ABSTRACT BODY:

Purpose: To compare monoscopic macula centered images taken by mydriatic handheld retinal imaging with SDOCT for detection of macular pathology in diabetic patients.

Methods: Mydriatic macular images of 177 eyes of 92 diabetic patients were taken with 3 handheld retinal imaging devices [Aurora (AU), Smartscope (SS), RV700 (RV)] and compared with the Cirrus 6000 SDOCT taken during the same visit. Images were evaluated for the presence of diabetic macular edema (DME) on monoscopic fundus photographs adapted from Early Treatment Diabetic Retinopathy Study (ETDRS) definitions [no DME, noncenter-involved DME (non-ciDME) and center-involved DME (ciDME)]. Presence of DME on SDOCT used DRCR Retina Network Cirrus gender-based thresholds of central subfield thickness. Sensitivity and specificity were calculated for each device with the SDOCT as gold standard.

Results: Mean age was 56.6±10.8 years and 38% were male. Severity by ETDRS grading: No DR 40.1%, mild NPDR 19.2%, moderate 14.7%, severe 10.2%, proliferative 15.8%, ungradable for DR 0%; no DME 72.9%, non-ciDME 6.8%, ciDME 17.0%, ungradable for DME 3.4%. Gradable images by SDOCT (N=174, 98.3%) showed no DME in 84.7%, non-ciDME in 4.9%, and ciDME in 10.4%. Epiretinal membranes (ERM) were the second most common pathology, present in 11.9% of eyes. Ungradable rate for images (poor visualization in >50% of the macula), was AU:12.3%, SS:16.0%, RV:8.6%. Summary results are shown in table 1. For non-ciDME, sensitivity and specificity were similar across devices (0.71 – 0.78, 0.93 – 0.96) but sensitivity for ciDME was highest with AU(0.76). For nondiabetic macular pathology across all devices, sensitivity was highly variable (0.13 – 0.67) but highly specific (0.99 – 1.00). Sensitivity for ERM was lowest across all devices (0.13 – 0.46).

Conclusions: Compared to SDOCT, monoscopic handheld macular imaging attains high specificity but low sensitivity in identifying macular pathology. Without stereopsis, 22-29% of eyes without DME on monoscopic photos have DME on SDOCT, and 28-37% of eyes with DME on monoscopic handheld imaging will have no DME on SDOCT. Additionally 54-87% of eyes with macular ERM are missed without SDOCT imaging. This suggests the importance of SDOCT integration to improve detection of macular pathology, leading to appropriate referrals in large-scale DR screening programs.

ABSTRACT BODY:

Purpose: Red eye (RE) is one of the most common ophthalmic disease induced by various factors as: bacteria, fungi, viruses or environmental conditions. The treatment of RE should be focused on an elimination of the primary cause and a reduction of symptoms. Topical antibiotics are prescribed in many cases of RE without a clear evidence on a bacterial etiology what can be a reason of an antibiotic resistance. During the inflammatory process caused by bacteria neutrophilic leucocytes are activated and release a leucocyte esterase enzyme (LE). The purpose of the study was to evaluate an activity of LE in the conjunctival sac of patients with acute RE.

Methods: The study was performed on 17 eyes of patients with subjective (itching, tearing, foreign body sensation, discharge) and objective (conjunctival redness and edema, discharge color, eyelid edema) symptoms of the acute RE. The discharge was collected from the lower conjunctival sac by a sterile swab and used for an assessment of LE activity and bacteria identification in microbiological cultures. LE activity was measured in a color chemical reaction with pyrrole amino acid ester and diazonium salt. An intensity of the pink-purple color of the reaction was divided into six grades (0 – lack of any color, 1 – light pink, 5 - dark purple).

Results: The activity of LE was the highest (grade 4-5) in 3 eyes and it correlated with the presence of the purulent discharge. Staphylococcus aureus was found in 2 of those eyes. There were not purulent discharges and any bacteria in 11 eyes with grade 0-1 of LE activity. There were 3 eyes with grade 3 of LE activity and without purulent discharge. Staphylococcus aureus was identified in 1 eye and Staphylococcus epidermidis in 2 eyes.

Conclusions: LE can be a useful marker for the identification the bacterial cause of ocular surface inflammations. LE activity measurement seems to be a quicker, easier and more precise diagnostic method in RE than bacterial culture. It can help to choose a proper treatment and reduce the usage of topical antibiotics in non-bacterial RE.

SUBMITTER (NAME ONLY): Ava Bittner

TITLE: Practice Patterns and Visual Improvements following Optometric Vision Rehabilitation Services at an Ophthalmologic Medical Center

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Bittner, J. Kageyama, M. Chun, Ophthalmology; Stein Eye Institute, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ava Bittner: Commercial Relationship: Code N (No Commercial Relationship) | Jennie Kageyama: Commercial Relationship: Code N (No Commercial Relationship) | Melissa Chun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A previous records review at a low vision rehabilitation (LVR) service in a department of ophthalmology revealed a relatively low rate of improvement in distance visual acuity (VA) by ≥ 2 lines with refraction for 11% of low vision (LV) patients, and did not consider improvements at near or LV assistive devices. We hypothesized that this published data may underestimate the potential benefits of LVR.

Methods: A retrospective review of electronic health records was conducted for 230 patients seen by three optometrists at the UCLA Vision Rehabilitation Center within the past six years with best-corrected VA ≥ 0.18 logMAR in the better eye at baseline. Presenting mean VA was 0.69 logMAR, half were female, and mean age was 69 years (range 5-98), 24% had congenital or retinal dystrophy, while 42% had age-related macular degeneration.

Results: To improve distance and/or near vision, a new spectacle prescription and/or LV devices were recommended for the vast majority (92%). LV devices were recommended to 61% of all patients: 43% were for near tasks and 18% were telescopic devices for distance; 54% of these devices were dispensed. For the 90% in whom refraction was completed, VA improved in either eye by ≥ 2 lines at distance for 24%, or at distance and/or near for 43%. Odds of post-refraction distance VA improvement by ≥ 2 lines was not significantly related to age, gender, whether they had any habitual correction or previous LVR exam, but was significantly more likely for those with worse presenting distance VA (OR: 2.6; 95% CI: 1.2-5.8; $p=0.02$). VA improved with refraction by ≥ 1 line at distance for 53%, or at distance and/or near VA in 67%. Nearly half (47%) had mild VA loss (0.18-0.54 logMAR), of whom 40% were prescribed a high add $\geq +4D$ for near, 48% were recommended LV devices, and 63% were recommended high adds and/or LV devices. There was a significant increase in the chief complaint of reading digital devices: 6% pre-pandemic ($n=3$ of 50) vs. 30% during the pandemic ($n=15$ of 50) ($p=0.002$).

Conclusions: To help increase referrals for LVR, it is important to promote the success rate for LVR services, which was greater in the present study than reported in the literature. Mild VA loss patients were also recommended LV strategies. Future studies should be conducted at other centers to determine whether these findings are similar to outcomes for other LVR practitioners.

TITLE: Choriocapillaris Vascular Flow Area as a Biomarker of Diabetic Retinopathy Severity

SESSION TITLE: OCT Angiography - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.W. Rowe, M. Scheive, K. Reinhart, A.R. Hajrasouliha, Indiana University Department of Ophthalmology, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lucas Rowe: Commercial Relationship: Code N (No Commercial Relationship) | Melanie Scheive: Commercial Relationship: Code N (No Commercial Relationship) | Kathryn Reinhart: Commercial Relationship: Code N (No Commercial Relationship) | Amir Hajrasouliha: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCT-A) offers the opportunity to safely and routinely image the choriocapillaris (CC), which is unable to be visualized by the established technique of fluorescein angiography. We performed a retrospective cohort study to compare the CC vascular flow area between diabetic patients with differing degrees of clinical diabetic retinopathy (DR) severity. We hypothesize that blood flow area in the CC can be used as a biomarker to correlate with clinical severity of DR.

Methods: This retrospective cohort study analyzed the measured flow area of the CC on quality OCT-A scans in non-diabetic control patients (n=206), diabetic patients without retinopathy (n=47), and diabetic patients with mild non-proliferative DR (NPDR) (n=40), moderate to severe NPDR (n=144), and proliferative DR (PDR) (n=81). A two-sample t-test was completed to compare CC flow area between control patients and diabetic patients with at least one quality OCT-A scan. A multivariate linear regression analysis was performed to compare CC flow area to clinical DR diagnosis when controlling for age, gender, and visual acuity in patients with at least one quality OCT-A scan.

Results: There was found to be a statistically significant decreased CC flow area ($p<0.05$) in diabetic patients compared to patients without diabetes. In comparison to diabetic patients without retinopathy, mild NPDR patients revealed an insignificantly increased CC flow area of 0.253 ($p=0.53$), while moderate to severe NPDR patients revealed a significantly decreased CC flow area of 0.691 ($p=0.04$) and PDR patients revealed a significantly decreased CC flow area of 1.11 ($p<0.01$).

Conclusions: CC vascular flow area, as measured by OCT-A, shows promise for the diagnosis and monitoring of DR as a biomarker of clinical disease severity. Future studies investigating longitudinal CC blood flow changes after anti-VEGF injections may be helpful in better understanding the treatment's effects.

TITLE: Aqueous misdirection syndrome masking as myopic surprise: a case report and review of literature

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Chean, D. Gabadage, S. Mukherji, Ophthalmology, Northampton General Hospital, Northampton, Northamptonshire, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Chung Shen Chean: Commercial Relationship: Code N (No Commercial Relationship) | Duminda Gabadage: Commercial Relationship: Code N (No Commercial Relationship) | Subhanjan Mukherji: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aqueous misdirection syndrome, also known as malignant glaucoma, is a rare but serious condition that can present after routine uncomplicated phacoemulsification procedure. Clinical presentations can be subtle and its fluctuating and recurrent nature makes diagnosis difficult. Its pathophysiology is not fully understood, posing therapeutic challenge. We report a case of aqueous misdirection-like presentation in a pseudophakic patient.

Methods: Case report

Results: A 68-year-old Caucasian woman with previous narrow anterior chamber (AC) angle treated with bilateral peripheral iridotomies on Brinzolamide eye drops presented with symptoms of anisometropia and a left eye (LE) myopic surprise a few months after an uncomplicated LE phacoemulsification procedure. Repeat biometry did not show shallow AC and intraocular pressure (IOP) was normal at initial presentation. However, 2 years and 7 months after the operation, IOP was raised. Topical cycloplegic and anti-glaucoma medications relieved signs and symptoms, but effect was temporary with fluctuating IOP. Nd: YAG laser capsulotomy with subsequent cyclodiode laser were performed with good effect on IOP control.

Conclusions: Clinical presentation of aqueous misdirection syndrome may be subtle and can occur weeks to years after routine uncomplicated phacoemulsification surgery. Short axial lengths, hypermetropia, female gender and shallow anterior chamber depths (ACD) are known risk factors. Myopic surprise may be the only initial presenting sign, and measurements of ACD, IOP and gonioscopic examination are essential when clinicians are suspecting aqueous misdirection syndrome on patients who has had recent uneventful cataract surgery.

TITLE: Retrospective Analysis of Demographic and Clinical Data from a School-Based Eye Clinic in Southeastern Michigan

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. KILLEEN, C. Dewey, Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): OLIVIA KILLEEN: Commercial Relationship: Code N (No Commercial Relationship) | Courtney Dewey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Limited data exists on the role of school-based eye clinics. An optometrist from the University of Michigan (UM) holds a biweekly clinic at Ypsilanti Community High School. We performed a retrospective analysis of clinical and demographic data to describe the population and design interventions to improve care.

Methods: Students presenting to clinic received comprehensive eye exams. We collected demographic and ocular data from initial visits 2/2015-7/2019. Follow up visits were excluded. Statistical analysis was performed using SAS 9.4. The UM IRB approved the study.

Results: 429 patients visited during this period. Average age was 14.2 ± 2.7 years. 55.7% were female, 59.7% Black, 17.9% White, and 10.9% Hispanic. 61.7% had Medicaid, 23.6% had private health insurance, and 14.8% were uninsured. 69.0% had a previous eye exam; there was no relationship between insurance and prior exam ($P=0.41$). Medical eye concerns included 4.2% with elevated intraocular pressure, 8.7% with amblyopia, and 0.23% with a cataract. For refractive error, 56.0% had myopia and 31.9% had hyperopia. 52.9% had presenting visual acuity (PVA) worse than 20/40 in both eyes and 15.0% had PVA 20/100 or worse in at least one eye. 58.4% had improvement in best corrected visual acuity (BCVA) of 2 or more lines; 62.7% of Black patients had 2 or more line improvement compared to 42.9% of White patients ($P=0.013$). There was no difference in BCVA improvement by insurance ($P=0.22$). 60.8% wore glasses previously; 24.1% were still wearing glasses. 56.9% of former glasses wearers reported glasses were lost or broken. There was no difference in glasses wear by insurance ($P=0.078$) or race ($P=0.10$). There was no difference in rates of myopia ($P=0.28$) or hyperopia ($P=0.052$) by race. 21 students were referred to UM for further care; 13 (61.9%) attended the appointment, 3 (14.3%) scheduled but did not attend, and 5 (23.8%) never scheduled.

Conclusions: The school-based clinic identified important pathology. Over half wore glasses previously, but less than a quarter still wore glasses. Glasses wear was not correlated to race or insurance, suggesting barriers to glasses beyond access to care. Many students referred for further care did not attend; barriers to follow up must be addressed.

ABSTRACT BODY:

Purpose: To determine whether photoacoustic microscopy (PAM) retinal imaging is safe and whether PAM causes damage to retinal structure or function in rabbit eyes.

Methods: 12 pigmented rabbit eyes received 5 consecutive days of PAM imaging with 5% of the ANSI limit laser energy to achieve high quality PAM imaging of more than 50% of the retinal surface area. One rabbit used for positive control by using 500% of the ANSI limit laser energy. Retinal morphology was examined by ophthalmic examination, fundus photography, red-free photography, fundus autofluorescence (FAF), fluorescein angiography (FA), indocyanine green angiography (ICGA), and optical coherence tomography (OCT). Retinal function was assessed by full field electroretinography (ff-ERGs). Retinal structure was evaluated by histopathology and transmission electron microscopy (TEM). Retinal cells apoptosis was examined by TUNEL assay. Evaluation was performed at 3 days, 1, 2, 3, and 4 weeks post PAM imaging.

Results: Retinal morphologic analyses showed no retinal hemorrhage, edema, detachment, vascular, or pigmentary abnormalities in the retina or choroid after PAM imaging. ff-ERG showed no significant difference in scotopic or photopic a- and b-wave amplitudes or implicit times between the control and experimental eyes. Retinal ultrastructural evaluation using TEM showed normal cellular structure after PAM. TUNEL assay showed no evidence of cells undergoing apoptosis. Retinal histopathology indicated that the architecture and thickness of the retinal layers was well preserved in all experimental eyes. The positive control at 500% of the ANSI limit demonstrated significant damage.

Conclusions: A comprehensive retinal safety evaluation demonstrates no damage to retinal structure or function for 4 weeks after retinal PAM imaging.

ABSTRACT BODY:

Purpose: Ocular surface infection by viruses within human adenovirus species D (HAdV-D) causes epidemic keratoconjunctivitis (EKC). Subepithelial infiltrate (SEI) formation in the cornea is the most significant long-term complication of EKC, and presents in about one-third of cases. However, the mechanism of SEI formation after adenoviral infection of the cornea remains uncertain. High-mobility group box protein 1 (HMGB1) is an endogenous danger signal molecule and chemokine that variably regulates inflammatory responses. Although HMGB1 has been implicated previously in viral infections, and may play a role in bacterial keratitis, its role in EKC has not been studied.

Methods: hTERT-immortalized human corneal epithelial (THE) cells and primary human corneal fibroblasts (HCFs) were infected with HAdV-D37 or HAdV-C5 at MOI = 5, and cell supernatants were collected through 48 hours post infection. Mass spectrometry (LC-MS/MS) analysis was performed on infected human corneal cells. Immunoblotting was performed on infected cell supernatants, and on cytoplasmic and nuclear cellular fractions, using acetylated HMGB1 antibody. ELISA for secreted HMGB1 was conducted on cell-free supernatants, and HMGB1 gene expression was studied using real-time qPCR. Confocal microscopy was performed to visualize HMGB1 translocation. Cytokine expression by HCFs treated with rHMGB1 was analyzed using human cytokine protein arrays.

Results: HAdV-D37 infection resulted in HMGB1 translocation from the nucleus to the cytoplasm and then to the extracellular space in THE cells, but not in HCFs. HAdV-C5, a virus not associated with EKC, did not induce secretion of HMGB1 from either cell type. Finally, recombinant active HMGB1 treatment of HCFs triggered expression of pro-inflammatory mediators.

Conclusions: This study provides insights into possible mechanism of corneal SEI formation in EKC. Our results suggest that HMGB1 expressed by adenovirus infected corneal epithelial cells could induce underlying stromal cells to express pro-inflammatory mediators, leading indirectly to the development of SEI. HMGB1 may be a viable therapeutic target for preventing the corneal stromal complications of EKC.

TITLE: Comparison of depressive symptoms between age-related macular degeneration and glaucoma patients who live in a developing country.

SESSION TITLE: AMD: Clinical and translational research I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.S. Tomishige, C.S. Germano, P.A. Ottaiano, R.M. Maccione, N. Kasahara, Oftalmologia, Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo, São Paulo, BRAZIL|

Commercial Relationships Disclosure (Abstract): Kenzo Tomishige: Commercial Relationship: Code N (No Commercial Relationship) | Caroline Germano: Commercial Relationship: Code N (No Commercial Relationship) | Patrícia Ottaiano: Commercial Relationship: Code N (No Commercial Relationship) | Renato Maccione: Commercial Relationship: Code N (No Commercial Relationship) | Niro Kasahara: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Depression is a serious and often under diagnosed medical condition in older people. Visual impairment increases the risk of depression to almost two-fold and it is prevalent in both glaucoma and age-related macular degeneration (AMD) patients. This topic has not been extensively studied in patients with eye diseases especially in low-middle income countries. The purpose of this cross-sectional, case-control study was to compare depressive symptoms between primary open-angle glaucoma (POAG) and AMD Brazilian patients.

Methods: Patients with AMD, POAG, and normal controls underwent a complete eye examination including measurement of best-corrected visual acuity, biomicroscopy, tonometry, eye fundus evaluation, and all participants answered the Portuguese short version of the Geriatric Depression Scale (GDS-15). This is a 15-item questionnaire with binary answer (yes or no) and a cut-off value of 6/7 has an optimal balance between sensitivity and specificity. The summed score was compared among the three groups with the ANOVA test.

Results: The sample comprised 48 patients with AMD, 56 with POAG, and 53 controls. All groups were matched for age, gender, ethnic distribution, and comorbidities. The mean score for AMD, POAG, and controls were 3.7 ± 2.9 , 4.3 ± 2.8 , and 2.4 ± 1.7 , respectively ($P = 0.006$). More AMD patients (28.5%) presented scores >5 as compared to 25% of POAG patients, and only 3.3% of controls ($P = 0.07$).

Conclusions: AMD and POAG patients are at higher risk for depression. This poses a challenge to Brazilian healthcare authorities and strategies to help patients maintain independence and good quality of life should target depression.

ABSTRACT BODY:

Purpose: MyD88 mediates inflammatory signaling in the retina. MyD88 inhibition delayed rod photoreceptor death in two mouse models of retinal degeneration. In this study, we performed quantitative proteomic analysis using liquid chromatography-tandem mass spectrometry iTRAQ to characterize early protein changes that may contribute to the protective effects of inhibiting MyD88 in rd10 mouse retinas.

Methods: Rd10 mice (male and female, PN day 18) were injected IP with 2 mg/Kg MyD88 inhibitor (neuroprotective dose) or control peptide (n=4 each). Retinas were collected 3 days later, proteins were extracted then trypsin digested, and incubated with 8-PLEX iTRAQ Reagents followed by analysis using Q Exactive mass spectrometer. Proteins were identified and quantified using Proteome Discoverer 2.2 software, bioinformatics enrichment analysis used PANTHER v.15.0 and interaction networks used the STRING database v.11. QPCR was used to confirm gene expression.

Results: A total of 332 proteins were identified with high (FDR<0.01) and medium confidence (FDR<0.05) with >2 unique matching peptides. Forty-two proteins were differentially expressed (fold change >1.2 or <0.83; p<0.05): 20 proteins were upregulated in the MyD88 inhibitor group and 22 were downregulated. The top biological processes were metabolic, developmental and regulation, and the top molecular functions were catalytic activity, binding and structural molecules. The upregulated proteins were enriched in crystallins, unfolded protein binding and structural molecular activity, and decreased proteins were enriched in pyrophosphatase activity, small molecule binding, and peptide biosynthesis. Notably, MyD88 inhibition led to upregulation of 7 stress-response crystallins. STRING analysis on the upregulated proteins showed 3 distinct physical interaction networks (p=1.94e-05): crystallins, cytosolic small ribosome subunit and aminopeptidase activity. Retinal expression of the crystallin genes was confirmed by QPCR.

Conclusions: This study provides a foundation for understanding molecular mechanisms regulating retinal homeostasis in rd10 mice. A novel link was identified between anti-apoptotic crystallins and MyD88 inflammatory pathway inhibition.

ABSTRACT BODY:

Purpose: Galectin-3 is a carbohydrate-binding protein that modulates vascular endothelial growth factor receptor 2 (VEGFR2) signal transduction, but the molecular mechanism of Gal3 in VEGF/VEGFR2 signal transduction has not been fully elucidated. To better define the role of VEGF in Gal3-induced VEGFR2 signaling, we determined whether exogenous Gal3 requires VEGF to activate VEGFR2 signaling and if exogenous VEGF requires any Gal3 to activate VEGFR2.

Methods: To examine the interaction between Gal3 and VEGFR2, Gal3 was conjugated to cyanogen beads and used for immunoprecipitation (IP). VEGFR2 activation was inhibited using the small molecule VEGFR2- selective tyrosine kinase inhibitor, sunitinib malate (10 μ M). Semi-quantitative PCR was used to measure the expression levels of E-selectin and VCAM-1 mRNA, genes that are downstream of VEGFR2. The knockdown of Gal3 was achieved in human retinal microvascular endothelial cells (HRECs) using siGal3, with nontargeting siRNA as a control. HREC surface proteins were labeled with NHS-SS-biotin and isolated using avidin beads. VEGF neutralization was attained with ranibizumab (10 μ g/ml). The ability of exogenous Gal3 (50 μ g/ml) to activate VEGFR2 kinase was measured at 0, 5, 10, 30, and 60 min after addition. Levels of total and phosphorylated VEGFR2 (Y1175), CD31, and tubulin were examined using western blot. HREC migration was determined using a wound-healing assay, in which confluent HRECs were mechanically scratched and cell migration was measured 15 hours after the addition of VEGF (10 ng/ml) or Gal3 (50 μ g/ml).

Results: VEGFR2 was IP-ed with Gal3. Exogenous Gal3 induced an increase in E- selectin (0.99 ± 0.07 vs 15.3 ± 1.2 , $p < 0.004$. N=3) and VCAM-1 (1 ± 0.03 vs 3.4 ± 0.3 , $p < 0.02$. N=3) expression compared to the control. Inhibition of VEGFR2 activation by sunitinib significantly reduced exogenous Gal3-induction of E-selectin (91%, $p < 0.001$. N=3) and VCAM-1 (67%, $p < 0.02$. N=3). Gal3 was knockdown by over 90% (0.064 ± 0.001 vs 1 ± 0.14 , $p < 0.05$. N=3). Loss of endogenous Gal3 did not alter VEGF-induced VEGFR2 internalization or migration in HRECs. Neutralization of VEGF significantly inhibited the migration of exogenous Gal3-induced HREC migration compared to the control (1.17 ± 0.059 vs 0.97 ± 0.066 , $p < 0.05$. N=6).

Conclusions: Any VEGF is necessary for Gal3 induced kinase activation and HREC migration but endogenous Gal3 is not sufficient for VEGF/VEGFR2 signal transduction.

ABSTRACT BODY:

Purpose: To investigate positional changes of the Bruch's membrane opening (BMO) relative to the anterior scleral canal opening (ASCO) during high myopia development in juvenile tree shrews.

Methods: Juvenile tree shrews were randomly assigned to two groups: normal visual experience (n=9) and monocular -10D lens treatment to induce high myopia, where the other eye served as a control (n=12). Lens treatment started at 24 days of visual experience (DVE). Refractive (Nidek ARK-700A, Marco Ophthalmic) and biometric (Lenstar LS-900, Haag-Streit) measurements were obtained daily. Optical coherence tomography (OCT) of optic nerve head (ONH) (Spectralis, Heidelberg Engineering) was performed weekly. BMO and ASCO were manually segmented and analyzed after nonlinear distortion correction (Grytz R, et al. IOVS 2020; 61: ARVO E-Abstract 4778) of each OCT scan.

Results: Offset between ASCO/BMO centroids gradually increased during axial elongation and high myopia development in the lens treated eyes. These positional changes were significantly different from control and normal eyes at 59 DVE (two-sided Wilcoxon rank sum test; $0.05 \pm 1.9\mu\text{m}$, $-0.05 \pm 1.4\mu\text{m}$ and $3.46 \pm 3.5\mu\text{m}$, mean \pm SEM in normal, control and myopic eyes respectively; $p < 0.05$). Largest changes in ASCO/BMO centroid offset occurred in myopic eyes towards the inferior-nasal quadrant with BMO points located outside the ASCO boundary. BMO/ASCO areas and ovality indices were not significantly different among the three groups.

Conclusions: Our results show relative deformations of BMO and ASCO that gradually increase during high myopia development in juvenile tree shrews. These morphological changes during juvenile myopia development may contribute to subsequent ONH remodeling and increased risk of glaucoma later in life.

ABSTRACT BODY:

Purpose: Preclinical testing of biologics is complicated by immunogenicity, which differs from immunogenicity in humans. It is necessary to mitigate immunogenic responses in order to effectively test the pharmacodynamics and pharmacokinetics of novel biologics, especially for repeat administration. The persistent retinal vascular leak (PRVL) rabbit model is a valuable tool for testing intravitreal (IVT) therapies; however, rabbits frequently mount a strong anti-drug antibody (ADA) response. We developed an antigen-independent immune tolerance protocol to 1) reduce ocular inflammation, and 2) reduce systemic production of ADAs while maintaining the model's vascular phenotype.

Methods: DI- α -amino adipic acid was administered IVT in rabbit eyes to induce the PRVL model (Rodrigues et al., 2018, IOVS). Daily administration of methotrexate (MTX; 30mg/kg s.c.; N=10) or PBS (N=10) was initiated 3 days prior to IVT challenge with a biologic and continued for 21 days. Ocular examinations, fundus angiography, and blood collections were conducted from weeks 2 through 12 to evaluate the effect of MTX on systemic ADA levels and incidence of ocular inflammation. Eyes were enucleated and fixed for histopathological assessment.

Results: The MTX dosing regimen was well tolerated. Incidence of moderate-severe ocular inflammation was eliminated in MTX-treated rabbits, which coincided with significantly reduced systemic ADA titer levels compared to PBS-treated controls. Histologic evaluation determined that 4/10 eyes of PBS-treated rabbits showed substantial lymphoplasmacytic infiltrate following IVT administration of the biologic while eyes of MTX-treated rabbits did not.

Conclusions: The reduction of systemic ADAs in the MTX group demonstrates that induction of immune tolerance in the PRVL rabbit model is feasible. A coinciding decrease in incidence of gross ocular inflammation was observed in vivo, and histologic results confirmed that MTX treatment eliminated infiltrate signatures typically associated with activation of adaptive immunity. This immune tolerance protocol can be used in future studies to reduce ocular inflammation, minimize study attrition, and increase confidence in drug exposure levels.

ABSTRACT BODY:

Purpose: This study explores the longitudinal rates of change between peripapillary optical coherence tomography angiography (OCTA) parameters and retinal nerve fiber layer thickness (RNFL) of glaucomatous and non-glaucomatous eyes.

Methods: A retrospective, longitudinal study collected 6x6mm optic disc OCTA scans (Cirrus HD-OCT 5000) of glaucomatous and non-glaucomatous eyes with at least 2 visits between 12 to 24 months apart. Non-glaucomatous eyes included healthy and glaucoma suspects from an academic glaucoma clinic. A commercially provided automatic segmentation software was used to create en face OCTA images of the radial peripapillary capillary (RPC) layer. Images with poor quality, segmentation error or motion artifacts were excluded. Furthermore, subjects with non-glaucomatous optic neuropathy, cystoid macular edema, diabetic retinopathy, and other retinal disease were excluded. Images were quantified using a research-oriented quantification software to measure OCTA parameters: vessel area density (VAD), vessel skeleton density (VSD), and flux; a commercial quantification software measured perfusion density (PD) and flux index (FI). RNFL scans (Cirrus HD-OCT 5000) were also collected. The rates of change of OCTA parameters and RNFL were estimated using multivariable linear mixed-effects models.

Results: RPC OCTA images from 151 eyes of 96 subjects (81 non-glaucomatous eyes and 70 glaucomatous eyes) were included. RNFL OCT scans from 139 eyes of 87 subjects (78 non-glaucomatous and 61 glaucomatous eyes) were included. With a mean follow-up of 16 months, there was significant reduction in all OCTA parameters for both non-glaucomatous and glaucomatous eyes (Table 1) with a trend of faster reduction in the glaucomatous group. In contrast, there was no significant change in RNFL over time for either the non-glaucomatous or glaucomatous eyes.

Conclusions: OCTA images of the RPC layer showed significant annual rates of decrease in vessel parameters in both non-glaucomatous and glaucomatous eyes followed for 12-24 months. In contrast, the rate of change in RNFL thickness of the same eyes within the same time period was not significant. OCTA may have greater clinical utility than RNFL for monitoring progression in eyes at risk for and with glaucoma.

ABSTRACT BODY:

Purpose: To assess tear dynamics in response to air puff deformation with two noncontact tonometers (NCTs).

Methods: The interaction between air puffs from two NCTs and the tear film were characterized using Phantom VEO 340s high-speed camera at a spatial resolution of 20 microns and a frame rate of 1500 fps. Exams were performed on right eyes of 20 healthy human volunteers with no history of dry eye or tear film instability. Each subject was examined before and after administration of one lubricant eye drop to the lower lid. 10 subjects received Ocular Response Analyzer (ORA) first followed by CorVis ST, while the rest received CorVis ST first followed by ORA. High-speed videos were further analyzed using Phantom Camera Control (PCC) software to quantify droplet size, instantaneous droplet velocity, and eyelid motion.

Results: No droplets were detected for first NCT device used (both ORA and CorVis ST). Among the 40 exams with an eye drop administered, two exams resulted in droplets with a predominant forward motion (one from each device), while 11 exams showed droplet formation where the drop had a downward trajectory and did not remain suspended in the air. All droplets were emitted from lashes whether predominantly forward or downward motion. No droplets originated from the corneal surface. The average droplet diameter among all exams with eye drop administration was $502.9 \pm 195.2 \mu\text{m}$ (range 210-970 μm). For the two exams with predominantly forward motion, two in-focus, forward-moving droplets were detected with each exam. Droplet velocities were 0.93 and 0.50 m/s for ORA and 1.72 and 1.32 m/s for CorVis ST exams.

Conclusions: As the air puff arrives at the corneal surface, the tear film is pushed radially away from the apex while remaining attached to the corneal surface (Figure 1). This behavior, explained by the Coanda effect¹, occurs due to the tendency of the tear film to follow the cornea curvature during deformation and results in droplets leaving the eye only at the eyelid boundary which interrupts tear flow. Droplet formation during NCT exams with different air puff strategies occurs only with eye drop administration, consistent with literature reports.

ABSTRACT BODY:

Purpose: Emerging evidence suggests that the COVID-19 pandemic, which has disproportionately affected people of African descent (AD), is disrupting health behaviors such as medication adherence. Studies have not yet assessed, however, whether medication adherence is differentially affected in people of AD, a population shown to have poorer adherence prior to the pandemic. We examined whether racial disparities exist in the impact of the COVID-19 pandemic on medication adherence in people of AD and European descent (ED).

Methods: We used a controlled interrupted time series design in which the interruption was the declaration of the COVID-19 pandemic in the United States on March 13, 2020. The 300-day follow-up period, which bracketed this declaration, started on October 16, 2019 and ended on August 10, 2020. Patients were selected from an ongoing longitudinal NIH-funded study initiated prior to the onset of the pandemic, if they had primary open-angle glaucoma, were prescribed ocular hypotensive medication and had adherence data spanning the 300 days of the study. The primary outcome was daily adherence defined as the number of doses taken divided by the number of doses prescribed, expressed as a percentage. Adherence was measured objectively using Medication Event Monitoring System (MEMS). Segmented regression analysis using the "slope change following a lag" impact model was performed and the Davies test was used to compare the slopes in the periods preceding and following the pandemic.

Results: 72 patients (35 of AD and 37 of ED) were included. Prior to the pandemic, mean adherence was $75 \pm 25\%$ in patients of AD and $91 \pm 15\%$ in people of ED ($p = 0.001$). In patients of AD, the slopes in the periods preceding (0.0% / day) and following (-0.07% / day) the pandemic were significantly different ($p < 0.001$). In patients of ED, the slopes in the periods preceding (0.01% / day) and following (-0.02% / day) the pandemic were similar ($p = 0.05$).

Conclusions: Medication adherence, a health behavior critical in the management of chronic diseases, was adversely affected by the COVID-19 pandemic in patients of African descent with glaucoma. The vulnerabilities exposed by the COVID-19 pandemic should be used to inform the development of interventions that will ensure continued use of medication during crisis periods, particularly in high-risk populations.

TITLE: Visualization of the human retinal pigment epithelial cell mosaic with and without adaptive optics using late phase indocyanine green imaging

SESSION TITLE: Advances in Retinal Imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Li, T. Liu, J. Liu, A.J. Bower, J. Giannini, R. Lu, N. Aguilera, J. Tam, National Eye Institute, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Joanne Li: Commercial Relationship: Code N (No Commercial Relationship) | Tao Liu: Commercial Relationship: Code N (No Commercial Relationship) | Jianfei Liu: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Bower: Commercial Relationship: Code N (No Commercial Relationship) | John Giannini: Commercial Relationship: Code N (No Commercial Relationship) | Rongwen Lu: Commercial Relationship: Code N (No Commercial Relationship) | Nancy Aguilera: Commercial Relationship: Code N (No Commercial Relationship) | Johnny Tam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There are now a number of adaptive optics (AO) based approaches for assessing retinal pigment epithelial (RPE) cells in the living human eye. However, AO instruments are not yet widely accessible. Since the size of RPE cells is near the resolution capabilities of commercial instruments, we explore in this study whether RPE cells labeled using indocyanine green (ICG) can be visualized without AO.

Methods: Following intravenous injection of ICG dye, the RPE cells are labeled and can be imaged in the late phase (IOVS 57(10):4376-4384, 2016). ICG images of the RPE were acquired in 10 eyes from 10 healthy subjects using a custom-built AO instrument (AO-ICG) and a Heidelberg Spectralis with a 30° lens (Spectralis30). For 6 of the eyes, additional ICG images were obtained using a Heidelberg Spectralis outfitted with a high magnification module (HMM) 8° lens. The appearance of RPE cells was validated through direct comparison between images taken with and without AO in matching retinal locations within each eye. Both AO and non-AO images were analyzed using custom software to identify RPE cells from which cell density and spacing values were calculated.

Results: Across all three types of images (AO, Spectralis30, HMM), a heterogeneous pattern corresponding to RPE cells could be observed with sufficient contrast and resolution to identify RPE cells. The patterns observed in non-AO images matched those observed in AO images acquired at identical retinal locations (correlation coefficient: 0.7 ± 0.1). Although AO images had the highest contrast and resolution, followed by HMM, and then Spectralis30, there were no statistically significant differences between RPE cell measurements obtained with and without AO (AO vs. HMM, AO vs. Spectralis30, and HMM vs. Spectralis30; $p > 0.5$ for all comparisons; Kruskal-Wallis with Tukey's honest significance multiple comparison test). Measurements of cell density and spacing, obtained over a range of eccentricities out to 5.5 mm, were consistent with published normative data (BOE 8(10):4348-4360, 2017).

Conclusions: The heterogeneous late phase ICG pattern, which has previously been shown to enable RPE cell measurements from AO images, can also be observed without AO. This technique opens up the possibility of assessing and quantifying the RPE cell mosaic at the cellular level using conventional clinical imaging, even without AO.

ABSTRACT BODY:

Purpose: To determine whether quantifying reflectance intensity in addition to layer thickness improves the ability to discriminate glaucomatous (GL) from healthy control (HC) eyes.

Methods: Posterior pole OCT scans (Spectralis, Heidelberg Engineering GmbH) were obtained in 188 GL and 360 HC eyes (61 B-scans, 768 A-lines each, spanning a 30°× 25° area). GL eyes were defined as having 24-2 visual field (VF) pattern standard deviation or glaucoma hemifield test outside normal limits on 2 consecutive tests. Automated segmentations within each B-scan were manually corrected when necessary. Mean thickness and intensity values for each A-line were measured for nerve fiber layer (NFL), ganglion cell layer (GCL), and inner plexiform layer (IPL). These intensity values were also normalized using the average value of the 7-pixels corresponding to the retinal pigmented epithelial (RPE) layer to generate axially (vertically) normalized (AN) intensity. Values were age-adjusted using the HC eyes. The average thickness, intensity and AN intensity values were calculated and used to create receiver operating characteristic (ROC) curves. Logistic regression models were used to assess whether intensity added additional diagnostic power.

Results: The median VF mean deviation in the GL eyes was -4.37 dB. The highest univariate areas under the ROC curve (AUROC) were for NFL thickness (NFLT: 0.916) and intensity (0.903, Table 1). The AUROC for GCL thickness (GCLT) was significantly smaller (0.882) than for NFLT ($p=0.04$), comparable to NFL intensity ($p=0.24$), but higher than all other parameters (all $p<0.001$). NFL intensity ($p<0.001$), NFLT ($p<0.001$) and GCLT ($p=0.01$) were significant predictors of the probability of having glaucoma. Addition of NFL intensity to thickness significantly improved this prediction ($p<0.001$). A model also including GCLT had higher AUROC (0.958) than any other combination (all $p < 0.02$, Figure 1).

Conclusions: In this group of mostly early GL eyes, the best diagnostic predictors were NFLT, NFL intensity, and GCLT. Current axial normalization of intensity values to RPE reflectance did not enhance diagnostic accuracy. Macular NFL reflectance intensity provides diagnostic information beyond thickness values alone and may have pathophysiological significance.

Bakker: Commercial Relationship(s);Boehringer Ingelheim:Code E (Employment);Boehringer Ingelheim:Code P (Patent)

ABSTRACT BODY:

Purpose: BI-X is an intravitreal anti-semaphorin 3A (Sema3A) agent under investigation in patients with laser-treated proliferative diabetic retinopathy and diabetic macular ischemia. We tested 4 hypotheses: H1) BI-X specifically binds to human Sema3A in an antibody-capture assay; in human retinal microvascular endothelial cell (HRMEC) assays, BI-X H2) prevents Sema3A- but not vascular endothelial growth factor-A (VEGF-A)-induced endothelial cell permeability and H3) prevents Sema3A-induced cytoskeletal collapse; H4) BI-X reduces ischemic avascular area and increases tip cell density in a mouse model of oxygen-induced retinopathy (OIR).

Methods: H1) Recombinant human, cynomolgus, mouse, rat and rabbit Sema3A were injected (40 µL/min for 600 s) over captured BI-X (0.5 µg/mL) and allowed to dissociate for 7200 s. H2) HRMECs were treated with either recombinant VEGF-A (100 ng/mL) or Sema3A (500 ng/mL), with and without BI-X (1 µg/mL) or anti-TNP (1 µg/mL) overnight. Permeability was determined based on the passage of FITC-coupled dextran through the endothelial cell layer. H3) Potency was determined with a concentration–response curve of recombinant human Sema3A. Cytoskeletal collapse was measured as reduction of cellular impedance. For specificity determination, HRMECs were stimulated with 0.5 µg/mL recombinant human Sema3A, 3C or 3E or 2 µg/mL recombinant mouse Sema3B or 3F with and without 2 µg/mL BI-X. H4) Newborn mice (n=23) were exposed to a 75% oxygen atmosphere from P7 to P12 and then returned to normoxia. The animals received a single 10 µg intravitreal injection of either BI-X or an IgG control antibody in each eye at P12. Tip cell density and avascular area were determined using retinal flatmounts prepared from eyes enucleated at P17.

Results: H1) BI-X binds to human, cynomolgus, mouse, rat and rabbit Sema3A with a K_D of 29 pM, 28 pM, 27 pM, 27 pM and 42 pM, respectively. H2) BI-X completely prevented the permeability induced by Sema3A, but not VEGF-A. H3) BI-X prevented cytoskeletal collapse induced by Sema3A (potency: 69 pM), but not Sema3B, 3C, 3E or 3F. H4) Tip cell density increased by 33% ($p<0.001$) and avascular area numerically decreased by 12% in BI-X-treated eyes compared with IgG control.

Conclusions: BI-X binds to human Sema3A with pM affinity, and specifically inhibits Sema3A function, preventing cytoskeletal collapse and endothelial cell permeability in vitro. BI-X also improved ischemia in a mouse model of OIR.

TITLE: Immortalized human conjunctival epithelial cells produce functional complement C3 and C4 proteins

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.F. Ziemanski, K.K. Nichols, Department of Optometry and Vision Science, The University of Alabama at Birmingham School of Optometry, Birmingham, Alabama, UNITED STATES|A.J. Szalai, The University of Alabama at Birmingham School of Medicine, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jillian Ziemanski: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Szalai: Commercial Relationship: Code N (No Commercial Relationship) | Kelly Nichols: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The complement cascade, best known for its role in host defense, has been shown to be strongly activated by immune complexes in many autoimmune diseases, suggesting that it may contribute to autoimmune dry eye disease (DED) such as Sjögren's syndrome (SS). The ocular surface is known to have a functional complement system, though the exact site(s) of complement-protein production remain unknown. As part of a larger project interrogating complement's role in SS-DED, we conducted a pilot study to assess whether complement proteins C3 and C4 were produced by immortalized human conjunctival epithelial cells (HCjE).

Methods: HCjE were maintained in a 6-well plate in KSFM + 5 ng/ml EGF + 50 µg/ml BPE for 2-4 days. Cell lysates were prepared, and total protein was quantitated (Pierce BCA kit). Samples of lysate (0.625-40 µg of total protein) were loaded in duplicate into 96-well plates, and the amounts of C3 and C4 were measured by Human Complement C3 and C4 ELISA kits (Abcam). To assess C3 and C4 function, we measured formation of soluble C5b-9 (sC5b-9) from HCjE lysates treated with heat-aggregated IgG, a known activator of the classical pathway of complement (CH50 EIA, Quidel). Briefly, 86 µl of IgG were added to 90 µg of HCjE total protein. The activated sample was diluted 1:2, 1:4, and 1:8 prior to performing an enzyme immunoassay targeting sC5b-9, a marker of the activated complement cascade.

Results: Across all HCjE lysates (n=12), the total protein concentration was 982.1 ± 115.19 µg/ml (mean \pm SD). Both C3 and C4 were detected in lysates with C3 being expressed at concentrations approximately 22-fold higher than C4. C3 was quantified at 0.152 ± 0.101 ng/µg of total protein and C4 at 0.007 ± 0.005 ng/µg of total protein. Upon activation by IgG, sC5b-9 was detected at dilutions of 1:2 (6.21 ± 1.20 CH50 U Eq/ml) and 1:4 (6.11 ± 0.45 CH50 U Eq/ml) but not at 1:8.

Conclusions: HCjE produce complement C3 and C4, suggesting that these proteins may be produced locally at the ocular surface. Supplementing HCjE lysates with IgG results in formation of sC5b-9, confirming that HCjE-derived C3 and C4 are functional and suggesting that HCjE likely produce all proteins (C1 through C9) required for the formation of sC5b-9 via the classical pathway. Further research is needed to confirm these findings in primary cells and to determine complement's role in SS-DE.

ABSTRACT BODY:

Purpose: Age-related endothelial dysfunction is associated with multiple eye diseases. One potential mechanism is the disturbance of the endoplasmic reticulum environment (ER stress). In healthy cells, ER stress is constantly sensed and mitigated by a sophisticated adaptive mechanism namely the unfolded protein response of the ER (UPR^{ER}). In this study, we characterize the status of ER homeostasis and the UPR^{ER} in aging endothelial cells and elucidate a potential mechanism underlying vascular aging.

Methods: Brain microvascular endothelial cells (BMECs) were isolated from mice at ages of 2-24 months. To induce ER stress, BMECs were treated with either 0.5 μ M of thapsigargin (TG) or 0.5 μ g/ml of tunicamycin (TM) for 6 hours. Expression of UPR^{ER} genes was assessed by quantitative RT-PCR (qRT-PCR).

Results: Cell morphology and cell growth appeared to be similar among BMECs from different-age groups. In unstimulated cells, the basal levels of UPR^{ER}, indicative by the expression of X-box binding protein 1 (XBP1), activating transcription factor 4 (ATF4), activating transcription factor 6 (ATF6), binding-immunoglobulin protein (BiP, also known as GRP78), and protein disulfide isomerase (PDI), were significantly higher in aging BMECs (20-24 months) compared to the young group (2-4 months). In stress conditions, TG and TM treatment induced a robust increase of the UPR^{ER} in young BMECs, and this response was significantly decreased with age. Specifically, aging significantly reduced the expression of XBP1, ATF4, ATF6, and C/EBP-homologous protein (CHOP). Likewise, the expression levels of ER chaperons and foldases, such as BiP, DNAJC3/p58IPK, and PDI were markedly upregulated by TM and TG treatment in young BMECs, but to a significantly less extent in aging cells. Interestingly, TM, but not TG treatment, significantly upregulated NADPH oxidase 4 (NOX4) expression in young BMECs and the response was blunted in the aging group.

Conclusions: Our results suggest that there is a sustained ER stress in aging endothelial cells that may contribute to the increased endothelial dysfunction, inflammation, and apoptosis in aging vasculature. Moreover, the ability of activation of UPR^{ER} is drastically impaired in endothelial cells with age. The dysfunction of the adaptive response to stress conditions may lead to the accumulation of unfolded/misfolded proteins resulting in chronic ER stress in aging endothelial cells.

ABSTRACT BODY:

Purpose: The elasmobranch little skate (*L. erinacea*) possesses a retina with only one type of photoreceptor, i.e. rods. A simplex retina like this allows for unique opportunities to study the vertebrate visual system. Unlike genetically modified rod-only models, this pure-rod retina has evolved naturally to the present state. Thus, we can study and describe the properties of rod circuitry within the context of a functional, evolutionarily optimized visual system, where all downstream components co-evolved to process signal from a single type of cell. Little is known about the wiring and synaptic architecture in the OPL of a pure-rod retina, where the first steps in visual information processing take place.

Methods: Eyes from little skate were hemisected and choroid-attached pieces of retina from the tapetal area were obtained. Retinal pieces were embedded in resin blocks and SB-3DEM was performed. The dataset analyzed here was from a region of interest in the OPL of the skate retina; width/height = 27.6µm, section thickness = 0.070µm, depth = 21.5µm. Voxel size was 4.5nmX4.5nmX70nm. 3D reconstructions and measurements of rod terminals with all invaginating and basal processes were done with Reconstruct and Amira software.

Results: There was great diversity in the types and # of invaginating and basal processes making contact with rods. ~12 anatomically distinct invaginating processes can be traced to one, or several different synaptic ribbons. These are presumed to belong to ON bipolar and horizontal cells. The full identity of each unique invaginating process could not be determined from this limited dataset. An additional ~3-4 processes made basal contacts outside of the invagination and are presumed to belong to OFF bipolar cells. The skate rod does not have an axonated terminal and ~4-6 filopodia of variable length can be traced to either neighboring rods, or yet unidentified cellular processes.

Conclusions: Skate rod terminal morphology suggests a hybrid rod-cone anatomy. The number of invaginating processes exceeds > 3-fold the usual number of four invaginating processes into a typical vertebrate mammalian rod. The multiple invaginating processes contacting skate rods are somewhat similar to the anatomical features typically observed in cone terminals.

Commercial Relationships Disclosure (Abstract): Marcus Mazzaferri: Commercial Relationship: Code N (No Commercial Relationship) | Sara Patterson: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Bordt: Commercial Relationship: Code N (No Commercial Relationship) | James Kuchenbecker: Commercial Relationship: Code N (No Commercial Relationship) | Dragos Rezeanu: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Barborek: Commercial Relationship: Code N (No Commercial Relationship) | Christian Puller: Commercial Relationship: Code N (No Commercial Relationship) | Maureen Neitz: Commercial Relationship: Code N (No Commercial Relationship) | Jay Neitz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human vision served by the midget system evolved to deduce the reflectance properties of objects. To do this, the visual system separates information about reflectance from information about the properties of the illuminant. Some of this information is available at the edges of objects because illumination changes occur gradually across a scene while reflectance changes rapidly at the edges. Images processed through the primate midget system extract this reflectance information by being filtered through stages such that the color appearance of objects is determined solely by the contrast at their edges (Fig 1A). A first stage of this filtering process takes place in the outer retina by lateral inhibition from horizontal cells. We sought to characterize the circuitry of the inner retina specific to the midget system that might provide an additional stage of filtering.

Methods: We used serial block-face scanning electron microscopy in the macaque central retina (Patterson et al., 2019, Sci Rep) to reconstruct neurons in the inner retina that receive synaptic input from midget ON bipolar cells.

Results: We reconstructed a type of wide-field amacrine cell (n=2 for synaptic analysis, n=3 for morphology) that receives 97% of its input from and provides 98% of its output as reciprocal inhibitory feedback onto midget ON bipolar cells. Based on their stratification (78% IPL depth), the characteristic morphology of their dendritic trees and their dendritic varicosities, these were identified as ON stellate varicose cells. The dendritic trees of reconstructed cells overlapped extensively, forming dense coverage of the midget ON bipolar cell terminals (Fig 1B). We reconstructed 99 presynaptic midget ON bipolar cells and found that each made on average 2.3 ribbon synapses onto and received 1.5 reciprocal feedback synapses from an ON stellate varicose cell.

Conclusions: A dense network of ON stellate varicose amacrine cells specific to midget bipolar cells could provide a second layer of inhibition in the inner retina. By virtue of the delay of the inhibition from an additional synapse, the interaction between bipolar cell terminals and amacrine cells could act as a temporal filter contributing to the removal of signals other than those produced by contrast edges in a scene.

TITLE: Patient preference regarding laser photocoagulation or cryoretinopexy for the treatment of retinal pathology

SESSION TITLE: Retinal detachment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Bakhsh, R.A. Shields, M.A. Tahboub, A. Capone, Beaumont Health, Royal Oak, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Saaquib Bakhsh: Commercial Relationship: Code N (No Commercial Relationship) | Ryan Shields: Commercial Relationship: Code N (No Commercial Relationship) | Mohammad Tahboub: Commercial Relationship: Code N (No Commercial Relationship) | Antonio Capone: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To date there has not been a study investigating patient preferences between laser photocoagulation or cryoretinopexy for the treatment of peripheral retinal pathology. We performed a retrospective single-center clinical survey study to assess patient preferences and investigate any underlying associations.

Methods: We performed a single-center, retrospective, twelve-question, patient-preference phone survey study of 100 qualifying patients (Figure 1). Details of the patients' age, gender, pathology location, laterality, laser type, laser spot size, power, number of spots, anesthesia type, number of cryopexy applications, same eye or fellow eye treatment, and time between treatments were also recorded. The primary outcome measure was the patient's preferred treatment with either laser, cryopexy, or no preference.

Results: Patients reported having experienced greater anxiety during the laser procedure (40%) (Figure 2A). 46% of patients reported experiencing more pain after treatment with cryopexy. Some patients had no pain during or after either procedure (Figure 2B). The incidence of adverse reactions after the procedure was higher for cryopexy. Slightly more patients (40%) perceived the laser to take longer than cryopexy (31%). The majority felt that it was easier to recover from laser (53%).

Patients who had undergone subconjunctival lidocaine for laser were more likely to prefer cryopexy ($p = 0.012$). There was a negative association between a patient's likelihood of preferring cryopexy and the number of applications ($p = 0.009$). Overall, 60% preferred laser, 25% preferred cryopexy, and 15% expressed no preference.

Conclusions: In conclusion, among patients who received both laser and cryopexy for the treatment of peripheral retinal pathology, the perception was that laser took longer than cryopexy but was easier to recover from. Overall, most patients (60%) preferred laser to cryopexy (25%). Subconjunctival anesthesia was less preferred to topical anesthesia for laser procedures. If cryopexy is to be performed, minimizing the number of freezes may improve the patient experience and recovery.

ABSTRACT BODY:

Purpose: The iOptik®/eMacula® uses spectacle-mounted micro-displays and specialty contact lenses to provide magnification and image modification, and may be useful for a range of tasks including reading, smart phone use and distance vision enhancement for the visually impaired. The purpose of this study was to evaluate this system's usefulness for near and distance visual tasks in people with low vision, as well as to assess users' opinions of it.

Methods: The system consists of a combination of two small micro-displays mounted for each eye in spectacle eyewear, a camera, and silicone elastomer contact lenses focused on a polarized display in the spectacle plane. The displays were connected to a computer which controlled the images on the screen. Visual acuity, contrast sensitivity, and reading testing were completed with habitual correction and low vision devices as well as with the iOptik/eMacula system, and a structured interview on device characteristics was completed following testing. Paired t-tests were used to compare vision and reading measurements between habitual correction and the iOptik/eMacula system.

Results: Nine participants with low vision were recruited from the low vision service at OSU. Mean±SD age was 53±17 and 77% were male. Mean better-eye baseline ETDRS VA with habitual correction was 50±7 (approximately 20/100), and mean contrast sensitivity was 1.56±0.20. Mean better-eye VA with the system was 86±5 (approximately 20/20), which was a significant improvement from habitual correction ($p<0.001$). Mean CS with the system was 1.60±.20, which was not significantly different from contrast sensitivity with habitual correction (1.56 ± 0.20 , $p=0.662$). All subjects were able to read 1M print with the system, and reading speeds were not significantly reduced compared to their habitual magnifiers ($p=0.436$). Subjects rated the comfort of the lens on each eye on a scale 1= poor and 10= excellent. The mean comfort score was 7.1 + 1.6. Three quarters of subjects responding felt the device would likely improve performance on tasks of daily living and increase independence.

Conclusions: An updated test version of the iOptik/eMacula system showed promise as an aid for distance and near tasks in people with low vision, and a majority of subjects thought the device would help with daily activities. Visual clarity and contrast sensitivity were improved from previous test versions.

ABSTRACT BODY:

Purpose: Photoreceptors rely on distinct lipid domains to maintain their specialized features. Unlike protein localization, identification of critical differences in membrane content has not yet been expanded to lipids, due to the difficulty of isolating hyper-localized samples. We have overcome this by using styrene maleic acid (SMA) to co-immunopurify membrane proteins and their native lipids from two regions of rod outer segment (ROS) disks.

Methods: We developed a novel antibody against ABCA4 and nanobody against peripherin2/rod outer segment membrane protein 1 complex (per/ROM) to increase native tissue immunopurification efficiency. Isolated ABCA4, per/ROM and rhodopsin samples copurified with lipids and were extracted and subjected to untargeted lipidomic and fatty acid analysis. Relative abundance of lipid species was used to compare the environments of each protein sample. Principle component analysis (PCA) was used to group the samples by aggregate lipid profile and identify similar regions within the bilayer.

Results: Extensive differences between center (rhodopsin) and rim (ABCA4 and per/ROM) samples included a lower PC to PE ratio and increased LC- and VLC-PUFAs in the center relative to the rim region, which were enriched in shorter, saturated FAs. The comparatively few differences between the two rim samples likely reflect specific protein-lipid interactions. The rim region proteins grouped together in our PCA, separating from the rhodopsin samples.

Conclusions: The results of our PCA and more detailed analysis confirm that many of the diverse components found in this study are spread anisometrically across the continuous ROS disk membrane, favoring the center or rim region. Some of this systematic inhomogeneity is likely critical to the maintenance of healthy phototransduction and should be probed more deeply. Our high-resolution profiling of the ROS disk lipid composition provides a model for future studies of other complex cellular structures, enabling the explication of asymmetric lipid class distribution in continuous membranes.

TITLE: Chemokine CCL5 promotes robust optic nerve regeneration and mediates many of the effects of CNTF gene therapy

SESSION TITLE: Neurodegeneration and neuroprotection

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Xie, Y. Yin, L. Benowitz, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lili Xie: Commercial Relationship: Code N (No Commercial Relationship) | Yuqin Yin: Commercial Relationship: Code N (No Commercial Relationship) | Larry Benowitz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ciliary neurotrophic factor (CNTF) is a therapeutic candidate for several ocular diseases and has been widely employed in studies of optic nerve regeneration. However, whereas recombinant CNTF (rCNTF) generally induces only low levels of optic nerve regeneration (unless SOCS3, suppressor of cytokine signaling-3) is deleted in retinal ganglion cells (RGCs), AAV-mediated CNTF expression in RGCs induces strong regeneration. Intravitreal virus injections induce moderate intraocular inflammation, and CNTF is a known immune modulator. We therefore tested whether the beneficial effects of AAV-mediated CNTF delivery are due to intraocular inflammation and elevation of pro-regenerative and neuroprotective factors.

Methods: rCNTF, AAV2-CNTF, AAV2-sh-CNTFR (targeting CNTFRa, the CNTF receptor) or control agents were injected intravitreally. Intravenous anti-Ly6G antibody (vs. isotype-matched IgG2a) was used to deplete neutrophils. C-C motif chemokine receptor 2 (CCR2) knockout mice were used to inhibit monocyte infiltration. Immunohistochemistry was used to identify various inflammatory cell types, inflammation-related growth factors (C-C motif chemokine ligand 5, CCL5, etc.) and relevant receptors. RT-PCR was used to quantify mRNA levels of these and other gene products. We also tested CCR5 general knockout, a receptor antagonist, and RGC-specific CCR5 knockdown.

Results: Whereas intravitreal rCNTF induced little axon regeneration, AAV2-CNTF had strong effects on RGC survival and axon regeneration. CNTFRa was expressed primarily in non-neuronal cells, and CNTFRa knockdown in RGCs did not alter AAV2-CNTF-induced regeneration. AAV2-CNTF attracted inflammatory cells, particularly in the optic nerve head, and increased mRNA levels for CCL5 9.5-fold. Either neutrophil depletion or blocking monocyte infiltration dramatically decreased AAV2-CNTF-induced RGC survival and axon regeneration. Administration of a CCR5 antagonist or RGC-specific CCR5 knockdown both reduced axon regeneration ~ 70%. In gain-of-function studies, intraocular rCCL5 stimulated considerable optic nerve regeneration in vivo

Conclusions: The beneficial effects of CNTF gene therapy after optic nerve injury are mediated through immune modulation and upregulation of CCL5. Our results also raise the possibility that other widely used gene therapies could act in an indirect manner via unanticipated indirect mechanisms

ABSTRACT BODY:

Purpose: Deep learning (DL) is a class of machine learning that utilizes neural networks to generate representations that allow for distinguishing categories of interest. Being an unsupervised feature generation method, large training sets are typically needed to learn appropriate representations to discriminate the categories of interest. While DL has been extensively explored in ophthalmology for diagnostic applications, it has not been extensively evaluated for predicting need for future treatment, arguably a more challenging problem compared to disease diagnosis and one where large imaging datasets with accompanying treatment response and outcome information may not be available. The purpose of this study was to investigate the ability of DL to predict need for anti-VEGF from ultra-widefield angiograms (UWFA) in eyes with diabetic retinopathy (DR).

Methods: A retrospective image analysis study was conducted on eyes with DR that had UWFA imaging. DL was applied to the late phase UWFA images to classify eyes as needing anti-VEGF or not. In order to evaluate the impact of sample size on DL performance, the study set was sampled into five subsets of increasing size. For each subset experiment, a class activation map (CAM) was generated per sample to identify regions of interest (ROI) that the DL model places attention on, when making its predictions.

Results: Two-hundred seventeen eyes from 189 patients were included. 141 eyes required anti-VEGF treatment. Five subsets with balanced class distributions were generated from this dataset. Subsets increase by a factor of 28 in size from 28 to 140 eyes. The 3-fold cross-validated AUROC indicates minimal correlation between dataset size and model performance. The best performing model had an average AUROC of 0.628 ± 0.087 over the subsets. Resulting CAMs frequently demonstrated inconsistent identified ROI across subsets suggesting that DL tended to be sensitive to the choice of training cases across every fold.

Conclusions: In this study, regardless of sample size, DL was unable to consistently identify image representations from limited UWFA samples to predict need for anti-VEGF therapy. These findings suggest that other handcrafted radiomic approaches, multi-modal DL, and integration of multiple features might need to be considered for predicting need for treatment.

ABSTRACT BODY:

Purpose: Matrix metalloproteinases (MMPs) are involved in the inflammatory retinal degeneration and pathology of retinitis pigmentosa (RP). In rodent models, intravitreal injections with recombinant tissue inhibitor of MMP (TIMP)-1 reduces the progression of rod cell death, modifies cone cell distribution with Müller glial (MG) gliosis. To gain insights into the TIMP-1 cellular mechanisms, MMP-9 and TIMP-1 expression patterns in MG cells were investigated in vitro under proinflammatory or oxidative conditions.

Methods: Human MG cell line (MIO-M1 cells) were treated for 24 h with either IL-1 β (10ng/mL), TNF- α (10ng/mL), or H₂O₂ (0 μ M-600 μ M) to observe their effect on MMP-9 and TIMP-1 expression including viability, growth, secretion and subcellular compartmentalization. MTT and SRB assays measured cell viability; gelatin zymography, MMP-9 secretion; ELISA assays, TIMP-1; fluorescent immunocytochemistry, intracellular protein expression. Each treatment parameter was evaluated and compared with untreated controls.

Results: Viable cell densities are mildly increased by cytokines, particularly, by IL-1 β (20-30%, p<0.01). MMP-9 secretion is also increased by IL-1 β (200%, p>0.05) or TNF- α (300%, p<0.05); however, TIMP-1 secretion is decreased by IL-1 β (32%, p>0.05) or increased by TNF- α (24%, p>0.05). H₂O₂ treatments have minimal effect on cell viability or secretion of either protein. MMP-9 and TIMP-1 are both expressed, not only in the cytoplasm, but also inside the nucleus: the former is diffusely detected, but the latter, in speckles. Intracellular TIMP-1 aggregation is detected in the cytoplasmic area upon IL-1 β treatment. With H₂O₂ treatments, the cell morphology changes from cobble to spindle shapes, and the nuclei become enlarged, compared with untreated control, dose-dependently, [5% at 100 μ M (p>0.05), 35% at 300 μ M (p<0.001), and 62% at 600 μ M (p<0.0001)], with the nuclear TIMP-1 speckle numbers increasing concomitantly. H₂O₂ treatment does not alter the MMP-9 intracellular distribution pattern.

Conclusions: Cytokines alter disproportionately MMP-9 and TIMP-1 secretions. Intracellular and nuclear TIMP-1 is dynamically modulated in response to proinflammatory and oxidative insults in MG cells, implicating unrecognized functional roles in MGs in the retina.

ABSTRACT BODY:

Purpose: To investigate the diagnostic accuracy of deep learning (DL) algorithms to detect primary open angle glaucoma (POAG) trained on fundus photographs from the Ocular Hypertension Treatment Study (OHTS).

Methods: 74,678 photographs from 3,272 eyes of 1,636 OHTS participants with a mean follow-up (range) of 10.7 (0.0, 14.3) years were used to train a ResNet-50 deep learning model to detect the OHTS I and II Endpoint Committee POAG determination based on optic disc (n=287 eyes, 3,502 photographs) and /or visual field (n=198 eyes, 2,300 visual fields) changes. OHTS training, validation and testing sets were randomly determined using an 85-5-10 percentage split by subject. Three independent test sets (1: UCSD Diagnostic Innovations in Glaucoma Study (DIGS), 2: ACRIMA (Spain) and 3: Large-scale Attention-based Glaucoma (LAG, China) were used to estimate the generalizability of the model. Areas under the receiver operating characteristic curve (AUROC) and sensitivities at fixed specificities were used to compare model performance. Evaluation of false positive rates at a fixed specificity of 90% was used to determine whether the DL model detected glaucoma before the Endpoint Committee determination.

Results: For the OHTS test set, the DL model achieved an AUROC (95% CI) of 0.87 (0.80, 0.91) for the overall OHTS POAG endpoint. For the OHTS endpoints based on optic disc changes or visual field changes, AUROCs were 0.90 (0.87, 0.93) and 0.87 (0.80, 0.91), respectively. False positive rates (at 90% specificity) were higher in earlier photographs of hypertensive eyes that later developed POAG by disc or visual field (19.1%), compared to hypertensive eyes that did not develop POAG (7.3%) during their OHTS follow-up. The diagnostic accuracy of the DL model developed based on the OHTS optic disc endpoint on the 3 independent datasets was lower with AUROC for DIGS of 0.74 (0.69, 0.79), ACRIMA of 0.74 (0.70, 0.77) and LAG of 0.79 (0.78, 0.81).

Conclusions: The high diagnostic accuracy of the current DL model suggests that DL can be used to automate the determination of POAG for clinical trials and management. In addition, the higher false positive rate in early photographs of eyes that later developed POAG suggests that DL models detected POAG in some eyes earlier than the OHTS POAG Endpoint Committee.

ABSTRACT BODY:

Purpose: Photoreceptor loss is the final endpoint in nonexudative Age-Related Macular Degeneration (dry-AMD) and no curative treatments are available. Targeted optogene delivery to higher order neurons of retina in geographic atrophy (GA) regions in these patients is a promising approach to improve vision. Here, we report development of an optical coherence tomography (OCT) guided near-infrared laser irradiation platform combined with Surface Plasmon Resonance (SPR) of nanoparticles to deliver ambient-light activatable multi-characteristic opsin II (MCOII) plasmids into human cells and degenerated mouse retina (rd1) in a specially targeted manner. The method is based on nano-enhancement of near-infrared optical field by of bound to specific cells.

Methods: After pretreatment with functionalized gold nanorods (fGNRs) for 2 hrs, OCT guided laser (980 nm) delivery of MCOII-mCherry plasmids was performed in HEK cells to determine optimal laser parameter and plasmid concentration. Reporter expression was assessed after 48 hrs of laser delivery using confocal fluorescence microscopy. MTT assay was performed to check cytotoxicity after laser gene delivery in HEK cells. For in vivo OCT - guided laser gene delivery, 8-12 week-old rd1 mice were intravitreally injected with a 2µl mixture of fGNR (0.2 µg/µl) and MCOII plasmids (0.5 µg/µl) into each eye. 3-4 hrs post injection, laser delivery was performed in one eye and the contralateral eye was used as a control. The laser beam power, outside eye, was kept at 20 mW for targeted gene delivery. First, real time OCT imaging was used to locate optic nerve, and ~0.7 mm x 0.7 mm rectangular region was irradiated with the scanning laser beam for 400 secs. After 4 weeks of gene delivery, eyes were enucleated, retinal flat mount was prepared and immunostained with anti-mCherry and RBPMS antibody.

Results: MCOII-mCherry expression in HEK cells was found to vary based on laser beam power. MCOII delivery using optimal laser power (determined in HEK cells) led to mCherry expression in the RGC cells of rd1 mice. MTT assay and OCT measurement after laser delivery indicated minimal cytotoxic effects. Non-targeted regions did not show mCherry expression in either HEK cells or rd1 retina.

Conclusions: OCT guided laser delivery is an efficient and targeted method to deliver therapeutic genes into degenerated retina.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is the major risk factor and treatment target of primary open-angle glaucoma (POAG). Exogenous nitric oxide (NO) increases outflow facility and lowers IOP. Since endogenous NO production is limited in part by altered activation of arginase with aging, we aimed to investigate the expression of arginases (Arg1 & Arg2) in the conventional outflow tissues and their potential role in IOP regulation over time.

Methods: Remnant human corneal rims after transplantation were fixed and embedded in paraffin for histological sections. Outflow tissues were incubated with antibodies against ARG1 or ARG2 followed by the secondary antibody for immunofluorescence-based protein expression analysis. The expression of ARG1 and ARG2 was also examined in primary human trabecular meshwork (TM) cells with or without cyclic stretch for 24 hours (n=5) using droplet digital PCR. IOP in three groups of littermate mice, wild type (C57BL6, n=40), Arg1^{+/-} (n=34), and Arg2^{-/-} (n=134) was measured using rebound tonometry once per week in both eyes from 24 weeks to death (up to 108 weeks). The IOPs of age-matched mice were compared using student t-test with a significance threshold of p<0.05. The images of anterior chamber and the iridocorneal angle were taken in mice older than one year using a Leica Envision SD-OCT R2200 system.

Results: ARG1 and ARG2 proteins are expressed in human conventional outflow tissues. In TM cells, the expression of ARG1/ARG2 did not change significantly in response to the mechanical stretch. In mice, the mean weekly IOP measurements were comparable among three groups until 45 weeks of age. While IOP levels of wild type mice progressively decreased from 13 mmHg to 12 mmHg at 50 weeks, and to 11 mmHg after 95 weeks, IOP of Arg1^{+/-} and Arg2^{-/-} mice was stable at 13 mmHg until up to 108 weeks. An open iridocorneal angle was confirmed in the old mice of all genotypes using SD-OCT imaging and histological morphological analysis.

Conclusions: ARG1 and ARG2 are expressed in the outflow tissues and cells. Partial loss of Arg1 or complete loss of Arg2 in mice abolished the age-related IOP decrease in aged wild type mice, suggesting their role in age-related IOP homeostasis.

ABSTRACT BODY:

Purpose: The protective effects of breastfeeding on various childhood malignancies have been established, but an association has not yet been determined for retinoblastoma (RB). We aimed to further investigate the role of breastfeeding in the development or severity of non-hereditary RB, specifically assessing its relationship to (1) age at presentation (2) ocular prognosis, and (3) extraocular involvement. We also assessed the role of socio-economic status (SES) in these outcomes.

Methods: A subgroup analysis was performed on a global dataset of 651 patients who received RB treatment and answered a neonatal questionnaire. 532 patients reported "breastfed" or "formula fed" feeding history and were included in the analyses. Patients noted to have a family history of RB (n=25) or sporadic bilateral RB (n=218) were excluded. Multiple regression was used to examine the predictive nature of breastfeeding status on age at presentation. Logistic regression was used to examine effects on enucleation status and lymph node involvement. Ordered logistic regression was used to examine the effects of breastfeeding on International Intraocular Retinoblastoma Classification System (IIRC) group, International Retinoblastoma Staging System (IRSS) stage, and distant metastases. Each model controlled for age, sex, SES and immunizations.

Results: Neither breastfeeding nor formula feeding was associated with differences in age (B = 0.66, 95% CI = -4.96, 6.27) or IIRC group (OR = 0.83, 95% CI = 0.41, 1.68) at presentation. In terms of clinical outcomes, neither breastfeeding nor formula feeding was associated with differences in enucleation (OR = 1.54, 95% CI = 0.80, 3.00), IRSS stage (OR = 1.37, 95% CI = 0.72, 2.60), lymph node involvement (OR = 0.51, 95% CI = .04, 6.73), or distant metastases (OR = 3.20, 95% CI = .40, 25.51). Consistent with previous studies, patients were significantly more likely to be diagnosed at a younger age if they reported higher SES (B=-5.62, 95%CI=-8.22, -3.01). Patients treated in high-income countries were more likely to present with a lower IRSS stage (OR = 9.67, 95% CI= 2.48, 37.69) and were less likely to necessitate enucleation (OR = 0.24, 95% CI= 0.06, 0.96).

Conclusions: This study suggests that breastfeeding neither impacts the sporadic development nor the severity of non-hereditary RB. As expected, children from higher SES countries have lower IRSS stage at presentation and lower overall risk of enucleation.

ABSTRACT BODY:

Purpose: Age related macular degeneration (AMD) is a multifactorial disease leading to loss of central vision; even though its complete pathogenesis is still unclear aging, genetics and smoking are the most important risk factors. Local hemodynamics may play a crucial role in the manifestation and progression of AMD pathologies.

Methods: A total of 179 eyes were recruited to this study, 149 eyes with intermediate AMD and 30 healthy controls. A total of 127 eyes were eligible for image binarization and included in the final analysis: Group 1: AMD eyes n=102 (80%) and Group 2: healthy controls n=25 (20%). 50 eyes presented soft or cuticular drusen (Group 1A), 35 eyes reticular pseudodrusen (Group 1B) and 17 eyes both types of drusens (Group 1C). Mean age in years in study sample was 77.9 ± 8.8 and the majority of the participants were women (70%).

Choroid and retinal vascular quantitative parameters were evaluated in an intermediate AMD population and compared with a control group. Spectral domain optic coherence tomography (SD-OCT) with enhanced depth imaging (EDI) and optic coherence tomography angiography (OCT-A), were acquired using OCT SPECTRALIS (Heidelberg Engineering, Heidelberg, Germany). Image binarization was used to obtain quantitative data of choroid and retinal capillary plexus evaluation.

Results: Considering choroid vascular parameters after binarization we found that Total subfoveal Choroidal Area (TCA) in Group 1 was $0.22 \pm 0.066 \text{ mm}^2$ and $0.29 \pm 0.083 \text{ mm}^2$ in Group 2. Luminal Area (LA) was also reduced in Group 1 ($0.1552 \pm 0.043 \text{ mm}^2$) compared with Group 2 ($0.203 \pm 0.053 \text{ mm}^2$) and those differences were statistically significant ($p < 0.05$). Regarding retinal capillary perfusion there was a trend to reduced vascular parameters in Group 1A in both superficial capillary plexus (LA: $9.44 \pm 1.1 \text{ mm}^2$) and in deep capillary plexus (LA: $9.80 \pm 0.89 \text{ mm}^2$) compared with Group 1B (LA: $10.13 \pm 1.3 \text{ mm}^2$ and $10.29 \pm 1.1 \text{ mm}^2$, respectively).

Conclusions: Our study corroborates that the chorioretinal vascular network are impaired in intermediate AMD patients. Retinal and choroidal vascular parameters could be attractive new prognostic markers for intermediate AMD. Future therapeutic approaches may target this vascular dysfunction and prevent disease progression in early and intermediate stages.

TITLE: Effects of Image Quality on Grading Photographs of Trachoma

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Odonkor, F. Naufal, B. Munoz, S.K. West, Dana Center for Preventive Ophthalmology, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michelle Odonkor: Commercial Relationship: Code N (No Commercial Relationship) | Fahd Naufal: Commercial Relationship: Code N (No Commercial Relationship) | Beatriz Munoz: Commercial Relationship: Code N (No Commercial Relationship) | Sheila West: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Trachoma is the leading infectious cause of blindness worldwide. Prevalence can be assessed by field grading or grading photographs. We hypothesize that poor image quality may contribute to differential grading of trachomatous inflammation—follicular (TF) between field and photo graders.

Methods: Field grades for TF and tarsal conjunctival photographs were obtained by a field grader from one or both eyes in 3118 children from Kongwa District, Tanzania, 2 years post-MDA. 2 additional graders graded and adjudicated each photo. We identified the eyes where the field and photo TF grades did not match and assigned each eye an image quality score and a potential reason for mismatch (e.g., different interpretation of follicle number or size, field documentation error, or no obvious reason). We also assigned image quality scores to a random sample of 180 eyes with matching field and photo TF grades.

Results: 5220 eyes had matching field and photo TF grades while 177 eyes had mismatched field and photo TF grades (Fig 1). There was no difference in image quality between mismatch eyes where the field grader assigned a grade of TF and mismatch eyes where the photo graders assigned a grade of TF ($p=0.6209$), but there was a significant difference in image quality between eyes with matching field and photo grades and eyes with mismatched field and photo grades ($p=0.0186$). However, no image quality issue stood out as significantly different between eyes with matching vs. mismatched TF grades (Fig 2). Disagreement over follicle number (54.8% of mismatch eyes) or size (42.9%) were the most common potential reasons for grade mismatch.

Conclusions: Since there was a significant difference in image quality between eyes with matching vs. mismatched field and adjudicated photo grades, image quality seemed to contribute to grading disagreements between field and photo graders. Poor image quality may alter photo graders' view of the tarsal conjunctiva and affect their determination of follicle size or number. However, as there was no difference in image quality between mismatch eyes with a field vs. photo grade of TF, image quality did not seem to influence the direction of the mismatch (i.e., which graders assigned a grade of TF).

ABSTRACT BODY:

Purpose: Traumatic brain injury(TBI) leads to cognitive, attentional and sensorimotor disturbances. Antisaccades and memory-guided saccades have been used to investigate inhibitory control and working memory respectively. However, no study has compared the extent of deficits across these tasks in TBI. In this study, we investigated the responses of delayed antisaccades and memory-guided pro- and antisaccades by systematically varying the delay in individuals with TBI and compared the performance across tasks.

Methods: Twenty-six subjects((mean age=22.4yr±6.6),12 males) with TBI participated. Subjects fixated on a central target and made either1)an antisaccade in response to a peripheral visible target for a delayed antisaccade task, 2)a prosaccade towards or 3)an antisaccade away from the remembered target cued for a memory-guided task. Saccades were made after a variable delay of 0,0.125,0.250,0.500 and 1s indicated by a visual cue. Saccadic latency, disinhibition errors (premature incorrect/correct saccades made before the cue) and directional errors(incorrect saccades made after the cue) were determined.

Results: A 5(delays)x3(tasks) repeated measures ANOVA with delays as within subject and tasks as between subject variables was conducted for latency, disinhibition and directional errors. There was a significant interaction effect between delays and tasks for latency ($F(8,281)=2.341$, $p=0.02$), directionally-correct ($F(6,204)=3.78$, $p=0.001$) and incorrect disinhibition errors ($F(6,244)=7.12$, $p<0.0001$) but not for directional errors ($p=0.62$). However, for directional errors, there was a significant main effect both for delay ($F(3.820,259.8)=15.08$, $p<0.0001$) and tasks ($F(2,75)=7.01$, $p=0.002$). The delayed antisaccade task demonstrated prolonged latency, increased directionally incorrect disinhibition and directional errors compared to memory-guided tasks while the memory-guided prosaccade task showed increased directionally correct disinhibition errors compared to antisaccade tasks.

Conclusions: Participants with TBI took longer time to generate delayed antisaccades and could not inhibit prosaccade responses towards the target during and after delay. For the memory-guided prosaccade task, the TBI participants could not inhibit premature prosaccades with longer delays. These deficits in voluntary saccades suggest impaired cognitive functions specific to response inhibitory control and impulsivity in TBI.

ABSTRACT BODY:

Purpose: To evaluate the ability of additional central testing locations to improve detection of macular visual field defects in glaucoma.

Methods: 440 healthy people and 499 patients with Glaucomatous Optic Neuropathy (GON) from seven different clinical settings were tested with a fundus tracked perimeter (CMP, CenterVue, Italy) using a 24-2 grid with 12 additional macular locations (24-2+, Figure 1). GON was identified based on expert evaluation of optic nerve head photographs and optical coherence tomography scans, independently of the visual field (VF). We identified macular defects using locations with measurements outside the 5% and 2% normative limits on Total Deviation (TD) and Pattern Deviation (PD) maps within the VF central 10 degrees. Detection was based on the total amount of affected macular locations (overall detection) or on the largest number of affected macular points connected in a contiguous cluster (cluster detection). Number of locations and the cluster size to identify significant defects were used to obtain equivalent specificity between the 24-2 and the 24-2+, calculated using false detections in the healthy cohort. P-values for detection improvement were calculated via bootstrap and considered significant at $p < 0.05$.

Results: At matched specificity, the cluster detection identified significantly more macular defects with the 24-2+ compared to the 24-2 with all considered maps ($p < 0.001$). The increase in percentage of detection was 8% and 10% for TD-5% and PD-5% maps, respectively, and 5% and 6% for the TD-2% and PD-2% maps. For the overall detection, an improvement was only observed for the TD-2% and PD-2% maps (9% increase, $p < 0.001$). There was good but not perfect agreement between the two grids (Venn diagrams in Figure 2). The percentage of detected macular defects ranged from 30% to 50%, depending on the map and detection method used.

