6 mm (13) field around the fovea with a 500x500 orthogonal raster scan (5 B-scan repeats, 3.7 s acquisition) from a prototype 400 kHz swept source OCT device.

Results: Compared to our previous motion correction scheme, inter-scan consistency improved further, and, if present, tilt inaccuracies and motion-induced blurring and double vessels were significantly reduced. However, lack of proper illumination correction compromised the benefits in 2 volumes.

Conclusions: Correct modeling of eye motion can significantly reduce motion-induced artifacts. While broader evaluation is indicated to prove generalization, already using only OCT data improved reliability beyond our combined OCT + OCTA approach based on the previous motion model.

ABSTRACT BODY:

Purpose: Recombinant Adeno-Associated Virus (AAV) gene therapy has remarkably advanced in the treatment of retinal diseases due to its safety and efficacy. Each of the AAV administration routes of delivery to the retina confers unique advantages and limitations. Intravitreal delivery is hindered by the internal limiting membrane barrier for primates, and induces humoral immune response, while subretinal delivery necessitates invasive surgery and generates retinal detachment. In contrast, suprachoroidal (SC) injection, targeting the space between the sclera and choroid, is emerging as a novel approach to deliver AAV into the posterior segment of the eye with least invasive procedure, but this route has not been fully elucidated in mouse model for different AAV serotypes. Here, we investigated the transduction efficiency, cell tropism and bio-distribution in mouse retina, for three serotypes of AAV via SC administration.

Methods: EGFP reporter gene driven by the ubiquitous promoter CBA was packaged in three conventionally used AAV serotypes. In 12-week old C57BL/6J mice, SC inject 1.0µl Fluorescein Sodium (1.0 x 10E-6 %) or the three scAAVs-CBA-EGFP solution respectively. Retinal structure was imaged pre-, post-injection and 1.5 weeks post-injection by funduscopy and optical coherence tomography (OCT). Transduction efficiency and tropism was assessed 1.5 weeks post injection by funduscopy and histology. Immune response was evaluated by immunostaining for Iba1 macrophages, CD45+ leukocyte and CD3+ T cells.

Results: The retina structure was tracked and shown the successful injection into the suprachoroidal compartment. Transduction of outer retina, and retinal pigment epithelium was observed with these three AAV serotypes by SC delivered, and 3 AAVs displayed varied efficiency and cell specificity. Meanwhile, the activation of inflammatory cells was observed pending on doses adopted. To be noted, retinal detachment was successfully evaded, together with a widespread distribution of the transduction in mouse retina layers.

Conclusions: This study unveils the feasibility of SC injection in mouse, facilitating the proof-of-concept and pre-clinical studies of retinal gene therapy in mouse models. Without the complications of retinal detachment, SC administration is a preferred route to deliver AAV into outer retina layers in comparison with subretinal route. SC injection can serve as an alternative intraocular delivery method of AAV.

ABSTRACT BODY:

Purpose: Recent papers highlight an important role played by oxidation and inflammation in dry eye disease (DED), mainly with over-exposure to screens and air-conditioned environments; but very few DED treatments target both factors. We performed a prospective, non-randomized, investigator masked study to assess the beneficial effect of a preservative free (PF) ophthalmic emulsion eye drop combining lipoic acid (LA), a well-known anti-oxidant agent, with high-molecular weight sodium hyaluronate (HMW HA), in the management of DED with regard to these two stresses.

Methods: 40 symptomatic moderate to severe DED patients were treated with a PF ophthalmic emulsion combining LA and HMW HA (4-6 times/day) for 35 days. Two visits were scheduled (D0&D35) to assess: quality of life (QoL; OSDI score); tears antioxidant levels of superoxide dismutase (SOD); ocular surface inflammation (conjunctival hyperemia); goblet cell (Gc) morphology (conjunctival impression cytology); and conjunctival staining (Oxford score). Subgroup analysis was initially planned considering the different DED etiologies. Statistical analysis was performed (D35 vs D0; paired t-test and Wilcoxon; $p < 0.05$).

Results: At D35, the OSDI score improvement was highly significant for all patients ($p < 0.01$). In the subgroup with deficient levels of antioxidants at D0 ($n=13$), a significant increase in both SOD1 ($p=0.01$) and SOD2 ($p=0.02$) was observed at D35. Total hyperemia decreased significantly in the subgroup of patients with the most severe inflammation at baseline (grade ≥ 2 ; $n=19$; $p=0.04$). For patients whose DED was associated with marked Gc anomaly at D0 ($n=13$), both cell density and thickness were significantly improved at D35 ($p=0.002$ and $p=0.003$, respectively). Oxford score was at the limits of significance in the subgroup of patients with notable anomalies at D0 (grade ≥ 6 ; $n=34$; $p=0.07$).

Conclusions: Regardless of the DED etiology, the use of a PF ophthalmic emulsion combining LA and HMW HA shows a beneficial effect on the ocular surface through the improved QoL score. Noteworthy, in patients presenting high oxidative and inflammatory conditions, significant improvement is highlighted on oxidative stress and inflammation markers; this synergic effect is likely due to the well-known properties of LA and HMW HA, enhancing DED management in environmental stress.

ABSTRACT BODY:

Purpose: In our daily life, we might walk under different challenging conditions, such as engaging in visual search or adapting to different lighting levels. These challenges might impose more fall risk to visually-impaired patients. This study was aimed to investigate the possible impact of visual search and lighting on walking in patients with peripheral field loss (PFL).

Methods: Five participants with binocular visual field less than 10° and 5 age-matched healthy controls were recruited. All participants were required to walk a 4-metres obstacle-free pathway at self-pace and step on a force platform at the end of pathway under 3 different lighting levels (100, 520 and 2100 lux). Six monitors were placed at two-metres away from the force platform in an arc-shape to cover ~120° field of view. While walking, they either fixated at a stationary cross or performed a visual search task by identifying a target among 5 distractors shown on the monitors. Inertial measurement unit synchronized with a high-speed camera were used to measure the changes of gait pattern in temporal parameters, including swing phase (%), double support (%), cadence (step/min) and average walking speed (cm/sec).

Results: Visual search task significantly affected the gait pattern, with reduced swing phase (Fix: 36.0%±1.8 vs Search: 35.3%±2.0; $p<0.01$) and increased double support (Fix: 26.7%±3.4 vs Search: 28.2%±3.8; $p=0.01$). It also significantly decreased cadence (Fix: 106±11 vs Search: 103±13 step/min) and average walking speed (Fix: 88.8±12.1 vs Search: 82.2±13.8 cm/s; $p<0.01$). Furthermore, significant interaction effects between group and visual task were found in cadence and average walking speed ($p<0.05$), showing that search task affected the temporal domain of gait in patients with PFL. However, no significant effect of lighting or interaction effect between lighting and group ($p>0.05$).

Conclusions: In this preliminary study, search task caused significant changes in the walking pattern in people with PFL. In contrast, environmental changes due to different lighting conditions did not show significant impact on the gait. Further study is needed to examine the causal relationship between the change of the walking pattern due to search task and the incidence of falls in this population and whether the mobility performance will be further compromised when patients need to negotiate obstacles during walking.

ABSTRACT BODY:

Purpose: Neuroregenerative research largely focuses on improving axonal regrowth, leaving dendrites mostly unstudied, despite their importance for neural circuit functioning. We previously determined the dendritic response of retinal ganglion cells (RGCs) during axonal outgrowth after optic nerve crush (ONC) in regeneration-competent adult zebrafish and revealed an antagonistic axon-dendrite interplay, wherein early dendritic retraction boosts axonal regrowth and RGC dendrites only regenerate after target innervation in the brain. One underlying mechanism might be an intraneuronal energy trade-off that prevents simultaneous axonal regrowth and maintenance/regrowth of dendrites. To test this idea, we focused on mitochondria, increasingly recognized to exert a critical role in axonal regeneration.

Methods: The mitochondrial distribution within RGC dendrites, axons and somas was characterized at several time points after ONC, using retinal flat mounts of mitochondrial reporter fish and a Python script. Cryosections were used to localize the mitochondria inside the optic nerve and optic tectum. To study mitochondrial dynamic changes upon injury, IHC and WB for biogenesis, fission, fusion and mitophagy markers were used.

Results: Early after ONC, mitochondrial numbers strongly decreased in the RGC dendrites as well as in their axonal projection areas in the optic tectum, concomitant with dendrite retraction and axonal degeneration in retina and tectum, respectively. Mitochondria re-appeared first in tectal RGC axons at the moment of reinnervation and in the RGC dendrites upon their repair. Regarding mitochondrial dynamics, a biphasic upregulation of biogenesis was found, respectively before the start of axon/dendrite regrowth, suggesting a role of the new mitochondria within these processes. While the level of fusion remained unchanged during the complete regenerative process, fission was strongly increased after ONC during dendritic retraction and axonal regrowth, as well as mitophagy.

Conclusions: The timed dendrite-axon-dendrite mitochondrial translocation after ONC fits the hypothesis that dendritic mitochondria reshuffle energy to the axons to boost repair, and that dendrite regrowth is aided by a return of mitochondria to the retina. Overall, our findings could generate pivotal insights into how re-directing intraneuronal energy channeling may promote neuronal repair in the CNS.

Rennert: Commercial Relationship: Code N (No Commercial Relationship) | Ruth Van Nispen: Commercial Relationship(s);MeiraGTx UK II Ltd.:Code C (Consultant) | Frank Verbraak: Commercial Relationship: Code N (No Commercial Relationship) | Ger H.M.B. van Rens: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is known that clinical factors such as visual acuity do not fully predict vision-related quality of life (VrQoL). Therefore, recognizing patients in need of additional support, e.g. early referral to low vision services, may be challenging for ophthalmologists during busy consultation hours. The aim was to determine which demographic and clinical characteristics are predictive of VrQoL in patients receiving intravitreal anti-vascular endothelial growth factor (VEGF) treatment for macular edema due to exudative retinal diseases.

Methods: Patients (n=712) were recruited from nine different locations of Bergman Clinics in The Netherlands. VrQoL was measured at baseline, 6 and 12 months using a newly developed itembank (EYE-Q) consisting of 47 items measuring VrQoL. The selected demographic characteristics potentially predictive of VrQoL were sex, age, civil status, education, employment status, and presence of non-ocular and ocular comorbidities. Selected clinical characteristics were visual acuity (VA), number of treated eyes, length of intravitreal anti-VEGF treatment, number of intravitreal anti-VEGF injections. Multivariate regression analysis was performed, using a forward selection procedure. The model was internally validated using the heuristic shrinkage factor.