Conclusions: Additional macular locations can improve detection of macular defects without loss of specificity.

ABSTRACT BODY:

Purpose: Mesenchymal stem/stromal cells (MSC) are well known for immunomodulation; however, the mechanisms involved in their benefits in the ischemic retina are unknown. In this study, we tested the hypothesis that MSC via upregulation of transcription factor forkhead box P3 (Foxp3) in T cells elicit immune modulation and thus protect against ischemic retinal damage

Methods: MSCs were generated from urine epithelial cells derived induced pluripotent stem cells (iPSC) through non-insertional reprogramming (iMSCs). Mitochondria transfer from MSC to immune cells was assessed by confocal microscopy, and oxygen consumption rates (OCR) were measured using Seahorse Flux Bioanalyzer. Activated splenocytes co-cultured with iMSC in differentiation medium were assessed with anti-Foxp3 antibody and analyzed by flow cytometry. Unilateral retinal ischemia reperfusion (I/R) were done in adult C57BL/6 mice by transiently elevating the intraocular pressure for 1 h. Uninjured eyes served as I/R controls. After 1 day of reperfusion, the animals were randomized to receive intravitreal iMSC (1000 cells/1mL) or saline (1mL). After 7 days, the retinal function was assessed by Electroretinogram (ERG). The retinal extracts were processed by qRT-PCR, and the retinal flat mounts were processed by confocal microscopy for Foxp3⁺ cells.

Results: In in-vitro cultures, iMSC transferred mitochondria to immune cells via F-actin nanotubes, significantly increased OCR for basal respiration and ATP production, suppressed effector T cells, and promoted differentiation of CD4⁺CD25⁺ Tregs in co-culture with mouse splenocytes. In in-vivo studies, iMSCs in I/R eye significantly increased Tregs in the retina compared to saline injected I/R eyes (63.4 ± 14.29 v/s 29.99 ± 6.69 cells/mm², p<0.05, anova). Furthermore, iMSC injected I/R eyes had decrease in retinal inflammation (IL1b: 6.09 ± 1.54 v/s 27.08 ± 8.69 fold p<0.01; Ccl2: 3.52 ± 0.96 v/s 13.6 ± 2.7 fold p<0.001,anova) and improved b-wave amplitudes compared to saline injected I/R eyes (at 1cd.s.m² 139 ± 48 v/s 48 ± 10 μ volt, p=0.05, t-test).

Conclusions: Our study demonstrates that iPSC derived MSCs can transfer mitochondria to T cells to enhance differentiation into Foxp3 Tregs. Additionally, our current data demonstrates that MSC can improve the retina's immune function through upregulation of Tregs to decrease inflammation to reduce I/R injury-induced retinal degeneration

TITLE: Evaluation of New Ophthalmology Curriculum for Medical Students

SESSION TITLE: Ophthalmology Training/Careers, Health Economics and Telemedicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Dong, S. Podila, L. Wolfel, G. Acosta, R.N. Mankad, A. Davis, University of New Mexico School of Medicine, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Qi Dong: Commercial Relationship: Code N (No Commercial Relationship) | Sahitya Podila: Commercial Relationship: Code N (No Commercial Relationship) | Logan Wolfel: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Acosta: Commercial Relationship: Code N (No Commercial Relationship) | Rushi Mankad: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Davis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ophthalmology education is underrepresented in many medical school curricula which can lead to decreased physician competency in identifying and treating primary eye diseases. The University of New Mexico (UNM) introduced 6 additional hours of flipped classroom education as part of a new ophthalmology curriculum. We conducted a cross-sectional study to assess the efficacy of the new curriculum.

Methods: All medical students at UNM were invited to take part in the study, but only second-year students received the new curriculum. The study comprised an opinion survey and a 12-question knowledge assessment quiz based on objectives set by the American Academy of Ophthalmology. Mean quiz scores and survey outcomes were calculated for each class and the results were compared using a one-way analysis of variance (ANOVA).

Results: 72 participants completed the survey and 58 completed the quiz. The survey indicated that second-year students felt the most comfortable among all four classes answering ophthalmology questions on the USMLE Step 1 exam. Fifteen (57.7%) second-year participants felt somewhat or very comfortable, compared to just 4 (23.5%) third-year, 1 (6.3%) fourth-year, and 0 (0%) first-year students. Similarly, 23 (88.5%) second-year students felt that ophthalmology training was somewhat or very important. By comparison, only 13 (76.5%) third-year, 7 (53.9%) first-year, and 8 (50.0%) fourth-year students agreed. Additionally, 3 (11.5%) second-year students reported interest in ophthalmology as a specialty, compared to 4 (30.8%) first-year, 0 (0%) third-year, and 1 (6.3%) fourth-year students.

The quiz portion of the study revealed that third and second-year students performed comparably, with average scores of 68.8% (SD 15.8%) and 67.3% (SD 13.0%), respectively. Fourth and first-year students performed worse at 48.7% (SD 21.2%) and 31.8% (SD 17.3%), respectively.

Conclusions: The survey results demonstrate students that underwent the new curriculum felt more confident answering ophthalmology questions and were more likely to consider ophthalmology an important subject. Although the quiz results were comparable between second and third-year students, this may be the result of third-year students performing additional self-education to prepare for the recent USMLE Step 1 exam. Similarly, fourth-year students are farther removed from their Step 1 exam, which may explain the reduced knowledge retention reflected by the quiz.

ABSTRACT BODY:

Purpose: The XEN gel stent was approved for ab-interno implantation and has been used for >10 years. Recently, surgeons worldwide have developed and adapted a novel approach, implanting the gel stent ab externo. This is the first evaluation of real-world data of the gel stent when placed ab externo.

Methods: In this multicenter, retrospective, chart review, consecutive ≥ 18 -year old patients with elevated intraocular pressure (IOP) requiring surgical intervention were included. Patients underwent ab-externo placement of gel stent alone or combined with phacoemulsification, with or without opening of the conjunctiva, ≥ 12 months before study inclusion. Mean IOP and number of topical IOP-lowering medications at baseline and 12 months were recorded, as well as ocular adverse events (AEs). Available preoperative, operative, and postoperative data were collected.

Results: The analysis included 472 eyes from 412 patients; 382 (80.9%) eyes received the gel stent alone. Mean age was 75.1 years (range, 21-98) and 54.7% of patients were female. Month-12 data was available for 193 eyes. Mean (standard deviation [SD]) IOP decreased from a medicated baseline of 20.8 (7.6) mmHg to 14.9 (5.1) mmHg at 12 months, a mean reduction of ~ 6 mmHg ($\sim 28\%$). 181 (93.8%) eyes required topical IOP-lowering medications at baseline vs 110 (57.0%) at 12 months, including 11 and 3 patients who also required oral therapy, respectively. The most frequent AEs were transient, self-resolving hypotony (< 6 mmHg – $n=66$, 22.8%), uncontrolled IOP requiring secondary surgical intervention ($n=39$, 13.5%), bleb leak ($n=37$, 12.8%), implant exposure/extrusion/conjunctival erosion ($n=20$, 6.9%) and choroidal effusion/hemorrhage/mixed effusion hemorrhage ($n=24$, 5.9%).

Conclusions: When placed via the novel ab-externo technique, the gel stent effectively lowered IOP and the IOP-lowering medication count, with a predictable and acceptable safety profile.

ABSTRACT BODY:

Purpose: Early onset macular drusen (EOMD) is a rare inherited retinal degeneration with similar clinical features to AMD. EOMD patients express high penetrance genetic variants in the complement factor H (CFH) gene that affect expression of the truncated isoform, factor H-like protein 1 (FHL-1). FHL-1 is highly localized to Bruch's membrane where it functions as an alternative pathway inhibitor of the complement system. However, little is known about the role of FHL-1 in the retinal pigmented epithelium (RPE). In this study, we generated and characterized EOMD-patient derived iPSC-RPE cells, and hypothesized that reduced FHL-1 expression results in the formation of basal deposits and reprogramming of RPE metabolism.

Methods: PBMCs isolated from EOMD patients were reprogrammed into iPSCs and differentiated into RPE using standard protocols. Sanger sequencing was performed to identify the novel CFH gene mutation. Minigene assays in HEK293T transfected cells were used to evaluate mutant FHL-1 expression. iPSC-RPE cultured on Matrigel-coated filters for 4-weeks were examined for ultrastructural differences using TEM. RPE cells cultured on flat bottom dishes were also harvested for WB, qPCR and immunocytochemistry of RPE markers, and targeted metabolomics was performed using LCMS/GCMS. iPSC-RPE from healthy age-matched donors were used as controls.

Results: EOMD patients expressed a novel c.351-2A>G mutation in the conserved AG dinucleotide at the 3' splice site of exon 4 in the CFH gene, resulting in exon 4 skipping and no expression of mutant FHL-1 protein in the minigene assay. iPSC-RPE generated from EOMD patients heterozygous for the mutation exhibited typical RPE morphology, pigmentation, and RPE marker expression, but had a 50% reduction in FHL-1 secretion. EOMD iPSC RPE cells formed large multilaminar crystalline-like deposits, consistent with the appearance of calcium oxalate. In addition, numerous electron lucent vesicles were noted in the basal deposits, and Oil Red O staining confirmed the presence of basal lipid deposits. Metabolite analysis revealed increased glucose consumption and lipid accumulation in the iPSC-RPE derived from EOMD patients.

Conclusions: EOMD iPSC-RPE have decreased FHL-1 expression, form basal laminar calcium and lipid deposits, and have increased glucose consumption and lipid accumulation, suggesting a crucial role for FHL-1 in the maintenance of RPE homeostasis.

TITLE: Fast subjective estimation of astigmatism with the Direct Subjective Refraction

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Rodríguez-Lopez, E. Esteban-Ibañez, Consejo Superior de Investigaciones Científicas, Madrid, Madrid, SPAIN|C. Dorronsoro, 2EyesVision, SPAIN|

Commercial Relationships Disclosure (Abstract): Victor Rodríguez-Lopez: Commercial Relationship(s);ID 100010434; LCF/BQ/DR19/11740032:Code F (Financial Support);P190451ES:Code P (Patent) | Eduardo Esteban-Ibañez: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Dorronsoro: Commercial Relationship(s);PCT/2014ES/070725:Code P (Patent);P190451ES:Code P (Patent);2EyesVision:Code I (Personal Financial Interest);2EyesVision:Code E (Employment)

ABSTRACT BODY:

Purpose: The subjective estimation of astigmatism, part of the subjective refraction, is a tiresome procedure. Here we extend the Direct Subjective Refraction (DSR), a technology to obtain fast and unsupervised subjective measurements of the refractive error, to estimate astigmatism

Methods: In the DSR method, a temporal defocus wave (TDW; fast and periodic changes in defocus induced by a tunable lens projected onto the eye) interacts with the longitudinal chromatic aberration of the eye. The flicker and color artifacts that appear on a stimulus, are minimum when TDW matches the retinal plane, so the patients can find subjectively their refractive error, unsupervised, with a staircase procedure. The stimulus for astigmatism is a set of magenta, red and blue lines, tested parallel and perpendicular to the axis of astigmatism reported by an autorefractometer (ARK1 Nidek). The TDW was produced by a visual simulator (SimVisGekko 2EyesVision) with frequency 15Hz and amplitude 0.5D. 4 subjects (25-49yo) performed the DSR with free accommodation in both eyes, 4 repetitions, 2 axes. The mean difference between axes provided the amount of astigmatism (J0, J45). DSR was compared with traditional subjective refraction (TSR) performed by an optometrist. Visual function with the DSR and the TSR corrections were evaluated with VisualAcuity (VA), StereoAcuity (SA), and direct comparison of perceived visual quality

Results: DSR was able to measure small astigmatism with high repeatability (SD average across repetitions and subjects ± 0.13 D). Comparing DSR with TSR, M, J0 and J45 components showed high correlation ($p=5e-16$, $5e-12$, $9e-12$; $r=0.98$, 0.98 , 0.94). The mean difference in astigmatism (J0: 0.08 ± 0.11 D, J45: 0.01 ± 0.06 D) and the 95%CI Limits of Agreement (J0: $[-0.14$ to $0.30]$, J45: $[-0.11$ to $0.14]$ D) have subclinical importance. Both final refractions produce similar VA (mean difference -0.1 ± 0.01 logMAR; paired t-test $p=0.35$) and SA ($29 \pm 8''$; $p=0.4$). On average, TSR takes 4.9 ± 1.5 min while each repetition of DSR takes 47 seconds (per eye, including sphere). In direct comparisons, 50% of subjects preferred the final correction with DSR over with TSR

Conclusions: Using temporal defocus waves, DSR is able to measure astigmatism, providing similar values than the TSR, but more repeatable. Each unsupervised DSR measurement (sphere and astigmatism) takes less than one minute, allowing clinicians to spend more time evaluating other visual aspects

ABSTRACT BODY:

Purpose: There are about 20 million ocular adenoviral cases per year in the United States. Epidemic keratoconjunctivitis (EKC) is the most highly contagious and most severe of these. EKC manifests with acute membranous keratoconjunctivitis and delayed-onset of corneal stromal infiltrates. Transcription factors (TFs) are sequence-specific DNA binding proteins. As intracellular parasites, viruses hijack host cellular proteins, including TFs, to control their gene expression and replication. We investigated the role of host TFs in the transcriptional regulation of a major EKC pathogen - human adenovirus species D type 37 (HAdV-D37).

Methods: We first performed in silico TRANSFAC database analysis to identify TF candidates for binding to the HAdV-D37 genome. Next, chromatin immunoprecipitation and high-throughput sequencing (ChIP-Seq) were performed in virus-infected A549 cells, including the TF YY1, previously reported to bind E1A. From the high-throughput sequencing reads (HiSeq 2500 system, illumina), motif analysis was performed, and the specific TF-viral DNA binding sites were validated by electrophoretic mobility shift assays (EMSA). Gene expression was studied in the setting of both TF-siRNA knockdown and overexpression, using RT-qPCR for viral transcripts spanning the whole genome.

Results: In silico analysis showed OCT4 as the TF with greatest binding affinity for the HAdV-D37 genome. By ChIP-Seq analysis, OCT4 and YY1 were shown to directly bind the viral DNA motifs, ATTTGCAT and CGCCATCTT, respectively, present in the non-coding regions of the inverted terminal repeat (ITR) and adjacent to E4 target genes. Both OCT4 and YY1 were shown to repress E3 (immune evasion genes) expression. Additionally, YY1 knockdown upregulated viral early gene expression, including E1B, E2A, and E2B.

Conclusions: OCT4 and YY1 directly bind to HAdV-D37 and downregulate E3 gene expression, potentially modulating host immune responses to infection. Our findings provide novel functions for non-coding viral DNA; in depth understanding of viral gene expression offers a unique perspective to treatment of ocular viral disease.

ABSTRACT BODY:

Purpose: Caveolae, flask-shaped plasma membrane containing caveolin-1 (Cav1) and Cavin1/PTRF, are thought to play important roles in several ocular diseases. Cav1 and Cavin1/PTRF are co-expressed in many tissues, and deletion of one significantly downregulates expression of the other, resulting in loss of caveolae. Cavin1/PTRF is required to sequester Cav1 into caveolae and is the only protein reported to have a stabilizing effect on Cav1. However, our data suggest that in Müller glia, Cav1 protein is stable without Cavin1/PTRF and exists preferentially outside caveolae (non-caveolar Cav1). Our goal is to identify the mechanism of Cav1 stabilization and define the protein components of non-caveolar Cav1 domains in Müller glia. Herein, we present proteomic data on Cav1-containing domains in the presence and absence of Cavin1/PTRF

Methods: We used quantitative mass spectrometry (MS), to assess the protein composition of non-caveolar Cav1 immunoprecipitates (IPs) from immortalized Müller glia (MIO-M1) cells and compared this composition to Cav1 IPs from cells transduced with adenovirus driving expression of Cavin1/PTRF. The Core Laboratory for Molecular and Cytometry Research at the University of Oklahoma Health Sciences Center performed MS analysis using the Thermo Lumos Fusion tribrid Orbitrap mass spectrometer. We used STRING database to predict protein interaction networks and molecular pathways.

Results: We have previously identified that Cav1 protein is stable in MIO-M1 cells without Cavin1/PTRF and are devoid of morphologically-identifiable caveolae. Expression of recombinant Cavin1/PTRF in MIO-M1 cells resulted in dramatic increases in caveolae as determined by transmission electron microscopy. Mass spectrometric analysis of Cav1 immunoprecipitates from Cavin1/PTRF-transduced and control cells revealed 175 proteins differentially-associated with Cav1 when Cavin1/PTRF is expressed (40 with increased association, including the expressed Cavin1/PTRF; 135 with decreased association). Proteins with significantly increased association included actin cytoskeletal components. Intriguingly, a number of ribosomal proteins showed significantly decreased association with Cav1 when Cavin1/PTRF was expressed

Conclusions: Cavin1/PTRF expression in MIO-M1 significantly increases actin cytoskeleton interaction with caveolae and reduces ribosomal association with non-caveolar domains

ABSTRACT BODY:

Purpose: Increased retinal and vitreous levels of inflammatory cytokines are observed in early diabetic retinopathy (DR) progression and are experimentally linked to several hallmark DR features, including leukostasis and vascular hyperpermeability. Cannabinoid (CB) receptor 2 agonism has been shown to decrease inflammatory cytokine production and leukocyte recruitment in various non-ocular inflammation models, suggesting that CB2 agonism could have similar therapeutic potential in DR-related inflammation. This study tested the potential of CB2-selective agonist, HU-308, to attenuate DR pathologies in response to diabetes-relevant inflammatory stimuli (DRS), including increased inflammatory cytokine expression, adhesion molecule expression, leukostasis, and vascular hyperpermeability.

Methods: Primary human Müller cells (hMC) were treated with IL-1 β (1ng/ml) for 8hrs, and HU-308 (0.1uM) was added at the onset of treatment and again 4hrs later. Human retinal microvascular endothelial cells (HRMEC) were pre-treated with HU-308 (1uM) for 2hrs and TNF α (0.1ng/ml) was added for an additional 2hrs. Relative expression of inflammatory mediators and leukocyte adhesion molecules was analyzed via qRT-PCR. To investigate vascular responses in vivo, C57BL/6 mice received daily IP injections of HU-308 (5.0mg/kg) for 1wk prior to receiving an intravitreal injection of TNF α (25ng/ml). Quantitative fluorescein angiography (qFA) and leukostasis analyses were performed 6 and 12hrs later, respectively.

Results: HU-308 significantly decreased IL-1 β -induced expression of IL-1 β by 29.5% ($p=0.0295$) in hMC. HU-308 significantly decreased TNF α -induced expression of leukocyte adhesion molecules ICAM-1 by 26.8% ($p=0.0380$) and E-selectin by 21.7% ($p=0.0141$) in hRMEC. In vivo, systemic HU-308 significantly decreased TNF α -induced leukostasis by 55.3% ($p=0.0401$) and TNF α -induced vascular hyperpermeability by 74.7% ($p=0.0039$).

Conclusions: Consistent with our hypothesis, CB2 agonism was found to decrease cellular cytokine expression and leukocyte adhesion molecule expression in response to DRS, as well as decrease leukostasis and vascular hyperpermeability in an in vivo model of acute retinal inflammation. These results demonstrate that CB2 agonism has significant therapeutic potential for preventing retinal inflammation characteristic of early DR.

TITLE: Conjunctival and Scleral Thicknesses with and without Conjunctival Ultraviolet Autofluorescence

SESSION TITLE: Corneal epithelium and Corneal tissue engineering and regenerative medicine

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Shaw, P. Rajasingam, B.A. Davis, M.J. Collins, School of Optometry and Vision Science, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Alyra Shaw: Commercial Relationship: Code N (No Commercial Relationship) | Pryntha Rajasingam: Commercial Relationship: Code N (No Commercial Relationship) | Brett Davis: Commercial Relationship: Code N (No Commercial Relationship) | Michael Collins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ultraviolet autofluorescence (UVAF) is a clinical technique used to visualise conjunctival changes thought to be due to excessive sunlight exposure and so is considered to be an outdoor sunlight biomarker with UV damage and myopia applications. We performed an experimental observation study aimed to measure the conjunctival and scleral thicknesses in participants with and without conjunctival UVAF to better understand the underlying tissues changes.

Methods: Conjunctival UVAF photographs (Nikon D90, 375 nm LEDs) and anterior OCT volume scans (Heidelberg, Spectralis) of the right eye were taken on 42 participants with healthy eyes aged between 19 and 43 years of age. The participants were classified according to the presence or absence of UVAF on the temporal and nasal conjunctivas of the right eye, resulting in 4 groups (Table 1).

The OCT images of the temporal conjunctiva were exported and analysed with a previously reported semi-automated procedure using custom written software. From these segmentations, tissue thicknesses were determined for the conjunctival epithelium, conjunctival stroma and sclera for the 21 horizontal line scans analysed between 0 to 4 mm from the scleral spur.

Results: Significant differences in thickness for all 3 tissues were observed with the presence of UVAF with a thinner conjunctival epithelium, thicker conjunctival stroma and thicker sclera (ANOVA $p < 0.001$). The UVAF area was located in the lower half of scans (lines 1 to 10) for the majority of the participants, where the greatest conjunctival stromal thickness changes occurred. Groups 3 and 4 (those with temporal UVAF) had the thickest conjunctival stromas (Figure 1). The temporal conjunctival stroma was thinner for group 1 (neither nasal or temporal UVAF) compared to group 2 (which also had no temporal UVAF, only nasal UVAF) (ANOVA posthoc analysis $p < 0.001$).

Conclusions: The conjunctival epithelium, conjunctival stroma and sclera all had significant changes in tissue thickness with the presence of UVAF. A significant difference in temporal conjunctival stromal thickness was observed when the presence of both nasal and temporal UVAF was considered, suggesting that the tissue may be thickening before UVAF is visible. This may help to further understand the sunlight-related damage to this tissue.

ABSTRACT BODY:

Purpose: Optoretinography is a novel technique that uses light-based measurements to reveal retinal activity. Adaptive optics optical coherence tomography (AOOCT) produces an optoretinogram by resolving individual photoreceptors and recording their physical/physiological responses to light stimuli. However, detecting the nanometer-scale changes measured by AOOCT to obtain optoretinograms is hampered by eye motion. In other laboratories, careful registration of a sequence of volume images is required. Here, we present a system whereby real time eye tracking based on adaptive optics scanning laser ophthalmoscopy (AOSLO) is used to correct the position of the AOOCT beam and compensate eye motion.

Methods: The custom AOOCT system is based on a swept source laser centered at 1040 nm with a sweep rate of 100 kHz and an axial resolution of 7 μm in tissue. A dichroic mirror combines the AOSLO and AOOCT beams, which share the AO correction but have independent scanning systems. AOSLO is used to visualize the photoreceptor layer in real time and report eye movement at a 960 Hz rate using strip-based registration. The AOOCT beam was stabilized on the retina by actuating a MEMS mirror in the beam path counter to the eye movement. A 100 ms long flash of narrowband light was deposited on a dark adapted retina to stimulate the photoreceptors. Nanometer-scale changes within a targeted set of cones were obtained by measuring the phase difference between the inner/outer segment junction and the cone outer segment tips as a function of time.

Results: The physiological response of the photoreceptors was revealed as an elongation of the cone outer segment in response to the stimulus. By quantifying the physiological changes, we were able to identify cones belonging to different spectral sub-classes, and we confirmed the result over datasets acquired in separate occasions.

Conclusions: We were able to successfully quantify the response of individual photoreceptors to light stimuli, paving the way to obtain optoretinograms for classifying the cones and measuring other neural activity in the human retina.

ABSTRACT BODY:

Purpose: OCA2 is caused by mutations in an ion channel critical for the maintenance of the pH set-point of the melanosome, the organelle that makes melanin. Melanosomal pH controls pigmentation because tyrosinase is pH sensitive. Currently, there are no treatment options for patients who suffer from OCA2. We discovered that the sAC cAMP pathway regulates melanosomal pH. We hypothesize that inhibition of sAC would correct melanosomal pH and pigmentation in OCA2 melanocytes and mice.

Methods: We measured melanosomal pH in wild type and OCA2 loss of function (LOF) melanocytes using the pH sensitive molecule DAMP and microscopy. We measured melanosomal pH on a per-organelle level and assessed changes across thousands of melanosomes and multiple cells (n=30). We measured tyrosinase activity in live melanocytes using ³H-tyrosine and detecting the accumulation of ³H-H₂O in the media (n=10). We generated a OCA2^{-/-}, sAC floxed (f/f), Tyr-CRE-ERT2 mouse model to study the effects of sAC LOF in tyrosinase expressing cells on an OCA2 LOF background. sAC LOF was induced on post-natal days 2-4 by topical application of 4-hydroxytamoxifen to the skin and eyes. Pharmacological inhibition of sAC was conducted by daily intraperitoneal (IP) injection of sAC inhibitors (36mg/kg) for one month.

Results: sAC inhibition restored melanosomal pH and tyrosinase activity to normal levels in OCA2 melanocytes. Oca2^{-/-};sAC^{-/-} (sACKO) mice (n=20) had darker hair color at P28 as compared to Oca2^{-/-};sAC^{f/f} (sACWT) littermates (n=9). HPLC analysis of hair showed a significant increase in total melanin in sACKO mice. In addition, iris and choroid pigmentation was significantly increased in sACKO mice as measured by slit lamp (n=23) and Fontana-Masson staining (n=5) as compared to sACWT mice (n=14 and n=4, respectively). Electromicroscopy of sACKO eyes (n=5) revealed an increase in mature melanosomes in both melanocytes and RPE cells as compared to sACWT littermates (n=4). Furthermore, IP injection of sAC inhibitors increased pigmentation of Oca2^{-/-} eyes as compared to vehicle (n=4).

Conclusions: Our data reveals that restoration of normal melanosomal pH by inhibition of sAC can improve the pigmentation of cells and mice with OCA2 LOF. We propose that therapeutics designed to restore melanosomal pH may provide treatment opportunities for patients with OCA2 and other forms of albinism.

ABSTRACT BODY:

Purpose: OCT scans contain large amounts of information which clinicians must consider when assessing the rate of glaucomatous progression. Yet images of the scans are small, so clinicians rely heavily on quantitative information provided in the form of global and sectoral layer thicknesses. We investigated which of these quantitative measures are most closely related to the subjective assessment of glaucoma experts who had all the OCT information available.

Methods: Eleven glaucoma specialists independently assigned scores for the rate of structural progression based on series of 5 biannual Heidelberg Spectralis OCT printouts from 100 glaucoma or glaucoma suspect eyes, from 51 participants in the Portland Progression Project longitudinal study. They also reviewed 20 of the series twice to assess repeatability. Scores were on a scale from 1 (improvement) to 7 (very rapid progression), and were averaged among clinicians. Generalized estimating equation linear models, weighted by intra-eye inter-clinician score variability, were used to predict the mean clinician score from the rates of change of Retinal Nerve Fiber Layer Thickness (RNFLT) or Bruch's Membrane Opening Minimum Rim Width (MRW), either globally or in the most rapidly thinning of the six sectors presented by the instrument's software.

Results: The average global RNFLT within the series was 79.3 μ m (range 41.4 to 126.6); average global MRW was 214.4 μ m. Of individual clinician scores, 95% varied by ≤ 1 point when repeated. The average mean clinician score was 2.6 (standard deviation 0.7, range 1.5 to 4.8). This score was more strongly correlated with the rate of change of RNFLT in the most rapidly changing sector ($R^2=0.657$ when expressed in %/y, or $R^2=0.582$ using μ m/y) than with the global RNFLT rate ($R^2=0.372$ and 0.305 respectively); see Figure 1. These comparisons persisted, albeit with smaller differences in R^2 , when the three outliers with apparent thickening of the RNFLT were excluded. Correlations with the rate of MRW thinning were consistently weaker (maximum $R^2=0.149$ for the most rapidly changing sector in %/y) than those for RNFLT for both global and sectoral analyses; see Figure 2.

Conclusions: The percentage rate of change of RNFLT in the most rapidly changing sector predicted experts' assessment of the rate of structural progression better than global rates. Sectoral RNFLT rates may be a useful addition to current clinical printouts.

ABSTRACT BODY:

Purpose: To develop and validate an automated approach to scoring OCT images of ocular inflammation in experimental animals using deep learning.

Methods: Ocular inflammation was generated using the primed mycobacterial uveitis (PMU) model. Anterior chamber and posterior chamber optical coherence tomography (OCT) images were obtained using the Envisu R2300. On each image, degree of inflammation was classified using a 6 step categorical system with scores ranging from 0-4+ by three masked graders (A). Training set images were labeled with the score assigned by at least 2 out of the 3 graders. Images were divided into a training, validation and test set in a 80:10:10 ratio and a Deep Learning classifier algorithm based on a modified ResNet50 but allowing higher resolution images, was developed. Accuracy of the classifier compared to the human score was determined for anterior and posterior chamber images separately. Agreement between the classifier and the human graders was determined using Cohen's linear weighted Kappa. Comparison between human and classifier scores was performed using a confusion matrix on the test set.

Results: 1115 images (575 anterior chamber, 540 posterior chamber) were scored by human graders. Agreement between human graders was 0.87 and 0.83 on AC and PC images respectively. Agreement between the automated classifier and the human graders was 0.56 and 0.68 for AC and PC respectively. Absolute accuracy of the automated classifier was 56% for AC images and 57% for posterior images. The confusion matrix analysis (B) determined that accuracy was highest for scores of 0 which was also the most frequent score in the training set.

Conclusions: In this study, we found that human graders demonstrated strong agreement if one step differences inscore were accounted for with a weighted kappa. This is consistent with prior studies of inter-human agreement scoring in uveitis. Automated classification did not perform as well as human graders. Better performance and agreement between the automated and human graders was identified for posterior chamber images than on anterior chamber images. Performance was likely limited by the disproportionate number of score 0 images in the training set. Additional images at each score level will be required to improve classification accuracy.

ABSTRACT BODY:

Purpose: Recent studies have shown that commensal microbiome secretes various metabolites that can exert important effects on the host immunity, control inflammation and alter cellular biological functions. The gut microbiome is strongly altered by diets. However, little is known regarding the effect of microbiome on corneal immunity and corneal genetic expression. The purpose of this study is to describe the effect of diet-induced gut dysbiosis on corneal immunity and corneal gene expression after wounding.

Methods: This study is approved by the Animal Care and Use of the University of Illinois at Chicago. Five-week-old female C57BL6 mice were fed on a normal chow diet (ND), isocaloric low fat control diet (LD) or a 21% milk fat diet (simulating a Western Style, WD) for six weeks. A 2mm corneal epithelial debridement was performed(n=10). Cecal samples from mice were used for microbial diversity analysis(n>3). Immunofluorescence staining of corneal wholemount tissue at time 0 and 18 hours of debridement was used to visualize immune cell distribution, including anti-CD45, anti-LY6G, anti-TCR delta gamma, etc. RNA Seq using Illumina NovaSeq 6000 was performed from corneas 18 hours post debridement. RNA STAR was used to align transcripts to mm10 mouse genome. DESeq2 was used to perform differential gene analysis.

Results: Mice fed different diets had significant alterations in gut microbial alpha and beta diversities. After corneal debridement, increased TCR was observed in LD group, and decreased LY6G was observed in HFD group ($p<0.05$). 3158 genes were differentially expressed with 225 genes with greater than two-fold change. Go terms of differentially expressed genes included responses to external stimulus, cell proliferation, migration, adhesion, defense response, immune system process, leukocyte migration, etc. Top over-represented KEGG pathways included ECM-receptor interaction, Cytokine-cytokine receptor interaction, Focal adhesion, Hematopoietic cell lineage, Leukocyte transendothelial migration, etc.

Conclusions: Gut microbial dysbiosis may alter corneal immune cell distribution and genes related to epithelial function and corneal immunity.

ABSTRACT BODY:

Purpose: There is a growing imbalance between clinical demand and capacity for exudative age-related macular degeneration (exAMD) in the UK National Health Service (NHS), but the degree of consequential sight loss remains unclear. This retrospective, observational clinical study aimed to quantify the delays to treatment which patients experience in a representative NHS centre, and to describe the associated visual outcomes.

Methods: The electronic medical record of a large provincial UK ophthalmology centre was interrogated for eyes diagnosed with exAMD in 2016 and treated with intravitreal injections (IVI) of aflibercept over a minimum of 3 years. The difference between all clinic appointments' planned and observed dates were calculated and totalled separately for each of the first 3 years of treatment. As a pragmatic observational study visual acuity (VA) was recorded as the best of unaided, spectacle corrected or pinhole corrected VA in early treatment of diabetic retinopathy (ETDRS) letters at the end of each year of treatment as well as the number of IVIs received. Descriptive and comparative statistics were performed with SPSS v.24 and unpaired t-tests were used to compare means.

Results: 175 eyes (89 left, 87 pseudophakic) from 175 patients (109 female, mean age 79.1 years) were identified. Mean VA change over a year of treatment was 5.3, -2.3 and -0.8 ETDRS letters with a mean of 1.8, 3.6 and 2.7 weeks of cumulative treatment delay in the first, second and third years of treatment respectively. 24 (14%), 49 (28%) and 42 (24%) eyes experienced a cumulative delay to planned treatment of 4 weeks or more in the first, second and third years of treatment respectively. VA change over a year of treatment was worse for patients experiencing 4 weeks or more of cumulative delay compared to those that did not, with mean changes of -0.6 (95%CI -6.0,4.8) versus 6.3 (4.1,8.4), -3.9 (-6.5,-1.2) versus -1.7 (-3.2,-0.1) and -3.7 (-6.3,-1.2) versus 0.1 (-1.4,1.6) over the first (p=0.02), second (p=0.15) and third (p=0.01) years of treatment respectively.

Conclusions: It is common for NHS exAMD patients to experience significant delays in their treatment, either due to service capacity or patient factors. These delays compromise visual outcomes, particularly within the first year. These data evidence the need for increasing care capacity and improving patient adherence to treatment for exAMD within NHS services.

ABSTRACT BODY:

Purpose: There remains a major clinical need for ways to overcome the shortage of cadaveric donor tissue needed to surgically treat corneal blindness worldwide. Our goal is to engineer matrix therapy that stabilizes deep corneal wounds and promotes epithelial regeneration and stromal remodeling without the need for a catalyst, light-activation, sutures, or donor tissue.

Methods: We have developed crosslinked matrices of collagen as well as collagen and hyaluronic acid that form under ambient conditions through strain promoted azide-alkyne cycloaddition (SPAAC), a bio-orthogonal form of copper-free click chemistry, after being applied to deep corneal wounds without the need for a catalyst or light energy source. In vitro cell culture, ex vivo organ culture, and in vivo rabbit corneal keratectomy models were used to evaluate the biologic activity of the gel constructs out to 2 months post-operatively. Slit lamp exam, fluorescein staining, anterior segment optical coherence tomography, pachymetry, tonometry, and immunohistochemistry were used to evaluate the corneas post-treatment.

Results: Collagen and collagen-hyaluronic acid gels crosslinked by SPAAC form in situ within minutes when applied to deep keratectomy wounds under ambient conditions without the need for a catalyst or light energy. We found that the hydrogels could be cured under an air interface or under a bandage contact lens, and could restore the smooth outer curvature of a keratectomized cornea. SPAAC crosslinking yielded gels that support multi-layered surface epithelialization, tight junction formation, new basement membrane deposition, and normal IOP and corneal thickness, and complete matrix remodeling at 2 months.

Conclusions: Bio-orthogonally crosslinked gels form in situ on corneal wounds under ambient conditions through copper-free click chemistry without the need for an external catalyst or light energy source. The gels support surface epithelialization and stromal remodeling out to 2 months, which suggests their promise as a therapeutic matrix for suture-free reconstruction of deep corneal wounds.

TITLE: Rare case of Wolfram-like Syndrome case due to a missense WFS1 mutation

SESSION TITLE: Genetics, (gen)omics, systems and computational biology in ocular health and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Mair, N. Fowler, P. Sudhakar, R. Maldonado, University of Kentucky College of Medicine, Lexington, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hailey Mair: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Fowler: Commercial Relationship: Code N (No Commercial Relationship) | Padmaja Sudhakar: Commercial Relationship: Code N (No Commercial Relationship) | Ramiro Maldonado: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In contrast to the classic autosomal recessive Wolfram syndrome, Wolfram-like Syndrome (WLS) is a rare, autosomal dominant disease caused by mutations in the WFS1 gene. It presents with optic atrophy, sensorineural hearing loss and diabetes mellitus. Here, we present a case of WLS without endocrine manifestations caused by a heterozygous missense WFS1 variant (c.2508G>T, p. Lys826Asn).

Methods: Single case with a heterozygous WFS1 variant (c.2508G>T, p.Lys836Asn), ophthalmic examination, multimodal imaging and genetic testing will be discussed.

Results: A 28-year-old Greek male was referred to our clinic for evaluation of bilateral optic nerve atrophy of unknown cause. Review of systems revealed bilateral sensorineural hearing loss for which he requires hearing aids. Family history was significant for early-onset severe hearing loss in his mother. The patient had best corrected visual acuity of 20/30 and 20/40 in the right and left eye, respectively. Pupillary responses, intraocular pressures and anterior segment exam were unremarkable. Fundus exam revealed normal appearance of the retina and bilateral tilted and pale optic nerves. Testing showed reduced contrast, color and depth perception. Visual fields showed supero-temporal and infero-nasal defects in both eyes. Optical coherence tomography revealed retinal nerve fiber layer global thinning in both eyes measuring 49 and 46 microns in the right and left eye, respectively. In addition, ganglion cell layer thickness was significantly reduced OU. MRI of the head and orbits was unremarkable. Blood work for toxic, infectious and nutritional causes of optic neuropathy were normal. Genetic testing was negative for mutations in OPA1, OPA3 and LHON panel; however, it revealed a heterozygous missense variant in WFS1 gene (c.2508G>T, p.Lys836Asn). To date, this variant is not present in gnomAd database and predicted to be pathogenic by in silico tools. His fasting blood glucose was 96mL/dL and hemoglobin A1C was 4.9%.

Conclusions: We present deep phenotyping of a previously described WFS1 variant (c.2508G>T, p. Lys836Asn) (Hogewind B. F., Pennings R. J., Hol F. A., et al. Autosomal dominant optic neuropathy and sensorineural hearing loss associated with a novel mutation of WFS1. Molecular Vision. 2010;16:26–35.). Our findings confirm this heterozygous variant in WFS1 as a cause of optic atrophy and hearing loss without neurologic, cardiac or endocrine problems.

ABSTRACT BODY:

Purpose: The Royal College of Surgeons (RCS) rat is a prominent photoreceptor degeneration model that is often used to determine the safety and efficacy of prospective age-related macular degeneration and retinitis pigmentosa therapies. We aim to characterize retinal structural and vascular pathologies in RCS rat using visible-light optical coherence tomography (vis-OCT).

Methods: The retinas of pigmented RCS rats (9 animals) were scanned by a fiber-based vis-OCT system with a 1.7 μm axial resolution, 70 kHz A-scan rate, 100 nm-bandwidth wavelengths centered at 560 nm. The animals were anesthetized with ketamine (80 mg/kg) / xylazine (5 mg/kg) cocktail. Volumetric raster scans were acquired near optic disc at the age of 1 month, 3 months, and 8 months. Each scan contains 256 A-lines in each B-scan, 2 repeated B-scans at each Y-location, and 256 Y-locations in 2×2-mm or 1×1-mm regions. Retinal layers were segmented, and the retinal thickness maps and en face angiograms of inner retina were generated.

Results: At the age of 1 month, the RCS rats demonstrated normal retinal structure and vasculature. The outer plexiform layer (OPL) and outer nuclear layer (ONL) are clearly visualized from the OCT B-scans (Fig. 1). Nerve fiber bundles and inner retinal vessels with normal densities are demonstrated by their en face images. At the age of 3 months, the ONL disappears indicating the photoreceptor loss. However, the retinal vasculature and nerve fiber bundles appear not be affected by the thinning of retinal tissue. At the age of 8 months, the pathologies progress more dramatically - inner nuclear layer (INL) and OPL also vanish. At this stage, we can see damaged nerve fiber bundles and poor retinal perfusion.

Conclusions: High resolution OCT and OCTA at visible light band can be used to characterize retinal dystrophy in RCS rats. This preliminary study suggests retinal vasculature could be impaired as a consequence of neuronal cell death.

ABSTRACT BODY:

Purpose: Dry eye disease is a multifactorial inflammatory and aqueous tear deficiency characterized by ocular irritation and potential visual impairment. As melanocortin agonists may represent a novel therapeutic avenue to treat inflammatory ocular diseases, this phase 2 study evaluated efficacy and tolerability of the melanocortin receptor pan-agonist PL9643 in adults with dry eye disease.

Methods: This randomized, placebo-controlled, double-masked study enrolled subjects with mild, moderate, or severe dry eye disease. All subjects received placebo solution (vehicle diluent) during a 2-week run-in period; selected subjects were then randomized 1:1 to receive either placebo or PL9643 topical ophthalmic solution bilaterally 3 times daily for 12 weeks. Co-primary endpoints were changes in inferior corneal fluorescein staining and ocular discomfort (Ora Calibra[®] scale) after 12 weeks. Secondary endpoints were changes in additional signs and symptoms of dry eye after 2 and 12 weeks, as well as the occurrence of adverse events (AEs) throughout the study. Efficacy endpoints were evaluated in the intent-to-treat (ITT) population and in the subset of subjects with moderate or severe dry eye disease.

Results: In the overall ITT population (N=160), significant improvements in corneal staining or ocular discomfort were not observed after 12 weeks. However, in the subset of subjects with moderate or severe disease (n=61), significant improvements were observed in the primary sign endpoint, inferior corneal fluorescein staining (LS mean difference [SEM], -0.5 [0.2], P<0.05), as well as in multiple other signs (superior and total corneal staining; temporal and total conjunctival staining) and symptoms (ocular discomfort) after 2 or 12 weeks. No treatment-related serious or ocular

AEs were observed, and no subjects receiving PL9643 reported ocular instillation pain. Fewer AEs occurred among subjects receiving PL9643 compared with placebo.

Conclusions: In subjects with moderate or severe dry eye disease, ophthalmic PL9643 solution led to significant subjective and objective benefits by the first evaluation at 2 weeks and maintained for 12 weeks. PL9643 was well tolerated, with a safety profile comparable to placebo. Positive results across multiple signs and symptoms support the continued development of PL9643 as a novel therapeutic method for treating dry eye disease.

ABSTRACT BODY:

Purpose: Saliency maps have gained popularity in medical artificial intelligence (AI) studies due to their ability to highlight significant regions for model prediction, allowing greater interpretability of models and raising the prospects of their integration in clinical practice. This study explores whether saliency maps increase clinician confidence in diagnosis via an AI supported workflow.

Methods: 60,133 retinal fundus photography images and labels were gathered from public datasets. These were used to train a classification model on the Google AutoML platform to detect referable and non-referable diabetic retinopathy. Saliency maps were produced using the XRAI algorithm supported by the same platform, providing region-based attribution, suitable for fundus images.

A survey was sent to 6 participants, including 4 ophthalmologists with fellowship-level subspecialty training in retinal disease, and two ophthalmology trainees. They were shown 50 randomly selected images, each repeated 3 times. The image was first presented with the predicted class, secondly by class and Softmax score, thirdly by including a heatmap. After each assistance level, the readers rated their confidence in the prediction via a 5-point Likert scale.

Results: Paired tests showed a significant difference in confidence rating between all assistance types, with saliency maps performing the poorest (3.12 ± 1.28 , $P < 0.001$). On a second analysis, we separated predictions into correct and incorrect groups. The unpaired test results show that heatmaps accompanying incorrect labels were associated with a lower confidence than correct ones (incorrect: 2.14 ± 1.15 , correct: 3.23 ± 1.25 , $P < 0.001$). Similarly, we considered the impact of referable and non-referable cases separately. Results showed no significant difference in confidence from heatmaps between the categories ($P = 0.097$).

Conclusions: Our results show that XRAI heatmaps are associated with lower confidence in model predictions compared to the other two strategies. We emphasize the importance of considering their impact specifically for incorrect predictions and non-referable DR. For the prior, saliency could cause confirmation bias, whereas for the latter, it may mislead if there are no positive findings. Whilst saliency may be of at least some value in model interpretability, for its implementation as diagnostic assistance, higher standards of localisation and meaningful rationale are required.

ABSTRACT BODY:

Purpose: To investigate associations of patient race and Hispanic ethnicity with age and severity of visual field loss in glaucoma patients at first visit.

Methods: All patients from Mass. Eye and Ear glaucoma service with Humphrey visual field (VF) measurements (SITA Standard or Fast 24-2) and an electronically available, questionnaire based self-reported race as either African, Asian, or European were selected. Hispanic ethnicity was represented as a questionnaire item separate from race. Age at the time of the first visual field measurement was associated with race as well as self-reported Hispanic ethnicity. Among all reliable (false positive/negative rate $\leq 20\%$, fixation losses $\leq 33\%$) first VF measurements of each patient, analogous race and ethnicity associations with VF mean deviation (MD) as a measure of glaucoma severity were determined.

Results: Among the 17,275 selected patients (56.5% female), 2,746 identified their race as African, 1,443 as Asian, and 13,086 as European; 869 did not respond to the Hispanic ethnicity item, while 427 identified as Hispanic (70 African, 6 Asian, 351 European). There was a significant (ANOVA, $p < 0.001$) main association between race and age at first visit (Fig. 1), with Asian being youngest patients (56.2 years), followed by Africans (57.7 years) and Europeans (62.2 years). Patients with Hispanic ethnicity were on average 6.3 years younger (54.8 years) at first visit (t-test, $p < 0.001$). Among the 17,275 first VFs of each patient, 13,918 met the reliability criteria. There was a significant race association with MD ($p < 0.001$; Fig. 2), with patients of African race having the most severe VF loss at first visit (-6.5 dB), followed by Asian (-4.4 dB) and European race (-3.6 dB). Hispanic patients had lower MD (-6.1 dB) than patients of non-Hispanic ethnicity (-4.0 dB) ($p < 0.001$). While Hispanic ethnicity among patients of African race was not associated with MD, among patients of European race, Hispanics had 2.2 dB lower MD at first visit ($p < 0.001$).

Conclusions: Patients of African and Asian race present younger at glaucoma service but still have more severe vision loss at first visit compared to European race patients. While Hispanic ethnicity among patients of African race was not associated with glaucoma severity, Hispanics or European race had significantly lower MD than patients of non-Hispanic European race.

ABSTRACT BODY:

Purpose: Individuals with vision loss are experiencing new and unique challenges due to physical distancing during the COVID-19 pandemic. We conducted a cross sectional study to understand challenges and to learn about adaptive strategies employed.

Methods: The Casey Eye Institute EHR (EPIC) was queried for patients meeting the following criteria: best corrected visual acuity of 20/70 or worse in the better seeing eye; age 18-100, and active email address. 762 requests for participation in completing a 23-question survey were emailed via REDcap and responses were received from 46 patients; 19 male and 27 female. The data was analyzed using SPSS statistical software. Comparisons were made between age, duration of visual impairment, severity of visual impairment to effects of physical distancing and adaptive strategies. Comparisons were made using the chi-squared test.

Results: 44% of participants reported that physical distancing impacted their willingness to run essential errands and 52% agree or strongly agree that they have difficulty maintaining physical distancing due to their visual impairment. 65% agree or strongly agree that changes to the layout of familiar places, to encourage physical distancing, makes navigating more difficult. There is an association between age and this difficulty with navigating due to changes to the layout ($p<0.01$). Younger participants rated navigating as more difficult with changes to the layout, not older participants. 72% agree or strongly agree that visual markers used to indicate 6 feet physical distance are helpful in public places. 39% of participants reported that they use strategies to maintain physical distancing when in public. The most common strategies included Sighted Guide or avoiding situations where others may be present. Individuals with vision loss for >10 years, but not since birth, are most likely to report using strategies to maintain physical distancing.

Conclusions: The need to physically distance during a pandemic poses unique challenges for individuals with vision loss. Policies for physical distancing should consider this population. Visual markers on the ground to indicate 6 feet of separation can be helpful and it is important to be mindful when making changes to the environmental layout. Further research to learn more about the strategies utilized by this population to adapt to these challenges is needed.

ABSTRACT BODY:

Purpose: In women receiving aromatase inhibitor (AI) therapy for breast cancer, dry eye is a significant cause of distress and treatment non-compliance. However, little is known of its effect on the ocular surface. This study aimed to compare dry eye clinical features in aromatase inhibitor (AI) therapy patients versus healthy postmenopausal women.

Methods: A comparative observational study of postmenopausal women treated with AI therapy versus healthy controls was conducted. Symptoms were assessed using a validated questionnaire (Ocular surface disease index [OSDI]). Dry eye clinical assessments and investigations (i.e. visual acuity, Schirmer's test II, non-invasive tear break up time [NIBUT], meibomigraphy) were performed. The primary outcome measure was dry eye symptoms measured via the OSDI and secondary outcome measures signs of dry eye disease.

Results: A total of 65 women were recruited, 25 AI and 40 healthy control patients. The mean age in the AI and healthy control group was 62 ± 10 and 60 ± 8 years ($p=0.132$), respectively. The mean OSDI score in the AI group was 24 ± 18 and controls 22 ± 24 ($p=0.174$). In the AI group, 16 patients were considered symptomatic ($OSDI \leq 13$) and 9 were asymptomatic. In the controls, 20 were symptomatic and 20 were asymptomatic for dry eye. Comparative analysis of the AI and control group found no significant difference between visual acuity ($p=0.728$) or Schirmer score ($p=0.108$). NIBUT was significantly longer in the AI group compared to controls ($p<0.001$) (11 ± 6 vs 3 ± 2 , respectively). Increased loss of meibomian gland was also observed ($p=0.022$) in the AI group (3 [IQR 2- 4]) compared to the controls (2 [IQR 1 – 3]).

Conclusions: Aromatase inhibitor therapy was associated with increased NIBUT and meibomian gland drop out. Increased NIBUT maybe due to tear film instability due to the higher meibomian gland drop. Meibography assessments could be used to screen women on AI therapy at risk of developing evaporative dry eye.

ABSTRACT BODY:

Purpose: Genome-wide association studies (GWAS) have identified significant association of SNPs located in the ATXN2 genomic region with primary open angle glaucoma (POAG) and intraocular pressure (IOP). The ATXN2 coding sequence includes a CAG repeat that when fully expanded (>34 repeats) causes spinocerebellar ataxia 2, and intermediate expansions (24-34 repeats) contribute to risk of amyotrophic lateral sclerosis (ALS) and other neurodegenerative disorders. In this study, we investigated this ATXN2 CAG repeat in POAG.

Methods: Fragment analysis was used to size the CAG repeat in 229 POAG cases and 213 controls selected from the NEIGHBORHOOD cohort. The entire repeat genomic region was sequenced using Haloplex next-generation sequencing (NGS) for the 229 POAG cases and 30 controls. SNPs in high LD (linkage disequilibrium) ($r^2 > 0.95$) with CAG repeats were used to test for association with POAG in the overall NEIGHBORHOOD case control cohort, and for association with POAG and related ocular traits in other published GWAS summary data.

Results: The CAG repeat size ranged from 19 to 27 in POAG cases and from 17 to 27 in controls. Both groups had a mean repeat size of 22, which is the average repeat size in normal populations. Among the 19 different repeat sequences identified by NGS, the most common sequence >22 was a 27 repeat ((CAG)₈(CAA)(CAG)₄(CAA)(CAG)₄(CAA)(CAG)₈) with a frequency of 2% in both cases and controls. All other repeats >22 had frequencies of <0.2% in the sequenced individuals. A SNP in high LD ($r^2 > 0.95$) with the 27 repeat (rs117129118) was not significantly associated with POAG (N=2606 cases, 2606 controls), or high-tension (N=1298) or low-tension glaucoma (N=561) in the NEIGHBORHOOD dataset (P>0.05). In published GWAS summary data, rs117129118 was also not associated with POAG, IOP, CDR, or CCT.

Conclusions: Expansion of the ATXN2 CAG repeat was not associated with POAG in a large case/control cohort suggesting that expansion of the ATXN2 CAG repeat does not alter glaucoma risk. These results suggest that other genetic variants in the ATXN2 locus contribute to POAG risk.

ABSTRACT BODY:

Purpose: Mutations in collagen type IV alpha 1 (COL4A1) and alpha 2 (COL4A2) cause a multisystem disorder characterized by variable cerebrovascular, ocular, renal and neuromuscular manifestations. The affected tissues are mainly derived from two distinct embryonic origins: the neural crest cells (NCCs) and the mesoderm germ layer. Approximately one-third of patients with COL4A1 and COL4A2 mutations have ocular anterior segment dysgenesis (ASD), including congenital glaucoma resulting from dysgenesis of structures derived from the periocular mesenchyme. Defects in NCC biology have long been proposed to contribute to ASD. Because vascular defects are common in patients with COL4A1 and COL4A2 mutations and can influence NCC survival and migration, we hypothesize that primary vascular defects may alter NCC biology underlying ASD.

Methods: Whole-mount immunofluorescence, confocal microscopy, and 3D reconstruction were performed on control and Col4a1 mutant mouse embryos at embryonic day (E) 9.5 and E10.5 using antibodies against CD31 to label vascular endothelial cells, and SOX10 to label migratory NCCs.

Results: Gross morphology and quantitative analysis of E9.5 Col4a1 mutant embryos showed abnormal cerebral vasculature remodeling compared to controls, revealing an early onset of cerebral angiogenesis defects. SOX10 and cleaved Caspase 3 labeling, respectively, revealed that Col4a1 mutant and control embryos had similar numbers of migrating cranial NCCs and a similar degree of cell death at both E9.5 and E10.5. However, compared to control littermates, cranial NCCs moving towards the eye region in E9.5 mutants showed abnormal migration, forming a less cohesive migratory stream. On the other hand, within the periocular mesenchyme of E9.5 and E10.5 Col4a1 mutant embryos, NCCs clustered more together and interacted more closely with the vasculature.

Conclusions: In agreement with our hypothesis, our results show for the first time that Col4a1 mutations lead to cranial NCC migratory defects in the context of early-onset defective angiogenesis. However, NCC number and survival are not affected by Col4a1 mutations. Further examinations are needed to understand both the molecular causes and consequences of the uncovered NCC migratory phenotype. Future work will also analyze the mesodermal contribution to ASD in Col4a1 mutants.

ABSTRACT BODY:

Purpose: To evaluate the short- and intermediate-term outcomes of the Ahmed glaucoma valve (AGV) in neovascular glaucoma (NVG), comparing eyes with and without a hypertensive phase (HP).

Methods: This was a single-center retrospective case series of consecutive NVG eyes that underwent AGV implantation with ≥ 6 -month follow-up. HP was defined as intraocular pressure (IOP) >21 mmHg at ≥ 2 visits within the first 3 months following surgery. Reported outcomes included failure at month 6 and at the most recent visit. Failure was defined as IOP >21 mmHg, progression to no light perception (NLP) vision, or glaucoma reoperations (all with IOP-lowering medications). Other secondary outcomes included IOP and number of glaucoma medications.

Results: 76 eyes of 74 patients (37 without HP and 39 with HP) with follow-up duration of 28.9 ± 25.7 months ($P=0.602$) were included. Patient demographics, visual acuity (VA), number of medications, NVG etiology, and perioperative retina treatment were similar in both groups. Baseline IOP was higher in the HP group ($P=0.001$). At month 6, 13 HP (33.3%) eyes vs. 3 non-HP (8.1%) eyes met the failure criteria ($P=0.01$). However, at the most recent visit, failure was higher in the HP group; the difference did not reach statistical significance (53.8% vs 35.1%; $P=0.113$). Kaplan-Meier analysis showed similar cumulative failure in both groups ($P=0.180$) (Figure 1). Reasons for failure were similar between groups ($P=0.237$): high IOP in 9 (26.5%) eyes, progression to NLP in 10 (29.4%) eyes, glaucoma reoperation in 14 (41.2%) eyes, and tube removal in 1 (2.9%) eye.

With the exception of post-operative day 1, IOP during the first 6 postoperative months was significantly higher in the HP group ($P<0.05$ for all). At the most recent visit, IOP was similar in both groups ($P=0.211$) (Figure 2A), but number of medications was higher in the HP group ($P=0.023$) (Figure 2B). Postoperative complications were similar and infrequent in both groups.

Conclusions: HP eyes had higher preoperative IOP and more commonly failed in the first 6 months following AGV implantation in NVG compared to non-HP eyes. This study did not detect a significant difference in surgical failure at the most recent visit between the two groups, but HP eyes required a significantly higher number of medications.

ABSTRACT BODY:

Purpose: Recent research suggests that normal tension glaucoma is a chronic progressive ischemic process in the optic nerve. This cross-sectional prospective study looked at the relationship among foveolar avascular zone (FAZ) area, a biomarker for retinal microvascular integrity, retinal ganglion cell (RGC) function assessed by pattern electroretinogram (PERG), and optic nerve head (ONH) rim area (RA) in glaucoma suspects (GS) with obstructive sleep apnea (OSA).

Methods: Nine consecutive GS participants (18 eyes) with normal visual fields tests and suspicious glaucomatous ONH appearance were enrolled and underwent a complete ophthalmologic examination, optical coherence tomography-angiography (OCTA), OCT, and pattern electroretinogram (PERG). FAZ area was measured using ImageJ software. Mediation Analysis Process by Andrew Hayes was tested. PERG parameters consisted of Magnitude (Mag, μV), Magnitude (MagD, μV), and MagD/Mag ratio. OCT RA was also used.

Results: Multiple linear regressions were calculated to predict RA (mm^2) based on age (years) and Mag (μV). A significant regression equation was found ($F(2,14)=6.234$, $p=0.012$) with an R^2 of 0.471. Predicted RA was equal to $1.245 + 0.102(\text{Mag}) - 0.006(\text{age})$. RA decreased by 0.006mm^2 for each year of age and decreased by 0.102mm^2 for every unit decrease in Mag. Only Mag was a significant predictor of RA ($p=0.037$). An identical regression model was found to be significant in predicting RA based on age and MagD ($F(2,14)=6.036$, $p=0.013$) with an R^2 of 0.463. Predicted RA was $1.275 + 0.100(\text{MagD}) - 0.006(\text{age})$. RA decreased by 0.006mm^2 for each year of age and decreased by 0.100mm^2 for every unit decrease in MagD. Only MagD was a significant predictor of RA ($p=0.042$). Mediation analysis revealed that FAZ area was a significant partial mediator in the relationship between MagD and RA. Both the direct (effect= 0.179 , $p=0.002$, 95% CI [0.073 , 0.286]) and indirect (effect= -0.055 , 95% CI [-0.137 , -0.006]) effects of MagD on RA remained significant, demonstrating that FAZ area is a partial mediator in this relationship.

Conclusions: We report PERG abnormalities in asymptomatic GS with OSA. Our data suggests early optic nerve and RA defects are mediated by chronic progressive microvascular abnormalities, possibly occurring simultaneously with vascular changes in optic nerve.

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) is characterized by terminal duct obstruction and/or changes to meibomian gland (MG) secretion. Pharmacological therapies for terminal duct obstruction in MGD are lacking. This clinical trial evaluated the safety and efficacy of AZR ointment/semi-solid drug, a novel MGD treatment.

Methods: A pre-planned interim-analysis (IA) of data from this multicenter, double-masked, vehicle-controlled, randomized, parallel group clinical trial (clinicaltrials.gov NCT03652051) was undertaken. Key participant inclusion criteria were an Ocular Surface Disease Index (OSDI) score of 13 to 33 and Meibomian Gland Score (MGS) <12. The IA involved participant groups that received sequentially higher concentrations of AZR (0.1% (n = 9), 0.5% (n = 7), or 1.0% (n = 7)) compared to vehicle (n = 9), in a 4:1 ratio within each group, over 3 months. Pre-specified efficacy measures included OSDI score, MGS and Meibomian Gland Yielding Liquid Secretion (MGYLS). Safety was evaluated using the adverse event (AE) rate.

Results: The mean (SD) age of each study group was similar (overall: 44.6 (19.7) years, n=33), and 52% of participants were female. At Month 3, a minimal clinically important improvement in dry eye symptoms (change in OSDI score ≥ 4.5 units) was observed in 22.2% (Vehicle), 22.2% (AZR 0.1%), 57.1% (AZR 0.5%) and 85.7% (AZR 1.0%) of participants. The difference between Vehicle and AZR 1.0% was significant ($p=0.03$). Least square mean change from baseline (higher scores indicate improvement) for MGS at Month 3 were: 4.5 ± 2.0 (Vehicle), 1.2 ± 2.0 (AZR 0.1%), 4.9 ± 2.1 (AZR 0.5%), and 12.2 ± 2.4 (AZR 1.0%). The difference between Vehicle and AZR 1.0% was significant ($p=0.03$). Results for MGYLS mirrored MGS. The percentage of participants with at least one ocular treatment-emergent AE was 44% (Vehicle), 44% (AZR 0.1%), 71% (AZR 0.5%), and 86% (AZR 1.0%). AEs were transient and did not impact willingness to continue study participation.

Conclusions: Clinically meaningful improvements in signs and symptoms were observed in individuals with MGD with AZR, with an acceptable safety profile. AZR-MD-001 has potential to be the first effective pharmacotherapy specifically for MGD.

TITLE: Ultrastructural features of rod synaptic terminals in the simplex retina of skate

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.S. Wagh, J.G. Fathi, A. Baatar, I.A. Anastassov, Biology, San Francisco State University, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Abhi Wagh: Commercial Relationship: Code N (No Commercial Relationship) | Jessamyn Fathi: Commercial Relationship: Code N (No Commercial Relationship) | Altan-Od Baatar: Commercial Relationship: Code N (No Commercial Relationship) | Ivan Anastassov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In duplex retinæ, the processing of visual information under scotopic and photopic light conditions is separated between the rod and cone photoreceptor systems. However, the elasmobranch little skate (*L. erinacea*) has a simplex retina, which contains only rods. This pure-rod retina can perform under scotopic and photopic light conditions with one complement of photoreceptors. We have little knowledge about the anatomical basis of this functional plasticity in skate rods.

Methods: Eyes from little skate were hemisected and choroid-attached pieces of retina from the tapetal area were obtained. Retinal pieces were embedded in resin blocks and SB-3DEM was performed. The dataset analyzed here was from a region of interest in the OPL of the skate retina with width/height = 34.4µm, section thickness = 0.075µm, and depth = 15µm. Voxel size was 4.5nmX4.5nmX75nm. 3D reconstructions and measurements of rod terminal features were done with Reconstruct and Amira software.

Results: The outer segments of skate rods display typical “stacked-disk” internal membrane morphology with the outer membrane separated in space from the disc membranes. A very short connecting cilium (CC) is present between the OS and the IS: d~250nm, length~400nm. Inner segments have multiple mitochondria and terminals have multiple synaptic ribbons. The majority of terminals have 2-3 synaptic ribbons. On rare occasions, terminals possessed 4 synaptic ribbons. Multiple invaginating processes can be identified (~12) and multiple filopodia of varying length extend from the periphery of each terminal.

Conclusions: Skate rods have a typical vertebrate rod OS morphology, but display hybrid characteristics in their inner segments and terminals. CCs are much shorter than in typical rods and resemble those of cones. The presence of multiple ribbons as organizing centers for transmitter release is an unusual characteristic for rods, but can be clearly seen in skate rods, suggesting the evolution of a hybrid morphology to accommodate functional plasticity.

TITLE: Fundus photography technique, clinical site experience, and the ability to acquire interpretable diabetic retinopathy fundus photos in a telemedicine program

SESSION TITLE: Imaging of posterior segment II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Kung, A. Hang, A. Husain, J. Jia, S. McMurtry, L. Cheng, J. Grachevskaya, J.D. Henderer, Y. Zhang, Lewis Katz School of Medicine at Temple University, Philadelphia, Pennsylvania, UNITED STATES|P. Kung, Stony Brook University Renaissance School of Medicine, Stony Brook, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Winston Kung: Commercial Relationship: Code N (No Commercial Relationship) | Preston Kung: Commercial Relationship: Code N (No Commercial Relationship) | Abraham Hang: Commercial Relationship: Code N (No Commercial Relationship) | Azam Husain: Commercial Relationship: Code N (No Commercial Relationship) | Jing Jia: Commercial Relationship: Code N (No Commercial Relationship) | Shyla McMurtry: Commercial Relationship: Code N (No Commercial Relationship) | Lorrie Cheng: Commercial Relationship: Code N (No Commercial Relationship) | Julia Grachevskaya: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Henderer: Commercial Relationship: Code N (No Commercial Relationship) | Yi Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In preparation for an artificial intelligence diabetic retinopathy initiative at Temple University Hospital, we changed our fundus photography screening protocol from a single fundus image per eye to two fundus images per eye. We also expanded the screening program from one primary care office to eight. We wished to determine whether these changes resulted in a significant difference in acquiring interpretable photographs and if there was a learning curve for new fundus photographers when expanding clinical sites.

Methods: The one-image protocol required a single macula-centered fundus photograph while the two-image protocol required both a macula-centered and an optic-nerve centered fundus photograph. The one-image protocol was in use at one site from 2016-2017 and the two-image protocol was in use at eight sites (including the original site and seven new sites) from 2018-2020. The percentage of interpretable photographs for each protocol and for each clinical site was measured and compared.

Results: 1377 photographs were taken using the one-image protocol and 928 (67.4%) were deemed interpretable. 3804 photographs were taken using the two-image protocol and 3009 (79.1%) were deemed interpretable (Figure 1). This was a statistically significant improvement ($X^2 = 237.29$, p-value < 0.001). When the 2018-2020 retinal screening exams were compared between the original site and new sites, there was no statistical difference in percentage of interpretable photos ($X^2 = 2.46$, p-value = 0.11), (Table 1).

Conclusions: Adding a second field of view yielded a greater percentage of interpretable photographs, which suggests that the two-image protocol may have helped minimize the impacts resulting from multiple additional clinical sites and varying photographer experience.

TITLE: Transcorneal electrical stimulation slows down visual field decline in retinitis pigmentosa in a current-strength-dependent manner

SESSION TITLE: Retinitis pigmentosa: clinical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Stett, Okuvision GmbH, Reutlingen, GERMANY|J. Franklin, Institute of Medical Statistics and Computational Biology, University of Cologne, Koeln, GERMANY|F. Gekeler, Department of Ophthalmology, Klinikum Stuttgart Katharinenhospital, Stuttgart, Baden-Württemberg, GERMANY|A. Schatz, Centre for Ophthalmology, University Eye Hospital, Eberhard Karls Universität Tübingen, Tübingen, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure (Abstract): Alfred Stett: Commercial Relationship(s);Okuvision GmbH:Code E (Employment) | Andreas Schatz: Commercial Relationship: Code N (No Commercial Relationship) | Florian Gekeler: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Franklin: Commercial Relationship(s);Okuvision GmbH:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Transcorneal electrical stimulation (TcES) is a clinically available method to slow down disease progression in retinitis pigmentosa (RP). We hypothesize that the effect of TcES on the rate of visual field loss obeys a dose-response relationship with current strength.

Methods: In a prospective, randomized study (clinicaltrials.gov: NCT01837901), one eye of each of 52 subjects with RP was transcorneally stimulated weekly for 30 minutes over a period of 52 weeks with biphasic current pulses (OkuStim, maximum 1.2 mA, 5 ms each phase, 20 Hz). The visual field areas (VFA) were repeatedly assessed in both eyes (Octopus 900, Goldman targets III4e, V4e). Stimulation current strength was 0% (sham), 150% and 200% of the patient's electrical phosphene threshold in 3 randomized groups of patients, respectively. In addition to the primary analysis, where the effect of TcES on the stimulated eyes was analyzed in relation to randomized group (Schatz et al., IOVS, 2017, 58:1), in the now presented secondary analysis, the percentage reductions of the VFA of the stimulated (R_1) and non-stimulated eyes (R_0) after 52 weeks of stimulation were analyzed in relation to the actual current strength. Mean current strength over 52 weeks stimulation was analyzed both as a continuous variable (linear regression) and an ordinal variable (5 classes, Jonckheere-Terpstra test).

Results: As the current strength increased, the VFA (V4e) decreased more slowly, whereby there was a significant linear relationship ($p = 0.049$) and a significant ordinal relationship ($p = 0.011$) between the differences in percentage reduction, ($R_1 - R_0$), and the current strength. In the eyes stimulated with more than 0.8 mA ($n = 9$), R_1 was $0.7\% \pm 7.2\%$ (mean \pm SD) compared with R_0 of $8.8\% \pm 9.1\%$ in the non-stimulated fellow eyes (difference between both eyes: $p = 0.098$, Wilcoxon signed rank test). In the sham group ($n = 20$) the mean percentage reductions R_1 and R_0 were $7.0\% \pm 11.1\%$ and $7.0\% \pm 16.1\%$. Analysis of VFA III4e yielded in no significant effect of TcES.

Conclusions: Our results are consistent with the hypothesis that by TcES the decline in VFA in patients with RP can be slowed significantly in a current-strength-dependent manner. Furthermore, they provide additional evidence that TcES is an efficient method that can stop or delay the disease progression in RP.

TITLE: Transdermal application of glycerol monolaurate ointment improves signs and symptoms of dry eye disease

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Flanagan, J. Diec, N. Yeotikar, D. Tilia, BHVI, Sydney, New South Wales, AUSTRALIA|J. Flanagan, D. Tilia, University of New South Wales School of Optometry and Vision Science, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Judith Flanagan: Commercial Relationship: Code N (No Commercial Relationship) | Jennie Diec: Commercial Relationship: Code N (No Commercial Relationship) | Nisha Yeotikar: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Tilia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine efficacy of transdermal glycerol monolaurate (GML) on signs and symptoms of dry eye disease (DED)

Methods: Participants (55; 78% female) with ≥ 1 expressible meibomian gland, and DED symptoms score >12 (OSDI) were randomly assigned to GML ointment (Lactic Acid 2%, GML 1% in petrolatum) or Control (White Petrolatum). Ointment was applied around the eye twice daily for 6 weeks. OSDI, blepharitis, meibum quality (MQ), meibomian gland expressibility (GE) were graded. Subjects were monitored at Wk1, 3 and 6 for changes relative to baseline (BL). Data were summarised as means \pm SD for variables on interval scales. Categorical variables were summarised as percentages. Subjective ratings and clinical grades were analysed using linear mixed models. Trial group differences were analysed at each visit if there was a significant interaction. Post hoc multiple comparisons were adjusted using Bonferroni's correction.

Results: There was no significant difference at BL between groups for any demographic, or physiological variable (all $p>0.05$). Significant reduction in OSDI was observed at Wk1 for both GML ointment and Control ($p=0.001$). Relative to Wk1, by Wk6 GML ointment showed further improvement in OSDI ($>65\%$, $p=0.003$) and GE ($p=0.003$) and approached significance in improvement in blepharitis ($p=0.051$) with no such improvements in Control. GML ointment showed greater improvement in OSDI at all visits compared to Control ($p\leq 0.038$). For subjects presenting with severe disease (≥ 4 out of 5 clinical signs) there was significant improvement in OSDI from BL over 6 weeks with GML ($p=0.009$) with $>72\%$ improvement relative to BL, and worsening with Control ($p=0.048$). Compared to Control, OSDI items relating to increased evaporation were significantly improved with GML ointment: windy conditions ($p=0.035$), low humidity ($p=0.030$), air conditioning ($p=0.022$). By Wk6, $>93\%$ subjects showed improvement with GML ointment for those subjects with worse BL GE (>1) ($p=0.001$) and >4 clinical signs ($p=0.003$) with no such improvement in Control.

Conclusions: Despite $>84\%$ of subjects presenting with only mild DED, the GML group achieved a minimal clinically important difference over 6 weeks, effecting improvement in signs and symptoms relative to degree of DED at BL suggesting greater benefits relative to worse dry eye at presentation.

TITLE: TNF α -RUNX1 Pathway Regulates Retinal Endothelial Cell Survival and Response to Oxidative Stress

SESSION TITLE: Biochemistry and molecular biology of the retina

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Whitmore, D.Y. Shu, M. Saint-Geniez, L.A. Kim, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|H. Whitmore, D.Y. Shu, M. Saint-Geniez, L.A. Kim, Harvard Medical School Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hannah Whitmore: Commercial Relationship: Code N (No Commercial Relationship) | Daisy Shu: Commercial Relationship: Code N (No Commercial Relationship) | Magali Saint-Geniez: Commercial Relationship: Code N (No Commercial Relationship) | Leo Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pro-inflammatory cytokine TNF α is increased in several angiogenic retinal diseases, including proliferative diabetic retinopathy (PDR). Our research on human micro-vascular retinal endothelial cells (HMRECs) has shown that high glucose and TNF α stimulation cause an additive effect on Runt-related transcription factor 1 (RUNX1) expression. This study aims to determine the role of RUNX1 in the modulation of the TNF α -stimulated oxidative stress response.

Methods: HMRECs were treated in supplemental growth factor free media for between 1 and 72 hours with D-glucose (30 mM), TNF α (5 ng/ml), RUNX1 inhibitors and combinations of these. Effects on gene expression were assessed by qRT-PCR. The Seahorse XF24 Mito Stress Test was used to determine the effects of these treatment conditions on mitochondrial respiration. One-way ANOVA was used for statistical analysis.

Results: TNF α +glucose significantly reduced both the spare ($p < 0.0001$) and maximal ($p < 0.01$) respiration capacity while increasing oxygen consumption ($p < 0.05$) in the Mito Stress Test. Additionally, after 48 hours TNF α significantly increased the expression of TNF-R1 (1.3 ± 0.1 fold, $p < 0.05$), while co-treatment of TNF α and RUNX1 inhibitor brought RUNX1 and TNF-R1 to basal levels (1.2 ± 0.2 fold, ns; and 0.9 ± 0.1 fold, ns; respectively). Superoxide dismutase 2 (SOD2) mRNA expression is significantly increased by TNF α +glucose stimulation (6.1 ± 0.1 fold, $p < 0.0001$, 48h). SOD2 expression is also increased by TNF α alone over a 1 - 72h timecourse analysis (5.7 ± 0.2 fold, $p < 0.0001$, 48h) and significantly reduced by RUNX1 inhibition (0.79 ± 0.1 fold, $p < 0.05$, 48h). In contrast, BCL-2 mRNA is upregulated with RUNX1 inhibition (1.4 ± 0.2 fold, $p < 0.005$, 48h).

Conclusions: These results suggest that while TNF α and glucose reduce mitochondrial respiratory capacity, inducing oxidative stress, SOD2 is significantly upregulated by TNF α -RUNX1 signaling and downregulated via RUNX1 inhibition. This indicates that SOD2 is acting as a protective factor to remove toxic superoxide in the presence of pro-inflammatory TNF α . Moreover, further pro-survival compensatory mechanisms appear to counter the decrease in SOD2 expression due to RUNX1 inhibition, via upregulation of anti-apoptotic BCL-2. This results in greater cell survival capability, even in a high oxidative stress environment.

ABSTRACT BODY:

Purpose: The KCNJ13 gene encodes the inwardly rectifying potassium channel Kir7.1. Nonsense mutations in this gene are known to cause Leber Congenital Amaurosis 16 (LCA 16), leading to early-onset vision loss. This form of autosomal recessive blindness is characterized by severe vision impairment, nystagmus, and photophobia in the pediatric population. We previously demonstrated a readthrough of the Kir7.1 restored the channel function. In this study, we tested the effect of treating the KCNJ13 nonsense mutation W53X with the novel eukaryotic ribosome selective glycoside compounds ELX-01 and ELX-03.

Methods: Human Embryonic Kidney (HEK293T) cells were plated on a 35mm culture dish until 60-70% confluence. Cells were then transfected with a plasmid carrying KCNJ13 nonsense mutation at 53rd amino acid (c.158G>A, W53X) and fused with Green Fluorescent Protein (GFP). After 24 hours of transfection, the cells were incubated with readthrough compounds ELX-01 and ELX-03 at 1mM for additional 24 hours. The cells were transferred to glass coverslips for whole-cell patch-clamp electrophysiology. Ringer's solution was continuously perfused as an external solution. Rubidium (Rb+) -Ringer's solution was used to test the Kir7.1 channel function.

Results: Detection of GFP fluorescence in GFP tagged W53X transfected HEK293T cell membranes confirmed Kir7.1 protein expression. Previously demonstrated, W53X transfection resulted in non-measurable Kir7.1 current because of the truncated protein product. After we treated these cells with ELX-01 and ELX-03 at 1 mM concentration, the current-voltage curve showed inward rectifying Kir7.1 current. The maximum inward current measured at -160 mV was -90.63 ± 8.23 pA and -68.66 ± 30.56 pA, respectively, compared to only -18.61 ± 7.23 pA without the drug treatment. Upon substitution with Rb-Ringer, the maximum current amplitude did not change in non-treated cell measuring -18.92 ± 5.18 pA but increased to -502.93 ± 50.65 pA, a ~5.64-fold increase with ELX-01 treatment. Similarly, ELX-03 increased the maximum current to -768.02 ± 137.84 pA, representing a ~7.1-fold increase.

Conclusions: Both ELX-01 and ELX-03 are able to restore the translation of full-length and functional Kir7.1 channels in HEK cells. Further evaluation of these compounds will ensure readthrough effects on LCA16 patient-derived iPSC-RPE and mouse models for preclinical validation.

TITLE: Association of Punctocanthal Epitheliopathy in Dry Eye Syndrome Secondary to Meibomian Gland Dysfunction

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.V. Greiner, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|J.V. Greiner, P. Oliver, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|P. Oliver, Clinical Eye Research of Boston, Winchester, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jack Greiner: Commercial Relationship: Code N (No Commercial Relationship) | Paula Oliver: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study extends our preliminary report describing an epitheliopathy of the often overlooked punctocanthal region (PCR) of the eyelid margins and further establishes its association with dry eye syndrome (DES) secondary to meibomian gland dysfunction (MGD). The PCR of the eyelid margins extends from the puncta to the nasal canthus.

Methods: Symptomatic dry eye patients (Group 1;n=100] had SPEED symptom scores of ≥ 6 and meibomian gland assessment (MGA) scores ≤ 12 . The degree of MGD was measured according to methods previously described using a Meibomian Gland Evaluator to determine the secretory status of 15 meibomian glands of the lower eyelid (Greiner: Cur Eye Res 2012;37:272). Asymptomatic patients (Group 2;n=100) had SPEED scores < 6 and MGA scores ≥ 20 . Lid margins were stained with lissamine green (LG) and graded after 90s on a scale of 0-3. A grade of 0 indicated staining of the Line of Marx (LM) only and 3 indicated severe staining extending from the LM posteriorly in the sagittal plane up to > 1.25 mm. Comparative grading was made on the temporal, central, and nasal lid margin over the tarsal plate as well as the lid margin over the PCR. Statistical analyses included Student's t-test with $P < 0.05$ as significant.

Results: The PCR occupies up to 1/5 of the length of the lid margin and is slightly larger in the upper lid (UL) [$P < 0.05$]. Punctocanthal epitheliopathy (PCE) was greater than the lid wiper epitheliopathy (LWE) over the temporal, central, and nasal tarsal regions in the UL and lower eyelids (LL) in both Groups 1 and 2 ($P < 0.001$). The PCE staining was greater in the LL than in the UL in both Groups 1 and 2 ($P < 0.001$) and there was greater staining in Group 1 ($P < 0.001$).

Conclusions: PCE was greater in symptomatic dry eye patients with MGD than in asymptomatic patients with minimally detectable MGD. Although the PCE staining pattern resembles that of LWE, LG staining was greater in PCE. The PCR experiences inherently different lid mechanics than that of the conventional lid wiping action. The location and minimal motion of the PCR preclude PCE resulting from mechanical wiping of the lid margin as in LWE. PCE more likely results as a consequence of evaporation since this portion of the UL and LL margins may not undergo complete closure with blinking or sleeping. These observations support the hypothesis that PCE is a clinically relevant and readily observable marker of DES.

TITLE: A Minimally Invasive Approach to Electrically Stimulating the Optic Nerve to Direct Retinal Ganglion Cell Axon Regeneration

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Gokoffski, J. Paknahad, G. Lazzi, Electrical Engineering, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kimberly Gokoffski: Commercial Relationship: Code N (No Commercial Relationship) | Javad Paknahad: Commercial Relationship: Code N (No Commercial Relationship) | Gianluca Lazzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A critical barrier to regenerating the optic nerve is directing long distance growth of damaged retinal ganglion cell (RGC) axons. We have generated significant evidence that suggests that the application of electric fields (EFs) may be a viable approach for promoting optic nerve regeneration. Here, we present an approach involving computational modeling paired with ex vivo and in vivo experiments to develop minimally invasive approaches to improve the voltage gradient along the electrically stimulated optic nerve.

Methods: We employed our AM/NEURON computational modeling tool to test different electrical stimulation strategies for improving the voltage gradient along the optic nerve. Ex vivo experiments with Long Evan rats were then performed for verification of computational predictions. Finally, we tested our best model in vivo using the optic nerve crush model. Electrodes were implanted and optic nerves were crushed. One week after crush, optic nerves were exposed to an asymmetric charge-balanced biphasic waveform for 5 hours daily x 10 days. Regenerative response past the crush site in stimulated animals was assessed by quantifying the number of axons at various distances past the injury site and compared to controls.

Results: Computational modeling showed the largest and most linear voltage gradient with the proposed stimulation setup. Ex vivo experiments showed that this setup generated an EF nearly 1.5X higher in amplitude compared to the intra-orbital/cranial electrodes (Voltage gradients: 176.5 ± 10.7 vs 102.7 ± 15.9 mV/mm (cathode); 80.7 ± 7.6 vs 35.6 ± 5.2 mV/mm (anode); $p < 0.0002$ and $p < 0.003$ respectively, $n=3$). Preliminary in vivo experiments showed that the minimally invasive set up was able to direct 3-fold more regeneration over controls, similar to rates directed by intra-orbital/cranial electrodes ($n=1$).

Conclusions: Here, we show that minimally invasive electrodes are more effective at generating an EF along the optic nerve compared to intra-orbital/cranial electrodes. Moreover, these electrodes are able to direct RGC axon regeneration after degeneration from crush injury has set in. This has important implications as there may be a delay between when patients develop optic neuropathies and their ability to receive care.

TITLE: The relationship between Multifocal Electroretinogram Implicit Times, Blood Glucose and Blood insulin in Patients with Diabetes and Prediabetes

SESSION TITLE: Electrophysiology: Advances, disease and injury

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Smith, C. Chao, K. Richdale, W.W. Harrison, University of Houston College of Optometry, Houston, Texas, UNITED STATES|T. Zderic, M. Hamilton, Health and Human Performance, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jennyffer Smith: Commercial Relationship: Code N (No Commercial Relationship) | Cecilia Chao: Commercial Relationship: Code N (No Commercial Relationship) | Ted Zderic: Commercial Relationship: Code N (No Commercial Relationship) | Marc Hamilton: Commercial Relationship: Code N (No Commercial Relationship) | Kathryn Richdale: Commercial Relationship: Code N (No Commercial Relationship) | Wendy Harrison: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Blood glucose (Bgl) concentration is known to have effects on retinal function testing, such as the multifocal electroretinogram (mfERG). Insulin is also known to impact pathophysiological processes in diabetes. However, there are no studies showing the relationship between insulin and retinal function at the time of testing. The purpose of this study is to assess the relationship between endogenous insulin and Bgl levels on mfERGs implicit times (IT) and amplitudes (Amp) in controls and subjects with pre-diabetes and diabetes (DM).

Methods: Forty-nine subjects participated in this cross-sectional study; 15 controls (HbA1c under 5.7%), 21 with pre-diabetes (HbA1c 5.7-6.4% with no DM medications), and 13 with type 2DM (HbA1c over 6.4% or on DM medications; average HbA1c 7.3%). Testing included endogenous insulin, Bgl, and HbA1c, all gathered within 15 minutes of mfERG testing. The last meal and time were surveyed. MfERG (VERIS) was completed on the right eye with 103 hexagons at near 100% contrast with a 4-minute m-sequence and a Burian-Allen electrode. MfERGs were evaluated for IT and Amp over the entire eye and at the fovea. Regression analyses, controlled for age, were used to determine associations between mfERG and blood analyses.

Results: There were significant associations between longer whole eye and foveal mfERG IT and higher Bgl ($r^2 = 0.17$ $p=0.012$; $r^2 = 0.11$ $p=0.05$). There was no relationship between insulin level and mfERG IT or Amp, but insulin was a confounder of the relationship between Bgl and IT. Including insulin in the model strengthens the relationship ($r^2 = 0.18$ $p=0.010$; $r^2 = 0.14$ $p=0.03$) for the whole eye and fovea, respectively. If Bgl and insulin are considered as a ratio (bgl/insulin) rather than independent factors, its relationship to IT is significant for the fovea ($r^2 = 0.18$ $p=0.045$), but not the whole eye ($p=0.42$). There was no relationship with mfERG Amp in any of these comparisons.

Conclusions: This study indicates that while Bgl is the most powerful influencer of retinal function in diabetes and prediabetes, insulin dysfunction may play a role. Insufficient insulin may be an important consideration for foveal health. Further studies with fasted participants and a wider range of HbA1c values are needed to determine insulin's implications in diabetic retinal neuropathy and retinopathy prevention.

ABSTRACT BODY:

Purpose: To evaluate the effectiveness of horizontal eyelid tightening and fornix suture placement in the surgical management of lower eyelid involutional entropion.

Methods: This retrospective study reviewed 602 lower eyelids (484 patients) with involutional lower eyelid entropion who underwent surgical repair between August 2010 through September 2020 in a community subspecialty oculoplastics practice. All patients were followed for greater than three months postoperatively. Exclusion criteria included inadequate follow up or multi component lower eyelid entropion. ICD 9 code 374.01 and ICD 10 codes H02.032 and H02.035 were used to identify charts for review.

Results: 658 patient charts were reviewed with a diagnosis of lower eyelid involutional entropion. Of these, 602 eyelids of 484 patients (56% male, 44% female; age range 50-100 years old, 98% >60 years of age; 52% left lower eyelid, 48% right lower eyelid) underwent entropion repair combining horizontal eyelid tightening with full thickness forniceal (Quickert) sutures. With at least three months follow up (range 3-60 months), the recurrence rate of lower eyelid entropion was 1.2% (7/602 eyelids). Of these recurrences four out of the seven were noted to have significant enophthalmos preoperatively. Another 1.2% (7/602 eyelids) developed sequential ectropion, which required surgical correction between one and twelve months following the original surgery. Suture abscesses, while uncommon, were present in 1.8% (11/602 eyelids) and managed with oral and/or topical antibiotics. Four of those patients underwent removal of the Quickert sutures. None of these cases resulted in recurrent entropion.

Conclusions: Horizontal lower eyelid tightening and Quickert (fornix) sutures are a reliable and effective management of lower eyelid involutional entropion with low recurrence and complication rates. We believe this is the largest known review of the success of this procedure to date.

TITLE: Impact of Revised Phone Triage System on Clinician Callback Rate and Call Resolution Time in an Ophthalmology Resident-Run Urgent Care Clinic

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Langue, D. Cui, S. Athukorala, N. Kansara, M.L. Camacci, I.U. Scott, E.M. Bowie, Ophthalmology, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Langue: Commercial Relationship: Code N (No Commercial Relationship) | David Cui: Commercial Relationship: Code N (No Commercial Relationship) | Shavini Athukorala: Commercial Relationship: Code N (No Commercial Relationship) | Neal Kansara: Commercial Relationship: Code N (No Commercial Relationship) | Mona Camacci: Commercial Relationship: Code N (No Commercial Relationship) | Ingrid Scott: Commercial Relationship: Code N (No Commercial Relationship) | Esther Bowie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the impact of a revised phone triage system on clinician callback rate and call resolution time in an ophthalmology resident-run urgent care clinic.

Methods: The Penn State College of Medicine Institutional Review Board deemed this study exempt from review. The data intake form utilized by staff answering patient phone calls into the Penn State Eye Center urgent care clinic was revised to include more detailed information regarding patients' symptoms, and staff training regarding each item on the form was provided by a senior ophthalmology resident. Proportion of calls that required clinician callback to clarify patient concerns and median time for call resolution were compared between patient phone calls immediately prior to (n=360) and immediately following (n=360) implementation of the revised phone triage system.

Results: Proportion of calls that required clinician callback to clarify patient concerns was 55% prior to and 36% following implementation of the revised phone triage system ($p<0.001$), and median call resolution time decreased from 174 to 136 minutes ($p=0.435$).

Conclusions: Implementation of a revised phone triage system, including staff training and a more detailed data intake form, was associated with a significant decrease in the proportion of patient calls that required clinician callback to gather additional information and a substantial decrease in median call resolution time.

ABSTRACT BODY:

Purpose: Devastated gut microbiota is reported to be the substantial cause of GVHD. We previously reported the positive effect of gut decontamination using oral gentamicin (GM) administration in cGVHD model. As the molecular mechanism, we focused on cellular senescence and senescence-associated secretory phenotype (SASP) which promoted cGVHD in our previous report. Deoxycholic acid (DCA) and lipoteichoic acid (LTA); gram-positive gut bacterial metabolite and component each are known to promote cellular senescence and ursodeoxycholic acid (UDCA) is conversely known to suppress cellular senescence through the microbiome. The purpose of this study is to pursue the mechanism of relationship between cGVHD and microbiome by comparing cGVHD magnification and cellular senescence among cGVHD mice models treated with GM, UDCA, or GM+DCA+LTA.

Methods: Allogeneic BMT was performed to produce cGVHD mice by the bone marrow transplantation (BMT) from B10.D2. to BALB/c mice after the irradiation (7Gy). The cGVHD mice were treated per orally with GM, UDCA, GM+DCA+LTA or the solvent vehicle which was set to be the control. We performed 16S rRNA gene sequencing analysis of the gut microbiota, ocular examinations, histological investigations, immunohistochemical examinations, flow cytometry analysis and quantitative PCR at 4-week timepoints after BMT.

Results: Compared with cGVHD targeted organs (lacrimal glands, lungs, livers, large intestines) in vehicle-treated cGVHD mice, those in GM-treated cGVHD mice had fewer expression of DNA damage marker, senescent markers, SASP factors, and accumulation of LTA. 16S rRNA gene sequencing analysis of the gut microbiota revealed that the percentage of gram-positive bacterial strains was significantly decreased with GM treatment. Ocular examination, body weight reduction, and histological investigation of LGs were significantly improved in UDCA-treated cGVHD mice but these examinations in GM+LTA+DCA-treated cGVHD mice were worse than in cGVHD mice treated with GM only. The expressions of senescent markers and SASP factors in UDCA-treated LGs were suppressed compared with those in vehicle-treated LGs but cellular senescence was promoted in GM+DCA+LTA-treated LGs than in LGs treated with GM only.

Conclusions: Our results suggest that there could be an association between the gram-positive gut microbiome and development of cGVHD through cellular senescence.

ABSTRACT BODY:

Purpose: To quantitatively assess functional and structural features in non-vitrectomized and vitrectomized DME patients after being treated with a FAc implant and to evaluate their influence in DME treatment response.

Methods: A retrospective review was conducted involving patients with DME who received a single intravitreal injection of the FAc implant at the Centro Hospitalar Universitário do Porto, Portugal. The study was designed to analyze the presence of quantitative structural OCT biomarkers at baseline and 12 months after FAc therapy according to vitreous status: vitrectomized eyes (group 1) and non-vitrectomized eyes (group 2). The secondary objectives were to analyze differences in treatment response and the need for additional therapy as well as to correlate those biomarkers with response to therapy. A significant functional improvement was considered a gain of at least 5 ETDRS letters. DME resolution was defined by $CFT \leq 300 \mu m$. The type of response was classified as (1) good responder when at 12-months post-FAc implant there was DME resolution with a significant functional improvement without additional treatments; (2) non-responder, when there was a $CFT > 400 \mu m$ or $\leq 10\%$ of CFT reduction and BCVA decrease (or BCVA gain < 5 letters); (3) moderate responder - between good and non-responder criteria; (4) non-good responders include non-responders and moderate responders.

Results: A total of 41 eyes from 30 patients were included in this study. At 12 months post-injection, group 1 patients had a lower central foveal thickness (CFT, $p=0.017$) and fewer hyperreflective dots (HRD, $p=0.028$) compared with group 2. Concerning the response, 30 (73%) patients presented a significant functional improvement with 17 (42%) having an increase of at least 15 ETDRS letters. Lower baseline BCVA and baseline SRF ($p=0.036$) were associated with an increase of at least 15 ETDRS letters ($p=0.012$). Overall, 13 (32%) eyes were judged to be good responders and 3 (7%) bad responders; therefore, 61% of eyes had a moderate response. Patients who needed additional therapy had a higher prevalence of subretinal fluid (SRF, 42% vs 3% $p=0.005$) at baseline.

Conclusions: This study supports the effectiveness of the FAc implant in the treatment of persistent or recurrent DME and reports significant changes in several SD-OCT parameters at 12 months post-FAc injection.

TITLE: Monofocal, Diffractive Trifocal and EDOF IOLs

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Xie, G. Lau, Surgical R&D, Bausch and Lomb, Clearwater, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jihong Xie: Commercial Relationship: Code N (No Commercial Relationship) | George Lau: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Using optical raytracing simulation method to model and compare the optical performance of intraocular lenses (IOLs) with three optical designs.

Methods: Different optical design technologies were adopted in creating three types of IOLs. The monofocal baseline model is designed with conventional aspherical surface which provides appropriate spherical aberration compensation for the cornea; the trifocal IOL is designed with diffractive trifocal structure added to the monofocal baseline which provides 1.65D (intermediate) and 3.3D (near) add power at the IOL plane; and the extended depth of focus (EDOF) IOL is designed with zonal modification of the baseline monofocal surface, which includes three concentric refractive zones with individually optimized power and spherical aberration combinations. The EDOF IOL targets to extend depth of focus to 1.65D (IOL plane) to match the intermediate focus of the trifocal model. The imaging property of three IOLs are modeled and compared in an optical model eye using optical raytracing, and optical through focus performance were analyzed in terms of MTF, Visual Acuity simulation and Point Spread functions (PSF).

Results: Figure 1 provides visual acuity simulation with incremental defocus introduced to the model eye, which indicates:

a) Monofocal baseline provides the highest image contrast (MTF) at distance focus, however diffractive trifocal and EDOF show good and comparable distance vision, e.g. VA 20/20 or better

b) Diffractive trifocal and EDOF have similar intermediate visual acuity performance, e.g., 0.2 LogMAR (20/30) or better at defocus ~1.25D/80cm, ~1.5D/66cm

Diffractive trifocal provides near vision up to 2.5D/40cm, however, due to the nature of diffractive design, the trifocal presents “gaps” (phase reversal) in the defocus curves, which may contribute to vision fluctuation. EDOF design does not show this side effect. Figure 2 further illustrates the mentioned point by PSF with incremental defocus (Top: EDOF, Bottom: D Trifocal). Star testing simulation also implies that “halo” is more visible for diffractive trifocal than for EDOF lens

Conclusions: Both EDOF and diffractive trifocal design can achieve high quality intermediate vision comparing to a baseline monofocal IOL, e.g., 0.2 LogMAR or better for defocus of ~1.25D/ 80cm ~1.5D/66cm. Between diffractive trifocal and EDOF, the EDOF provides superior image quality by greatly reducing the side effects of “halo” and focusing fluctuation.

ABSTRACT BODY:

Purpose: Inflammation is an early pathogenic event in diabetic retinopathy (DR). Activation of the cannabinoid-2 (CB2) receptor by endocannabinoids (eCB) promotes anti-inflammatory effects, suggesting potential therapeutic relevance in DR. 5,6-epoxyeicosatrienoic acid ethanolamide (5,6-EET-EA) is an eCB thought to reduce inflammation via CB2 activation. We investigated the potential of 5,6-EET-EA to mitigate DR-relevant inflammation, including adhesion protein expression and vascular permeability, both in vitro and in vivo.

Methods: Human Müller cells (HMC) were treated with 1ng/ml IL-1 β +/- 0.5 μ M 5,6-EET-EA and proper control reagents for 2hrs, washed, and treated again with 5,6-EET-EA or vehicle only for 6hrs to generate conditioned media (CM). Human retinal microvascular endothelial cells (HRMEC) were treated with CM for 2hrs before lysis for qRT-PCR analysis of cell adhesion proteins E-selectin (SELE), VCAM, and ICAM. Transendothelial electrical resistance was measured in HRMEC treated with 1ng/ml TNF α +/- 0.5 μ M 5,6-EET-EA. In vivo, mice were intravitreally injected with 15ng/ml TNF α +/- 0.5 μ M 5,6-EET-EA. Retinal vascular permeability was measured by quantitative fluorescein angiography (qFA) 6hrs after treatment.

Results: CM from IL-1 β -treated HMC increased expression of SELE by 63-fold, VCAM by 90-fold, and ICAM by 3.8-fold in HRMEC ($p < 0.001$). When 5,6-EET-EA was present during IL-1 β treatment of HMC, the CM reduced these induction levels in HRMEC by 58% for SELE, 66% for VCAM, and 39% for ICAM ($p < 0.001$). TNF α decreased HRMEC monolayer resistance by 15% 4hrs after treatment ($p < 0.001$). 5,6-EET-EA restored 68% of the deficit after 12hrs of treatment ($p < 0.001$) to levels comparable with controls ($p = 0.881$). In vivo, TNF α caused a 4-fold increase in vessel leakage ($p = 0.009$), whereas 5,6-EET-EA rescued TNF α -induced leakage to near-control levels ($p = 0.029$ vs. TNF α , $p = 0.739$ vs. control).

Conclusions: Our results indicate that 5,6-EET-EA offers anti-inflammatory relief of DR-relevant damage at multiple endpoints. 5,6-EET-EA reduced expression of multiple adhesion proteins in HRMEC stimulated by DR-relevant inflammation, and it decreased vascular permeability in both HRMEC and an acute model of retinal inflammation in vivo. Administration of exogenous eCB and/or CB2 activation may serve as valuable anti-inflammatory therapies for early-stage DR treatment.

TITLE: Slit-scanning ophthalmoscopy to measure ultra-widefield peripheral refraction along nasal/temporal and superior/inferior meridians

SESSION TITLE: Refractive control: Molecular and Anatomical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.G. Foote, C. Leahy, M. Everett, J. Straub, Carl Zeiss Meditec Inc, Dublin, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Katharina Foote: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Conor Leahy: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Matt Everett: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment) | Jochen Straub: Commercial Relationship(s);Carl Zeiss Meditec, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: Autorefractors typically measure over a limited range of visual field angles. Retinal imaging, particularly ultra-widefield (UWF) imaging, has demonstrated utility in visualizing the periphery. UWF slit-scanning ophthalmoscopes can measure peripheral refraction over a wider field of view (FOV) and are faster and easier to use than open-field autorefractors. A prospective study was performed to examine UWF imaging feasibility to extend peripheral refraction measurement range to a full 130°.

Methods: A modified widefield slit-scanning ophthalmoscope (CLARUS™ 500, ZEISS, Dublin, CA) with prototype software was used to test 5 subjects with spherical equivalent refractions ranging from -12.25D to 0.00D. In order to capture overlapping 90° fields, images were acquired with the internal fixation at central position, and then with $\pm 20^\circ$ offsets along each meridian. The vertical component of refraction over the full FOV was determined from the slit-scan data. Fundus features were used to co-register and merge the fields, resulting in a 130° peripheral refraction map.

Results: An extended view of UWF peripheral refraction was obtained for emmetropic and myopic subjects. In Fig 1, a sample UWF absolute peripheral refraction map is shown. In Fig 2, relative peripheral refraction along the full nasal/temporal and superior/inferior meridians is displayed. These measures were computed from an average of 1° strip for each subject. Most myopic subjects show characteristic relative peripheral hyperopia along the nasal/temporal meridian and relative myopia along the superior/inferior meridian. Lid/lash artifacts prevented a full range of measurements in superior/inferior regions.

Conclusions: This study demonstrated a capability of providing data on an unprecedented FOV. Peripheral refraction measurements acquired on myopic eyes followed established trends. Consistent with literature, this study showed hyperopia increases more in the nasal/temporal field than in the superior/inferior field. This measurement technique could be useful for enhancing research in the field of myopia.

ABSTRACT BODY:

Purpose:

Telemedicine diabetic retinopathy (DR) screening has become increasingly valuable in underserved communities. Poor photo quality significantly hampers screening efforts and can occur due to technical error or pathologies such as cataract, small pupils, or even vitreous hemorrhage. We performed a retrospective study to determine the final diagnoses at an in-person dilated fundus exam of patients who had ungradable telemedicine screening exams. We then compared them to patients with gradable screening exams.

Methods: From March 2018 to March 2020, we evaluated 1902 adult patients with diabetes who presented to one of several primary clinics in North Philadelphia. Non-dilated fundus photos were taken by a trained technician and read remotely by an optometrist. Patients who screened positive for DR, or had ungradable images due to poor view of the fundus were referred to an ophthalmologist for a dilated fundus exam. Initial screening results were compared to final diagnoses, and statistical analyses were performed using Fisher's exact test.

Results:

133 patients attended a follow-up appointment, of which 48 (36%) were referred for DR and 85 (64%) for ungradable images (Table 1). 33/48 (69%) patients who had DR on screening had some degree of DR on the final exam, although only 17/48 (35%) received the same grading on both exams. In comparison, only 16/85 (19%) patients who had ungradable photos had DR on their final exam ($p < 0.001$).

Of those who had ungradable images who did have DR on final diagnosis, there was a significant difference in distribution of disease severity compared to those who had gradable images (Table 2; $p = 0.039$). In those with ungradable images, there was a higher percentage of patients that had proliferative DR (44% vs. 15%) and a lower percentage that had mild NPDR (19% vs. 52%). However, the result was only marginally significant due to small sample size when the 1 unspecified DR patient was removed ($p = 0.057$).

Conclusions: Telemedicine is less effective in identifying patients who have DR when the image is ungradable. However, these patients may present with more severe pathology that worsen image quality, highlighting the importance of follow-up in these patients.

ABSTRACT BODY:

Purpose: To investigate short term changes of axial length (AxL), visual acuity (VA), contrast sensitivity (CS) and halo size with simulated 2-zone centre distance bifocal contact lens designs, with positive (+ve) defocus of different magnitudes, produced with adaptive optics (AO).

Methods: An AO system allowed subjects to view a micro-display through the simulated optical designs while AxL and vision performance were measured. 16 young subjects had AxL measured by a Lenstar before and after 40 mins of watching a movie on the micro-display through five AO induced optical designs (control, +3 DS and three 2-zone bifocal designs) (Figure 1). 8 subjects participated in the VA study, 4 in the CS study and 5 in the halo study. For VA, CS and halo tests, a 2-zone bifocal was used with a central distance zone of 2.5 mm and peripheral plus ranging from +1 to +10 D. For VA, high-contrast tumbling E letters were displayed on the AO system micro-display. The E letter for CS tests had three sizes of 0.3, 0.4 and 0.65 logMAR. Halo size measurements for the bifocal designs were performed through a split channel setup in the AO system.

Results: Greatest AxL reductions occurred for +3 D defocus and the bifocal design with peripheral +6 D (both $p < 0.005$). The +6 D periphery design also produced greater shortening of AxL compared to the +3 D periphery ($p < 0.001$). Increasing +ve defocus in the periphery caused a loss of VA ($F = 14.11$, $p < 0.005$) (Figure 2). However, the peak loss of VA occurred at about +2 D peripheral defocus and improved slightly for higher levels of defocus. The effect of increasing peripheral defocus on CS varied with the size of the test letter ($F = 57.84$, $p < 0.005$). For the largest letter, the effect of increasing +ve defocus was minimal, whereas for smaller letters, increasing peripheral +ve defocus continued to decrease CS. When the clear central zone size was fixed, higher plus power in the periphery was found to produce a larger halo.

Conclusions: Increasing peripheral plus power in a 2-zone simulated bifocal caused a greater reduction in short-term AxL. The peak loss of high contrast VA occurred at relatively low levels of peripheral defocus, whereas the loss of CS increased for smaller letter targets, as the defocus increased. Halo size increased with increasing peripheral plus defocus.

ABSTRACT BODY:

Purpose: To measure the Stiles-Crawford effect (SCE) with innovative technology to evaluate the changes in the directionality and photoreceptor alignment with accommodation.

Methods: A uniaxial Maxwellian system (spot size in pupil 0.5 mm diameter) was employed incorporating a spatial light modulator (Kopin SLM KCM-SK01-AA CyberDisplay®) to flicker at 2 Hz between two 2.3° fields corresponding to test (peripheral pupil) and reference (pupil center) positions. The participant's task was to determine thresholds at 13 positions along the horizontal pupil meridian by indicating if the test field was brighter or dimmer than the reference field. Thresholds were determined by a simple staircase procedure after four reversals at each pupil location. After dilating right eyes with 2.5% phenylephrine, seven emmetropes were tested at 0 D to 6 D accommodation stimulus levels in 2 D intervals. The data were fit by the Gaussian function, both if the fits were unforced or forced to pass through the threshold expected for the reference point. The directionality (ρ) and peak location values (x_{\max}) were compared for unforced and forced fits.

Results: As there were only small differences between the two fitting approaches, only unforced fits are mentioned in the text. The regression slopes on accommodation stimulus were not significant ($-0.0001 \text{ mm}^{-2}/\text{D}$, $R^2=0.0002$, $p = 0.94$) (Fig 1). There was a tendency for (x_{\max}) to shift temporally with increasing accommodation across the 6 D stimulus range. While this was not significant for regression fitting ($-0.058 \text{ mm}/\text{D}$, $R^2 = 0.06$, $p = 0.20$) (Fig 2), a paired t-test for 0 and 6 D accommodation stimuli showed significant change of 0.62 mm ($t(6) = 2.50$, $p = 0.046$).

Conclusions: The directionality did not change with accommodation, but the pupil peak location showed a significant temporal shift of approximately 0.62 mm with 6 D accommodation stimulus. It is possible that substantial changes in the directionality and a shift in the direction of peak location might occur at very high levels of accommodation.

TITLE: Corneal mechanical sensitivity in individuals with chronic pain

SESSION TITLE: Cornea Trauma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Baksh, University of Miami, Coral Gables, Florida, UNITED STATES|C. Lieux, A. Galor, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Brandon Baksh: Commercial Relationship: Code N (No Commercial Relationship) | Caroline Lieux: Commercial Relationship: Code N (No Commercial Relationship) | Anat Galor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine corneal mechanical thresholds in individuals with chronic pain using a Belmonte aesthesiometer.

Methods: We performed a cross-sectional study of South Florida veterans with chronic pain conditions (>3 months duration) seen at an eye clinic. Individuals were split into two groups based on the location of their pain: Group 1 included individuals with chronic pain conditions that involved the trigeminal system (e.g. migraine, burning mouth syndrome, trigeminal neuralgia, and trigeminomandibular disorder) while Group 2 included individuals with chronic pain conditions that did not involve the trigeminal system (e.g. back pain, knee pain). Dry eye symptoms and signs, systemic co-morbidities, and quality of life indices were also assessed via standardized questionnaires. Corneal mechanical thresholds were assessed using a modified Belmonte aesthesiometer. Our main outcome measure was comparison of mean corneal mechanical thresholds between our two groups via the independent t-test. Multivariable linear regression analysis was also performed to evaluate predictors of corneal mechanical threshold (dependent variable) while considering multiple independent variables (e.g. demographics, pain location, dry eye symptoms, signs, co-morbidities, quality of life). All reported p-values are two-tailed and $p < 0.05$ was considered statistically significant.

Results: The mean age of the 577 individuals included in the study was 61 ± 10.5 years; 89% were male, 45% self-identified as white, and 25% as Hispanic. Mean corneal mechanical threshold was lower among individuals with chronic trigeminal pain ($n=123$) compared to those without ($n=454$), 75 ± 43 vs 86 ± 43 mL/min, $p=0.015$. Multivariable analysis on 320 individuals with data for all variables demonstrated quality of life questionnaire scores (standardized $\beta = -0.49$, $p=0.002$), dry eye symptoms ($\beta = -0.30$, $p=0.039$), and presence of chronic trigeminal pain ($\beta = -0.44$, $p=0.002$) remained significant predictors of corneal mechanical detection threshold, with an overall $R^2=0.34$ for the model.

Conclusions: Chronic trigeminal pain, worse quality of life, and dry eye symptoms predicted lower corneal mechanical thresholds (higher sensitivity). This suggests a link between chronic trigeminal pain, quality of life, and corneal sensitivity.

ABSTRACT BODY:

Purpose: To assess OCT and OCT angiography (OCTA) features in optic neuropathic diseases.

Methods: OCTA macular 6x6-mm and peripapillary 4.5x4.5-mm scans were obtained from the diseased eye of each patient and one eye of each normal participant, which included both structural and angiographic images. The flow signal was calculated using the split-spectrum amplitude-decorrelation angiography algorithm. The capillary density (CD) of peripapillary nerve fiber layer plexus (ppNFLP), vessel density (VD) of macular ganglion cell layer plexus (mGCLP) and macular superficial vascular complex (mSVC) were analyzed using a custom software with shadow removal, reflectance compensation and projection-resolved algorithms. The thickness of the peripapillary retinal nerve fiber layer (ppRNFL) and macular ganglion cell complex (mGCC), ganglion cell-inner plexiform layer (mGCIPL) was measured on structural OCT images.

Results: Nine patients (13 eyes) with optic neuropathy, including 8 eyes/6 patients with nonarteritic anterior ischemic optic neuropathy, 1 eye with posterior ischemic optic neuropathy, and 4 eyes/2 patients with pituitary tumor, and 31 age-matched normal participants were included. The ppNFLP CD, mGCLP VD, mSVC VD, and thickness of ppRNFL, mGCC, and mGCIPL were all significantly reduced in eyes with optic neuropathies (Table 1). The OCTA diagnostic accuracy of optic neuropathic disease, measured by the area under the receiver operating curve (AROC), was 0.921 for ppNFLP CD, 0.868 for mGCLP VD, 0.841 for mSVC VD (sensitivity at 95% specificity was 84.6%, 69.2%, and 53.8%, respectively). For structural OCT parameters, the AROC was 0.809, 0.921, and 0.834 for ppRNFL, mGCIPL, and mGCC thickness, respectively (sensitivity at 95% specificity was 61.5%, 92.3%, and 61.5%, respectively). The patterns of loss on OCT and OCTA maps correlated well with visual field (VF) (Figure 1). The ppNFLP CD had the best correlation with VF mean deviation, then the thickness of ppRNFL, mGCIPL, mGCC, and the VD of mSVC, and mGCLP (Pearson's $r = 0.793, 0.737, 0.721, 0.689, 0.626, 0.589$, respectively, all $P < 0.001$).

Conclusions: OCT and OCTA provide detailed visualization of the peripapillary and macular retinal changes, which correlate well with visual field loss. The patterns of loss could be useful for the diagnosis and classification of optic neuropathies, while the quantification of thickness and perfusion parameters could be useful for assessing disease severity and progression.

ABSTRACT BODY:

Purpose: Type 1 Diabetes Mellitus (T1DM) is a lifelong autoimmune disease that places individuals at risk for macrovascular as well as microvascular complications such as diabetic retinopathy (DR) which may lead to vision loss. Foveal Density (FD), which takes into consideration vascular branching complexity, may be a better indication of retina health than Foveal Avascular Zone (FAZ), a standard currently used.

Methods: Data from 122 subjects (8-78 years, 33% male) (109 T1DM, 13 non-T1DM) collected over a period of up to 5 years (2015-19). Demographics included age, onset of DM, and self-reported HbA1c. Measurements of the FAZ and FD were calculated from 3mm x 3mm scans with the Optovue AngioVue HD on the RTVue XR Avanti OCTA (Fremont, CA). Statistical analyses included linear regression, multivariable linear regression, and paired T test, completed in SPSS.

Results: Significant negative correlation was found between duration of diabetes and FD OU ($p=.00039$) with no correlation found with FAZ OU ($p=.60$), insulin pump use, duration of pump use, or onset of T1DM. We noted significant negative correlation between average HbA1c and FD OU ($p=.010$) compared to FAZ OU ($p=.95$). Mean FAZ and FD for non T1DM subjects were .281 and 50.8, respectively, mean FAZ and FD for T1DM were .238 and 49.2. No significant difference was found in either FAZ or FD between T1DM/non-T1DM groups (FAZ $p=.129$, FD $p=.069$). In a subgroup of 12 (75% T1DM, age 17-72 years) subjects for which we had FAD and FZ measurements spanning 5 years, there was statistically significant decline found in FD OU over that period ($p=.006$) with no correlating statistically significant trend found in FAZ OU ($p=.06$).

Conclusions: While FD and FAZ have a close correlation, FD may be a more accurate representation of retinal health due to vascular branching complexity rather than measurement of the vascular margins. This demonstrates that FD is inversely proportional to HbA1c, suggesting vascular branching is more sensitive to tight glycemic control than expansion of the FAZ. Duration of diabetes was also identified as a possible influencer of declining FD in retinal health. Decline in FD has been reported in worsening retinal outcomes, making OCTA a valuable tool in assessing retinal health in both T1DM and non-T1DM populations. Baseline OCTA measurements at onset of T1DM management should be an integral part of routine ophthalmic care.

TITLE: Optic Nerve Head Elastography (ONH) for Detecting Glaucoma Progression

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Balasubramanian, A. Salehi, The University of Memphis Herff College of Engineering, Memphis, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Madhusudhanan Balasubramanian: Commercial Relationship: Code N (No Commercial Relationship) | Ali Salehi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Changes in stiffness of the micro-environment of the ONH region is a significant risk factor for onset and progression of glaucoma (Hopkins A, et al, Am J Physiol Cell Physiol 2020) . Deformation of the ONH or its strain is dependent on the elastic modulus of the constituent elements of the ONH. Therefore, ONH strain is a predictor of changes in the stiffness of its micro-environment or changes in the effective force acting in the ONH region. We present computational approaches for estimating ONH elastography measures from optical images of the retina.

Methods: Confocal microscopy images of a cow lamina cribrosa from an experimental glaucoma study were used (Balasubramanian M, et al, IOVS 2004). Cow eyes obtained fresh were cut equatorially and the posterior segments perfused in oxygenated Dulbecco's solution were positioned in a controlled pressure chamber specifically designed to clamp onto the focusing objective. Images of the lamina cribrosa were acquired 60 minutes after stabilizing the chamber pressure at 12 mmHg and 60 minutes after elevating the chamber pressure to 60 mmHg. Deformation field depicting structural changes in the lamina cribrosa was estimated from the successive confocal images using the equations governing patterns of brightness changes or optical flow. Specifically, the governing partial differential equations of optical flow (strong form) was solved using a multiscale finite element method with hierarchical basis functions. Several candidate descriptors of elastography namely a) absolute strain magnitude, b) maximum normal strain, c) maximum shear strain, d) Von Mises coefficient, e) vorticity (as a measure of rigidity), f) divergence (degree of expansion) and g) relative strain ratio were estimated.

Results: Figure 1 shows planar structural changes in the architecture of the lamina cribrosa estimated non-invasively using our computational approaches. Figure 2 shows elastography of the cow lamina cribrosa under experimental pressure elevations. From the elastography maps, it can be observed that the laminar beams are at elevated strain levels under pressure elevations.

Conclusions: Computational approaches are useful for non-invasively estimating ONH strain from optical images of the retina (elastography). These elastographic measures are likely to be useful for predicting onset and progression of glaucoma as well as for clinical management of glaucoma using standard optical scans of the retina.

ABSTRACT BODY:

Purpose: The impact of chronic inflammation on the retina in the absence of inheritable/acquired disease or trauma has not been widely investigated. We have previously shown, in a mouse model of chronic neuroinflammation (GFAP-IL6), that the number of microglia found in the retina is increased in response to chronic inflammation. Here, we assessed the impact of chronic neuroinflammation on retinal neurons themselves. Further, we evaluated efficacy of oral Meriva curcumin as a potential neuroprotectant.

Methods: The impact of inflammation on the retina was assessed by determining the length of the photoreceptor outer segments, thickness of outer nuclear layer (ONL) and inner nuclear layer (INL), and the density of cones. Heterozygous GFAP-IL6 mice (n=4), a model of chronic neuroinflammation, aged ~4 months were compared to their wild-type littermates (n=4). A separate cohort of GFAP-IL6 animals aged 4 months was treated with oral curcumin (n=5 ;140mg/kg) for 1 month (fed from 3 to 4 months) as a potential therapy to alleviate neuroinflammation.

Results: Chronic IL6 expression was found to cause a significant decrease in ONL thickness when comparing WT to GFAP-IL6 retinal sections, suggesting a loss of photoreceptors. Indeed, a reduction in overall cone density (labelled with peanut agglutinin) was observed in GFAP-IL6 mice although M-cone density (labelled with M-opsin) was unchanged suggesting S-cones are preferentially affected by chronic neuroinflammation. While rod photoreceptors may have been lost, no significant differences were seen in rod outer segment length between genotypes. There was a trend of reduced INL thickness, but this was not statistically significant. No obvious GFAP expression was observed in Müller cells in any group. However, significant GFAP staining could be found in astrocytes residing outside the inner limiting membrane although no obvious difference could be seen between groups. In the Meriva curcumin treated animals, both cone density and ONL thickness were indistinguishable from wild-types suggesting a significant neuroprotective effect.

Conclusions: Chronic inflammation leads to a reduction in cell bodies in the ONL as well as a reduction in cone density. Our results indicate that curcumin supplementation can protect the retina from these harmful effects of chronic neuroinflammation and may be a candidate to improve outcomes in patients with degenerative retinal disease.

ABSTRACT BODY:

Purpose: Macular Pigment Optical Density (MPOD) can be measured with Heidelberg Spectralis dual wavelength autofluorescence by setting the plateau reference at different perifoveal eccentricities, where the MPOD value is arbitrarily defined as zero. Previous studies have used different plateau references, and there is a lack of evidence whether the choice of plateau location affects MPOD measurements across various macular disorders. We compared the MPOD values obtained with 2 commonly used plateau references of 6° and 9° in non-advanced Age-Related Macular Degeneration (AMD) and control patients.

Methods: Cross-sectional study where we prospectively enrolled 295 eyes of 166 individuals; 210 with non-advanced AMD (19 early AMD, 191 intermediate AMD) and 85 controls (>50 years) after institutional IRB approval. Participants were imaged and classified with color fundus photographs for AMD (Age-Related Eye Disease Study classification). Imaging was performed using Heidelberg Spectralis dual wavelength autofluorescence. MPOD sum of volume at 2° (SoV-2°) values were calculated by setting plateau reference to 6° and 9°. A linear mixed-effects model was used to find association of the pairwise difference between SoV-2° values using 9° and 6° plateau references, with the various predictors of MPOD values, including age, presence of AMD, intra-ocular lens status, AREDS supplement use, and smoking history.

Results: On average, SoV-2° was 13% higher when calculated using the 9° reference plateau point (mean ± std. = 3227 ± 1172) instead of the 6° reference (mean ± std. = 2853 ± 1034), with 374 ± 315 as the mean ± std. within-eye pairwise difference between the two plateau references. The SoV-2° calculated for 9° and 6° references were highly correlated ($R = 0.96$, $p < 0.001$). The pairwise difference between SoV-2° calculated with the 9° and 6° reference was not associated with age, presence of AMD, intra-ocular lens status, AREDS supplement use, or smoking history.

Conclusions: The MPOD sum of volume measurements calculated using the 9° or 6° references appear to be equivalent in non-advanced AMD and control patients. This work will enable direct comparison of the findings between studies using different plateau references.

TITLE: Post-operative regimens after vitreoretinal Surgery. Is there a difference?

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Abou-Jaoude, J. Kitchens, Retina Associates of Kentucky, Lexington, Kentucky, UNITED STATES|M. Abou-Jaoude, S. Hyder, Ophthalmology, University of Kentucky College of Medicine, Lexington, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michelle Abou-Jaoude: Commercial Relationship: Code N (No Commercial Relationship) | Sayyada Hyder: Commercial Relationship: Code N (No Commercial Relationship) | John Kitchens: Commercial Relationship(s);Alcon:Code C (Consultant);Allergan:Code C (Consultant);Alimera:Code C (Consultant);Bayer:Code C (Consultant);Genentech:Code C (Consultant);Novartis:Code C (Consultant);Regeneron:Code C (Consultant);Optos:Code C (Consultant);Zeiss:Code C (Consultant)

ABSTRACT BODY:

Purpose: Traditional extended drop regimens after vitreoretinal surgery can be burdensome, and whether abbreviated ointment-based regimens are equally effective has not been addressed in literature. We performed a retrospective consecutive case series from a single surgeon before and after a regimen switch to assess rates of cystoid macular edema (CME) and endophthalmitis between patients who received an extended drop regimen versus short term ointment therapy for routine vitreoretinal cases.

Methods: A retrospective chart review of 245 eyes that underwent routine vitreoretinal surgery from a single surgeon at multiple sites was conducted with IRB approval. Data collected included patient age, diagnosis, lens status, type of surgery, use of subconjunctival medications, use of sub-tenon kenalog (STK), final ocular fill, and postoperative regimen (4 weeks of drops versus one week of ointment). Routine surgeries were defined as pars plana vitrectomy for vitreous opacities, non-diabetic vitreous hemorrhages, epiretinal membranes, full-thickness macular holes, and vitreomacular traction. Exclusion criteria included follow-up of less than two weeks, surgery for retinal detachment, history of significant diabetic retinopathy/edema, significant unrelated retinal disease, or uveitis. Statistical analysis was done with SPSS (IBM, 27e). Binary logistic regression was conducted using a p-value threshold of 0.05 for confounding variables, and odds ratios were calculated.

Results: Of 245 eyes, 111 received antibiotic/steroid ointment for one week and 131 received an extended steroid drop taper with one week of antibiotic drops. 1/111 in the ointment developed endophthalmitis, and no patients in the drop group. 35/111 eyes in the ointment group versus 48/131 eyes in the drops group developed CME requiring treatment, and statistically significant risk factors across groups included type of surgery, use of STK, and age. No statistically significant differences were found in development of CME between the two therapy groups (p-value: 0.94, OR CI: 0.54-1.78).

Conclusions: We found no difference in the development of CME between the two postoperative regimen cohorts. Only one case of endophthalmitis was found, so statistical analysis was not possible for this endpoint. Further validation is required, but shorter ointment regimens may be a more feasible and equally efficacious alternative to extended drop regimens for routine vitrectomy.

ABSTRACT BODY:

Purpose: Metastatic Uveal Melanoma (UM) is usually fatal within one year of symptom onset. There are a variety of biomarkers that can stratify patients' metastatic risk, but identifying them requires intraocular tumor biopsy. Liquid biopsy offers a less invasive alternative without the risks of retinal detachment and intraocular hemorrhage. We investigated whether the aqueous humor (AH) has sufficient tumor-derived cell-free DNA (cfDNA) to function as a liquid biopsy for UM.

Methods: This case series includes 7 eyes of 7 UM patients from whom 12 AH samples were taken during routine brachytherapy plaque placement and/or removal. Double stranded DNA (dsDNA), single stranded DNA (ssDNA), RNA, and microRNA (miRNA) were quantified with respective Qubit High Sensitivity Assay Kits (Thermo Fischer) for each sample. CfDNA was then isolated and sequenced on an Illumina platform to assess genome-wide somatic copy number alterations (SCNAs).

Results: AH derived cfDNA was detected in all samples (dsDNA mean = 0.7 ng/μL, range 0.01-7.5 ng/μL; ssDNA mean = 2.0 ng/μL, range 0-21.3 ng/μL). RNA was detected in 2 of 12 samples (mean = 1.6 ng/μL, range = 0.7-2.5 ng/μL), and miRNA was detected in 11 of 12 samples (mean = 1.7 ng/μL, range = 0.094-16.2 ng/μL). There was a significantly higher concentration of all nucleic acids (dsDNA, ssDNA, RNA, and miRNA) in post-radiation samples than pre-radiation samples (median = 0.085 ng/μL in pre-radiation, 0.333 ng/μL in post-radiation, $W = 1$, $z = -3.46$, $p = 0.00027$, Wilcoxon Signed-rank test). Confirmed UM genomic alterations of 6p gain, 6q loss, and 8q gain were identified in one post-radiation AH sample from an eye with an iridociliary body tumor. These SCNAs are characteristic of UM. No SCNAs were found in the AH from the pre-radiation sample in the same eye, or any of the other AH samples sequenced to date.

Conclusions: The AH is a source of cfDNA in eyes with UM, with a higher yield of all nucleic acids detected after brachytherapy radiation treatment. UM associated SCNAs were identified in the AH of one eye with an iridociliary tumor after radiation only; we hypothesize this may be due to intratumoral necrosis from the radiation as well as the proximity of the primary tumor to the AH. These results represent the first time that UM SCNAs have been identified in cfDNA isolated from the AH, and this provides preliminary evidence that the AH can serve as a liquid biopsy for UM.

ABSTRACT BODY:

Purpose: There is controversy regarding the importance of blood pressure (BP) in the development of Diabetic Macular Edema (DME). We performed a retrospective, observational study to determine the effect of BP prior to the diagnosis of diabetic retinopathy (DR) on the risk of developing DME.

Methods: We analyzed twenty years of data (2001-2020) from the Synthetic Derivative, Vanderbilt's electronic health record de-identified database. Patients with any DR aged 18 and above were included. Systolic and diastolic BP values two years before the diagnosis of DR were extracted and their average was termed "Historic BP" (Figure 1). Using severity classifiers from The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High BP, patients were stratified into four groups: Normotensive, Prehypertension, Stage 1 hypertension (HTN), and Stage 2 HTN. From that point forward, each record was reviewed for DME, defined by the presence of appropriate claims data and review of the primary notes. A Cox proportional hazard model tested the effect of Historic BP severity on the hazard of developing DME adjusting for age at DR diagnosis, sex, race, HbA1c, BMI, and diabetes mellitus type/duration. Vanderbilt's Institutional Review Board deemed use of this de-identified database to be exempt.

Results: Of 1,350 patients identified with DR, 285 (21%) developed DME. A likelihood ratio test showed that Historic BP severity was significantly associated with developing DME ($p=0.0069$). Compared to the Normotensive group, patients with Pre-HTN ($HR=1.8$; 95%CI 1.1-3.0; $p=0.0145$), Stage 1 HTN ($HR=2.0$; 95%CI 1.2-3.2; $p=0.0102$), and Stage 2 HTN ($HR=3.3$; 95%CI 1.6-6.7; $p=0.00087$) were associated with an increased DME risk, independent of covariates. Historic HbA1c levels were associated with increased risk of DME ($HR=1.2$; 95%CI 1.2-1.3; $p<0.001$). However, other covariates did not increase the risk of DME.

Conclusions: This data suggests an increased risk of developing DME for patients with progressively more severe HTN levels compared to Normotensive patients. Thus, historical elements beyond the acute presence of HTN, such as chronic degenerative changes in the walls of arteries may predispose individuals to the development of DME. Further investigation of these findings would offer a novel understanding regarding the significance of HTN in DME development.

ABSTRACT BODY:

Purpose: We propose two fully automated deep-learning-aided frameworks for detecting referable and vision threatening DR (rDR and vtDR) from volumetric and en face structural and angiographic optical coherence tomography (OCT) data.

Methods: 3×3-mm macular OCTA scans were acquired from the eyes of 50 healthy participants and 293 patients with diabetes (with or without DR) using a spectral-domain OCTA system (Avanti RTVue-XR, Optovue Inc). Masked trained retina specialists graded the disease severity based on the Early Treatment of Diabetic Retinopathy Study (ETDRS) scale using 7-field fundus photography. rDR was defined as level 35 or worse, or any level with diabetic macular edema (DME). vtDR was defined as level 53 or worse, or level with DME. A 3D (EfficientNet-3D-B0) and a 2D (DcardNet-36) frameworks were constructed. Each was trained separately for rDR and vtDR. The rDR/vtDR detection performance of 3D and 2D frameworks were respectively optimized using the area under the receiver operating characteristic curve (AUC) and specificity at sensitivity over 95%. Class activation maps (CAMs) were also generated from each framework. Performance was evaluated with 5-fold cross-validation, with 60%, 20%, and 20% of the data split for training, validation, and testing, respectively.

Results: The 3D framework achieved AUC of 0.89 ± 0.04 for rDR and 0.88 ± 0.02 for vtDR. The 2D framework superior AUC of 0.95 ± 0.02 for rDR ($p=0.0130$) and 0.94 ± 0.02 for vtDR ($p=0.0009$). 2D framework demonstrated higher overall diagnostic accuracy, sensitivity, and AUC (t-test on 5-fold cross-validation output) (Table 1). By overlaying CAM on OCTA three-dimensionally, we found the regions with higher values in the CAMs were mostly focused on the non-perfusion areas (NPA) and fluid areas (Fig. 1).

Conclusions: We demonstrated that a deep-learning based framework can detect rDR and vtDR based on OCTA volume and 2D framework shows superior diagnostic power than 3D framework as trained by the currently available dataset.

ABSTRACT BODY:

Purpose: To evaluate factors associated with post-residency research productivity among graduates of US ophthalmology programs.

Methods: A retrospective review was conducted of publicly available information of residents from 30 US ophthalmology programs, randomly selected from the top 100 Doximity-ranked programs. Demographics, academic factors, fellowship, and career choices of all graduates between 2009 and 2014 were documented. The current H-index, a measure of scientific output and citations, was also recorded. Publications from pre-residency, residency, and post-residency, including fellowship, were enumerated. Differences in publications between the 5yrs post-residency and the pre-residency/residency period were used as metrics of productivity. Analysis was conducted using Student's T-test, Pearson correlation, multivariate logistic regression, and odds ratio (OR) calculations with STATA-14 software. Significance was set at $p < 0.05$. Residents with incomplete data were excluded.

Results: 758 out of 768 residents, 306 females (40.4%) and 452 males (59.6%), met inclusion criteria. The mean (SD) number of pre-residency/residency publications was 1.7(4.0) and post-residency was 4.0(7.3) with a mean (SD) H-index of 4.2(4.9). Top rank residency ($p = 0.0013$), Alpha Omega Alpha (AOA) medical honor status ($p = 0.0015$), US medical school graduates ($p < 0.001$) and academic career ($p < 0.001$) were all significantly associated with higher pre/post-residency mean publication difference. Pursuing fellowship training was associated with higher total publications ($p < 0.001$). Of all pre-residency degrees, PhD had the greatest odds of high post-graduate publications (defined as > 4). There was a positive correlation between pre/intra-residency and post-residency publications ($\text{Rho} = 0.441$; $p < 0.001$) and mean difference of pre/post-residency publications for residents at a program and that program's rank ($\text{Rho} = 0.497$; $p < 0.001$). Multivariate logistic regression revealed, in order, academic career ($\text{OR} = 3.38$; $p < 0.001$), Heed fellows ($\text{OR} = 3.12$; $p = 0.031$), > 2 residency publications ($\text{OR} = 2.89$; $p < 0.001$), AOA status ($\text{OR} = 2.0$; $p = 0.004$), and top-rank residency ($\text{OR} = 1.89$; $p = 0.007$), had greatest odds of > 4 post-graduation publications.

Conclusions: Higher post-residency productivity was associated with multiple factors with choice of an academic career, Heed fellowship and residency productivity playing key roles.

TITLE: Rate of acute postoperative endophthalmitis after phacoemulsification using intracameral moxifloxacin

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Riffel, A. Quick, University of Kansas Medical Center, Kansas City, Kansas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Justin Riffel: Commercial Relationship: Code N (No Commercial Relationship) | Anjulie Quick: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ophthalmologists are increasingly utilizing intracameral (IC) antibiotics for prophylaxis during cataract surgery. We performed a retrospective chart review to evaluate the rate of acute postoperative endophthalmitis (POE) after cataract surgery using IC moxifloxacin at a tertiary academic center.

Methods: International Review Board approval was obtained from the University of Kansas Medical Center prior to the study. We conducted a retrospective chart review of phacoemulsification surgeries with or without intraocular lens placement. Surgeries were performed as either standalone procedures or in combination with other ophthalmic surgeries. The surgeries were performed by six cataract surgeons at a single institution between February 1, 2018 and August 10, 2020. All patients included in analysis received IC moxifloxacin during surgery. Patients who underwent combination surgeries received postoperative topical antibiotics in addition to IC moxifloxacin, while those who underwent standalone cataract surgery received IC moxifloxacin alone. Patients who did not receive IC moxifloxacin due to a preexisting fluoroquinolone allergy were excluded from analysis. Analysis included the rate of acute POE following all surgeries and the occurrence of any adverse reactions to IC moxifloxacin administration in those with a preexisting fluoroquinolone allergy.

Results: 2,359 eyes underwent cataract surgery (standalone and combination surgeries combined) over the study period. Zero cases of acute POE were observed after all 2,359 surgeries (0%). There were no reports of adverse reactions to IC moxifloxacin administration in the 43 patients identified as having a preexisting fluoroquinolone allergy (72 surgeries total), despite the most commonly listed preexisting allergic reaction to fluoroquinolones being "rash or itching."

Conclusions: Our academic center's rate of acute POE after cataract surgery using IC moxifloxacin is 0%. No adverse reactions to IC moxifloxacin administration were reported in patients with preexisting fluoroquinolone allergy. Importantly, no cases of acute POE were identified in patients who underwent standalone cataract surgery using IC moxifloxacin without the addition of postoperative topical antibiotics.

TITLE: Influence of Frailty on the Structure-Function Relationship in Glaucoma

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Quach, J.R. Vianna, Ophthalmology, Dalhousie University, Halifax, Nova Scotia, CANADA|O. Theou, Medicine, Dalhousie University, Halifax, Nova Scotia, CANADA|J. Quach, O. Theou, Physiotherapy, Dalhousie University, Halifax, Nova Scotia, CANADA|

Commercial Relationships Disclosure (Abstract): Jack Quach: Commercial Relationship: Code N (No Commercial Relationship) | Olga Theou: Commercial Relationship: Code N (No Commercial Relationship) | Jayme Vianna: Commercial Relationship(s);EadieTech:Code C (Consultant)

ABSTRACT BODY:

Purpose: Frailty is defined as a state of increased vulnerability to adverse health outcomes among people of the same chronological age. The purpose of this study was to evaluate the role of frailty on the structure-function relationship in glaucoma.

Methods: In this cross-sectional study, we consecutively recruited patients who had diagnosis of open-angle glaucoma by a glaucoma specialist. On the same visit, global retinal nerve fibre layer thickness (RNFLT) was measured by optical coherence tomography (OCT; 3.5 mm diameter peripapillary scan) and mean deviation (MD) was measured by 24-2 visual field (VF) examinations. We selected data from one random eye per patient for analysis. Frailty was measured by a questionnaire via phone call within 4 months of the OCT and VF examination. The questionnaire included 34 questions generating a frailty index (FI) score from 0 (healthy) to 1 (severely frail). This FI was based on a previously validated 36-item FI, with exclusion of 2 items related to glaucoma (cataract surgery and self-reported vision). The measured RNFLT values were adjusted for age and Bruch's membrane opening area. We created a multivariable linear regression model with MD as the dependent variable and RNFLT and FI as predictor variables. Furthermore, the interaction between RNFLT and FI was tested in a second model to explore whether frailty moderates the structure-function relationship. All regression models were adjusted for age and sex.

Results: We included 55 individuals (55% male) with mean (standard deviation; range) age of 70.3 (8.2; 45.0-89.0) years, mean adjusted RNFLT of 76.4 (14.1; 42.9-115.0) μm , mean MD of -2.99 (3.93; -17.94-1.34) dB, and mean FI score of 0.12 (0.08; 0.00-0.42). The multivariable linear regression model showed a significant association between adjusted RNFLT and MD (coefficient: 0.17 dB/ μm , p-value < 0.01) but not between FI score and MD (coefficient: 0.02 dB/FI*100, p-value = 0.87). There were no significant interactions between FI score and adjusted global RNFLT thickness (p-value = 0.93). The effect of frailty on the structure-function relationship is visualized in Figure 1.

Conclusions: In this relatively non-frail sample, FI score does not predict MD and is not a significant moderator of the structure-function relationship in glaucoma.

ABSTRACT BODY:

Purpose: Standardized tools do not exist to monitor volumetric or morphological changes in the periorbital region and ocular adnexa due to pathology such as oculofacial trauma, thyroid eye disease, and the natural aging process. We, therefore, developed a low-cost, 3D printed hybrid device and technique to quantifiably evaluate 3-dimensional oculofacial volumetric changes.

Methods: Images were taken using two Google Pixel 3 smartphones, which were attached to automatic rotating platforms using 3D printed mounts. The platforms were attached to height-adjustable poles with an 18 in and 10 in ring light. Cameras were centered 1.5 ft from the face at eye-level and their rotating axes angled at 12.5 degrees from center (Fig 1A). Subjects placed their faces through a foam backdrop with checkered squares, which were used as image registration landmarks (Fig. 1B). Subjects were instructed to remain motionless during the 60 seconds of image acquisition. Images with and without 3D printed phantom lesions (black domes) affixed above the brow were acquired. Images were processed in Metashape (Agisoft, St. Petersburg, Russia), a 3D reconstruction software. 3D rendered objects were then imported into Autodesk's Meshmixer where 3D facial renders were registered to each other (Fig. 1C-E). Digitally reconstructed 3D dome volumes were then measured within Meshmixer and compared to their respective calculated volumes. Calculations were based on dome diameters measured with a micrometer.

Results: 3D renderings of the ocular adnexa for 3 subjects were achieved using 60 photos acquired on our custom designed hardware. Differences between calculated and digitally analyzed volumes of 3D printed phantom lesions showed a percent difference of $2.33 \pm 2\%$ for 2060 μL , $4.79 \pm 2\%$ for 244 μL , and $25 \pm 17\%$ for 27.5 μL . Digitally measured phantom lesion volumes were accurate to within 6.8% of the calculated volumes as small as approximately 250 μL ; small dome volumes were digitally undermeasured about 25%.

Conclusions: We demonstrated a technique using a 3D printed hybrid device to analyze and quantify oculofacial volumetric changes with a resolution of approximately 250 μL .

TITLE: Geographic access disparities to clinical trials in retinopathy of prematurity in the United States

SESSION TITLE: Healthcare Delivery and Quality of Care

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.R. Soares, Retina, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rebecca Soares: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify geographic and socioeconomic variables predictive of residential proximity to retinopathy of prematurity (ROP) clinical trial locations.

Methods: This was a cross-sectional, retrospective study. Deidentified census-tract level data from public datasets and trial-level data from ClinicalTrials.gov were analyzed. We used an origin-destination cost-matrix to calculate the driving distance and travel time from the population-weighted United States (US) census tract centroid to the nearest clinical trial site. We then used data from the U.S. Census Bureau's American Community Survey and the Centers for Disease Control and Prevention to identify census-tract level socioeconomic factors predictive of driving distance and time. The primary outcomes were time traveled >60 minutes and distance traveled >60 miles from population-weighted census tract centroid to the nearest ROP clinical trial site.

Results: In a multivariable model, driving time >60 minutes had a significant association with rural vs. urban location [1.19 (1.17-1.22), adjusted odds ratio (aOR) (95% confidence interval), $p < 0.0001$], percentage of population <200% of federal poverty level (FPL) compared to the first quartile [second quartile 1.04 (1.03-1.05), third quartile 1.07 (1.06-1.08), fourth quartile 1.17 (1.16-1.19), $p < 0.0001$], and South [1.06 (1.05-1.07)] and West [1.24 (1.22-1.26), $p < 0.0001$] region as compared to Northeast. Driving time was inversely associated with county-level number of births < 1500g per 1000 people 0.98 (0.98-0.98), $p < 0.0001$. Similar predictors were found in distanced traveled >60 miles.

Conclusions: Conclusions: There are geographic maldistributions of clinical trial sites for ROP in the United States. Those with higher travel burden are more likely to reside in a census tract that is rural, low-income, and from areas outside the Northeast. Conversely, patients from counties with higher rates of very-low birth weight infants are less likely to live further from clinical trial sites.

ABSTRACT BODY:

Purpose: The cystine/glutamate antiporter (system xc-) mediates exchange of extracellular cystine for intracellular glutamate. The xCT knockout mouse (KO), in which the light chain subunit (xCT) of system xc- is removed, results in accelerated retinal aging relative to age matched wild-type (WT) mice due to alterations in glutamate and anti-oxidative mechanisms. We have previously shown that lack of xCT alters the glutamate/glutamine cycle and glycolytic metabolism. In this study, we extended our investigation to examine the effect of xCT removal on mitochondrial activity, reactive oxygen species (ROS) production, and oxidative damage.

Methods: Retinas from C57BL/6J and xCT KO mice were collected at 6 weeks (6W) and 9 months (9M). Mitochondrial activity and ROS production were measured via high-resolution respirometry using the Oroboros Oxygraph-2K system (n=6). Succinate, glutathione (GSH) levels and protein carbonyl and lipid peroxidation were measured in whole retinas using biochemical assays (n=6). GSH distribution in the retinal layers was quantified after silver-intensified immunogold labelling (n=6).

Results: High-resolution respirometry revealed 2-fold higher baseline ROS levels in the 6W KO retina compared to WT (ANOVA, $p < 0.05$), but levels were similar in the 9M mice. While whole retina GSH levels did not change between strains or age groups, GSH was significantly decreased in KO photoreceptors nuclear layer compared to WT at 6W. In addition, there were increased levels of protein carbonyls ($p < 0.05$) and 4-HNE ($p < 0.01$) in the 6W KO retina compared to WT. Succinate levels were similar at either age and in both strains of mice. However, high-resolution respirometry revealed increased respiratory complex I activity ($p < 0.01$), a trend for decreased respiratory complex II activity, and decreased mitochondrial ROS production in 6W KO retinas compared to WT ($p < 0.05$).

Conclusions: Loss of xCT function results in reduced photoreceptor GSH levels, increased baseline ROS, increased oxidative stress but decreased mitochondrial ROS production which may alter ROS signalling pathways important for normal retinal function. These early changes are back to normal in the 9M xCT KO which may suggest early metabolic and mitochondrial changes due to xc- pre-conditions the retina to accelerated aging.

TITLE: Peri-procedural risk of retinal artery occlusion in patients undergoing transcatheter cardiac interventions in the United States

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.L. Linderman, J. Chow, J.C. Wang, Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|G.C. Linderman, M. Mori, K. Schuster, Surgery, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Wendy Linderman: Commercial Relationship: Code N (No Commercial Relationship) | George Linderman: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Chow: Commercial Relationship: Code N (No Commercial Relationship) | Makoto Mori: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Schuster: Commercial Relationship: Code N (No Commercial Relationship) | Jay Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Transcatheter procedures are increasingly used to treat a variety of cardiac conditions, but the risk of clinically significant peri-procedural retinal artery occlusion (RAO) has not been well characterized. In this study, we use the National Inpatient Sample (NIS) to determine the risk of peri-procedural RAO in transcatheter aortic valve replacement (TAVR) and percutaneous coronary intervention (PCI).

Methods: Patients who underwent TAVR and PCI were identified in years 2006 to 2017 of the NIS. NIS is a large, nationally representative sample of hospitalizations, which allows for characterization of rare events like RAO. Rates of transient, branch, central, and peripheral RAO were computed based on non-primary ICD-9/10 diagnosis codes assigned at discharge. The rate of peri-procedural stroke was also calculated for these procedures as a positive control, as these rates are well-characterized in the literature. Because NIS lacks present-on-admission flags to exclude pre-existing RAO, we report the rate of RAO as an upper bound of the true periprocedural rate. Sample weights published by the NIS were used to produce nationally representative estimates. To determine the significance of differences between rates, p-values were calculated by z-test.

Results: 161,829 patients underwent TAVR and 6,970,152 patients underwent PCI. The rate of all RAO in patients undergoing TAVR was 6.4/10,000 (95% CI 3.7 to 9.2), and non-transient RAO was 4.3/10,000 (95% CI 2.1 to 6.6). In patients undergoing PCI, the rate of all RAO was 2.0/10,000 (95% CI 1.7 to 2.2), and non-transient RAO was 6.0/100,000 (95% CI 4.9 to 7.6). The rate of stroke in patients undergoing TAVR and PCI was 2.1% (95% CI 1.9 to 2.2%) and 0.58% (95% CI 0.56 to 0.60%), respectively, consistent with previously published rates. The rate of peri-procedural RAO was higher in TAVR than in PCI (p-value < 0.001). The rate of peri-procedural stroke was higher than peri-procedural RAO in both TAVR and PCI (p-values < 0.001).

Conclusions: Peri-procedural RAO as a complication of TAVR and PCI is rare, with true rates likely to be less than 9/10,000 and 2/100,000, respectively. Peri-procedural RAO is significantly more common in TAVR than in PCI and less common than stroke in both procedures.

ABSTRACT BODY:

Purpose: We have developed a bi-modal artificial intelligence(AI) system with deep learning algorithms to comprehensively identify pathological retinal features based on optical coherence tomography(OCT) and fundus photography(FP). Here, we designed a prospective experiment to validate its real-world clinical performance at a district hospital.

Methods: The AI system can identify 14 pathological and anomalous features from OCT(including drusen, macular hole and so on) and 12 pathological and anomalous features from FP(including diabetic retinopathy, pathological myopia and so on). To evaluate the performance of AI and the value of the system in clinical assistant diagnosis, we deployed the system to the Baoshan Branch of Shanghai Renji Hospital for a three-month(from August 2020 to October 2020) clinical validation. Topcon Maestro 3D OCT-1 in Radial scanning mode was used for data capturing which can obtain 12 radial 6mm macular OCT images and a 45-degree FP of the macula in a single acquisition. A total of 667 eyes from 363 patients(Female 186, 51.2%; Mean age 54.3, SD 11.0) where both OCT and FP were good quality were included in this validation. The OCT and FP reports generated by AI were independently reviewed by a senior ophthalmologist. The reviewer's judgement was considered as the gold standard.

Results: Table 1 shows the AI performance of OCT and FP on 667 eyes. For the 14 OCT features, the average sensitivity, specificity and accuracy were 97.2%, 98.7% and 98.6%, and for the 12 FP features were 94.9%, 99.2% and 98.9%, respectively. Since both OCT and corresponding FP were collected, different, complementary features in OCT and FP were found when judging retinopathy. There were 292 (43.7%) abnormal eyes recognized by OCT, 354(53.0%) by FP and 439(65.8%) by combining OCT and FP(Figure 1).

Conclusions: We examined the AI performance for detecting pathological and anomalous features in OCT and FP. For the features validated, AI performance can meet the requirements for community screening applications and primary hospital auxiliary diagnostic scenarios. Furthermore, the combination of OCT and FP can significantly improve the disease recognition performance of AI, because of the complementary information in simultaneously acquired OCT and FP.

ABSTRACT BODY:

Purpose: To investigate spatial patterns of preclinical visual fields and their association with future development of glaucoma.

Methods: We selected reliable 24-2 preclinical VFs for each eye from a multi-center dataset. Preclinical VFs were defined as mean deviation (MD) ≥ -1 dB, glaucoma hemifield test (GHT) within normal limits and pattern standard deviation (PSD) probability $> 5\%$. An unsupervised artificial intelligence method termed archetypal analysis was applied to determine the preclinical VF patterns from total deviation values. The VF patterns and global indices (age, MD, PSD) of the baseline VF were associated with the incidence of subsequent glaucoma diagnosis (defined by MD ≤ -3 dB and abnormal GHT and PSD probabilities on VFs measured at least 3 months from the baseline) using Cox survival regression with mixed effects addressing the issue of inter-eye correlations. Model selection was performed using Bayesian information criterion (BIC).

Results: We determined 10 preclinical VF archetypal patterns from 44,410 VFs including two variants of normal VF archetypes (ATs 1 and 5), superior and inferior loss (ATs 4 and 9), superior and inferior peripheral loss (ATs 10 and 8), nasal and temporal loss (ATs 3 and 7), nasal-temporal peripheral loss (AT 6) and central scotoma (AT 2). Among the 17,192 eyes with follow-up tests, 7.1% of the eyes were subsequently diagnosed with glaucoma at an average of 4.3 years with a standard deviation of 2.9 years. From univariable regressions, subsequent glaucoma diagnoses were positively associated ($p < 0.001$) with age, PSD, and ATs 3, 4, 6, 7, and negatively associated ($p < 0.001$) with MD and ATs 1, 2 and 5. From multivariable regressions with AT features, glaucoma diagnoses were positively associated ($p < 0.001$) with ATs 3, 4, 6, 7 and 9 after feature selection. When combining ATs with global indices, glaucoma diagnoses were positively correlated ($p < 0.001$) with age, PSD, and AT 3, and negatively correlated ($p < 0.04$) with ATs 1 and 8. AT 10 remained in the optimal model with an insignificant p value. The model combining the VF patterns with global indices strongly outperformed the model using global indices alone (BIC value lowering of 160; BIC lowering of > 6 indicates strong model improvement).

Conclusions: Preclinical VF patterns were assessed and quantified for the first time to our knowledge. These VF patterns can be used to improve prediction of future glaucoma diagnoses.

ABSTRACT BODY:

Purpose: Intrinsically photosensitive retinal ganglion cells (ipRGCs) absorb short wavelength light via melanopsin mediating circadian photoentrainment, pupil responses, alertness & cognition, functions which persist despite blindness. Giant ipRGCs, which send signals to LGN/visual cortex implying a role in visual perception, show an inhibitory opponent S cone off response. Human long-latency ipRGC ERGs elicited with silent substitution utilize high contrasts which can lessen ipRGC isolation. We used selective chromatic adaptation to stimulate ipRGCs & S cones to reveal ipRGC ERGs & VEPs (Rabin et al. Eye 2020). Our purpose was to extend this effort & develop new metrics to quantify ipRGCs.

Methods: 20 adults (mean age 25 ± 3 , 14 females) participated after informed consent. A Ganzfeld (Diagnosys, LLC) was used to present 200-msec. blue flashes (448 nm) on a rod & LM cone saturating amber background (590 nm, 560 cd/m^2) to stimulate S cones (426 nm peak) & ipRGCs (480 nm). Simultaneous flash ERGs and VEPs were recorded in 1000 msec epochs after 30 sec. of adaptation to the amber background over a 4-log unit range (16.7 to .0167 cd/m^2). Digital values (μV vs. msec.) were averaged to compute mean ERGs ($n=20$) & VEPs ($n=14$). Control ERGs on the amber background showed no ERG to the ISCEV scotopic flash (0.01 $\text{cd/m}^2/\text{sec.}$) & a small S cone ERG to the 300X brighter standard flash indicating no recordable input from rods, M & L cones.

Results: ERGs revealed a small amplitude S cone ERG followed by a wave of negativity derived from S cone inhibitory input to ipRGCs. Amplitudes were quantified as this negative trough to the first positive peak (ipRGC on response). Log amplitude increased with log luminance ($F=13,787$, $P<.0001$, $r^2=1$). ipRGC latency was quantified as the difference between negative trough & positive peak latencies which was highly correlated with amplitude ($P<.0001$, $r^2=0.76$). The ratio of ipRGC amplitude/latency (throughput) provides a new metric which combines the two variables & is highly dependent on luminance ($P<.02$, $r^2=0.76$). The flash VEP 1st positive peak (decreased in glaucoma), increased exponentially with ipRGC amplitude ($r^2=0.91$), a potential visual perceptual metric of ipRGCs.

Conclusions: Selective chromatic adaptation reveals retinal & cortical function of ipRGCs, including unique inhibitory input from S cones & putative metrics of visual perception. Planned research will examine pupils using the same visual stimulus.

TITLE: Comparative Outcomes of Intravitreal Triamcinolone Acetonide-Moxifloxacin with Intracameral Dexamethasone-Moxifloxacin-Ketorolac in Cataract Surgery

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Kuriakose, S. Cho, S. Nassiri, F. Hwang, Eye Institute, Loma Linda University, Loma Linda, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Robin Kuriakose: Commercial Relationship: Code N (No Commercial Relationship) | Soungmin Cho: Commercial Relationship: Code N (No Commercial Relationship) | Saman Nassiri: Commercial Relationship: Code N (No Commercial Relationship) | Frank Hwang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intravitreal or intracameral antibiotic-steroid formulations are effective in preventing infection and controlling postoperative intraocular inflammation in cataract surgery. This study sought to compare the effectiveness of intravitreal triamcinolone acetonide-moxifloxacin versus intracameral dexamethasone-moxifloxacin-ketorolac in cataract surgery.

Methods: A retrospective longitudinal comparative study among 401 consecutive eyes receiving either intraoperative triamcinolone acetonide-moxifloxacin or dexamethasone-moxifloxacin-ketorolac was performed between November 2016 and January 2020. Primary endpoints at postoperative day one (POD1), week one (POW1), and month one (POM1) included corneal edema, anterior chamber inflammation (ACI), and intraocular pressure (IOP).

Results: On POD1, there was no statistically significant difference between the two groups (OR: 1.11 [0.66-1.86]; $p=0.69$) but at POW1, dexamethasone-moxifloxacin-ketorolac had significantly more ACI compared to triamcinolone acetonide-moxifloxacin (OR: 2.11 [1.22-3.66]; $p=0.008$). By POM1, there was no significant difference ($p=0.98$). At all time points, corneal edema severity was not significantly different. IOP was found to be significantly elevated in the triamcinolone acetonide-moxifloxacin group compared to the dexamethasone-moxifloxacin-ketorolac group by POM1 (15.64mmHg versus 13.16 mmHg, $p=0.001$). There was no statistical difference in rates of CME (OR: 0.13 [0.01-1.51]; $p=0.06$) and there were no cases of endophthalmitis.

Conclusions: While triamcinolone acetonide-moxifloxacin demonstrates earlier postoperative inflammatory control compared to dexamethasone-moxifloxacin-ketorolac, both are effective in the postoperative recovery of cataract surgery. Additionally, intravitreal triamcinolone acetonide-moxifloxacin causes a slightly higher but significant IOP compared to intracameral dexamethasone-moxifloxacin-ketorolac. This study reinforces them as viable alternatives to traditional postoperative drops.

ABSTRACT BODY:

Purpose: Traumatic brain injury (TBI) is characterised by a host of physiological and cognitive deficits such as attention problems. In the present study, we systematically reviewed previous literature that investigated whether and how TBI affects the ability to allocate visuospatial attention i.e., the ability to use and respond to endogenous and exogenous visual cues.

Methods: A literature search using keywords such as “traumatic brain injury” and “visual attention” found 50 papers. Of these, 18 met our inclusion criteria and a systematic review was conducted. 16 studies met the criteria for inclusion in our meta-analysis and 80 effect size estimates of various visual search and attention allocation tasks were obtained. These effect sizes were computed from 459 TBI cases and 458 matched controls using the random effect model.

Results: The systematic review indicated a large degree of variability in task design and a lack of consensus for assessing attention allocation between endogenous and exogenous attention tasks. The combined effect size of the impact of TBI on visuospatial attention allocation was large ($g=0.79$, $p<0.0001$) with medium heterogeneity ($I^2=68.39\%$). Subgroup analyses revealed an increase in deficit for moderate-to-severe and severe TBI compared to mild TBI ($F(2,76)=24.14$, $p<0.0001$, $g(\text{mild})=0.32$, $g(\text{moderate-to-severe})=0.95$, $g(\text{severe})=1.27$). Task type (no cue, endogenous or exogenous cue) had a significant impact on effect size ($g(\text{no cue})=0.98$, $g(\text{endogenous cue})=0.70$, $g(\text{exogenous cue})=0.45$, $p=0.0051$) indicating that higher order processes were affected to a greater degree than bottom-up processes. Meta-regression analyses revealed significant improvement in visual attention deficit with time ($p(\text{mild})=0.031$, $p(\text{moderate-to-severe})=0.002$, $p(\text{severe})<0.0001$) with recovery from mild injury occurring after approximately 460 days.

Conclusions: Visual attention is largely in deficit as a result of TBI. However, injury severity and the type of visual attention allocation (endogenous vs. exogenous) are significant factors in indicating the degree of deficit. Assessment of visual attention, using a systematic attention allocation task, may provide a useful clinical measure of cognitive impairment after TBI and could be used to detect and monitor TBI, indicate recovery over time or be used to assess the effectiveness of treatment and rehabilitation programs.

ABSTRACT BODY:

Purpose: An ideal epiretinal implant for treating vision loss would stimulate each retinal ganglion cell (RGC) of each distinct type according to its natural function, to reproduce the neural code of the retina. However, no methods exist to determine the normal, healthy light response properties of each RGC of each type in a region of retina that is no longer light-responsive. This study presents a method to infer a model of RGC light responses using only intrinsic features of recorded electrical activity.

Methods: Analysis was performed on 283 recordings from populations of ON and OFF parasol RGCs in isolated macaque retina using 512-electrode arrays. The type of each recorded RGC was determined from its light responses. To emulate interfacing to a blind retina, a classifier was used to infer the type (ON or OFF) of each cell using two features of recorded electrical activity, without reference to the light stimulus: the average electrical image (EI) of a spike over the electrode array, and the autocorrelation function (ACF) of spike times. EIs were also used to infer receptive field locations. A linear-nonlinear Poisson (LNP) light response model was then inferred for each cell using its true cell label, its estimated location, and the average spatiotemporal filter and nonlinearity in the population. The prediction accuracy of inferred models and models fitted to measured responses was compared, for white noise and natural scenes stimuli (Fig. 1).

Results: K-means (k=2) clustering of the top 2 principal components of ACFs reliably separated ON and OFF parasol cells in individual retinas. However, cluster labels (ON, OFF) could not be reliably determined from ACFs, due to inter-retina variability. Instead, ACF clusters were labeled using "votes" from a cell-by-cell linear classifier of selected EI features. This approach achieved 94% mean accuracy on 25 test retinas. Across six retinas, the RGC light response models produced a mean correlation between inferred models and data of 0.48 and 0.51, and between fitted models and data of 0.63 and 0.57 (an upper bound), for white noise and natural scenes stimuli respectively.

Conclusions: Intrinsic features of electrical activity can be used to infer RGC light response models.

ABSTRACT BODY:

Purpose: In our previous study, stem cell factor (SCF) and its receptor, cKIT, are identified as novel regulators of angiogenesis at hypoxia and pathological neovascularization in the eye, which suggests that suppression of SCF/cKIT signaling would be a new pharmacological strategy for the treatment of ocular vascular diseases such as neovascular age-related macular degeneration (nAMD). In this regard, the present study aims to determine the efficacy and safety of newly developed fully human monoclonal IgG targeting cKIT (NN2101) in the murine model of nAMD.

Methods: Inhibitory effect of NN2101 on SCF-induced angiogenesis was evaluated by western blotting and in vitro angiogenesis assays. Efficacy of intravitreal injection of NN2101 alone and its combination with aflibercept was determined using mice with laser injury-induced choroidal neovascularization (CNV). One week later, choroidal tissues were harvested for further analysis. Ocular toxicity and pharmacokinetics of intravitreal injection of NN2101 were assessed in mice and rabbits, respectively. All data were analyzed for normality, followed by an unpaired Student's t-test, one-way ANOVA with Bonferroni's test, or Kruskal-Wallis test.

Results: In hypoxic human vascular endothelial cells, NN2101 completely blocked the SCF-induced activation of cKIT/ β -catenin signaling pathways and increase in cell migration, tube formation, and proliferation. In mice with laser-induced CNV, an intravitreal injection of NN2101 (1.0 μ g) significantly alleviated CNV formation with a comparable efficacy of aflibercept (2.5 μ g) (Kruskal-Wallis test, $*p < 0.01$, $n > 6$ mice). Combined intravitreal injection of suboptimal doses of NN2101 and aflibercept substantially enhanced anti-angiogenic efficacy (Kruskal-Wallis test, $*p < 0.05$, $n > 7$ mice). In addition, NN2101 neither caused ocular toxicity nor interfered early retinal vascular development in mice. Ocular Pharmacokinetic analysis of the rabbits after intravitreal injection administration of NN2101 showed that NN2101 rapidly distributed and remained in retinal and choroidal tissues even after 30 days or more.

Conclusions: NN2101, a fully human monoclonal antibody targeting cKIT, may be a novel promising therapeutic and can enhance the potency of existing anti-vascular endothelial growth factor agents for the treatment of nAMD.