Results: The study population included 344 male participants (48.3%). Mean age was 76.2 years. The majority of participants were diagnosed with exudative age-related macular degeneration (63.3%) and 81.9% received one-sided treatment with anti-VEGF. Most participants (92.4%) had a VA of the better eye equal to or better than 0.5 LogMAR. Factors predictive of a lower VrQoL were a poorer LogMAR VA of the better eye (β 0.97, 95% CI 0.378 to 1.17), female sex (β 0.31, 95% CI 0.18 to 0.45), living alone (β 0.24, 95% CI 0.09 to 0.39), older age (β 0.01, 95% CI 0.00 to 0.02), a longer length of intravitreal anti-VEGF treatment at baseline (β 0.06, 95% CI 0.01 to 0.11), and the presence of non-ocular and ocular comorbidities (β 0.21, 95% CI 0.08 to 0.35 and β 0.13, 95% CI 0.03 to 0.24). The heuristic shrinkage estimate was 0.96.

Conclusions: Visual acuity appeared to be the strongest predictor of VrQoL in patients with macular edema receiving intravitreal anti-VEGF treatment, however other patient characteristics must also be considered for the risk assessment of low VrQoL and may be a reason for referral to low vision services.

TITLE: Role of Hyaluronan on Aging Meibomian Glands

SESSION TITLE: Lacrimal gland and Meibomian gland

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: V.J. Coulson-Thomas, M. Sun, I. Moreno, K.N. Mutoji, T.F. Gesteira, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|T.F. Gesteira, Optimvia, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Vivien Coulson-Thomas: Commercial Relationship: Code N (No Commercial Relationship) | Mingxia Sun: Commercial Relationship: Code N (No Commercial Relationship) | Isabel Moreno: Commercial Relationship: Code N (No Commercial Relationship) | Kazadi Mutoji: Commercial Relationship: Code N (No Commercial Relationship) | Tarsis Gesteira: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Meibomian gland (MG) produces the lipid layer of the tear film, and changes to the MG that lead to a decrease or alteration in lipid quality/content may lead to MG dysfunction (MGD), a major cause of evaporative dry eye disease with prevalence ranging from 39% to 50%. We have previously shown that hyaluronan (HA) regulates MG morphogenesis and homeostasis. We hereby investigated the role of HA in aging MGs.

Methods: Combined hyaluronan synthase (Has) 1 and 3 null mice, namely Has1^{-/-};Has3^{-/-}, and wild-type mice were used to determine the role of HA in the aging eyelid and MGs. Eyelids were obtained and analyzed at 6 months and 1 year of age. MG morphology, volume, lipid production and HA distribution were analyzed. Susceptibility to developing dry eye disease (DED) was also evaluated.

Results: At 6 months of age, wild-type mice presented a small number of atrophic glands, whereas Has1^{-/-};Has3^{-/-} mice did not present any atrophic glands at this same time point. At 1 year of age, wild-type mice presented ~15 atrophic glands, whereas Has1^{-/-};Has3^{-/-} mice still did not present any atrophic glands at this same time point. Has1^{-/-};Has3^{-/-} mice presented a 5-fold increase in MG volume and a 3-fold increase in lipid production per area at 1 year. Consequently, Has1^{-/-};Has3^{-/-} mice presented resistance to developing DED. Importantly, as previously shown, mice lacking the enzymes Has 1 and 3 up-regulated Has 2, and, consequently, presented an increase in HA throughout the tarsal plate and MGs at both time-points analyzed.

Conclusions: An increase in HA production within the tarsal plate is able to prevent MGD in aging mice, which in turn, makes these mice resistant to DED when compared to aged-matched wild-type mice.

TITLE: Accommodation and vergence conflict in young hyperopes

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Neupane, C. Mestre, K.S. Connolly, D.W. Lyon, T. Candy, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|Y. Wu, V. Sreenivasan, Alcon Laboratories Inc, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sonisha Neupane: Commercial Relationship: Code N (No Commercial Relationship) | Clara Mestre: Commercial Relationship: Code N (No Commercial Relationship) | Yifei Wu: Commercial Relationship: Code N (No Commercial Relationship) | Vidhyapriya Sreenivasan: Commercial Relationship: Code N (No Commercial Relationship) | Katie Connolly: Commercial Relationship: Code N (No Commercial Relationship) | Don Lyon: Commercial Relationship: Code N (No Commercial Relationship) | T Rowan Candy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Young children with hyperopia must accommodate more than a typical adult to achieve focused retinal images and promote typical visual development. In coordinating the coupling between accommodation and vergence they could underaccommodate to the target to maintain alignment, accommodate and converge relatively accurately, or accommodate accurately but over-converge leading to esophoria (with good fusional divergence) or esotropia. This study looked at the accommodation, vergence and fusional abilities of young uncorrected hyperopes.

Methods: A PlusOptix PowerRef3 (Simultaneous Purkinje image eye tracking and eccentric photorefractometry) recorded the alignment and refractive state of 20 hyperopic children (0-10 yrs; Sph. Equiv. refractive error: +2.25 to +6.50D) and 49 control participants (0-10 yrs; Sph. Equiv. refractive error: -0.25 D to +2.00 D) while they viewed cartoon movies at 33cm. Accommodative performance and vergence position were determined in monocular and binocular conditions and prism bars were introduced to drive fusional vergence. Fusional limits were defined as the last prism for which alignment was maintained and, in each case, the role of accommodation was assessed simultaneously.

Results: The median accommodative error was 1.6D lag for hyperopes (range: 0.50D lead to 4.3D lag) and 1.5D lag for the controls (range: 0.80D lead to 3.5D lag) at 33 cm. The median phoria was 1pd exophoria for hyperopes (range: 2pd esophoria to 5pd exophoria) and 3pd exophoria for controls (range: 9pd esophoria to 8pd exophoria). The median fusional vergence ranges in the hyperopic group were 16 pd of divergence (range: 4-32 pd) and 24 pd of convergence (range: 12-40pd) which were similar to the control group (16 pd of divergence, range: 4-24pd & 20pd of convergence, range: 20-40pd). In the hyperopic participants, the median relaxation of accommodation was 1.2D during divergence with a median increase of 1.2D during convergence. The median changes in the control group were 1.7D relaxation of accommodation during divergence and median increase of 1.2D during convergence. These values were less than predicted by a typical AC/A ratio.

Conclusions: Most of the hyperopes had a small exophoria and a typical accommodative lag. Their fusional range and ability to manipulate accommodation to achieve fusion were also clinically similar to the control group. They seemed able to accommodate typically and maintain alignment for this task.

ABSTRACT BODY:

Purpose: Disease-causing variants in RPGR (retinitis pigmentosa GTPase regulator) account for 70-90% of cases of X-linked Retinitis Pigmentosa (RP) and is currently the subject of multiple ongoing clinical trials. We sought to determine the extent of cone function impairment by assessing color discrimination.

Methods: Twenty four subjects (23 adults, 1 child; aged 14 – 35) with RPGR-associated RP were assessed using the Trivector component of the low vision version of the Cambridge Colour Test (IvCCT). Contrast sensitivity (CS) using the Pelli-Robson chart and best corrected visual acuity (BCVA) were also evaluated. A subset of 15 subjects additionally undertook testing with the Ellipse component of the IvCCT and the American Optical Hardy Rand Rittler (AO-HRR) plates. Tests were performed monocularly in both eyes and repeated three times.

Results: Testing with IvCCT demonstrated a wide range of color discrimination abilities in the study group, from near normal to severe impairment. The median saturation threshold along the protan, deutan and tritan axes, as assessed by the Trivector assessment were: 19.8, 21.4 and 55.7 respectively. The median ellipse area was 2212.7. (For comparison, a normal trichromatic subject has a saturation threshold of less than 10 in all three axes and ellipse area smaller than 340.)

Color discrimination along the tritan axis was the most severely affected, indicated by both IvCCT components used. Out of the three axes, saturation threshold along the tritan axis correlated most strongly with both BCVA [Pearson correlation coefficient (PCC) = -0.69, $p < 0.001$] and CS (PCC = -0.74, $p < 0.001$). PCC for ellipse area with BCVA and with CS was -0.57 ($p = 0.026$) and -0.66 ($p = 0.007$) respectively.

Both Trivector and Ellipse assessments also correlated with performance using AO-HRR plates, indicating consistency across methods [PCC of minimum -0.77 across three axes ($p < 0.001$) and -0.81 ($p < 0.001$)] respectively.

Conclusions: Both the Ellipse and Trivector components of the IvCCT are able to identify mild to severe color vision impairment in a group of genetically confirmed RPGR-associated RP subjects. The preponderance of tritan axis impairment suggests early loss of S-cone function in the disease. The monitoring of color vision with such methods provides information about cone function and disease progression, which may prove useful when assessing the efficacy of novel therapies.

ABSTRACT BODY:

Purpose: Myopic retinal stretching enlarges the space between retinal cells and increases the critical area for spatial summation, potentially leading to a remodeling of neural contact. Thus, this study aimed to investigate the effect of high myopia on contrast discrimination at the fovea and peripheral retina.

Methods: Thirty-six young participants (aged 19 to 41 years), including 17 high myopes (HM, spherical equivalent: -15.00 to -8.88D) and 19 emmetropes (EM, spherical equivalent: -0.63 to 1.00D), were recruited. Monocular threshold versus pedestal contrast (TvC) curves were generated at the fovea, 10° and 20° temporal retina across eight pedestal contrasts (0.1%, 0.32%, 1%, 3.2%, 5.6%, 10%, 17.8%, 32%). The contrast increment threshold at each pedestal level was determined from three-down-one-up staircases in a two-interval-forced-choice paradigm. Vertical Gabor patches (2 cycles per degree) generated by Psykinematix were used as the visual stimuli. Contrast detection thresholds (i.e., 0% pedestal contrast) were also measured for normalizing the TvC curves. The contrast increment and detection thresholds for the fovea and 10° temporal retina were tested at 2 meters and 20° temporal retina at 1 meter. The slopes of the TvC curve from 3.2% to 32% pedestal levels in log-log coordinate and the normalized contrast increment thresholds were compared between the two groups.

Results: The normalized foveal TvC curves of HM and EM were highly overlapped, and both reached their trough at approximately 1% normalized pedestal contrast, i.e., when the tested pedestal contrast was close to the detection threshold. In contrast, the peripheral TvC curves of HM were slightly elevated, especially at 0.1%, 0.32%, and 1% pedestal contrast tested at the 20° temporal retina. The difference in increment threshold at 1% pedestal contrast reached a significant level (median in HM vs. EM, 1.98% vs. 1.24%, $p=0.035$). No significant between-group difference in the slopes of the TvC curve were found at the fovea (median in HM vs. EM, 0.82 vs. 0.81, $p=0.60$), 10° (0.78 vs. 0.71, $p=0.14$), or 20° retina (HM vs. EM, 0.72 vs. 0.72, $p=0.32$).