ABSTRACT BODY:

Purpose: Use of the D Eye attachment for the iphone as an optic nerve imaging option in patients in the COVID19 pandemic

Methods: Inclusion criteria: 20/20-20/50 vision, informed consent was obtained. D-Eye digital retinal camera (Padova, Italy) was used on the dilated and undilated eyes of patients. The camera was attached to an iphone 6 (Apple, Cupertino CA), video mode was used to attain an image of the optic nerve and internally timed on the iphone 6). Optos California model (Dunfermline, Scotland) was then used to take optic nerve images of both dilated and undilated eyes of patients for comparison. The start time and end time was recorded from the timestamp of the first and last image taken on Optos, then the difference between both timestamps was calculated to obtain time spent on OPTOS.

Results: For dilated patients (n=14, 26 eyes), the average time taken to obtain a clear video of both eyes using D-Eye was 28.5 seconds. The average time to take images of both eyes using OPTOS was 1.71 minutes. The p-value of the average time is 0.000373.

For undilated patients (n=10, 20 eyes), the average time of a clear video of both eyes using D-Eye was 29.8 seconds. The average time to take clear images of both eyes using OPTOS was 1.2 minutes. The p-value of the average time is 0.000213.

Conclusions: The D-Eye smartphone device and its short image acquisition time may be useful with wheelchair patients or with patients who want to be seen quickly in the COVID setting indoors or outdoors. We look forward to future studies of the D-Eye in the COVID era and ophthalmology.

ABSTRACT BODY:

Purpose: The present study reports patients with endophthalmitis-related retinal detachment (RD) managed with vitrectomy.

Methods: The present study included consecutive eyes who had surgery for endophthalmitis-related RD at CHU de Québec – Université Laval (Canada) between April 2009 and November 2019. The data were collected retrospectively. The main variables were: etiology of endophthalmitis, classified into endogenous and exogenous (posttraumatic, corneal ulcer, post cataract surgery and post intraocular injection), causing microorganisms found in the intraocular fluid (IOF), type and description of RD, best corrected visual acuity (BCVA) after vitrectomy, and retina status at final follow up. The main outcomes were the final visual acuity and retina status at final follow up.

Results: 17 eyes (14 males and 3 females) were included in this study. The mean age was 59 ± 20 (17-97) years. We identified many types of RD (8 tractional RD, 6 total RD, 2 rhegmatogenous RD, and 1 serous RD). Microorganisms were detected in 14 cases out of 17 (82.4%): Staphylococcus epidermidis in 3 cases, Staphylococcus lugdunensis in 1 case, Propionibacterium acnes in 2 cases and Streptococcus spp. in 3 cases (viridans, salivarius and pneumoniae). Concomitant microorganisms were found in 5 cases (Strep. B-hemolytic group G + Staphylococcus epidermidis, Propionibacterium acnes + Staphylococcus epidermidis + mycogenous elements, Streptococcus pyogenes + Staphylococcus epidermidis + Propionibacterium acnes, Streptococcus oralis + Streptococcus mitis and Staphylococcus saprophyticus + Staphylococcus warneri). The mean follow up duration was 13 months. The BCVA at last follow up was variable: 1 patient (5.9%) had a BCVA $\geq 20/40$, 6 patients (35.3%) had a BCVA between 20/40 and 20/400, 3 patients (17.6%) had a BCVA of counting fingers (CF), 4 patients (23.5%) had a BCVA of hand motions (HM), 2 patients (11.8%) had a BCVA of light perception (LP), and 1 patient (5.9%) had no light perception (NLP). 9 of 17 retina (52.9%) were successfully reattached, 5 of 17 retina (29.4%) were reattached with silicone oil, 1 retina was reattached with macular atrophy and 1 retina was reattached with macular fibrosis. One patient had evisceration of the eye.

Conclusions: Endophthalmitis-related RD is associated with poor visual acuity outcome (11 patients (64.7%) had CF, HM, LP or NLP as visual outcome) and microorganisms were frequently found in the IOF (71%).

ABSTRACT BODY:

Purpose: To administer an on-line questionnaire in Australia to understand healthcare consumers experience with current visual field (VF) tests, and opinions regarding future improvements to VF tests.

Methods: A Qualtrics survey was distributed via Glaucoma Australia (support group for people with glaucoma), and to people with glaucoma who had previously participated in our research. The survey assessed three domains: 1) demographics and experience with visual field tests; 2) opinions regarding test duration and frequency; and 3) perspectives on future developments. Surveys with 100% question completion were analysed, resulting in a total of 152 responses. Median (IQR) is given for non-categorical data.

Results: Respondent demographics were: age 66 (60 - 72) years; most (70%) had experience of more than 11 visual field tests, with 37% having experience of more than 20 tests. Participants estimated that they completed visual field tests in 6 (5 - 8) minutes. The reported VF visit frequency was: once a year (29%), twice a year (57%), thrice a year (9%), every two years (3%), with others being less often. Opinions regarding test duration and frequency were as follows: participants were willing to accept an addition of 5 (3 - 6) minutes for a single VF test if more information about their VF could be obtained. We asked how many total tests per visit they would be prepared to undergo if evidence emerges that more than 1 test per appointment is useful: 1 test (7%), 2 tests (55%), 3 tests (18%), and >3 tests (20%). More respondents were prepared to increase tests per visit than increase visits per year. Table 1 describes participant responses regarding future VF developments.

Conclusions: Healthcare consumers prioritise information over test duration and are willing to undertake more or longer tests to obtain more information. This study provides valuable information on healthcare consumer preferences for VF tests, and may help scientists and industry design and understand healthcare consumer preparedness for new VF methods.

ABSTRACT BODY:

Purpose: Light-at-night is an effective method to arrest the dark adaptation of rod photoreceptors and thereby reduce the metabolic activity of the retina, with the aim of reducing oxygen consumption associated with hypoxia that is present in the retina of patients with diabetic retinopathy. The present study evaluated the feasibility of wearing an illuminated sleep mask in patients with diabetes treated for clinically-significant macular edema (CSME) with intravitreal injections.

Methods: Patients with diabetic retinopathy initiating monthly injections of bevacizumab or ranibizumab for CSME were enrolled in a pilot study that used light masks to deliver light-at-night. Patients were randomized to one of two different light regimens in order to differentiate the tolerability of the device from that of the light-at-night treatment. One group received masks equipped with green LEDs (520nm) with an intensity chosen to inactivate the dark current (100 LUX). The other set of masks were configured with red LEDs (670nm) below the threshold necessary to prevent dark adaptation (<5 LUX). Primary outcome was the ability to use the device continuously over the 12-month trial. Secondary outcome was the number of anti-vascular endothelial growth factor (VEGF) injections.

Results: Out of 30 patients consented, 11 participants (37%) failed to adopt the light mask, returning the device within the first week. Five out of nine participants (56%) assigned to masks with red LEDs withdrew or failed to complete the 12 monthly study visits, while two out of ten participants (20%) assigned to the masks equipped with green LEDs did not complete the trial (OR 0.10 CI 0.01 to 0.95, P = 0.046). Using an intention-to-treat analysis found no difference in the number of intravitreal injections administered to participants with red versus green masks (12.3 versus 10.8, P = 0.122). Self-reported compliance with nightly use of the sleep mask was poor. Only an average of 63% of logs documenting nightly battery changes were returned by participants who completed the trial (range 19% to 100%).

Conclusions: Use of a lighted sleep mask poses a challenge for a majority of patients treated for CSME with anti-VEGF injections. There is insufficient evidence to evaluate the effectiveness of light-at-night delivered by this means as a complementary therapy for diabetic retinopathy.

ABSTRACT BODY:

Purpose: To Evaluate the correlation of baseline characteristics of vascularized drusen with the risk of progression to choroidal neovascularization (CNV) using optical coherence tomography angiography (OCTA).

Methods: This was a post-hoc longitudinal analysis of eyes from the PROCON study, a 24-month masked controlled study evaluating intravitreal quarterly aflibercept for prophylaxis against conversion to exudative disease in 128 patients with intermediate non-exudative AMD in the study eye and exudative AMD in the fellow eye. OCTA B-scans were analyzed at baseline to detect eyes with vascularized drusen (presence of flow within the drusen). Eyes were graded for conversion to exudation using fluorescein angiography and structural OCT. Characteristics of vascularized drusen were evaluated at baseline and the last available visit in eyes with no conversion, or the visit immediately prior to conversion in eyes that converted.

Results: Eight vascularized drusen in 6 eyes identified by OCTA were included. Two eyes developed CNV after 15 and 9 months. In the 4 eyes with no CNV development, the mean [SD] baseline height, width, and area at the maximum height of vascularized drusen were 75.667 [11.96], 196.833 [57.41], and 0.012 [0.005] microns, respectively. In the two eyes with CNV development, the mean [SD] baseline height, width, and area at the maximum height were 88.5 [19.09], 265 [25.46], and 0.015 [0.001] microns, respectively (P-values > 0.05 for differences between two groups).

In 1 non-converted eye the vascularized druse was not detected on the follow up visit. The mean [SD] of the vascularized drusen height, width, and area at the maximum height at the 24-month follow-up in eyes with no conversion were 69.800 [8.07], 234.00 [86.28], and 0.012 [0.005] microns, respectively. These values were 90.5 [7.78], 256 [45.25], and 0.020 [0.005] microns for the two eyes with conversion (P-value = 0.03 for differences in druse height and >0.05 for width and area between two groups at follow up). No overlying retinal pigment epithelium disruption was noted over vascularized drusen on either baseline or follow up. Two drusen in eyes with conversion and three drusen from two non-converted eyes showed ellipsoid zone line disruption.

Conclusions: In this study, the 2 eyes with conversion had larger vascularized drusen at baseline. Larger studies are required to explore the association of vascularized drusen characteristics and CNV development.

ABSTRACT BODY:

Purpose: Inflammation is a critical player in the etiology and pathogenesis of Age-related Macular Degeneration (AMD). Humanin G (HNG) is a Mitochondrial Derived Peptide (MDP) that is cytoprotective in AMD. The goal of this study was to test our hypothesis that the inflammation markers- CD62P i.e., P Selectin and CD62E i.e., E Selectin proteins, are increased in AMD and HNG treatment in vitro leads to reduction in their protein levels.

Methods: In this study, we used: 1) blood plasma isolated from AMD patients and age-matched control subjects, and 2) AMD and control transmitochondrial RPE cybrid cell lines. HNG was exogenously added to AMD cybrids, which have identical nuclei from the mitochondria-deficient ARPE-19 cells but differed in mitochondrial DNA (mtDNA) content derived from clinically characterized AMD patients and control subjects. Cell lysates were extracted from untreated and HNG-treated AMD and control cybrids, and then analyzed using the Luminex multiplex assay to determine the protein levels of CD62P and CD62E.

Results: The CD62P protein levels were 152% higher in AMD plasma samples (2.52 ± 0.41 , $n=3$) vs. Controls (1 ± 0.2 , $n=3$) ($p=0.03$). Treatment with HNG led to a 37% decrease in CD62P protein levels in control cybrid cell lysates (Untreated: 1 ± 0.34 ; HNG-treated: 0.63 ± 0.04) and a 21% decrease in CD62P protein levels in AMD cybrid cell lysates (Untreated: 1 ± 0.24 ; HNG-treated: 0.79 ± 0.09). Furthermore, CD62E protein levels were 176% higher in AMD plasma samples (2.76 ± 0.48 , $n=3$) vs. Controls (1 ± 0.28 , $n=3$) ($p=0.03$). Treatment with HNG led to 18% decrease in CD62E protein levels in AMD cell lysates (Untreated: 1 ± 0.02 ; HNG-treated: 0.82 ± 0.02). No difference was found in CD62E protein levels between untreated vs. HNG-treated control cell lysates.

Conclusions: In summary, we observed: 1) significantly higher levels of CD62P and CD62E proteins in AMD plasma samples compared with control plasma samples, and 2) HNG reduced the CD62P and CD62E protein levels in cell lysates, thereby suggesting that HNG may rescue the mtDNA-mediated inflammation in AMD cybrids. In conclusion, this study presents novel findings that suggest the role of 1) CD62P and CD62E in AMD pathogenesis and 2) HNG as a potential target for reducing Selectins-associated inflammation in AMD. Further studies are required to establish the role of HNG in reducing inflammation by decreasing the protein levels of Selectins in AMD.

ABSTRACT BODY:

Purpose: To analyze the effects of the conjugated p(g3T2) polymer, a rapidly expanding material that can increase its volume by a factor of 100, on human retinal pigment epithelium cell proliferation in vitro.

Methods: Human retinal pigment epithelium cells (ARPE-19) were plated for 24 hours on p(g3T2)-coated well plates. The polymer has a polythiophene backbone with ethylene glycol side chains. To coat the plates, 20µL per well of a 1mg/mL polymer/DMSO solution was applied. The plates were shaken gently until the solution was dry. Non-polymer-coated plates were plated with ARPE-19 cells in the same culture media; this was used as the control for this study. Using the label-free confluence measurement of Incucyte® system over a 132-hour time period, both plates were analyzed for percent cell confluency by analyzing the occupied area of the wells, and then a two-way repeated-measures (RM) ANOVA was performed.

Results: The p(g3T2)-coated plate showed an increase in overall percent confluency from 35.5% to 79.7% over 132 hours (Figure 1). When compared to the control, the confluency of the p(g3T2)-coated plate became significantly lower after 56 hours and remained lower throughout the rest of the study (p=0.0002). In addition, the overall confluency rate of the p(g3T2)-coated polymer was lower than that of the control visualized in the differing slopes in Figure 1.

Conclusions: The increase in ARPE-19 cell proliferation when plated on the p(g3T2)-coated plate suggests the p(g3T2) polymer did not cause any severe toxic effects. The polymer did produce a lower percentage of confluency when compared to the control. This may be due to the polymer physically hindering the cells from adhering to the surface of the plate. This pilot study suggested that p(g3T2) had a mild effect on ARPE-19 cell proliferation, but no apparent widespread cell death was observed. Further studies using different cell lines and ex vivo tissues treated with p(g3T2) are underway to establish a preclinical safety profile of this polymer with many potential therapeutic applications.

ABSTRACT BODY:

Purpose: While most deep learning-based retinal ganglion cell (RGC) neuronal axon and dendritic tracing algorithms have superior performance over conventional ones, they usually require a large amount of manually annotated training data and do not generalize well when the types of neurons in training and testing datasets are significantly different. We developed and tested an automated deep learning-based neuronal tracing approach that can be applied to trace the axons and dendrites in different types of retinal ganglion cell images that does not require manually traced neuronal images for training.

Methods: A data mining algorithm is proposed to learn the noise patterns from raw retinal ganglion cell images. These noise patterns were incorporated into 2,400 digitally reconstructed neuron images downloaded from open source databases of neuronal morphologies to obtain a training dataset of synthetic neuron images. A deep learning-based image segmentation model, ResUNet, was then employed to trace the axons and dendrites in neuronal images. This deep learning model was trained using our synthetic dataset and evaluated on two different testing datasets, including a different synthetic neuron dataset with 300 images and an RGC neuron dataset with 52 images. For the synthetic testing dataset, the digitally reconstructed neurons were utilized as the ground truth images for tracing, while manual tracing results from human experts were considered as the gold standard for the RGC datasets.

Results: Our neuron tracing model can effectively trace the axons and dendrites in both synthetic and RGC neuron images. Quantitatively, our model achieves average foreground, background and overall accuracy of 0.880, 0.994 and 0.993 on the synthetic dataset, 0.757, 0.990 and 0.990 on the RGC dataset, respectively.

Conclusions: The tracing results demonstrate that our neuronal image generation algorithm can accurately produce training data. More importantly, unlike all the other deep-learning-based neuron tracing algorithms, our approach does not require manually traced neuronal image during training and significantly improves raw data analysis times.

ABSTRACT BODY:

Purpose: Anti-vascular endothelial growth factor (VEGF) injections are first-line therapy for retinal vein occlusion (RVO). However, it is challenging for patients to maintain appropriate care due to the high frequency of injections required for anti-VEGF therapy. This study examines the response of retinal biomarkers to lapses in anti-VEGF treatment in RVO patients.

Methods: A retrospective chart review evaluated patients with branched retinal vein occlusion (BRVO) or central retinal vein occlusion (CRVO) at the Cleveland Clinic from January 2012 to June 2020. Patients 18 or older were divided into two cohorts: RVO patients with no lapse in anti-VEGF treatment (control group) and RVO patients with a lapse ≥ 3 months (lapse group). Notably, patients on treat-and-extend or pro re nata protocols were excluded. Central subfield thickness (CST) and visual acuity (VA) were collected at baseline, the first appointment post-lapse, and at 3, 6, and 12 month follow up appointments. Relationships between continuous variables were assessed using t-tests while relationships between categorical variables were assessed using Pearson Chi-Square or Fisher Exact tests.

Results: Lapse patients (n=69) and control patients (n=69) had similar baseline CST ($347.7 \pm 127.8 \mu\text{m}$ vs $365.6 \pm 139.4 \mu\text{m}$, $p=0.436$) and VA (64.1 ± 20.6 ETDRS vs 58.9 ± 20.2 ETDRS, $p=0.588$). Lapse patients experienced a significant increase in CST after discontinuing anti-VEGF therapy (lapse: $398.7 \pm 191.3 \mu\text{m}$, control $338.9 \pm 119.9 \mu\text{m}$, $p=0.034$). This persisted 12 months post-lapse and after re-initiation of anti-VEGF agents (lapse: $381.6 \pm 161.1 \mu\text{m}$, control: $307.5 \pm 95.4 \mu\text{m}$, $p=0.017$). Lapse patients also experienced a decrease in VA after lapse (lapse: 54.5 ± 25.0 ETDRS, control: 64.7 ± 17.5 ETDRS, $p<0.001$) that recovered after 6 months.

Conclusions: Patients with BRVO or CRVO with any lapse in treatment are at risk for poorer outcomes. Though VA normalizes upon treatment resumption, patients experience a statistically and clinically significant increase in CST that does not recover. Further analysis may focus on the impact of persistent anatomic change present 1 year after anti-VEGF resumption.

ABSTRACT BODY:

Purpose: Optimal treatment of anterior segment bacterial or fungal infections is compromised by the restrictions on obtaining adequate microbial samples from the living eye resulting in identification in only about 50% of cases. The goal of this study has been to test a new instrument designed as a noncontact, safe and accurate in experimental infections of the rabbit cornea. Corneal scanning required 10-20 sec. Both genus and species data was obtained for most organisms.

Methods: Sterile miniblade (Beaver-Visitec International, MA, USA) was used to make corneal scratches and ten microliters of a bacterial suspension containing 1×10^5 colony forming units (CFU) per microliter *P. aeruginosa* or *Staphylococcus aureus*, MRSA was topically applied to the scratched cornea. Raman spectrum imaging was carried out at day 1 and day 3 post infection. The custom-built Raman spectroscopy system consist of a near-infrared laser (785nm) as the excitation source. To image the mouse cornea, a special holder was built and integrated into a XYZ motorized stage. The light collected was focused onto the slit of a spectrometer (Andor, Kymera 328i). A back-illuminated deep-depleting thermoelectrically cooled 1024×127 pixel CCD (Andor, iDus 401) was used for the acquisition of Raman spectra. Additional rabbit corneas were infected with *C. albicans* (ATCC 2091), *A.fumigatus* (ATCC 3626) , or *F. solani* (ATCC 46492) and imaged at three days post-infection. Principal component analysis was the primary method of analysis.

Results: Our modified Raman Spectroscopy system analyzes the interaction of light with materials and living cells and tissues providing information about the structure of the scanned substance. As a non-destructive technique it reflects protein structure.

The spectrum for *S. aureus* (ATCC 29213) and *P. aeruginosa* (ATCC 9027) revealed peaks such as uracil, phenylalanine, amide I and amide III. However, the amplitudes of these spectra peaks varied according to the organism making the organisms readily differentiated. Spectra for the three fungi were individually differentiated. Principal component analysis confirmed the raw data results.

Conclusions: The new method presented here has advantages over competing techniques of conventional pathogen identification or confocal, MALDI or immunological methods as it is rapid, non-damaging and gives both genus and species information.

ABSTRACT BODY:

Purpose: Existing visual field testing algorithms rely on manually crafted rules to determine the contrast sensitivity of a light stimulus at each step as well as the stopping criterion, which is suboptimal in terms of testing accuracy and speed. We developed and tested a deep reinforcement learning (DRL)-based visual field testing algorithm that achieves greater performance gain in terms of testing accuracy, speed, and robustness than the Zippy Estimation by Sequential Testing (ZEST) algorithm.

Methods: Our algorithm formulates the procedure of white-on-white static automated perimetry (SAP) as a reinforcement learning problem, with the perimeter modeled as an intelligent agent that could interact with the patient. At each step, the agent can choose to present a stimulus with a specific intensity to the patient or activate a stop signal to end the test and predict the sensitivity. By training the agent on our visual field dataset with 275 normal and 433 glaucomatous visual fields, a new rule is learned by the agent. This rule can guide the agent to perform a series of optimized actions in each test, which leads to the highest testing accuracy with the fewest number of stimuli presentations.

Results: The proposed algorithm was evaluated on both synthetic datasets and our patient visual field dataset under different prior distributions. Experimental results show that our algorithm is 9.4% faster and 5.6% more accurate than ZEST ($p = 0.025$). Meanwhile, our algorithm can generalize better than ZEST when the distribution of testing data is different from the initial distribution.

Conclusions: Our results demonstrate that our DRL-based visual field testing algorithm performs better than ZEST. By maintaining higher accuracy with reduced testing time, our algorithm increases clinic efficiency, improves patient satisfaction, and improves testing results with less patient fatigue. Moreover, the improved generalization ability our algorithm ensures test reliability and robustness of our algorithm.

ABSTRACT BODY:

Purpose: In the covid crisis and beyond, it is critical that we find home-based monitoring tools to measure progressive glaucomatous damage. The primary purpose of this study is to examine the correlation between glaucomatous visual field loss and contrast sensitivity (CS) measured using a home based app.

Methods: 30 patients across the glaucomatous disease spectrum and with good central visual acuity tested a home based app, the Berkeley Contrast Squares (BCSA), that measures CS. The BCSA is a free-downloadable tool that records users' binocular contrast sensitivity and is valid for varying degrees of visual acuity. Patients were sent a video (4min 46s) via email that contained detailed instructions on how to download and use the BCSA at home. The test-retest window was 15 weeks. Validity analyses was calculated using a mixed effects linear regression with log contrast sensitivity as the predictor and visual field as the outcome.

Results: In glaucoma patients the overall correlation for test-retest reliability was 0.94. Validity analyses showed high correlations between home-based contrast testing and 10-2 VF ($p=0.002$) and 24-2 VF ($p=0.05$). A change in 0.1 Log Weber corresponded to a 0.8 dB decline in 24-2 VF MD (95%CI [0.24 to 18.0])) and a 1.3 dB decline in 10-2 VF MD (95% CI [5.2 to 21.0]).

Conclusions: A free downloadable app provides a highly repeatable measure of CS. These results significantly correlate with functional visual field loss. This study suggests that the Berkeley Contrast Squares App has potential to be adopted as a home monitoring tool to track the progression of glaucoma between regular office visits.

ABSTRACT BODY:

Purpose: To evaluate optical coherence tomography angiography (OCTA) changes in patients with non-proliferative diabetic retinopathy (NPDR)

Methods: This is a preliminary study to explore early vessel parameter changes after an anti-VEGF intravitreal injection in eyes with macular edema and NPDR. The electronic medical record was reviewed to obtain information regarding disease severity, presence of diabetic macular edema and treatment. OCTA information was reviewed and six quantitative OCTA features including VCI (vessel complexity index), VAD (vessel area density), VSD (vessel skeleton density), BVT (blood vessel tortuosity), VDI (vessel diameter index), and VPI (vessel perimeter index) were recorded. Statistical analyses were performed using MATLAB (Mathworks, Natick, MA, USA).

Results: A total of 23 eyes of 19 patients were evaluated across three visits. Mean visual acuity was 20/40 at visit 1, 20/50 at visit 2 and 20/50 at visit 3. From visit 1 to visit 2, 21 eyes remained stable, 3 eyes improved, and 6 eyes worsened in severity. From visit 2 to visit 3, 20 eyes remained stable, 7 eyes improved and 2 eyes worsened.

VCI was 0.37 ± 0.23 at visit 1, 0.46 ± 0.32 at visit 2, and 0.39 ± 0.32 at visit 3 (visit 1 and 2, $p=0.09$). VAD was 0.43 ± 0.27 at visit 1, 0.54 ± 0.31 at visit 2, and 0.48 ± 0.33 at visit 3 (visit 1 and 2, $p=0.01$). VSD was 0.45 ± 0.28 at visit 1, 0.54 ± 0.31 at visit 2, and 0.45 ± 0.32 at visit 3 (visit 1 and 2, $p=0.03$ and visit 2 and visit 3, $p=0.08$). BVT was 0.56 ± 0.22 at visit 1, 0.41 ± 0.27 at visit 2 and 0.44 ± 0.26 at visit 3 (visit 1 and 2, $p=0.01$ and visit 1 and visit 3, $p=0.04$). VDI was 0.25 ± 0.33 at visit 1, 0.18 ± 0.26 at visit 2, and 0.22 ± 0.25 at visit 3 (visit 2 and 3, $p=0.006$). VPI was 0.58 ± 0.29 at visit 1, 0.44 ± 0.26 at visit 2, and 0.61 ± 0.31 at visit 3 (visit 1 and 2, $p<0.001$, visit 2 and 3, $p=0.001$). See Figure 1 for an example of a patient with NPDR and OCTA changes.

Conclusions: Quantitative OCTA features including VAD, VSD, VPI, and BVT changed significantly between visits and can detect early changes in NPDR.

ABSTRACT BODY:

Purpose: Previous studies have implied that sight restoration may result in reduction in (tactile-visual) cross-modal plasticity in primary visual cortex (V1), a potential impediment to recovery. However, using tactile-evoked V1 responses has not been shown to be an effective biomarker for plasticity, due to the extensive inter-subject variability reported in absolute activation baseline. In this work, we propose a novel index for measuring the tactile-visual plasticity in sight restoration that may more effectively quantify cross-modal plastic changes.

Methods: We recruited 2 blind retinitis pigmentosa subjects, implanted with Argus II retinal prosthesis per an approved IRB at the University of Michigan: P1 (male) and P2 (female), both implanted in the left eye and right-handed while received the implant 4 and 5 years ago, respectively. We collected functional MRI data from the subjects during right-hand tactile tasks. Activations were calculated in each subject's native space in the identified regions of interest (ROIs) for V1 and left primary somatosensory cortex (S1) in terms of strength (mean z statistics) and extent (%activated voxels in the ROI, FDR<0.05). Our proposed indices were calculated as the ratio of the strength of activation in S1 to V1 (S1 strength:V1 strength) and the ratio of extent of activation in S1 to V1 (S1 extent:V1 extent).

Results: Our results indicated that the S1 strength:V1 strength and S1 extent:V1 extent were higher in P1 (2.7 ± 0.8 and $9.7\% \pm 12.5\%$) with larger average device usage (1 hour/day) compared with P2 (2.1 ± 0.7 and $2.5\% \pm 1.2\%$) with less usage (2 hours/week). This cross-modal effect could not be uncovered by merely relying on the absolute strength/extent of activation in V1 for P1 (1.4 ± 0.4 and $22.5\% \pm 17.6\%$) compared with P2 (1.7 ± 0.3 and $40.0\% \pm 18.5\%$).

Conclusions: We hypothesize that our proposed S1:V1 index more accurately quantifies differences in strength and extent of activation by taking into account the relative contribution of V1 and S1 in processing a tactile task in each subject. We also propose that the extent of device usage, and not necessarily the time-since-implantation, cited in prior studies, is an effective factor for reversing cross-modal changes. Data from larger numbers of subjects with this rare condition are needed to further investigate our proposition.

TITLE: Visual Acuity Outcomes in Patients with Post-Surgical Suprachoroidal Hemorrhage

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Fan, K. Fan, J.L. Hudson, H. Al-khersan, T. Lazzarini, H.W. Flynn, Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jason Fan: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Fan: Commercial Relationship: Code N (No Commercial Relationship) | Julia Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Hasenin Al-khersan: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Lazzarini: Commercial Relationship: Code N (No Commercial Relationship) | Harry Flynn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate recent visual acuity (VA) outcomes in patients with suprachoroidal hemorrhage (SCH) after surgery, and to identify clinical features associated with visual prognosis.

Methods: A retrospective case series of 20 eyes from 20 patients diagnosed with SCH after cataract or glaucoma surgery between Jan. 2014 and Oct. 2020. Tabulated variables included age, sex, hypertension, diabetes, anticoagulation status, lens status, previous ocular surgery, surgery type causing SCH, presenting VA, presenting intraocular pressure (IOP), concurrent pathology on presentation (including flat anterior chamber, vitreous hemorrhage, retinal detachment), duration of apposition, management of SCH (observation, primary drainage, or delayed vitrectomy (PPV)), and post-operative outcomes (VA and IOP). The following LogMAR assignments were utilized: counting fingers = 1.9, hand motion = 2.3, light perception = 2.7, and no light perception = 3. OLS and logistic regression analyses were used for continuous and binary variables, respectively.

Results: The mean patient age was 81 years (SD 13.9), and 14 of 20 eyes were pseudophakic. In the series: 9 cases were post-glaucoma surgery, 7 post-cataract surgery, 4 post-corneal surgery (DSEK or PKP), and 2 from perforated corneal ulcers. SCH developed intraoperatively in 3 cases and post-operatively in 17 cases. The average VA on presentation was 2.45 LogMAR (SD 0.625), and average IOP was 20.1 mmHg (SD 16.9). 10 cases were managed with observation, 9 with delayed PPV, and 1 with delayed drainage. The average post-operative VA was 2.26 LogMAR (SD 0.66) on POD1, and 1.81 LogMAR (SD 0.94) on POM1. Presenting VA was predictive of POD1 ($b=0.563$, $p=0.013$) and POM1 VA ($b=0.74$, $p=0.022$).

Conclusions: Findings from this case series suggest that advances in the management of post-operative SCH have led to improved visual outcomes. A similar study performed at our institution 20 years prior showed that only 8/51 (16%) patients achieved 20/200 vision or better, and 14/51 (27.5%) patients had NLP vision after SCH. In this current series, 6/20 (30%) achieved 20/200 vision or better, and only 3/20 patients (15%) had NLP vision after SCH. Although no specific intervention was found to be predictive of better outcomes, further study of additional cases is required for a comprehensive comparison.

TITLE: Frequency of anti-VEGF intravitreal injections (IVI) after post-injection endophthalmitis in patients with neovascular age related macular degeneration (nvAMD)

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.M. Binczyk, D. Plemel, M. Tennant, Ophthalmology, University of Alberta, Edmonton, Alberta, CANADA|

Commercial Relationships Disclosure (Abstract): Natalia Binczyk: Commercial Relationship: Code N (No Commercial Relationship) | David Plemel: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Tennant: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Controversy exists regarding the impact of post injection endophthalmitis on IVI frequency in patients with nvAMD. We performed a retrospective chart review to assess the effect of anti-VEGF related endophthalmitis on injection frequency in patients with nvAMD.

Methods: All cases of post-IVI endophthalmitis occurring in Edmonton, Alberta, Canada between 2012-2019 were reviewed. Electronic records were analyzed for frequency of IVI, visual acuity (VA), central foveal thickness (CFT), intraretinal fluid (IRF) and subretinal fluid (SRF) height in endophthalmitis eyes and fellow unaffected control eyes. Microsoft Excel was used for data analysis.

Results: Out of 23 eyes with endophthalmitis, 21 (91%) maintained follow up for at least 12 months post endophthalmitis. 16 out of 23 fellow unaffected eyes required IVI and were used as controls. There was a statistically significant reduction in IVI frequency and VA in the first year post as compared to pre endophthalmitis (Tables 1 and 2). No significant reduction in IVI frequency was observed in the second-year post endophthalmitis for case eyes, nor at any time in the control eyes. There was no significant change in CFT, IRF/SRF, or percentages of dry retinas in either cases or controls.

Conclusions: In patients with nvAMD, eyes with post injection endophthalmitis receive fewer IVIs in the first year post endophthalmitis. Control eyes continue to receive intravitreal anti-VEGF at a statistically unchanged frequency over the same time period. Markers including CFT, IRF/SRF, and percentage dry retinas remain statistically unchanged, suggesting disease stability despite a decrease in injection frequency. Larger studies are needed to further clarify the impact of endophthalmitis on the frequency of IVI.

TITLE: Disparities in Dry Eye Severity and Access to Dry Eye Care in Racial and Ethnic Minorities

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Cui, P. Mathews, G. Li, L. Guo, S. Van Court, E. Akpek, Wilmer Eye Institute, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): David Cui: Commercial Relationship: Code N (No Commercial Relationship) | Priya Mathews: Commercial Relationship: Code N (No Commercial Relationship) | Gavin Li: Commercial Relationship: Code N (No Commercial Relationship) | Lee Guo: Commercial Relationship: Code N (No Commercial Relationship) | Shanna Van Court: Commercial Relationship: Code N (No Commercial Relationship) | Esen Akpek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess dry eye severity and access to dry eye care in racial and ethnic minorities.

Methods: Patients with dry eye seen at a tertiary academic medical center, evaluated between 2003 to 2020 were identified using international classification of disease codes M35.0, H16.222, H04.123, 710.2, 375.15. According to self-identified demographics for race and ethnicity, four cohorts of patients were created: Asian, Black, Hispanic, and White. Retrospective review of electronic health records was performed to collect demographics, socioeconomic factors, prior access to dry eye care, and clinical dry eye parameters at baseline as well as last visit.

Results: A total of 464 patients were included (156 White, 85 Asian, 157 Black, and 66 Hispanic). Compared to White patients (3.2%), a greater proportion of minorities lacked health insurance or were on Medicaid (Asians 10.6%, $p=.019$; Blacks 8.3%, $p=.054$, Hispanics 18.2%, $p<.001$). Blacks and Hispanics had a lower estimated median household income than Whites (Whites \$98,260; Blacks \$75,554, $p<.001$; Hispanics \$86,839, $p=.0331$). At baseline visit, lower proportion of minorities had received prescription treatment or in office dry eye procedure (Whites 61.5%; Asians 43.5%, $p=.007$; Blacks 30.57%, $p<.001$; Hispanics 43.9%, $p=.016$). There was no difference with regard to autoimmune disease prevalence at final visit, or diagnosis during follow-up ($P > .05$). In addition, at baseline visit, minorities (compared to Whites) had worse clinical dry eye parameters for mean conjunctival lissamine green staining score (Whites 1.69; Asians 2.44, $p=.032$; Hispanics 2.60, $p=.012$), corneal fluorescein staining score (Whites 1.56; Asians 2.25, $p=.005$; Blacks 2.47, $p<.001$; Hispanics 2.42, $p=.001$), and tear osmolarity (Whites 299.54 vs Blacks 307.98, $p=.001$). Following appropriate treatment, patients with a minimum of 18 months of follow up had no statistically significant differences for any clinical dry eye measurements at final visit.

Conclusions: Our findings demonstrate that racial and ethnic minorities present with worse dry eye parameters. This might be due to disproportionate access to dry eye care, potentially secondary to socioeconomic barriers as well as underappreciation of dry eye among minorities leading to differential treatment by providers.

ABSTRACT BODY:

Purpose: To date, optical coherence tomography angiography (OCTA) studies in retinal vein occlusions have primarily characterized collateral vessels (CVs) in the macula. The goal of this study was to use wide-field swept-source OCT angiography (WF SS OCTA) to characterize the morphology and functional significance of both macular and extramacular CVs in patients with a history of branch retinal vein occlusion (BRVO).

Methods: Twenty-eight eyes with a history BRVO were imaged using 12x12mm WF SS OCTA. CVs and non-perfusion area (NPA) were identified by two independent reviewers using ImageJ. Mixed effects multivariate regression analyses of factors associated with NPA and visual acuity were performed. Region of interest analysis of individual CVs was performed to identify correlations between CV size, depth and retinal location.

Results: Overall, 43% of eyes with BRVO showed evidence of collateral vessels on WF SS OCTA. Of these CVs, 55% were found in the macular region and 45% were extramacular. Analysis of collateral depth revealed that 87.3% of CVs coursed at least partly through the deep capillary plexus (DCP), while the remaining 12.7% of CVs were found to be strictly superficial. No CVs confined only to the DCP were identified. Pearson's correlation analysis of individual collateral vessels revealed that CV depth increased with distance from the optic disc ($r = 0.36$, $p = 0.007$) and CV size increased with distance from the fovea ($r = 0.38$, $p = 0.005$). Multivariate regression analysis did not reveal statistically significant associations between CVs and NPA, or between CVs and visual acuity. Worse visual acuity (higher logMAR score) was associated with greater NPA ($p < 0.001$). NPA was in turn associated with greater central subfield thickness, a marker of macular edema ($p = 0.022$).

Conclusions: A large fraction of CVs that form after BRVO are extramacular, and the morphology of CVs varies as a function of retinal location. These results illustrate the importance of WF SS OCTA in BRVO, as heterogeneity in CV structure may correlate with distinct functional roles.

TITLE: Copolymer surface modification for the modulation of lens epithelial cell behaviour

SESSION TITLE: Posterior Capsular Opacification and Fibrosis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Karim, L.A. Wells, Chemical Engineering, Queen's University, Kingston, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Sumaiya Karim: Commercial Relationship: Code N (No Commercial Relationship) | Laura Wells: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Responsive surfaces can be created by modifying materials with switchable molecules to optimize the properties at the surface for modulating cell behaviour. Azobenzene can reversibly switch from the trans- to the cis-conformation with 365 nm light. Photo-responsive surfaces can reversibly influence protein adsorption and cellular interactions. Evidence suggests the design and material of intraocular lenses (IOLs) influence lens epithelial cell (LECs) behaviour to propagate complications post-lens replacement surgeries. This research develops photo-switchable surfaces for IOLs using azobenzene to modulate LEC behaviour.

Methods: Circular glass coverslips were coated in 35% methacrylic acid (MAA) with isodecyl acrylate (IDA), which has shown to improve healing responses (Wells and Sefton, 2014). These coatings were grafted with 4-(phenylazo)benzoic acid with an amine-terminated triblock copolymer as a spacer using carbodiimide chemistry. Azobenzene changes using UV (ultraviolet) light exposures, followed by observing 325 nm peaks to identify the trans-conformation with UV-VIS (ultraviolet-visible) light spectroscopy. Human LECs (B3-LECs) were incubated on modified coatings and with or without UV light to measure their viability using the alamarBlue and LIVE/DEAD assays.

Results: MAAcoIDA coatings were grafted with $7.4 \pm 2.2 \text{ nmol/cm}^2$ of azobenzene. UV-VIS spectroscopy confirmed that grafted azobenzene on the surface retained the ability to photoisomerize shown through reductions in absorbance at 325 nm (Fig. 1). Current work shows a red-shifted absorbance maximum as trans-azobenzene complexes with β -cyclodextrin and still undergo photoisomerization with the cis-conformation unable to bind with β -cyclodextrin.

B3-LECs incubated with unmodified MAAcoIDA and azo-functionalized coatings had no changes in viability over 48 hours ($p > 0.05$) (Fig. 2). There were no changes in viability when B3-LECs were exposed to low-power (2.5 mW/cm^2 , 45 minutes) ($p > 0.05$) and high-power UV light (18 mW/cm^2 , 45 minutes[SK1]) ($p > 0.05$). Cells grown with azobenzene-grafted copolymers under UV light are expected to have changes in behaviour.

Conclusions: These studies modified regenerative copolymers with azobenzene, which can reversibly bind with β -cyclodextrin. The resulting coatings show low toxicity and are expected to modulate LEC behaviour upon UV exposures with intensities demonstrated not to effect LEC viability.

ABSTRACT BODY:

Purpose: Retinal neovascularization (RNV) is critical to the pathogenesis of many eye diseases, including diabetic retinopathy, a leading cause of vision loss among working-age adults. A novel, controllable photo-mediated ultrasound therapy (PUT) is demonstrated to treat RNV in an in vivo rabbit model. PUT selectively removes angiogenesis by combining low intensity nanosecond pulse duration laser and ultrasound without damaging surrounding tissue.

Methods: An integrated therapeutic ultrasound (0.5 MHz bursts, 10% duty cycle, 10 Hz), laser treatment system, and CCD camera system was devised. An Nd:YAG laser produced 1064 nm laser pulses with 5-ns pulse duration and 10-Hz pulse repetition rate. Laser treatment was initiated at the beginning of each ultrasound burst with a spot size of 5 mm. An in vivo rabbit model of RNV was developed in 6 Dutch Belted pigmented rabbits with intravitreal injection of DL-alpha-aminoadipic acid (AAA) to induce stable, long-term RNV. Eight weeks after injection, RNV rabbits were treated with PUT and serially monitored for up to 4 weeks after treatment with fundus photography, fluorescein angiography (FA), OCT, and indocyanine green angiography (ICGA).

Results: In the PUT treatment group, RNV in the treatment area was effectively removed with minimal damage to the surrounding retinal and choroidal structures. Rapid regression of RNV was shown within 1-day following treatment, and vessel blockage within the treatment area remained stable for at least 4 weeks with persistent regression of RNV (Fig 1). A significant average reduction in RNV of $58.4\% \pm 1.9\%$ was observed 21 days after PUT treatment. In the control group, where no treatment was used, persistent RNV remained stable for up to 52 weeks.

Conclusions: The experimental results demonstrate that a single treatment of PUT can rapidly and effectively remove RNV in this rabbit model with effects that persist for at least 1 month. Minimal treatment side effects are observed.

ABSTRACT BODY:

Purpose: To evaluate pneumatic vitreolysis (PVL) as treatment for vitreomacular traction (VMT) in eyes with and without full-thickness macular hole (FTMH)

Methods: Two multi-center studies conducted across 28 sites in the US. Protocol AG was a randomized clinical trial comparing PVL using C_3F_8 gas with observation (sham injection) in eyes with VMT less than 3000 μm in adhesion length and no FTMH. Protocol AH was a single-arm study assessing PVL using C_3F_8 gas for closure of FTMH no more than 250 μm wide at the narrowest point (AH). Baseline standardized visual acuity (VA) was required to be between 20/32 and 20/400 in AG, and between 20/25 and 20/400 in AH. PVL (AG and AH) or sham injection (AG only) was given at baseline; rescue vitrectomy could be performed if prespecified criteria were met. Primary outcome of AG was central VMT release without rescue at 24 weeks. Primary outcome of AH was FTMH closure without rescue at 8 weeks; central VMT release without rescue at 24 weeks was a secondary outcome. Change in VA from baseline, receipt of rescue vitrectomy, and ellipsoid zone integrity were secondary outcomes in both studies. Shape discrimination hyperacuity was tracked for AG. Rates of retinal tears and detachment were key safety outcomes.

Results: Protocol AG enrolled 46 participants with VMT; at baseline, mean age was 72 years, 67% were female, mean VA was 68.5 letters (Snellen equivalent 20/50), 7% had an epiretinal membrane in the central subfield, and median length of vitreomacular adhesion in the central subfield was 495 μm . Protocol AH enrolled 35 participants with VMT and FTMH; mean age was 69 years, 69% were female, mean VA was 55.8 letters (Snellen equivalent 20/80), 3% had an epiretinal membrane in the central subfield, and mean MH width at the narrowest point was 82 μm . Results have been analyzed and reviewed by the Data and Safety Monitoring Committee, but per National Eye Institute requirements for NIH-funded clinical trials, primary results cannot be made publicly available before publication. Submission and publication of the manuscript are anticipated before presentation of the results at the 2021 ARVO annual meeting.

Conclusions: Conclusions will follow from the results presented.

ABSTRACT BODY:

Purpose: The purpose of this study is to assess the impact of neurolept anesthesia administration timing on the perception of pain in patients undergoing refractive laser-assisted cataract surgery (ReLACS).

Methods: This is a prospective REB randomized control trial at an ambulatory surgical center in Toronto, Ontario, Canada. Patients undergoing cataract surgery were selected in a consecutive manner. Patients were randomized to either receiving neurolept anesthesia following completion of the ReLACS procedure and just prior to draping the eye (standard, n = 38), or, prior to the initiation of the ReLACS procedure (early, n = 35). Primary outcome metrics included pain scores on the visual analogue scale (VAS) from zero (no pain) to ten (unbearable pain) at post-operative day zero (POD0) and post-operative week one (POW1). Secondary outcome measures included a State-Trait Anxiety Inventory (STAI) pre-operative anxiety questionnaire (measured on a scale of 20-80), surgeon and anesthesiologist patient cooperation scores measured on a scale of zero (no event) to three (marked eye and head movement and lid squeezing), ocular metrics (anterior chamber depth, intraocular pressure, surgical time, phacoemulsification energy), and perioperative vitals.

Results: Mean pain scores of early and standard groups at POD0 were 0.59 and 0.79 (p = 0.38), respectively, and at POW1 were 0.76 and 0.87 (p = 0.71), respectively. Linear regression analysis of pain scores incorporating all independent variables (ocular metrics and perioperative vitals) between both groups were also not statistically significant at POD0 (p = 0.40) and POW1 (p = 0.17). In all patients, each 1 mm increase of anterior chamber depth caused an increase of 1.23 pain units (p = 0.02) at POW1. For pain scores at POW1 in all patients, the second eye had an increase of 0.70 pain units (p = 0.02) relative to the first eye.

Conclusions: In patients undergoing refractive laser assisted cataract surgery, there was no difference in pain scores between early and standard timing of neurolept anesthesia administration at both POD0 and POW1. Patients perceived increased levels of pain in the second eye at POW1 relative to their first eye. Furthermore, an increase in ACD was also strongly correlated with an increase in pain scores at POW1.

ABSTRACT BODY:

Purpose: The tub^{-/-} (tubby) mouse (rd5) has long been known to express a complex retinal dystrophy-obesity phenotype with features abridging the Bardet-Biedl (BBS) and Alström (ALMS) syndromes, but to date there is only 1 report of a human counterpart (Borman et al. Hum. Mutat. 2014). Here we report the second ever family presenting with a tubby-like phenotype in association with TUB mutations in 2 affected Caucasian brothers, PT1 and PT2 (49 and 46 yo)

Methods: Testing included visual acuity, semi-automated kinetic perimetries (SKPs), flash electroretinograms (ERGs), macular and retinal nerve fiber layer (RNFL) ocular coherence tomography (OCT), fundus autofluorescence, photos, and fluorescein angiography (FA). Smell function was also assessed (UPSIT scratch-and-sniff test). Whole exome sequencing genotyping was conducted within the Undiagnosed Disease Network project

Results: Both patients exhibited photoreceptor degeneration with disseminated chorioretinal atrophic nummular lesions peripherally and at the arcades, bilateral bull's eye maculopathy with partial foveal residue, and moderately to severely reduced acuity. SKPs were markedly constricted, and ERGs markedly reduced. In both patients a disproportionate vision loss compared to the retinal phenotype led to the identification of RNFL thickening and disc inflammation on FA, which were found to be linked to a secondary autoimmune involvement that responded in part to periocular/intravitreal steroids and oral immunosuppressives. Both patients had BMI>36, borderline cognition, decreased smell, and no dystrophic extremities. PT2 had dilated cardiomyopathy and hypertension. PT1 had sensorineural hearing loss. Both patients shared the c.1359_1360delAG, p.R453Sfs*10, and the splice site c.1380+1G>A TUB mutations. Heterozygous changes in other genes were also identified in both patients, and a novel change in the RP1L1 gene in PT2

Conclusions: We provide further evidence that human TUB mutations are associated with a complex tubby-like syndromic retinal ciliopathy abridging the BBS and ALMS spectrum. The cause for the systemic phenotypic variability remains to be elucidated. Vision loss was augmented by secondary autoimmune phenomena that may be linked to the known role of TUB in regulating microglial phagocytosis through MERTK, a gene known to be associated with pathogenic secondary autoimmunity in both RCS rats and Mertk^{-/-} mice

ABSTRACT BODY:

Purpose: To assess risk factors for development of endophthalmitis following open globe injury.

Methods: A retrospective chart review of all patients treated for open globe injury at the University of Michigan from January 2000 through July 2017 was conducted. Exclusion criteria included intravitreal injection or intraocular surgery in the 30 days prior to injury or less than 30 days of follow-up. A total of 586 out of 993 eyes were included in the study. The main outcome measure was the rate of endophthalmitis in these eyes.

Results: 25/586 eyes (4.3%) presented with endophthalmitis, or developed endophthalmitis following globe closure. Of these, 12/25 eyes (48.0%) presented with endophthalmitis and 13/25 eyes (52.0%) developed endophthalmitis after globe closure. Multivariate logistic regression analysis identified time to globe repair (OR 4.5, CI 1.9-10.7, p = 0.0008), zone I injury (OR 3.6, CI 1.1-11.0, p = 0.0282), and need for additional surgery (OR 5.5, CI 1.5-19.7, p = 0.0092) as factors associated with increased risk of developing endophthalmitis. Subconjunctival antibiotics (OR 0.3, CI 0.1-0.7, p = 0.0036) were associated with decreased risk of developing endophthalmitis.

Conclusions: Prompt closure of the globe and use of subconjunctival antibiotics may reduce the risk of endophthalmitis in open globe injuries. Furthermore, a one-time dose of prophylactic antibiotics with same day discharge and delayed IOFB removal with intravitreal injection of antibiotics did not increase the rate of endophthalmitis. Open globe injuries can be visually devastating and understanding what factors predict and protect against endophthalmitis is paramount to achieving the best possible visual outcomes.

Commercial Relationships Disclosure (Abstract): Salvador Garza: Commercial Relationship: Code N (No Commercial Relationship) | Monica Herrera-Rodriguez: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Hernandez-Delgado: Commercial Relationship: Code N (No Commercial Relationship) | Marcelo Salan-Gomez: Commercial Relationship: Code N (No Commercial Relationship) | Sergio Eduardo Guevara-Quintanilla: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Valdez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the meibography scores according to age in Hispanic population

Methods: Retrospective observational case series. A sample of 192 records from patients referred to the Cornea and Refractive Surgery Service from Ophthalmology Institute Hospital Zambrano Hellion, Tecnologico de Monterrey from January 2020 to December 2020. Patients diagnosed with dry eye were included in the study. Meibography was performed using the OCULUS Keratograph 5M. The meibography scale used measured the percentage of gland dropout from a score of 0 (No gland dropout) to 3 (more than 66% gland dropout). A statistical analysis between the score and the patients age followed.

Results: From the entire study sample, a random sample of 40 patients (80 eyes) was included. 26 (65%) were female and 14 (35%) were male. The age range was from 14-87 years with an average of 45.3 years. The lowest meibography score reported was 0 and the highest 3. The mean of both eyes was calculated for each patient and then compared to their age. An average of 1.47 ± 0.72 was calculated in those younger than 65 years and an average of 2.9 ± 0.22 in those 65 years or older. A statistically significant ($p < 0.05$) moderate positive correlation ($r = 0.39$) between age and a worse score in the meibography was found.

Conclusions: We found that meibography scores tend to get worse with the passage of time. Such a different mean meibography score between those younger than 65 years and those older, may suggest that changes may also accelerate after certain age. A larger sample size could increase the Pearson coefficient.

ABSTRACT BODY:

Purpose: Computational modeling has been used to better understand how intraocular pressure (IOP), intracranial pressure (ICP), and choroidal swelling influence deformation of the human optic nerve head (ONH). Here, we expand on these models to investigate how pathophysiological levels of choroidal swelling occurring during spaceflight (Laurie+, IOVS 2018) compare to the effects of other pathological conditions, e.g. glaucoma (elevated IOP) and idiopathic intracranial hypertension (elevated ICP).

Methods: We used our established computational model of the posterior eye (Feola+, IOVS, 2018), which included the choroid and Bruch's membrane to examine choroidal changes over a cardiac cycle. Our baseline condition represented an individual in the upright position: IOP=15 mmHg, ICP=0 mmHg, mean arterial pressure=57 mmHg, and no choroidal swelling (0 uL). We then applied supra-physiologic or "pathologic", loading conditions including choroidal swelling (50 uL of swelling), elevated IOP (30 mmHg), and elevated ICP (20 mmHg), and then calculated the peak first and third principal strains in the prelaminar neural tissue (PLNT), lamina cribrosa (LC), and retrolaminar neural tissue (RLNT) relative to our baseline condition.

Results: Variation in material properties resulted in a wide range of predicted strains under supra-physiological loading (Figure). In the PLNT, increasing choroidal swelling affected the magnitude and range of peak strains. Within the lamina cribrosa, elevated IOP caused the highest peak compressive strains. Elevated ICP resulted in the largest strains in the RLNT.

Conclusions: Computational modeling indicates that pathologic choroidal swelling places biomechanical strain on tissues of the ONH that are similar or larger than the peak strains associated with elevated IOP and ICP. Changes in the choroid likely play a larger role in ophthalmic pathologies, such as spaceflight-associated neuro-ophthalmic syndrome (SANS) than previously recognized.

ABSTRACT BODY:

Purpose: We have reported that subconjunctival slow-released 48/80 stimulated continuous degranulation of choroidal Mast cells (MCs) and resulted in loss of retinal pigment epithelium (RPE), reduced electroretinogram (ERG) and thinning of retina and choroid, i.e. a geographic atrophy (GA)-like phenotypes in the rat. Moreover, quiescing MCs with oral administration of the MC stabilizer, ketotifen fumarate (KTF), prevented these changes. We herein evaluated whether topical administration of KTF has the potential to prevent these GA-like changes.

Methods: First, we analyzed the levels of KTF in plasma, RPE/choroid/sclera, retina and brain, administered orally and topically twice daily for 5 days, in the eye tissues of normal Sprague Dawley rats. Second, the rats were divided into three groups: group 1, the rats were implanted 48/80 in a hydrogel in the superior subconjunctival space and treated with 1% (10mg/ml) of KTF eye drops; group 2, rats were implanted with 48/80 hydrogel and treated with phosphate buffer saline (PBS); and group 3, rats were implanted with an empty hydrogel only and treated with 1% KTF eye drops. KTF and PBS was topically administered twice daily for 8 weeks. Rats were sacrificed 1, 2, 4 and 8 weeks (w) after implantation. MCs were stained with nonspecific esterase (NSE), RPE labeled with RPE65 in whole mount choroids, and retinal and choroidal area determined in cryosections stained with picosirius red. Dark-adapted ERG was also performed to evaluate retinal function.

Results: We found the highest level of KTF (average 5.6 nM/mg) in the RPE/choroid/sclera of the rats given topical administration in the pharmacokinetic study. At 1w and 2w after implantation, daily treatment with KTF prevented MC from degranulation (38 % reduction at 1w and 38.5 % at 2w of PBS treated, n=6 and n=3, p<0.001 and p<0.01, respectively). The RPE loss with 48/80 was significantly prevented by KTF treatment at 2w and 4w compared to PBS treatment (59.8 % and 34.8 %, n=3 and n=6, both p<0.001). There was a significant difference for preventing the ERG amplitude declining in KTF treated rat at 8w (n=6 per group).

Conclusions: Topical KTF eye drops had efficacy in preventing MCs degranulation and loss of RPE in our GA-like rat model. These data suggest that topical KTF eye drops might be a new therapeutic drug for treating GA.

ABSTRACT BODY:

Purpose: To characterize the independent contributions of the two most common age-related macular degeneration (AMD) loci (the CFH-CFHR5 locus on chromosome 1 [Chr1] and the ARMS2/HTRA1 locus on chromosome 10 [Chr10]) to (1.) risk of conversion to late-stage disease and (2.) to atrophy enlargement once converted into non-exudative late AMD.

Methods: Individuals with AMD and homozygous for risk variants at Chr1 ('Chr1-risk') or at Chr10 ('Chr10-risk'), respectively, recruited at the John A. Moran Eye Center and its ancillary satellite locations, were analyzed. Multimodal imaging data was reviewed to confirm and expand AMD grading, including incomplete and complete retinal pigment epithelium and outer retinal atrophy (iRORA and cRORA), respectively. Total atrophy lesion size was quantified from fundus autofluorescence images using semi-automated software or by manually outlining lesion boundaries on serial, near infrared reflectance images combined with optical coherence tomography volume scans. Survival analyses were performed using Cox proportional hazard models. Associations between genetic group and square-root transformed atrophic area were assessed using multivariable mixed-effect regression models.

Results: Subjects from the Chr10-risk group (n = 92) were more likely (factor of 2.6 [1.3;5.5]) to convert to a late stage phenotype, as compared to the Chr1-risk group (n = 309) (p = 0.01), after adjusting for age and AMD severity at first

visit. The difference was primarily driven by conversion to macular neovascularization, which occurred earlier in the Chr10-risk group as compared to conversion to atrophy. Evaluation of 108 subjects (150 eyes) with manifest cRORA showed that eyes of the Chr10-risk group ($n = 39$) exhibited a significantly more rapid square-root atrophy enlargement rate, as compared to eyes from the Chr1-risk group (111 eyes) (estimated difference 0.14 mm/year [0.11;0.17], $p < 0.001$).

Conclusions: These findings reveal distinct differences in the contribution of the two major AMD genetic loci to late stage AMD phenotypes, which are likely caused by distinct biology associated with Chr1- and Chr10-directed disease. It will be prudent to consider the impact of these two loci in the design and interpretation of results in future AMD clinical trials.

ABSTRACT BODY:

Purpose: AMD is a multi-factorial retinal disease, which affects millions of elderly people worldwide. We have previously demonstrated that the in/del sequence along with its downstream promoter region can significantly induce HTRA1 transcription in the transfected cell line 661W. Furthermore, our previous study of Htra1 transgenic mice driven by a CAG promoter showed a CNV-like phenotype after 12 months, while the use of a retinal pigment epithelial cell specific promoter by others has demonstrated polypoidal choroidal vasculopathy (PCV)-like phenotypes but not CNV. Therefore, we hypothesize that CNV is triggered by overexpression of HTRA1 in tissues outside of the eye. Here, we analyze the HTRA1 concentration in blood to correlate secretion of HTRA1 with the in/del in AMD.

Methods: Quantitative RT-PCR was performed to identify the HTRA1/Htra1 mRNA level across different human and mouse tissues, respectively. PCR and direct sequencing were performed to identify indel genotype in human samples from Japan, India, Australia, and the USA. To compare allelic or genotypic frequencies, the Chi-square test was used in additive models of each case group with controls. To identify the HTRA1 concentration in these blood samples (including serum and plasma), the ELISA was performed. The expression vector with the indel-HTRA1 was transfected into 661W, COS-7, and HEK-293 cells to observe HTRA1 secretion by ELISA. Moreover, ELISA was also performed in iPSCs derived from AMD patients.

Results: HTRA1/Htra1 was ubiquitously expressed across different tissues in both human and mice. Overexpression of Htra1 in mice demonstrated increased Htra1 protein serum concentration. Comparison of AMD patients with controls showed a significantly increased HTRA1 concentration in blood of AMD patients. Moreover, the increased secretion of HTRA1 protein was observed in the in/del-HTRA1 transfected cells and iPSCs derived from AMD patients. Furthermore, the HTRA1 protein blood level rises progressively with age in controls but remains high in AMD patients.

Conclusions: The in/del genotype is associated with AMD leading to an increase of HTRA1 secretion. The HTRA1 blood level is significantly higher in AMD patients with GA or CNV than age-matched controls, strongly suggesting that AMD is triggered by systemic increases of HTRA1 reaching the retinal choroidal capillaries through the bloodstream.

Commercial Relationships Disclosure (Abstract): Keshav Patel: Commercial Relationship: Code N (No Commercial Relationship) | Konstantin Astafurov: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Port: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic significantly disrupted outpatient ophthalmologic care. Factors such as income, race, language and age may contribute to healthcare barriers which were exacerbated by the pandemic. Patients requiring ophthalmologic care, especially those on a regimen of anti-VEGF intravitreal injections, faced challenges in receiving routine treatment. Patients treated for diseases such as age-related macular degeneration (AMD) risk permanent vision loss if treatment is delayed. This study seeks to explore the sociodemographic factors that influenced patient follow-up during the COVID-19 pandemic.

Methods: The electronic medical record for the NJ Retina group was searched for subjects that had intravitreal injections with any anti-VEGF medication to treat AMD, using CPT and ICD-10 codes respectively, in January-February of 2020. These patients were divided based on if they attended the follow-up injection appointment within 2 weeks past the recommended interval. Information from their charts was used including age, sex, marital status, race, ethnicity, language, insurance type, time as a patient and zip code. Median household income data by zip code in New Jersey, from the US Census Bureau, were used to estimate average household income. Statistical analysis of factors was performed using SPSS v26 software.

Results: 4242 patients had intravitreal injections during the chosen timeframe. 3527 of them attended their follow-up appointment and 715 did not. Those who followed up tended to be younger and patients of the practice for longer than those who did not. Those who followed up had a higher percentage of people who were white, married and insured (table A). A logistic regression was performed to ascertain the effects of age, sex, marital status, language, insurance and income on the likelihood of follow up (table B). This model was statistically significant and demonstrated that decreased age, being married, speaking English and having Medicare or a Group Policy as primary insurance were independent predictors of follow-up.

Conclusions: Sociodemographic factors, including age, marital status, race, language and insurance status were associated with significant differences in patient follow-up for intravitreal injections to treat AMD during the COVID-19 pandemic.

ABSTRACT BODY:

Purpose: In myopia development, the choroid provides an essential interface to translate retinal signals into scleral remodelling, but the mechanisms remain elusive. Using scanning acoustic microscopy (SAM) with 7- μ m lateral resolution, we studied the dependency of the choroidal biomechanical properties in myopic guinea pigs (GP) eyes.

Methods: Thirteen 1-week old GPs were form-deprived for 1 week in the right eye to induce myopia while the left eyes were untreated. GPs were then euthanized and both eyes enucleated, flash-frozen and 12- μ m thick serial cryosections were obtained in either a vertical (superior/inferior) or horizontal (nasal/temporal) orientation across the posterior pole. Specimens were scanned with a custom-made SAM with a 250-MHz transducer. Bulk modulus (K) and mass density (ρ) 2-dimensional maps were calculated from the SAM data via a frequency-domain approach. SAM maps were manually segmented to isolate choroidal stroma. To assess the biomechanical properties locally, the choroid was divided into adjacent regions of interest (ROIs) sized 0.2 mm laterally and 0.65 mm in anterior-posterior direction. Within each ROI, the mean and standard deviation of each parameter were calculated. The association between biomechanical parameters and region, myopia status and eccentricity relative to the optic nerve was assessed with linear regression analysis.

Results: Relative myopia ranged from -3 to -9.3D. Among control eyes, mean K in the temporal region was greater than the nasal (containing the central axis, +448 MPa, $p < 0.001$). Per 1 mm in increased eccentricity, nasal K increased by 70 MPa in control eyes ($p = 0.046$). Temporal K decreased by 100 MPa in myopic eyes ($p = 0.015$). Among myopic eyes, ρ was 0.03 g/cm^3 greater in the superior vs. nasal region ($p = 0.04$). In the nasal region, ρ was 0.03 g/cm^3 greater in control vs. myopic eyes ($p < 0.01$). Per 1 mm in increased eccentricity, superior ρ increased by 0.01 ($p = 0.003$) and nasal ρ by 0.01 g/cm^3 in control eyes ($p = 0.02$), whereas in myopic eyes, nasal ρ decreased by 0.03 g/cm^3 ($p = 0.04$) and temporal ρ by 0.04 g/cm^3 ($p < 0.001$).

Conclusions: Choroidal stroma biomechanical properties display myopia-, eccentricity- and region-dependent differences. Our results support the idea that myopia development and possibly scleral remodelling depends on microstructural and biomechanical alterations in the choroidal stroma.

ABSTRACT BODY:

Purpose: Glaucoma damages the retinal nerve fiber layer (RNFL). Animal models show that the ratio of RNFL reflection at 488 nm and 820 nm provides sensitive detection of optic neuropathy. This study investigated RNFL reflection ratio in normal and glaucoma patients.

Methods: Tomography imaging mode of the Heidelberg Retinal Angiography (HRA) was used to take fundus images with filters set to BP (500 – 560 nm) and IR (820 nm). For each wavelength, a series of 64 images scanning through the retina was obtained (Fig. 1c). A circle with radius of 3.2 mm was defined (Fig. 1a). Reflection profile around the circle was calculated for each image. For each wavelength, the maximum reflection profile (R_{BP} and R_{IR}) was identified. The profiles before and after (thin arrows in Fig. 1c) the maximum reflection at distance of $\pm 2/3$ times of the average RNFL thickness measured by OCT were also obtained. To remove the contribution of the deep layers' reflection, $R_{BP0} = R_{BP} - R_{BP_After}$ and $R_{IR0} = R_{IR} - R_{IR_After}$ were calculated. Reflection ratio $r_0 = R_{BP0}/R_{IR0}$ was then calculated. To eliminate the effects of the optical properties of the anterior chamber, the ratio, $r_{before} = R_{BP_before}/R_{IR_before}$, was calculated. The relative reflection ratio of the RNFL was then calculated as $r = r_0/r_{before}$ and used in this study.

Results: Four normal and four glaucoma eyes were studied. In normal eyes, r varied little around the optic nerve head (ONH) with the value ranging from 0.95 to 1.18 (Fig. 1d). In contrast, r of glaucoma eyes varied greatly around the ONH and significantly lower than the normal (Fig. 1e).

Conclusions: Findings were consistent with the animal experiments (Huang et al. ARVO E-abstract 4780, 2020). Because RNFL reflection at different wavelengths were associated with different axonal ultrastructure, changes of the reflection ratio may provide a complimentary assessment of the RNFL damage in glaucoma eyes.

TITLE: The Impact of the COVID-19 Pandemic on Intravitreal Bevacizumab Use

SESSION TITLE: AMD: Clinical and translational research I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Perlroth, K. Mishra, D.V. Do, Byers Eye Institute, Stanford Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Ashton Perlroth: Commercial Relationship: Code N (No Commercial Relationship) | Kapil Mishra: Commercial Relationship: Code N (No Commercial Relationship) | Diana Do: Commercial Relationship(s); Genentech: Code C (Consultant); Regeneron: Code F (Financial Support); Kodiak Sciences: Code I (Personal Financial Interest); Santen: Code C (Consultant); Novartis: Code F (Financial Support); Asclepix: Code C (Consultant); Aerie: Code F (Financial Support); Boehringer Ingelheim: Code F (Financial Support); Allergan: Code C (Consultant)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has led to stay-at-home orders which may lead to fewer medical and ophthalmology visits. Efficacy of treatments for retinal vascular diseases such as wet age-related macular degeneration (wet AMD) depend on strict adherence to regimens of anti-vascular endothelial growth factor (VEGF) injections. The purpose of this study is to describe and compare the number of bevacizumab injections administered in 2019 and 2020 to determine if the COVID-19 pandemic may have affected usage.

Methods: We conducted a single-center, retrospective observational study which compared the number of bevacizumab injections in January through November 2020 with the number of bevacizumab injections in 2019. The total number of injections for each month and year were compared.

Results: The total number of bevacizumab injections in 2020 (Jan-Nov) was 683 compared to 801 in 2019 (Jan-Nov), a 14.7% reduction ($p = 0.02$). Significantly fewer injections were administered in March, April, and May 2020 ($p < 0.01$), and from August to November ($p < 0.01$). The fewest number of injections for 2020 were administered in April ($n = 45$) and May ($n = 45$).

Conclusions: In this patient population, a significant reduction in bevacizumab injections occurred during the COVID pandemic, and the drop in injections was first seen in March 2020 which coincided with stay-at-home orders within the catchment area. These data suggest that the Covid-19 pandemic likely affected the number of patients coming to the retina clinic. Additional data is needed to determine if other factors may have contributed to this decline, and if these missed visits has adversely affected visual acuity outcomes.

ABSTRACT BODY:

Purpose: Ductal epithelial hyperkeratinization is believed to play a key role in the loss of gland function in the development of meibomian gland dysfunction (MGD). This study evaluates a novel topical keratolytic therapy (selenium disulphide) for MGD and associated evaporative dry eye disease (DED).

Methods: Participants with MGD were randomly assigned (1:1) twice weekly, evening application of either AZR-MD-001 0.5% ointment (Azura Ophthalmics) or AZR-MD-001 vehicle, in a multicenter, investigator-masked, vehicle-controlled, randomized, parallel group study (trial registration # NCT04391959). The main outcome measures compared between the active compound and vehicle, include Meibomian Gland Score (MGS), the number of meibomian glands yielding lipid secretion under application of 1.25g/mm² pressure (Meibomian Gland Evaluator, J&J Vision), and Ocular Surface Disease Index (OSDI) symptom score.

Results: Between July and October 2020, 30 participants (50% female) were enrolled. Mean (SD) participant age on enrolment was 58 (17) years and 64% had been diagnosed with MGD at least 5 years previously. Baseline MGS was 6.34 (3.92) and OSDI score was 38.2 (10.8). Seven patients discontinued; 1 for tolerability issues (burning on application) and 6 for protocol violations. All other participants completed the Month 1.5 visit. Data unmasking to allow full analysis follows the final Month 3 visit for the last participant in early January 2021.

Conclusions: Uniquely targeting hyperkeratinisation as a root cause of MGD, this novel topical pharmacotherapy demonstrates potential to alter meibomian gland function and symptoms associated with DED secondary to MGD. Reported ocular surface outcomes of this trial, revealed following unmasking, represent the first level 1 scientific evidence to consider the efficacy of AZR-MD-001 0.5% in treating MGD.

TITLE: Children with amblyopia have deficiency in searching real world images

SESSION TITLE: Amblyopia and Pediatric Ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Satgunam, K. Nagarajan, Brien Holden Institute of Optometry and Vision Science, LV Prasad Eye Institute, Hyderabad, Telangana, INDIA|G. Luo, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): PremNandhini Satgunam: Commercial Relationship: Code N (No Commercial Relationship) | Krishnaveni Nagarajan: Commercial Relationship: Code N (No Commercial Relationship) | Gang Luo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Based on poor conjunction search performance in individuals with amblyopia, it is speculated that these individuals would have difficulties in their day-to-day activities. We investigated visual search performance in this cohort with real world images.

Methods: A real world image was displayed on a computer screen along with a search target. Participant was asked to find the search target within the displayed image and click on it. Two groups of children participated: controls (monocular visual acuity 20/25 or better) and patients having anisometropic amblyopia (anisometropia ≥ 1.5 D and interocular visual acuity difference ≥ 2 lines). Three viewing conditions (binocular, dominant eye, and non-dominant (or amblyopic) eye) were tested in a random order. In each of these conditions 30 images were presented. Dominant eye in the control group was determined using the Porta test. Search performance was assessed using integrated performance (IP) that accounts for both accuracy and time taken. Eye movements were tracked with Eyelink1000. Saccade count, run count (number of repeated viewing) and average fixation duration were analysed.

Results: 23 patients (mean age: 10 ± 0.6 years) and 13 controls (10 ± 0.9 years) participated. Dominant eye visual acuity was comparable between the two groups ($p=0.54$). The mean interocular-visual acuity difference in patients was $\log\text{MAR } 0.35 \pm 0.03$. As expected, patients had the worst search performance [$\text{IP}=0.14 \pm 0.01$] in the amblyopic eye. However, their performance was also significantly ($p<0.03$) poor in both binocular [$\text{IP}=0.19 \pm 0.01$] and dominant eye [$\text{IP}=0.18 \pm 0.02$] when compared to the controls' binocular [$\text{IP}=0.26 \pm 0.02$] and dominant eye $\text{IP}=0.25 \pm 0.03$] viewing conditions. While the average fixation duration between patients and controls were comparable ($p=0.9$), the saccade (patients= 20.1 ± 1.5 , controls= 15 ± 1.1 , $p=0.03$) and run counts (patients= 8.2 ± 0.77 , controls= 6.1 ± 0.4 , $p=0.03$) were significantly more in patients.

Conclusions: Despite having normal acuity in the dominant eye, children with anisometropic amblyopia show a visual search deficiency for real world images. This is similar to the performance observed in conjunction search, which requires feature binding. The poor visual search performance could be due to deficiencies in higher cortical functions rather than low-level visual functions. More run counts to revisit the same image areas suggests deficiency in visual coding.

TITLE: Resident-driven telehealth visits after cataract surgery: Minimizing exposures during COVID-19

SESSION TITLE: Cataract Surgery/Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.P. Chen, T.A. Chen, T. Ahmad, C. Sun, N. Parikh, S. Ramanathan, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Stephanie Chen: Commercial Relationship: Code N (No Commercial Relationship) | Tiffany Chen: Commercial Relationship: Code N (No Commercial Relationship) | Tessnim Ahmad: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Sun: Commercial Relationship: Code N (No Commercial Relationship) | Neeti Parikh: Commercial Relationship: Code N (No Commercial Relationship) | Saras Ramanathan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During the coronavirus (COVID-19) pandemic, reducing unnecessary clinic visits is critical to limit risk of exposure for patients and providers. We hypothesized that final visual outcomes and postoperative complication rates in patients with postoperative week 1 (POW1) telehealth visits would be similar to patients with in-person POW1 visits in this retrospective cohort study.

Methods: All uncomplicated cataract surgeries performed by senior residents with routine postoperative day 1 (POD1) exams and POW1 telehealth visits conducted from July 1, 2020 to December 31, 2020 at a single academic institution were reviewed. Controls were drawn from uncomplicated surgeries performed by senior residents with in-office POW1 visits during the same period the year prior (7/1/19 – 12/31/19). Visual outcomes, including final corrected distance visual acuity (CDVA) and deviation of manifest refraction from the target refraction, were compared between the two groups, along with rates of significant postoperative complications.

Results: Thirty-eight patients (51 eyes) with POW1 telehealth visits and 44 patients (57 eyes) with POW1 in-office visits were included in the study. There were no statistically significant differences in baseline demographics or preoperative CDVA and biometry measurements between the two groups. The average final postoperative month 1 (POM1) logMAR CDVA was 0.030 and 0.021 ($p=0.284$) in the telehealth and in-office groups, respectively, with 44 (86%) telehealth eyes and 51 (90%) in-office eyes within 0.50 D of the target refraction ($p=0.610$). Six eyes (12%) in the telehealth group and 3 eyes (5%) in the in-office group developed complications noted at the POM1 visit ($p=0.222$), comprised of pseudophakic cystoid macular edema (CME) or mild persistent/recurrent postoperative iritis. In all instances, the CME and iritis resolved with topical steroids and/or NSAIDs, with final CDVA 20/30 or better.

Conclusions: There was no statistically significant difference in final CDVA, refractive outcomes, or postoperative complication rates in eyes undergoing POW1 telehealth as compared to in-office visits. In uncomplicated cataract surgeries, POW1 telehealth visits can be a safe and effective alternative to in-office visits to minimize exposure risks during the COVID-19 pandemic.

ABSTRACT BODY:

Purpose: The commonly used fixed-concentration technique of gas fill, following retinal re-attachment by pars plana vitrectomy (PPV), fluid-air exchange (FAX) and endolaser (EL), involves an approximately 30-50cc lavage with iso-expansile or slightly expansile concentrations of either C3F8 or SF6 gas. This retrospective case series evaluated the efficacy and safety of a gas-sparing fixed-volume technique to achieve extended tamponade.

Methods: Following FAX and EL, trocars were removed and sclerotomies were closed with trans-conjunctival vicryl suture, leaving the retina temporarily under air. Using a 30-gauge needle on a 3cc syringe, 1.0cc of 100% C3F8 or SF6 was injected into the vitreous cavity through the pars plana. Using the same syringe, gas volume was then removed as needed while palpating the globe, ensuring that the eye was left at physiological intraocular pressure (IOP). The main outcome measures included post-operative ocular hypertension (OHTN, defined as IOP>24mmHg) rate, gas bubble duration, anatomical retinal re-attachment rate, and occurrence of endophthalmitis.

Results: The fixed-volume gas fill technique was used on 13 eyes of 13 patients (9 males, 4 females) with an average age of 51 years (range 39-67 years) (Table 1). Ten patients had rhegmatogenous RDs (RRDs), two had diabetic tractional RDs (TRDs) and one had combined diabetic TRD with RRD. Post-operative OHTN rate for C3F8 was 45% (5 out of 11 patients) within the first week (Table 2). Two of these patients had pre-existing glaucoma, one had history of ocular trauma, and two were diabetics. The post-operative OHTN was responsive to medical therapy. Neither of the 2 SF6 patients had post-operative OHTN. The average gas bubble duration for C3F8 was 8 weeks (range 6-12 weeks), and that for SF6 was 2 weeks. Anatomical retinal re-attachment rate was 92% (12 out of 13 patients). There were no cases of post-operative endophthalmitis.

Conclusions: The fixed-volume gas fill technique in this case series had similar post-operative OHTN rates compared to the fixed-concentration technique reported in the literature (6-67% of eyes with SF6, and 18-59% of eyes with C3F8), with similar gas duration and retinal re-attachment rates. The fixed-volume technique may have a few advantages, including gas conservation; and, avoiding hypotony during sclerotomy closure, especially with larger gauge sclerotomies.

ABSTRACT BODY:

Purpose: Biallelic pathogenic variants in G protein subunit beta 5 (GNB5) gene causes developmental delay, seizures, hypotonia, sinus node dysfunction and retinal defects featuring bradyopsia and rod ON-bipolar dysfunction. This study investigated the pathogenicity of a homozygous variant of uncertain significance in GNB5 annotated as GNB5L: c.920T>G (p.L307R); GNB5S: c.794T>G (p.L265R) identified in a patient through Whole Exome Sequencing who was newborn screening positive for 3-methylcrotonyl-CoA carboxylase (3-MCC) deficiency with clinical features unexplained by 3-MCC.

Methods: Various clinical signs were ascertained by chart review. Detailed eye exams and extended electroretinogram (ERG) were performed. Fibroblast cell line was derived from patient's skin biopsy for gene expression and protein localization using digital PCR, Western Blot and Immunohistochemistry (IHC). Bioluminescence Resonance Energy Transfer (BRET) – based signaling assay and measuring stability of Regulator G-protein signaling (RGS) complexes in expression assays were used to investigate the impact of the variant on the function of Gβ5-s.

Results: The ocular features of the 9 year-old proband included high myopia, normal fundus and a subtle cone photo-transduction recovery deficit. Her extra-ocular features included severe intellectual disability (ID) and repeated cardiac arrests. The 3-MCC deficiency was confirmed with molecular finding of homozygous MCCC1 (c.1394C>T p.T465I) variant and decreased enzyme activity. The severity of her ID was atypical for 3-MCC deficiency and more in keeping with GNB5-disorder. Cardiac arrest is only known to GNB5-related disorder. In vitro study showed severe loss of function of abolishing the ability of Gβ5-s containing RGS complexes to deactivate signaling via D2 dopamine receptor due to destabilization of RGS complexes. Fibroblast culture demonstrated minimal change in GNB5 expression and translation by digital PCR and Western blots. Differences in subcellular co-localization of Gβ5 and its binding partners were seen with IHC.

Conclusions: Proband's ERG phenotype is consistent with defective function of GNB5L whereas her cardiac and neurodevelopmental phenotype together with the in vitro functional analysis indicates defective GNB5S function. This study highlights the importance of detailed phenotyping and need of functional assays to aid variant classification.

ABSTRACT BODY:

Purpose: Physical separation is the most effective means of protecting patients and clinical staff from the spread of the coronavirus. In order to be able to continue clinical studies in a safe environment, we have developed an imaging workflow that uses fully remote-controlled diagnostic OCT devices in clinical studies.

Methods: Retinal OCT imaging was performed using commercially available OCT devices, remote desktop access software and consumer video conferencing technology on mobile phones and tablets. This method completely separates the patient from the operator and creates the safest condition during the COVID-19 pandemic. We have used CIRRUSTM HD-OCT 5000 (ZEISS, Dublin, CA), CIRRUSTM 6000 (ZEISS, Dublin, CA), and PLEX® Elite 9000 (ZEISS, Dublin, CA). We have used Facetime, Zoom, and Microsoft Teams video conferencing software and TeamViewer remote desktop software.