Conclusions: Opposing to our hypothesis, retinal stretching in HM did not affect the foveal contrast discrimination. However, it appeared to diminish the facilitation effect of the TvC function in the peripheral retina, which might be due to the alteration in spatial pooling at low contrast.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a progressive disease of the macula that at advanced stages leads to blindness in the elderly population. While the neovascular form is characterized by choroidal blood vessels invading the retina, the dry form leads to atrophy of the retinal pigment epithelium (RPE) and degeneration of photoreceptors. Genes involved in lipid metabolism, including ATP-binding cassette transporter A1 (ABCA1) were associated with AMD through genome-wide association studies. ABCA1 is strongly expressed in the RPE and required for lipid metabolism and export. AMD-associated genetic variants near the ABCA1 gene were shown to modulate its expression in patient-derived lymphoblastoid cell lines, suggesting that these variants may lead to disturbed lipid transport in the human RPE.

Methods: Patient induced pluripotent stem cells (iPSC) harboring homozygous ABCA1 genotypes for increased (rs1883025:C and rs2740488:A) or decreased (rs1883025:T and rs2740488:C) risk for AMD were differentiated into RPE. These iPSC-RPE cells were analyzed for ABCA1 gene and protein expression, their ability to phagocytize photoreceptor outer segments (POS) and the efficiency of cholesterol efflux. Experiments were conducted under normoxic and hypoxic (4% O₂) conditions to mimic the physiological conditions in the ageing eye. Furthermore, ABCA1 expression and function was also examined after Liver X receptor (LXR) agonist treatment, a regulator of cholesterol homeostasis.

Results: iPSC-derived RPE cells showed similar gene expression and morphological characteristics of RPE cells in vivo. Interestingly, hypoxia-treated RPE cells exhibited reduced ABCA1 expression and dysregulation of several hypoxia-associated genes (e.g. PDK1 and ADM). Diminished ABCA1 expression was also observed in increased risk genotype-bearing iPSC-RPE cells treated with an LXR agonist compared to iPSC-RPE cells carrying the reduced risk ABCA1 genotype. Subsequently, the lack of ABCA1 expression hampered cholesterol efflux, leading to lipid accumulation in iPSC-RPE cells.

Conclusions: In conclusion, this study points towards a functional effect of AMD-associated genetic variants in ABCA1 on cholesterol efflux in iPSC-RPE cells and suggests that this model system may be used to study the mechanism of altered lipid metabolism in the development of AMD.

ABSTRACT BODY:

Purpose: To assess whether there is a bias towards certain visual acuity (VA) values when using an EDTRS logMAR chart and intraocular pressure (IOP) measurement using Goldmann Applanation Tonometry (GAT).

Methods: This study involved VA and IOP data from 27 secondary care providers in the UK using the medisoft electronic medical record (EMR) platform and from the UK BioBank Eye and Vision Consortium (UKBB). Trial data was used from the ABC and LIGHT trial. LogMAR VA values were compared per line, from letter position 1-5 using the remainder modulus (RM) and IOP devices including GAT, iCARE, Tonopen and Airpuff were analysed in the EMR data, as well GAT IOP data from the LIGHT trial and ocular response analyser (ORA) data from the UKBB. Chi-squared tests comparing the frequency of RM 1-5 for LogMAR VA, as well for IOP for all devices was performed for all the data.

Results: There was significantly unequal distribution between the letter positions, which favoured RM 5 in our EMR data ($1=209295$, $2=10368$, $3=113341$, $4=122606$, $5=425664$, $X^2(4,N=974,592)=377889.8$, $p<0.001$). The UKBB also confirmed a significantly unequal distribution of values per RM on the LogMAR chart ($1=8759$, $2=14000$, $3=18014$, $4=11641$, $5=13472$, $X^2(1,N=65,886)=14292$, $p<0.001$). Comparatively the ABC trial did not show any significant difference in the frequency of RM positions ($1=255$, $2=277$, $3=314$, $4=269$, $5=285$, $X^2(4,N=1400)=6.941$, $p=0.141$). EMR data showed a significantly unequal distribution in even vs. odd IOP values for GAT compared to other IOP measuring devices (even/odd, GAT $83129/489324$, iCARE $307929/288118$, Tonopen $262890/255362$, Airpuff $8776/66882$, $X^2(3,N=2,510,935)=96863.010$, $p<0.001$). Similarly, the LIGHT trial showed there was significantly unequal distribution for IOP values when using GAT (even/odd, $6433/4642$, $X^2(1,N=718)=292.61$, $p<0.001$). UKBB showed a small but statistically significant unequal distribution between values using ORA (even/odd, $32288/31731$, X

$\chi^2(1, N=64,109)=4.865, p=0.028$).

Conclusions: LogMAR VA had a significantly unequal distribution and GAT IOP values were significantly more likely to be even in our EMR data set. These findings were backed up by UKBB and trial data. This rounding of LogMAR VA and GAT IOP could be due to examiner bias. Outcomes of this study may have consequences in clinical practice and therapeutic trials may require greater scrutiny.

ABSTRACT BODY:

Purpose: To assess intergrader agreement when interpreting retinal images acquired with handheld retinal imaging devices for DR screening.

Methods: Mydriatic retinal images acquired using 3 hand-held retinal cameras [Aurora (AU), Smartscope (SS), RV700 (RV)] were compared with Early Treatment Diabetic Retinopathy Study 7-field standard photography (ETDRS photos). All handheld retinal images were independently evaluated by 2 grader-certified nonphysician staff and 1 retina specialist (RPS). The ETDRS photos were evaluated by a senior retina specialist (PSS). All graders had completed a structured certification program in DR assessment. Grading was performed using the International Classification for DR. Agreement was measured using kappa (κ) statistics, multirater κ across graders and sensitivity/specificity was calculated for vision threatening DR [(vtDR): severe NPDR or worse].

Results: Images from 177 eyes of 92 patients with diabetes were evaluated. Severity by ETDRS photos: no DR 40.1%, mild NPDR 19.2%, moderate 14.7%, severe 10.2%, proliferative DR 15.8%. Ungradable rate for DR was AU: 0%; SS: 4.5%; RV: 4.0%; and ETDRS: 0%. Results are presented in table 1. Multirater κ for DR severity (0.58 – 0.65) and vtDR (0.71 – 0.74) was uniform across all devices. Agreement (κ) for DR severity between ETDRS photos and graders was similar across nonphysician graders across devices (0.46 – 0.48) and highest with retina specialist evaluation across devices (0.70-0.78). Sensitivity/specificity for vtDR on ETDRS photo for nonphysician graders was over 0.95 in all devices but specificity was 0.87-0.89. Retina specialist specificity for vtDR was 0.96-0.97.

Conclusions: In assessing DR severity, substantial over-all agreement (0.58-0.74) among all graders was achieved emphasizing the benefit of a structured program of grading certification. Retinal images obtained using all 3 handheld cameras achieved the highest agreement with ETDRS photos (0.70-0.78) when evaluated by a retinal specialist. Among the nonphysician graders for all devices, sensitivity for vtDR was over 90% but specificity remained 87-89%. These findings suggest that in DR screening programs using hand-held retinal imaging, secondary grading of eyes with vtDR by more experienced graders may be necessary to minimize unnecessary referrals that would otherwise decrease the effectiveness of screening programs.

TITLE: Intravitreal administration, but not systemic administration, of VEGF Mini-Trap effectively inhibits neovascularization in the Oxygen Induced Retinopathy (OIR) in mice

SESSION TITLE: Stem cells / gene therapy/ transplantation/ laser/ local therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Cheung, J. Cao, C. Romano, Regeneron Pharmaceuticals Inc, Tarrytown, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eunice Cheung: Commercial Relationship(s);Regeneron Pharmaceuticals,Inc.:Code E (Employment) | Jingtai Cao: Commercial Relationship(s);Regeneron Pharmaceuticals,Inc.:Code E (Employment) | Carmelo Romano: Commercial Relationship(s);Regeneron Pharmaceuticals,Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Vascular Endothelial Growth Factor (VEGF) plays an essential role in normal and pathological angiogenesis. Aflibercept is a potent VEGF inhibitor that binds all isoforms of VEGF-A as well as the VEGFR1 ligands placental growth factor (PlGF) and VEGF-B. When administered systemically (IP) or intravitreally (IVT), VEGF Trap effectively blocks pathological retinal neovascularization in OIR model (IOVS 2006; 47:E-Abstract 1750; IOVS 2011:E-Abstract 3210). In this study, we evaluated the effects of aflibercept (full length) in comparison to VEGF Mini-Trap (REGN7483, Fc cleaved aflibercept) in the murine OIR model.

Methods: C57Bl6 mouse pups were placed in a hyperoxic environment (75% O₂) at postnatal day (P)6 and returned to room air at P11. Study 1 (IVT Screen Study): OIR pups were injected IVT with human Fc 0.25µg, aflibercept 0.125µg, or REGN7483 0.125µg, respectively, at P13 and collected at P16. Study 2 (IVT Dose Response Study): OIR mice were injected IVT with Fc 0.25µg, REGN7483 at 0.025µg, 0.25µg, and 2.5µg, or aflibercept at 0.05µg, 0.5µg, and 5µg at P13 and collected at P16. Study 3 (IP Study): OIR mice were injected IP with Fc 5mg/kg, aflibercept 10mg/kg, or REGN7483 at 5mg/kg, 15mg/kg, and 50mg/kg, respectively, at P12 and collected at P16.

Results: Study 1: Although at equimolar doses IVT Fc, aflibercept, and REGN7483 showed similar avascular areas, aflibercept and REGN7483 notably reduced neovascular tufts compared to Fc. Study 2: IVT aflibercept and REGN7483 reduced tufts in a dose-dependent manner, compared to Fc. There were no differences in abnormal area between aflibercept and REGN7483 at matched molar doses. Study 3: IP aflibercept resulted in a significant tuft reduction, compared to Fc and all REGN7483 groups.

Conclusions: These studies in mice show that VEGF Mini-Trap administered IVT and not systemically demonstrated anti-angiogenic activity. These studies validate that VEGF Mini-Trap dose-dependently inhibits pathological neovascularization. These studies also document the equipotency of intravitreal VEGF Mini-Trap with intravitreal full-length aflibercept. The lack of systemic efficacy of Mini-Trap is likely due to more rapid clearance systemically, although this study did not directly measure PK.