Results: From March to November 2020, we have conducted 12 remote clinical studies. Imaging was performed by 4 different operators. We have imaged 158 eyes of 79 healthy volunteers aged from 30-65 years old. During each imaging session we captured between 4 and 10 OCT scans per eye. Every imaging session was performed entirely remotely with the volunteer in the office and the operator controlling the device from their home. Figure 1 shows the setup of a remote-controlled imaging setup illustrating the remote desktop software shown on a laptop computer as well as the Facetime video conferencing setup.

Conclusions: We have demonstrated that during pandemics like COVID-19, OCT retinal imaging studies can be performed in a safe environment by completely separating patient and operator and using video conferencing and remote desktop software. We were able to complete all OCT scan acquisitions requested in the clinical studies. The exam time did not appear to be longer than during in-person exams.

ABSTRACT BODY:

Purpose: The lack of risk factors and biomarkers to predict the outcome in lowering intraocular pressure (IOP) is a critical barrier to provide safe and effective surgical interventions for patients with glaucoma. Beyond the trabecular meshwork, which represents the proximal tissue for aqueous humor drainage, there is limited knowledge on the resistance mechanisms of distal drainage including Schlemm's canal, collector channels, and downstream aqueous and intrascleral veins in the perilimbal sclera. The purpose of this study is to resolve the complex anatomy in the aqueous vein-sclera tissue complex.

Methods: Aimed at differentiating between the aqueous veins and intrascleral veins, we perfused enucleated porcine eyes with optical contrast agent in red. A multispectral photoacoustic microscopy system with laser illuminations at 532 nm and 1200 nm was fabricated targeting the contrast agents in aqueous veins, and the collagen and lipid content in the perilimbal sclera. The laser beams are collimated to 3 mm in diameter in separate light paths, merged by a dichroic mirror, and focused at the tissue sample surface by an objective lens with a focal length of 30 mm. A galvanometer orients the laser beams in 2-dimension before the objective lens, forming a 10 mm x 10 mm field of view. The thermoelastic effect of the illumination generates acoustic waves in the targeted tissue components, which are captured by an ultrasound transducer. The temporal resolution of the transducer, in addition to the 2-dimension optical scanning, forms a 3 dimensional representation of the anatomies in the tissue sample.

Results: The system was examined with optical phantoms. Images at the two optical wavelengths show the capability to distinguish the aqueous veins and the scleral tissue. Fig. 1 shows a representative image of aqueous veins in a porcine eye by assembling images acquired at multiple locations. Details of the aqueous veins anatomies are shown in the subpanels.

Conclusions: Photoacoustic imaging demonstrates proof-of-concept for the ability to distinguish and resolve anatomy of the aqueous veins and perilimbal sclera. Coupled with tools for manipulating and monitoring IOP, this technology can advance knowledge of the aqueous humor dynamics and the biomechanics of the aqueous vein and perilimbal sclera tissue complex.

ABSTRACT BODY:

Purpose: Beta peripapillary atrophy (β PPA) has been shown to be associated with open-angle glaucoma (OAG), its severity and risk of progression. The pathophysiological mechanism leading to β PPA development remains uncertain. Scleral stiffness is thought to be a major determining factor for strain at the optic nerve head. Hence we hypothesize that ocular rigidity (OR), an important biomechanical parameter of the eye which accounts primarily for the stiffness of the sclera, may be involved. The purpose of this study is to evaluate the relationship between OR and the extent of β PPA in eyes with OAG.

Methods: OR was measured using an optical method developed by our group (Beaton et al., 2015; Sayah et al., 2020). Time-lapse optical coherence tomography (OCT) imaging and automated choroidal segmentation was used to measure the average submacular choroidal thickness (CT) and the pulsatile choroidal volume change (Δ CT). By deriving the pulsatile ocular volume change and measuring the pulsatile pressure change by dynamic contour tonometry, OR was estimated using Friedenwald's equation. The total β PPA area was quantified using the calipers provided by the Spectralis Heidelberg software. OR differences in OAG subjects with and without β PPA, as well as correlations of OR, CT and Δ CT with β PPA area were assessed using SPSS.

Results: Sixty-seven eyes of 63 subjects with OAG were considered in the study. No significant difference in OR was found in eyes with and without β PPA ($p=0.806$). β PPA area and OR were both correlated with ocular axial length (AL) ($r_s=0.314$, $p=0.01$ and $r_s=-0.401$, $p=0.001$ respectively), whereas β PPA area and age were not ($p=0.811$). OR and β PPA area were not significantly correlated ($p=0.601$), even after controlling for AL ($p=0.857$). β PPA area was inversely correlated with CT ($r_s=-0.392$, $p=0.001$) and Δ CT ($r_s=-0.275$, $p=0.024$). Gamma peripapillary atrophy was significantly correlated with AL ($r_s=0.369$, $p=0.002$) and CT ($r_s=-0.314$, $p=0.010$), but not with Δ CT ($p=0.146$) and OR ($p=0.691$).

Conclusions: Interestingly, although OR and β PPA area were both correlated with AL, OR and β PPA area were not significantly correlated in our cohort. However, we did find an inverse correlation between β PPA and both CT and Δ CT in eyes with OAG. This data suggests that reduced choroidal thickness and reduced choroidal pulsatility are associated with the presence of β PPA in OAG.

ABSTRACT BODY:

Purpose: To propose a predictive model for visual acuity (VA) in eyes with diabetic retinopathy (DR) using optical coherence tomography (OCT) and OCT angiography (OCTA) scans.

Methods: We acquired 3×3-mm central scans with a commercial OCT system (Avanti RTVue-XR, Optovue, Inc.). Two OCTA parameters, 3-dimensional para-FAZ vessel density (3D-PFVD) and fractal dimension of deep capillary plexus (DCP), and two OCT parameters, central 1-mm fluid volume and ellipsoid zone (EZ) defect area, were derived from the scans (Figure 1). The central macular thickness (CMT) and foveal avascular zone (FAZ) area, available from the commercial software, were also recorded. We applied a linear multivariate regression to correlate macular parameters with VA at baseline and at 12 months. The Mann-Whitney U test evaluated the VA prediction errors ($VA_{predicted} - VA_{actual}$) of the model created from baseline visits as applied to the baseline vs. 12-month follow up visits.

Results: This study included 234 eyes with DR of varying severity (Early Treatment of Diabetic Retinopathy Study (ETDRS) letter score range: 40-93), 81 eyes of them had 12-month follow up visits (ETDRS letter score range: 51-92). 3D-PFVD ($r=0.610$, $P<0.001$), DCP fractal dimension ($r=0.606$, $P<0.001$), EZ defect area ($r=-0.574$, $P<0.001$) and central fluid volume ($r=-0.536$, $P<0.001$) all achieved better correlations than CMT ($r=-0.464$, $P<0.001$) or FAZ area ($r=-0.117$, $P=0.075$). The regression model combining both OCTA and OCT parameters had significantly ($P<0.001$) better VA prediction performance ($r=0.75$) than that including OCTA parameters only ($r=0.65$). The model created from baseline visit achieved comparable performance when applied to 12-month follow up visits ($P=0.18$).

Conclusions: We have demonstrated OCT- and OCTA-derived parameters that correlate better with VA than CMT and FAZ area. A multivariate regression model combining the parameters created from the baseline visit achieved excellent correlation with VA for both baseline and 12-month follow up visits.

ABSTRACT BODY:

Purpose: To investigate the complex structural changes in the optic nerve head (ONH) with the development of glaucoma and to find novel biomarkers to describe the structural phenotype of the glaucomatous ONH.

Methods: We recruited 3,782 subjects (2233 glaucoma, 1549 non-glaucoma) and imaged the ONH of each subject using optical coherence tomography (OCT). Using a deep learning network, we automatically segmented seven neural and connective tissue layers of the ONH. The segmented OCT images were then reduced to a few latent features (LFs) and reconstructed using an autoencoder. A network with MLP layers was used concurrently to classify the images as glaucoma or non-glaucoma from the LFs. We then performed a principal component analysis (PCA) on LFs and identified the principal components (PCs). Subsequently, we altered the magnitude of each PC in steps and reported how it impacted the morphology of the ONH. To facilitate visualization, we used Uniform Manifold Approximation and Projection (UMAP) to further reduce the LFs to a 2D space.

Results: The image reconstruction quality and diagnostic accuracy increased with the numbers of LFs; with 54 LFs, the Dice coefficient for the reconstructed images was 0.86 ± 0.04 , and the accuracy was $92.0 \pm 2.3\%$. Using UMAP, we were able to dissociate non-glaucoma eyes from glaucoma eyes into two distinct clusters (Fig. 1; AUC = 0.96). The PC1 values for non-glaucoma and glaucoma eyes were significantly different ($p < 10^{-9}$), and by varying it from a high value (non-glaucoma eye) to a low value (glaucoma eye), we observed thinning of neural and connective tissue layers, decrease in minimum rim width, and increase in prelaminar depth. When PC1 was changed incrementally, we observed ONH structural changes (non-glaucoma to glaucoma zone) that may reflect progression.

Conclusions: Our network identified novel biomarkers and revealed the structural changes in the glaucomatous ONH. PC1 summarized multiple and simultaneous structural variations into a single number, and by changing its magnitude, the ONHs transitioned from a non-glaucoma to a glaucoma zone. The paradigm introduced herein may help us describe the structural phenotype of the glaucomatous ONH.

SUBMITTER (NAME ONLY): Konstantin Astafurov

TITLE: Long-term outcomes of a surgical technique for scleral suture fixation of a posteriorly dislocated lens-bag complex without conjunctival opening (Hoffman pockets)

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Astafurov, J. Prenner, H. Fine, M. Wheatley, Ophthalmology, Rutgers—Robert Wood Johnson Medical School, New Brunswick, New Jersey, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Konstantin Astafurov: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Prenner: Commercial Relationship: Code N (No Commercial Relationship) | Howard Fine: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Wheatley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To present long-term outcomes of a surgical technique for rescuing and sclerally fixating a posteriorly dislocated lens-bag complex without the need for conjunctival incision.

Methods: A retrospective chart review of 17 patients (19 eyes) who underwent posterior chamber intraocular lens (IOL) rescue using Hoffman pocket technique was performed. Data were collected on patients with greater than 1 year follow up after surgery. Out of 19 surgical eyes, 6 had greater than 5 year follow up.

Results: The average follow up for all surgical eyes was 37 months (3.2 years). For all eyes with greater than 12 month follow up, the average preoperative vision was 20/343, and the final average vision was 20/46. In the group of surgical eyes with greater than 5 year follow up, the average follow up time was 69 months (5.8 years) with the average preoperative vision 20/305, and the final average vision 20/34.

Four out of 19 eyes had decentration of the sutured intraocular lens, 3 of which required additional surgical repair: two early – less than 6 months after the initial surgery, and one late – 5 years after the initial surgery. In one of those eyes the lens-bag complex was repositioned using the same surgical technique, and in two eyes an IOL exchange for anterior chamber IOL was performed.

Conclusions: Outcome data at greater than 1 year follow up support Hoffman pocket technique as a valuable surgical approach for the rescue of a dislocated lens-capsular bag complex. The rate of recurrent IOL malposition with this technique is relatively low, with most of those events occurring early after the surgery.

ABSTRACT BODY:

Purpose: To investigate the therapeutic effects of diquafosol sodium (DQS) and tocopherol acetate (TCP) mixture in a mouse model of experimental dry eye (EDE).

Methods: After being exposed to desiccating stress for 5 days, mice were treated with eye drops consisting of 3% DQS alone or mixed with 0.005% or 0.01% TCP. Tear volume, tear film break-up time (TBUT), corneal fluorescein staining scores (CFSS), and tear film lipid layer grades (TFLLG) were measured at 0, 5 and 10 days after treatment. Ten days after treatment, the ROS production, MDA levels, and CD4+interferon (IFN)- γ T cells were measured in the cornea and conjunctiva, and the levels of tumor necrosis factor (TNF)- α , interleukin (IL)-1 β , IL-6, and chemokine CC motif ligand 4 (CCL4), and counts of goblet cells were measured in the conjunctiva.

Results: TBUT of the DQS and 0.005% or 0.01% TCP mixture group showed significant increases at 10 days after treatment, compared with the EDE and DQS alone groups ($P < 0.05$). CFSS significantly decreased in the DQS and 0.01% TCP mixture group when compared with EDE and DQS alone groups at 5 and 10 days after treatment ($P < 0.05$). The DQS and 0.01% TCP mixture group showed a significant increase in TFLLG compared with the EDE and DQS alone groups at 10 days after treatment ($P < 0.05$). DQS mixed with 0.005% or 0.01% TCP group showed lower ROS production and MDA levels than in the EDE and DQS alone groups ($P < 0.05$). Furthermore, the DQS and 0.01% TCP mixture group also showed higher conjunctival goblet cell density, and lower CD4+ IFN- γ T cells, and levels of TNF- α , IL-1 β , and CCL4 than in the EDE and DQS alone groups ($P < 0.05$).

Conclusions: The DQS and TCP mixture eye drops had a beneficial effect on the tear films and ocular surface of murine dry eye. When compared to DQS eye drops, the application of DQS and TCP mixture eye drops can be more effective by improving clinical parameters including TFLLG, TBUT, and CFSS, reducing ROS, inflammatory molecules, and T cells, and increasing conjunctival goblet cell density for EDE.

TITLE: Ophthalmology Inquiries on Reddit: What Should Physicians Know?

SESSION TITLE: Ocular Trauma and corneal disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Zhu, NVISION Eye Centers, Rowland Heights, California, UNITED STATES|A. Dave, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Dagny Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Amisha Dave: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patients are increasingly turning to social media to discuss personal medical questions. Despite being a popular social media site, Reddit has often been overlooked as a source of data on patient perspectives and concerns in the field of ophthalmology. We analyzed posts in the Ophthalmology subreddit, r/Ophthalmology, to better understand what conditions patients are talking about online and how often those who make posts are referred to different forms of medical care by commenters.

Methods: This cross-sectional study analyzed posts and their comments from March 18, 2018 to November 9, 2020. All posts and comments on r/Ophthalmology are public and were accessed using the Python Reddit API Wrapper. Posts and comments that were deleted or removed on or prior to November 9, 2020 were not included. The text of posts and comments were analyzed for unique references to ophthalmic conditions from the American Academy of Ophthalmology's Eye Health A-Z through a keyword search. Additionally, this text was analyzed for mentions and recommendations to different types of medical care.

Results: A total of 919 posts were collected from the timeframe above. An auto-moderator makes a comment on every post to discourage patients from asking personal medical questions. Despite this, over two-thirds (612/919) of posts mentioned medical treatment for eye conditions in either a post, comment, or both. Within posts, flashes and floaters are the most common condition with 48/312 (15%) unique mentions followed by glaucoma (7.4%) and retinal detachment (6.7%) (Figure 1). Within comments, cataracts are the most common condition with 71/586 (12%) unique mentions followed by glaucoma (8.9%) (Figure 2). Almost half of all posts mention ophthalmology and 9% go as far as to recommend the poster seek ophthalmic care. One-third of posts have no mention or recommendation of any type of medical care (Figure 3).

Conclusions: These findings show that patients are seeking information about their eye health on the r/Ophthalmology subreddit and that Reddit users are engaging with these types of posts. It is important for the vision community to understand what conditions patients are asking about online and how commenting patients respond to these posts to better educate all patients in the office.

TITLE: Collagen gels crosslinked by photoactivation of riboflavin for corneal defect repair

SESSION TITLE: Corneal Biology: Epithelial Repair, Neuropathy, Stroma, and Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Seo, G. Fernandes-Cunha, F. Chen, P. Le, C. Logan, D.C. Mundy, D. Myung, Ophthalmology, Stanford University, Stanford, California, UNITED STATES|D. Myung, Ophthalmology, VA Palo Alto Health Care System, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Youngyoon Amy Seo: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Fernandes-Cunha: Commercial Relationship: Code N (No Commercial Relationship) | Fang Chen: Commercial Relationship: Code N (No Commercial Relationship) | Peter Le: Commercial Relationship: Code N (No Commercial Relationship) | Caity Logan: Commercial Relationship: Code N (No Commercial Relationship) | David Mundy: Commercial Relationship: Code N (No Commercial Relationship) | David Myung: Commercial Relationship(s);Stanford University:Code P (Patent)

ABSTRACT BODY:

Purpose: Corneal disease and injuries resulting in stromal defects put the cornea at risk of perforation and/or permanent scarring leading to blindness. A biomaterial that not only occupies a defect but also supports epithelialization may improve clinical outcomes and has the potential to reduce the need for further surgical intervention and the cadaveric donor corneal tissue it typically requires. Light activation of riboflavin is being used to crosslink and strengthen stromal collagen in cases of corneal ectasia. Here, we evaluate the use of this modality to also crosslink exogenously supplied collagen in situ at corneal wound sites.

Methods: Riboflavin was mixed with native, unconjugated collagen type I of varying concentrations and exposed to blue and UV light at increasing time intervals. Mechanical properties of the resulting collagen gels, including both storage and loss moduli as a function of exposure time, were studied using a rheometer. Collagen gels photoactivated with riboflavin were then evaluated in an in vivo deep keratectomy model in rabbits, where a 3.5 mm diameter and ~50% depth stromal defect was filled with the gel which was light-cured in situ. The treated eyes were clinically examined and excised after 1 week for immunohistochemical evaluation.

Results: Rheological experiments demonstrated successful gelation of collagen with increasing stiffness as a function of light exposure time using both blue light and UV light. The gels formed in situ by photoactivation of riboflavin were clinically well-tolerated and supported corneal epithelialization after 1 week in vivo. Immunohistochemical analysis exhibited expression of 4-hydroxynonenal (4-HNE) within the epithelium and alpha-smooth muscle actin within the surrounding stroma.

Conclusions: Our study suggests that riboflavin-mediated crosslinked of exogenous collagen type I has the potential to fill and stabilize corneal defects with a matrix that can support epithelialization. Further work to characterize the biological response of the cornea to this modality is merited.

TITLE: Diagnostic performance of automated circumpapillary retinal nerve fiber layer (RNFL) segmentation with high-resolution swept-source optical coherence tomography in Glaucoma

SESSION TITLE: Imaging in Glaucoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Yow, D. Wong, B. Tan, L. Schmetterer, SCBE, Nanyang Technological University, Singapore, Singapore, SINGAPORE|A. Yow, D. Wong, B. Tan, J. Chua, L. Schmetterer, Singapore Eye Research Institute, Singapore, SINGAPORE|R. Husain, Singapore National Eye Centre Glaucoma Department, Singapore, SINGAPORE|

Commercial Relationships Disclosure (Abstract): Ai Ping Yow: Commercial Relationship: Code N (No Commercial Relationship) | Damon Wong: Commercial Relationship: Code N (No Commercial Relationship) | Bingyao Tan: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Chua: Commercial Relationship: Code N (No Commercial Relationship) | Rahat Husain: Commercial Relationship: Code N (No Commercial Relationship) | Leopold Schmetterer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a progressive optic neuropathy that leads to loss of retinal ganglion cells and thinning of retinal nerve fiber layer (RNFL), causes visual field loss and ultimately irreversible blindness. Thinning of RNFL can be quantified by performing objective thickness measurement along circumpapillary RNFL using optical coherence tomography (OCT), for glaucoma diagnostic and monitoring purposes. However, manual measurement is tedious. We evaluate the diagnostic performance of automated circumpapillary RNFL segmentation in swept-source OCT (SS-OCT) images.

Methods: SS-OCT volumes of the optic nerve head (ONH) comprising 250 glaucomatous and 75 normal eyes were collected using a Plex Elite 9000 (Carl Zeiss Meditec, USA) OCT system. Each acquired volumetric scan was processed to reconstruct a single circumpapillary cross-sectional image along a 3.46mm diameter circle centred at the ONH. A trained deep convolutional neural network using a U-Net architecture was then used to segment the circumpapillary RNFL from the cross-sectional images. A global RNFL thickness value was tabulated for each eye by averaging the obtained RNFL profile. Receiver operating characteristic (ROC) analysis was used to assess the overall diagnostic performance.

Results: Mean severity of the glaucoma eyes in our study was -3.64 ± 0.20 dB. For the glaucoma eyes, the mean thickness of the segmented RNFL was 84.97 ± 0.74 μ m, which was significantly different ($P < .001$) from that of the normal eyes (104.24 ± 1.21 μ m). As shown in Fig 1, our automated RNFL segmentation achieved an area under the ROC curve (AUC) of 0.91 (95% CI: 0.86 to 0.94). Example segmentation results are shown in Fig 2.

Conclusions: The results show a high diagnostic accuracy for circumpapillary RNFL segmentation for glaucoma detection, indicating the potentiality of automatic segmentation of circumpapillary RNFL in both healthy and glaucoma cases for detecting glaucoma.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is the leading cause of blindness in the working-age population. Identifying early retinal microvascular changes relevant to DR has the potential to detect DR prior to physical manifestations in the eye. This study aims to determine a set of microvascular biomarkers that are responsible for the development and progression of DR.

Methods: A retrospective study cohort consisting of baseline and follow-up images of 30 healthy and 30 diabetic participants randomly chosen from the LANDMark study. Diagnosis of DR was based on Early Treatment of Diabetic Retinopathy Study scale. A set of 84 geometric microvascular parameters (GMP) were generated from macular centred images using a semi-automated, multi-step web-based Vascular AnalySis Program (VASP). VASP automatically identified vessel boundaries, categorized vessels into arteries or veins, and divided the fundus into multiple zones. An experienced grader confirmed and adjusted the outputs produced by VASP (when necessary), and GMPs were then generated. We analysed the four evolution of all 84 GMPs returned by VASP and compared each parameter between the two groups. Demographic comparisons were performed using a Chi χ^2 test and parameter analysis was performed using a Generalised Linear Model to correct for confounders.

Results: The mean age of diabetic cohort was 57 ± 11 years, with their average BMI significantly greater than the healthy cohort ($28 \pm 6 \text{ kg/m}^2$, $p=0.03$). Supine systolic and diastolic blood pressure were significantly higher ($p<0.001$ & 0.03) in diabetes. From the 84 generated GMPs, five were significantly different between the two groups. In relation to the diabetic cohort, these topographic differences can be summarised as: increased tortuosity for all vessels in Zone C ($p=0.002$), increased tortuosity thickness for arteries and veins in Zone B,C ($p=0.02$ & 0.03), increased asymmetric width ratio for vessel branches in Zone C ($p=0.01$), and the combined width of 2 major vein trees in Zone C increased ($p=0.04$).

Conclusions: Our study found a significant increase in five novel GMPs exclusive to diabetes. Following further research, these objective measurements could be used as biomarkers to identify patients at risk of developing referable DR and enable timely treatment, thus reducing the risk of blindness.

ABSTRACT BODY:

Purpose: To compare Tracking Scanning Laser Ophthalmoscopy (TSLO) measurements of eye fixation in elite D1 baseball players against a control group of healthy, non-baseball players as a preliminary investigation into the mechanism of Quiet Eye.

Methods: Thirty-four young, healthy control subjects (CS) (19F, 15M) aged 13-27 and 26 male D1 baseball players (BP) aged 18-22 participated in the study. For the CS analysis, two 30-second videos were split into three, separate 10-second recordings. Subjects were instructed to fixate on the upper right corner of a 5°x 5° 840nm imaging raster. For the BP, at least three 10-second videos were recorded per eye utilizing the same fixation stimuli and instructions as the CS. Offline, custom MATLAB software was used to stabilize the videos, extract eye motion at 480Hz, and compute microsaccade amplitude, peak velocity, peak acceleration, drift proportion, and drift amplitude. The bivariate contour ellipse area (BCEA) was calculated for each participant.

Results: A mixed effects model was conducted for each fixation measure to see if there was a difference in means (SD) between BP versus CS. Microsaccade mean amplitude was 0.30° (0.15) vs 0.46° (0.21) for BP vs CS ($p < 0.005$). Microsaccade mean peak velocity was 38.99°/sec (24.85) vs 79.68°/sec (49.13) for BP and CS ($p < 0.0005$). Microsaccade peak acceleration was 10510.05°/sec² (9742.58) vs 30997.33°/sec² (22431.55) for BP vs CS ($p < 0.0001$). Drift proportion was 0.88 (0.09) vs 0.84 (0.08) for BP vs CS ($p < 0.05$). BCEA of the drift was 0.10°² (0.13) vs 0.22°² (0.21) for BP vs CS ($p < 0.005$). There was no statistically significant difference in drift amplitude between BP and CS.

Conclusions: D1 baseball players exhibited more stable fixations in performing the given fixation task on TSLO as demonstrated by smaller mean microsaccade amplitudes, velocity, acceleration, and greater drift proportion. Whether this increased fixational stability is the result of an innate ability or is the result of the visual training required to play the visually demanding sport of baseball is still undetermined and warrants further investigation. Additional evaluation of eye motion with TSLO may provide promising insight into the mechanisms of Quiet Eye and on-field performance for baseball players in sports vision.

TITLE: Single cell RNA sequencing reveals cellular and molecular complexity of adult lacrimal gland

SESSION TITLE: Lacrimal gland and Meibomian gland

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H.P. Makarenkova, V. Delcroix, O. Mauduit, T. Umazume, Molecular Medicine, The Scripps Research Institute, La Jolla, California, UNITED STATES|C.S. De Paiva, Ocular Surface Center, Department of Ophthalmology, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Helen Makarenkova: Commercial Relationship: Code N (No Commercial Relationship) | Vanessa Delcroix: Commercial Relationship: Code N (No Commercial Relationship) | Oliver Mauduit: Commercial Relationship: Code N (No Commercial Relationship) | Takeshi Umazume: Commercial Relationship: Code N (No Commercial Relationship) | Cintia De Paiva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Single-cell RNA sequencing using 10X Genomics platforms is an effective way to reveal the heterogeneity of the lacrimal gland, define specific cell lineages, and to identify novel or poorly studied cell types.

Methods: We used unbiased high-throughput single-cell RNA sequencing (scRNA-seq) to identify the transcriptional profiles of adult lacrimal glands and analyzed the transcriptomes of lacrimal gland cells obtained from 3 adult mice. Transcriptionally similar cells were aggregated and analyzed using R Studio, Seurat, and the recently developed Rosalind software. Validation of each cluster has been done by genetic cell lineage labeling combined with analysis of label retaining cells and immunostaining.

Results: Unsupervised clustering resulted in the identification of 21 cell clusters. We have identified 8 epithelial cell clusters: basal ductal contractile cells, expressing several actins, keratins (Krts) and Btg2 (with anti-proliferative properties); basal ductal cells of the progenitor type, expressing Krts, KIT, Wfdc2, and Cnnd, luminal ductal cells, expressing a specific marker of luminal cells Krt19, intercalated duct cells with progenitor cell properties, three different types of acinar cells, expressing Aqp5, and myoepithelial cells, expressing smooth muscle actin (Acta2) and other contractile genes. Stromal and immune cells were identified based on the expression of vimentin (Vim), Ptprc (CD45), Pecame1, and Acta2. We identified 13 types of stromal cells, including two populations of endothelial cells, pericytes - smooth muscle cells of endodermal origin, expressing Acta2 and desmin (Des), two populations of fibroblasts: matrix producing fibroblasts and growth factor expressing fibroblasts. We also identified several clusters of immune cells, such as natural killer cells, tissue specific macrophages, small clusters of cytokines producing macrophages, antigen presenting cells, mast cells, and tissue resident T cells: CD4⁺ T cells, CD8⁺ T cells and Tregs. Analysis of label retaining cells combined with lineage tracing, immunostaining and image analysis confirmed classification of lacrimal gland epithelial cells. Thus, similar to scRNA-seq data, progenitor cells have been found within the basal layer of ducts and within intercalated ducts.

Conclusions: Single cell RNA-sequencing uncovered discrete transcriptional signatures of specific cell types within poorly identified cell populations.

ABSTRACT BODY:

Purpose: Recent studies have suggested the superior diagnostic ability of swept-source optical coherence tomography (SSOCT), versus spectral-domain OCT (SDOCT), in localizing glaucomatous defects in eyes with low to moderate myopia. Here, we compare SSOCT and SDOCT retinal nerve fiber layer thickness (RNFL) measurements in highly myopic (HM) eyes, to determine if the difference in SSOCT and SDOCT RNFL (diffRNFL) is correlated with axial length (AL).

Methods: 43 eyes from 34 HM patients (AL 28.0 ± 1.6 , 24.0 to 31.6mm) were scanned with SSOCT (PLEX Elite) and SDOCT (Cirrus). RNFL was measured and segmented into 4 quadrants and 12 clock-hour segments. Linear regression analysis was performed to evaluate the association between diffRNFL and potential baseline predictor variables (AL, age, gender, laterality, lens status, glaucoma diagnosis [GLC], myopic macular degeneration [MMD] severity, peripapillary atrophy [PPA] severity, disc tilt severity, and presence of intrachoroidal cavitation [ICC]).

Results: In univariate regression analysis, AL was significantly associated with diffRNFL in the inferior quadrant ($\beta=13.50\mu\text{m}$, $p<0.001$), but not in the overall mean, nasal, superior or temporal quadrants (all $p>0.05$). After adjusting for potential confounding variables (MMD, tilt, ICC, GLC and PPA), multivariate analysis demonstrated that every 1mm increase in AL was associated with a $9.33\mu\text{m}$ increase in inferior quadrant diffRNFL ($p=0.03$). When holding potential confounders (including AL) constant, there was a $12.29\mu\text{m}$ greater inferior quadrant diffRNFL per unit increase in PPA severity ($p=0.046$).

In multivariate analysis of SDOCT RNFL values, after adjusting for potential confounders (MMD, tilt, ICC, GLC and PPA), every 1mm increase in AL was associated with a $7.47\mu\text{m}$ decrease in inferior quadrant RNFL ($p=0.001$). In contrast, multivariate analysis of SSOCT RNFL, after adjusting for potential confounders (MMD, tilt, ICC, GLC and PPA), showed that inferior quadrant RNFL was not significantly associated with AL ($p=0.64$).

Conclusions: The difference in SSOCT and SDOCT measurements of inferior quadrant RNFL was shown to increase with longer AL. Moreover, inferior quadrant RNFL was unaffected by AL on SSOCT, but decreased with longer AL on SDOCT. Taken together, this suggests SSOCT may provide more robust RNFL measurements in HM eyes in which there is suspicion for myopic glaucoma.

ABSTRACT BODY:

Purpose: Fundoscopic examination clinical ophthalmology provides a sense of depth for ophthalmologists to better evaluate ocular health and disease progression. Optical coherence tomography can capture three-dimensional anatomy, but is not routinely available in the developing world. Therefore, we designed a cost-effective stereoscopic camera system able to produce optically registered photos of the fundus, which can be used for ophthalmic diagnosis and management in low resource settings.

Methods: Fundoscopic images were taken using the Raspberry Pi (RPI) compute module 3+, RPi stereo camera module, and two 5-megapixel RPi camera modules. Each RPi camera module was encased in a 3D printed custom adapter allowing 6 degrees of freedom (forward/backward, left/right, up/down), attached to a Zeiss 6x18 T monocular, and then connected to a custom 3D printed binocular indirect ophthalmoscope case for the Heine Omega 180 (Fig 1B). The RPi camera modules' central axes were manually aligned using text and a grid on a sample paper. The fundus was visualized through a Volk Digital Clear Field indirect ophthalmic lens that fit into a custom 3D printed focusing track. Light from the Heine Omega 180 was used for transpupillary illumination of the fundus for image acquisition. The entire image capture system was attached to an existing slit lamp for ease of test administration. All custom 3D printed parts were constructed using Polylactic Acid on the Fused Deposition Modeling 3D printer Prusa MK3. Both video capture and image acquisition were controlled by an in-house graphical user interface written in Python using the OpenCV library.

Results: The tonal quality (brightness, contrast, color balance) of the color retinal photographs demonstrate adequate image quality for use in diagnostic evaluation. The optic nerve, macula, and retinal blood vasculature can be clearly visualized.

Conclusions: We built an economic stereoscopic camera system that can capture clear images of the fundus, which can also be remotely accessed for teleophthalmology. Moreover, the high image quality-to-price ratio, stereoscopic function, and remote access make our camera system sustainable in developing countries.

ABSTRACT BODY:

Purpose: There is a strict boundary within the anterior segmental epithelium where more differentiated corneal epithelial cells are clearly segregated from their limbal epithelial counterparts. Expression patterns of Eph/Ephrins as well as miRNAs show compartmentalization at the limbal/corneal junction. We have shown that reciprocal expression patterns of EphA2 and Ephrin-A1 are likely to contribute to normal limbal-corneal epithelial compartmentalization. Moreover, miRNA (miR)-184 is prominently expressed in corneal epithelial cells, and acts as a negative regulator of corneal angiogenesis. Therefore, we investigated whether Eph/Ephrin signaling is responsible for the miR-184 expression pattern in cornea.

Methods: RNA-seq analysis was performed on human limbal and corneal epithelial cells (HLEC and HCEC) treated with antagomirs or Ephrin-A3 overexpression, and validated by real time qPCR and western blotting. Retroviral transduction was used to manipulate Ephrin-A levels. Antagomirs and siRNA knock-down were used to study changes in miR-184 levels by Taqman PCR.

Results: We show that similar to miR-184, miR-210 is prominently expressed in corneal epithelial cells while expression of its well-known target, Ephrin-A3, is restricted to limbal basal cells. Interestingly, antago-210 markedly decreased miR-184 levels, suggesting that miR-210 positively regulates miR-184. Ephrin-A3 overexpression reduced miR-184 levels in HLECs, while Ephrin-A3 knocked down in antago-210 treated cells reversed the reduction seen in miR-184 levels. A transcription factor with a putative binding site on the miR-184 regulatory region was increased both with Ephrin-A3 and antago-210 treatment. Knock-down to reduce ATF3 levels showed increased miR-184 levels, suggesting a role for ATF3. Although antago-210 treatment resulted in increased EphA2 and reduced Ephrin-A1 levels, manipulation of EphA2/Ephrin-A1 expression had no effect on miR-184 levels. However, EphA1, a close relative of EphA2, is enriched in limbal epithelium and siRNA depletion of EphA1 in limbal epithelial cells enhances miR-184 levels and prevents inhibition of miR-184 expression by Ephrin-A3.

Conclusions: Our data clearly demonstrate a link between miR-210 and EphA1/Ephrin-A3 signaling in restricting miR-184 expression within corneal epithelial cells. The functional significance of such regulation insures proper limbal vascularity while keeping the cornea avascular.

ABSTRACT BODY:

Purpose: Corneal disease and scarring are major causes of blindness, with a need for improved treatment approaches. Hyaluronic acid (HA), a naturally occurring, biocompatible glycosaminoglycan with known corneal wound healing effects, is rapidly cleared from the eye. Supramolecular, non-covalent crosslinking modalities, including host-guest interactions, have been developed as ways to create biomaterial polymer networks with dynamic, reversible crosslinks. Here, supramolecular HA (s-HA) hydrogels were formed by cyclodextrin (CD) and adamantine (Ad) host-guest interaction to serve both as a potential vehicle for endothelial cells and as a possible promoter of epithelial wound healing.

Methods: S-HA hydrogels were synthesized by host-guest interaction between HA-CD and HA-Ad or HA-Ad-FITC. Primary corneal endothelial cells (CECs) were grown in culture and either covered with or encapsulated in s-HA hydrogel and evaluated using a live/dead assay at Time 0, Day 1, 2, and 3. To study epithelial healing, a total corneal epithelial debridement was performed, followed by application of s-HA, linear HA, or saline, with fluorescein examination on Day 1, 2, and 3 to determine wound size, and enucleated and fixed in paraformaldehyde for cryosectioning and immunohistochemical analysis on Day 3. Cryosections were stained for actin or nuclei, or immunostained for CD45 or vimentin and analyzed by confocal microscopy.

Results: Following encapsulation and needle injection, CECs showed greater than 90% viability, demonstrating the s-HA hydrogel to be a suitable vehicle. On Day 1, CECs remained dispersed within the hydrogel, but by Day 3, a subset of cells were seen to adhere to the tissue culture plate. In rats, all injured corneas were healed by Day 3. Animals treated with s-HA exhibited less corneal edema, fewer activated cells in the subepithelial stroma following wound closure, and reduced stromal expression of both CD45 and vimentin, with thickness and staining patterns more similar to normal controls than the linear HA or saline-treated eyes. Additionally, linear HA and saline treated eyes showed increased actin filament formation within stromal keratocytes compared to s-HA treated eyes and normal controls.

Conclusions: Supramolecular HA hydrogels have potential for corneal endothelial cell encapsulation as a delivery vehicle, as well as enhanced epithelial wound healing.

ABSTRACT BODY:

Purpose: The optimal procedure to manage simple rhegmatogenous retinal detachment (RRD) is still debated. We performed a retrospective, propensity-matched cohort analysis to compare primary repair failure and final visual acuity (VA) following rhegmatogenous retinal detachment (RRD) repair using pars plana vitrectomy (PPV) only or PPV with scleral buckle (PPV-SB).

Methods: Chart review was done of all 1516 consecutive patients operated for uncomplicated RRD repair using PPV (n=816) or PPV-SB (n=700) and sulfur hexafluoride gas (SF_6) or perfluoropropane gas (C_3F_8) at a tertiary care center between 2014 and 2018. Patients with other etiologies of RD were excluded. Choice of procedure was at the discretion of the treating surgeon. We used a propensity score to obtain a 1:1 nearest-neighbor matching with a caliper of 0.2 accounting for age, sex, laterality, lens status, myopia, macula status, number of detached quadrants and tears, presence of inferior RD and tears, symptoms duration, visual acuity (VA) at baseline, and tamponade agent. Patients with missing data were excluded.

Results: After matching, both groups (n=368 in each group) were well balanced for baseline characteristics, tamponade agent used, and follow-up durations. At presentation, patients had symptoms for 12.2 ± 14.8 days and 2.6 ± 0.8 quadrants were affected with 2.1 ± 1.5 retinal tears. Most patients were macula-off (n=443, 60%) and baseline VA in logMAR was 0.99 ± 1.09 . Treatment mostly used SF_6 (n=581, 79%).

Mean follow-up was 15.6 months. There were less recurrences of RRD in the PPV group (PPV: n=18, 5% vs. PPV-SB: n=41, 11%; $p=0.002$). More surgeries per patient were required to correct these recurrences in the PPV-SB group (PPV: 1.06 ± 0.28 surgeries vs. PPV-SB: 1.14 ± 0.42 ; $p=0.002$). Proliferative vitreoretinopathy and/or epiretinal membrane as a cause of recurrence was higher in the PPV-SB group (PPV: n=10, 3% vs. PPV-SB: n=26, 7%; $p=0.006$). VA in the PPV group was better at 3 months (PPV: 0.38 ± 0.47 vs. PPV-SB: 0.47 ± 0.50 ; $p<0.001$) and final follow-up (PPV: 0.27 ± 0.33 vs. PPV-SB: 0.35 ± 0.49 ; $p=0.009$).

Conclusions: Following uncomplicated primary RRD repair, there were less recurrences and better VA at follow-up in patients who underwent PPV only compared to PPV-SB.

ABSTRACT BODY:

Purpose: Selective laser trabeculoplasty (SLT) enhances outflow facility but depends on angle openness to be performed. Any angle-closure glaucoma (ACG) is not a good candidate for SLT, although if angle shallowness is reversed by any means, laser energy can be applied in the trabecular tissue and have a therapeutic effect. The aim of this retrospective study was to investigate the results of SLT in patients with angle-closure glaucoma with accessible angle view after a procedure to deepen the anterior chamber.

Methods: A retrospective assessment of the medical records of consecutive angle-closure glaucoma cases treated with SLT was performed in a specialized center in western Mexico. Forty-five cases from 26 patients were selected; using the data of one eye per patient, selected in at random. Baseline data and information from the follow-up visits for one year were analyzed. The studied variables were best-corrected visual acuity (BCVA), Goldmann IOP, number of antiglaucoma medications, collateral procedures (surgery/laser), visual field indexes, cup to disc (CD) ratio, thickness of retinal nerve fiber layer (RNFL), thickness of the ganglion cell layer, success procedural rate (pre-established criteria) and presence of complications.

Results:

Patients included in the study (14 females, 12 males) had a mean age of 63.0 ± 10.1 years. Mean time from prior anterior chamber deepening procedure[1] (8, iridotomy; 6, iridoplasty; 5, phaco+IOL, 5, iridotomy+ iridoplasty; 2, iridotomy+phaco+IOL) and SLT was 12.8 ± 10.0 months. Baseline IOP (19.1, S.E. 0.38 mmHg) was significantly less ($p=0.001$) than all five post-SLT timepoints (table 1). No significant changes in the BCVA ($p=0.18$), VFI (0.11), RNFL (0.13), and CD ratio (0.40) were found before and after the laser procedure. Baseline number of glaucoma medications (median, 2; range, 1-4) was significantly greater as compared to the last visit (median, 2 ; range 1-3; $p=0.0001$). Success rate at one year was 65.4%. A transient IOP spike occurred in only 2 cases and was solved with a conservative approach. No other complications were recorded.

Conclusions: According to the current results, SLT could be offered as a good additive treatment for angle-closure glaucoma when the irido-corneal angle can be adequately viewed after an anterior chamber deepening procedure is performed.

ABSTRACT BODY:

Purpose: To determine the efficacy and safety of intravenous (IV) tocilizumab (TCZ) in patients with non-infectious retinal vasculitis who failed conventional immunomodulatory therapy (IMT) and anti-tumor necrosis factor-alpha (anti-TNFa) therapy.

Methods: Medical records of seven patients with retinal vasculitis treated with monthly or biweekly IV TCZ (8 mg/kg) at a university uveitis clinic were reviewed to include demographics, ocular findings, previous treatment modalities, optical coherence tomography, and wide-angle fluorescein angiography (WAFA). Patients included in this index study were refractory to at least one IMT and anti-TNFa agent. Outcome measures were changes in visual acuity (VA), central macular thickness (CMT), and WAFA score. The Angiographic Scoring for the Uveitis Working Group (ASUWOG) system was utilized for FA scoring.

Results: Ten eyes of seven patients received TCZ therapy for a diagnosis of retinal vasculitis. The median age of patients was 14 years (range, 7-24). 57% of subjects were female. Clinical diagnosis of patients was chronic juvenile idiopathic uveitis (n:4), idiopathic retinal vasculitis (n:2), and HLA-B27-associated uveitis (n:1). Previous treatments of patients include methotrexate (n: 6), adalimumab (n:4), infliximab (n:6), and golimumab (n:2). The mean duration of TCZ therapy, up to most recent visit, was 7.1±3.5 months. The mean VA improvement was +4.0±5.6 ETDRS letters. None of the patients showed worsening in the VA. The mean CMT reduced from 373 ± 100mm to 298 ± 40mm (p>0.05), and the mean FA score reduced from 12.7 ± 4.8 to 4.2 ± 3.7 (p<0.001). Repeated infusions of TCZ were well tolerated by all subjects. One patient developed mildly elevated liver transaminases, which subsequently normalized. Figure demonstrates WAFA and OCT findings in a representative patient.

Conclusions: IV TCZ is a potentially effective and safe therapeutic option for the management of retinal vasculitis refractory to conventional IMT and anti-TNFa therapy.

ABSTRACT BODY:

Purpose: Regulator of G-protein signaling 5 (RGS5) is a responsible molecule for pathological tumor neovascularization and has been reported to be involved in cancer, wound healing, and fibrosis. In this study, we investigated the expression of RGS5 in proliferative diabetic retinopathy (PDR).

Methods: Thirty vitreous humor and six fibrovascular membrane (FVM) samples were collected during vitrectomy in patients with PDR. Thirty vitreous humor and six FVM samples were collected during vitrectomy in patients with epiretinal membrane as controls. The expression of RGS5 in FVM was identified by immunostaining. The mRNA expression level of RGS5 was detected by quantitative RT-PCR, and the concentration of RGS5 in vitreous humor was detected by ELISA.

Results: Immunostaining showed co-staining of RGS5 and α SMA in FVMs from PDR patients. The mRNA expression levels of RGS5 were significantly higher in PDR patients compared with controls ($P<0.01$). RGS5 levels in the vitreous humor were significantly higher in PDR patients compared with controls ($P<0.001$). Among PDR patients, mean RGS5 level in the vitreous humor were significantly higher in eyes with FVM than in eyes without FVM ($P<0.02$).

Conclusions: Our results suggest that RGS5 may be involved in the development of FVM associated with PDR.

ABSTRACT BODY:

Purpose: To explore the role of vasin, a common constituent of human aqueous humor, and a known regulator of TGF- β activity in the etiology of glaucoma and trabecular meshwork physiology.

Methods: Vasin levels in the aqueous humor of glaucoma patients (POAG and Uveitis) were determined by mass spectrometry and ELISA. The effects of vasin on TGF- β 2 induced activation of SMAD signaling, and the effects of ADAM17 on vasin secretion in human TM, were evaluated by immunoblot analyses.

Results: Aqueous humor derived from both primary open-angle glaucoma (POAG, n=20)) and uveitis glaucoma (n=12) patients showed a significant but moderate decrease in vasin levels compared to age and gender matched non-glaucoma (cataract) patients. Recombinant vasin significantly suppressed TGF- β 2-induced SMAD 2/3 phosphorylation and α -smooth muscle actin, in human TM cells compared to control TM cells. The profile of extracellular vasin of human TM cells was found to be different with treatment of ADAM17 inhibitor. Although vasin has been reported to be anti-apoptotic and localized to the mitochondria in mouse embryonic fibroblasts, the protein exhibited vesicular distribution in human TM cells.

Conclusions: These results reveal that levels of the active form of vasin (secreted extracellular domain of the transmembrane form of vasin) are decreased in the aqueous humor of POAG and uveitis glaucoma patients. Vasin is known to antagonize TGF- β 2 signaling in human TM cells. Taken together, these findings suggest a crucial role for vasin in the etiology of glaucoma, and support the potential therapeutic significance of vasin in treatment of glaucoma.

ABSTRACT BODY:

Purpose: Although infrequent, reoperations for recurrent or persistent full thickness macular holes have been shown to have a lower success rate based on anatomic and functional outcomes. The optimal approach to these recurrent or persistent macular hole cases who have already undergone removal of the posterior hyaloid and primary ILM removal remains under active investigation. Given the variety of surgical approaches utilized around the world, there is a need for a relatively large series to demonstrate real world visual compared to anatomic outcomes after surgery for recurrent macular holes alone. Based on the multitude of published and successful surgical techniques, a direct comparison of approaches was undertaken.

Methods: Clinical charts of all patients who underwent recurrent macular hole surgery between 2010 and 2020 were reviewed to identify appropriate patients. Operative notes were reviewed for secondary vitrectomy procedures and the surgical technique was recorded. Particular attention was paid to phakic status and whether the internal limiting membrane was removed at the time of primary macular hole repair. Best corrected visual acuity (BCVA) was obtained at 3 months and 6 months post operatively. OCT measurements were reviewed to obtain average macular hole thickness. Eyes were excluded who carried a diagnosis of pathologic myopia (spherical equivalent greater than -8), central retinal vein occlusion, or a history of ocular trauma. All eyes in whom a macula hole was identified along with a retinal detachment were excluded for concurrent cases.

Results: 29 patients were identified to have undergone surgery for recurrent macular hole with complete followup. Patient demographics included a mean age 66.3 ± 17 . 16 patients received ILM flap, 4 patients underwent macular amniotic membrane graft, 2 macular redetachment, 7 use of silicone oil tamponade, and 5 a combination of these techniques. Mean BCVA at baseline was 20/125 and remained at 20/125 equivalent at 3 months. At 6 months the vision had declined to 20/160. The closure rate with all techniques was 81.8% after repeat surgery.

Conclusions: Although anatomic success was achieved in the majority of cases, visual improvement did not always correlate. Additional work is needed to identify better vision salvaging techniques in surgery for recurrent or persistent macular holes.

ABSTRACT BODY:

Purpose: Dry eye disease is a multifactorial disease accompanied by ocular damage. Basic fibroblast growth factor (bFGF) plays an essential role in wound healing, however, its role in dry eye induced ocular damage remains controversial. In this study, we elucidated cellular and molecular major markers of eye inflammation after the use of bFGF in preclinical settings.

Methods: We established in vitro inflammatory model by stimulation of IFN- γ and TNF- α in human corneal epithelial cell (HCEC) and conjunctival epithelial cell (HconEpic). We observed cellular responses, including cell viability, migration, and secretion of cytokines w/o bFGF. In vivo model was established by scopolamine-stimulation in C57BL/6J mouse. bFGF was applied and sodium hyaluronate eye-drop was used as positive control. Corneal damage was evaluated by fluorescein staining. Cytokines and mucus were assayed with ELISA and IHC staining.

Results: bFGF promotes proliferation and migration of HCEC and HconEpic. Under low-dose IFN- γ and TNF- α induced inflammation, bFGF effectively protected cells from death. We have noticed that IL-1 α , IL-1 β , IL-6 and MMP9 by HCEC, IL-6 and MMP9 by HconEpic were upregulated upon IFN- γ and TNF- α stimulation. bFGF downregulated the level of IL-1 α , IL-1 β , IL-6 and MMP9 in HCEC. A slight inhibitory effect on the expression of IL-6 by bFGF was observed in HconEpic. Regarding results from cytokine studies, we obtained consistent results from in vivo study. bFGF also showed therapeutic effect on dry eye as evidenced by increased tear secretion, attenuated fluorescein staining of corneas, decreased corneal matrix swelling and fewer number of vessels around conjunctiva. Interestingly, sodium hyaluronate showed no effect on mucus secretion, while bFGF obviously improved the mucus to a normal level.

Conclusions: bFGF showed protective effects on ocular surface epithelial cells in moderate inflammation by promoting cell proliferation, migration and regulating cytokine production. bFGF attenuated mouse dry eye induced ocular damage and increased mucus secretion. All evidence indicated that bFGF could be a prospective approach for the treatment of dry eye, at least in non-severe dry eye disease.

ABSTRACT BODY:

Purpose: Diabetic macular edema (DME) is a common cause of vision loss among diabetics. Optical coherence tomography (OCT) remains a vital component in the evaluation and management of diabetic macular edema. We sought to evaluate whether Draper's novel vertical transect analysis (VTA), when applied to OCT images in eyes with DME, might accurately predict treatment endpoints.

Methods: A post-hoc analysis was performed on OCT images and clinical data from the TYBEE clinical trial. TYBEE is a multicenter, randomized, masked clinical trial to evaluate the safety and efficacy of suprachoroidal triamcinolone acetonide along with intravitreal Eylea compared with Eylea monotherapy in patients with DME and without prior pharmacologic treatment. Best corrected visual acuity (BCVA) was determined at the clinical sites participating in the clinical trial. OCT central subfield thickness (CST) and Diabetic Retinopathy Severity Score (DRSS) were determined at a central Reading Center. OCT images were processed by automatic segmentation then manually adding a line for the fovea. The vertical transect analysis was then performed on baseline and post-treatment OCT images (both processed and unprocessed) with regression analysis.

Results: BCVA significantly correlated with VTA applied to processed baseline plus post-treatment OCT images ($P=0.044$) and with VTA applied to processed baseline OCT images ($P=0.038$). The change in visual acuity from baseline to post-treatment did not significantly correlate with VTA applied to unprocessed baseline OCT images ($P=0.086$) or with processed baseline OCT images ($P=0.300$). The CST significantly correlated with VTA applied to unprocessed ($P=0.048$) and processed ($P=1.87e-4$) baseline plus post-treatment OCT images and to processed ($P=0.007$) baseline OCT images. However, the change in CST from baseline to post-treatment did not significantly correlate with VTA applied to both unprocessed ($P=0.629$) and processed ($P=0.412$) baseline OCT images. The DRSS and change in DRSS from baseline to post-treatment did not significantly correlate with VTA applied to any OCT images.

Conclusions: There was correlation between BCVA/CST and VTA but no correlation between DRSS and VTA. With more study, VTA has the potential to be a powerful clinical and research tool to predict clinical endpoints in patients undergoing treatment for diabetic macular edema.

ABSTRACT BODY:

Purpose: The use of artificial intelligence (AI) remains limited in cataract imaging diagnosis because there is a lack of numerous standardized images and analysis models. An AI model for cataract diagnosis could potentially be created by slit-light images and machine-learning. We aimed to determine whether our machine-learning model based on images recorded with a slit-lamp device would have the comparable diagnostic performance to that of ophthalmologists.

Methods: A dataset comprising 18,596 frames collected retrospectively were used for training and cross-validation of a machine-learning algorithm. Cataract diagnosis, cataract severity grading, and surgical indication prediction between our model and evaluations performed by ophthalmologists were assessed the use of a slit-lamp device to record cataract video and machine-learning system. A sensitivity, specificity, positive predictive value, and negative predictive value for cataract diagnosis and surgical indication. The area under the receiver operating characteristic curve for each cataract grading. Weighted kappa statistics for cataract video analysis and cross-validation.

Results: Our model could diagnose cataract with sensitivity, 99.60% (95% confidence interval [CI], 99.40–99.70), and specificity, 96.00% (95% CI, 83.40–99.30), compared to the diagnostic performance of ophthalmologists. The results of cataract severity grading were nuclear cataract (NUC) 0: Area under curve (AUC), 0.987 (95% CI, 0.947–1.000); NUC1: AUC, 0.916 (95% CI, 0.888–0.945); NUC2: AUC, 0.862 (95% CI, 0.844–0.879); and NUC3: AUC, 0.943 (95% CI, 0.931–0.955). For overall cataract grading, the accuracy was 87.80% (kappa, 0.811 [95% CI, 0.791–0.831]). The surgical indication prediction with a sensitivity of 91.80% (95% CI, 82.00–95.10) and specificity of 92.30% (95% CI, 86.10–94.40). The cross-validation accuracy was 86.0% (kappa, 0.800 [95% CI, 0.780–0.820]).

Conclusions: We successfully created a high-performance cataract diagnostic AI using machine-learning from images recorded with a portable slit-lamp device, which can simplify the cataract diagnostic process and be of particular use in settings where access to ophthalmologic services is not available.

ABSTRACT BODY:

Purpose: Glaucoma is a progressive optic neuropathy characterized by retinal ganglion cell (RGC) degeneration and visual field loss. Dysregulation of iron homeostasis and oxidative stress have been implicated in the pathogenesis of glaucoma. EYS611 is a novel non-viral gene therapy delivering sustained intraocular concentration of human transferrin (Tf), an endogenous iron chelator. We previously demonstrated that EYS611 slowed disease progression in acute and chronic rat models of retinal degeneration supporting its development for retinitis pigmentosa and dry age-related macular degeneration. To evaluate whether EYS611 could be protective in glaucoma, we evaluated the effect of Tf in a rat model of ocular hypertension (OHT).

Methods: OHT was induced by injection of magnetic microbeads into the anterior chamber of adult Brown Norway rats (n = 5/group). Animals then received four weekly intravitreal injections of Tf (240 µg/eye) or vehicle (BSS). Naïve rats served as normotensive internal controls and remained untreated. Intraocular pressure (IOP) was measured during the 4 week-experimental period. Pattern electroretinogram (pERG) was measured prior to OHT, then 2 and 4 weeks after OHT. RNA-binding protein with multiple splicing (RBPMS) immunolabeling of flat-mounted retinas was used for RGC quantification at 4 weeks.

Results: IOP in rats with OHT was significantly increased over naïve controls by 48h and remained elevated for the entire 4-week experimental period. Both treated groups had lower pERG amplitude compared to naïve controls on weeks 2 and 4. Significantly lower RGC density (-49.7%) was reported in BSS-treated animals at week 4 in comparison to naïve animals (958 ± 146 cells/mm² vs. 1927 ± 61 cells/mm², $p < 0.0001$) whereas RGC density in Tf-treated rats was not statistically different from RGC density of naïve animals ($p = 0.17$). Tf administration preserved RGC by about 70% compared to BSS-treated animals with OHT (1628 ± 92 and vs. 958 ± 146 cells/mm², $p 0.0013$).

Conclusions: These results demonstrate the ability of Tf to protect RGCs exposed to elevated IOP, suggesting that iron chelation could benefit glaucoma patients. These proof-of-concept findings and previous data demonstrating sustained intraocular production of Tf following non-viral gene transfer strongly support the evaluation of EYS611 for long-term and effective neuroprotection in glaucoma.

ABSTRACT BODY:

Purpose: To associate ten macular retinal layer thicknesses with cognitive speed and executive function.

Methods: From the age and sex stratified, population-based LIFE-Adult-Study, spectral domain optical coherence tomography (OCT) volume scans of the macula (97 horizontal B-scans, each consisting of 512 A-scans) were selected from participants with reliable measurements (quality ≥ 20 dB) who underwent cognitive assessment by both parts of the trail-making test (TMT; illustrated in Fig. 1A), with TMT Part A testing cognitive speed and Part B assessing executive function. On each B-scan, ten retinal layers were segmented (Fig. 1B). Separately for each of these layers, at each of the 49,664 A-scans, partial Pearson correlations between layer thickness and each TMT part adjusted for age were calculated. P-values were adjusted for multiple comparisons by the false-discovery method.

Results: 17,759 eyes of 8,958 subjects were included (4,670 female/4,288 male; age range: 20-79 years). Figure 2 shows the pointwise partial correlation maps for each layer and test. Inner retinal layers were stronger associated with both TMT subtests than outer layers. The largest percentage of significant retinal locations was found for the retinal nerve fiber layer (RNFL; TMT-A/B: 72%/68%), followed by the ganglion cell layer (GCL; TMT-A/B: 48%/26%). Generally, TMT-A (cognitive speed) was stronger associated with layer thicknesses than TMT-B (executive function), but amount and spatial arrangement of the associations are similar for both subtests, with the notable exception of the outer photoreceptor segment thickness, which is significantly correlated over 29% of the macula with TMT-A but entirely uncorrelated with TMT-B. Thinner inner layers over large macular areas are related to worse cognitive performance. Layer thinning spares areas nasal to the fovea for RNFL and is ring-shaped around the fovea for most other inner layers.

Conclusions: Previous dementia studies related cognitive decline to thinning of a single retinal layer (RNFL) and typically analyzed areas close to the optic disc. Here, we analyze ten retinal layers of the macula and demonstrate

associations between worse cognitive performance and reduced retinal layer thickness over large areas. This was most pronounced for RNFL and GCL, two layers that are also closely related to optic nerve damages, but selected effects also occurred in outer layers.

ABSTRACT BODY:

Purpose: Transscleral optical phase imaging (TOPI) has been developed in order to visualize retinal pigment epithelium (RPE) cells in vivo. In addition, it reveals a background reflectance pattern which is investigated in this study as the choriocapillaris structure.

Methods: Healthy volunteers and participants with non-neovascular AMD were recruited for TOPI, associated with conventional imaging: spectral domain optical coherence tomography, autofluorescence, color and infrared fundus imaging. Six squares of 5.04x5.04 degrees were acquired with TOPI: one was foveal, four were localized in the macular quadrants with 3.8° eccentricity, and one to the investigators discretion. The resulting TOPI images were confronted with information from conventional multimodal imaging. The results are presented in a descriptive way.

Results: Included were 51 healthy eyes from 30 volunteers (mean age 35±11 years; 37% females), and 10 eyes of 8 AMD patients (mean age 75.5±5.5 years, 50% females). The RPE cells visualized in healthy participants showed a hexagonal pattern with a darker center and a lighter border. However, this pattern was seen on reticular pattern of linear zones with lighter and darker background grey, of 2 to 3 RPE cells width. This reticular background pattern was highly regular in healthy eyes. In AMD eyes with atrophic changes it became a dominant image feature due to high contrast, showing more irregularity. However, in deeper atrophy, the reticular pattern was lost and only larger choroidal vessels were visible. All observations suggested that the reticular pattern corresponds to the choriocapillaris.

Conclusions: TOPI reveals, in vivo, the human choriocapillaris structure in addition to the RPE cells. This novel imaging capacity may be of great value in order to study various pathologies involving the choriocapillaris.

ABSTRACT BODY:

Purpose: Minimal persistent inflammation at the conjunctival and nasal epithelium of asymptomatic rhinitis patients has been detected, revising therapeutic strategy to target the inflammatory response in preference to symptom-based therapy. We have previously shown increased density and morphology of dendritiform cells in the cornea and conjunctiva in active allergic conjunctivitis during the pollen season. This study aimed to assess whether the changes in dendritic cells persisted during the silent symptom-free phase of allergy.

Methods: Twenty allergic participants (mean age 43.3 ± 14.3 years, 55% female) were examined during active allergic conjunctivitis and when the allergy was in silent phase (at least 4 symptom-free weeks). In vivo confocal microscopy (HRTIII) was performed on the right eye in five locations (central cornea, inferior whorl, temporal corneal periphery (1mm inside limbus), temporal corneal limbus, and temporal bulbar conjunctiva (2-3 mm away from limbus)). Five best-focused, non-overlapping images from each location and one from the inferior whorl were analysed. Dendritiform cells (DC) were counted manually, and morphology of corneal cells was recorded using grading scales for cell body size, dendrite length, and dendrite shape. Differences between phases (Wilcoxon Signed Rank test) and between regions (Friedman with post-hoc tests) were examined.

Results: DC density in the conjunctiva was higher in the active phase than the silent ($p=0.001$) but was not significantly different between phases at any of the corneal regions (central $p=0.70$; periphery $p=0.32$; limbus $p=0.14$; inferior whorl $p=0.84$). DC density was higher at the limbus than all other locations ($p \leq 0.001$) during both phases, and the fewest DC were observed at the inferior whorl. During the active phase, DC cell body size at all corneal locations was larger ($p \leq 0.03$), and dendrites were longer at the corneal periphery and limbus ($p < 0.01$), than in the silent phase. Conjunctival DC morphology was assessed qualitatively and observed in both phases to have long thin dendrites and in some participants a wire-netting pattern.

Conclusions: This study demonstrated the persistence of dendritiform immune cells in the cornea, but not in the conjunctiva, in the absence of symptoms in patients with allergic conjunctivitis. These cells were observed to have a lower morphology grade suggesting a less activated state.

ABSTRACT BODY:

Purpose: To evaluate the status of Vascular Endothelial Growth Factor-A (VEGF-A) in lacrimal gland Adenoid cystic carcinoma (ACC) and to correlate with high risk clinicopathological features.

Methods: A retrospective analysis of 30 histopathologically proven ACC patients was undertaken. Clinicopathological features were recorded & 1-55 months follow up was available. TNM staging was done (AJCC, 8th edition). VEGF-A expression was evaluated by immunohistochemistry (IHC) (clone VG1). The association between VEGF-A and clinicopathological variables was analysed using Fisher's exact test; survival by Kaplan-Meier and statistical analysis using log-rank test. Cox regression was performed to determine its prognostic significance.

Results: Of the 30 ACC cases, there were 15 females and males respectively with a mean age of 38 ± 25.8 years. Large tumor size (>2 cm) was found in 86.6% (26/30) cases. The growth pattern was cribriform (n=16), solid (n=9) and mixed (n=5). Perineural invasion was present in 33.3% (10/30), intracranial extension in 16.6% (5/30) & bone erosion in 33.3% (10/30) cases. Exenteration was performed in 23.3% (7/30). Recurrence developed in 60% (18/30), systemic metastasis and death both in 20% (6/30) cases. VEGF-A overexpression was seen in 46.6% (14/30) cases. Clinicopathological correlation revealed VEGF-A to be significantly associated with solid histologic pattern ($p=0.04$) and intracranial extension ($p=0.01$). On Kaplan-Meier analysis, expression of VEGF-A ($p=0.002$), solid histologic pattern ($p=0.004$), perineural invasion ($p=0.003$), bone erosion ($p=0.000$), T3-T4 stage ($p=0.004$), intracranial extension ($p=0.01$) and exenteration ($p=0.01$) significantly correlated with reduced disease free survival. Univariate analysis showed significant correlation of VEGF-A overexpression, solid histologic pattern, perineural invasion, bone erosion, T3-T4 stage, intracranial extension, exenteration and metastasis. On multivariate analysis VEGF-A (HR: 15.2, 95% CI: 1.9-119.4, $p=0.010$) and bone erosion (HR: 21.0, 95% CI: 1.7-247.8, $p=0.015$) were found significant prognostic factors along with metastasis (HR: 5.3, 95% CI: 1.0-26.8, $p=0.04$).

Conclusions: Overexpression of VEGF-A along with bone erosion and metastasis are all important poor prognostic factors in the outcome of lacrimal gland ACC. Studies on a larger cohort is necessary to further validate VEGF-A as a potential therapeutic target in the management of lacrimal gland ACC.

ABSTRACT BODY:

Purpose: An arc shaped black shadow ("black sign") has been observed when using ophthalmoscopy on keratoconus patients (fig. A). We aimed to develop and validate a novel method (Patent pending) for detection of clinical and subclinical keratoconus (KC and KCS) based on the presence of this black sign.

Methods: A device was designed to enable to the clinician to hold the ophthalmoscope at an appropriate angle and distance and attach it to a smartphone (iPhone XS Max) to take a picture of the eye. The clinician using the device was masked to the KC status of the subjects. A masked observer determined the presence of the black sign in the downloaded images. AutoCAD software was used to measure the sign's width. KC, KCS and healthy subjects were included in this study. A diagnosis of KC was based on abnormal tomography and at least one clinical sign of KC. KCS had only abnormal topography. Both eyes were included in the analysis for KC and KCS, while only the right eye for controls. Subjects underwent corneal tomography (Sirius, CSO) and a full ocular exam. KC severity was graded based on Belin ABCD Criteria. Sex, age and tomography parameter differences between groups were evaluated by Chi square and Mann Whitney tests. Spearman correlations were performed between the width of the black sign and ABCD Criteria.

Results: Twenty KC and KCS subjects (24 eyes with KC and 12 eyes with KCS, 10 males, mean age 28.2 ± 9.1 , range 20-56 years) and 35 healthy controls (19 males, mean age 25.1 ± 6.7 , range 20-52 years) participated in this study. Groups were similar in age ($U=246.5$, $p=0.07$) and sex ($\chi^2=0.09$, $p=0.76$) but different in spherical equivalent ($p<0.01$), anterior and posterior keratometry ($p<0.001$), thinnest and central corneal thickness ($p<0.0001$) and front and back apex curves ($p<0.0001$).

The black sign was observed in all KC and KCS images but in none of the controls. The width of the black sign was negatively correlated to Belin Criteria (A, Anterior Elevation: $r=-0.74$, $p<0.0001$; B, Back Elevation: $r=-0.79$, $p<0.0001$; C, Thinnest Corneal Thickness: $r=-0.58$, $p<0.0001$; D, Distance Visual Acuity: $r=-0.36$, $p=0.03$).

Conclusions: This novel method may differentiate between KC and KCS and healthy controls based on the presence of the black sign. The thickness of the black sign is negatively correlated to KC severity. Therefore, this method can be used for screening population and following the progression of the diseases.

ABSTRACT BODY:

Purpose: While subretinal injection of adeno-associated virus (AAV) gene therapy vectors can successfully treat several inherited retinal diseases, some patients display inflammatory events. The eye is known as an immune-privileged site but anti-capsid and anti-transgene immune responses have been reported in some patients, possibly contributing to the loss of transduced cells. We previously reported that a subretinal injection of AAV8 triggers a systemic anti-transgene T-cell response in a dose-dependent manner, and that an antigen introduced into the subretinal space can provide a systemic antigen-specific immunosuppression referred to as subretinal-associated immune inhibition (SRAII). Here, we hypothesize that peptides from the transgene product, have utility as SRAII inducers when introduced simultaneously with the AAV.

Methods: A single subretinal injection of AAV8 with peptides from the transgene product was performed. The transgene cassette encoding GFP and HY male antigen, containing MHC class I- and MHC class II-restricted T cell epitopes (UTY and DBY peptides immunodominant in H-2b female mice), was packaged into AAV8 under the ubiquitous PGK promoter and injected subretinally with or without HY peptides at day 0 in female wild type C57BL/6 and pathophysiological rd10 mice. ELISpot and multiplex assays were done 3 to 14 days post injection for systemic anti-transgene specific primary T-cell response evaluation, or at day 21 (following a subcutaneous challenge at day 14 with HY peptides adjuvanted in CFA) for memory T-cell response analysis.

Results: We found in both models that: (i) subretinal injection of 2.10e9 or 5.10e10 vg of AAV8-PGK-GFP-HY triggered a dose-dependent systemic primary and memory anti-transgene Th1/Tc1 responses, (ii) the simultaneous co-injection of AAV8 and of HY peptides inhibited both CD8+ and CD4+ T-cell specific primary and memory responses against HY even at high dose (5.10e10 vg) of AAV.

Conclusions: SRAII phenomenon seems to be a powerful systemic immunosuppressive mechanism specific to a transgene expressed in an eye. Since we have confirmed these results in the rd10 pathophysiological context, co-injection of the transgene product and the therapeutic vector may be considered as a new immunomodulatory strategy to control inflammatory reactions in the context of ocular gene therapy.

ABSTRACT BODY:

Purpose: For patients that undergo cataract surgery, Spectacle Independence (SI) is one of the desired clinical outcomes, especially when implanted with presbyopia correcting intraocular lenses (IOLs). Although Through Focus Visual Acuity (TFVA) can be accurately predicted based on preclinical simulations and measurements [1], there is a need for a robust model to allow predictions of SI ahead of clinical trials.

Methods: It is expected that the TFVA curve measured on an implanted subject is related to the SI outcome. However, establishing a direct correlation between TFVA and SI is challenging. In this work, we build on previous work and further characterize the link between observed TFVA curves and the SI outcome. We use a Machine Learning (ML) approach to train several different algorithms to classify TFVA curves into SI and non-SI. These include LR, LDA/QDA, KNN, NB, SVM. The training data used for these classification algorithms are binocular TFVA curves (from -3D to 0D, 0.5D steps) and answers to questionnaires related to the subjects SI compiled from multiple clinical studies with a variety of implanted lens models. We use a subset of this full clinical set as a validation check on the different algorithms and compare the results to those obtained with the model developed previously. Additionally, we compare the performance impact of also including each subject's manifest refraction in the training data.

Results: Results show an improvement with respect to the accuracy (at least 10%) of our previous model when classifying curves from the validation dataset. We also find that the strongest predictors of SI in this context are the VA scores in the near range (-3 to -2D) consistent with previous findings. We also compare the predictions of SI for average clinical and preclinical curves with the observed SI in the clinical datasets showing good correlation between them. Including manifest refraction in the training data did not noticeably improve prediction accuracy.

Conclusions: We conclude that the tested ML models, TFVA can be used to predict the SI outcome with a reasonable degree of accuracy and can already give directional information when used with preclinical data. They give improved accuracy as compared to the previous model. However, the attained accuracy (above 70%) may indicate that other factors could also play a role in the SI and could be used to improve predictions further.

TITLE: Effect of axial and lateral fixational eye movements in corneal topography measurement with OCT

SESSION TITLE: Keratoconus and biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. de Castro, E. Martinez-Enriquez, P. Urizar, A. Curatolo, S. Marcos, Instituto de Optica Daza de Valdes, Madrid, Comunidad de Madrid, SPAIN|

Commercial Relationships Disclosure (Abstract): Alberto de Castro: Commercial Relationship: Code N (No Commercial Relationship) | Eduardo Martinez-Enriquez: Commercial Relationship: Code N (No Commercial Relationship) | Pilar Urizar: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Curatolo: Commercial Relationship: Code N (No Commercial Relationship) | Susana Marcos: Commercial Relationship(s);WO2012146811A1:Code P (Patent)

ABSTRACT BODY:

Purpose: The topography of the cornea can be quantified three-dimensionally with Anterior Segment Optical Coherence Tomography (OCT) systems. However, the measurement is not instantaneous and during the scan, fixational eye movements may influence the results. We used simulations to model the influence of axial and lateral eye movements in the variability of repeated corneal topography measurements.

Methods: We used experimental data from two custom-built Fourier domain anterior segment OCT systems collected in 28 participants. The first system was a spectral OCT (OCT1), with a repetition rate of 25K A-scans/s and 10x10mm (300x50 A-scans) lateral range, and the second a swept source OCT (OCT2), 200K A-scans/s, scanned 15x15mm (300x150 A-scans). The measurement time was 0.6 and 0.41 s respectively. Simulations of the acquisition in both systems were performed assuming lateral and axial eye movements using the MATLAB Image System Engineering Toolbox for Biology (ISETBIO). On each OCT scanner position, eye shifts were applied in the x y and z directions and the sag calculated. To simulate higher eye movements a factor F of 1.5 was applied. The central 3 mm of the data were fitted by a sphere (radius R) and the residuals were fitted by Zernike polynomials (6th order coefficients, zC). The standard deviation (std) of the fittings to simulated data and experimental results were compared.

Results: The maximum shift from the fixation point simulated by the eye movement model was 40 μm . OCT1/OCT2 average std across subjects was 0.18/0.17 mm for R, 3.96/3.46 for the 3rd and 3.33/1.65 μm for the 4th order zC. Simulations std for F=1 and 1.5 was 0.15/0.07 and 0.18/0.13 mm for R, 2.35/1.15 and 2.99/1.84 for the 3rd and 1.47/1.16 and 2.19/1.76 μm for the 4th order zC, respectively. When only lateral movements were considered, the simulations predicted 50% lower std values.

Conclusions: The simulations of the raster scan acquisition of corneal topographies including fixational eye movements modeled with the ISETBIO Toolbox predict with high accuracy the experimental variability in the fitting parameters when axial movements are included. While the statistics of the axial eye movements may be different than those in the lateral direction, these simulations can serve to understand the sources of variability in topography measurements and to evaluate different scanning patterns.

ABSTRACT BODY:

Purpose: Melanin naturally presents in the eye including the iris, retinal pigment epithelium, and choroid. The concentration of the melanin changes with aging¹. Polarization-sensitive OCT (PS-OCT) enables the measurement of the degree of depolarization (DOP) of the eye. Recent studies have shown that DOP is a feasible way to measure the melanin in animals² and human³. However, the DOP signal is highly correlated with the light intensity⁴. In this study, we developed an ad-hoc calibration method to decouple the DOP and intensity in a customized PS-OCT. In a guinea pig model, we longitudinally measured the DOP and estimated the melanin distribution in a guinea pig model for 8 weeks in vivo.

Methods: To mitigate the correlation between image intensity and DOP, we fitted an empirical function between SNR and DOP with measured data from an Albino eye (Fig. 1a), assuming no physical depolarization induced by pigmentation. The calibrated DOP was obtained by subtracting the original DOP from the reference DOP in the SNR-DOP function. A total of 10 eyes from 5 guinea pigs (4 pigmented; 1 albino) were imaged weekly with a PS-OCT for 8 weeks. We evaluated the difference of DOP signals associating with pigmentation, ages, and individuals.

Results: We found that the SNR-DOP empirical function was consistent in different datasets from different albino animals (Fig. 1a). After applying the calibration, the DOP contrast was better in agreement with the distribution of melanin, mainly concentrated in the choroid, (Fig. 1b 1c). We quantified calibrated DOP in retinal volume scans (Fig. 2i 2ii) and found it was increasing in pigmented eyes with age (Fig. 2iii).

Conclusions: In this study, we demonstrated that the DOP from a PS-OCT could be calibrated to present better contrast of pigmentation in the eye. We observed the DOP was increasing with age in young pigmented guinea pigs, revealing that melanin accumulated in the choroid.

ABSTRACT BODY:

Purpose: Wolfram syndrome characterised by diabetes mellitus (DM), sensorineural hearing loss (SNHL), optic atrophy and diabetes insipidus arises from bi-allelic variants in WFS1. Less commonly, heterozygous variants are associated with a similar phenotype. In this retrospective, observational study, a group of patients with variants in WFS1 underwent detailed phenotypic analysis.

Methods: A series of 8 patients from 6 families were ascertained from the New Zealand Database of Inherited Retinal and Optic Nerve Disease. Targeted Sanger sequencing or next generation sequencing using an ocular gene panel were performed. Detailed phenotyping included retinal imaging, electrophysiology, neuroimaging and endocrine investigations.

Results: 8 patients (5 female, 3 male) from 6 families (2 Māori, 2 Asian, 1 Pasifika, 1 NZ European) were ascertained. Four families (6 patients) had likely pathogenic variants in WFS1 consistent with recessive disease in 3 and possible dominant disease in one. All 6 patients had optic atrophy with temporal>nasal disc pallor and marked nerve fibre layer thinning on optical coherence tomography. DM was identified in 5 of 6 patients (average age of onset 9 ± 4 years), 2 had SNHL, 2 had reduced fertility and one had diabetes insipidus. The patient with a heterozygous variant found by Sanger sequencing, had optic atrophy, DM, congenital SNHL, DM and premature ovarian insufficiency. Her initial presentation was with optic atrophy with very high blood sugars were identified as part of subsequent systemic investigations. She also had cortical blue dot cataract and persistent bilateral microcystic macular edema despite optimised glycemic control. It is possible that she has a second large copy number variant not identified by Sanger sequencing.

Two further probands had an identical variant (p.Val606Gly) of uncertain significance predicted to be damaging by multiple in silico tools, and with an allele frequency of 3.54×10^{-5} on gnomAD. This was homozygous in one patient with isolated extensive posterior chorioretinal atrophy onset in her 5th decade and heterozygous in a patient with optic atrophy, SNHL and impaired glucose tolerance onset in his 6th decade.

Conclusions: The phenotypic spectrum related to WFS1 variants is highly variable with only one patient in this series representing the full Wolfram spectrum. For patients presenting with optic atrophy, DM investigations are warranted.

ABSTRACT BODY:

Purpose: During cataract surgery the lens is destroyed with ultrasound and its fragments become projectiles that may cause irreversible damage to the corneal endothelium. To increase the stability of the surgical environment and to coat the endothelium with a protection layer, Ophthalmic Viscosurgical Devices (OVDs) are injected into the anterior chamber. We present a method to quantitatively evaluate the still poorly understood protective properties and distribution of OVDs.

Methods: For this work we imaged 100 porcine eyes. Each eye was imaged twice, resulting in 200 Optical Coherence Tomography (OCT) volume scans which stretched over $6 \times 6 \times 2.9 \text{ mm}^3$ (X x Y x Z) sampled at $512 \times 128 \times 1024$ pixels. All images were acquired with a ZEISS LUMERA® 700 with ZEISS RESCAN® 700. Simulated cataract surgery was performed using a BSS-milk-solution (100:1) to create a high-contrast layer beneath the OVD (fig.1 A-C). Through the first part of the here presented pipeline we manually segmented the cornea (epithelium and endothelium) and the OVD BSS-solution boundary layer of approx. 3000 b-Scans. In the second part of the pipeline, a UNet based convolutional neural network (CNN) was trained to automatically segment the cornea (fig.1 (i)), BSS-milky emulsion (fig.1 (ii)) and background (fig.1 (iii)).

Results: We measured for the first time the thickness of the OVD protection layer over a field of view of 6 by 6 mm. We accurately segmented a large data base of 200 OCT volumes and could quantitatively determine the protective properties of OVDs via thickness maps (fig.2 B). From these thickness maps we were able to derive the spatial distributions of every measurement (fig.2 B). We also found that there are notable differences between the layer thicknesses of the different kinds of OVDs.

Conclusions: We presented a method to evaluate for the first time the thickness and homogeneity of protection layers formed by OVDs over a wide field of view, using OCT. This method will in a next step be utilized to investigate the minimal required OVD layer thickness to effectively protect the corneal endothelium.

ABSTRACT BODY:

Purpose: Efforts to develop novel therapies for geographic atrophy (GA) in age-related macular degeneration (AMD) are limited by the paucity of preclinical animal models. Here, we developed a model of GA using viral transduction of retinal pigment epithelium (RPE) with fluorescent reactive oxygen species-generating proteins (RGPs) in mouse eyes to enable focal, titratable acceleration of oxidative stress in RPE mitochondria.

Methods: We performed subretinal injections of an AAV8 vector expressing KillerRed, mCherry, or control GFP under an RPE-specific Bestrophin (VMD2) promoter and a mitochondrial targeting sequence into the eyes of wild-type C57BL/6J mice. At 3 weeks after viral transduction, we focally exposed a $500 \times 500 \mu\text{m}^2$ square region of the retina to 300-700 μW of 561nm light over 20 minutes using a custom scanning-laser ophthalmoscopy (SLO) system to activate the fluorescent RGPs and induce RPE oxidative stress. Structural changes in the retina over 4 weeks were measured in vivo using optical coherence tomography (OCT) and ex vivo by immunostaining with antibodies to rhodopsin to assess rod outer-segments and cone arrestin to assess cone density on histological sections, and ZO-1 to assess the RPE mosaic on RPE flatmounts.