ABSTRACT BODY:

Purpose: Diabetic macular edema (DME) is characterized by an increase in retinal thickness and anti-Vascular Endothelial Growth Factor (VEGF) injections decrease macular fluid volume to improve outcomes. Improvement in retinal volume by OCT is used both as an indicator of disease control and the variability in treatment response is considered a poor prognosis for visual acuity (VA). The purpose of this study was to track retinal fluid volume fluctuation and discern prognostic patterns to indicate positive and negative treatment outcomes.

Methods: This was a retrospective cohort study of 147 DME eyes from patients seen at the Cole Eye Institute Cleveland Clinic from January 1st, 2012 to October 1st, 2019. Patients with visits and spectral domain optical coherence tomography (OCT) scans at 0, 3, 6, and 12 months were selected. Total retinal fluid (TRF), IRF (Intra-retinal fluid), and SRF (Subretinal Fluid) volumes were quantified using the Notal OCT Analyzer (NOA) algorithm. Demographic data and injection status were also collected at each timepoint from electronic medical records. A linear mixed-effects regression (LMER) model was used to calculate the relationship between TRF, IRF, SRF, and VA by quartiles.

Results: The mean total anti-VEGF injections given was 8.57 ± 2.43 . Mean VA at baseline and 12 months was 65.03 ± 13.03 and 70.43 ± 11.68 (p<0.001) ETDRS letters respectively. The mean total retinal fluid (TRF) at baseline and 12 months was 1.06 ± 1.14 mm³ (mean + SD) and 0.51 ± 0.67 mm³. The mean IRF at baseline and 12 months was 10.25 ± 11.16 mm³ and 5.01 ± 6.58 mm³ respectively. Baseline VA was a significant predictor of final VA (p<0.001) in the LMER. The LMER analysis also showed that patients in the 3rd Quartile had -4.39 ETDRS letter gain (p=0.048) and those in the 4th Quartile had -7.09 ETDRS letter gain (p=0.002) at 12 months compared to those in the 1st Quartile. SRF changes were not significantly correlated to final VA (p=0.381).

Conclusions: Patients with higher levels of IRF were associated with decreased VA gain from baseline to 12 months. Further testing in treatment-naïve patients could identify a specific threshold at which IRF contributes to more or less VA gain. Clinicians can apply these findings to patient care and personalize treatment plans for each visit based on retinal fluid levels and VA.

TITLE: Quality of life and participation in children with visual impairment: comparisons to reference groups

SESSION TITLE: Visual Impairment and Quality of Life

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E. Elsmann, M. Koel, R. Van Nispen, G. van Rens, Ophthalmology, Amsterdam UMC
Locatie VUmc, Amsterdam, Noord-Holland, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Ellen Elsmann: Commercial Relationship: Code N (No Commercial Relationship) | Mitchel Koel: Commercial Relationship: Code N (No Commercial Relationship) | Ruth Van Nispen: Commercial Relationship(s);MeiraGTx UK II Ltd:Code C (Consultant) | Ger H.M.B. van Rens: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate quality of life and participation in children aged 3-17 years with visual impairment (VI) compared to reference groups and between subgroups with increasing severity levels of VI.

Methods: Participants were recruited from Dutch nationwide low vision services. Parents of children aged 3-17 years (n=502) and children aged 13-17 years (n=74) completed the Child and Adolescent Scale of Participation (CASP). Both children aged 7-17 years and their parents (n=268) completed the Kidscreen-27. CASP scores of children aged 3-11 years and Kidscreen scores were compared to age and/or gender appropriate population-based samples and effect sizes (ES) were calculated. Because of lacking population-based samples for older children, CASP scores of children aged 12-17 years were compared to children with chronic conditions or disabilities. In addition, the association between severity of VI and quality of life or participation was analysed with linear regression models within the VI sample.

Results: Children performed significantly worse on Physical Wellbeing (ES: 0.18) and Social Support & Peers (ES: 0.23), but better on the School Environment (ES: -0.36) Kidscreen subscales compared to reference groups. Similar results were found for parents (ES: 0.35, 0.13, -0.14, respectively), and they also reported worse scores on the Parents & Autonomy subscale (ES: 0.18). Children's participation was significantly worse compared to a population-based sample (ES: 1.58), but significantly better compared to children with various chronic conditions and disabilities, both reported by parents and children themselves (ES: -1.90 and -3.06, respectively). After correcting for potential confounders, having moderate or severe VI/blindness was significantly associated with worse participation as reported by parents relative to those with no VI.

Conclusions: Quality of life of children with VI is affected especially regarding Physical Wellbeing and Social Support & Peers when compared to a reference population and their participation is considerably worse. Participation was more affected in children with more severe VI. These results contribute to the understanding of the impact of VI and interventions targeting physical health, social skills and participation are warranted.

TITLE: To determine the relationship between corneal endothelial parameters with diabetes mellitus and diabetic retinopathy

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. jha, OPHTHALMOLOGY, MILITARY HOSPITAL GAYA, GAYA, BIHAR, INDIA|A. Verma, OPHTHALMOLOGY, Sankara Nethralaya, Chennai, Tamil Nadu, INDIA|A.R. ALAGORIE, OPHTHALMOLOGY, Tanta University, Tanta, EGYPT|

Commercial Relationships Disclosure (Abstract): ashok jha: Commercial Relationship: Code N (No Commercial Relationship) | Aditya Verma: Commercial Relationship: Code N (No Commercial Relationship) | AHMED ALAGORIE: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the central corneal thickness, corneal endothelial cell density, and morphology in patients with type 2 diabetes mellitus (DM)

Methods: In this prospective study, corneal endothelial parameters including central corneal thickness (CCT), endothelial cell density (ECD), coefficient of variation in cell size (CV), and hexagonality (Hex) were assessed by specular microscopy (EM 3000 Tomey Nishi-Ku, Nagoya, Aichi, Japan) in patients with type 2 DM and compared with age-matched control group. Further analysis was done to assess the influence of diabetic retinopathy severity, duration of DM, and level of glycosylated hemoglobin (HbA1c) on the corneal endothelium

Results: The study cohort included 592 eyes of 592 diabetic patients and 596 eyes of 596 control subjects. On comparing the two groups, a significant difference was found in CCT ($522.1 \pm 36.6 \mu\text{m}$ in DM, $514.9 \pm 37.1 \mu\text{m}$ in controls; $P=0.001$), ECD ($2484.5 \pm 299.5 \text{ cells/mm}^2$ in DM, $2555.9 \pm 258.2 \text{ cells/mm}^2$ in controls; $P = 0.017$), CV (40.3 ± 6.1 in DM, 37.2 ± 6.1 in controls; $P<0.001$) and Hex (39.9 ± 5.2 in DM, 44.6 ± 6.0 in controls; $P<0.001$). The longer duration of DM (>10 years) and poor glycemic control ($\text{HbA1c} > 7.5\%$) were associated with similar results. A significantly reduced ECD ($P<0.001$) and Hex ($P<0.001$) and higher CV ($P = 0.007$) and CCT ($P = 0.01$) was noted when assessed against various stages of DR. Spearman correlation between duration, HbA1C, and DR status and the corneal parameters showed a significant negative correlation for ECD and Hex, and a significant positive correlation for CCT and CV respectively. Multivariate regression analysis showed that increasing age was significantly associated with lower ECD ($P<0.001$), Hex ($P<0.001$), and CCT ($P=0.004$); and a higher CV ($P<0.001$). Also, increasing HbA1c was associated with significantly lower ECD ($P<0.001$) and a higher CV ($P=0.002$)

Conclusions: Diabetes mellitus, especially if long-standing or poorly controlled, has deleterious effects on corneal endothelium and thickness. The presence of diabetic retinopathy may further warrant a thorough corneal evaluation, especially when planning intraocular surgery

ABSTRACT BODY:

Purpose: The critical period (CP) is a post-natal time in which neuronal cell death occurs in development of the mouse retina. In the case of photoreceptors (PRs), the CP is important for creating a balance between the number of PRs and the metabolic resources. In rodent models, many PR-related abnormalities commence during the CP. It has been established in previous studies that a hyperoxic environment is effective in limiting PR death, but no functional studies have been performed to see whether it is translated to vision. The experiments were conducted to test the hypothesis that hyperoxia would ameliorate stress and cell death during the CP and improve retinal function and morphology in both C57 (wild type) and C3H mice, a rapidly progressing degenerative model for retinitis pigmentosa (RP).

Methods: Both C57 and C3H mice were exposed to normoxia (21% oxygen, control), hyperoxia (75% oxygen), or hypoxia (12% oxygen) from post-natal days (P) 7-20. Slides double-labelled for G8 and TUNEL (markers for stress and cell death, respectively) were used to obtain cell counts at P: 10, 12, 16, and 28. Optical coherence tomography (OCT) and scotopic Electroretinograms (ERG) were used to assess the effect of oxygen levels on retina morphology and function, respectively. The OCTs were only conducted on C57 mice, while the ERGs were executed on both C57 and C3H mice.

Results: The OCT revealed that the outer nuclear layer (ONL) was thicker in C57 mice exposed to hyperoxia than control animals. Treatment with hyperoxia resulted in a significant increase in the mean ERG A-and B-wave amplitudes in both C57 and C3H mice. The cell count data indicated that hypoxia decreased while hyperoxia increased the number of PR cells during the CP.

Conclusions: These findings indicate that hyperoxia reduces PR cell death and improves function during the CP in the normal neonatal mouse retina and the C3H model of RP. Further studies are warranted to examine whether the beneficial effects of hyperoxia on slowing degeneration in C3H mice are more pronounced in less aggressive models of RP that resemble disease progression in humans.

ABSTRACT BODY:

Purpose: To evaluate whether significant anterior chamber inflammation and/or cystoid macular edema (CME) occurs in patients with tube-iris touch after Ahmed glaucoma valve (AGV) implantation.

Methods: This is a cross-sectional study. Patients aged ≥ 18 years old who underwent AGV implantation at least 3 months prior to the study were included. Patients with any uveitis, corneal haze, prior macular diseases or prior intraocular surgery (with the exception of cataract surgery) were excluded. Tube-iris touch was identified by slit lamp examination and confirmed with anterior segment optical coherence tomography. Anterior chamber (AC) inflammation was graded using Standardization of Uveitis Nomenclature classification. CME was evaluated using spectral domain OCT to measure central foveal thickness (CFT).