Results: AAV8-mediated expression of KillerRed in RPE resulted in global outer retinal and RPE disruption prior to light exposure, while expression of mCherry and GFP showed intact retinal architecture at baseline. Optical activation of AAV8-mCherry triggered a focal area of outer retinal and RPE atrophy resembling GA, with $12 \pm 4\%$ loss in outer nuclear layer (ONL) thickness, $32 \pm 9\%$ loss in photoreceptor outer segment (OS) length, and $15 \pm 7\%$ loss in RPE thickness, while focal activation of AAV8-GFP did not produce any detectable retinal damage. Immunohistochemistry revealed focal atrophy, with $29 \pm 4\%$ reduction in rod outer segments and $17 \pm 6\%$ reduction in cone density, and RPE disruption and loss within the area of light exposure.

Conclusions: Optogenetic activation of AAV8-mediated mCherry expression in RPE using SLO generates focal outer retinal and RPE atrophy in mouse eyes, and may serve as an inducible model of oxidative stress and GA. This model could be adapted to nonhuman primates for preclinical testing of novel therapies for atrophic AMD.

ABSTRACT BODY:

Purpose: MicroRNAs (miRNAs) are small post-transcriptional regulators offering promising molecules as biomarkers or targets for innovative approaches to treat complex diseases such as age-related macular degeneration (AMD). Hsa-miR-4513 appears an excellent candidate as it contains a seed polymorphism (rs2168518) which is specifically associated with the neovascular (NV) form of AMD. So far, little is known about the biological mechanisms underlying this association. We therefore aimed to identify allele-specific target genes of hsa-miR-4513 to clarify its contribution to NV.

Methods: We performed high-throughput RNA sequencing (RNA-Seq) in a miRNA overexpression model in human umbilical vein endothelial cells transfected with hsa-miR-4513, separated by the rs2168518 alleles. Promising allele-specific target genes were independently verified by quantitative reverse transcription PCR (qRT-PCR) and further validated via protein expression. Allele-specific miRNA binding was analyzed with a luciferase reporter assay. Further, publicly available databases were utilized to link target genes to phenotypes previously described to be associated with hsa-miR-4513.

Results: Overall, we identified 23 allele-specific target genes of hsa-miR-4513 by RNA-Seq and independently replicated 19 of these via qRT-PCR. Western Blot analysis and luciferase reporter assays conducted for five to six exemplary genes further confirmed the allele-specific regulation of these genes by hsa-miR-4513. Remarkably, multiple allele-specific target genes of hsa-miR-4513 are linked to various phenotypes while two genes, namely CDKN2A and TBC1D5, have been reported before to be related to eye phenotypes.

Conclusions: Our study revealed multiple promising allele-specific target genes of hsa-miR-4513, which offer the unique opportunity to elucidate the association of this miRNA with NV. Especially CDKN2A and TBC1D5 are highlighted as interesting allele-specific target genes and provide a basis for further follow-up studies.

TITLE:

Effects of chromatic saturation on visual search performance in individuals with congenital colour vision deficiency

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.R. HATHIBELAGAL, Brien Holden Institute of Optometry and Vision Science, LV Prasad Eye Institute, Hyderabad, Telangana, INDIA|

Commercial Relationships Disclosure (Abstract): AMITHAVIKRAM HATHIBELAGAL: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Individuals with congenital Colour Vision Deficiency (CVD) tend to have lower accuracy and longer reaction times in search-based colour tasks. This study investigated the effects of chromatic saturation on visual search performance in individuals with colour vision deficiency.

Methods: Seven individuals with CVD (3 protans and 4 deuterans; all males; average age: 30 ± 2 years) participated in this study. The colour vision defect was identified by HRR plates. Four images (depicting natural sceneries or flowers/fruits or birds/animals or everyday task) for each of the 15 colour combinations (red/green, red/white, red/grey, red/purple, red/orange, red/brown, red/black, green/grey, green/white, green/yellow, green/brown, green/blue, orange/yellow, brown/orange and black/brown) were manipulated into two categories namely 'low' (-75 %) and 'high' saturation (+75 %) using the GIMP software (Version 2). The altered image sets (low and high) along with 'original' set (unaltered) were presented on a colour-calibrated monitor using the Psychopy program (Version 2.7). The CIE 1931 (x, y) co-ordinates for each colour were obtained based on the tristimulus measured using an XRite Colorimeter. The participants viewed the screen binocularly from a test distance of 1m. The instructions for identifying the specific-coloured target in each presentation preceded the image by three seconds. The participants had to respond within 3 seconds following the image presentation by clicking on the target in the image. The display monitor was screen-recorded throughout the test which was later manually analyzed to derive the correctness of the response. The visual performance was computed as a product of accuracy percentage and reciprocal of the reaction time (s).

Results: Overall the improvement in visual performance (≥ 10 % than original) in 'high' saturation conditions was observed for green/blue, brown/black and red/green combinations. On the other hand, increasing saturation for combinations such as orange/brown and green/yellow deteriorated the visual performance (≥ 10 % poorer than original) in both the groups.

Conclusions: The improvement/worsening of visual search performance on increasing the saturation of the images depends on specific colour combinations. Therefore, specific recommendations for increase in colour saturation for improvement in visual performance can potentially be developed.

ABSTRACT BODY:

Purpose: To investigate the association between gut microbiome composition and retinal degeneration rate in RCS rats raised in specific pathogen free (SPF) and non-SPF conditions.

Methods: RCS rats were born and raised in Sheba Medical Center animal facility under SPF (n=69) and non-SPF conditions (n=48). Fecal samples were individually collected every two weeks for microbiome analysis and the rats were examined for retinal structure by Spectral Domain Optical Coherence Tomography (SD-OCT), blue light autofluorescence fundus (BL-FAF) imaging and histopathology. Retinal function was assessed by Electroretinogram.

Results: Gut microbiome significantly differed between rats that were raised in non-SPF vs. SPF conditions. 90 different bacterial amplicon sequence variant (ASVs) were increased in non-SPF and other 34 bacterial ASVs were increased in SPF raised rats. Specific bacterial ASVs showed increased abundance with increasing rat age, and those were observed in earlier ages in rats raised in non-SPF conditions compared to rats raised in SPF conditions (p=0.002).

BL-FAF imaging revealed significantly smaller hypofluorescent lesions in rats raised in SPF conditions. This was more specifically noted at the age of 12 weeks, where the hypofluorescent lesion area was 6.8 fold higher non-SPF rats vs. rats raised in SPF conditions (p=0.003). Significantly shorter latencies were recorded for scotopic a- and b-waves and photopic b-waves in rats raised in SPF conditions as early as 4 weeks of age compared to rats raised in non-SPF conditions (p=0.02, p<0.001, p<0.001 respectively). At age of 8 weeks, the scotopic a-wave latency recorded in rats raised in non-SPF conditions was 1.7 fold longer (57.69 ± 11.57 ms) compared to rats raised in SPF conditions (33.11 ± 2.93 ms, p=0.04). SD-OCT total retinal thickness was higher in the superior part of the retina in rats raised in SPF conditions (294.83 ± 12.64 mm) compared with rats raised in non-SPF conditions (260.327 ± 10.76 mm, p=0.05).

Conclusions: Microbial diversity and age-related microbial dynamics were observed in non-SPF vs. SPF rats, in parallel to more rapid and severe retinal degeneration, and may present potential intervention strategy for slowing disease progression.

TITLE: 10-year Incidence of Open-Angle Glaucoma in Highly Myopic Eyes as Compared with Non-highly Myopic Eyes in the Beijing Eye Study

SESSION TITLE: GL- Predictive Biomarkers

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Wang, C. Wei, J. Xu, L. Xu, J. Jonas, Beijing Institute of Ophthalmology, Beijing Tongren Hospital, CHINA|J. Jonas, Medical Faculty Mannheim of the Ruprecht-Karls-University of Heidelberg, GERMANY|

Commercial Relationships Disclosure (Abstract): Ya Xing Wang: Commercial Relationship: Code N (No Commercial Relationship) | Chuan Chuan Wei: Commercial Relationship: Code N (No Commercial Relationship) | Jie Xu: Commercial Relationship: Code N (No Commercial Relationship) | Liang Xu: Commercial Relationship: Code N (No Commercial Relationship) | Jost Jonas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the 10-year incidence of open-angle glaucoma (OAG) in highly myopic eyes as compared with non-highly myopic eyes in the population-based longitudinal Beijing Eye Study (BES).

Methods: Out of 4439 participants aged 40+ years who took part in the BES in 2001, 2695 participants (60.7%) were re-examined in 2011, while 397 (8.5%) individuals had died. The study population was into a highly myopic group (refractive error ≤ -6 diopters [D]), moderately myopic group (-3 to -6 D), low myopic group (-1 to -3 D), and emmetropic/hyperopic group (> -1 D). Incident glaucoma was defined as new development of glaucomatous optic neuropathy in 2011. A flicker method was used to compare aligned photographs of the optic nerve head and retinal nerve fiber layers, taken at baseline and after 10 years. The anterior angle was evaluated with anterior segment optical coherence tomography.

Results: Incident OAG was found in 74 participants among 2492 participants free of glaucoma at baseline, with the 10-year incidence of $3.0 \pm 0.3\%$ (95% confidence interval (CI): 2.4 to 3.7%). The incidence was highest in the high myopia group ($12.3 \pm 3.2\%$, odds ratio (OR): 6.5, 95% confidence interval of OR: 2.8, 15.1), followed by the moderately myopic group ($8.2 \pm 1.9\%$, OR: 4.1, 95% CI: 2.0, 8.7) and the low myopic group ($5.8 \pm 1.2\%$, OR: 2.8, 95% CI: 1.5, 5.3), as compared with the emmetropic group ($2.1 \pm 0.3\%$). OAG incidence was higher in participants with older age, higher intraocular pressure, thinner cornea, and with a larger cup-disc diameter ratio (all $P \leq 0.01$) in the emmetropic eyes. In the highly myopic group, OAG incidence was associated with male sex ($P=0.03$) and marginally associated with a thinner cornea ($P=0.06$), but not with age ($P=0.27$).

Conclusions: In a 10-year follow-up, high myopia was a major risk factor for the development of OAG with a 6.5-fold risk increase as compared with emmetropic eyes in an adult Chinese population recruited by a population-based manner.

Carmen Acosta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze whether tear volume changes induced by ocular inflammation or instillation of warm saline solution affect corneal surface temperature (CST) values in guinea pigs.

Methods: Young guinea pig eyes of both sexes were used in the study. Tear volume was measured as the mm of wet phenol red threads applied on the lower lid for 30s. CST was measured from infrared video images taken with an infrared video camera. Temperature value immediately after eye opening and its change during the following 10 seconds were analyzed using dedicated software. In a group of guinea pigs previously sensitized to ovalbumin, experimental parameters were obtained at basal condition and after inducing allergic keratoconjunctivitis (AK) by ocular application of ovalbumin. In a separate group of naïve animals, measures were performed in basal conditions and after increasing the aqueous component of the tear film by topical application of different volumes (5-10 µl drops) of saline solution warmed up to 37°C avoid changing the temperature of the cornea (mean basal value: 36.5±0.1°C).

Results: During AK, all the animals presented conjunctival hyperemia, and significant increase in tear volume (+10.3±3.8 mm, n=6; p<0.05) and CST values (+0.25±0.12°C; p<0.01). When the aqueous component of the tear film was artificially increased in naïve guinea pigs by instillation of warm saline tear volume increased significantly (+14.8±1.9 mm and +21.0±2.1 mm, for of drops of 5 and 10 µl, respectively; p<0.001), and CST values decreased between 0.14°C and 0.96°C, proportionally to the drop volume (r=-0.405, Pearson correlation coefficient, p<0.05).

Conclusions: Corneal surface temperature increases during ocular allergic keratoconjunctivitis, probably due to the conjunctival and limbal hyperemia induced by inflammation. The corneal surface temperature values obtained by infrared thermography in this condition may be underestimated because surface temperature values seem to be affected by the amount of liquid over the cornea. The influence of tear volume on corneal surface temperature values should be considered when using infrared thermography as a complementary tool in ocular surface disorders diagnosis.

ABSTRACT BODY:

Purpose: Colorimetric analysis of optic nerve images for assessing their hemoglobin distribution (Laguna ONhE) (1-4) is tested in combination with perimetry.

Methods: Deep learning training was used to identify nerve edges, laterality of the eye, image quality, vessel segmentation and classification (normal vs glaucoma). Data was compiled into a "Globin Distribution Function" (GDF), which was also associated with visual field irregularity indices: Pattern Standard Deviation (PSD), square root of loss variance (sLV), and threshold coefficient of variation (TCV) (5).

477 normal eyes and 333 confirmed and suspected glaucoma eyes, which were examined with three fundus cameras, two perimeters and two visual field strategies. The results were compared with Cirrus OCT.

Results: GDF sensitivity identifying glaucoma was 75.7% for a specificity of 99.0%. The most sensitive OCT index was the Rim Area (sensitivity 67.0%, $P=0.0131$). Its association with visual field irregularity produced the following AUC's: GDF&PSD-sLV = 0.963-0.986 and GDF&TCV = 0.965-0.987, while Rim Area&PSD = 0.927-0.960, Vertical Cup/Disc&PSD = 0.929-0.961 and RNFLT&PSD = 0.894-0.933 ($P<0.0001$ in all cases). For 99% specificity, GDF&TCV achieved 80.8% sensitivity and RNFLT&PSD 72.4%.

In cases where the morphological or functional indices had an unusual level in regard to 95% of normal subjects, the GDF&TCV achieved AUC's of 0.99-1.00 and sensitivities of 87.3-96.0% for 99% specificity.

Conclusions: Laguna ONhE associated to perimetry offers relevant diagnostic results in glaucoma, although new studies might be necessary to consolidate such results.

ABSTRACT BODY:

Purpose: To investigate mobile element insertions (MEIs) in exon 4 of RP1 and develop a simple approach to detect RP1 MEIs by searching unprocessed short reads.

Methods: A total of 494 unrelated patients with inherited retinal diseases were genotyped. Proband-only whole-genome sequencing (WGS) or trio WGS was performed in 16 unsolved families after targeted or whole exome sequencing. WGS revealed an RP1 Alu insertion in exon 4 in 2 families. The Linux program grep was developed to search for common MEIs in RP1 exon 4. A 26-bp “probe” sequence containing the known junction sequence of the MEI and corresponding wild-type 26bp sequence was used (See https://github.com/jin0008/RP1_aluinsertion). Additional screening for this mutation was performed in 273 unrelated patients.

Results: Among the 273 patients, 5 families had a heterozygous RP1 Alu insertion. In patients with heterozygous RP1 Alu insertion, 3 patients with the compound heterozygous c.5797C>T:p.(Arg1933*) variant had macular dystrophy and 2 patients with more proximal truncating variants (c.4196del and c.4582_4584del) had early-onset cone-rod dystrophy. The AluY insertion resulted in c.4052_4053ins:p.(Tyr352Alafs*9), which was confirmed by polymerase chain reaction and gel electrophoresis. No homozygous RP1 Alu insertion was found in our cohort. A simplified grep search code revealed a variant allele frequency of 0.282 (interquartile range, 0.232–0.383), with no false-positive results in 120 control samples.

Conclusions: The MEI in RP1 exon 4 is common founder mutation in Korean, occurring in 1.8% of our cohort. The RP1 Alu grep program detected AluY insertion in RP1 efficiently without preprocessing of raw data or complex installation processes.

ABSTRACT BODY:

Purpose: Leber Congenital Amaurosis 16 (LCA16) is a severe form of inherited ocular channelopathy caused by point mutations in KCNJ13, which affect the retinal pigment epithelial (RPE). AAV-gene therapy related immune responses, CRISPR/Cas9 gene editing associated off-targets, and unintended indels pose some challenges in clinical use of such treatments. We used Adenosine and Cytosine CRISPR base editors (ABE and CBE) for proof-of-concept correction of KCNJ13 point mutations (c.158G>A [p.W53X] and c.431T> C [p.L144P]) using nanoparticle-mediated delivery to induced pluripotent stem cell-derived RPE (iPSC-RPE).

Methods: Base editing was carried out using either ABE or CBE mRNA with a guide RNAs specific to the W53X or L144P mutant allele. A HEK293-FRT stable cell line expressing Kir7.1-L144P and Kir7.1- W53X were base edited via electroporation using CBE and ABE mRNA respectively. LCA16-W53X patient-specific fibroblasts and iPS-RPE cells were also targeted with ABE mRNA delivered using nanoparticles. Base editing efficiency, protein expression, localization, and channel function were assessed in edited cells and were compared with non-edited mutant and WT cells. Potential off-targets were screened to evaluate the accuracy and efficacy of CRISPR BEs.

Results: CBE mRNA for L144P correction in HEK cells resulted in 66% editing. The degenerate nature of codons for provides additional flexibility to correct L144P point mutation. Higher rate (~24%) were observed in treated L144P-cells due to multiple bystander cytosines at the targeted locus.

ABE mRNA for W53X (TaG>TgG) correction in HEK stable cells showed 50% editing efficiency than RNP approaches (25% efficiency). Nanoparticle-mediated delivery of ABE-mRNA and sgRNA in fibroblasts (47% editing) and iPSC-RPE (20% editing) established its use for in vivo BE delivery. Control fibroblast cells lacking the mutant allele showed about 1% indels. On target indel mutagenesis (<3%) and deep sequencing of potential off-target sites (<1%) indicated

high accuracy of the ABEs. Electrophysiology assays demonstrated robust rescue of channel function in the edited iPSC-RPE cells.

Conclusions: Our results show application of CRISPR base editing for precise correction of point mutations with reduced off-targets compared to CRISPR/Cas9-mediated gene editing. Restoration of channel function in edited iPSC-RPE cells suggests potential of CRISPR BE as a treatment for childhood blindness.

ABSTRACT BODY:

Purpose: Acquired vitelliform lesions (AVL) are a CAM5 optical coherence tomography (OCT) feature in age-related macular degeneration (AMD; PMID 33348085) and may be a distinct pathway leading to complete retinal pigment epithelium (RPE) and outer retinal atrophy (cRORA; PMID 29103793). This study aimed to correlate OCT to histology in eyes with AMD, evaluate AVL content, identify clinical and diagnostic biomarkers, and to generate hypotheses about the AVL lifecycle.

Methods: Donor eyes (n=2) underwent multimodal ex vivo imaging prior to histologic processing. Light microscopy was corresponded to OCT B-scans. Transmission electron microscopy was used for qualitative and quantitative analysis of AVL content via point-counting stereology. AMD eyes exhibiting AVL by OCT (and if available, color fundus photography and fundus autofluorescence) were selected retrospectively from two 3°clinics. In vivo OCT from 41 eyes followed up to 12 years was evaluated.

Results: Histology confirmed characteristic AMD deposits, photoreceptor (PR) degeneration, and AVL material located foveally between the PR and RPE. Light and transmission electron microscopy revealed an inhomogeneous AVL composition including RPE organelles (3–22 % of volume), outer segments (OS, 2–10 %), lipid droplets (0.2–12 %), and a flocculent material (57–59 %). Clinical cases showed high prevalence of subretinal drusenoid deposit (SDD), subfoveal predilection and AVL growth / regression phases. Most resorbing / collapsing AVL disappeared within 1 year after maximum AVL expansion (max. exp.). Hyperreflective foci and ellipsoid zone dis-integrity were rarely observed before AVL formation and frequently at max. exp. Hyperreflective thickening of the RPE-basal lamina-Bruch's membrane (RPE-BL-BrM) band was always observed at max. exp. and not before AVL formation.

Conclusions: AVL includes an extracellular deposit with varying amounts of RPE granules, some OS, and a major component remaining to be identified. Histologic composition and clinical appearance of AVL content and adjacent RPE-BL-BrM band indicate that RPE granules translocate from the RPE layer and are a transitory part of the AVL. Subfoveal predilection, autofluorescence, association with SDD, and growth / regression phases raise the possibility that AVL formation includes dysregulation of PR-specific molecular pathways, as suggested for SDD and drusen (PMID 23266879).

TITLE: Effects of peripheral refractive errors when negotiating steps

SESSION TITLE: Peripheral optics and vision

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Tabernero, Electromagnetismo y Electrónica, Universidad de Murcia, Murcia, Murcia, SPAIN|E.A. Villegas, P. Artal, Laboratorio de Óptica, Universidad de Murcia, Murcia, Murcia, SPAIN|

Commercial Relationships Disclosure (Abstract): Juan Tabernero: Commercial Relationship: Code N (No Commercial Relationship) | Eloy Villegas: Commercial Relationship: Code N (No Commercial Relationship) | Pablo Artal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the impact of different types of peripheral refractive errors (positive, negative and cylindrical) when subjects perform a functional test of ascending and descending steps.

Methods: A circular hole subtending 32-degree over the retina was practiced on the surface of four types of ophthalmic lenses: i) plano lenses (null dioptric power), ii) positive and negative lenses (± 2 D and ± 4 D) and iii) oblique cylindrical lenses ($+2$ D and $+3$ D) oriented at 45-degree. The lenses were mounted over standard frames with the hole aligned to the particular line of sight of six subjects, allowing intact vision across the 32-degree central field and inducing a variety of refractive errors in the rest of the peripheral visual field. The task for the subjects was to negotiate a floor obstacle consisting of two ascending steps (13 cm high each), an elevated platform (1 m long) and two descending steps (equal high as the ascending steps). Each subject performed four trials with each spectacle. A camera equipped with a fish-eye lens captured the movement (at 110 Hz) of the subjects' feet navigating the obstacle. Two LEDs were attached to subjects' shoes to mark the feet trajectories. Kinovea software was used to track the LED trajectories that were exported and analysed using Mathematica software.

Results: Average navigation times through the obstacle (with respect to the case of plano lenses) were a 15% (SD $\pm 13\%$) and a 5% (SD $\pm 10\%$) slower when subjects wore the $+4$ D and $+2$ D lenses respectively. Similarly, with the cylindrical lenses, navigation times were $18 \pm 19\%$ ($+3$ D) and $6 \pm 9\%$ ($+2$ D) slower than with plano lenses. However, with the -2 D negative lenses, navigation times did not increase with respect to plano lenses ($-1 \pm 9\%$) and they barely increased with the stronger -4 D negative lenses ($6 \pm 11\%$). Kinematic analysis of the trajectories showed a more cautious gait approach (more steps, slower gait) and more foot misplacements when wearing the positive and cylindrical lenses than with negative lenses.

Conclusions: Superimposed positive and cylindrical peripheral refractive errors had instantaneous effects on functional vision when negotiating steps. These data may be relevant when considering the potential effect in daily activities of increased peripheral refractive errors in cataract patients after implantation of standard intraocular lenses.

ABSTRACT BODY:

Purpose: PRECISE is the first study to evaluate treatment outcomes in patients having neovascular age-related macular degeneration (nAMD) and diabetic macular edema (DME) with an inadequate response to aflibercept (AFL) who were switched to ranibizumab pre-filled syringe (RBZ-PFS) in a routine clinical setting. There are limited data from real-world on treatment switch in patients showing inadequate response to ongoing AFL and thus far, there is no report on treatment switch exclusively to RBZ-PFS. Here, data of currently enrolled patients with DME are presented.

Methods: PRECISE is an observational, multicenter, real-world switch study in prior AFL-treated Canadian patients with nAMD and DME. Eligible patients, aged ≥ 18 years, who received ≥ 3 AFL injections, were switched to RBZ-PFS based on clinician's discretion and treated as per the product label. Primary endpoint is the mean change in central retinal thickness from baseline to Day 90. Secondary endpoints include best-corrected visual acuity change, treatment regimen and safety. The study aims to enroll ~396 eyes (nAMD/DME=320/76) from 15 clinical centers across Canada.

Results: Amongst patients with DME, 8.6% and 91.4% had Type 1 and Type 2 diabetes, respectively, with 91.4% on medication. Median time since diagnosis to treatment switch to RBZ-PFS was 2.8 years in DME cohorts. Prior to study entry, median number of treatments with any anti-VEGF were 21/13 and AFL injections were 18/10 in the DME cohort. Key reasons for treatment switch in the DME patients were (i) lack of response to treatment (persistent fluid: 80.0%, loss of vision: 2.9%, unsatisfactory vision gains: 2.9%); (ii) unable to extend dosing (2.9%); (iii) safety concerns (ocular: 2.9%; systemic: 0%), and (iv) other (5.7%). Other baseline characteristics of switched patients and preliminary treatment outcomes will be presented.

Conclusions: Real-world evidence from the PRECISE study provides useful information that the key reason for treatment switch was lack of response to AFL treatment, primarily due to presence of fluid in the macula. Results from our study will further our current understanding and enhance routine clinical care of these patients.

KG:Code E (Employment) | Achim Sauer: Commercial Relationship(s);Boehringer Ingelheim Pharma GmbH & Co. KG:Code E (Employment)

ABSTRACT BODY:

Purpose: The discovery of small-molecule drugs for intravitreal administration would benefit of simple methods to evaluate vitreal clearance for the screening of new drug candidates. The current methods available have limitations in their applicability to small-molecule drugs and suitability to predict vitreal clearance in human. Permeability of posterior eye tissues is often described as the rate-limiting step for small-molecule clearance and a suitable permeability assay would ease clearance prediction. Therefore, we evaluated the use of Caco-2 cell intrinsic permeability as a surrogate for the permeability of posterior ocular tissues to predict vitreal clearance.

Methods: We measured Caco-2 permeability of a set of small-molecule drugs and predicted their vitreal clearance calculated from diffusion and permeability clearances for the rabbit eye. We used the geometric mean of the directional permeabilities as an estimate of intrinsic permeability to avoid the effect of transporters expressed in Caco-2 cells. We then compared the predicted clearances to rabbit vitreal clearances available in literature and in-house at Boehringer Ingelheim.

Results: Most of the predicted clearances were within a two-fold range of the measured values. For low permeability compounds ($<5 \times 10^{-6}$ cm/s), diffusion to the aqueous humor was predicted as the major route of elimination in the rabbit. For high permeability compounds ($>30 \times 10^{-6}$ cm/s), diffusion to the posterior segment was predicted to be the rate-limiting step, suggesting that diffusion rate determines the upper limit of vitreal clearance for any compound when not considering possible degradation within the vitreous.

Conclusions: Caco-2 intrinsic permeability is a suitable surrogate for posterior segment tissue permeability to predict vitreal clearance of small molecules in rabbits. For an accurate prediction, the effect of diffusion rates on the clearance should also be considered. The prediction can be applied to human by using human eye dimensions in the calculation.

ABSTRACT BODY:

Purpose: The failure of trabeculectomy has been related to the chronic ocular surface inflammation produced by the long-term use of topical anti-glaucoma medications. Our aim was to find out whether previous topical hypotensive therapy also influences the outcome of another type of glaucoma surgery, non-penetrating deep sclerectomy (NPDS).

Methods: This is a retrospective study of patients diagnosed of open-angle glaucoma who underwent NPDS at the Glaucoma Unit, Valladolid Clinic Hospital, Spain in the last 5 years. Eyes were divided into two groups based on intraocular pressure (IOP) values at 12 months after NPDS: success group (IOP<21 mmHg) and failure group (IOP>21 mmHg). All patients were under topical hypotensive therapy with up to 3 active substances in commercialized topical formulations, either separately or in combination. Normal distribution of variables was determined with Shapiro-Wilks test. The relationship between both groups was statistically analyzed in 5 variables by Mann-Whitney test: number of active substances used, drops per day, benzalkonium chloride (BAK)-containing drops per day, polyquad-containing drops per day, and duration of pharmacological treatment.

Results: We included 48 eyes from 34 patients (16 females, 18 males; mean age 72.5±13 years). Previous mean IOP was 22.2±6.4 mmHg. Patients had been using topical anti-glaucoma therapy for 5.4±6.8 years before surgery. NPDS surgical success rate was 87.5%, meaning that there were 42 patients in the success group and 6 in the failure group. Change in IOP 12 months after NPDS was -7.9±6.8 mmHg in the success group and +1.3±11.8 in the failure group, respectively. The number of drops per day was significantly ($p=0.037$) greater in the failure group (3.2 ± 0.4) than in the success group (2.5 ± 0.8). There were not significant differences between groups in the other 4 variables analyzed, although the number of BAK-containing drops per day and the duration of pharmacological treatment were higher in the failure group.

Conclusions: The negative impact of long-term hypotensive topical treatment in NPDS outcome seems to be related with the amount of eyedrops instilled per day. Consequently, medical treatment should be minimized as much as possible before opting for this surgical anti-glaucoma therapy.

ABSTRACT BODY:

Purpose: In the two-photon vision, a non-linear optical effect in the visual pigments, namely the two-photon absorption, causes the human eye to perceive pulsed infrared light as visible light with approximately halved wavelength. The phenomenon is characterized by highly localized stimulation of the retina with no glare, which can be a very useful feature in developing novel devices for ophthalmic diagnostics. In this work, we focus on longitudinal spatial properties of two-photon stimuli and study the influence of beam defocus on visibility thresholds upon two-photon excitation with infrared light (1040 nm) compared with visible light at 520 nm. The findings may be useful for the interpretation of two-photon perimetry results as well as for the design considerations of future two-photon ophthalmological devices.

Methods: We employed a custom-build, dual-wavelength (1040 nm and its second harmonic at 520 nm) microperimeter to measure visual thresholds (in two-photon and one-photon vision, respectively) by using the 4-2-1 staircase strategy. We tested 3 healthy dark-adapted volunteers with dilated pupils and accommodation blocked by administration of 1% Tropicamide drops. The stimuli were scanned circumferences of 1.0 deg diameter presented with varying degrees of defocus (-5 D to +5 D). The diameters of both beams at the pupil plane were equal to 1.1 mm. Experiments were conducted in scotopic and photopic (4.28 log phot Td) conditions obtained by Maxwellian view illumination of the retina with 520 nm light. The study was approved by the Ethics Committee of the Collegium Medicum, NCU.

Results: We observed no changes in the effect of defocus on normalized visibility threshold in the range (-1 D to +1 D) for both wavelengths. For larger values of beam's defocus (> 4 D and < -4 D), there are differences between 520 nm and 1040 nm beams (more pronounced increase in IR thresholds). The observed differences are statistically significant for scotopic case.

Conclusions: The results are consistent with the phenomena resulting from diffraction. For a given numerical aperture, the effect of two-photon excitation is similar to the one-photon case, as the properties of nonlinear excitation (quadratic dependence of the signal on intensity) are largely compensated by diffraction (i.e., twice longer Rayleigh range). The results highlight the leading role of optical, rather than neuronal or physiological factors in two-photon infrared vision.

ABSTRACT BODY:

Purpose: Presence of dry eyes in children with VKC is often under recognised and clinical tests like tear-film break up time test using fluorescein dye (TBUT) and Schirmer's are difficult to perform. The aim of the study was to compare dry eye in children with VKC as compared to normal children using dry eye symptom score, clinical tests and OSA (SBM, sistemi).

Methods: This case control study was conducted between May 2019 to Nov 2019. Children with VKC were recruited as cases and those with only refractive errors as controls. The clinical parameters recorded in VKC children were type and extent of VKC, Bonini's grading and corneal fluorescein staining. Both cases and controls underwent TBUT, schirmer's II test and OSA. The OSA parameters recorded were non-invasive TBUT (NiBUT), meibomian gland (MG) loss, tear meniscus height and lipid layer type. The OSA and clinical parameters were compared between the cases and controls and were correlated with the modified ocular surface disease index (OSDI) symptom scores.

Results: 83 children with VKC (9 ± 1 years) and 30 controls (11 ± 1 years) were enrolled. Seasonal disease was seen in 63% and perennial form was seen in 37%. The proportion of limbal, palpebral and mixed type of VKC was 5%, 40% and 55%. The proportion of male patients was more in the VKC group (83% vs 27%, $p=0.0$). TBUT was found to be lower in VKC children (8.8 ± 4.5 secs) as compared to the controls (10.8 ± 5.5 secs); $p=0.04$. Dry eyes (TBUT <10 secs) was seen in 59% in VKC and 30% in control group ($p=0.015$). OSDI scores were significantly higher in the VKC group (32 ± 18 vs 15 ± 11 ; $p=0.0$). Among the OSA parameters only the pattern of lipid layer was found to be different among the two groups, the open meshwork being more common in the VKC group (70% vs 47%; $p=0.01$). The NiBUT was lower in the VKC group but did not achieve statistical significance (7 ± 3 secs vs 8 ± 2 secs, $p=0.05$). The corneal fluorescein staining positively correlated with limbal papillae ($r=0.334$, $p=0.00$) and negatively with TBUT ($r=-0.384$, $p=0$). None of the clinical or OSA parameters correlated with the OSDI scores except the lipid layer morphology.

Conclusions: Children with VKC had higher prevalence of dry eyes, lower TBUT and higher OSDI scores as compared to children without it. The tear film morphology seen in OSA could be an indicator of dry eyes in children.

TITLE: Functional validation of a CRISPR/Cas9 strategy correction of the two most prevalent USH2A mutations in iPSC-derived retinal organoids

SESSION TITLE: Retinal Organoids: Cell Diversity and New Strategies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Sanjurjo Soriano, A. Roux, I. Meunier, V. Kalatzis, Institute of Neuroscience Montpellier (INM)-INSERM U1298-Université de Montpellier, FRANCE|

Commercial Relationships Disclosure (Abstract): Carla Sanjurjo Soriano: Commercial Relationship: Code N (No Commercial Relationship) | Anne-Françoise Roux: Commercial Relationship: Code N (No Commercial Relationship) | Isabelleanne Meunier: Commercial Relationship: Code N (No Commercial Relationship) | Vasiliki Kalatzis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mutations in USH2A are the most frequent cause of the syndromic IRD Usher syndrome type 2 (USH2), and the non-syndromic autosomal recessive retinitis pigmentosa (arRP). There are two recurrent USH2A mutations (c.2276G>T and c.2299delG), which account for approximately half the patient cohorts. Currently, there is no available treatment and disease models for these mutations are not available. We previously reported successful CRISPR/Cas9 correction of these two recurrent mutations in patient iPSC. Here, we differentiated isogenic corrected and non-corrected iPSC lines onto retinal organoids to functionally validate the strategy and to obtain a disease model of these two recurrent mutations.

Methods: Isogenic corrected and non-corrected iPSC lines together with a wild-type (WT) iPSC line were differentiated onto retinal organoids using a combinatory two-dimensional (2D) and 3D protocol. iPSC-derived retinal organoids were maintained as floating cultures until processing of the sample. Four different time points (56, 100, 150, 225 days) were analyzed by qPCR and immunofluorescence studies for the expression of common photoreceptor markers. Photoreceptor ultrastructure was also investigated using electron microscopy (EM).

Results: The generated iPSC-derived retinal organoids express common photoreceptor markers such as CRX, Recoverin, Rhodopsin, Rhodopsin-kinase, Opsins, Cone-arrestin. In addition, they express outer segments (OS) photoreceptor markers such as ABCA4, PDE6B and PRPH2. The photoreceptors within the retinal organoids present key features of photoreceptor maturation, such as a connecting cilium and OS, as observed by EM. Characterization of corrected and non-corrected retinal organoids show a clear reversion of the aberrant phenotype in the CRISPR-corrected organoids compared to the USH2A mutant organoids, functionally validating our CRISPR strategy.

Conclusions: The results presented here provide hope for a future therapy applicable to a large number of patients carrying USH2A mutations. The functional validation of the CRISPR strategy in retinal organoids, brings this therapy one step closer to clinical translation. In addition, insights into the differential pathophysiology of USH2 and arRP have been obtained.

ABSTRACT BODY:

Purpose: To examine the repeatability of a visual function (VF) test battery and its power to discriminate between structurally defined age-related macular degeneration (AMD) stages.

Methods: Subjects with no AMD and Beckman defined early(e), intermediate(i) and late(l) AMD were recruited across 18 European study sites. All subjects performed a VF battery at day 0 and 14 ± 7 comprising chart-based [Best-Corrected Visual Acuity (BCVA), Low Luminance Visual Acuity (LLVA), Moorfields Acuity Test (MAT), Pelli Robson Contrast Sensitivity (CS) and International Reading Speed Test (IReST); and novel tests [Mesopic (MesAT) and Scotopic (ScoAT) average thresholds by S-MAIA microperimetry and AdaptDx Rod Intercept Time (RIT)]. Repeatability of all measures was assessed by Intraclass Correlation Coefficients (ICC). Discriminant ability to distinguish between those with and without AMD and between neighbouring disease severity states was evaluated using Receiver Operator Characteristic (ROC) analyses, reporting Area Under the Curve (AUC) and partial (pAUC) at 80% specificity. Here we report the ability to distinguish between no AMD and iAMD.

Results: 301 subjects were recruited. 290 completed both visits [eAMD (n=28), iAMD (n = 167), lAMD (n=41) and no AMD (n=54)]. The cohort was roughly 2/3rd female (62.1%) with a mean age of 71. Repeatability was higher for chart-based than novel tests, with chart-based ICCs ranging from 0.88 (CS) to 0.96 (BCVA), whereas novel test ICCs ranged between 0.27 (RIT) and 0.93 (ScoAT) when all cases were considered and 0.73 (RIT) and 0.93 (ScoAT) when 3 extrapolated RIT values were removed. Discriminatory power of chart-based tests between no AMD and iAMD was moderate with AUCs of between 0.57 (IReST, pAUC = 0.04) and 0.77 (CS, pAUC = 0.08). Considering novel tests, discriminatory ability of microperimetry between no AMD and iAMD was moderate, and higher for scotopic testing (MesAT: AUC = 0.67; pAUC = 0.05; ScoAT: AUC = 0.70; pAUC = 0.06), whereas RIT values were slightly better, particularly when pAUCs were considered (RIT: AUC = 0.71; pAUC = 0.09).

Conclusions: Though CS, MesAT, ScoAT and RIT demonstrate moderate discriminatory power between no AMD and iAMD, a sizable proportion of iAMD subjects had normal VF. Given the substantial phenotypic variation in structurally defined iAMD, subgroup analyses are required to identify those with poorest VF and potential structural correlates.

ABSTRACT BODY:

Purpose: To assess a mass screening in general population, mainly European, using the Laguna ONhE system to detect glaucoma.

Methods: 285,320 retinographies obtained in numerous locations with various fundus cameras were analyzed fully automatically and unsupervised via Internet, between January 2019 and December 2020. Deep Learning was used for identifying the eye (left or right), segmenting the disc and vessels, detecting image quality and generating a glaucoma classifier. A multi-factor index called Globin Distribution Factor (GDF) described in previous publications (1-9) was used. The amount of hemoglobin, the cup/disc ratios and the areas of the rim sectors were also estimated.

Results: 6.1% of cases were discarded because the system detected poor image quality, or absent or sectioned optic disc. 4.9% of the cases that could be analysed showed GDF below -15 (percentile 1% of the normal population) and 87.6% above 0 (percentile 5% of the normal population) (Figure). Cases with low GDF showed abnormal data in areas and indices associated with glaucoma (Table).

Conclusions: Although the data collection model did not allow individual diagnostic confirmation, GDF scores were consistent with the expected prevalence of glaucoma in the general population (10). Data and rates among such cases differ from normality as might be expected in glaucoma.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the most common cause of central vision loss globally. Neovascular AMD (nAMD) is currently treated with regular intraocular injections of anti-VEGF therapies, to which some patients are unresponsive, while multiple injections are not well-tolerated and can cause complications including infection. We previously demonstrated intraocular delivery of recombinant interleukin-33 (IL-33) reduced laser-induced choroidal neovascularisation (CNV) pathology in a mouse model, offering a promising new treatment. Additionally, an eyedrop of bevacizumab complexed to a cell penetrating peptide (CPP) reduced lesion size equivalent to intravitreal injection delivery in a mouse CNV model. Thus, we propose combining IL-33 immunotherapy and our delivery agent, IL-33+CPP6, to be developed as a topical formulation.

Methods: Human recombinant IL-33 was complexed with the CPP to assess cell toxicity, MTT and LDH assays for 48h over a dose range of 0.2–200pg/ul in cultured human RPE (ARPE-19) and human ocular choroidal fibroblasts (HOCFs). HOCF scratch assay was performed and cells treated with media, vehicle, CPP, IL-33 (200pg/ul) or IL-33+CPP and imaged over 48h. The percentage wound closure (end vs start width) was measured using Cell IQ software. N=3, repeated on 3 independent occasions.

Results: IL-33+CPP complexes were non-toxic to ARPE-19 or HOCFs across a dose range (0.2–200pg/ul). In ARPE-19 cells and HOCFs, there were no differences after treatment in total viable cell number (total cell LDH; P=0.8306, P=0.9641, ANOVA) or significant changes in cellular viability (MTT assay; P=0.9772, P=0.2910, ANOVA). Importantly IL-33+CPP had equivalent significant biological effects to IL-33 alone, reducing wound healing (~15% less wound closure at 48h vs media/vehicle/CPP6). Across groups in scratch assay, there was a significant effect on percentage wound closure (P=0.0430, ANOVA), with borderline significance in post-hoc analysis (Tukey) between media and IL-33 (P=0.0529) and IL-33+CPP (P=0.0639) treatments.

Conclusions: IL-33+CPP is a promising treatment in a formulation of a drop for nAMD. IL-33+CPP demonstrates non-toxicity and has preserved biological effect as direct IL-33 administration. Further experiments will assess ocular penetration and in vivo efficacy of our topical administration.

ABSTRACT BODY:

Purpose: To perform both qualitative and quantitative analysis of OCT-GAN and Compensation algorithms for shadow removal from Single-frame optical coherence tomography (OCT) B-scans.

Methods: 2,328 OCT B-scans (75x averaging) and 2,328 single-frame B-scans were acquired through the center of the optic nerve head (ONH) using Spectralis OCT (Heidelberg Engineering, Germany) for both eyes of 13 subjects. Extracted features from three perceptual loss networks pre-trained on Imagenet datasets were used with manual segmentations of retinal shadows (where 1 represented a shadow pixel and 0 represented a lack thereof) to train a generative adversarial network (referred to as OCT-GAN) to simultaneously remove retinal shadows and speckle noise. OCT-GAN and OCT compensation were then used on 97 single-frame OCT B-scans from one OCT volume and results were compared qualitatively (for shadow removal and speckle noise) and quantitatively using layerwise pixel intensities (LPI), an indicator for brightness of a specific retinal layer, and the intralayer contrast (ILC), a measure of shadow visibility ranging from 0 (shadow-free) to 1 (strong shadow). ILC was computed in the Retinal Pigment Epithelium (RPE) layer and LPI was computed for the Retinal Nerve Fiber Layer (RNFL), the Ganglion Cell Layer (GCL) + Inner Plexiform Layer (IPL), the Inner Nuclear Layer (INL), and the Outer Plexiform Layer (OPL).

Results: The mean ILC decreased from 0.40 ± 0.087 to 0.10 ± 0.074 ($74.3 \pm 19.2\%$) vs 0.21 ± 0.17 ($51.0 \pm 36.1\%$) for OCT-GAN and OCT compensation respectively, indicating shadow removal for both techniques. LPI increased by $4.34 \pm 3.66\%$, $4.58 \pm 4.36\%$, $8.29 \pm 6.91\%$, $0.4 \pm 3.80\%$ for OCT-GAN but decreased by $56.0 \pm 12.9\%$, $70.0 \pm 7.70\%$, $74.3 \pm 7.30\%$, $69.7 \pm 15.6\%$ for compensation for the RNFL, GCL+IPL, INL, and OPL layers, respectively. OCT-GAN images had visibly less speckle than compensated images and lacked artifacts commonly found in compensated images (inverted shadows, hyper-reflective spots, noise over-amplification at high depth). Both OCT-GAN and compensation were unable to completely remove large retinal shadows.

Conclusions: OCT-GAN had better shadow removal in the RPE layer and did not suffer from layer dimming commonly observed with compensation. Both algorithms could be considered as pre-processing steps to improve the diagnosis and prognosis of glaucoma from OCT images.

TITLE: Evaluation of retinal viability after simulation of vitreoretinal surgery in porcine eyes ex vivo

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Romano, Ophthalmology, Humanitas Gavazzeni - Castelli, Bergamo, ITALY|M. Romano, Ophthalmology, Humanitas University, Milan, ITALY|L. Giurgola, C. Gatto, J. D'Amato Tothova, R&D, Alchimia srl, Ponte San Nicolò, ITALY|

Commercial Relationships Disclosure (Abstract): Mario Romano: Commercial Relationship: Code N (No Commercial Relationship) | Laura Giurgola: Commercial Relationship(s);Alchimia srl:Code E (Employment) | Claudio Gatto: Commercial Relationship(s);Alchimia srl:Code E (Employment) | Jana D'Amato Tothova: Commercial Relationship(s);Alchimia srl:Code E (Employment)

ABSTRACT BODY:

Purpose: To evaluate retinal viability in porcine eyes ex-vivo after simulation of vitreoretinal surgery by combined use of medical devices including BSS, vitreal staining, ILM staining, perfluorooctane and silicone oil endotamponade with minimal and with residues removal.

Methods: 25 porcine eyes were obtained from local slaughterhouse, disinfected with povidone iodide 5% and vitreoretinal surgery was simulated according to the following conditions: A) No surgery control: eye bulbs were kept for 30 min at room temperature (RT); B) Sham Surgery: vitreoretinal surgery with the sole use of BSS, 30 min at RT; C) Cytotoxic control: vitreoretinal surgery with BSS, injection of 1-H-perfluorooctane on retina, contact time 30 min at RT; D) Surgery with residues: vitreoretinal surgery with the use of BSS, vitreal staining, ILM staining, perfluorooctane and silicone oil endotamponade, leaving high residues of all materials; E) Surgery with removal of residues: vitreoretinal surgery with the use of BSS, vitreal staining, ILM staining, perfluorooctane and silicone oil endotamponade with careful removal of the residues. Each simulated condition was tested at least in quadruplicate by two technicians. Immediately after surgery, the retina was extracted from each eye bulb and at least 16 samples with 3 mm diameter were prepared. Retinal cells viability was determined after extraction, using TOX-1 In Vitro Toxicology Assay Kit, MTT based (Sigma-Aldrich, Italy). A viability < 70% is the cytotoxicity threshold.

Results: Retina extracted from eye globes subjected to no surgery (A) and sham surgery (B) showed optimal cell viability (96 to 100%). Retina extracted after the surgery with residues removal (E) showed good cell viability (average 86%), while retina from eye bulbs after surgery with high residues (D) and cytotoxic control (C) resulted in high retinal cytotoxicity corresponding to low average cell viability of 40% and 29%, respectively.

Conclusions: The tested conditions indicated that vitreoretinal surgery performed with the combined use of the medical devices (vitreal stain, ILM stain, perfluorooctane and silicone oil endotamponade) do not affect retinal viability if the residues of used medical devices are properly removed. The presence and accumulation of high residues derived from the medical devices used during vitreoretinal surgery could negatively impact retinal viability.

Commercial Relationships Disclosure (Abstract): Xinwen Yao: Commercial Relationship: Code N (No Commercial Relationship) | Yijie Ho: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Chua: Commercial Relationship: Code N (No Commercial Relationship) | Damon Wong: Commercial Relationship: Code N (No Commercial Relationship) | Bingyao Tan: Commercial Relationship: Code N (No Commercial Relationship) | Leopold Schmetterer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Schlemm's canal (SC), a ring-shaped structure encircling the cornea, is responsible for intraocular pressure regulation and plays an important role in the onset and progression of glaucoma. This study explores the possibility of full circumferential three-dimensional (3D) reconstruction of SC in living human by using a megahertz (MHz) swept-source optical coherence tomography (OCT) prototype at 1060nm for motion-free SC imaging and a semi-automatic algorithm for SC segmentation from the OCT intensity images.

Methods: Eight volumetric scans were acquired around the limbus of both eyes of one healthy volunteer. Each scan was located at one of the cardinal and intercardinal positions to fully cover the SC. An external fixation target was introduced to ensure normal incidence at the corneal surface at each position. The fast scan was along the longitudinal direction of the SC at each of the cardinal positions, while kept in horizontal direction at the intercardinal position. Each volume took less than one second to complete. The OCT B-scans that contain SC were selected and processed for segmentation. A semi-automatic active contour segmentation algorithm was implemented and the segmented 3D SC mask from each volume was stitched. Quantitative metrics derived from the 3D segmentation were presented and analyzed.

Results: Figure 1 shows the rendering of the stitched SC segmentation for both eyes. The rapidly changing size as well as the branching of collector channels was faithfully depicted in the 3D reconstruction. Table 1 summarizes the quantitative metrics. The mean cross-sectional area (CSA) as well as the maximum opening of SC was highest in the superior position in the right eye, while temporal-superior in the left. The tendency of increased collector channels in the inferior quadrant compared to the superior was noticed as well.

Conclusions: We demonstrated full circumferential SC imaging using 1060 nm MHz SS-OCT in living human eyes without motion artifacts. The semi-automatic active contour segmentation algorithm was applied in the B-scans along the longitudinal direction of the SC, which yielded reliable 3D SC segmentation results. The full circumferential imaging and segmentation of SC enabled more sophisticated analysis of SC morphology, offering a new way for examination of the aqueous outflow pathway.

TITLE: In Vivo Imaging of the Sclera in Guinea Pigs

SESSION TITLE: Molecular and Structural

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Dong, W. Wei, Beijing Tongren Hospital, Beijing, Beijing, CHINA|J. Jonas, Ruprecht-Karls-Universität Heidelberg Philosophische Fakultät, Heidelberg, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure (Abstract): Li Dong: Commercial Relationship: Code N (No Commercial Relationship) | Wen-Bin Wei: Commercial Relationship: Code N (No Commercial Relationship) | Jost Jonas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the feasibility of in vivo imaging of the sclera using spectral-domain optical coherence tomography (SD-OCT) in normal guinea pigs.

Methods: Nineteen pigmented guinea pigs with an age of 3-4 weeks were included in the study. Under general anesthesia, all animals underwent sonographic measurements of the axial length using an A/B scan and OCT imaging of the posterior ocular segment. At study end, the animals were sacrificed and the eyes of 10 animals were histopathologically examined. We measured the scleral thickness on the OCT images and upon histomorphometry. The reproducibility of the measurements was additionally assessed.

Results: On the OCT images, the sclera was presented as hyperreflective signals beneath the choroid. The scleral thickness measured near the optic nerve head (mean: $105.7 \pm 23.1 \mu\text{m}$) was not significantly correlated with axial length (Pearson correlation coefficient $r=0.02$, $P=0.40$). A high correlation was found for the comparison of intra-observer measurements of scleral thickness (intraclass correlation coefficient (ICC)=0.92, 95% CI: 0.86-0.96; $P<0.001$), and a high agreement was present for the inter-observer reproducibility ($r=0.99$; $P<0.001$). The Bland-Altman plots showed that 7.9% (3/38) of the points were located outside of the 95% limits of agreement. The scleral thickness as measured on the OCT images was significantly higher than that the values obtained by histomorphometry ($116.0 \pm 26.0 \mu\text{m}$ versus $77.6 \pm 13.4 \mu\text{m}$; $P=0.002$), with a low correlation coefficient ($r=0.07$).

Conclusions: Our study shows the feasibility of SD-OCT for in vivo imaging of sclera in guinea pigs with an acceptable intra-observer repeatability and inter-observer reproducibility. This technique provides support for examining the role of the sclera in ocular disorders in studies involving guinea pigs.

ABSTRACT BODY:

Purpose: To characterise the phenotype in eight cases with macular disease and determine the cause and molecular mechanism underpinning their condition.

Methods: Patients underwent ophthalmic examination and probands from each family were subject to exome or genome sequencing, and PCR amplification of the breakpoint followed by cloning and Sanger sequencing or direct Sanger sequencing. Microsatellites in or near the CRX locus were genotyped for haplotype analysis.

Results: All eight cases carry the same heterozygous 126 kb deletion encompassing TPRX1, CRX and SULT2A1. 294 base pairs of sequence at each end of the deletion is 78% identical, corresponding to Alu repeats, suggesting these have driven non-allelic homologous recombination (NAHR) to create this deletion. The deletion was absent from 382 controls screened by breakpoint PCR and 13,096 Clinical Genetics patients with a range of inherited conditions screened by array CGH. The Database of Genomic Variants highlights two potentially similar deletions in a study of 29,084 patients with developmental disorders, though precise breakpoints are unclear. Microsatellite genotypes suggest that the seven families studied herein are not closely related, but SNP genotypes immediately adjacent to the breakpoints point to a distant ancestral founder.

Conclusions: Previous reports found that heterozygous putative CRX null alleles were associated with a normal ocular phenotype, implying loss of function of one copy of CRX is tolerated. However, we now show that CRX whole-gene deletion causes a dominant macular disease with late onset, proving that CRX haploinsufficiency causes retinal dystrophy. Previous reports of haploinsufficiency in asymptomatic carriers could be the result of variable expressivity, non-penetrance in younger carriers, or a relatively mild phenotype that was overlooked. Since heterozygous deletions of this size may be difficult to detect, and given the previous published suggestion that heterozygous CRX null alleles do not cause retinal disease, this variant may have been overlooked in previous genetic screens.

TITLE: The Mouse Sodium Iodate Model Exhibits Acute Retinal Inflammation

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Beets, M. Porcu, T. Hu, J. Feyen, Oxurion NV, Leuven, BELGIUM|

Commercial Relationships Disclosure (Abstract): Karen Beets: Commercial Relationship(s);Oxurion NV:Code E (Employment) | Michaël Porcu: Commercial Relationship(s);Oxurion NV:Code E (Employment) | Tjing-Tjing Hu: Commercial Relationship(s);Oxurion NV:Code E (Employment) | Jean Feyen: Commercial Relationship(s);Oxurion NV:Code C (Consultant)

ABSTRACT BODY:

Purpose: Sodium iodate (NaIO_3)-induced retinal degeneration is a widely used model to investigate late stage dry age-related macular degeneration (AMD), a multifactorial disease characterized by retinal degeneration, retinal pigment epithelium (RPE) damage, oxidative stress and inflammation that ultimately leads to blindness and for which no therapy is currently available. The aim of this study was to characterize expression of inflammatory markers in the mouse NaIO_3 model.

Methods: Male C57BL/6J mice (7- to 8-week-old) were intraperitoneally injected with 50mg/kg NaIO_3 or phosphate buffered saline. One or three days later, protein lysates were prepared from retina and RPE/choroid tissues. The expression of ten different cytokines (IFN γ , IL1 β , IL2, IL4, IL5, IL6, CXCL1, IL10, IL12p70 and TNF α) were analyzed using the mouse proinflammatory panel 1 (Mesoscale).

Results: In the retina, NaIO_3 treatment significantly increased IL1 β , IL6, CXCL1 and TNF α levels at both day one and three. Interestingly, these protein levels decreased from day one to day three. In the RPE/choroid, NaIO_3 treatment significantly increased IL1 β and CXCL1 levels at day three. In contrast to the retina, IL1 β and CXCL1 levels increased from day one to day three. Other cytokine levels were unaffected or below the lower limit of detection.

Conclusions: In conclusion, NaIO_3 treatment results in acute increase of specific inflammatory proteins in the retina and RPE/choroid. The data suggests that, after the NaIO_3 insult, the inflammatory marker levels first peak in the retina, followed by the RPE/choroid. Overall, the mouse NaIO_3 model is an attractive tool to investigate AMD hallmarks, including inflammation.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa type 45 (RP45) is an autosomal-recessively inherited blinding disease caused by mutations in the cyclic nucleotide gated channel subunit beta 1 (CNGB1) gene. The disease leads to progressive retinal degeneration affecting rod photoreceptors and subsequently cone photoreceptors. Gene augmentation therapy using recombinant adeno-associated virus (rAAV) vectors poses a tangible and potentially curative therapeutic option. In this study, we developed a novel gene augmentation therapy for rod-targeted delivery of human CNGB1 using an rAAV5 (rAAV5.hCNGB1) and evaluated its efficacy in the Cngb1 knockout (Cngb1^{-/-}) mouse model of RP45.

Methods: We designed a novel rAAV vector optimized for specific and efficient expression of full-length human CNGB1 in rods under the control of a short human rhodopsin promoter (hRHO194), and packaged it with AAV serotype 5. Increasing doses of rAAV5.hCNGB1 were delivered subretinally in 4-week-old Cngb1^{-/-} mice and the therapeutic effect was assessed short-, mid- and long-term. Transgene expression and retinal morphology were investigated via immunohistochemistry. Visual recovery was analyzed in vivo by electroretinography (ERG) while morphological preservation was monitored via spectral-domain optical coherence tomography (SD-OCT). Additionally, spatial navigation was tested by a visual Water Maze to evaluate the processing of visual information in treated mice.

Results: Treatment with rAAV5.hCNGB1 achieved substantial preservation of rod and cone photoreceptors in Cngb1^{-/-} mice. Furthermore, we show that the supplemented hCNGB1 was capable of forming functional heteromeric rod CNG channels with the endogenous mouse CNGA1 subunit leading to recovery of rod photoreceptor function. CNGB1 expression increased dose-dependently and resulted in increased ERG-b-wave amplitudes and therefore in enhanced visual acuity in Cngb1^{-/-} mice. Moreover, Cngb1^{-/-} mice were able to process the gained retinal function and showed significant improvement when navigating in the dark. This rescue effect persisted for at least 9 months post injection.

Conclusions: The novel rAAV5.CNGB1 vector supports efficient and specific human CNGB1 protein expression in affected murine rod photoreceptors resulting in recovered rod function and deceleration of retinal degeneration in the Cngb1^{-/-} mouse model of RP45.

TITLE: 5-year treatment patterns in patients with DME following intravitreal (IVT) anti-VEGF therapy

SESSION TITLE: Diabetic macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Garmo, A. Menezes, Genentech Inc, South San Francisco, California, UNITED STATES|P. Emami-Naeini, UC Davis Eye Center, Sacramento, California, UNITED STATES|N. Boucher, R. Fernando, Vestrum Health, Ottawa, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): Vincent Garmo: Commercial Relationship(s);Genentech, Inc.:Code E (Employment) | Parisa Emami-Naeini: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Boucher: Commercial Relationship(s);Vestrum Health:Code E (Employment) | Rusirini Fernando: Commercial Relationship(s);Vestrum Health:Code E (Employment) | Alicia Menezes: Commercial Relationship(s);Genentech, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: To describe the long-term impact of treatment (tx) regimens on vision outcomes in patients (pts) with diabetic macular edema (DME) who received IVT anti-vascular endothelial growth factor (VEGF) therapy from a large US electronic health record (EHR) database.

Methods: EHR data (Vestrum Health; 01-01-2014 to 06-30-2020) were analyzed. Tx naïve pts were followed for 5 yrs from first tx (i.e. index) with IVT anti-VEGF. Pts were stratified by baseline visual acuity (VA) and also evaluated for other DME-related tx, including IVT steroids, focal laser, and pan-retinal photocoagulation (PRP).

Results: 1657 eyes were stratified and analyzed by index VA. On average, pts received 6.8 anti-VEGF injections in yr 1, and ~4 injections per yr in following yrs. Overall, pts gained 4.0 Early Treatment Diabetic Retinopathy Study (ETDRS) letters from baseline to 5 yrs (65.6 vs 69.6 letters; ~ 20/40 Snellen), though pts lost roughly 3 letters from their peak of 72.5 letters at yr 1. 80% of pts with $\geq 20/40$ index VA were able to maintain VA of $\geq 20/40$ at 5 yrs, while only 58%, 31%, and 30% of pts with 20/40–20/100, 20/100–20/200 and $< 20/200$ index VA, respectively, were able to reach $\geq 20/40$ at 5 yrs (Fig 1). At the end of yr 1, pts who received 1–4 (28%), 5–6 (17%), 7–8 (20%), and ≥ 9 (35%) injections in the first yr gained 2.9, 7.6, 7.9, and 9.4 letters, respectively. Pts receiving 1–4 injections in yr 1 had the highest baseline VA (67.0 vs. 64.3 letters in ≥ 9 group), but had the lowest VA at yr 5 (68.1 vs. 70.7 letters in 9+ group) (Fig 2). More injections correlated with improved VA ($P < 0.001$). In subsequent yrs, VA was mostly lost or unchanged (–1.2, –0.9, 1.1, and –0.8 letters at yr 3; –1.7, –0.5, –0.4, and 0.2 at yr 5). 33% of pts received laser tx (focal or PRP) in yr 1, dropping to 16%, 11%, 7% and 5% in yrs 2, 3, 4 and 5, respectively.

Conclusions: Overall, pts with DME gained vision through 5 yrs, but were not able to maintain peak vision following yr 1 of tx. More injections were associated with improved VA gains at yr 1 and beyond, suggesting increased injections could result in lasting improved vision. Pts with $\geq 20/40$ index vision, and pts receiving more injections at baseline maintained better overall vision throughout the study, suggesting that early and frequent tx is likely to result in optimal long-term vision.

ABSTRACT BODY:

Purpose: Increasing incidences of multidrug-resistant infections in endophthalmitis threaten our ability to treat and manage this condition. Host immunity is often-overlooked in the clearance of these infections. We aimed to study the differential host immune response observed during Multidrug-resistant- *Pseudomonas aeruginosa* (MDR-PA) endophthalmitis by studying their gene expression in a murine model.

Methods: Exogenous *P. aeruginosa* endophthalmitis was induced in C57BL/6 mice using clinical isolates of MDR-PA and drug-susceptible *Pseudomonas aeruginosa* (S-PA). Disease progression was monitored by slit-lamp examination and assigning clinical scores at 6hr and 24hr p.i., following which eyes were enucleated and bacterial burden was estimated. The extent of retinal damage was assessed by H&E and GFAP staining. PMN influx was determined by CD45 and Myeloperoxidase (MPO) staining. Microarray analysis was performed using SuperPrint G3 Mouse Gene Expression v2 chip, and data was analysed using Genespring GX 11.5 software.

Results: Intravitreal injection of MDR-PA and S-PA at 10,000 cfu, resulted in non-resolving ocular inflammation as evidenced by increased corneal haze, diminished vitreous clarity and red reflex. Higher bacterial load was observed in MDR-PA infected mice at 24h Vs S-PA infected eyes (5.6×10^5 CFU/eye vs 4.2×10^5 CFU/eye), correlating with increased clinical severity in MDR-PA infected eyes ($p=0.003$). Histological analysis revealed higher CD45-positive cells ($p=0.01$), GFAP positive cells ($p=0.05$), and MPO-positive cells ($p=0.02$) in the retinal layers of the MDR-PA infected mice. Temporal microarray analysis identified 5674 genes that were differentially upregulated in MDR-PA mice and included; IL-6, IL-15, IL-7, IL-1 β , NCF-1 and 2, Complement factor B and Pyruvate kinase while IL-9, PDGF- β , Anocatmin-6 and ATP-binding cassette were downregulated. Gene ontology and pathway analysis revealed the involvement of immune cells trafficking, apoptosis, tissue destruction markers, production of reactive oxygen species, and regulation of lipid metabolism.

Conclusions: Our study demonstrates, for the first time a differential host immune response by MDR-PA compared to S-PA in a mice model of endophthalmitis, and this can be used to identify anti-inflammatory targets for MDR-PA endophthalmitis.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa is a leading cause of blindness in industrialized countries, for which there is still no established prevention, treatment or cure. In the past decade, retinal prostheses emerged as promising technology to restore vision. On the other hand, optic nerve stimulation was proposed as an attractive alternative to retinal prostheses, by acting directly on the axons of the ganglion cells and avoid exclusion criteria of retinal implants. Our goal is to develop a novel self-opening intraneural electrode array (OpticSELINE) based on a 3D concentric bipolar configuration, where a local return electrode surrounds each stimulating electrode. This solution was chosen to achieve higher stimulation resolution by confining the electrical stimulation.

Methods: Intraneural electrode arrays were manufactured using wafer-scale processes. Sixteen concentric bipolar electrodes were fabricated with a 3D multilayer process in platinum / platinum black over a polyimide flexible substrate. Electrochemical characterization was performed before and after platinum black coating. In parallel, a hybrid FEM / NEURON simulation of the optic nerve was performed to evaluate the performance of the concentric bipolar electrode configuration. To performFor in-vivo experimentsvalidation, the OpticSELINE was implanted in the optic nerve of anesthetized rabbits, while the electrical activity of the contra-lateral visual cortex was recorded.

Results: The electrochemical study showed that platinum black reduces the impedance module below 10 kOhm and the charge storage capacity was nearly 5 times higher compared to bare platinum for actives sites of 0.0013 mm^2 . The hybrid simulation showed that the area of the optic nerve activated by a current pulse is greatly reduced using concentric bipolar electrodes compared to standard monopolar configuration. Preliminary in-vivo results show that the amplitude of electrical evoked-potentials is lower when stimulation is applied with the local return configuration with respect to the monopolar one.

Conclusions: This technology has the potential to allow stable and selective stimulation of the optic nerve during chronic implantations. The advancement will improve the use of the OpticSELINE as visual prosthesis for blind patients and as tool to further investigate the effect of the electrical stimulation in the visual system.

ABSTRACT BODY:

Purpose: Ultrasound is a commonly available tool to assess the properties of the posterior eye, allowing us to characterize morphological changes and mechanical properties with kinetic exam. Here, we determine if the stress and strain of eye movements result in gaze-induced deformation of posterior staphyloma in highly myopic (HM) eyes.

Methods: A prospective imaging study was performed on 101 HM eyes (axial length range: 27.0 to 39.3 mm) of 52 patients with a clinical diagnosis of posterior staphyloma. 10 MHz B-scan ultrasound images oriented along the visual axis were acquired while subjects fixated in 5 directions (primary, nasal, temporal, down and up gaze). An algorithm was used to assess the local radius of curvature (K in mm^{-1}). Specifically, an intensity-based segmentation algorithm tracked the vitreoretinal boundary and calculated K using differential calculus applied to the traced boundary. Positive K implies anterior convexity, whereas negative K implies posterior convexity. Larger K value implies a greater spatial change. The standard deviation (std) of K represents the level of non-uniformity along the curve of the entire posterior wall. One static frame for each scan direction was chosen to calculate the average and std of K in each direction. The Kruskal-Wallis test with the Tukey-Kramer method (as post hoc multiple comparisons) was performed to assess statistical significance between groups.

Results: Overall, we found significant gaze-induced posterior eye shape changes among the different gazes when grouped together ($p < 0.001$). Specifically, among the vertical scans, the average K in upgaze was 0.019 mm^{-1} greater than in primary gaze ($p < 0.001$). Also, the average K in upgaze was 0.021 mm^{-1} greater than in downgaze ($p < 0.001$). Std of K in upgaze was 0.081 mm^{-1} greater than in primary gaze ($p < 0.001$). Also, std of K in upgaze was 0.058 mm^{-1} greater than in downgaze ($p < 0.001$). There were no significant gaze-induced posterior eye shape changes with horizontal eye movements (all $p > 0.05$).

Conclusions: Significant gaze-induced staphyloma deformation was confirmed by ultrasound B-scan-based assessment, which is consistent with studies suggesting the association of environmental factors, such as excessive nearwork, with myopia development and progression.

ABSTRACT BODY:

Purpose: It has been postulated that the age pigment lipofuscin mediates photochemical reactions, which can contribute to oxidative stress in the outer retina. Chronic oxidative stress may lead to the onset of age-related macular degeneration (AMD). Lipofuscin is a composite granule with several chromophores, including a pyridinium bis-retinoid A2E, which according to the common belief, is responsible for photoreactivity and phototoxicity of this age pigment. Even though in simple model systems the photochemical reactivity of A2E was shown to be moderate or even low, it exhibited significant phototoxicity in retinal pigment epithelium cells in vitro. This vitamin A-derivative accumulates with senescence in retinal tissues and by forming adducts with biomolecules, may induce potential phototoxicity. In this study, we examined if the complexation of A2E with a model protein affected photoreactivity of this bis-retinoid.

Methods: The formation of non-covalent complexes of A2E with bovine serum albumin (BSA) was determined by UV-Vis absorption and emission spectrophotometry. The photochemical reactivity of bis-retinoid A2E and its complex with BSA was analyzed by time-resolved singlet oxygen phosphorescence, electron paramagnetic resonance (EPR)-spin trapping, and EPR-oximetry, using an appropriated spin trap and spin probe, respectively, and oxidation of the fluorogenic coumarin boronic acid probe.

Results: The obtained data indicate that A2E after complexation with the model protein exhibited enhanced photoreactivity generating, upon irradiation with blue light, reactive oxygen species, particularly singlet oxygen. Aerobic photoexcitation of A2E-BSA complexes resulted in the formation of protein hydroperoxides suggesting that A2E was able to oxidize this model protein in vitro.

Conclusions: The ability of A2E to oxidize model protein upon excitation with blue light suggests that the pyridinium bis-retinoid may also oxidatively modify cellular proteins and change their key properties.

TITLE: Location-specific patterns of inner retinal thinning in intermediate Age-related Macular Degeneration

SESSION TITLE: AMD: Clinical and translational research II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Trinh, M. Kalloniatis, L. Nivison-Smith, Centre for Eye Health Ltd, Kensington, New South Wales, AUSTRALIA|M. Trinh, M. Kalloniatis, L. Nivison-Smith, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure (Abstract): Matt Trinh: Commercial Relationship: Code N (No Commercial Relationship) | Michael Kalloniatis: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Nivison-Smith: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine inner retinal thickness changes of intermediate age-related macular degeneration (iAMD) eyes using grid-wise cluster analysis for macular optical coherence tomography (OCT) volume scans.

Methods: OCT macular cube scans ($30^\circ \times 25^\circ$) were acquired for 91 eyes with iAMD from 91 participants, and 91 sex- and age-similar normal eyes from 91 participants. Thicknesses of the retinal nerve fibre layer (RNFL), ganglion cell layer (GCL), and inner plexiform layer (IPL) were defined at 60-64 locations across an 8×8 grid ($3^\circ \times 3^\circ$ per grid) centred on the fovea. Previously developed topographical clusters, i.e. locations of isometric normative thicknesses, were used to define location-specific comparisons between iAMD and normal eyes.

Results: Location-specific analysis of iAMD versus normal eyes demonstrated various patterns of thickness changes in each inner retinal layer. The RNFL displayed no significant differences across the macula; the GCL displayed thinning towards the fovea (mean difference \pm SEM: $-1.63 \pm 0.5\%$ to $-5.07 \pm 1.07\%$, $P < 0.01$ to < 0.0001) and borderline thickening towards the peripheral macula ($1.26 \pm 0.48\%$, $P < 0.01$); the IPL displayed diffuse thinning ($-2.23 \pm 0.53\%$ to $-4.1 \pm 0.74\%$, $P < 0.001$ to < 0.0001).

Conclusions: Location-specific thickness changes in the GCL and IPL support potential anterograde trans-synaptic degeneration in intermediate AMD, with sparing of the RNFL. These data may better guide clinical diagnosis and monitoring of intermediate AMD to include inner retinal measures.

Commercial Relationships Disclosure (Abstract): Takao Hirano: Commercial Relationship: Code N (No Commercial Relationship) | Yoshiaki Chiku: Commercial Relationship: Code N (No Commercial Relationship) | Ken Hoshiyama: Commercial Relationship: Code N (No Commercial Relationship) | Toshinori Murata: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is well known that there is a high prevalence of vitreoretinal interface abnormalities, such as epiretinal membrane and incomplete vitreoretinal separation, in patients with diabetic retinopathy (DR). Xephilio OCT-S1 (Canon) can capture a swept source OCT image up to 23 mm with a single acquisition and is expected to provide detailed evaluation of the vitreoretinal interface over a wide field. We aimed to evaluate the vitreoretinal interface with wide-field OCT in eyes with DR.

Methods: This cross-sectional study included 193 eyes of 112 patients (mean [SD] age, 63[12] years; 41 females, 71 males) with DR. All patients underwent 23 mm OCT imaging using OCT-S1 through the fovea, with the focus placed at -3.0 diopter to the vitreous cavity, to visualize the vitreoretinal interface in more detail. All eyes staged by diabetic retinopathy severity were classified into posterior vitreous detachment (PVD) stages and categorized by the presence or absence of vitreoretinal interface abnormalities.

Results: The cohort of eyes with no DR (16 eyes; mean age: 68[14] years) consisted included seven eyes with stage 2 PVD, nine eyes with stage 4 PVD, and no eyes with vitreoretinal interface abnormalities. The eyes with non-proliferative diabetic retinopathy (NPDR; 81eyes; mean age: 65[11] years) included eight eyes with stage 0 PVD, 11 eyes with stage 1 PVD, 13 eyes with stage 2 PVD, six eyes with stage 3 PVD, and 43 eyes with stage 4 PVD. Of these, 23% had vitreoretinal interface abnormalities. The eyes with PDR (96 eyes; mean age: 59[11] years) included eight eyes with stage 0 PVD, seven eyes with stage 1 PVD, 21 eyes with stage 2 PVD, 24 eyes with stage 3, and 36 eyes with stage 4 PVD, of which 43% had vitreoretinal interface abnormalities.

Conclusions: Although there was no significant difference in the composition of the PVD stage according to DR severity, the proportion of vitreoretinal interface abnormalities increased with severity.

ABSTRACT BODY:

Purpose: The color of the optic nerve's central vessels, visible over the white myelin background, may serve as a reference to evaluate the increase in lens absorption to short wavelength radiation. It would allow observing premature lens aging in diabetic patients.

Methods: Fundus images were obtained from 354 normal and 307 diabetic eyes with a Topcon TRC-NW300 fundus camera (Topcon, Japan). Image quality, laterality of the eye, nerve position and nerve and vessel segmentation were automatically assessed by using the Deep Learning training for the Laguna ONhE program which is mainly used for glaucoma (1-4). A multiple regression equation was calculated based on the RGB components of the vessels so as to deduce the biological age of normal subjects. This equation was also used for the diabetic population.

Results: The biological age of normal subjects was estimated with a standard error (SE) of 5.93 years. Estimated age = $27.25 + (-0.366 \cdot R) + (1.556 \cdot G) + (-1.59 \cdot B)$ ($r = 0.911$, $p < 0.0001$). Much more aging was observed in diabetic patients $SE = 10.556$ ($r = 0.614$, $p < 0.0001$), as well as a greater dispersion (Figure).

Conclusions: Crystalline lens aging can be estimated by observing the changes in color of the retinal central vessels as they pass through the optic disc. These data confirm previous normal results obtained with the fundus camera DEC-200 (MiiS, Taiwan)(5). At the moment we have not been able to reproduce these results, with equal precision, in all the fundus cameras. We have the hypothesis that some more modern or more sophisticated fundus cameras may have an intense filtering of ultraviolet radiation.

TITLE: Velocity discrimination in infantile nystagmus syndrome (INS)

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Dai, K.M. Cham, L.A. Abel, Optometry & Vision Sciences, The University of Melbourne, Melbourne, Victoria, AUSTRALIA

Commercial Relationships Disclosure (Abstract): Bing Dai: Commercial Relationship: Code N (No Commercial Relationship) | Kwang Cham: Commercial Relationship: Code N (No Commercial Relationship) | Larry Abel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Research on infantile nystagmus syndrome (INS) and velocity discrimination is limited, and no research has examined velocity discrimination in subjects with INS at their null position and away from it. This study aims to investigate how individuals with INS perform, compared with controls, when carrying out velocity discrimination tasks. Particularly, the study aims to assess how the null position affects their performance.

Methods: INS subjects (N=21) and controls (N=16) aged 12 and above were recruited. They were required to perform horizontal and vertical velocity discrimination tasks at two gaze positions. For INS subjects, testing was done at the null position and 15° away from the null. If there was no null, testing was done at primary gaze position (straight-ahead) and 15° away from primary. For controls, testing was done at primary gaze position (straight-ahead) and 20° away from primary. Horizontal and vertical velocity discrimination thresholds were determined by a Weber fraction ($\Delta V/V$). Two-way ANOVAs were used for statistical analysis.

Results: INS subjects showed significantly higher horizontal ($37.59 \pm 18.56\%$) and vertical ($28.12 \pm 12.40\%$) velocity discrimination thresholds compared with controls (horizontal: $19.85 \pm 10.06\%$, vertical: $19.75 \pm 9.39\%$) at both gaze positions ($P < 0.001$). Within the INS group, 12 INS subjects who had an identified null position showed significantly lower horizontal ($27.00 \pm 7.90\%$) and vertical ($23.08 \pm 8.58\%$) thresholds at the null than at 15° away from it (horizontal: $37.61 \pm 18.08\%$, vertical: $28.89 \pm 9.23\%$, $P < 0.05$).

Conclusions: Velocity discrimination was impaired in INS subjects, with better performance at the null. These findings could assist us in understanding of how INS actually affects the daily activities of patients, and aid us in developing new clinical visual function assessment for INS.

ABSTRACT BODY:

Purpose: The viscous properties of topical eye drops play an important role in the lubrication of the ocular surface. In the present study, we compared the shear-stress dependent viscous properties of high-molecular weight hyaluronic acid (HMWHA) versus low molecular-weight hyaluronic acid (LMWHA) combined with trehalose using a novel optical rheometer for accurate viscosity analysis of liquid samples. In addition, the viscosity of natural tears was studied.

Methods: The measurements of viscosity were done using the Fluidicam RHEO technology (FORMULACTION, Toulouse France), a fully automated rheometer combining microfluidic and imaging technologies. Measurements were done at a shear rate range between 3000 s^{-1} to $30\,000 \text{ s}^{-1}$ in order to mimic the shear stress during eye blinking on the ocular surface. A HMWHA lubricant product (0.18% HA) was compared to a product containing LMWHA (0.15% HA) combined with trehalose (Thealoz Duo, Thea Pharma, Clermont Ferrand, France). In addition, natural tears as obtained from healthy subjects were used as comparator.

Results: As expected for a non-Newtonian liquid, the natural tears showed almost no change in viscosity in response to changes in shear stress (natural tear viscosity was $0.91 \text{ mPa}\cdot\text{s}$ at 3000 s^{-1} , and $0.80 \text{ mPa}\cdot\text{s}$ at $30\,000 \text{ s}^{-1}$). The hyaluronic-acid based eye drops had a higher viscosity compared to natural tears ($p < 0.001$). The LMWHA product containing trehalose showed a viscosity of $2.26 \text{ mPa}\cdot\text{s}$ at 3000 s^{-1} that decreased to $1.77 \text{ mPa}\cdot\text{s}$ at $30\,000 \text{ s}^{-1}$. The HMWHA product had the highest viscosity ($p < 0.001$ versus LMWHA product containing trehalose) of $4.73 \text{ mPa}\cdot\text{s}$ at 3000 s^{-1} decreasing to $2.44 \text{ mPa}\cdot\text{s}$ at $30\,000 \text{ s}^{-1}$. The decrease of viscosity with increasing shear rate was more pronounced for the HMWHA product (-48%) than for the LMWHA product containing trehalose (-20%).

Conclusions: The present study confirms that neither natural tears nor the hyaluronic acid-based lubricants are Newtonian liquids. Combination of LMWHA with trehalose demonstrated a rheological behaviour closer to natural tears than the HMWHA product.

TITLE: Effect of increased vascular endothelial growth factor on fluorescence lifetime of human retinal microvascular endothelial cells in vitro

SESSION TITLE: Retinal Cell Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Schmidt, K. Kern, Y. Miura, Institute of Biomedical Optics, University of Lübeck, Lübeck, GERMANY|Y. Miura, Department of Ophthalmology, University of Lübeck, Lübeck, GERMANY|

Commercial Relationships Disclosure (Abstract): Kilian Schmidt: Commercial Relationship: Code N (No Commercial Relationship) | Katharina Kern: Commercial Relationship: Code N (No Commercial Relationship) | Yoko Miura: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor (VEGF) is known to disrupt tight junction of vascular endothelial cells and induce their proliferation, leading to vascular leakage and neovascularization as seen in diabetic retinopathy. The aim of this study is to investigate the effect of VEGF on cell metabolism and the fluorescence lifetime of retinal microvascular endothelial cells using fluorescence lifetime imaging microscopy (FLIM).