Results: 103 eyes (84 patients) were included. The tube was inserted into the anterior chamber in 33 eyes (32%) and the sulcus in 70 eyes (68%). Tube-iris touch was identified in 47 eyes: 10 shunts (21.3%) had anterior chamber placement and 37 (78.7%) had sulcus placement. Pigmented and inflammatory cells in the AC were found in 5 of 47 eyes (10.6%) with tube-iris touch and 3 of 56 eyes (5.4%) without tube-iris touch ($P=0.34$), presenting a non-significant difference in AC inflammation between the two groups. Mean CFT was 245 and 250 microns for the tube-iris touch and no tube-iris touch groups, respectively ($P=0.60$).

Conclusions: Tube-iris touch following AGV implantation is not associated with increased post-operative AC inflammation or cystoid macular edema regardless of whether the tube is placed in the anterior chamber or ciliary sulcus.

ABSTRACT BODY:

Purpose: The purpose was to investigate predictors of vision and health-related quality of life (QOL) one year after corneal transplantation.

Methods: Patients (N=233, mean age 68) were recruited from eleven hospitals across the Netherlands. In this longitudinal prospective cohort study, patients were assessed 1 month before and 3, 6 and 12 months after corneal transplantation using the Low Vision QOL questionnaire (LVQOL) and the EuroQOL 5 Dimensions questionnaire (EQ-5D). Demographic and clinical characteristics were considered as potential predictors. Linear mixed models were used to analyse the LVQOL, and generalized estimating equations for dichotomized EQ-5D scores due to skewed data.

Results: LVQOL-scores improved over time ($b=13.4$; 95%CI 9.0 to 17.8 at 12 months). Worse baseline logMAR visual acuity of the best eye predicted worse LVQOL-scores ($b=-13.8$; 95%CI -19.1 to -8.5). Worse baseline scores on the Eye Complaint Questionnaire and the Dry Eye Questionnaire (DEQ) predicted worse LVQOL-scores (respectively $b=-0.9$; 95%CI -1.1 to -0.7; $b=-1.2$; 95%CI -1.2 to -0.7). The odds of having a perfect EQ-5D score did not change over time, however, the odds of having a perfect score were lower when having comorbidity (odds ratio, OR 0.41; 95%CI 0.3 to 0.6) or at higher age (OR 0.97; 95%CI 0.94 to 0.99 at 12 months). Patients with worse DEQ-scores had a lower odds of having a perfect EQ-5D over time (ORs between 0.95 and 0.97 and 95%CI between 0.91 and 1.0). Finally, people eligible for lamellar keratoplasty had a higher odds of having a perfect score compared to penetrating keratoplasty (OR 2.6; 95%CI 1.5 to 4.4).

Conclusions: Vision-related QOL improved considerably over time with a linear upward trend, which means that the corneal transplantation seems to be very effective and has an important positive impact on daily life. Low visual acuity and eye complaints related to corneal disease were important predictors of vision-related QOL. Long term follow-up data will show whether this upward trend will continue. Although there were some significant predictors, effects of transplantation for health-related QOL were less outspoken. However, many patients had a (near) perfect score at baseline, hence no room for improvement. The results of this study may contribute to realistic communications about expectations of corneal transplantation and to recommendations for patient-centered care.

ABSTRACT BODY:

Purpose: Genetic risk scores (GRS), sums of additive genetic risk, have strong potential for application in clinical risk stratification and early disease diagnosis in primary open-angle glaucoma (POAG). Recent studies in primarily European-descent population samples suggest that GRS associate with POAG case status, diagnosis age, and disease-specific outcomes. Further study in diverse populations is necessary to ensure generalizability of GRS in POAG, particularly as POAG is generally worse in people of African descent (earlier onset, higher prevalence and likelihood of vision loss/blindness). We investigated a POAG-specific GRS of published risk variants and apply it to the diverse Million Veteran Program (MVP), an ongoing observational cohort study and mega-biobank with >825K Veterans.

Methods: GRS summing 83 POAG-associated risk alleles in MVP samples with POAG phenotype, imputed genetic data, and harmonized ancestry and race/ethnicity (HARE) data. Association analyses of unweighted and effect estimate-weighted GRS and binary POAG phenotype were performed via logistic regression in European-descent (3382 cases, 58,829 controls) and African-descent (2448 cases, 5665 controls) samples. Unadjusted models and models adjusting for age, sex, age*sex interaction, and 10 sample-specific principal components were evaluated. GRS score deciles and quartiles were tested for association with POAG phenotype via logistic regression. Receiver operating characteristic (ROC) curves were composed and statistically compared.

Results: GRS was significantly associated with POAG in unadjusted and adjusted models ($P < 5E-05$). While odds ratio estimates generally increased across deciles, the trend was stronger in the European-descent sample than in the African-descent sample; this was consistently supported by ROC plots and statistical hypothesis testing. GRS identified European-descent cases more consistently than African-descent cases (top quartiles: 37%, 29%, respectively). Unweighted GRS outperformed the weighted GRS in all models.

Conclusions: The ability of known POAG-associated variants to differentiate POAG cases from controls was dampened in African-descent population sample compared to European-descent. These outcomes drive the necessity of further diverse POAG genomic studies.

ABSTRACT BODY:

Purpose: Utilizing a 3D Bioprinted tissue system consisting of vascularized choroidal tissues co-cultured with confluent RPE monolayers, we aim to model the developmental processes of the Outer Blood Retinal Barrier (OBRB). Recently, we included mature macrophages in this system, which become polarized into M1 and M2 macrophages by environmental cues inside tissues likely to fulfil specialized functions. As macrophages are integral to maintaining choroidal function, this study aims to investigate the role of polarized pro-inflammatory (M1) and pro-angiogenic (M2) macrophages, in both the early development and degeneration of the Retinal Pigment Epithelium (RPE) in the 3D-OBRB.

Methods: Endothelial cells, choroidal fibroblasts, and ocular pericytes were encapsulated in a collagen-derived gel and 3D-printed on a degradable scaffold with hydrogels to facilitate microvascular networks. iPSC-RPEs were seeded on the apical side of the scaffold 7 days after bioprinting. Finally, primary activated M1 (pro-inflammatory), M2(pro-angiogenic), and M1+M2 polarized macrophages were added to the tissue at the time of printing (at varying concentrations and ratios), as well as at 28 days post printing. Confocal microscopy, quantitative cytokine analysis, trans-epithelial electrical resistance measurements (TEER), were used to analyze RPE health and components.

Results: When M1 and M2 macrophages were added separately on the day of printing or at day 28 post printing, we observed minor changes in TEER. However, these single macrophage populations were able to strongly influence RPE cytokine secretions; with both M1 and M2 separately increasing wet-AMD associated apical secretions. When M1 and M2 macrophages were combined on the day of printing however, TEER of the RPE monolayers degraded after 5 weeks, with increasing TEER decrease associated with increasing M2 content.

Conclusions: The addition of macrophages in this model system influence the growth/survival of our 3D cultured tissues. This 3D-in vitro model may enable investigations into immune mechanisms influencing OBRB development in humans, maximizing ease of access without heavily sacrificing physiological relevance.

ABSTRACT BODY:

Purpose: To compare optical coherence tomography angiography (OCTA) derived flux with conventional OCTA measures of retinal vascular density

Methods: 3 x 3 mm² fovea-centered images were acquired from healthy human subjects using a commercially available swept-source OCTA (SS-OCTA). Imaging was performed while subjects were breathing either room air (RA), 100% O₂, or 5% CO₂. Retinal perfusion was quantified in each condition using previously described measures of vessel area density (VAD) and vessel skeleton density (VSD) derived from binarized OCTA images. Vessel area flux (VAF) and vessel skeleton flux (VSF) are two novel measures of retinal perfusion based on non-binarized intensities from raw OCTA images. Flux approximates the number of red blood cells moving through a vessel segment per unit time and more accurately reflects small changes in blood flow. Retinal vascular reactivity (RVR) is reported as the percentage change in each OCTA measure between gas conditions (O₂-RA and CO₂-RA). Analyses were performed for all-vessel (including arterioles and venules) as well as capillary-only OCTA images. Statistical significance was determined using paired t-tests and a linear mixed effects model with a p-value of < 0.05.

Results: 84 OCTA images (one image per gas condition) from 29 subjects were included (mean age 45.9 ± 19.5 years; 48.3% male). Flux measures, VAF and VSF, showed significantly greater relative magnitude of change compared to density measures, VAD and VSD, in all gas conditions. In CO₂ condition, the change was 168% greater in VAF than VAD (p = 0.002), and 124% greater in VSF than VSD (p = 0.004). Similarly, in O₂ condition, the change was 43% greater in VAF than VAD (p = 0.003), and 57% greater in VSF than VSD (p = 0.01), Fig 1. Flux measures also had a significantly greater magnitude of change in capillary-only images compared to all-vessel images. The change in VAF in capillary-only images was 20% greater in CO₂ (p = 0.01), and 25% greater in O₂ (p = 0.001) condition compared to all-vessel images. VSF showed a similarly significant trend.

Conclusions: OCTA-derived flux measures quantify autoregulatory changes in retinal blood flow at the capillary level with a greater effect size than conventional vessel density measures.

ABSTRACT BODY:

Purpose: To investigate differences between retinal capillary blood flow and visual function in healthy male and female subjects of African (AD) and European (ED) descent.

Methods: A total of 201 healthy subjects (171 ED, 30 AD) were evaluated for: systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), intraocular pressure (IOP) measured via Goldmann applanation tonometry, and calculations of ocular perfusion pressures: (OPP=2/3MAP-IOP), systolic OPP (SOPP=SBP-IOP), diastolic OPP (DOPP=DBP-IOP), and mean OPP (MOPP=MAP-IOP). Retinal blood velocities and the percentage of measured area without active retinal capillary blood flow (estimated as % of retina with no detectable flow) in the superior (SNF) and inferior (INF) superficial retina were assessed with Heidelberg Retinal Flowmetry. Visual function was assessed with both Early Treatment Diabetic Retinopathy Study (ETDRS) and Vector Vision contrast sensitivity (CS) charts. Unpaired t-tests were performed with $p < 0.05$ considered statistically significant.

Results: In all healthy subjects, the percentage non-vascularized retina was significantly higher in females compared to males in both the superior (SNF: 17.6%, vs. 15.5%; $p = 0.009$) and inferior (INF: 18.1% vs. 14.6%; $p = 0.0002$) superficial retina. There were no statistically significant differences in age between groups (female: 44.2 years, male: 43.3 years; $p > 0.05$). The associated blood velocities were also significantly higher in females in both the superior and inferior retina ($p = 0.0003$; $p = 0.0001$, respectively). Healthy subjects of AD had significantly higher systemic blood pressures and all calculations of ocular perfusion pressures compared to those of ED ($p < 0.05$). CS detection was significantly higher in males compared to females (CS Row D: 0.897 vs. 0.727; $p = 0.032$) while ETDRS detection was significantly worse in females compared to males (0.133 vs. 0.084; $p = 0.044$).

Conclusions: In this cohort of healthy subjects, females had a higher percentage of retinal avascular area and associated blood velocities in both the superior and inferior retina compared to males. Visual acuity and contrast sensitivity detection were also worse in females, while healthy subjects of AD had significantly higher blood and perfusion pressures than those of ED.

ABSTRACT BODY:

Purpose: To examine factors associated with use of minimally invasive glaucoma surgery (MIGS) at the time of phacoemulsification in patients with primary open angle glaucoma (POAG) in the 2016-2017 California (CA) Medicare Population.

Methods: The study population included all patients with administrative billing codes for POAG and phacoemulsification in the 2016-2017 CA Medicare database. Exposures that were examined included age, gender, race, Charlson Comorbidity Index (CCI) score, age-related macular degeneration (AMD), diabetic retinopathy (DR), and severe cataract. The main outcome measure was use of MIGS at the time of phacoemulsification. This was defined by procedure codes for trabecular micro-bypass stent, goniotomy, canaloplasty, or cyclophotocoagulation. Logistic regression modeling was used to identify multivariable predictors of MIGS use at the time of phacoemulsification separately in 2016 and 2017, with all study covariates included in the statistical model.

Results: In the CA Medicare population, there were 11,003 POAG patients in 2016 and 11,269 in 2017 who underwent phacoemulsification, of whom 3,987 (36.2%) had MIGS in 2016 and 4,331 (38.4%) in 2017. In 2016, multivariable associations with MIGS included age 80-84 (odds ratio [OR]=0.86, 95% confidence interval [CI]=0.75, 0.98), 85-89 (OR=0.80, 95% CI=0.68, 0.94), and 90+ (OR=0.74, 95% CI=0.59, 0.93) versus 65-69, Asian (OR=0.83, 95% CI=0.74, 0.93) and Hispanic (OR=0.88, 95% CI=0.79, 0.99) versus white race, CCI score 1-2 versus 0 (OR=0.91, 95% CI=0.82, 1.00), and DR (OR=0.74, 95% CI=0.63, 0.86). In 2017, multivariable associations with MIGS use included age 85-89 (OR=0.74, 95% CI=0.63, 0.86) and 90+ (OR=0.70, 95% CI=0.56, 0.88) versus 65-69, Asian (OR=0.86, 95% CI=0.77, 0.96) and Hispanic (OR=0.90, 95% CI=0.80, 1.00) versus white race, DR (OR=0.75, 95% CI=0.65, 0.87), CCI 1-2 (OR=1.10, 95% CI=1.00, 1.22) and 3-4 (OR=1.13, 95% CI=1.01, 1.27) versus 0, and severe cataract (OR=1.10, 95% CI=1.02, 1.19).

Conclusions: In California Medicare patients with POAG and phacoemulsification in 2016 and 2017, a higher proportion received phacoemulsification alone compared to phacoemulsification with MIGS. Potential factors associated with decreased MIGS use included older age, Asian and Hispanic race, and diabetic eye disease. Further studies are needed on patient selection for MIGS during phacoemulsification.

TITLE: Biomechanical Modeling of Actively Controlled Rectus Extraocular Muscle (EOM) Pulleys

SESSION TITLE: Ocular dysmotility and misalignment: Basic and Clinical studies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Q. Wei, Bioengineering, George Mason University, Fairfax, Virginia, UNITED STATES | J.L. Demer, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES |

Commercial Relationships Disclosure (Abstract): Qi Wei: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Demer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Active Pulley Hypothesis posits that Listing's Law (LL) is implemented mechanically by connective tissue pulleys actively positioned by the rectus EOMs (Demer et al., IOVS, 42:1280-1290, 2000). A computational model is needed to clarify this scheme. We developed a new biomechanical model of active horizontal rectus pulleys and examined its behavior.

Methods: A previously developed 3-D neuro-biomechanical model of the orbit (Wei et al., Prog. Biophys. Mol. Biol., 103:2-3:273-283, 2010) was augmented to realistically simulate pulley mechanics. The orbital (OL) and global (GL) layers of the horizontal rectus EOMs were modeled as separate strands. The pulley sleeve was modeled as a tube suspended by elastic strands and receiving the OL insertion. Stiffnesses and orientations of pulley suspensions were determined empirically to limit EOM side-slip while allowing anteroposterior pulley travel. Independent neural drives of the OL greater than GL were assumed. The model was refined in secondary gazes by incremental iterations to implement realistic behavior using the simplest mechanical configuration and neural control strategy.

Results: Quantitatively realistic behavior required both insertion of each OL on its pulley, and differential control of OL and GL tensions. Actively-controlled pulleys stabilized medial (MR) and lateral rectus (LR) paths during vertical ductions. From 30° supra- to 30° infraduction, LR and MR pulleys shifted vertically by less than 1 mm from central position, realistically demonstrating anterior path inflections ~half the gaze angle as necessary for LL. During progressive rotation from 30° add- to 30° abduction, simulated LR and MR insertional forces agreed quantitatively with corresponding empirical measurements (Collins et al., IOVS, 20(5):652-664, 1981). Predicted innervations of horizontal rectus GL and OL, as well as of cyclovertical EOMs, were consistent with previous empirical and computational work.

Conclusions: A novel bilayer biomechanical model realistically implements mechanical behavior of actively-controlled pulleys in secondary gazes that is quantitatively consistent with available EOM force and path data in humans. This simulation, which is consistent with LL, suggests that horizontal rectus pulleys must be under influence of OLs differently innervated from GLs, since physiological behavior could not be implemented without these features.

ABSTRACT BODY:

Purpose: To evaluate early total retinal fluid index (TRFI) instability as a potential imaging biomarker for future intolerance of extended anti-VEGF treatment intervals based on recurrence of exudative activity in nAMD.

Methods: This was a post hoc analysis of the phase II OSPREY clinical trial comparing brolucizumab to aflibercept over 56 weeks. Eyes were initially treated with an anti-VEGF agent every 4 weeks for the first 3 months and were then extended to 8-week intervals through week 40 (matched phase). At that time the brolucizumab group was further extended to 12-week intervals. A treatment agnostic approach was used for this analysis. SD-OCT cube scans were imported into a novel machine-learning enabled OCT feature extraction tool, which automatically segmented intraretinal fluid (IRF), subretinal fluid (SRF), and retinal layers including the internal limiting membrane (ILM) and retinal pigment epithelium (RPE). TRFI, defined as the percentage of IRF and SRF between the ILM and RPE, was calculated for the central macula (CM, defined as the central 2-mm zone). Early TRFI instability was defined as an increase in CM-TRFI of $\geq 0.1\%$ from week 4 to 8. High fluid compartment volatility was defined based on eyes in the 75th percentile for fluid volume fluctuation from week 12 to 56. Optimal anatomic response was defined as achieving a dry retina with minimal or no fluid recurrence.

Results: A total of 81 eyes were included in this analysis. Between week 4 and week 8, 9.8% (8/81) of eyes demonstrated a $\geq 0.1\%$ increase in CM-TRFI. Among eyes with early CM-TRFI instability, only 25% achieved optimal anatomic response compared to 78% of all other eyes ($p < 0.01$) during the matched phase. Of eyes with early CM-TRFI instability, 88% had high IRF and/or SRF volatility following treatment interval extension compared to 41% of eyes without early CM-TRFI instability (odds ratio: 10.0; $p = 0.02$).

Conclusions: Eyes with early CM-TRFI instability during the anti-VEGF loading phase demonstrated greater risk of treatment extension intolerance and overall poorer anatomic response to anti-VEGF therapy. CM-TRFI changes during early treatment may provide important insights to eyes at high risk for exudative recurrence with treatment extension.

ABSTRACT BODY:

Purpose: Deep learning with convolutional neural networks (CNN), a method of supervised machine learning that uses multiple layers to progressively extract higher level features, is becoming increasingly popular in recent years in the field of ophthalmology. The goal of this study is to implement and test a trained deep learning algorithm using pre-operative corneal topography scans in order to 1) classify between keratoconus and normal corneas 2) stage the disease according to Amsler-Krumeich scale and 3) predict whether a patient will likely to benefit from crosslinking treatment.

Methods: Scans of baseline visits for all patients that had a diagnosis of keratoconus (case group) and those who have been assessed for refractive surgery (control group) between January 2007 and June 2019 were analyzed. A CNN was implemented and trained with our custom dataset of corneal topographies (with 80% and 20% validation). In total, 2410 scans were included (1163 keratoconus and 1247 controls) for stage 1, 985 keratoconus scans were classified according to the Amsler-Krumeich scale for stage 2, and 138 keratoconus scans (69 progressed and 69 stabilized) were labeled for stage 3.

Results: For stage 1, the deep learning model with data including all four pentacam parameters (anterior and posterior corneal elevations, anterior curvature and pachymetry maps) showed a validation accuracy of 0.995 in discriminating between keratoconic and normal corneas. For individual map analysis, corneal pachymetry showed the lowest validation accuracy of 0.771, whereas the other parameters anterior corneal elevation, posterior corneal elevation and anterior curvature maps showed accuracies of 0.987, 0.984 and 0.978 respectively. For stage 2, the algorithm was able to stage the disease with a validation accuracy of 0.735 (excluding manifest refraction as an input parameter) and 0.878 (including manifest refraction as an input parameter). For stage 3, the accuracy in correctly predicting the progression of keratoconus was 0.536.

Conclusions: Deep learning using topography scans obtained from the pentacam effectively differentiates keratoconus versus normal corneas as well as stages the disease according to established criteria. The algorithm was not able to predict the likelihood of disease progression based solely on the pre-operative topography, which may partially be attributed to the reduced sample size given the rarity in disease progression.

ABSTRACT BODY:

Purpose: This work adapts a previous heterogeneous model of the murine retinal vasculature to be relevant to human. Oximetry and structural data are used to translate the mouse model into a human model that can predict blood flow and tissue oxygenation in the retinal arterial architecture.

Methods: A theoretical model of the human retina is extrapolated from a previous mouse model based on confocal microscopy images. The vasculature is represented as a directed graph where each edge corresponds to a blood vessel with a specific diameter and length. Oximetry data from the human retina are used to convert the murine vascular network to a human network by adapting: (i) the number of main arterial branches and the angles between them, (ii) vessel diameters, and (iii) vessel lengths. In the human model, oxygen levels in the retinal arterioles and surrounding tissue are calculated using Green's functions. Blood flow, pressure, and viscosity are also computed.