Methods: An immortalized cell line of the human retinal microvascular endothelial cells (HRMEC) were treated either with 10 ng/ml VEGF₁₂₁, only with the vehicle (400 nM hydrogen chloride), or without any addition (control) for 48 hours. Cell metabolic activity and mitochondrial membrane potential were assessed using MTT and JC-10 assays. Mean fluorescence lifetime (t_m) was measured using two-photon microscopy combined with FLIM (excitation at 740 nm, detection with a single channel for 380 nm to 680 nm). t_m of cell nuclei and mitochondria were analyzed separately with SPCImage software.

Results: The MTT assay showed an increase in cellular metabolic activity, and the JC-10 assay detected a significant increase in mitochondrial membrane potential in cells treated with 10 ng/ml VEGF. In FLIM, t_m of the mitochondria was significantly longer than in the nuclei of the same cells under all three conditions. FLIM further revealed that the cells treated with 10 ng/ml VEGF showed longer t_m in mitochondria than control and vehicle-treated cells, where the difference was on the verge of statistical significance ($p = 0.08$). Comparing the ratios between t_m of mitochondria and cell nuclei, VEGF-treated cells showed a significantly higher ratio ($p < 0.05$).

Conclusions: The results of the MTT and the JC-10 assays suggested that VEGF may increase mitochondrial activity of HRMEC, and FLIM could indicate these changes in a label-free live cell imaging. Elongation of t_m in mitochondria of VEGF-treated cells may suggest the increase of protein-bound nicotinamide adenine dinucleotide (NADH), further indicating the increased function of mitochondrial respiration. VEGF-induced changes in FLIM on retinal cells may provide insight into the clinical application of fluorescence sensing in different chorioretinal pathological conditions, where VEGF plays a significant role.

ABSTRACT BODY:

Purpose: The photopic negative response (PhNR) is a late component of the light-adapted full-field electroretinogram (ERG) that reflects the function of retinal ganglion cells. In response to standard stimuli, a positive component, the i-wave, is superimposed on this response, creating a pre- and post-i-wave trough, termed PhNR1 and PhNR2. We explored relative contributions of genetic and environmental factors to variance in these PhNR components using a classic twin study.

Methods: As part of a larger study, 210 largely healthy adult twins from the TwinsUK cohort underwent full-field electroretinography incorporating standards set by the International Society for Clinical Electrophysiology of Vision (ISCEV). Responses were recorded using conductive fibre electrodes in the lower conjunctival fornix and averaged from both eyes. PhNR parameters were derived from the standard LA 3.0 response (amplitudes measured from baseline and peak times measured from the time of flash delivery). Coefficients for intra-pair correlation were calculated for monozygotic (MZ) and dizygotic (DZ) pairs (Pearson coefficients unless the parameter deviated from a normal distribution in which case Spearman coefficient was calculated).

Results: Full-field ERGs (including PhNRs) and zygosity data were available for 206 twins in total (59 MZ and 44 DZ pairs), 94% were female. The mean (SD) age for the cohort was 63 (11) years. Mean (SD) amplitudes were 11.1 (4.9) and 17.1 (5.7) microvolts for PhNR1 and PhNR2 respectively; mean (SD) peak times were 42.8 (2.5) and 63.3 (4.4) ms respectively. Correlation coefficients for MZ pairs were 0.74 and 0.61 for amplitudes, and 0.50 and 0.36 for peak times. Respective DZ coefficients were 0.38 and 0.39 for amplitudes, and 0.24 and 0.29 for peak times. The peak time distribution for PhNR2 deviated significantly from normal.

Conclusions: This is the first twin study to explore both PhNR components. Coefficients of intra-pair correlation were consistently higher for MZ than DZ twins for all parameters, indicating that genetic factors are likely to be important in shaping these responses. The differences between MZ and DZ correlations appeared more marked for the PhNR1 component, suggesting this may be relatively less affected by environmental factors.

ABSTRACT BODY:

Purpose: Phenotypes of diabetic retinopathy, particularly B and C, have been shown previously to be associated with risk of progression and development of sight-threatening complications (macular edema and proliferative retinopathy). In this work, we have further characterized these type 2 diabetes (T2D) retinopathy phenotypes, in terms of systemic and ocular features.

Methods: Patients with T2D and nonproliferative retinopathy (NPDR) were examined using 7-fields color fundus photography (CFP) and optical coherence tomography (OCT and OCTA). Phenotype classification was performed based on microaneurysm turnover (MAT, on CFP) and central retinal thickness (CRT, on OCT). Phenotype B was identified by low MAT (< 6) and increased CRT and Phenotype C by higher MAT (≥ 6) with or without increased CRT. ETDRS grading of seven fields CFP was performed. The following systemic factors were also evaluated: age, sex, diabetes duration, lipidic profile, inflammatory cytokines and hemoglobin A1c (HbA1c).

Results: 141 eyes with NPDR, one eye per patient, 81 with phenotype B and 60 with phenotype C were included in the analysis. The patients presenting phenotype C had higher HbA_{1c} levels ($p=0.048$) and patients with phenotype B had higher values of HDL cholesterol ($p=0.036$) and interleukin-8 ($p=0.027$). Phenotype C was characterized by lower macular vessel density ($p\leq 0.012$) and thinning of the ganglion cell layer (GCL; $p=0.006$). As expected by the initial phenotype characterization, phenotype C showed higher MAT ($p<0.001$) and phenotype B higher values of retinal thickness (CRT, $p<0.001$). Phenotype C was also identified in eyes with more severe ETDRS level (50%, ETDRS 43-47) than phenotype B (17% ETDRS 43-37).

Conclusions: Of the two phenotypes of NPDR in T2D associated with risk of developing sight-threatening complications, phenotype C is characterized by microvascular alterations represented by higher MAT and increased capillary closure on OCTA and by neurodegenerative changes, represented by GCL thinning, whereas phenotype B is characterized locally by increased CRT and systemically by increased levels of inflammatory markers.

ABSTRACT BODY:

Purpose: Sub-retinal fibrosis remains a challenge to vision even after administering optimal treatments for AMD. Here, we propose porous silicon microparticles (pSiMPs) as reservoir of interferon gamma (IFN γ)-an antifibrotic cytokine, that allow slow release for >30 days minimising rapid clearance and low bioavailability in the eye. Using experimental models, we show that single injection of pSiMPs loaded with IFN γ (pSiMPs- IFN γ) into the vitreous may suffice to adequately treat AMD.

Methods: The pSiMPs were prepared from standard silicon wafer etching using electrochemical anodization in HF/ ethanol mixtures, followed by ultrasonic fracturing. Microparticles were size excluded and characterised using scanning electron microscopy (SEM).

The pSiMP surface was subjected to 1-allyl-2,3-isopropylidene glycerol hydrosilylation to add an active aldehyde moiety to enhance protein binding. WST cell proliferation assay was used to establish the biocompatibility of these pSiMPs.

Transforming growth factor-beta (TGF- β) was used to induce fibrosis in ARPE 19 cells. After 14 days of TGF- β exposure, the cells were treated with pSiMPs- IFN γ . Cell extracts were collected at 7-day interval up to four weeks and their collagen content (indicator of fibrosis) was evaluated using western blot and Sirius red-fast green (RG) staining. Further, we are evaluating our reservoir system in retinal mimics developed using human mesenchymal stem cells and CNV rat model to explore its preclinical potential.

Results: The average particle size characterized by SEM imaging was 20.5 \pm 7 μ m. FTIR-ATR confirmed the addition of aldehyde group to the pSiMPs. The WST assay confirmed that the cells were viable on incubation with pSiMPs up to 96 hours.

The collagen content increased on addition of TGF- β . On addition of pSiMPs- IFN γ , the collagen content decreased steadily over four weeks. Polarised microscopy imaging of RG staining of cells confirmed these results. Total collagen content evaluation reassured a similar pattern indicating that IFN γ is continually released from the pSiMPs.

Conclusions: Through this study, we have demonstrated that the pSiMPs can be used as a reservoir system for sustained intravitreal delivery of IFN γ to reduce fibrosis in AMD. This system can be extended to other eye conditions where posterior segment delivery of therapeutics is limited.

ABSTRACT BODY:

Purpose: Deep neural networks (DNNs) for optical coherence tomography (OCT) classification have been proven to work well on images from scanners that were used during training. However, since the appearance of OCT scans can differ greatly between vendors, these DNNs often fail when they are applied to scans from different manufacturers. We propose a DNN architecture for age-related macular degeneration (AMD) grading that maintains performance on OCTs from vendors not included during training.

Methods: 2,598 and 680 Heidelberg Spectralis OCT scans from the European Genetic Database were used for development and testing, respectively. We tested transferability with 339 AMD-enriched Topcon OCTs from the Rotterdam Study.

AMD severity classification was determined manually in accordance with the Cologne Image Reading Center and Laboratory and Rotterdam Classification, respectively. Classifications were harmonized for the evaluation of the DNNs.

The proposed DNN considers each B-scan separately using a 2D ResNet-18, and internally combines the intermediate outputs related to each B-scan using a multiple instance learning approach. Even though the proposed DNN provides both B-scan level and OCT-volume level decisions, the architecture is trained end-to-end using only full volume gradings. This specific architecture makes our method robust to the variability of scanning protocols across vendors, as it is invariant to B-scan spacing.

We compare this approach to a baseline that classifies the full OCT scan directly using a 3D ResNet-18.

Results: The quadratic weighted kappa (QWK) for the baseline method dropped from 0.852 on the Heidelberg Spectralis dataset to 0.523 on the Topcon dataset. This QWK drop was smaller ($p = 0.001$) for our approach, which dropped from 0.849 to 0.717. The difference in area under the Receiver Operating Characteristic (AUC) drop was also smaller ($p < 0.001$) for our approach (0.969 to 0.906, -6.5%) than for the baseline method (0.971 to 0.806, -17.0%).

Conclusions: We present a DNN for AMD classification on OCT scans that transfers well to scans from vendors that were not used for development. This alleviates the need for retraining on data from these scanner types, which is an expensive process in terms of data acquisition, model development, and human annotation time. Furthermore, this increases the applicability of AI for OCT classification in broader scopes than the settings in which they were developed.

TITLE: The Transition from PRN to Treat and Extend: Do Patients See the Difference?

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Chebolu, J. Walsh, Ophthalmology, Albany Medical Center, Albany, New York, UNITED STATES|J. Busingye, Ophthalmology, Albany VA Hospital, Albany, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Apoorv Chebolu: Commercial Relationship: Code N (No Commercial Relationship) | Josh Walsh: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Busingye: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate patients with choroidal neovascularization (CNV), retinal vein occlusion (RVO), or diabetic macular edema (DME) transitioned from a pro re nata (PRN) to a treat-and-extend (TAE) protocol.

Methods: Retrospective chart review of patients treated with intravitreal anti-vascular endothelial growth factor (anti-VEGF) injections initially on a PRN protocol transitioned to a TAE protocol for at least 6 months of follow-up. Best corrected visual acuity (BCVA) and central foveal thickness (CFT) on optical coherence tomography were collected.

Results: Eighty-one eyes from 74 patients treated for 211.5 ± 43.7 and 43.5 ± 1.3 weeks on PRN and TAE protocols, respectively. Overall, BCVA improved from 0.61 ± 0.07 to 0.57 ± 0.06 logMAR following this transition ($p=0.22$). Eyes with a worse BCVA at initiation of the TAE protocol ($<20/70$; $n=32$) were noted to have a significant improvement from 1.17 ± 0.11 to 0.92 ± 0.10 logMAR ($p < 0.01$). Among different disease cohorts, the RVO eyes ($n=17$) experienced the greatest improvement in visual acuity 0.84 ± 0.16 to 0.67 ± 0.13 logMAR ($p=0.18$). A significant improvement in CFT was noted following the transition, 341.2 ± 13.6 to 261.0 ± 8.3 μm ($p < 0.001$). The number of anti-VEGF injections per year increased from 3.2 ± 0.3 to 9.5 ± 0.3 following the transition from the PRN to TAE protocol ($p < 0.001$). Six patients were lost to follow-up due to frustration with the TAE protocol and 2 patients elected to restart a PRN protocol after attempting the TAE protocol.

Conclusions: Transitioning from a PRN to a TAE protocol offers most patients significant anatomic benefits with less robust functional benefits. Interestingly, in a small sample size the RVO eyes experienced the most substantial BCVA improvement. An important consideration in this transition is the increased annual injection burden, which may be met with objection by certain patients who prefer the PRN protocol.

TITLE: M-CHARTS evaluation and comparison of two Aflibercept regimens for neovascular age-related macular degeneration

SESSION TITLE: AMD: Clinical and translational research II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Schroeder, M. Loevestam-Adrian, Lunds Universitet, Lund, SWEDEN|

Commercial Relationships Disclosure (Abstract): Marion Schroeder: Commercial Relationship(s);Bayer Pharma AG:Code F (Financial Support);Bayer Pharma AG:Code R (Recipient) | Monica K Loevestam-Adrian: Commercial Relationship(s);Bayer Pharma AG:Code F (Financial Support);Bayer Pharma AG:Code C (Consultant);Novartis:Code C (Consultant);Allergan:Code C (Consultant);Santen:Code C (Consultant)

ABSTRACT BODY:

Purpose: To compare multiple functional and physiological outcomes with M-CHARTS values in patients treated with aflibercept for neovascular age-related macular degeneration (nAMD) in two arms, label vs treat-and-extend (TAE).

Methods: This prospective study randomized 41 eyes of 41 treatment-naïve patients with nAMD to two regimens. Arm 1 was treated with aflibercept according to label with three monthly injections, followed by bimonthly injections to the end of year one, thereafter the regimen changed to TAE. Arm 2 received the TAE regimen over the total study period of 18 months. Number of injections, best-corrected visual acuity (VA), near visual acuity (NVA), full-field and multifocal electroretinography (ffERG, mERG), optical coherence tomography (OCT) had been presented in a previous report. The present study evaluated M-CHARTS variables, including a questionnaire, horizontal metamorphopsia (MH), vertical metamorphopsia (MV), and vision-related quality of life (QoL) with the National Eye Institute Visual Function Questionnaire (NEI-VFQ-25).

Results: In arm 1, 19 eyes presented with available baseline and follow-up data for M-CHARTS values, 18 eyes in arm 2. From baseline to the final follow-up, the MV score improved significantly in arm 1 from $.65 \pm .53$ to $.44 \pm .53$; $p=.029$, and in arm 2 from $.49 \pm .48$ to $.20 \pm .29$; $p=.007$. The MH score showed significant improvements in arm 1 from $.74 \pm .55$ to $.41 \pm .51$; $p=.028$, but no significant changes in arm 2 from $.64 \pm .63$ to $.33 \pm .48$; $p=.075$. The M-CHARTS questionnaire score showed decreased subjective perception of metamorphopsia in arm 1 from $1.79 \pm .85$ to $1.58 \pm .69$; $p=.331$; in arm 2 from $2.17 \pm .78$ to $1.56 \pm .784$; $p=.022$. During the 18 months, we found no significant correlation between changes of MV, MH or M-CHARTS questionnaire results and changes of VA, NVA, ffERG, mERG, and QoL composite score. When comparing the mean change of variables over time and between regimens, we only found a statistically significant difference between the two arms in two vision-related subgroups of the NEI-VFQ-25, general vision; $p=.001$, and near activities; $p=.012$.

Conclusions: MV emerged as statistically significant variable to follow-up and quantify metamorphopsia. As earlier described, M-CHARTS variables presented as independent parameters. The outcomes of the two aflibercept regimens showed no significant differences, besides two vision-related items of the NEI-VFQ-25.

ABSTRACT BODY:

Purpose: Living kidney donors are typically considered to have normal kidney function. Recently, concerns have been raised on the long-term risk of both cardiovascular and chronic kidney disease (CKD) following kidney donation. However, quantitative risk assessment tools are lacking. We propose a retinal imaging approach to gain insights into the timing of vascular changes in kidney donors.

Methods: We prospectively recruited three groups: 30 healthy subjects, 30 patients with stable CKD, and 30 kidney donors. Optical coherence tomography angiography images of one eye per participant were acquired. Image processing was performed using a U-Net neural network to segment the vasculature. The binarised image was converted into a vascular network object (graph) from which vessel characteristics were extracted. We obtained retinal measurements (e.g., nodes in the graph, size and shape of intercapillary space) from each region of interest in the retina, up to a total of 593 phenotypes. Multivariate models, corrected for age and gender, assessed statistically significant retinal characteristics that discriminated CKD from health.

Correlated vascular measures were removed and the remaining measures used to perform principal component analysis (PCA) to visualise patient distributions in a 2-dimensional (2D) space. Finally, clustering analysis was performed to investigate the separability between these two groups. Using the same PCA transformation, we projected kidney donors in our 2D space to observe their distribution in the healthy-CKD plane. Also, we investigated if donor PCA projection was associated with estimated glomerular filtration rate (eGFR), a routine clinical measure of kidney function.

Results: Our results show that PCA separates healthy subjects from those with CKD (accuracy=0.82). When we projected kidney donors into the same 2D space, they distributed across the two previous clusters, suggesting that some donors have similar retinal vascular characteristics to CKD whilst others resemble health. These differences were not associated with eGFR.

Conclusions: Our data suggest that retinal imaging may be used to discriminate those with normal kidney function from those with CKD. Whether these differences might link to patient outcomes remains unclear. Retinal imaging may identify living kidney donors at risk of future CKD and cardiovascular disease.

ABSTRACT BODY:

Purpose: To perform OCT-based analysis of RPE and photoreceptor atrophy progression in patients enrolled in the FILLY trial.

Methods: SD-OCT (Spectralis) images from the FILLY trial, a sham controlled phase 2 clinical study of geographic atrophy (GA) with intravitreal pegcetacoplan, an investigational therapy targeting complement C3, were analyzed. A-scan based manual annotation of the absence of the following bands was performed on baseline and year one SD-OCT volumes: retinal pigment epithelium (RPE), ellipsoid zone (EZ) and external limiting membrane (ELM). These manual annotations were also used to develop and validate an algorithm to automatically delineate GA areas. The growth rate of the resulting areas was calculated using the square root transformation. The difference in growth between treatment regimens (monthly injection (AM), injection every other month (AEOM), and sham (SM)) was calculated using the Kruskal-Wallis-test. Post-hoc pairwise testing was performed using Bonferroni correction for multiple testing.

Results: 145 OCT images were annotated from baseline and 115 from year 1. In total, 113 matched (38 AM, 36 AEOM, 39 SM) OCT volumes were included for analysis. Results are presented as mm change and interquartile range (IQR). Median growth of RPE-loss was 0,158 [0,057 – 0,296] in the AM group, 0,190 [0,106 – 0,336] in the AEOM group and 0,255 [0,188 – 0,359] in the SM group. The difference between AM and SM was statistically significant ($p = 0,014$).

Median growth of EZ-loss was 0,127 [0,041 – 0,247] in the AM group, 0,179 [0,101 – 0,293] in the AEOM group and 0,232 [0,130 – 0,349] in the SM group. Likewise to RPE-loss, the difference between AM and SM was statistically significant ($p = 0,017$).

There was no significant difference in ELM-loss growth between the treatment groups ($p = 0,114$).

Conclusions: Analysis of SD-OCT imaging provided consistent results in the measurement of GA lesion growth compared to FAF. In addition to significantly slower growth of RPE atrophy, SD-OCT data showed significant reduction in EZ impairment, indicative of slowed disease progression in patients treated with pegcetacoplan monthly. Therefore, a combination of SD-OCT imaging and advanced analysis may be the optimal methodology for measuring disease activity and potential therapeutic efficacy in GA.

ABSTRACT BODY:

Purpose: Validation of a modified version of an NCCA (NCCAm) and comparison with the Cochet Bonnet Aesthesiometer (CBA) in subjects with normal corneas.

Methods: The NCCA device described by Murphy et al (1996, 1998) to measure corneal sensitivity was modified as follows: The air reservoir was placed outside the enclosure and the fan inside, and a 3-way solenoid valve was used to save space. An adapter for the Goldmann tonometer was designed to hold the nozzle to ease accessibility at a standard slit lamp. A 250 µm filter was added to the patient line as a precaution against dust and contaminants. A user-friendly calibration feature was implemented while a manual valve was added to the exhaust line to ensure equalization of pressure in the exhaust and patient lines. The device allows for fine pressure adjustments down to 0.02 mbars. The configuration chosen was a 0.5 mm nozzle diameter, 0.9 second puff duration and 1 cm distance to cornea.

The left eye central corneal sensitivity of 21 subjects (12 females) was tested using the NCCAm and the CBA gold standard was used for comparison. The NCCAm pressure started at 0.01 mbar (subthreshold) and increased in 0.02 mbar intervals until the participant felt the stimulus (ascending threshold). Then the pressure was decreased until the patient no longer felt a stimulus and the last felt pressure was recorded (descending threshold). The mean of the two measurements was their NCCAm result. This was repeated for 3 rounds at 5 minute intervals.

Results: All CBA measurements were normal (6.0 cm). The NCCAm ascending threshold was repeatedly higher (mean 0.06 mbars; $p < 0.001$) than the descending threshold, but this difference was stable (linear mixed-effect model: $F = 0.5$, $df = 2$, $p = 0.62$). Furthermore, an intra-class analysis (ICC) showed an excellent agreement between the three rounds ($\rho_{ICC} = 0.90$ [95% CI: 0.83-0.95]). NCCAm mean (\pm SD) threshold values of 0.177 ± 0.045 mbar ranging from 0.085 to 0.532 mbar were obtained. Consistent with Murphy 1996, the NCCAm allows corneal sensitivity measurement below the detection threshold of CBA.

Conclusions: The NCCAm is a compact user-friendly device enabling reliable corneal sensitivity measurements. It also allows the detection of inter-subject differences that are not detected with the traditional CBA.

ABSTRACT BODY:

Purpose: Advanced stages of macular degeneration are the main causes of blindness that involve irreversible photoreceptor loss. Visual cycle is dependent on the photosensitive photoreceptors and retinal pigmented epithelium (RPE). Provision of RPE alone is insufficient and existing methods to generate photoreceptors are not reproducible and inefficient. Therefore, our aim is to develop an alternative method that generates clinically safe and functional photoreceptors to treat vision loss. Our hypothesis is that transplantable competent photoreceptor progenitors are able to engraft and mature in vivo, thereby promoting visual response.

Methods: We have generated a previously unavailable human recombinant retina-specific laminin isoform LN523 that recapitulates the inter-photoreceptor matrix. Human pluripotent stem cells are efficiently differentiated towards photoreceptor progenitors after 32 days in a two steps method, with the support of this analogous retina matrix. This method is chemically defined and xenogen-free which does not involve re-plating and manual dissections. Day 32 photoreceptor progenitors co-expressing CRX and RCVRN were transplanted in the sub-retinal space of rabbit and rd10 mice model. Electroretinogram (ERG) was performed to test the functional visual response in the post-transplanted mice model.

Results: This method is highly reproducible based on the single cell transcriptomic and immunohistochemical analyses tested on four different human pluripotent stem cell lines. The differentiated photoreceptor progenitors were found to engraft and express mature photoreceptor markers in the retina in vivo where they also present promising evidence of synaptic connectivity with degenerated rabbit host retina. Additionally, the transplanted photoreceptor progenitors preserve the host photoreceptor outer nuclear layer and also exhibited statistically significant improved photoreceptor a-wave response based on ERG analysis in nine P30 rodent rd10 model.

Conclusions: We found an alternative photoreceptor differentiation platform using our novel retina specific laminins. This method potentially promotes retina function and may constitute an important step towards the future use of hESC-derived photoreceptors to treat vision loss.

TITLE: Long-term changes of fundus autofluorescence in chronic central serous chorioretinopathy

SESSION TITLE: Imaging of posterior segment II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Lee, K. Kim, E. Kim, S. Yu, Kyunghee university medical center, KOREA (THE REPUBLIC OF)

Commercial Relationships Disclosure (Abstract): Junwoo Lee: Commercial Relationship: Code N (No Commercial Relationship) | Kiyoun Kim: Commercial Relationship: Code N (No Commercial Relationship) | Eung Suk Kim: Commercial Relationship: Code N (No Commercial Relationship) | Seung-Young Yu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate long-term clinical outcomes and fundus autofluorescence (FAF) changes in patients with chronic central serous chorioretinopathy (CSC) according to different FAF patterns.

Methods: This retrospective study included 22 eyes of 20 patients from 5 years follow-up diagnosed with central serous chorioretinopathy. Best corrected visual acuity, subfoveal choroidal thickness, fundus autofluorescence (FAF) patterns with spectral domain optical coherence tomography, the number of intravitreal anti-VEGF injection and the number of PDT were examined.

Results: Initial fundus autofluorescence patterns of 22 eyes were grouped as blocked (9, 40.91%), mottled (1, 4.55%), hyper (6, 27.27%), hyper/hypo (5, 22.73%), or descending tract (1, 4.55%). Average onset age was 49.77 ± 8.19 . After 5 years, FAF pattern progression showed total 12 eyes (54.55%), blocked (100.0%), mottled (0.0%), hyper (33.3%), hyper/hypo (20.0%), descending tract (0.0%). Mean fundus hypofluorescence change was $0.42 \pm 0.67 \text{ mm}^2$. Visual prognosis was associated with changes of hyper/hypofluorescence area in fundus autofluorescence image.

Conclusions: Progression of FAF was observed in eyes with more progressive patterns. Visual prognosis with chronic central serous chorioretinopathy more correlate with hyper/hypofluorescence change.

ABSTRACT BODY:

Purpose: Multidrug resistance protein 4 (MRP4) is an energy-dependent membrane transporter responsible for cellular efflux of a broad range of xenobiotics and physiological substrates. Here, we aimed to investigate the effects of ageing and MRP4 deficiency using gene expression microarray and morphological and electrophysiological analyses of the mouse retina.

Methods: Mrp4-knockout (null) mice and wild-type (WT) mice were reared in the same condition to 8-12 weeks (young) or 45-55 weeks (aged). RNA was extracted from 6 retinas for each mouse genotype (WT and Mrp4-null), and RNA microarray using Agilent SurePrint G3 Mouse Gene Expression Arrays 8x60K Ver. 2.0 and the following KEGG pathway analyses were performed. Then, retinal wholemount immunostaining, immunohistochemical and H&E staining of tissue sections were conducted to assess changes in retinal layers and retinal cell types among 4 age/genotype categories (young/aged WT mice and young/aged Mrp4-null mice). Finally, electroretinogram was recorded to detect the difference in retinal function between aged WT and aged Mrp4-null mice.

Results: Microarray analysis identified 186 differentially expressed genes from the retinas of aged Mrp4-null mice compared with aged WT mice, and subsequent gene ontology and KEGG pathway analyses showed that differently expressed genes were related to lens, eye development, vision, and transcellular barrier function which are involved in metabolic pathways or viral infection pathways. No significant change in thickness was observed for each retinal layer among 4 age/genotype categories. In addition, immunohistochemical analyses of retinal cell type did not exhibit an overt change in cellular morphology or distribution among 4 age/genotype categories, either. Electroretinogram responses showed no significant differences in the amplitude or the latency between aged WT mice and aged Mrp4-null mice.

Conclusions: Although it affects gene expression profile in the mouse retina, ageing would be an insufficient stress to cause some damage to the retina in the condition of MRP4 deficiency.

ABSTRACT BODY:

Purpose: To investigate temporal changes of deep learning quantified imaging biomarkers in intermediate age-related macular degeneration (iAMD) in eyes developing initial outer retinal atrophy associated with incipient macular atrophy (iMA).

Methods: Eyes with iAMD from the sham treatment cohort of a prospective randomized clinical trial (LEAD study) were included. SD-OCT scans were acquired every 6 months for a follow up of 3 years. All eyes were re-graded for the development of iMA (choroidal hypertransmission (HT) > 125µm + evidence of RPE irregularities) on OCT in the absence of signs of exudation (IRF, SRF). Inner nuclear layer/outer plexiform layer (INL/OPL) subsidence (with at least subsidence of the INL-OPL and OPL-ONL junctions) was also annotated in all time-points for all iMA cases. Photoreceptor (PR) thickness, ONL thickness, drusen thickness (DT) and HT were measured using AI algorithms. Morphological changes before and after INL/OPL subsidence, as well as differences between areas of pathological and intact outer retina (subsidence/drusen/non-drusen area) were assessed using mixed effect models considering both eyes and multiple lesions per eye.

Results: Out of 280 eyes, 54 eyes developed iMA, of which 52 eyes presented with INL/OPL subsidence prior to iMA. Progressive PR thinning was present as the first sign of outer retinal changes with a mean thinning of -0.34 µm/month; 95% CI: -0.36,-0.33). ONL thinning was present after PR thinning (mean: -0.47 µm/months; 95% CI: -0.51,-0.44). DT decreased and HT appeared after the last visit before INL/OPL subsidence (Figure 1). A significant difference between INL/OPL subsidence area, drusen area and non-drusen area was identified for longitudinal PR thinning, ONL thinning, DT and HT (all p<0.001, except DT: p=0.047).

Conclusions: PR thinning on in-vivo OCT is an initiating sign of developing outer retinal atrophy in non-neovascular AMD. Subsequently, ONL thinning becomes apparent, DT declines and HT appears, leading to iMA in the vast majority of cases. Precise assessment of deep learning quantified retinal biomarkers using longitudinal in-vivo OCT volumes allows accurate identification and evaluation of early morphological alterations. These findings give new insight into the pathomechanism of atrophy development in AMD and provide novel possibilities in disease monitoring.

TITLE: Electronically Monitored Steroid Eye Drop Adherence After Trabeculectomy Compared to Short-Term Surgical Success

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Dosto, T.V. Johnson, E. McGlumphy, H.A. Quigley, Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Niccolo Dosto: Commercial Relationship(s);Kali Care:Code F (Financial Support) | Thomas Johnson: Commercial Relationship(s);Kali Care:Code F (Financial Support) | Elyse McGlumphy: Commercial Relationship(s);Kali Care:Code F (Financial Support) | Harry Quigley: Commercial Relationship(s);Kali Care:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To measure adherence with steroid eye drops after trabeculectomy with an electronic monitoring device compared to short-term achievement of target IOP.

Methods: Open angle glaucoma patients who underwent trabeculectomy were instructed on use of an electronic monitor attached to a topical steroid drop bottle that recorded drop use in real time through wireless technology. Patients were prescribed only 1% prednisolone acetate every 2 hours while awake for 1 week, then 4 times a day for 1 week tapered by 1 drop/week until week 6. Postop visits were at 1, 3 and 6 weeks, 3 and 6 months, and 1 year. Primary outcome was percent adherence compared to achievement of IOP target. Secondary outcomes were comparison of adherence to a questionnaire estimating adherence to daily glaucoma drops, grading of bleb morphology, reported pain, and anterior chamber inflammation grade.

Results: Data were available for 60 subjects at 6 weeks, 24 at 6 months and 10 at 1 year postop. Devices recorded drop use in 82 of 85 subjects. Total adherence was $90 \pm 14\%$ with q2h frequency at $79 \pm 18\%$. Total adherence did not significantly differ by age, race or sex, nor was it related to inflammation or pain for 6 weeks. 82% achieved target IOP at 6 weeks (49/57, 3 incomplete). Adherence was $78 \pm 18\%$ for eyes \leq target IOP at 6 weeks and $86 \pm 16\%$ for those $>$ target ($p=0.27$). 15/49 subjects \leq target and 7/8 $>$ target at 6 weeks were women ($p=0.0043$). Eyes with 6-week IOP < 6 mm Hg had lower adherence than those ≥ 6 mmHg (ratio taken/ideal drop adherence: 84% vs 0.92%, $p=0.07$). Predicted adherence from a daily glaucoma drop questionnaire did not correlate with steroid drop adherence. At 6 months, 16/24 reached IOP target, while 10/10 eyes were below target at 1 year. Those achieving target IOP without further glaucoma surgery were not more adherent than those who were over target (74% vs. 80%, $p=0.50$).

Conclusions: Detailed eye drop adherence data can be obtained electronically in real time, showing substantial adherence with postop steroid drops after glaucoma surgery. With the protocol of steroid drops used here, the observed adherence was not related to success of IOP control at 6 weeks or 6 months after surgery. Low postop IOP at 6 weeks was potentially related to poorer adherence.

ABSTRACT BODY:

Purpose: Several studies provided compelling evidence that the immune system is involved in the pathogenesis of open-angle glaucoma (OAG). Reactive oxygen species and cytokines produced by the gut microbiome may play a role in this process, traveling from the gut mucosa to the eye. Therefore it is of interest to find changes in the microbiome of patients with OAG.

Methods: Population-based cohort study. All participants underwent extensive ophthalmic examinations, including intra-ocular pressure (IOP), retinal nerve fiber layer (RNFL), and vertical cup-to-disc ratio (VCDR) measurements, and provided a stool sample. A 16S rRNA gene profile dataset was generated and PICRUST tool was used to obtain predicted bacterial functions. Beta-diversity was calculated and compared using Bray-Curtis dissimilarity matrices. The relationship between alpha-diversity and OAG and OAG-associated parameters was assessed by logistic and linear regression analyses, respectively, adjusted for age, sex, body-mass index, and medication use. The same analyses were performed to assess these relationships at taxa level.

Results: When comparing OAG cases with controls, no differences in alpha- and beta diversity were observed. On taxa level, a higher abundance of the family Rikenellaceae, more specifically the genus Alistipes (OR [95% CI]=1.69 [1.17-2.54]), was associated with higher OAG risk (OR [95% CI]=1.60 [1.11-2.38]). The family Clostridiaceae1 was associated with a lower IOP (estimate=-0.121; p-value=0.001) and smaller VCDR (estimate=-0.024; p-value=0.002). At genus level, Clostridiumsensustricto1 showed the same effects (estimate=-0.120; p-value=0.002 and estimate=-0.023; p-value=0.003, respectively). Predicted functional metagenome analysis showed an association between the lysosome and OAG (OR [95% CI]=2.50 [1.18-4.68]) and RNFL (estimate=-5.273; p-value=0.007).

Conclusions: This study showed associations between the gut microbiome and OAG, as well as with OAG-associated parameters. Predicted functional metagenome analysis revealed the lysosome as potentially interesting for the development of glaucoma. Although replication studies are necessary, our findings display a new pathway in the pathogenesis of glaucoma.

ABSTRACT BODY:

Purpose: Approximately 50% of patients diagnosed with uveal melanoma (UM) develop metastatic disease, with a median overall survival of 4 to 15 months. Current treatment options display limited benefit, hence, the need to identify novel drugs to treat primary and metastatic UM. Histone deacetylase 6 inhibitors (HDAC6i) show promise as anti-cancer agents and are under clinical trial investigation for several cancers. The goal of this study is to: 1) uncover the ability of select HDAC6i to prevent primary and metastatic UM cell growth in vitro and 2) to understand how HDAC6i prevent UM cancer hallmarks.

Methods: Correlation between HDAC6 expression and patient survival was determined in UM patient samples from The Cancer Genome Atlas (TCGA) database (n = 80). Survival of UM cells derived from primary (Mel285 and Mel270) and metastatic (OMM2.5) tumours was evaluated following selective inhibition of HDAC6, using clonogenic cell survival assays. Cells were treated with 10, 20 or 50 µM of three selective HDAC6i (Tubastatin A, ACY-1215 and Tubacin; N = 3) for 96 hours and cultured for an additional 10 days. Apoptotic populations were detected in ACY-1215 treated OMM2.5 cells (24 or 96 hours) by YOPRO-1/propidium iodide staining using flow cytometry. To uncover the mechanism of action of HDAC6i, mass spectrometry analysis was performed on whole proteome of OMM2.5 cells treated with 20 µM ACY-1215 for 24 hours (N = 4).

Results: HDAC6 expression in UM patient samples from TCGA database revealed that low levels of HDAC6 expression correlated to a statistically significant reduction in overall survival (p = 0.0033) and progression free survival (p = 0.024) probabilities. A dose dependent reduction in cell survival was observed across all three UM cell lines treated with HDAC6i. OMM2.5 cells treated with 50 µM ACY-1215 for 96 hours resulted in extensive apoptosis with <2% of cell populations surviving compared to vehicle controls (>90% survival). Whole proteome profiling of ACY-1215 treated OMM2.5 cells identified 4423 proteins with 352 significantly altered compared to vehicle control treated cells.

Conclusions: Our findings suggest that HDAC6i are efficacious as anti-UM agents. Further investigations will utilise in vivo zebrafish xenograft models and validation of mechanism of action.

TITLE: Clinical Outcome of Anti-VEGF in type 1 Choroidal Neovascularization secondary to Central Serous Chorioretinopathy

SESSION TITLE: Imaging of posterior segment II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Park, K. Kim, E. Kim, S. Yu, Kyung Hee Medical Center, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure (Abstract): Jong Beom Park: Commercial Relationship: Code N (No Commercial Relationship) | Kiyoun Kim: Commercial Relationship: Code N (No Commercial Relationship) | Eung Suk Kim: Commercial Relationship: Code N (No Commercial Relationship) | Seung-Young Yu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the type 1 choroidal neovascularization (CNV) patients with central serous chorioretinopathy (CSC) patterns of fundus autofluorescence (FAF) abnormalities

Methods: This retrospective study included 19 eyes of 19 patients who were diagnosed with type 1 choroidal neovascularization with central serous chorioretinopathy (CSC) patterns of fundus autofluorescence abnormalities and characteristics of pachychoroid spectrum. Fundus autofluorescence patterns with spectral domain optical coherence tomography, best corrected visual acuity, subfoveal choroidal thickness and patterns of intravitreal anti-VEGF injection in type 1 choroidal neovascularization patients were analyzed.

Results: A total of 19 patients were consisted of 12 males and 7 females. The mean patients age was 68.79 ± 7.55 years and the mean subfoveal choroidal thickness was 301.79 ± 96.35 micron. Central serous chorioretinopathy (CSC) pattern of fundus autofluorescence abnormalities of type 1 choroidal neovascularization patients were grouped as mottled (36.8%), hyper (26.3%), hyper/hypo(36.8%). The mean number of intravitreal anti-VEGF injection per year was significantly lower in the hyper/hypo group than in the hyper group ($p=0.046$). Also there was a significant positive correlation between the subfoveal choroidal thickness and the interval of loading phase to maintenance phase of intravitreal anti-VEGF injection ($r=0.458$, $p=0.049$).

Conclusions: The central serous chorioretinopathy (CSC) patterns of fundus autofluorescence (FAF) abnormalities in type 1 choroidal neovascularization patients are helpful when predicting the number of intravitreal anti-VEGF injection per year. Additionally the interval of loading phase to maintenance phase of intravitreal anti-VEGF injection can be considering by the subfoveal choroidal thickness of type 1 choroidal neovascularization patients.

TITLE: Variant in the TNFRI gene associated with response to topical anti-TNF α antibody fragment OCS-02 in patients with dry eye disease

SESSION TITLE: Corneal Immunology and T cell Responses

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: V.L. Perez, Ophthalmology, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Victor Perez: Commercial Relationship(s);Oculis:Code C (Consultant)

ABSTRACT BODY:

Purpose: In a Phase 2 study, a novel topical ocular anti-TNF α antibody fragment, OCS-02, was found to be significantly more effective than vehicle in relieving ocular discomfort associated with severe dry eye disease (DED). An exploratory pharmacogenetics analysis identified genetic factors that may influence the response to OCS-02 in patients with DED.

Methods: Genomic DNA from consenting patients was extracted from blood samples. Genotyping data were generated using TaqMan[®] technology. Candidate genes and single nucleotide polymorphisms (SNPs) were selected for pharmacogenomic analysis based on the drug target (TNF- α) or its receptor (TNFRI), or association with Sjogren's syndrome. A total of 8 SNPs were analyzed. A mixed model repeated measures analysis with Bonferroni correction was used to test the association between genotype and the primary efficacy outcome measure (change from baseline in global ocular discomfort score at Day 29). To test the interaction between genotype and treatment, an ANCOVA model was used with baseline global discomfort score, age and race included as covariates. For SNPs found to be associated with the primary endpoint, the percentage of patients with improvement in global ocular discomfort score > 20 (i.e. high responders) was analyzed by genotype using Fisher's exact test.

Results: Samples from 86 patients in the per protocol population treated (OCS-02, n = 43, vehicle, n = 43) were utilized for pharmacogenomic analysis. Among the 8 SNPs tested, only one showed a significant effect on the response to OCS-02 after Bonferroni correction ($p < 0.0001$). This effect was only present in patients treated with OCS-02. Genotype-treatment interaction analysis using ANCOVA also found that the identified SNP was significantly associated with response. The proportion of OCS-02 patients with high responder status was significantly greater for the CC genotype ($P < 0.05$, Fisher's exact test); no significant effect was observed in patients treated with vehicle.

Conclusions: This pharmacogenetic analysis demonstrated a statistically significant association between response to OCS-02 in patients with DED and a SNP biomarker. The CC genotype was significantly associated with high response to OCS-02. Additional studies are needed to better understand the role of unique SNPs in dry eye disease and susceptibility to anti TNF α therapies.

TITLE: Contrast sensitivity and Higher-Order Aberrations in Keratoconus subjects

SESSION TITLE: Aspects of Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Doron, E. Shneor, Dept. Optometry, Hadassah Academic College, Jerusalem, Jerusalem, ISRAEL|D.P. Pinero, Dept. Optics, Pharmacology and Anatomy, Universitat d'Alacant, Alicante, SPAIN|

Commercial Relationships Disclosure (Abstract): Ravid Doron: Commercial Relationship: Code N (No Commercial Relationship) | David Pinero: Commercial Relationship: Code N (No Commercial Relationship) | Einat Shneor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Keratoconus (KC) has negative impact on visual quality that is commonly explained by contrast sensitivity reduction. Ocular higher-order aberrations (HOA) are significantly increased in Keratoconus subjects and has been shown to correlate with a decrease in contrast sensitivity. However, the link between contrast sensitivity and HOA in the early stages of the disease is unclear. This study aim was to evaluate contrast sensitivity and HOA in mild KC and subclinical Keratoconus (KCS) subjects.

Methods: Subjects underwent a complete ocular exam including autokeratometry, corneal tomography (Sirius, CSO), autorefraction and ocular HOA (L-80 wave+, Luneau). Diagnosis of KC was based on abnormal topography/tomography and at least one standard KC clinical sign. The criteria for KCS was abnormal/topography and or tomography but without clinical signs. Contrast sensitivity was tested using a psychophysical two-alternative forced-choice Gabor patches in three spatial frequency (6, 9 and 12 cycles/degree). Analysis included both eyes for KC and KCS subjects, but only one eye (randomly assigned) for healthy controls. Data were compared between controls and KC and KCS group and between KC and KCS group with VA of 0.00LogMar using Mann Whitney test and Fisher's exact test. Friedman and Wilcoxon signed-rank tests compared contrast sensitivity for different frequencies. Spearman correlation test was done to analyze the correlation between ocular HOA and contrast sensitivity.

Results: Twenty-two KC and KCS subjects (38 eyes: 28 KC, 10 KCS, mean age 25.6 ± 5.0 years, VA 0.08 ± 0.12 LogMar, 20 had VA of 0.00 LogMar) and 35 healthy control subjects (35 eyes, mean age 25.0 ± 2.6 years, VA 0.00 ± 0.00 LogMar) were included in the study. The control group showed lower ocular HOA ($p < 0.000$) and higher contrast sensitivity for 6, 9 and 12 cpd ($p < 0.001$) compared to KC and KCS group and compared to KC and KCS group with 0.00VA. Most ocular HOA were negatively correlated to contrast sensitivity in all three frequencies for KC and KCS group and for 9 and 12 cpd for KC and KCS with 0.00VA.

Conclusions: KC and KCS subjects with normal VA showed reduction in contrast sensitivity and higher ocular HOA compared to controls. In addition, ocular HOA were negatively correlated to contrast sensitivity for 9 and 12 cpd. This suggests that HOA underlies the poor vision quality of KC subjects.

ABSTRACT BODY:

Purpose: Lens epithelial explants provide a useful tool for studying lens cell proliferation and fiber cell differentiation in vitro. Vitreous humor can induce both epithelial cell proliferation and characteristics of fiber cell differentiation including the accumulation of b- and g-crystallins and cell elongation in explants. Here we performed an analysis of transcriptional changes induced by both explanting and by the addition of vitreous. We sought to determine how closely the transcriptome of vitreous-induced fiber cells in explants mirrors that of endogenous lens fiber cells.

Methods: Lens epithelial explants were prepared from 8-day old FVB/N mice. RNA was extracted from fresh lens epithelium, from lens explants after 1 day in culture without vitreous, and from lens explants after 1, 5, and 10 days of treatment with 50% vitreous and sent for RNA-sequencing. Raw sequence reads were aligned to the mouse transcriptome and gene counts were summarized for differentially expressed genes (DEGs), then used for downstream evaluation such as clustering and gene ontology analysis. The DEG criteria was $\log_2FC > 1.5$ and $p < 0.05$. Explant RNA-Seq data was compared to that of endogenous FVB/N newborn lens epithelial cells and lens fiber cells.

Results: Gene expression analysis showed that the explants upregulated genes related to immune response and inflammation. Vitreous induced a short-term increase in Cdk1 and reduction in the expression of many crystallin transcripts. However, during the 10 days of vitreous exposure, the explants exhibited an overall loss of transcripts normally enriched in lens epithelial cells (e.g. Sulf1, Flt1, Cdh1, and Gja1) and a gain of transcripts characteristic of fiber cell identity (e.g. Cryba4, Cryg1, Crybb1, Dnase2b, Mip, and Lim2). Gene ontology analysis of the upregulated genes in vitreous-treated explants revealed enrichment for terms relating to developmental process, anatomical structure development, regulation of ERK1 and ERK2 cascade, positive regulation of MAPK cascade.

Conclusions: RNA-Seq analysis revealed that in contrast to endogenous fiber cells, vitreous-exposed explants induced expression of genes related to injury response. However, after 10 days of vitreous exposure, the overall transcriptome of lens epithelial explants matched that of newborn lens fiber cells far more closely than that of endogenous lens epithelium.

TITLE: Application of Rasch model to score the SF-36 instrument administered to a sample with acanthamoeba keratitis

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Kumaran, N.A. Carnt, S. Yeo, K. Pesudovs, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA]

Commercial Relationships Disclosure (Abstract): Sheela Evangeline Kumaran: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Carnt: Commercial Relationship: Code N (No Commercial Relationship) | Sing Ling Stephanie Yeo: Commercial Relationship: Code N (No Commercial Relationship) | Konrad Pesudovs: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The medical outcomes short form (SF-36) survey is widely used to measure generic health related quality of life (QoL). The survey covers eight key health concepts and is traditionally scored using summative scoring technique. The aim of this study was to apply Rasch analysis, a modern probabilistic measurement model to score the SF-36 survey that was administered to a clinical sample of contact lens wearers with acanthamoeba keratitis (AK).

Methods: The SF-36 survey was completed by 77 AK patients from Moorfields Eye Hospital, UK. Ordinal responses to the SF-36 items were coded such that higher value indicate better QoL. The Andrich rating scale Rasch model was applied using the Winsteps program (version 4.4.8). The psychometric properties (category functioning, measurement precision, fit statistics, and dimensionality) of the original SF-36 subscales and Rasch-derived subscales were explored and person measures (scores) corresponding to valid subscales were obtained.

Results: The median age (range) of the participants was 33.6 years (19.9 –76.5) and 42 (54.5%) were female. Of the eight original subscales, three, namely the physical functioning (PF), role limitations due to physical health (RLPH) and role limitations due to emotional problems (RLEM) did not form valid scales due to low measurement precision (person separation index <1). Re-analysis starting with all 36 items in the model and testing for principal components yielded five valid scales consistent with the original design: role limitations (9 items), general health (5 items), pain (2 items), emotional well-being (5 items) and energy/fatigue (4 items). A newly organized “role limitations” scale encompassed items from the original SF-36 subscales of RLPH, RLEM and social functioning. The physical functioning items did not form a valid scale and were eliminated. The final Rasch-derived scales exhibited optimal category functioning, unidimensionality and excellent reliability (Wright’s sample independent person /test reliability > 0.85). These psychometrically valid, interval scales were able to generate meaningful person measures.

Conclusions: Five psychometrically valid SF-36 scales were derived using Rasch analysis for this sample with AK. These could be used to assess the burden of AK disease in contact lens wearers and potentially in other eye conditions.

TITLE: Objective Analysis of Capsulorhexis factors and Posterior Capsular Opacification in 246 Post-Mortem Eyes

SESSION TITLE: Posterior Capsular Opacification and Fibrosis

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: G. Nassrallah, C. Mastromonaco, R. Denis, A.B. Dias, N. Saheb, M.N. Burnier, McGill University, Montreal, Quebec, CANADA]

Commercial Relationships Disclosure (Abstract): Georges Nassrallah: Commercial Relationship: Code N (No Commercial Relationship) | Christina Mastromonaco: Commercial Relationship: Code N (No Commercial Relationship) | Raphaelle Denis: Commercial Relationship: Code N (No Commercial Relationship) | Ana Dias: Commercial Relationship: Code N (No Commercial Relationship) | Nabil Saheb: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Meticulous construction of an adequate capsulorhexis is the cornerstone of successful cataract surgery. The rate of development of posterior capsular opacification (PCO) has been found to be reduced when capsulorhexis are made smaller, centrally and overlapping the optic. However, there have not been recent studies assessing for the capsulorhexis factors contributing to PCO in post mortem eyes with intraocular lenses (IOL) and operated using newest phacoemulsification machines. This study aims to evaluate the capsulorhexis structure in post-mortem eyes and determine factors associated with PCO.

Methods: A total of 246 post-mortem pseudophakic human eyes were obtained from the Minnesota Eye Bank and examined at the MUHC-McGill University Ocular Pathology & Translational Research Laboratory. Microscope photographs were taken of the eyes in Miyake view and of the extracted lens-capsule complex. PCO and Soemmering's Ring (SR) density, were quantified using Automated Detector Opacification Software (ADOS) as a factor of intensity and area. Miyake views and graphical analysis software were used to assess capsulorhexis area, area of non-overlap of the anterior capsule with the IOL, size of the shortest anterior capsular leaflet, and area of anterior capsule coverage on the IOL. Linear regression analysis was used to determine the relationship of these factors with PCO and SR formation as well as statistical significance.

Results: Capsulorhexis area showed a weak negative correlation ($R^2 = 0.06$) with PCO formation ($P < 0.0001$), although with only a modest effect (slope = -0.019). Anterior capsular coverage area was positively correlated with both PCO ($R^2 = 0.10$, slope = 0.027, $P < 0.0001$) and SR ($R^2 = 0.02$, slope = 0.213, $P = 0.011$), but again with only weak association. Area of non-overlap of the anterior capsule with the IOL and size of the shortest anterior capsular leaflet were not significantly associated with PCO or SR formation.

Conclusions: The pathogenesis of PCO development after cataract surgery is multifactorial. This study shows that with modern operating technology, rhexis factors have at best a modest influence on PCO formation. Factors such as time from surgery to death and intra-operative capsular polishing technique likely play a more significant role.

ABSTRACT BODY:

Purpose: PAX6 mutations lead to aniridia, a panocular disorder that usually involves iris and foveal hypoplasia, cataract, corneal dystrophy, as well as abnormalities of the optic nerve.

Here, we describe the development of two molecular approaches for the functional characterization of coding and non-coding variants with uncertain significance (VUS) and their impact on the canonical PAX6 splicing in aniridia patients.

Methods: For in vitro splice assays, a genomic segment encompassing the region of interest of PAX6 along with flanking sequences was amplified by PCR from genomic DNA and was cloned into an expression vector. VUS were introduced in the wild-type minigene constructs by site-directed mutagenesis. The minigene assays were performed by transient transfection into kidney HEK-293 and/or retinal ARPE-19 cell lines.

For ex vivo splice assays, lymphoblastoid cell lines (LCL) were established by Epstein Barr virus transformation of blood lymphocytes from patients carrying VUS and control healthy individuals.

Both HEK-293 transfected cells and lymphoblastoid cells were harvested and total RNA was extracted and reverse transcribed. The splicing patterns of mRNA transcripts were compared by semiquantitative PCR and sequencing.

Results: We have developed four minigene wild-type constructs involving the full exonic and intronic sequences of PAX6: i) the 5'UTR region (exons 1 to 4), ii) exons 5a and 6, iii) exons 5 to 7 and iv) exons 8 to 11, respectively. To date, a total of 13 variants have been assayed. 11 out 13 showed aberrant splicing patterns that include different mechanisms such as single or multiple exon skipping, exon elongations, intron retentions and new pseudoexon inclusions by the alternative use of cryptic splicing sites.

Ex-vivo expression analysis in LCL from 5 carrier patients showed alterations on splicing patterns. Two out five were also tested by in vitro splice assays and the findings on splicing patterns correlate with those observed in minigene assays.

Conclusions: Minigene PAX6 assays carrying multiple exons and LCL studies are useful strategies to gain insight into the pathogenicity of the poorly explored non-canonical splice PAX6 variants. These methods along with in silico analysis are easy-to-carry approaches for robust splice variant analysis and to help bring molecular diagnosis to aniridia patients.

ABSTRACT BODY:

Purpose: The aim of this study was to understand patients' knowledge and attitudes towards laser versus anti-vascular endothelial growth factor (VEGF) injections used to treat sight-threatening DR in a low-middle income country, Vietnam. The main purpose was to provide data to help the Ministry of Health make evidence-based decisions that can improve DR management in Vietnam.

Methods: This is a descriptive qualitative study. Participants provided information about four topics: their knowledge of diabetes and DR, views on their treatment, perceived barriers to treatment and suggestions on how to improve care. Semi-structured interviews were conducted with 12 patients with DR from Ho Chi Minh City and six from Hanoi, Vietnam. Data were analysed using thematic framework analysis.

Results: The average age of participants was 53.7 years (SD±11.6 years), and 7/18 (38.9%) were female. Among the 18 participants interviewed, five (27.8%) accepted laser treatment and four accepted anti-VEGF injections (22.2%), with the remainder refusing treatment. Patients reported that it is the doctors who select the most appropriate DR treatment for their patients in Vietnam, and they often explain the benefits and risks of the chosen treatment. Patients accept that treatment clinics are busy, but regardless, they would like to receive more information on treatment schedules and likely prognosis and potential visual outcomes they can hope for. Pain was reported as a side effect of laser by two patients, with one patient reporting pain after anti-VEGF injections. The main barriers to treatment were the high cost of treatment and other out-of-pocket costs (e.g. related to travel). Patients wanted to have fewer treatment and monitoring appointments and attend clinics that are nearby in order to minimise the impact on their daily life.

Conclusions: The current study has identified themes patients reported on their treatments with laser and anti-VEGF injections for DR. Reducing treatment costs, optimising treatment protocols so fewer in-person attendances are required to complete a course of treatment, and expanding the network of clinics offering treatment outside urban areas have been the lead topics for discussion. These findings are crucial to inform policy changes in Vietnam and might be generalisable to other low-resource settings.

ABSTRACT BODY:

Purpose: Leber congenital amaurosis type 4 (LCA4), a severe form of inherited retinal dystrophy, is an autosomal recessive disorder caused by mutations in aryl hydrocarbon receptor interacting protein-like 1 (AIPL1). AIPL1 is a photoreceptor-specific co-chaperone that is crucial for the correct folding and assembly of the cGMP phosphodiesterase PDE6 complex. AIPL1 is highly heterogeneous, but W278X -which encodes a premature stop codon in the last exon of the AIPL1 transcript- is the most common (50-65% frequency) LCA4 pathogenic allele. The position of the W278X mutation renders it potentially amenable to translation readthrough inducing drug (TRID) therapy, which aims to override the premature stop codon with the incorporation of near-cognate tRNA amino acids.

Methods: In order to test TRID therapy as a potential treatment for LCA4, induced pluripotent stem cells (iPSC) were derived from 4 different LCA4 patients, comprising one W278X homozygote and 3 W278X compound heterozygotes. Retinal organoids (ROs) were differentiated and extensively characterised. 10ug/ml PTC124 was tested on patient ROs from D120 onwards, when AIPL1 expression is observed in developing photoreceptor cells.

Results: LCA4-ROs were indistinguishable from control in terms of organoid structure, retinal cell development and differentiation kinetics. Both control and LCA4-ROs generated the full complement of retinal cell types, with an outer nuclear layer (ONL) comprised of photoreceptors with presumptive inner/outer segment structures. However, LCA4-ROs lack detectable AIPL1 protein in the ONL, and PDE6A and PDE6B are absent, recapitulating key aspects of LCA4. PTC124-treated W278X+/+ and +/- LCA4-ROs displayed partial rescue of AIPL1 protein, proving that PTC124 is indeed able to drive readthrough of the W278X allele. Moreover, low-level restoration of PDE6B was seen in W278X+/+ LCA4-ROs.

Conclusions: Patient-derived LCA4 ROs recapitulate the key molecular features of LCA4, validating it as a useful in vitro system in which to interrogate novel therapies. Excitingly, PTC124 was able to partially restore AIPL1 protein in W278X-/+ and +/- LCA4-RO photoreceptors with limited rescue of PDE6B in W279X+/+ RO, potentially due to the increased amount of W278X transcript in these ROs. These results demonstrate that translational readthrough therapy might be a promising approach to LCA4 treatment.

ABSTRACT BODY:

Purpose: Over the past 10 years, authors refined myopia control strategies (MCS) after following 800 children at the Montreal School of Optometry Clinic (EOUM).

Methods: EOUM approach is based on 3 pillars: normal binocular function (BV), control of the central and peripheral blur, and of the environment. A dose-response approach is applied. This means to use/design optical devices bringing the highest convex power in the pupil area, without inducing blur at distance, with no impact on BV. MCS are selected on : rate of progression, age of myopia onset, corneal parameters, pupil area, risk factor for ocular pathology, patient's lifestyle, compliance. Goal is to generate a customized approach for each patient. In this poster, treatment algorithm is explained. For this study, data are extracted from the file of each patient who: consulted between Jan 2017-Dec 2018 and were kept under the same design/concentration. Clinical population is composed of 310 patients (35% Cauc.-45% Asian), median age of 11 (range 5-18). The treatment options were orthokeratology (4 designs; N=140), multifocal soft contact lenses (SMCL; 5 designs; N=128), and low dose atropine (LDA 0.01%-0.05%; N=42).

Results: Results are analyzed through sophisticated statistical models. The goal of modeling was to assess whether myopia control type had a statistically significant effect on AL progression over time, and, if so, to estimate the 12-24 month progression differences between MCS. Models were fit that accounted for within-subject correlation. Overall results indicate that AL growth, at 1-2 years, was the lowest when using OK lenses (0.13/0.29um [95%CI 0.100-0.158/0.26-0.34] vs SMCL (0.18/0.36um [95%CI 0.14-0.21/0.30-0.41) or LDA (0.19/0.37um [95%CI 0.14-0.25/ 0.29-0.46). OK advantage was statistically significant at 1 year vs SMCL(p=0.03) or LDA(0.034), but not significant at 2 years (SMCL p=0.055; LDA p=0.10). SMCL was comparable to LDA at 1(p=0.54) and 2 years (p=0.77). Detailed results will be presented in part 2.

Conclusions: Montreal experience reveals that customized approach is effective. This means that it brings AL evolution close to non-myopic kids when MCS is properly selected. OK gives better results at 1 year but the 3 methods become similar at 24 months.

ABSTRACT BODY:

Purpose: Ophthalmic examination in large population-based cohorts is challenging and time-consuming. To address this, (1) we built a myopia proxy that can be applied in large population-based studies and (2) validated the proxy by confirming its association with educational attainment and a polygenic risk score (PRS) for myopia.

Methods: Data were collected between 2014-2017 from 88,646 Dutch adults from the Lifelines cohort. We did a three-step analysis. In Step 1, we performed principal component analysis (PCA) to responses of five refraction-status questions posed to Lifelines participants. In Step 2, we measured the refractive state in a subset of Lifelines participants (n=209) and performed logistic regression using myopia (mean spherical equivalent [MSE] < -0.5 D) as dependent and the principal components (PCs) (with an eigenvalue ≥ 1) as independent variables. We used ROC curve analyses to identify specificity, sensitivity, and the classification threshold. In Step 3, the classification equation was applied to the remaining Lifelines participants from Step 1. The value of the proxy was then explored by determining the prevalence of myopia and calculating its association with educational attainment and a PRS of myopia. Analyses were adjusted for age and sex.

Results: 77,213 participants (58.1% females) were eligible for the PCA. Of these, about three-quarters (73.4%) were wearing either glasses or contact lenses. Using measured MSE as a gold standard, the first two PCs had a specificity (95% CI) of 92.4% (87.3-96.6%), and sensitivity (95% CI) of 89.1% (80.0-96.4%) for myopia. The area under the ROC curve (95% CI) was 94.5% (90.6-98.4%). The age-standardized prevalence (95% CI) of myopia was 34.7% (34.3-35.1%). Compared to low education level, the odds ratios (95% CI) of myopia were 1.60 (1.53-1.70, $P = 4.04 \times 10^{-82}$) and 2.40 (2.30-2.54, $P = 2.19 \times 10^{-252}$) for medium and high education levels, respectively (Figure A). Similarly, PRS analysis showed a dose-response relationship with myopia (Figure B). Compared to the lowest decile of the PRS, the highest decile had an OR (95% CI) of 4.24 (3.68-4.91, $P = 5.27 \times 10^{-86}$) for myopia.

Conclusions: Self-administered refractive error questions are effective in capturing myopic cases in a population-based setting.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) might be an important target cell type in the development of posterior staphyloma as the mutation of megalin (a multiligand receptor) in RPE cells induces high myopia (HM) and staphyloma. Staphyloma results from elongation of the eye, thinning of the choroid, and a posterior protrusion that stretches the retina and the RPE/choroid/sclera complex. In addition to genetic factors, environmental factors and particularly light exposure is recognized as a major factor for HM development. There is an interaction between light exposure, circadian cycle and the concentration of hormones, such as corticosteroids but the exact role of light and corticoids on the expression of genes involved in HM and staphyloma has not been analyzed in RPE cells. The aim of this work was to analyze the expression of genes involved in HM and staphyloma in human RPE cells derived from iPSc in response to light or corticoids exposure.

Methods: Human iPSC-derived RPE (iRPE) cells were treated with aldosterone, cortisol and cortisol + RU-486 for RNA-Seq transcriptome analysis. In a second experiment, iRPE cells were exposed at 180j/cm² light dose at 8:00 a.m. during 5 consecutive days to white light (2700K), blue (454nm) or red (631nm) light. On day 5, iRPE cells were collected for RNA extraction at 9:00 a.m., 12:00 p.m. and 8:00 p.m. Circadian clock (PER1, PER2, PER3, CLOCK, BMAL1, CRY1, CRY2), tissue remodeling- (MMP2, TIMP2, ABCA4, COL1A1) corticosteroids- (NR3C2, NR3C1, HSD11B2) and connexin-related (GJD2) genes expression were assessed by RT-qPCR.

Results: Treatment of iRPE cells with corticosteroids induced changes in gene expression of PER1, ABCA4, COL1A1, GJD2 and DKK1. These genes have been found to be associated with the development of HP. Moreover, only exposure to blue light induced in iRPE cells an overexpression of the glucocorticoid receptor (NR3C1) and a decrease in GJD2 transcripts, while the expression of most of genes of interest was differentially regulated in all lighting conditions when compared to unexposed control cells.

Conclusions: Data suggest a biological crosstalk between corticosteroids mechanisms of action and detrimental alteration of the circadian rhythm by inappropriate light exposure, resulting in the activation of molecular events implicated in posterior staphyloma pathogenesis in highly myopic individuals.

ABSTRACT BODY:

Purpose: To evaluate the effect of loss to follow-up (LTFU) on eyes treated with intraocular and periocular steroid injections.

Methods: Patients receiving intraocular or periocular steroid injections for retinal diseases and who were subsequently LTFU for at least 180 days after injection were included. Charts were reviewed for visual acuity (VA), intraocular pressure (IOP), and central foveal thickness (CFT) at the treatment visit before LTFU, the first return visit, and visits 3, 6, and 12 months later.

Results: Fifty-three eyes of 47 patients were identified. Mean age was 62.3 years, mean LTFU duration was 295 days, and mean follow-up period after returning was 392 days. Indications for steroid injections were: uveitis-associated cystoid macular edema (CME) 23/53 (43.5%), diabetic macular edema (DME) 13/53 (24.5%), post-surgical CME 13/53 (24.5%), and retinal vein occlusion (RVO) 4/53 (7.5%). The injection preceding LTFU was periocular triamcinolone in 31/53 (58%) eyes and intravitreal steroid in 22 of 53 eyes (42%) (dexamethasone intravitreal implant in 15/53 (28%) and triamcinolone in 7/53 (14%)). Compared to mean VA prior to LTFU [0.59, Snellen ~20/77], the mean VA was not significantly different at each time point after return (first return visit [0.62, Snellen ~20/83, p=0.6], month 3 [0.55, Snellen ~20/70, p=0.6], month 6 [0.55, Snellen ~20/70, p=0.5], month 12 [0.64, Snellen ~20/87, p=0.6]).

Overall, at all return visits, there was a slight increase in IOP. At the first return visit, 8/53 (15%) had IOP \geq 21 mmHg (range= 8-31) but only 2 patients required treatment with a single new anti-hypertensive medication. No patient required glaucoma surgery. The DME group showed greater mean IOP at first return visit [17.45 mmHg, p=0.04] and at 12 month after return [20.25 (5.2), p=0.02] compared to before LTFU (13.76 mmHg). CFT increased after return visit (392 mm) compared to prior to LTFU (369 mm, p=0.35). The mean CFT declined significantly by month 6 [294 mm, p=0.005] and month 12 [269 mm, p<0.001].

Conclusions: Eyes LTFU after receiving steroid injections did not experience significant morbidity. Mean VA, IOP, and CFT were not significantly worse immediately after LTFU and 12 months later, though patients with DME did experience a more significant increase in IOP.

ABSTRACT BODY:

Purpose: Treatment of rare corneal diseases besides transplantation are sparse. Delivery of biologics such as siRNA and mRNA could provide effective treatments however it still remains challenging due to the numerous ocular barriers.

Irradiation of light absorbing nanoparticles (NPs) leads to an ultrafast heating causing evaporation of the surrounding medium and the formation of vapor nanobubbles (VNB) which when collapsed porate cell membranes allowing intracellular delivery of macromolecules. This method, photoporation, has been studied in the past years to deliver different cargos. In this project we investigate bioinspired poly-dopamine (PDA) NPs to improve biologics delivery in the corneal epithelium.

Methods: Freshly enucleated bovine eyes were used to isolate and culture primary bovine corneal epithelial cells (pBCEC) or used intact as an ex vivo model to test different PDA NP sizes (90 nm vs. 260 nm) and concentrations ($8.0\text{-}160 \times 10^7$ nps/ml). These NPs were irradiated by a nanosecond pulsed laser (3 ns at 532 nm with fluences of $0.9\text{-}2.7 \text{ J/cm}^2$) to allow VNB formation. These NPs were investigated on their ability to form pores after laser treatment allowing to transfect pBCEC with FITC-dextran of different molecular weights (10 kDa, 150 kDa and 500 kDa).

Results: We observed 10 kDa dextran were more efficiently delivered than 500 kDa dextran (80% vs 40% respectively) likely due to their smaller molecular weight. Comparing 90 nm and 260 nm sized NPs in optimized conditions did not show a difference in delivery yield and only a slight change in relative mean fluorescent intensity (up to 1.3 times higher for 500 kDa dextran). The 260 nm NPs did however show an increased toxicity at equal concentrations.

Intact bovine eyes were treated with 90 nm PDA NPs and 10 kDa dextran. Optimal concentrations determined in vitro however did not show increased uptake compared to dextran alone. Increasing the PDA concentration (500 fold) however showed clearly increased uptake as visualized through full cornea microscopy and corneal sections.

Conclusions: In this work we have successfully synthesized 90 and 260 nm biocompatible PDA NPs. We have shown these NPs were able to create VNB and porate the cell membrane as observed with the increase in delivery efficiency in vitro. In an intact bovine eye, we have been able to efficiently deliver dextran to the corneal epithelial layer.

ABSTRACT BODY:

Purpose: In previous research we have shown that the App^{NL-G-F} mouse retina mimics the early, preclinical stages of Alzheimer's disease, and that retinal imaging offers unique opportunities for research and drug discovery [1] . In this follow-up study, we have used in vivo and ex vivo retinal imaging in conjunction with immunohistochemistry and molecular assays, in a range of mouse models of neurodegenerative diseases characterized by protein aggregation, to identify the pathological correlates of imaging biomarkers.

Methods: Mouse models of alpha-synuclein, tau, and amyloid overexpression/aggregation underwent a battery of retinal examinations, including in vivo optical coherence tomography and electroretinography as well as ex vivo hyperspectral imaging (HSI; Snapscan, Imec). HSI spectra were analyzed as previously described [1]. Retinal samples were collected for immunohistochemistry and molecular studies of protein aggregation.

Results: Diverging patterns of retinal dysfunction and/or degeneration were observed in the different mouse models, illustrating the varied impacts of these protein aggregates on retinal structure and function. Moreover, while all protein aggregates led to HSI changes in the 450-600 nm range, distinct signatures were observed. Immunohistochemical and molecular studies revealed that the observed HSI changes correlated both with levels of the protein aggregates that are the hallmarks of these diseases, and with levels of soluble oligomers.

Conclusions: HSI can be used to quantify retinal amyloid beta, underscoring its potential as a biomarker for Alzheimer's diagnosis and disease monitoring. Moreover, our research indicates that the HSI signatures of alpha-synuclein, tau, and amyloid aggregates are distinct. These findings add further evidence to suggest that retinal HSI may have utility in the diagnosis and stratification of proteinopathies associated with the most common forms of human neurodegenerative diseases.

TITLE: Effects of phenylephrine on proximal and distal conventional outflow vessels in living animals

SESSION TITLE: Blood flow/ Ischemia/reperfusion/Aqueous humor dynamics/IOP

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Li, K. Choy, K. Hake, S. Farsiu, D.W. Stamer, Duke University, Durham, North Carolina, UNITED STATES|C.R. Ethier, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Guorong Li: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Choy: Commercial Relationship: Code N (No Commercial Relationship) | Kristyn Hake: Commercial Relationship: Code N (No Commercial Relationship) | Sina Farsiu: Commercial Relationship: Code N (No Commercial Relationship) | C Ethier: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Stamer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Increased resistance to aqueous humor outflow through conventional outflow tissues is a primary risk factor for glaucoma, however, underlying mechanisms are not fully understood. The majority of outflow resistance occurs where the trabecular meshwork (TM) and inner wall of Schlemm's canal (SC) interact. Yet, 25-40% of outflow resistance is generated by vessels distal to SC. Phenylephrine (PE), a mydriatic eye drop, is a vasoconstrictor that reduces rabbit conjunctival venous diameter and velocity, and induces IOP fluctuations in humans. The aim of this study was to investigate the effects of PE on outflow tissue morphology and IOP in living mice.

Methods: Both genders of Balb/c and C57BL/6 mice were used (Duke animal protocol A001-19-01). Anterior ocular tissue behaviors were visualized in living animals by SD-OCT (Bioptigen) in response to topical 1.25% PE alone or with 0.5% tropicamide (trop). Red blood cells (RBCs) in Schlemm's canal (SC) were visualized in Balb/c mice using bright field microscopy of anterior segment flat mounts. IOP was measured by tonometry (TonoLab). Aqueous humor flow patterns were observed using 0.1µm green fluorescent beads perfused into living eyes and quantified using custom software.

Results: Average IOP increased post drug treatment (40-120 min) with either topical PE (2.05 ± 0.85 mmHg, n=3) or PE+trop (2.88 ± 0.20 mmHg, n=6). Treatment with either PE or PE+trop appears to cause elevated episcleral venous pressure as indicated by RBC accumulation in SC over 2 quadrants from ~5 to 120 min post drug treatment. Cross-sectional area of SC lumen became smaller ~20 min post PE+trop treatment by $32.2 \pm 6.2\%$ (n=3). Meanwhile, a decreased amount of fluorescent beads appeared in outflow tissues 40 min post PE+trop treatment compared to PBS-treated controls. Finally, PE had similar effects in mice to those known to occur in human eyes: a decrease of anterior segment depth, anterior ciliary body motion, and pupillary dilation.

Conclusions: Phenylephrine induced RBCs accumulation in SC and decreased amount of tracer accumulation in TM, which could be due to PE constricting distal outflow vessels. Interestingly, PE decreased SC lumen area indicating that PE effects on ciliary body and iris may also be involved in the changes of outflow function as pilocarpine does. PE effects on outflow function may be via both conventional and uveal outflow pathways and should be further investigated.

TITLE: Usability and feasibility study of a vision-specific E-health intervention to reduce fatigue in adults with visual impairment.

SESSION TITLE: Visual Impairment - Services and Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Veldman, H.P. van der Aa, G. van Rens, R.M. Van Nispen, Ophthalmology, Amsterdam Universitair Medische Centra, Amsterdam, NETHERLANDS|

Commercial Relationships Disclosure (Abstract): Manon Veldman: Commercial Relationship: Code N (No Commercial Relationship) | Hilde van der Aa: Commercial Relationship: Code N (No Commercial Relationship) | Ger H.M.B. van Rens: Commercial Relationship: Code N (No Commercial Relationship) | Ruth Van Nispen: Commercial Relationship(s);MeiraGTx UK II Ltd:Code C (Consultant)

ABSTRACT BODY:

Purpose: Former research shows that 57% of the adults with visual impairment experience symptoms of severe fatigue. As there is no evidence based treatment, we developed a blended vision-specific cognitive behavioral and self-management based E-health intervention, called E-nergEYEze, to reduce fatigue in visually impaired adults. The intervention is (digitally) guided by social workers and digital features are explained by computer trainers. The purpose was to investigate the usability and feasibility regarding accessibility of the prototype.

Methods: E-nergEYEze has been developed based on evidence-based practice by a design team, who provided input for relevant themes and content based on new and existing modules. A usability study was conducted among 5 adults (mean age 54y, 80% male) with different eye conditions and severity of vision loss. Participants were asked to test E-nergEYEze while applying the think-aloud method, followed by a semi-structured interview. A thematic approach was used to analyze the data, after which the prototype was modified. A feasibility study was performed among 10 adults (mean age 50y, 60% male) with visual impairment and severe fatigue. The primary outcome was the Checklist Individual Strength subscale fatigue severity measured before and 3 months after baseline measurement.

Results: The prototype required substantive adjustments, lay-out changes and additional guidance by professionals. Participants of the usability study were interested to follow the intervention themselves. The feasibility study showed a significant reduction of severe fatigue (Wilcoxon Matched-Pairs test; z-score -2.652, p-value 0.008, SD 3.03-8.20). All participants recommended the intervention to others and gave E-nergEYEze a median score of 8.0 (range 7-10). One participant was lost to follow-up due to personal circumstances and two because of different expectations of the intervention.

Conclusions: Results of the E-nergEYEze prototype pilot study are promising in reducing fatigue in adults with visual impairment. As the design, severity of the visual impairment and skills on assistive technology determine the ability to access E-health for people with visual impairment, we carefully considered accessibility for users with visual impairment in the development of E-nergEYEze. Cost-effectiveness of E-nergEYEze is currently investigated in a randomized controlled trial.

TITLE: Initial Aflibercept Versus Vitrectomy with Panretinal Photocoagulation for Vitreous Hemorrhage (VH) From Proliferative Diabetic Retinopathy (PDR): A DRCR Retina Network Randomized Clinical Trial

SESSION TITLE: Diabetic retinopathy - diagnosis and therapies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A.N. Antoszyk, Ophthalmology, Charlotte Eye Ear Nose and Throat Associates, CHARLOTTE, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Andrew Antoszyk: Commercial Relationship(s);JAEB:Code C (Consultant);Roche:Code F (Financial Support);Regeneron:Code F (Financial Support);Genentech:Code F (Financial Support)

ABSTRACT BODY:

Purpose: Vitreous hemorrhage (VH) from PDR is a frequent cause of visual acuity (VA) loss in diabetics, but the optimal management strategy is unclear. We compared the effect of initial treatment with intravitreal aflibercept vs vitrectomy with panretinal photocoagulation (PRP) on VA and the ability to perform regular activities

Methods: Adults at 39 sites in US and Canada, with VA loss due to VH from PDR, were randomly assigned to initial treatment with aflibercept (N=100) or vitrectomy with PRP (N=105) and followed for 2 years. Aflibercept treatment began with 4 monthly injections. All eyes could receive aflibercept or vitrectomy during follow-up per prespecified criteria. The primary outcome was mean VA over 24 weeks (area under the curve)adjusted for baseline VA. Secondary outcomes included VA at 4 weeks and 2 years and the percentage of activity impairment due to VA on the Workplace Productivity and Impairment Questionnaire (100%=completely prevented regular activities; 0%=no effect).

Results: At baseline, mean age was 57 years, 115 (56%) were male, and mean VA was 34.5 letters (Snellen equivalent (SE) 20/200). Over 2 years, 33 aflibercept group eyes (33%) received vitrectomy and 34 vitrectomy group eyes (32%) received aflibercept. Excluding deaths, 90% completed the 2-year visit. Mean VA over 24 weeks was 59.3 vs 63.0 letters (SE 20/63 vs 20/63) with aflibercept vs vitrectomy (adjusted difference=-5.0, 95% CI, -10.2 to 0.3; P=.06), respectively. At 4 weeks, mean VA was 52.6 letters vs 62.3 letters (SE 20/100 vs 20/63) with aflibercept vs vitrectomy (adjusted difference=-11.2 [95% CI, -18.5 to -3.9] P = .003) and at 2 years, 73.7 vs 71.0 (SE 20/40 vs 20/40) (adjusted difference=2.7 [95% CI, -3.1 to 8.4], P= .36) letters, respectively. The mean reduction in activity impairment due to VA over 24 weeks with aflibercept was 21% versus 27% with vitrectomy (adjusted difference=7% [95% CI, 1% to 13%], P=.02); at 2 years, the difference was 3% (P=.31).

Conclusions: Among eyes with vitreous hemorrhage due to PDR, there was no significant difference in mean VA over 24 weeks after initiating treatment with aflibercept vs vitrectomy with PRP. Initial vitrectomy improved participants' VA and ability to perform daily activities faster than aflibercept.

TITLE: Predictive Identification of the Fastest Progressing Geographic Atrophy Lesions based on Deep Learning in the Phase 2 FILLY clinical trial of Pegcetacoplan

SESSION TITLE: AI in the retina: Prediction models

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Bogunovic, D. Lachinov, J. Mai, G.S. Reiter, S. Riedl, W. Vogl, U. Schmidt-Erfurth, Medizinische Universitat Wien, Wien, Wien, AUSTRIA|

Commercial Relationships Disclosure (Abstract): Hrvoje Bogunovic: Commercial Relationship(s);Apellis:Code F (Financial Support) | Dmitrii Lachinov: Commercial Relationship: Code N (No Commercial Relationship) | Julia Mai: Commercial Relationship: Code N (No Commercial Relationship) | Gregor Reiter: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Riedl: Commercial Relationship: Code N (No Commercial Relationship) | Wolf-Dieter Vogl: Commercial Relationship: Code N (No Commercial Relationship) | Ursula Schmidt-Erfurth: Commercial Relationship(s);Novartis:Code C (Consultant);Genentech:Code C (Consultant);Kodiak:Code C (Consultant);Roche:Code C (Consultant);Heidelberg Engineering:Code C (Consultant);RetInSight:Code C (Consultant);Apellis:Code F (Financial Support)

ABSTRACT BODY:

Purpose: In patients with geographic atrophy (GA) secondary to age-related macular degeneration (AMD), the speed of progression is highly variable. To evaluate the potential of artificial intelligence (AI) for therapeutic dosing frequency, we trained a deep learning-based algorithm to predict the growth of GA lesions and to identify patients with the fastest growing lesions ("fast progressors").

Methods: OCT scans (512x49x496 voxels, Heidelberg Engineering) of study eyes of patients with GA; that were enrolled in FILLY phase II clinical trial to study the effect of pegcetacoplan (APL-2), and investigational therapy targeting complement C3. GA lesion size at baseline and year 1 was manually annotated on fundus autofluorescence (FAF) by a reading center using RegionFinder and on OCT by an expert reader. Fast progressors were defined as the top 20% of the lesion size growth distribution. A deep learning method was then trained to predict the one year GA growth from a baseline OCT scan. Predictive performance was evaluated using a five-fold cross-validation.