Results: A scaling factor of 3.6 was used to convert murine diameters to human values based on data averaged from five experimental studies. A mouse-to-man scaling factor of 5.4 for vessel length was obtained based on oximetry images and position of the fovea. Figure 1A shows the predicted values of blood flow along a particular vascular pathway of the human model. Figure 1B depicts the predicted levels of the partial pressure of oxygen (PO_2 , in mmHg) throughout the human arteriolar network. The arteriolar model is not connected to the downstream capillaries and venules, so the figure is a proof of principle but does not give precise levels of PO_2 .

Conclusions: This study provides a mathematical model of the human retinal vasculature that can predict blood flow and oxygen levels within a spatially heterogeneous arteriolar network. The heterogeneous arrangement of arterioles in this model accounts for the complex geometry of blood vessels and diffusion of oxygen from multiple sources into one tissue point; however, it does not account for the oxygen supplied by the capillaries. This heterogeneous model of the retinal arterioles will be connected to a series of compartments representing the capillaries and veins to create a hybrid model description of the retinal microcirculation.

ABSTRACT BODY:

Purpose: The purpose of this study is to characterize visual light discomfort threshold (VLDT) reliability measured with the ocular photosensitivity analyzer (OPA) and to measure the effect size of differences in VLDT of ultraviolet (UV) and neutral density (ND) control lenses compared with a 476 nm high pass filter (HPF) lens. The OPA generates light stimuli (white LEDs) of varying intensities utilizing unequal ascending and descending steps along with subjective feedback to yield the VLDT.

Methods: This was a 6-visit, single-center, non-dispensing, randomized, single-masked, repeated measures 3×3 crossover study. To determine the optimum rest interval, VLDT was measured across six consecutive trials using 5, 10, and 15 minute intertest periods. Then, using the optimum rest interval, VLDT was measured with the UV filter lens, with the HPF lens, and with the ND filter lens. Skin color, iris color and macular pigment optical density (MPOD) were measured using colorimetry, iris color scale, and heterochromatic flicker photometry, respectively. Of the 11 subjects from the per-protocol population, 3 (27.3%) were female and 8 (72.7%) were male. The average age (±SD) was 24.2 (±3.3) years. VLDT was analyzed using generalized linear mixed models with the lognormal distribution. Type I error was controlled for multiple comparisons.

Results: The intra-class correlation (ICC) was 0.88, 0.92 and 0.87 for the 5, 10, and 15 minute resting intervals, respectively. Within subject variance estimate was 0.26, 0.16, and 0.27 log(lux) for the 5, 10, and 15 minute resting intervals, respectively. The residual variance was not statistically different among resting periods based on the overall homogeneity of variance test (p=0.140). However, the ICC was slightly higher and the residual variance was lower for the 10 minute interval, so the 10 minute interval was used in subsequent experiments. Skin color and MPOD were not statistically significant covariates. VLDT did not vary between the two control lenses. Median VLDT ratio was significantly different than unity for the HPF relative to the both controls. Relative to control, the HPF reduced transmitted source energy by approximately 28% while the VLDT increased by more than 70%.

Conclusions: It is suggested that high energy visible (HEV) light contributes disproportionately to visual light discomfort. Alternatively, an HEV filter is highly efficacious at reducing visual light discomfort.

ABSTRACT BODY:

Purpose: Pseudoexfoliation syndrome (PEXS) and glaucoma (PEXG) are assumed to be a general elastosis with accumulation of PEX material in ocular and extraocular tissues, yet, the exact pathophysiology is not known. PEXG, the most common type of secondary open-angle glaucoma (OAG), is characterized by large intraocular pressure (IOP) peaks with progressive visual field loss. Recently, agonistic autoantibodies (AAb) against the β 2 adrenergic receptor (AR) were shown to be present in sera of patients with primary and secondary OAG and seemed to be linked to IOP.^{1,2} The present study aimed to investigate the presence of agonistic and inhibitory autoantibodies directed against the β 2-AR in sera of patients with PEXS and PEXG.

Methods: 49 individuals were included: 39 patients (15 PEXG, 9 PEXS, 15 primary OAG) and 10 controls. All patients underwent standard ophthalmological examination with Octopus G1 perimetry. AAbs in serum samples were analyzed by frequency modulation of a specific rat cardiomyocyte bioassay in vitro. Identification of the interacting loop of the β 2-AR and immunoglobulin G analysis were done. The study was approved by the local ethics committee and was done in accordance with the tenets of the Declaration of Helsinki. Informed consent was achieved.

Results: Serum samples of controls were β 2-AAb negative (0.16 ± 0.5 beats/15 sec). No agonistic β 2-AAb (0.24 ± 0.4 beats/15 sec), yet inhibitory β 2-AAb (after additional incubation with $3 \mu\text{M}$ clenbuterol: 5.84 ± 1.7 beats/15 sec), were observed in 80% of PEXS patients, partially blocking the clenbuterol effect (11.10 ± 0.9 beats/15 sec). Loop analysis showed that inhibitory β 2-AAb were directed against the 3rd extracellular loop of β 2-AR. Additionally, they were of IgG3 subtype in PEXS patients. Contrary, PEXG patients showed agonistic β 2-AAb (5.62 ± 0.9 beats/15 sec), yet no inhibitory β 2-AAb. The beating rate was not significantly different between PEXG and POAG patients (3.89 ± 2.8 beats/15 sec; $p > 0.05$). Even synergistic β 2-AAb were observed in sera of 2 PEXG patients (after additional incubation with $1 \mu\text{M}$ clenbuterol: 16.33 ± 0.9 beats/15 sec), overtopping single incubation with $1 \mu\text{M}$ clenbuterol (11.5 ± 0.3 beats/15 sec).

Conclusions: As autoimmune mechanisms were observed to be involved in glaucoma pathogenesis, agonistic and inhibitory β 2-AAb seem to be a part of this multifactorial interplay.

ABSTRACT BODY:

Purpose: Dehydrodolichyl diphosphate synthase (DHDDS) is ubiquitously expressed and serves an essential function throughout the body, yet certain defects in the gene cause non-syndromic retinitis pigmentosa (RP59). To understand the basis for this retina selectivity, we generated and characterized two novel Dhdds knock-in mouse models: Dhdds^{T206A/T206A} and Dhdds^{T206A/K42E}

Methods: Heterozygous (Dhdds^{T206A/+}) knock-in (KI) mice were generated on a C57Bl/6J background using CRISPR/Cas9 technology (UAB Transgenic & Genetically Engineered Models Core). Dhdds^{T206A/+} littermates were crossed to generate Dhdds^{+/+}, Dhdds^{T206A/+}, and Dhdds^{T206A/T206A} mice, and with Dhdds^{K42E/K42E} to generate Dhdds^{T206A/K42E} mice (to at least 3rd (F3) generation). All mutations were verified by PCR and sequence analysis. Phenotypes were assessed by SD-OCT and electroretinography (ERG). Retinal structure was assessed for Dhdds^{T206A/T206A}, Dhdds^{T206A/+}, Dhdds^{T206A/K42E}, and wild type (WT) mice (N=3-5) at PN 1 and 3 mo., while ERG was performed at PN 3 mo. Statistical analysis: Student t-test, with p<0.05 as significance threshold.

Results: SD-OCT showed no significant differences in retinal morphology, comparing mutant vs. WT mice. Outer nuclear layer (ONL) thickness (μm; mean±S.D.): Dhdds^{T206A/T206A} (55±5); Dhdds^{T206A/+} (54±6); Dhdds^{T206A/K42E} (56±5); vs. WT (55±7). Total retinal thickness (μm): Dhdds^{T206A/T206A} (222±8); Dhdds^{T206A/+} (220±8); Dhdds^{T206A/K42E} (220±9); vs. WT (222±6). Dhdds^{T206A/+} ERG maximum response amplitudes at saturation were not significantly different from WT values under dark-adapted (scotopic) or light-adapted (photopic) conditions. However, photopic ERG amplitude of Dhdds^{T206A/K42E} mice were significantly different from WT values, and trending lower for Dhdds^{T206A/T206A} mice. Additionally, scotopic b-/a-wave ratios (values in parentheses) of Dhdds^{T206A/T206A} (1.2:1) and Dhdds^{T206A/K42E} (1.3:1), vs. WT (2:1) mice were significantly diminished.

Conclusions: Homozygous (T206A/T206A) and compound heterozygous (K42E/T206A) Dhdds knock-in mouse models of RP59 exhibit negative ERGs under light- and dark-adapted conditions, indicative of defective photoreceptor-to-bipolar cell synaptic transmission. There may be common retina-specific target(s) that could explain the lack of systemic effects associated with DHDDS mutations in RP59.

Cukras: Commercial Relationship: Code N (No Commercial Relationship) | Laryssa Huryn: Commercial Relationship: Code N (No Commercial Relationship) | Wadih Zein: Commercial Relationship: Code N (No Commercial Relationship) | Brian Brooks: Commercial Relationship: Code N (No Commercial Relationship) | Brett Jeffrey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To quantify photoreceptor degeneration outside ellipsoid zone (EZ) loss in ABCA4-associated retinopathy, and investigate the association of this photoreceptor degeneration with EZ loss progression.

Methods: As part of a prospective, natural-history study (NCT01736293), patients with a Stargardt disease (STGD1) phenotype and at least one pathogenic ABCA4-mutation underwent spectral-domain optical coherence tomography (SD-OCT) annually. SD-OCT data (37 B-scans, 30°×15°) were segmented using custom deep-learning-based software and standardized (Z-scores) to account for retinal topography and age. Standardized thickness data of the outer nuclear layer (ONL), photoreceptor inner segments (IS) and outer segments (OS) were extracted along evenly spaced contour lines surrounding the EZ loss boundary (spacing of 0.43°). Peri-papillary A-scans (2.5° from disc margin) were excluded. Linear mixed models were used for all analyses considering the hierarchical data structure (visits in eyes in patients). Last, random forest regression was applied to predict EZ loss progression rates.

Results: A total of 95 eyes from 48 patients with a median [IQR] follow-up of 4.19 years [2.88, 5.95] were included. Patients exhibited an average (sqrt transformed) EZ loss progression rate of (estimate [95% CI]) 0.10 mm/y [0.09 – 0.11]. ONL thinning extended well beyond the area of EZ loss; ONL thinning occurred along a steep gradient and the average distance from the EZ loss boundary to normalization of ONL thickness (i.e. within ±2 Z-score units) was 4.36° [4.11 – 4.62]. IS and OS thinning was less pronounced in gradient and extent of change; the average distance from the EZ loss boundary to layer thickness normalization was 0.86° [0.61 – 1.11] for OS and 2.43° [2.17 – 2.68] for IS. ONL, OS and IS thickness outside of EZ loss explained (patient-wise leave-one-out cross-validated R^2) 23.6% of the variability in future sqrt EZ loss progression rates.

Conclusions: Patients with ABCA4-associated retinopathy exhibit significant alterations of photoreceptor laminae outside of EZ loss. This degeneration is prognostic for future EZ loss progression. Deep-learning-based analysis of photoreceptor laminae may help to monitor disease progression beyond mere enlargement of EZ loss.

ABSTRACT BODY:

Purpose: To study the natural history of retinal degeneration related to disease-causing sequence variants in the USH2A gene, the Foundation Fighting Blindness Consortium is conducting a 4-year multicenter, international natural history study titled Rate of Progression in USH2A-related Retinal Degeneration (RUSH2A). Herein we evaluate baseline mesopic microperimetry (MP) and spectral domain optical coherence tomography (OCT) metrics and their relationships with other baseline characteristics.

Methods: One eye of each patient had MP with a MAIA system and OCT was tested on both eyes with a Heidelberg Spectralis unit. General linear models were used to assess the association between demographic and clinical characteristics, including gender, race, age, disease duration, smoking, use of dietary supplements, MP mean sensitivity, and OCT ellipsoid zone (EZ) area. The association between MP mean sensitivity and OCT EZ with visual acuity (VA), and central subfield thickness (CST within the center 1mm) was assessed using Spearman correlation coefficients.

Results: All study participants (N=127) had OCT, while MP was obtained at selected sites (N=91). Comparing participants with Usher syndrome type 2 (USH2, N=80) to autosomal recessive non-syndromic RP (ARRP, N=47), the central structural measures of OCT EZ ($3.1 \pm 5.7 \text{ mm}^2$ vs $4.3 \pm 5.6 \text{ mm}^2$, $p=0.26$) and CST ($253.1 \pm 57.5 \text{ }\mu\text{m}$ vs $263.6 \pm 32.9 \text{ }\mu\text{m}$, $p=0.26$) were similar. Longer disease duration was associated with smaller OCT EZ ($p<0.001$) and lower mean sensitivity ($p=0.01$). Comparing MP in USH2 participants (N=55) to those with ARPP (N=36), mean sensitivity was similar by diagnosis ($5.4 \pm 4.9 \text{ dB}$ vs $6.7 \pm 5.1 \text{ dB}$, $p=0.22$). Point-wise sensitivity from repeated MP tests confirmed that central points (within 10-degree) had better sensitivity than peripheral ones (Figure 1). Better VA, larger OCT EZ area, and larger CST were associated with greater MP mean sensitivity ($r>0.3$ and $p<0.01$). Better VA and larger CST were also associated with larger OCT EZ area ($r>0.6$ and $p<0.001$).

Conclusions: The baseline RUSH2A data revealed similar OCT and MP metrics between the USH2 and ARRP participants. Longer disease duration was associated with more severe abnormalities in retinal structure and function. MP and OCT measures may be useful to monitor disease progression in future studies of USH2A-mediated disease.

TITLE: Structural and Functional Progression of Glaucomatous Damage to the Macula with Comorbid Systemic Hypertension

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.Y. Chang, D. Blumberg, G.A. Cioffi, D.C. Hood, J.M. Liebmann, C. De Moraes, Ophthalmology, Columbia University, New York, New York, UNITED STATES|L.A. Al-Aswad, Ophthalmology, NYU Grossman School of Medicine, NYU Langone Health, New York, New York, UNITED STATES|D.C. Hood, Psychology, Columbia University, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Angela Chang: Commercial Relationship: Code N (No Commercial Relationship) | Dana Blumberg: Commercial Relationship: Code N (No Commercial Relationship) | Lama Al-Aswad: Commercial Relationship: Code N (No Commercial Relationship) | George Cioffi: Commercial Relationship: Code N (No Commercial Relationship) | Donald Hood: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Liebmann: Commercial Relationship: Code N (No Commercial Relationship) | C Gustavo De Moraes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Hypertension (HTN) is a risk factor that may affect glaucoma progression. There is a weak positive correlation between blood pressure (BP) and IOP, and lower ocular perfusion is associated with glaucoma prevalence and progression. Macular damage was once thought to be significant only in late stages of glaucoma, but recent studies have shown it can occur earlier. This study examines glaucomatous structural progression of the global retina nerve fiber layer (RNFL) and the macula ganglion cell layer (GCL+) with optical coherence tomography (OCT) and functional progression with visual fields (VF) and their relationship with hypertension.

Methods: 191 eyes of 119 patients enrolled in a prospective, longitudinal study (Structural and Functional Progression of Glaucomatous Damage to the Macula study) were analyzed. These patients were tested with 10-2 and 24-2 VF and spectral-domain OCT obtained at 4-6 month intervals. 72 eyes (37%) had self-reported diagnosis of HTN. Linear mixed effects regression was used to test the relationship between summary statistics from VF and OCT and HTN diagnosis. The goodness-of-fit of relationships was assessed with Bayesian Information Criterion.

Results: The average (95% CI) 24-2 and 10-2 MD rate of progression was -0.31 dB/year (-0.43 to -0.19) and -0.36 dB/year (-0.48 to -0.24), respectively. The rate of progression for OCT was -1.14 microns/year (-1.53 to -0.75) for global RNFL and -0.89 microns/year (-1.30 to -0.48) for global macula GCL+. There was no significant difference in rate of progression between HTN and non-HTN patients with any OCT or VF parameter. Yet, models with better goodness-of-fit when testing the relationship between HTN and progression had the following OCT parameters: global macula GCL+, inferior macula GCL+, mean GCL+ of macular vulnerability zone (MVZ), and mean macula GCL+ of less vulnerability zone (LVZ), and VF parameters: 10-2 PSD and 10-2 MD.

Conclusions: HTN was not significantly associated with progression using any parameter. However, based on ranked model fits, macular structural and functional parameters had best performance fitting the progression data, suggesting their usefulness as endpoints. Studies defining HTN based on 24-hour BP monitoring and including modalities of treatment may better elucidate whether this prevalent systemic disease is an independent risk factor for glaucoma progression.

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) transplantation holds potential for restoring lost vision in glaucoma and other optic neuropathies, but attempts thus far have been limited by low integration into the recipient retina. In organotypic retinal explants, we recently showed that disruption of the internal limiting membrane (ILM) allows donor RGCs to enter the retina. Here, we assess the effects of proteolytic ILM digestion and traumatic optic nerve injury on retinal localization of RGC somas and neurites following intravitreal transplantation in living mice.

Methods: Human embryonic stem cells expressing tdTomato at the BRN3B locus were differentiated into RGCs using an established protocol. Pronase-E was injected intravitreally into mice at various concentrations and ILM integrity was assessed 2 weeks later using laminin immunofluorescence. Optic nerve crush (ONC) was performed using cross-action forceps for 5 seconds. RGCs (50,000 cells) were transplanted intravitreally 2 weeks after pronase injection or optic nerve crush ($N \geq 13$ per group). Localization of donor RGC somas and neurites was quantified 2 weeks after transplantation using high-resolution 3D reconstructions of confocal microscopy z-stacks.

Results: Intravitreal pronase had a narrow effective concentration window: $<0.06\text{U/mL}$ showed little effect on the ILM, $>0.10\text{U/mL}$ induced frequent intraocular hemorrhage, but 0.08U/mL induced sizeable ILM defects without bleeding. Whereas $>90\%$ of transplanted eyes harbored surviving donor RGCs, $<1\%$ of transplanted cells remained at 2 weeks in control retina. By contrast, ONC and pronase treatment each doubled donor RGC survival ($p < 0.05$). The percentage of surviving donor RGC somas migrating into the host RGC layer ($1.4 \pm 0.7\%$ in control eyes) increased by >4 -fold with ONC ($5.8 \pm 1.5\%$, $p < 0.01$) and >12 -fold with pronase ($18.1 \pm 7.2\%$, $p < 0.001$). Appropriate donor RGC neurite localization to the inner plexiform layer occurred only after pronase treatment.

Conclusions: Both proteolytic ILM digestion and endogenous RGC injury through ONC increased survival and structural migration of transplanted human donor RGCs into the retinal parenchyma. Targeted interventions to promote functional integration of RGCs into the recipient retina, including ILM circumvention, may be required for RGC replacement to restore visual function in human patients with optic neuropathy.

ABSTRACT BODY:

Purpose: NMNAT1 is expressed ubiquitously, but mutations in this gene lead to retina-specific disease. The molecular mechanisms underlying disease pathogenesis, and why the retina is uniquely affected by mutations in NMNAT1, are poorly understood. We used a mouse model of NMNAT1-mediated disease to address the hypothesis that reduced NMNAT1 enzymatic function results in nuclear NAD⁺ depletion and transcriptional alterations specifically in the retina.

Methods: RNAseq and metabolomic analyses were performed on retina and kidney tissue collected from mice with the p.Val9Met mutation in Nmnat1 (a model of NMNAT1-associated disease) and wild type (WT) littermate controls. Samples were collected at 2 and 3 weeks of age, which is prior to the onset of retinal degeneration that begins at about 4 weeks of age. Western blotting, IHC, and qRT-PCR were performed to further assess the alterations in gene and protein expression identified by RNAseq. All experiments were conducted in compliance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research.

Results: Nmnat1^{V9M/V9M} mice had a retina-specific reduction in the levels of NAD⁺ (P < 0.0001, unpaired t-test) that was not observed in other tissues, including the kidney, brain, skin, and heart. The kidney was used as a control tissue for RNAseq, and there were no differences in gene expression between WT and Nmnat1^{V9M/V9M} kidney samples at 2 or 3 weeks of age. Although no differences in gene expression were detected in the neural retinas of 2-week-old mutant and WT mice, by 3 weeks of age there were over 2,600 differentially expressed genes in the retinas of Nmnat1^{V9M/V9M} mice. These genes were enriched for immune pathways, phototransduction, apoptosis, and variety of other processes. Western blotting, qRT-PCR, and IHC were used to confirm the alteration in expression of several of the most highly significant genes, such as Gfap and Lad1.

Conclusions: These findings suggest that reduced NMNAT1 activity results in a retina-specific reduction in NAD⁺ and retina-specific transcriptional reprogramming prior to retinal degeneration. This includes increased expression of PARPs, the main nuclear consumer of NAD⁺, and other genes associated with DNA damage. Future work aims to further identify how mutations in NMNAT1 lead to this rapid alteration in gene expression and how these alterations contribute to retinal degeneration.