Results: 155 study eyes were included in the analysis that completed the one-year follow-up and had a sufficient image quality to allow for the training and evaluation. Patients from each study arm were considered and fast progressors were identified independent of treatment. Of the top 20% of patients (n =31), 15 were in the sham treatment arm, 11 were treated with APL-2 every other month, and 5 were treated with APL-2 monthly. Atrophy measured on FAF and on OCT showed a concordance of $R^2=0.9$. The evaluation showed that the growth was predicted with a correlation of $R=0.57$, $R^2=0.32$, and the detection of fast progressors achieved an area under the curve AUC of 0.83 (CI: 0.75-0.90) corresponding to a sensitivity of 0.78 and specificity of 0.70.

Conclusions: Fully automated prediction of GA lesion growth from OCT scans is possible, and it allows identification of fast progressors, who may need more intensive treatment. FAF atrophy measurements were consistent with the OCT-based ones. The results of this pilot study are a promising step toward clinical decision support tools for therapeutic dosing and guidance of patient management on a large scale, once such treatments become available.

TITLE: Ocular distribution and exposure of AU-011 after suprachoroidal or intravitreal administration in an orthotopic rabbit model of human uveal melanoma

SESSION TITLE: Recent Advances in Uveal Melanoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Savinainen, C.C. Rich, Aura Biosciences, Cambridge, Massachusetts, UNITED STATES|H.E. Grossniklaus, S. King, Emory Eye Care Center, Atlanta, Georgia, UNITED STATES|J. Wicks, Stage Bio, Mt Jackson, Virginia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Anneli Savinainen: Commercial Relationship(s);Aura Biosciences:Code E (Employment) | Hans Grossniklaus: Commercial Relationship: Code N (No Commercial Relationship) | Shin King: Commercial Relationship: Code N (No Commercial Relationship) | Joan Wicks: Commercial Relationship: Code N (No Commercial Relationship) | Cadmus Rich: Commercial Relationship(s);Aura Biosciences:Code E (Employment)

ABSTRACT BODY:

Purpose: The aim of this study was to compare the ocular distribution and exposure, after suprachoroidal (SC) and intravitreal (IVT) administration of AU-011 in a rabbit model of human uveal melanoma. AU-011 (belzupacap sarotalocan) is designed to be a highly tumor targeted treatment for uveal melanoma that causes acute cellular necrosis with pro-immunogenic cell death, which triggers a secondary immune response. AU-011 has shown promising preliminary results in a Phase 1b/2 clinical trial for primary choroidal melanoma delivered by IVT administration. A Phase 2 clinical trial is ongoing to evaluate SC administration.

Methods: Human uveal melanoma 92.1 cells were implanted in the choroid of rabbit eyes. Once tumors reached ~5mm in basal diameter, AU-011 was administered by SC or IVT injection. Ocular tissues including tumor samples were taken at multiple time points up to 48 hours post injection. The bioanalytical method for exposure in vitreous, choroid/retina and tumor were based on an electrochemiluminescence immunoassay. Distribution of AU-011 in the tumor was evaluated by immunohistochemical staining using a monoclonal rat antibody against the virus-like particle component of AU-011.

Results: After SC administration, we observed negligible levels of AU-011 in the vitreous and high exposure levels in the tumor and choroid/retina. The exposure remained high in the tumor up to 48 hours post injection for both routes of administration. The exposure of AU-011 in the tumor was approximately 5x higher when AU-011 was administered by SC injection compared to IVT injection. Mean concentrations were 12459 +/- 5190 and 1996 +/- 421 ng/mL, respectively. Positive IHC staining support that AU-011 was present in the tumor after both SC and IVT administration. AU-011 staining was observed penetrating throughout the tumor in the SC injected group whereas AU-011 staining in the IVT injected eyes demonstrated that AU-011 was mostly localized on the apex or vitreal surface of the tumor.

Conclusions: These data suggest that SC administration is superior to IVT administration with an improved tumor distribution, higher tumor bioavailability and less unintended exposure in the vitreous and other key ocular structures, which may result in an improved therapeutic index. AU-011 is currently being evaluated in two clinical trials, one with SC and one with IVT administration.

TITLE: Optical coherence angiography changes in macular area in patients with proliferative diabetic retinopathy treated with panretinal photocoagulation: Preliminary results of a prospective study

SESSION TITLE: Diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Chatziralli, E. Dimitriou, D. Kazantzis, G. Theodossiadis, P. Theodossiadis, 2nd Department of Ophthalmology, National and Kapodistrian University of Athens, GREECE|

Commercial Relationships Disclosure (Abstract): Eirini Chatziralli: Commercial Relationship: Code N (No Commercial Relationship) | Eleni Dimitriou: Commercial Relationship: Code N (No Commercial Relationship) | Dimitrios Kazantzis: Commercial Relationship: Code N (No Commercial Relationship) | George Theodossiadis: Commercial Relationship: Code N (No Commercial Relationship) | Panagiotis Theodossiadis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Controversy exists regarding the impact of panretinal photocoagulation (PRP) in retinal perfusion in patients with proliferative diabetic retinopathy (PDR). The purpose of this prospective study was to evaluate the changes of foveal avascular zone (FAZ) area and vessel density (VD) in superficial (SCP) and deep capillary plexus (DCP) in association with functional changes in patients with PDR treated with PRP.

Methods: Participants in this study were 16 patients with PDR and no macular edema, who were eligible for PRP. All participants underwent best-corrected visual acuity (BCVA) measurement, optical coherence tomography (OCT) and OCT angiography (OCTA) at baseline (before treatment) and at months 1 and 3 after completion of PRP treatment. Comparison of OCTA parameters and BCVA between baseline and months 1 and 3 after PRP was performed. Correlation of OCTA parameters and BCVA was also done.

Results: 22 eyes of 16 patients with PDR were included in the study. There was a statistically significant decrease in FAZ area at month 3 of the follow-up period compared to baseline ($p < 0.001$), while no difference was noted at month 1 of the follow-up period ($p > 0.05$). Of note, FAZ became significantly more circular 3 months after PRP ($p = 0.022$). There was no statistically significant difference in VD in both SCP and DCP at month 1 and 3 of the follow-up period ($p > 0.05$ in all comparisons). The FAZ area was associated with BCVA during the whole follow-up period ($p < 0.001$, $p = 0.014$ and $p < 0.001$ for baseline and months 1 and 3 respectively).

Conclusions: Although VD was not significantly affected by PRP at the short-term follow-up of 3 months in patients with PDR, the FAZ area became significantly more circular and decreased significantly at month 3 of the follow-up period, suggesting that re-distribution of blood flow may occur in hypo-perfused foveal capillary plexus after PRP in patients with PDR.

ABSTRACT BODY:

Purpose: Adaptive optics scanning light ophthalmoscope (AOSLO) is considered to be well-positioned to detect early manifestations of retinal pathology. Additionally, offsetting the confocal aperture in the AOSLO enables the blocking of specular reflection from the inner retina and the enhancement of the image contrast of the retinal structures. Our purpose was to investigate the ultrastructure of hard exudates (HEs) in patients with retinal vein occlusion (RVO) using offset pinhole AOSLO.

Methods: Six eyes of 6 patients (2 men and 4 women; mean age, 67 years) with RVO were studied. The prototype offset pinhole AOSLO (Canon Inc., Tokyo, Japan) used in this study is capable of real-time correction of ocular aberrations during imaging, which allows a transverse resolution of approximately 3 μm (beam diameter: 6.7 mm) with pupil dilation. The pinholes were offset by 180 μm (3.75 airy disk diameter) in opposite directions in the plane horizontal to the retina. The HEs were examined by color fundus photography (CFP), and the offset pinhole AOSLO at 6 and 12 months after the onsets.

Results: On CFP, the HEs associated with RVO were seen as yellowish cylindrical structures, which were considered to be obliquely oriented in the Henle's fiber (Fig. 1). In contrast, the offset pinhole AOSLO resolved homogeneously hyperreflective crystalline units inside the cylindrical structure of the HEs (Fig. 1). The mean size of the crystalline units was $32.7 \pm 2.8 \mu\text{m}$ at 6 months. Parts of the crystalline units of the HEs were longitudinally disrupted, and the unit formations of the HEs were obscured at 12 months (Fig. 1).

Conclusions: Using offset pinhole AOSLO for eyes with RVO, the crystalline units of HEs and the longitudinal changes were observed with high contrast, which could not be elucidated by CFP.

TITLE: Melanin identification using spectroscopic OCT and clinical feasibility evaluation

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Merkle, D.J. Harper, B. Baumann, Center for Medical Physics and Biomedical Engineering, Medizinische Universität Wien, Wien, Wien, AUSTRIA|M. Glösmann, Core Facility for Research and Technology, Veterinärmedizinische Universität Wien, Wien, Wien, AUSTRIA|G. Garhofer, Department of Clinical Pharmacology, Medizinische Universität Wien, Wien, Wien, AUSTRIA|

Commercial Relationships Disclosure (Abstract): Conrad Merkle: Commercial Relationship: Code N (No Commercial Relationship) | Danielle Harper: Commercial Relationship: Code N (No Commercial Relationship) | Martin Glösmann: Commercial Relationship: Code N (No Commercial Relationship) | Gerhard Garhofer: Commercial Relationship: Code N (No Commercial Relationship) | Bernhard Baumann: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Melanin content in the retina can be identified non-invasively by polarization-sensitive optical coherence tomography (PS-OCT), however few clinical OCT systems have the hardware required to perform this analysis. Here, we propose to use traditional OCT at the clinical 840 nm wavelength range to obtain similar identification of melanin content through spectroscopic analysis to make this biomarker available to more clinical systems.

Methods: In this study, a custom PS-OCT ophthalmoscope for rodent retinal imaging was used to acquire PS-OCT and traditional OCT data simultaneously. Retinal data was acquired from a very-low-density lipoprotein receptor (VLDLR) mouse model using a traditional volumetric angiogram scan profile with 5 B-scan repeats at each slow-axis position. The VLDLR model presents with substantial retinal lesions and migration of melanin into the inner retina. Spectroscopic processing split the OCT spectrum into 20 channels across an 85 nm band from 803 to 888 nm (Figure 1). Clinical feasibility testing used the central 10 channels for a narrower 40 nm bandwidth from 825 to 865 nm. A spectroscopic filter was developed to highlight positive spectral slopes associated with melanin and was compared against PS-OCT and traditional OCT in the VLDLR model.

Results: Images of melanin using the spectral filter method produced similar features to those obtained from PS-OCT including melanin migration and disruption of layers containing melanin in the VLDLR model. It was noted that the spectral filter was in general noisier than the PS-OCT signal and presented artefactual signals below large vessels. While the spectral filter images were further noisier using the 40 nm clinical bandwidth rather than the full 85 nm bandwidth, key features could still be distinguished. Intensity images were not able to specifically distinguish the above features.

Conclusions: The presented spectral filter for melanin identification was able to show similar information to PS-OCT. While the spectral filter did not provide as robust of a signal as PS-OCT, it did not require PS-OCT hardware, which few clinical OCT systems possess. For this reason, this spectroscopic approach may allow more rapid enhancement of clinical OCT by using existing clinical systems with spectroscopic post-processing.

ABSTRACT BODY:

Purpose: Although DMEK has lower rates of immune reaction in non-vascularized low-risk eyes, the outcome of DMEK in vascularized eyes, has been unknown. Therefore, the aim of this study was to analyze the clinical outcome of DMEK in vascularized high-risk eyes.

Methods: This retrospective single-center consecutive study included the patients after DMEK which were selected from the prospective Cologne DMEK Database between 2012 and 2017 at University of Cologne, Germany. This study was performed in accordance with the tenets of the Declaration of Helsinki, and the protocol was approved by the local ethical review committee (14-373). The clinical outcomes were evaluated from the medical record.; best corrected visual acuity (BCVA; converted to logarithm of the minimum angle of resolution [logMAR]), central corneal thickness (CCT), endothelial cell density (ECD), rebubbling, cystoid macular edema (CME), immune reactions, and graft failure are evaluated. In addition to the standard ophthalmic examinations, neovascularization (NV) was graded from the slit-lamp pictures in a standardized fashion, as previously described.

Results: In this study, 24 eyes of 24 patients were selected (mean age, 65.0 years; mean follow-up duration, 14.8 months [6–36 months]), which included 14 vascularized eyes after failed PK, nine vascularized eyes with long-standing bullous keratopathy, and one vascularized eye with chemical burn. There was no primary graft failure in any case. The BCVA improved from 1.60 ± 1.02 logMAR, preoperatively, to 0.47 ± 0.37 logMAR, 12 months postoperatively ($p < 0.001$). The CCT decreased from 824 ± 193 μ m, preoperatively, to 544 ± 48 μ m, 12 months postoperatively ($p = 0.001$). The donor corneal endothelial cell density (ECD) decreased from $2,272 \pm 723$ cells/mm², preoperatively, to $1,570 \pm 279$ cells/mm², 12 months postoperatively. The total loss of ECD after the surgery was $40.7\% \pm 13.0\%$. Eight of 24 eyes (33.3 %) required rebubbling. There was no cystoid macular edema during the follow-up in this case series. Immune reactions occurred in one of 24 eyes (4.2 %) after DMEK. Interestingly, the NV score significantly improved from 2.00 ± 0.49 quadrants to 1.53 ± 0.50 quadrants ($p = 0.014$, Wilcoxon test). The representative picture is shown in Figure 1.

Conclusions: DMEK could be a good option to treat endothelial dysfunction with vascularized high-risk eyes successfully.

ABSTRACT BODY:

Purpose: The correct performance of daily life activities, e.g. walking and manipulating objects, requires good postural control. Self-confidence to perform daily activities is a function decreased in the elderly. Age-related macular degeneration (AMD) patients report decreased level of confidence in performing specific activities without losing balance or becoming unsteady. This topic, however, has not been extensively studied in patients with eye diseases especially in low-middle income countries. This cross-sectional, case-control study aimed to compare the self-confidence between primary open-angle glaucoma (POAG) and AMD Brazilian patients.

Methods: Patients with AMD, POAG, and normal controls underwent a complete eye examination including measurement of best-corrected visual acuity, biomicroscopy, tonometry, eye fundus evaluation, and all participants answered the Brazilian-Portuguese version of the Activities-specific Balance Confidence (ABC) scale. The ABC scale is a 16-item questionnaire with 11-point subscales. Each individual item measures the level of confidence in performing a specific task without losing balance or becoming unsteady by asking participants to assign scores ranging from 0 (no confidence) to 100% (totally confident). A 50-80% score indicates a moderate level of physical functioning. Scores were compared among groups with the ANOVA test.

Results: The sample comprised 48 patients with AMD, 56 with POAG, and 53 controls. All groups were matched for age, gender, ethnic distribution, and comorbidities. The ABC scale score was lower for both POAG (63.5 ± 25.7) and AMD (69.9 ± 24.9) as compared to controls (95.3 ± 9.1 , $P < 0.000$); POAG patients scored lower than AMD ($P = 0.026$, Tukey HSD).

Conclusions: In this cohort of Brazilian subjects, POAG patients reported lower self-confidence performing daily activities without losing balance more than AMD patients and are at higher risk of falling. This observation might be related to loss of peripheral vision.

ABSTRACT BODY:

Purpose: Once diagnosed with a disease, patients develop organized patterns of beliefs about their condition. Negative illness perceptions can lead to poor recovery and increased healthcare use regardless of objective measures of disease severity. This topic has not been extensively studied in patients with eye diseases especially in low-middle income countries. Individuals' perceptions vary across different populations and affect coping styles. This cross-sectional, case-control study aimed to compare the illness perception between primary open-angle glaucoma (POAG) and age-related macular degeneration (AMD) Brazilian patients.

Methods: Patients with AMD, POAG, and normal controls underwent a complete eye examination including measurement of best-corrected visual acuity, biomicroscopy, tonometry, eye fundus evaluation, and all participants answered the Brief Illness Perception Questionnaire (Brief IPQ) to assess mental defeat. The Brief IPQ has 9 items rated using a 0-to-10 response scale. Five of the items assess cognitive illness representations: consequences, timeline, personal control, treatment control, and identity. Two of the items assess emotional representations: concern and emotions. One item assesses illness comprehensibility. The summed score was compared among the groups with the ANOVA test.

Results: The sample comprised 48 patients with AMD, 56 with POAG, and 53 controls. All groups were matched for age, gender, ethnic distribution, and comorbidities. Both AMD and POAG patients scored higher than normal controls (50.4 ± 10.5 , 49.5 ± 14.4 , and 10.7 ± 17.6 , respectively, $P < 0.000$). The difference between AMD and POAG did not reach statistical significance (Tukey HSD $P = 0.978$).

Conclusions: Despite clinically and pathogenically different diseases, POAG and AMD patients had similar illness perceptions in a cohort of patients who live in a middle-income country. These results can help patients to take specific actions to regulate their emotions and improve the treatment outcome of their illness.

ABSTRACT BODY:

Purpose: To investigate the impact of baseline vitreomacular interface (VMI) status and anti-vascular endothelial growth factor (Anti-VEGF) therapy on treatment outcomes in patients with diabetic macular edema (DME) treated with aflibercept, bevacizumab or ranibizumab.

Methods: Post hoc analysis of prospective randomized 12-month multicenter clinical trial data from patients enrolled in the DRCR.net Protocol T study. The source of the data is the DRCR Retina Network, but the analyses, content and conclusions presented herein are solely the responsibility of the authors and have not been reviewed or approved by DRCR Retina Network. In this study, 660 patients with DME were randomly assigned to aflibercept, bevacizumab or ranibizumab. Optical coherence tomography images from patients who completed the month 12 visit of the study were analyzed at the baseline and at the last visit to identify the presence of total vitreomacular adhesion (VMA), partial vitreomacular adhesion, vitreomacular traction syndrome and total posterior vitreous detachment (PVD). Grading for all the above-mentioned variables were made by two trained and certified readers of the Vienna Reading Center.

Results: Six hundred sixty eyes (660 patients) were randomized in the Protocol T study. Six hundred twenty-nine were eligible for this post hoc analysis based on the study criteria. Total adhesion patient group gained 3.7 more ETDRS letters whereas patients with partial VMA gained 3.1 more ETDRS letters on average compared to the total PVD group at the end of the 12 months follow up ($p < 0.001$). Baseline VMI status had no significant influence on CST at the 12 months visit ($p = 0.144$). All three investigated agents used in the Protocol T study showed equal effectiveness on the improvement of VA and on the reduction of macular edema, independently of baseline VMI status.

Conclusions: This study adds evidence that the VMI status impacts functional outcomes in patients with DME treated with anti-VEGF agents. Patients with total or partial VMA at baseline may derive greater improvements in visual acuity after anti-VEGF treatment compared with those with total PVD.

TITLE: Frequency and Type of Incidentally Found Pathology During Pars Plana Vitrectomy with Secondary Intraocular Lens Placement

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Khatri, M.D. Karl, M.P. Ohr, Ophthalmology, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Imran Khatri: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Karl: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Ohr: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is a lack of literature describing the frequency of incidentally found pathology during pars plana vitrectomy (PPV) with insertion of a secondary intraocular lens (IOL). We performed a retrospective chart review to report on the frequency and type of pathology discovered during PPV with secondary IOL insertion.

Methods: Operative notes for surgeries performed by a single surgeon at an academic tertiary hospital between January 1, 2015 and January 1, 2020 were reviewed. A total of 208 PPV with insertion of secondary IOL surgeries were performed during this time. Eyes with a prior history of significant trauma (n=31), history of complicated cataract surgery at the time of initial IOL insertion (n=11), a history of prior PPV in the operative eye (n=16), or with inadequate data in patient chart (n=3), were excluded (n=61). Variables recorded from charts were age, gender, laterality, lens status, presence and type of peripheral retinal pathology on both pre-operative and intra-op scleral depressed exam, whether intra-operative intervention was performed for this pathology, and whether secondary IOL placement was deferred due to pathology discovered.

Results: Out of the initial 208 cases reviewed, 146 eyes from 140 patients (89 male, 51 female) met inclusion criteria. Of these 146 eyes, 30 (20.5%) had incidental pathology discovered intraoperatively where treatment was deemed necessary. The attached figure displays the type of pathology found. Unspecified retinal breaks were found in 10 out of 30 eyes, retinal holes in 5 out of 30, horseshoe tears in 2 out of 30, retinal tufts in 5 out of 30, lattice degeneration in 8 out of 30, retinal hemorrhage in 1 out of 30, and an ora bay in 1 out of 30.

Of the total 146 eyes, 18 (12.3%) were treated with laser, 14 (9.6%) were treated with cryotherapy, and 11 (8.2%) received gas (C3F8, n = 4 [2.7%]; SF6, n = 8 [5.5%]). Of the 146 eyes, 8 (5.48%) were discovered to have peripheral pathology that deferred secondary IOL placement and required a second surgery for lens placement, if the patient desired.

Conclusions: Incidentally discovered pathology is common during pars plana vitrectomy for placement of a secondary intraocular lens. Surgeons should proceed cautiously and perform careful scleral depressed exam intraoperatively to minimize risk of leaving untreated pathology in vitrectomized eyes.

TITLE: Evaluation of the Blue Light Hazard weighting in phototoxicity in a rat model

SESSION TITLE: Metabolism and protein processing: retina, photoreceptors and RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Françon, Université de Paris, Paris, Île-de-France, FRANCE|F.F. Behar-Cohen, Hôpital Cochin, Paris, Île-de-France, FRANCE|A. Françon, F.F. Behar-Cohen, A. Torriglia, Centre de Recherche des Cordeliers, Paris, Île-de-France, FRANCE|A. Torriglia, INSERM, Paris, Île-de-France, FRANCE|

Commercial Relationships Disclosure (Abstract): Anaïs Françon: Commercial Relationship: Code N (No Commercial Relationship) | Francine Behar-Cohen: Commercial Relationship: Code N (No Commercial Relationship) | Alicia Torriglia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Currently, the evaluation of the phototoxicity of light sources focuses on their blue component. Light spectra are weighted using the Blue Light Hazard (BLH) curve that peaks at 445nm. Thus, the blue component is considered as the only source of phototoxicity. The other wavelengths of the spectrum, such as green or red, are assumed to be non-toxic for the retina. In addition, the phototoxicity threshold for blue light at 445nm is used to define the limit exposure value (LEV) and corresponds to an energetic retinal dose of $11\text{J}/\text{cm}^2$ for rodents. Here, we aim to evaluate the state that only blue wavelengths are phototoxic and the pertinence of the current LEV.

Methods: Male Wistar rats were exposed to light-emitting diodes (LED) displaying different wavelengths and at various retinal doses. Damages induced by light exposure were evaluated by immunostaining and TUNEL staining on retina sections or flat mounts of the retinal pigmented epithelium (RPE).

Results: We show that at a retinal dose 20-fold lower than the phototoxicity threshold, blue and white LED induce a significant retinal degeneration characterized by rod demise. When analyzing cell death and oxidative stress after exposure to LED, BLH-weighted retinal doses of $0.2\text{J}/\text{cm}^2$ and $0.02\text{J}/\text{cm}^2$ for blue and white LED respectively constitute the thresholds at which almost no damage is observed. Moreover, addition of a red component, by simultaneous exposure of rats to white and red LED, significantly decreases photoreceptor cell death. LED-induced damages are also observed in the RPE with changes in the RPE cell structure and size, and patches accumulation of rhodopsin aggregates.

Conclusions: Taken together these results suggest that the phototoxicity threshold for rat could be overestimated by a factor of 50. Moreover, we note differences in the effects of blue and white LED at similar retinal doses, highlighting the negative impact of the other wavelengths contained in white light on phototoxicity. Also, the protective effect of the red component underlines the different effects of each part of the spectrum, indicating that the evaluation of phototoxicity should not be restricted to the blue part of the spectrum. Thus, the use of the BLH weighting to assess the LEV must be reconsidered.

ABSTRACT BODY:

Purpose: Leber congenital amaurosis type 2 (LCA2) and early-onset severe retinal dystrophy (EOSRD) are linked to visual impairment with nyctalopia and visual acuity reduction in early childhood. In 2017, the first gene therapy voretigene neparvovec (LuxturnaTM) for patients with LCA and EOSRD caused by bi-allelic mutations in the RPE65 gene has been approved. Here we report on an example of short-term change in the foveal morphology after functionally successful gene therapy with voretigene neparvovec in a 15-year old patient.

Methods: The clinical examinations included best corrected visual acuity (BCVA), spectral domain optical coherence tomography (OCT) and adaptive optics retinal imaging.

Results: During follow-up over a period of three months after the treatment an improvement of the photoreceptor structure could be observed in OCT, with a clear demarcation of the external limiting membrane and changes in the photoreceptor mosaic on adaptive optics retinal imaging. These morphological rescue parameters correlated in part with the improvement in foveal mediated vision after the treatment and adaptive optics imaging. Although the visual acuity improved only slightly at month 3, objective central cone evaluation with chromatic pupil campimetry showed an increase in the central function. In daily life, the patient reported her visual experience after the treatment as 'brighter'.

Conclusions: Rapid changes in the photoreceptor morphology after successful gene therapy in patients with LCA/EORD can be quantifiable on individual level.

ABSTRACT BODY:

Purpose: To investigate morphological risk factors and their precise quantification using deep learning algorithms for INL/OPL subsidence (at least subsidence of INL-OPL and OPL-ONL junctions) in patients with incipient macular atrophy (iMA) using a local survival model.

Methods: A series of anatomical features were extracted with deep learning methods in a cohort of eyes with bilateral large drusen at baseline: photoreceptor (PR) thickness, outer nuclear layer (ONL) thickness and drusen thickness (DT). Areas of INL/OPL subsidence were manually annotated in every eye which developed iMA during the 36-months follow-up. For each eye, the retina was divided in three zones at the visits preceding the first observed subsidence: zone of INL/OPL subsidence at first appearance, zone over drusen (>40µm height) and reference zone (rest of the 3mm circle, centered on fovea); an example is presented in figure 1. Average values for the anatomical features were computed for each zone. A mixed effects Cox survival model (one group per eye) was fitted to estimate the hazard ratio for each zone.

Results: Out of 280 eyes, 54 eyes developed iMA, of which 52 eyes, presented with INL/OPL subsidence prior to iMA, were selected. For each anatomical feature (PR, ONL and DT), the average zone values were normalized and fed to the survival model. The fitted model coefficients were -0.83 for PR ($p<0.001$), -0.56 for ONL ($p<0.01$) and -0.25 for DT ($p=0.15$). Negative values indicate higher risk for thinner PR, ONL and DT. Therefore, PR thinning and ONL thinning were found to be significant risk factors of INL/OPL subsidence development in iMA patients with a hazard ratio at one standard deviation under the mean of 2.86 and 2.13, respectively. However, drusen thickness was not found to be a significant factor.

Conclusions: Survival analysis of anatomical features in early INL/OPL subsidence eyes allowed us to identify PR thinning and ONL thinning as risk factors for the development of INL/OPL subsidence. This indicates that these subtle changes occur in the outer retina before becoming clinically apparent as macular atrophy. This highlights the importance of protecting PR integrity for potential early intervention in AMD. AI algorithms are essential to identify and precisely measure subclinical early morphological changes on OCT.

SUBMITTER (NAME ONLY): Alessandra Carmichael-Martins

TITLE: Improved Adaptive Optics Scanning Laser Ophthalmoscope and lens for gonioscopic imaging

SESSION TITLE: Adaptive optics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Carmichael-Martins, T. Gast, B. King, S.A. Burns, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alessandra Carmichael-Martins: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Gast: Commercial Relationship: Code N (No Commercial Relationship) | Brett King: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Burns: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To improve a gonioscopy lens (Goniolens) design coupled to a pupil-steerable Adaptive Optics Scanning Laser Ophthalmoscope (AOSLO) for high-resolution imaging of the iridocorneal angle (ICA). While glaucoma is a multifactorial disease, intraocular pressure (IOP) is the only modifiable risk factor and many treatments are aimed at the trabecular meshwork (TM). We recently reported using AO gonioscopy to image the TM at high resolution (King et al. 2019). However, the source of optical aberrations in normal gonioscopic imaging is unclear, and most Goniolenses are not optimized for this purpose. We propose a new Goniolens design to improve optical image quality and light coupling from an enhanced AOSLO to allow imaging of different regions of the TM.

Methods: The design of the Indiana University AOSLO was altered to 1) increase distance to the patient and 2) allow beam steering to image different regions of the ICA while maintaining optical quality. A Goniolens was designed using ray tracing software (Zemax®) to improve performance given manufacturing and operating constraints. Light coupling from the AOSLO was improved by steering the imaging beam as it enters the Goniolens, while maintaining optical performance. Optical aberrations induced at the surfaces of the lens and model eye, as well as image quality at different positions of the ICA were analyzed.

Results: The AOSLO design allows beam steering via a tiltable field mirror over an area of 45x70mm at the pupil plane within the diffraction limit, allowing rotation of the Goniolens on the eye to image different sectors of the ICA. An air-spaced doublet button lens design reduced spherical aberration and improved RMS from 0.4λ , with the original singlet, to 0.04λ . Beam steering in the button lens enables access to the anterior segment with precise localization from the iris surface to the corneal endothelium with spot sizes of $\sim 5\mu\text{m}$ with only defocus and astigmatism AO correction.

Conclusions: A novel Goniolens was designed to improve optical quality and coupling between a new AOSLO and the TM. Beam steering facilitates imaging as the lens is rotated to different sectors of the ICA, and the beam can be steered from the pupil plane to target different tissues within the angle. This technique may allow further structural characterization of the TM in patients, and to monitor changes in glaucoma and following treatment.

TITLE: Retinal Blood Flow Dysregulation Precedes Neural Retinal Dysfunction in Type 2 Diabetic Mice

SESSION TITLE: Blood flow, ischemia, reperfusion

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Nagaoka, J. Hanaguri, H. Yokota, M. Watanabe, S. Yamagami, Ophthalmology, Nihon University School of Medicine, Tokyo, Tokyo, JAPAN|

Commercial Relationships Disclosure (Abstract): Taiji Nagaoka: Commercial Relationship: Code N (No Commercial Relationship) | Junya Hanaguri: Commercial Relationship: Code N (No Commercial Relationship) | Harumasa Yokota: Commercial Relationship: Code N (No Commercial Relationship) | Masahisa Watanabe: Commercial Relationship: Code N (No Commercial Relationship) | Satoru Yamagami: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We investigated the susceptibility of retinal neurovascular coupling and neural function to type 2 diabetes.

Methods: The longitudinal changes in retinal neuronal function and blood flow response to a 3-minute flicker light stimulation and a 10-minute systemic hyperoxia were evaluated every 2 weeks in diabetes db/db mice and their corresponding controls (db/m) from age 8 to 20 weeks. The retinal blood flow and neural activity were assessed using laser speckle flowgraphy and electroretinography (ERG), respectively.

Results: The body weight and blood glucose levels were significantly higher in db/db mice while systemic blood pressure and ocular perfusion pressure were unchanged with age. The resting retinal blood flow was comparable between two groups throughout the study. Flicker light and hyperoxia elicited a consistent increase and decrease in retinal blood flow, respectively, in db/m mice independent of age. However, these flow responses were significantly diminished in db/db mice at 8 weeks of age and then became unresponsive to stimulations at 12 weeks.

Subsequently, the ERG implicit times for oscillatory potential wave was significantly increased at 14 weeks of age while the amplitude of all waves and the implicit time of a-wave and b-wave remained unchanged.

Conclusions: The retinal blood flow responses to flicker light and hyperoxia are gradually diminished during the progression of diabetes and the ERG alteration occurs at the time corresponding to exhausted retinal blood flow regulation. The deficiency of neurovascular coupling and flow regulation in the retina appears to precede neural dysfunction in the mouse with type 2 diabetes.

ABSTRACT BODY:

Purpose: Myopia is a complex refractive error trait with a rapidly increasing prevalence and visual burden world-wide. GWA studies have currently identified >500 common variants for refractive error, but they have not yet dissected many rare variants with potentially large effects. This study aimed to identify these variants using exome chip screening in a large multi-ancestry cohort.

Methods: A total of 10 population-based cohorts from CREAM were included in the current study and grouped into Indo-Europeans and East Asians. Exome array genotypes (Illumina HumanExome-12) were jointly called to increase the number of rare (i.e. MAF<1%) variants. Three other CREAM studies, the Raine Eye Health Study, Beaver Dam Eye study and EPIC-Norfolk, were used as replication cohorts.

Different approaches to analyses are useful because they have different strengths in their ability to identify candidate genes. We analyzed spherical equivalent (SER in diopters (D)) using the EMMAX version of the variable threshold (VT) test, which increases power on rare variants (compared to single variant tests) by creating a new gene-based marker. We meta-analyzed the p-values of all datasets (discovery and replication) together using the method described by Fisher, implemented in the R package metap. We conducted an IPA pathway analysis to assess enriched pathways and to prioritize genes based on predefined criteria.

Results: The total discovery study included 17,904 (13,037 Indo-European and 4,867 East-Asian) individuals with a mean (SD) SER of 0.01 (2.30) D. In the meta-analysis, which combined the VT results across all cohorts, 43 genes were found to be genome-wide significant (defined as $\leq 1 \times 10^{-5}$). The most significant gene was GDF15 on chromosome 19 ($P = 5.12 \times 10^{-9}$). 40% of the identified genes showed an association with a human ocular disease, 21% evidence of human ocular expression and 12% demonstrated an ocular phenotype in knock-out mice. Cell cycle processes and embryonic development were implicated as important underlying pathways. Among the most biologically plausible gene hits were CHST6 and GRHL2 ($P=8.99 \times 10^{-7}$ and $P= 1.42 \times 10^{-6}$ respectively); both associated with corneal dystrophies.

Conclusions: Using exome chip, we identified rare variants for refractive error in 43 novel genes. Further validation studies are necessary to evaluate their role in refractive error development.

ABSTRACT BODY:

Purpose: Motion correction of retinal OCT imaging is required for accurate assessment of diseases. We have developed Lissajous scan OCT which enables motion correction while preserving global structure. This study aims at comparing the image quality of Lissajous scan OCT with those of the conventional raster scan.

Methods: The Lissajous and raster scan OCT have been obtained by a custom-made 1.0- μm swept-source OCT device with a scan speed of 100,000 A-line/s. The motion-corrected raster scan OCTA has been obtained with DRI OCT Triton (Topcon Corp., Tokyo, Japan). For Lissajous scan OCT, the eye movements are estimated by co-registering small portions of the Lissajous scan. And motion-free three-dimensional volumes and en face images of OCT and OCT angiography (OCTA) images are created by using the estimated motion amounts.

Fifty-two eyes of 62 patients with retinal abnormalities were scanned over a $3 \times 3 \text{ mm}^2$ area. The motion-corrected superficial retinal OCTA images of Lissajous scan and raster scan have been evaluated by an expert grader and scored with six levels (0: low to 5: high). In 21 eyes of 21 subjects, cross-sectional OCT B-scan of Lissajous scan and raster scan have been compared.

Results: Figure 1 shows motion-corrected en face superficial OCTA images of a representative case. The mean score of motion-corrected superficial OCTA images were 3.7 for raster and 3.4 for Lissajous. Although the score of raster scan is slightly high, the difference was not statistically significant ($p\text{-value}=0.067$, Wilcoxon's signed-rank test). Figure 2 shows representative OCT B-scans of the raster and Lissajous scan at the almost same location. In 19 out of 21 eyes, both raster and Lissajous scans showed the same score. In 2 out of 21 eyes, Lissajous-scan-based B-scans showed a better score.

Conclusions: Lissajous scan OCT achieves comparable image quality in en face OCTA and cross-sectional OCT imaging to those of raster scan OCT.

TITLE: Arvcf maintains lens transparency through the stability of the adherens junctional complex in lens fiber cells

SESSION TITLE: Lens Cell Biology and Regulation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T.F. Plageman, K. Herman, N. Houssin, J. Martin, College of Optometry, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Timothy Plageman: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Herman: Commercial Relationship: Code N (No Commercial Relationship) | Nathalie Houssin: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Martin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The role of cell adhesion in lens transparency is difficult to assess because of the developmental and physiological roles known adhesion proteins play in this process. We have discovered that Arvcf, a member of the p120-catenin subfamily of catenins which binds to the juxtamembrane domain of cadherins and regulates GTPase signaling, is strongly expressed in lens fiber cells and is important for maintaining lens transparency with age. Arvcf knock-out (KO) mice develop cortical cataracts at approximately 6 months of age without other developmental anomalies. Because of its potential role in lens fiber cell adhesion, it is hypothesized that the loss of Arvcf promotes cortical opacities due to a reduction in the stability of the cadherin complex and adhesion junctions between lens fiber cells.

Methods: The role for Arvcf in the lens was tested through biochemical screening and histological analysis of lenses from control and knock-out mice. Additionally, high-resolution microscopy methods including super-resolution confocal and scanning electron microscopy were utilized to assess changes to fiber cell morphology and protein localization.

Results: Lens fiber cell lysates from control and Arvcf KO mice were analyzed via mass spectroscopy following immunoprecipitation with N-cadherin antibody in order to determine how protein interactions were affected by the loss of Arvcf. We found that several proteins with known roles in promoting the stability of adherens junctions to have a significantly reduced ability to associate with N-cadherin including b-catenin, a-N-catenin and actin. Confocal analysis and quantitative localization experiments confirmed a significant reduction of these proteins between the junctions of lens fiber cells. Super-resolution imaging also demonstrated that the localization of cadherin associated proteins is significantly attenuated within the normally Arvcf-rich interlocking protrusions that emanate from the tricellular junctions of lens fiber cells in the region of cortical transparency loss of the lens.

Conclusions: These data indicate that the Arvcf protein maintains cortical transparency through the stabilization of the cadherin complex within interlocking protrusions and bicellular junctions of lens fiber cells. In addition, these results suggest that cortical cataracts may be caused by a decrease in cell adhesion between lens fiber cells.

TITLE: Utilization of metal complexes in the tears biomarkers assay

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Milionis, C.N. Banti, K. Sarakinou, S. Hadjidakou, Department of Chemistry, University of Ioannina, GREECE|I. Milionis, Eye Clinic, University Hospital Ioannina, Ioannina, Epirus, GREECE|

Commercial Relationships Disclosure (Abstract): Ilias Milionis: Commercial Relationship: Code N (No Commercial Relationship) | Christina Banti: Commercial Relationship: Code N (No Commercial Relationship) | Koralia Sarakinou: Commercial Relationship: Code N (No Commercial Relationship) | Sotiris Hadjidakou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Reduced urea concentration, could lead to disorganization and decompose of the tear film which is related with Ocular Surface Diseases (OSD). Moreover, urea is an indicator for OSD, such as Dry Eye Syndrome (DES). Recent epidemiological studies show that DES is a common disorder, which appears especially in the elderly population, affecting up to 20 % of adults. The lack of clinical symptoms makes the diagnosis of DES very difficult. Nowadays, a colorimetric enzymatic method for determining urea is used in cell and tissue culture supernatants, urine, plasma, serum, and other biological samples. Therefore the development of new urea assay is a matter of research interest.

Methods: Copper(II) - urea complexes $\text{Cu}_2(\text{CH}_3\text{COO})_4\text{U}_2$ (1) and $\text{Cu}(\text{NO}_3)_2\text{U}_4$ (2), (U= urea) have been synthesized and characterized. Compounds 1-2 were used for the qualitative and quantitative determination of urea by Thin Layer Chromatography (TLC) densitometry assay and Fluorescence Spectroscopy:.

Results: For the determination of urea in tears, the graphs of the TLC spots intensity vs the concentration of standard solutions of 1 and 2 are used. The concentrations of 1 and 2 vs spot's intensity (Int) are linearly fitted. Tears were collected using Whatman paper and they were added into DMSO solution which contain copper(II) salts. The content of urea in the sample is determined by the complex:Urea molar ratio in 1 and 2. The quenching (by 66 (1) or 48 (2) %) at the energy emitted when the tears/DMSO solution were incubated with copper acetate or nitrate is also correlated with DES diagnosis.

Conclusions: The concentration level of urea in the tear fluid is a diagnostic biomarker for the detection of the dry eye syndrome (DES). The complexes 1 and 2 are used for their chromatographic and spectroscopic characteristics which consequently lead to the identification and determination of urea in tears. Although more experiments should be carried out before a reliable method could be established, however, the importance of urea in eye disorders diagnosis makes TLC-densitometry and fluorescence spectroscopy a possible candidate for the development of a novel urea assay

ABSTRACT BODY:

Purpose: The retinal camera using Transscleral Optical Phase Imaging (TOPI) provides in vivo images of retinal pigment epithelium (RPE) cells. We performed a clinical study to characterize healthy RPE cells and to assess the repeatability and the safety of the RPE imaging.

Methods: Healthy volunteers were recruited. After a standard eye examination, spectral domain optical coherence tomography, infrared, autofluorescence and color fundus imaging, they underwent TOPI examination. Six 5.04x5.04°, high resolution, in vivo images of RPE cells at different locations, associated with 30x30° infrared reflectance images, were acquired per eye. The ophthalmic examination was repeated 1 to 3 weeks after TOPI. RPE images were analyzed with a custom automated software to extract cell features. The coefficient of variation (CoV) of three parameters was established on 31 areas, imaged 3 to 7 times and realigned.

Results: Included were 52 eyes (axial length 24.1±0.96 mm) of 31 participants (age 36.5±13.2 years, range 21-70; 20 males, 11 females). Multimodal imaging showed no difference before and after TOPI. The cell features extracted from the RPE images covering an eccentricity of 1.9° to 16.9° from the fovea were: RPE density 3610±321 cells/μm², cell area 238±23 μm², intercellular distance 14.3±1.1 μm, circularity 0.88±0.019, elongation 0.63±0.025, border distance CoV 0.16±0.013, solidity 0.95±0.001. The number of neighboring cells was close to 5.7±0.1 whatever the age, eccentricity and axial length. Cell density remained constant with age and eccentricity, while it decreased with axial length (R²0.62). Morphological features slightly varied with age, with reduced circularity (R²0.22), increased elongation (R²0.21) and border distance CoV (R²0.22). The CoV calculated for density, area and intercellular distance were 3.9±1.7%, 4.4±1.9% and 2.7±3.1.

Conclusions: The present study demonstrates that in vivo human RPE imaging using TOPI is safe and repeatable. The quantitative analysis provides the first and significant database of in vivo RPE cell features, consistent with the previous in-vivo studies on RPE cells, that can be used as normative database for future diagnostics of retinal diseases at the single cell level.

SUBMITTER (NAME ONLY): Emily Witsberger

TITLE: Refractive Outcomes of Superficial Keratectomy for Salzmann Nodular Degeneration

SESSION TITLE: Corneal transplantation and surgery

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E. Witsberger, L. Maguire, S.V. Patel, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Emily Witsberger: Commercial Relationship: Code N (No Commercial Relationship) | Leo Maguire: Commercial Relationship: Code N (No Commercial Relationship) | Sanjay Patel: Commercial Relationship(s); GlaxoSmithKline: Code C (Consultant); Senju Pharmaceuticals: Code C (Consultant); Santen Inc.: Code C (Consultant); Emmecell: Code C (Consultant)

ABSTRACT BODY:

Purpose: Salzmann nodule degeneration is associated with induced cylinder and irregular astigmatism that improve after nodule excision. The purpose of this study was to quantify changes in manifest refractive error and corneal curvature at 1 month and ≥ 12 months after Salzmann nodule excision.

Methods: In a retrospective consecutive series, changes in manifest refractive error (spherical-equivalent), mean keratometric power (Km), and best-corrected visual acuity (BCVA) were compared for 73 eyes of 58 patients who underwent superficial keratectomy for Salzmann nodular degeneration by 2 surgeons at Mayo Clinic in Rochester, MN between 2014 and 2019. Eyes with ocular comorbidities that might affect visual acuity or keratometry were excluded. Comparisons between preoperative and postoperative measurements were made by using generalized estimating equation models.

Results: Mean patient age was 66 years, and 68 patients (93%) were female. Spherical-equivalent manifest refractive error was -0.27 ± 2.66 D before nodule excision and became more myopic (-1.10 ± 2.78 D) at 1 month after nodule excision ($n=69$, $p<0.01$) with no change at 12 months ($n=14$, $p=0.13$). A myopic shift ≥ 0.5 D occurred in 65% of eyes, and >1.0 D in 36% of eyes. K_m increased from 42.7 ± 2.1 D before nodule excision to 44.2 ± 1.8 D at 1 month after excision ($n=49$, $p<0.01$). BCVA improved from 0.18 ± 0.15 logMAR (Snellen equivalent 20/30) before nodule excision to 0.06 ± 0.15 logMAR (20/23, $n=69$, $p<0.001$) at 1 month after excision with no change at 12 months ($n=14$, $p=0.73$).

Conclusions: In addition to the known change in cylinder, Salzmann nodule excision is associated with a clinically important myopic shift in most eyes caused by corneal steepening. Patients should be counseled about the likelihood of a myopic shift after nodule excision, and cataract surgery should be deferred to at least one month after nodule excision for keratometric stability.

TITLE: Comparison of Therapist Ratings to Low Vision Patient Self-Reports

SESSION TITLE: Visual Impairment and Quality of Life

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Nguyen, K. Fujiwara, C. Bradley, R.W. Massof, Wilmer Eye Institute, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Hang Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Kyoko Fujiwara: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Robert Massof: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare occupational therapist (OT) Functional Independence Measure (FIM) ratings of functional abilities to low vision patient self-reports using the Activity Inventory (AI).

Methods: 136 low vision rehabilitation patients served by 10 different OTs rated the importance and difficulty of goals in the AI before and after rehabilitation. For each goal rated with nonzero importance and difficulty, the patient's OT also rated the patient's independence using the FIM.

Ratings were analyzed using a Rasch model: The Method of Successive Dichotomizations (MSD), in R with item measures anchored. This allowed us to compare person measures estimated from patient ratings and from therapist ratings on the same scale.

Results: Rater bias can be estimated from the intercepts of Deming regression lines fitted to the pre- and post-rehabilitation data. The intercept for pre-rehabilitation data was -1.48 logits (SE = 0.24), while for post-rehabilitation it was 0.09 logits (SE = 0.24). This shows that patients and OTs were in agreement post-rehabilitation, but that OTs underestimated patients' functional abilities at baseline. In both cases the slopes were not significantly different from 1. The average difference between person measures from pre to post was 1.60 logits for OTs and 0.28 logits for patients rating themselves.

Conclusions: Our findings indicate a strong bias leading to overestimation of improvement in functional ability measures based on OT ratings relative to outcome measures based on patient self-reports in low vision rehabilitation.

TITLE: Enhanced visualization of hyperpigmentation using near infrared multiply scattered light imaging

SESSION TITLE: AI in the retina/ AMD imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.S. Muller, A.E. Elsner, J.A. Papay, Aeon Imaging, LLC, Bloomington, Indiana, UNITED STATES|A.E. Elsner, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Matthew Muller: Commercial Relationship(s);Aeon Imaging, LLC:Code I (Personal Financial Interest);Aeon Imaging, LLC:Code P (Patent) | Ann Elsner: Commercial Relationship(s);Aeon Imaging, LLC:Code I (Personal Financial Interest);Aeon Imaging, LLC:Code P (Patent) | Joel Papay: Commercial Relationship(s);Aeon Imaging, LLC:Code E (Employment)

ABSTRACT BODY:

Purpose: To enhance AMD screening by improving the visibility of hyperpigmentation (HP) using near infrared (NIR) multiply scattered light imaging.

Methods: We compared two datasets of non-mydratic confocal and multiply scattered light images taken with the Digital Light Ophthalmoscope (DLO) (Aeon Imaging, LLC) using red (630 nm) and NIR (860 nm) light. The red and NIR dataset consisted of 21 subjects aged 48.2 \pm 15.3 yr, and 20 subjects aged 53.1 \pm 13.7 yr, respectively.

The DLO is a confocal retinal camera that projects illumination lines onto the retina that are synchronized to the readout of a CMOS rolling shutter camera. Multiply scattered light imaging is performed in real-time by applying leading and lagging timing offsets between the center of the illumination lines and detection aperture. The offsets were set to 0.5x and 1x the aperture widths of 51 and 102 micron for the red and NIR images, respectively.

DLO image frames were automatically registered, manually reviewed, and averaged. The coefficient of variation (CV) of the retinal background temporal to the OD macula was calculated in the confocal red and NIR images. HP was identified in 5 of the 20 NIR subjects. The Michelson contrast of the HP regions was computed for the NIR confocal, both offsets, and the mean of each leading and lagging offset pair.

Results: Choroidal vessel contrast contributed to a higher mean CV using red vs. NIR light (0.14 \pm 0.05 vs. 0.07 \pm 0.03). In an example AMD subject, the max HP signal in red-light images was achieved with confocal imaging, at 4.2 standard deviations < the adjacent mean background. In the corresponding NIR images, the max HP signal occurred at a 102 micron offset, at 5.0 standard deviations < the mean. Averaging the NIR offset pairs suppressed shadowing caused by drusen, reducing the variation in the adjacent background and further increasing the HP signal to 11.1 standard deviations < the mean.

The Michelson contrast in the NIR images of the 5 HP subjects was 0.09 \pm 0.01, 0.07 \pm 0.01, 0.06 \pm 0.01, 0.10 \pm 0.01 and 0.10 \pm 0.01 in the confocal, 51 micron offset, mean 51 micron offset pair, 102 micron offset, and mean 102 micron offset pair, respectively.

Conclusions: Real-time visualization of HP in the presence of nearby drusen can be improved by averaging the leading and lagging offset images. Averaging reduced distracting intensity variation in the adjacent retina while maintaining the Michelson contrast.

ABSTRACT BODY:

Purpose: We have previously shown that a subset of AAVHSCs (AAVHSC7, 15 and 17) cross the non-human primate blood-retinal barrier (BRB) and blood-brain barrier (BBB) following a single intravenous dose. We have now extended this analysis to a panel of 11 AAVHSC capsids. AAVHSCs can be used to transduce various cell types in the central nervous system and edit the genome of dividing cells in a nuclease-free manner. Here we investigate the tropism of AAVHSCs, specifically to the visual pathways, and investigate whether AAVHSCs can induce genome editing in human disease relevant retinal cells using ex vivo (human retinal explant cultures) models.

Methods: We delivered AAVHSCs intravenously (IV) to juvenile Cynomolgus macaques (non-human primates; NHPs), negative for neutralizing Clade F antibodies, with either formulation buffer (FB) or one of a total of 11 variant AAVHSC (4-7E13 vgs/kg, n = 25 macaques) vectors that contain a gene transfer construct expressing CBA.eGFP. We harvested brains and eyes at 2 weeks post-dose and monitored vector genomes (vgs) by ddPCR and eGFP expression by immunohistochemistry. In addition, two NHPs were dosed subretinally (SR @ 1E12 vgs/eye) with AAVHSC15-CBA.eGFP or FB. Human retinal explants were incubated with FB, or with (2.5E11vgs/explant) AAVHSC15-CMV.eGFP (n = 6), or AAVHSC15.B2M (n=12), a construct that contains homologous arms to edit the human beta-2-microglobulin (B2M) genomic locus.

Results: All AAVHSCs cross the BRB and BBB following a single-IV delivery in NHPs. The majority of AAVHSC capsids transduce retinal cells and retinofugal pathways including the retinogeniculate and retinotectal nuclei. Following a single-SR dose, AAVHSC15 transduces photoreceptors (PRs) and retinal pigment epithelial cells (RPE) in NHPs. Similarly, PRs are transduced in human retinal explants. Using next-generation sequencing, we confirm AAVHSC15.B2M-mediated integration into the human B2M locus.

Conclusions: In NHPs, AAVHSCs exhibit capsid selectivity along key relay points of the visual pathways. AAVHSCs are capable of transduction and genome editing in therapeutically relevant retinal cells based on results obtained in vivo (NHPs) and ex vivo (human). In human organotypic retinal explants, we demonstrate transduction and nuclease-free genome editing in disease relevant cell types.

ABSTRACT BODY:

Purpose: This study aims to determine the patient's refractive error from the foveal pit's morphology using tridimensional modeling of the foveal pit and machine-learning algorithms.

Methods: Eighty-five subjects (47 males and 38 females) with ages ranging from 18 to 27 were evaluated. We divided the study into three stages: (1) clinical, (2) extraction of the foveal pit morphology, and (3) machine-learning models. (1) The axial length (AL) and spherical equivalent (SE) of each participant were obtained with an IOL Master 700 and an autorefractometer. The spherical equivalent was also verified through wet retinoscopy. We classified the groups in terms of their mean axial length and spherical equivalent. (2) A 3D foveal pit model of each participant was obtained from images obtained with a Spectralis OCT (Heidelberg Engineering). We obtained three areas along with the pit: the rim, the mid, and the flat. The volume of the pit, the macula, and the retina were also calculated. (3) Then, we trained seven machine learning models: Artificial Neural Network (ANN), Classification and Regression Trees (CART), k-Nearest Neighbors (kNN), Linear Discriminant Analysis (LDA), Ordinal Logistic Regression (OLR), Support Vector Machines (SVM), and Random Forest (RF).

Results: (1) The short-eye group has an average axial length of 22.5 mm (21.82/22.89 mm) and a spherical equivalent of +0.5 D (+0.25/+1.5 D), the emmetropic group has an average axial length of 23.62 mm (23.08/24.46 mm), and an average spherical equivalent of -0.25 D (-2.0/+1.25 D), and the long-eye group has 25.48 mm (24.7/26.60 mm) of axial length and -3.75 D (-6.0/+0.5 D) of spherical equivalent. (2) We found that the rim's area presents the highest correlation with the refractive error of the patient. Mid and the flat areas are also good predictors of the patient's refractive status. Pit volumes showed a strong association with participants' refractive status. (3) The random Forest model shows the best performance with a predictive power of 77%.

Conclusions: The random Forest model shows the best performance in predicting axial refractive errors. This model was able to properly classify 77% of the subjects in one of the three groups: short-eyes (21 mm axial length), normal-eyes (23 mm axial length), and long-eyes (25 mm axial length).

TITLE: The Anti-Scarring Role of Lycium Barbarum Polysaccharide on Cornea Epithelial-Stromal Injury

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Wong, A.C. Lo, Y. Chan, K.C. Shih, Ophthalmology, The University of Hong Kong, HONG KONG|

Commercial Relationships Disclosure (Abstract): William Wong: Commercial Relationship: Code N (No Commercial Relationship) | Amy Lo: Commercial Relationship: Code N (No Commercial Relationship) | Yau Kei Chan: Commercial Relationship: Code N (No Commercial Relationship) | Kendrick Shih: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The study is to assess whether Lycium barbarum polysaccharide (LBP) solution can be a novel therapy in modulating fibroblasts differentiation after corneal epithelial- stromal injury in a three-dimension model.

Methods: A 3D model made of PDMS elastomers is created to mimic the anatomy and physiology of the corneal stroma. The chip consists of a cell culture chamber and is connected to two channels where medium or LBP is supplied. Human fibroblasts are suspended in collagen to form a three-dimensional hydrogel construct. Cells are pre-treated with optimized 2 mg/mL LBP for 24 hours, followed by 10 ng/mL TGF-b1 for another 24 hours.

Results: Fibroblasts pre-treated with LBP showed a decreased expression of alpha-smooth muscle actin, which is a prominent marker of myofibroblasts. Pro-fibrotic proteins such as vimentin, collagen II and collagen III are as well reduced. Cell-laden hydrogel pre-treated with LBP revealed no significant contraction compared to that in control group ($p=0.29$) while group pre-treated with TGF-b1 showed increased contraction by 17.3% ($p<0.001$). The stiffness of the hydrogel treated with TGF-b1 alone had an increase by 3.55-fold ($p=0.02$) yet that in the LBP group showed no significant difference compared to that in control group ($p=0.9964$)

Conclusions: LBP can be a potential topical therapy to prevent corneal scarring prior to surgery. Optimized LBP concentration can potentially lead to fewer adverse effects compared to standard pharmacological treatments while minimizing fibroblast differentiation.

TITLE: Differences of the Endothelial Mosaic of Fuchs Endothelial Dystrophy examined by Non-Contact and Contact Corneal Specular Microscopes

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.C. Abib, Anatomy, Universidade Federal do Parana, Curitiba, PR, BRAZIL|F.C. Abib, Cornea, Prof. Fernando Abib Eye Clinic, Curitiba, Paraná, BRAZIL|

Commercial Relationships Disclosure (Abstract): Fernando Abib: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Descemet Membrane Excrescences (DME) characterizes Fuchs Endothelial Dystrophy (FED). The most severe affected areas of the Endothelial Mosaic (EM) are the central and paracentral, the most preserved is superior. Specular Microscopy is a non-invasive examination to access the EM. The selection of the best CSM, Non-Contact (NC) or Contact (C), it helps to understand the degree of EM involvement in the FED, as a whole. Purpose: To know the profile and the degree of impairment of the EM by DME in the central area (CA) and in the furthest areas from the CA possible to be evaluated in FED patients examined by NC CSM and C CSM.

Methods: Cross-sectional study: 34 eyes of 17 patients with FED diagnosis at the Clinica de Olhos Prof. Dr. Fernando Abib (Curitiba, Brazil).

NC CSM (Tomey EM4000, USA) and C CSM (BioOptics, USA) were used to score the damage of the EM by EMD (Figure 1) in examinations performed consecutively by the same examiner. The scored areas of the EM: CA and furthest areas from the CA at 4 hours (4h), 8 hours (8h), and 12 hours (12h). The mean score (MS) of the examined areas were presented by statistical descriptive. The comparison of the MS between the studied areas with NC and C CSM will be reported in percentage of total agreement and up to one degree of disagreement ($\Delta 1$). Comparisons of MS of NC CSM versus C CSM were made at CA, 4h, 8h, and 12h using the T-Test for 2 dependent means (level of significance <0.05).

Results: Percentage of agreement (Figure 2) - CA: total agree 44%, $\Delta 1$ Agree 85%; 4h: total agree 2.9%, $\Delta 1$ agree 20%; 8h: total agree 11.7%, $\Delta 1$ agree 14.7%; 12h: total agree 0%, $\Delta 1$ agree 14.7%.

Comparison between NC and C CSM at the studied areas (Figure 2): CA not significant ($p>.05$); 4h significant ($p<.05$); 8h significant ($p<.05$); 12h significant ($p<.05$).

Conclusions: Examinations performed on FED patients, by NC CSM and C CSM in the CA of the EM, show similar results; at the most distant EM areas possible to be examined from the center by these devices (4h, 8h, 12h) the results are totally different.

The endothelial mosaic least affected by EMD was found when the same eyes were examined by C CSM, which means that NC CSM acquire EM images closer of the central area and C CSM get images beyond of those acquired by NC CSM. It is confirmed that C CSM assess the periphery of EM, NC CSM does not.

ABSTRACT BODY:

Purpose: In 2014 the American Academy of Ophthalmology recommended patients receive genetic testing for inherited eye diseases. This recommendation, along with sponsored genetic testing programs, has greatly increased utilization of genetic testing. While genetic testing can inform a clinical diagnosis and determine the inheritance pattern, the genetic basis of ocular diseases is diverse, requiring large comprehensive gene panels. This it can also lead to many candidate variants per patient, increasing the risk of a genetic misdiagnosis. Differing standards on variant calls, especially around variants of uncertain significance (VUS), can lead to different genetic interpretations.

The Clinical Genome Resource (ClinGen) is an international consortium funded primarily by the National Human Genome Research Institute of NIH to promote the standardization of gene and variant interpretation to improve clinical care. The Ocular Clinical Domain Working Group (CDWG) within ClinGen was established in 2019 to address this need for inherited eye diseases.

Methods: The CDWG convened an executive committee of clinicians and researchers with expertise in retinal, glaucoma and neuro-ophthalmology disorders. Expert panels (EP) are being developed to tackle gene curation (GCEP) to assess the association between a particular gene and a disease phenotype and variant curation (VCEP) to assess the pathogenicity of variants within selected genes with respect to a specific phenotype. The variant curation process has been given US FDA recognition.

Results: We established 2 GCEP's (Retina and Glaucoma/Neuro) and 4 VCEP's (OPA1, Glaucoma, LCA, X-linked retinal dystrophy) with an additional ABCA4 VCEP in development. The membership, curation protocols and gene curation results are available on the ClinGen website (<https://clinicalgenome.org/>). Variant classifications and supporting data will be available in the NIH ClinVar database.

Conclusions: By assessing the strength of gene/disease associations, standardizing FDA recognized gene-specific variant curation guidelines, sharing genomic data amongst expert members and incorporating data from existing

disease databases, the number of VUS will decrease, improving the value of genetic testing as a diagnostic tool and guiding patient eligibility for the growing clinical pipeline of genetic therapies for inherited retinal diseases.

ABSTRACT BODY:

Purpose: The multipotent progenitor monocyte population in PBMCs have been used to generate cell which can be reconditioned called Reconditioned Monocytes (RM). These RMs have been sourced to differentiate in Retinal Neuron like Cells (RNLCs) in our lab. The RNLCs have shown to be a viable alternate to conventional cell-based therapy. Therefore, we aimed to analyse the potential of patient derived RNLCs for in vitro disease modelling for Retinitis Pigmentosa and a mutation specific in vitro model.

Methods: Differentiating RP patient derived PBMCs into RNLCs was established by the two- step approach. Wherein, the PBMCs were isolated by density centrifugation method. The PBMC layer was collected and the adherent monocyte cells were supplemented with dedifferentiation media for 6 days. The reconditioned monocytes cells were then supplied with re-differentiation media until the cells attain the retinal phenotype at day 8. For the disease modelling study the cells were characterized by in vitro apoptosis profiling and compared with exome and clinical data.

Results: Figure 1: Cumulative assessment of 40 RP patients against 30 healthy donors indicated that at D1 the monocytes were equally viable however apoptosis rates varied in the RP RLNCs with diverse patterns due to individual mutations' appearance in the RLNCs and surmounting the effect. Thus, individual mutation specific patterns were studied. Figure 2: (A) RP1 displayed higher rate of apoptosis on day14 when compared to D6 and D10. (B) RP7 displayed higher rates of RNLC apoptosis on D6 while the RLNC were increasing viable at subsequent D10 and D14.

Conclusions: Thus, the source retinal gene mutation manifests in the peripheral monocyte derived RLNCs and shows patterned apoptosis due to the directional manifestation of the developmental genes. In vitro study of patient specific behaviour of retina towards degeneration can help understand the effect of any drug or cell-based therapy and mimic the patient condition to clinically characterize the rate of degeneration in a step towards targeted personalized medicine.

TITLE: Ahmed vs. Baerveldt Implant Outcomes in Resident Performed Surgeries

SESSION TITLE: Surgery and Wound Healing I and II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Du, T. Tai, New York Eye and Ear Infirmary of Mount Sinai Ophthalmology, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jeanette Du: Commercial Relationship: Code N (No Commercial Relationship) | Tak Yee Tania Tai: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As glaucoma drainage implants (GDI) are increasingly used to treat refractive glaucoma, numbers of these surgeries performed by trainees have also increased. The objective of this study is to assess the safety and success of GDI surgeries performed by residents as primary surgeon. Baerveldt surgeries and post-operative care may be more complex than Ahmed surgeries, and therefore may have different outcomes in the hands of residents than in the hands of more experienced surgeons. Efficacy and complications will be compared with those reported in the literature.

Methods: This is a retrospective study conducted at a single academic institution. Records of subjects who underwent either Baerveldt glaucoma implant (BGI) or Ahmed glaucoma valve (AGV) placement from 2011-2016 were reviewed. Patients with prior penetrating keratoplasty, GDI surgery, or combined GDI-cataract surgery were excluded. Baseline patient characteristic and clinical data up to 4 years after surgery were obtained. Surgical success rate was defined as IOP maintained ≤ 21 and ≥ 5 , without need for further glaucoma surgeries or NLP vision.

Results: A total of 121 subjects were included in the study. 44 eyes received the Ahmed FP7 implant and 77 eyes received the Baerveldt 250 mm or 350 mm implant. Average pre-operative IOP was 32.3 mmHg. At months 1, 3, 6, 12, and 24, overall average IOP was 18.7, 17.2, 15.9, 15.6 and 15.0 mmHg, respectively. Average IOP was significantly different between AGV and BGI eyes only at months 3 and 6. The average number of glaucoma medications pre-operatively and at last follow up was 3.9 and 2.7, respectively. Success rates were not significantly different between the two devices at 6, 12, or 24-months (Table). There was no significant difference between Kaplan-Meier survival curves for the two devices ($p=0.074$).

Conclusions: GDI surgery performed by residents was effective in lowering IOP and decreasing number of pressure-lowering drops in patients with refractory glaucoma for up to 24-months. IOP was significantly higher for AGV versus BGI surgeries at months 3 and 6, corresponding with the hypertensive phase associated with AGV implantation. There were no significant differences in success rates detected between the devices. Longer follow up time and assessment of complication rates may better characterize the safety and efficacy of tube surgeries performed by residents.

ABSTRACT BODY:

Purpose: To evaluate the natural history of visual acuity (VA) and visual field (VF) sensitivity in choroideremia (CHM). Choroideremia (CHM) is an X-linked degenerative retinal disease caused by deletions or mutations in the CHM gene which impacts the Rab escort protein-1 (REP-1). Study of the natural history of CHM may inform future therapeutic approaches.

Methods: A global retrospective chart review of anonymized patient records from 8 institutions. Eligibility criteria included male and born between 01Jan1930 to 31Dec2005, genetically confirmed CHM, and ≥ 2 clinic visits spanning ≥ 5 years. Data including VA and kinetic VF sensitivity (measured by sum total meridian degrees) were collected.

Results: Deidentified medical charts from 125 males (age at clinic visit ranged 2-82 years) were collected. All had recorded VAs that were converted to a LogMAR score. Age and VA demonstrated a non-linear relationship: VA remained fairly stable through the fourth decade of life then worsened by a rate of 0.026 LogMAR per year. Kinetic VF sensitivity was available for 107 eligible subjects (age 7-82 years) and decreased with age. There was a statistically significant age-effect interaction by VF test type for both the I4e and V4e stimuli for each of the left and right eyes ($p < 0.001$). A 1-year increase in age decreased the I4e visual field by approximately 10.4 sum total meridian degrees for the left and right eyes; the V4e visual field decreased by approximately 24.3 sum total meridian degrees for the left and right eyes.

Conclusions: In a cohort of genetically confirmed CHM patients, VF deterioration occurs at a higher rate than visual acuity early in the disease, whereas VA decreases are more profound in the later stages.

ABSTRACT BODY:

Purpose: hRPC secrete neurotrophic factors that promote photoreceptor cell survival and function. This paracrine mechanism has shown promise as a therapy for RP agnostic to genetic subtype. A phase 2b trial was conducted to evaluate intravitreal injection of allogeneic hRPC for treatment of RP.

Methods: Patients with RP and best-corrected visual acuity (BCVA) between 20/80 and 20/800 were randomized to two treatment groups (single injection of 3.0×10^6 or 6.0×10^6 hRPC) or sham. The primary efficacy endpoint was mean change in BCVA at month 12. Secondary endpoints included a low luminance mobility test (LLMT), contrast sensitivity (CS), kinetic visual fields (VF), and a visual function questionnaire VA LV VFQ-48 (VFQ). Analyses included a per protocol population and a post hoc analysis in a target subgroup meeting the following criteria: 1) study eye with baseline central fixation, 2) study eye without severely constricted field ($\geq 12^\circ$ diameter), and 3) study eye did not have significantly worse BCVA than fellow eye (≤ 15 letters).

Results: 84 total patients were randomized; 8 were excluded from the per protocol analysis for protocol violations and 2 were lost to follow up (N=74). Mean changes in BCVA from baseline to month 12 were +2.81, +2.96, and +7.43 letters in sham (N=26), 3.0×10^6 hRPC (N=25), and 6.0×10^6 hRPC (N=23) groups, respectively. In the post hoc analysis of the target subpopulation, mean changes in BCVA from baseline to month 12 were +1.85, -0.15, and +16.27 letters in sham (N=13), 3.0×10^6 hRPC (N=13), and 6.0×10^6 hRPC (N=11) groups, respectively (p=0.003 for 6.0×10^6 hRPC vs sham). Improvements in the 6.0×10^6 group were also observed in all other secondary endpoints. hRPC treatment was well tolerated with generally minor and transient adverse events; there was one treatment related serious adverse event in the 3.0×10^6 hRPC arm (ocular hypertension that resolved with treatment), but none in the higher dose arm of 6.0×10^6 hRPC.

Conclusions: Intravitreal injection of hRPC is a novel approach for treatment of RP, independent of the genetic subtype. This phase 2b study demonstrates a strong safety profile and encouraging biological activity, warranting progression to phase 3.

TITLE: 'Physiologic' Eye Growth in Myopic Children

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Nixon, X. Cheng, N.A. Brennan, Johnson and Johnson Vision, Jacksonville, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alex Nixon: Commercial Relationship(s);Johnson and Johnson Vision:Code E (Employment) | Xu Cheng: Commercial Relationship(s);Johnson and Johnson Vision:Code E (Employment) | Noel Brennan: Commercial Relationship(s);Johnson and Johnson Vision:Code E (Employment)

ABSTRACT BODY:

Purpose: Emmetropic eyes show 'physiologic' eye growth, an ongoing elongation of the eye during childhood and teenage years in the absence of substantial refractive change, attributable to loss of crystalline lens power. It has been hypothesized that a proportion of growth in myopic eyes is also physiologic and not directly linked to refractive progression. However, Mutti et al (OVS, 2012;89:251) among others have reported that lens thinning ceases rather abruptly during myopia onset, raising the question of the existence of this component of growth in myopes in the absence of significant changes to corneal curvature.

Methods: Subject data were drawn from control groups described in Cheng et al (Acta Ophthalmol 2020;98:e346). Changes in spherical equivalent cycloplegic autorefraction (Δ SECAR; WAM-5500) and axial length (Δ AL; IOLMaster) were available for untreated right eyes of myopes aged 8 to 11 years at one (N= 151) and two (N= 99) years follow-up. Total least squares regression was performed across feasible values of λ (ratio of the measurement variance of Δ SECAR to that of Δ AL). The intercept of the regression line when Δ SECAR was equal to zero was taken to be physiological eye growth (figure 1). 95% CIs for this intercept were obtained by bootstrapping.

Results: The results were sensitive to λ , but even in the extreme case of $1/\lambda = 0$, the lower limit of the 95% CI was greater than zero, providing evidence for existence of physiologic growth in myopes (figure 2). No consistent change in physiological eye growth across age was detected within this group. Gradients relating Δ SECAR to Δ AL match expectations from optical calculations.

Conclusions: This analysis supports the existence of physiological eye growth in myopic children. Estimated size of physiological growth at 1- and 2- years seems to be less than that reported for emmetropes.

Commercial Relationships Disclosure (Abstract): Eduardo Martinez-Enriquez: Commercial Relationship(s);US2017 0316571:Code P (Patent);EP20382385:Code P (Patent) | Miriam Velasco-Ocana: Commercial Relationship: Code N (No Commercial Relationship) | Susana Marcos: Commercial Relationship(s);PCT/ES2012/070185:Code P (Patent);US2017 0316571:Code P (Patent);EP20382385:Code P (Patent)

ABSTRACT BODY:

Purpose: To estimate anterior segment geometry upon accommodative demand for different ages, which will give insights on new strategies for presbyopia correction

Methods: 43 subjects participated in the study (ages 21 to 64; SE: +1.25 to 8.25D). Images of the eye's anterior segment were obtained while the subject viewed monocularly a Snellen E-letter, using custom 3-D spectral Optical Coherence Tomography (s-OCT, 840 nm, 25000 A-scans/s, axial range: 7 mm, axial pixel resolution: 3.4 μ m). 5 measurements (3-D images) were acquired (300 A-scans x 50 B-scans, 11-mm lateral range) for each of the different accommodative demands induced with a Badal optometer: 0-6 D (1 D-steps). Custom algorithms were used for geometrical quantification of Anterior Chamber Depth (ACD), Lens Thickness (LT), Anterior Lens Radius (RAL) and Posterior Lens Radius (RPL). Change of these geometrical parameters in the non-accommodative state (0D) with age, and change of the parameters per diopter of accommodative demand (acD) with age (i.e., how the geometry changes in response to an accommodation stimulus as a function of age) were evaluated in terms of linear correlations.

Equation of the best fitting line, Pearson correlation coefficient (r), and p -values for testing the hypothesis of no correlation were obtained

Results: For the non-accommodative state (0D), LT increased significantly with age ($p < 0.01$; $LT = 3.16 + 0.02 \cdot \text{age}$; $r = 0.76$), and the rest of parameters decreased significantly with age: ACD ($p < 0.01$; $ACD = 3.38 - 0.008 \cdot \text{age}$; $r = -0.37$), RAL ($p < 0.01$; $RAL = 13.07 - 0.06 \cdot \text{age}$; $r = -0.56$) and RPL ($p < 0.01$, $RPL = 6.79 - 0.012 \cdot \text{age}$; $r = -0.51$). Changes of the parameters per diopter (mm/D) with age were also obtained. $\Delta LT / \text{acD}$ decreased significantly with age ($p < 0.01$; $\Delta LT / \text{acD} = 0.11 - 0.0018 \cdot \text{age}$; $r = -0.84$), and the rest of parameters increased significantly with age: $\Delta ACD / \text{acD}$ ($p < 0.01$; $\Delta ACD / \text{acD} = -0.06 + 0.00096 \cdot \text{age}$; $r = 0.75$), $\Delta RAL / \text{acD}$ ($p < 0.01$; $\Delta RAL / \text{acD} = -1.14 + 0.02 \cdot \text{age}$; $r = 0.83$) and $\Delta RPL / \text{acD}$ ($p < 0.01$; $\Delta RPL / \text{acD} = -0.32 + 0.006 \cdot \text{age}$; $r = 0.71$). No parameter changed significantly with accommodative demand from around 55-60 y.o.

Conclusions: All the analyzed geometrical parameters decreased significantly with age in the non-accommodative state (0D) except for the LT, that increased, so that the lens becomes more rounded with age. Besides, changes of all the parameters in response to an accommodation stimulus are smaller in absolute value with age, leading to presbyopia around 55-60 y.o.

ABSTRACT BODY:

Purpose: To identify and measure rod-mediated visual field thresholds using two-color dark-adapted chromatic (DAC) perimetry in a subset of participants in the RUSH2A study, determine the percentage of participants that retain rod function, and explore the relationship between dark adapted visual fields (DAVF) from DAC perimetry and parameters of rod function from electroretinogram (ERG) and full-field stimulus thresholds (FST).

Methods: At 6 sites, participants from the Rate of Progression of USH2A-related Retinal Degeneration (RUSH2A) 4-year natural history study of Usher syndrome type 2 (USH2) and non-syndromic autosomal recessive retinitis pigmentosa (ARRP) were invited to participate in the DAVF ancillary study. Dark-adapted retinal sensitivity was tested using cyan and red test protocols on the DAC perimeter (Medmont), and loci where cyan relative to red sensitivity was > 5 dB were considered rod mediated. Measures of full-field rod mean sensitivity, number of rod loci, maximum sensitivity, DAVF full-field hill of vision (DAVF V_{TOT}), and 30-degree hill of vision (DAVF V_{30}) were determined. Correlations between DAVF measures and standard clinical measures were estimated, as were kappa statistics (κ) for agreement between DAVF and other modalities regarding evidence of rod function.

Results: 49 participants (55% female, 95% white) were screened for DAVF rod function; 38/49 (78%) were found to have evidence of rod function. For comparison, 15/49 (31%) had measurable rod ERGs. For those 40 years of age or older, 7 with unmeasurable ERGs retained some rod visual field. DAVF maximum sensitivity was highly correlated with FST white thresholds ($\rho = -0.80$, $p \leq 0.001$). DAVF mean sensitivity, DAVF V_{TOT} , and DAVF V_{30} were more moderately correlated with FST white thresholds ($\rho = -0.71$, -0.72 , and -0.61 , respectively; all $p \leq 0.001$). Agreement regarding evidence of rod function with DAVF was relatively poor for both FST white ($\kappa = 0.35$, 95% CI = [0.14, 0.57]) and ERG Rod B-Wave ($\kappa = 0.16$, 95% CI = [0.004, 0.31]).

Conclusions: Our results suggest rod-mediated function is present in many patients with symptomatic USH2A-related retinal degeneration, including many without measurable rod ERGs. FST and DAVF represent two potential measures of rod function suitable for longitudinal measures in clinical trials for inherited retinal degenerations.

ABSTRACT BODY:

Purpose: To investigate differences in the relationship between ocular and systemic vascular biomarkers in male and female open-angle glaucoma (OAG) patients of African (AD) and European (ED) descent.

Methods: This analysis included a total of 131 confirmed early to moderate OAG patients (99 ED, 32 AD) evaluated for: intraocular pressure (IOP) via Goldmann tonometry, systolic, diastolic, and mean arterial blood pressures (SBP/DBP/MAP) via automated ambulatory sensor, and ocular perfusion pressure (OPP=2/3MAP-IOP), systolic OPP (SOPP=SBP-IOP), diastolic OPP (DOPP=DBP-IOP), and mean OPP (MOPP=MAP-IOP) were calculated. In addition, visual contrast sensitivity (CS) detection via Vector Vision Systems was assessed. Measurements were evaluated between AD and ED and between male and female OAG patients using unpaired t-tests with $p < 0.05$ considered statistically significant.

Results: In the overall sample of all OAG patients (both AD and ED), biomarkers of systemic blood pressure and various calculations of OPP were significantly higher in males compared to females ($p = 0.000-0.032$). Additionally, OAG patients of AD had significantly higher systolic and diastolic blood pressures and corresponding OPP compared to those of ED ($p = 0.008-0.047$). In all OAG patients, male OAG subjects had higher CS detection compared to females, OAG patients of ED had higher CS detection than OAG patients of AD, and female OAG patients of ED had higher CS detection compared to female OAG patients of AD ($p < 0.05$, all comparisons).

Conclusions: In this cohort of OAG patients, biomarkers of systemic and ocular perfusion were significantly different between male and female OAG patients of AD and ED. Specifically, systemic blood pressure and calculations of OPP were significantly higher in male compared to female OAG patients as well as in OAG patients of AD compared to ED. Higher CS detection was found in male compared to female OAG patients and in OAG patients of ED compared to AD. Individualized approaches to glaucoma management that consider patient demographics including gender and race may improve the precision of patient care.

ABSTRACT BODY:

Purpose: As trachoma is eliminated, field graders lose exposure to the disease and become less adept at identifying follicular trachoma (TF). New solutions to complete field surveys including photography and telemedicine may be needed to ensure elimination and accurately monitor for re-emergence. Expert grading of images is costly and time intensive. Our purpose was to validate crowdsourcing for follicular trachoma image interpretation.

Methods: Tarsal plate images acquired using a smartphone-based device during a 2019 field survey in Tanzania (n=1000) were posted to the Amazon Mechanical Turk (AMT) crowdsourcing marketplace for grading as "not-TF," "possible TF," "probable TF" or "definite TF." Each image was graded by 7 unique graders who received \$0.05 USD per image. The grades were summed to create a raw score (0-21) which was analyzed by receiver-operating characteristic (ROC) using images with concordant field and expert photo grades to determine the optimal diagnostic set-point. Kappa, sensitivity and specificity were then analyzed at various prevalences of disease.

Results: 7000 grades were rendered in 1 hour for \$420 USD. The raw score produced an area under the ROC of 0.940 (95% CI 0.902-0.977). Optimizing the setpoint to a raw score of 7 produced a kappa of 0.43, sensitivity of 84.8%, specificity of 90% and % correct (to master/field grade) of 89.3% in the full sample with a prevalence of 5.7% TF. When normal images were randomly removed from the sample to mimic the prevalences used to validate field graders (30% & 75% TF), the kappa ranged from 0.71-0.74 which is within the acceptable range per the World Health Organization. Images with discordant field and expert grades were more likely to receive a raw score in the middle of the range suggesting disagreement among crowdsourcers as well.

Conclusions: Crowdsourcing was able to rapidly and accurately identify TF on smartphone-acquired photographs with minimal training. Agreement with a reference standard is poor in a sample with low TF prevalence, but when held to the same standard as a skilled field grader in the current training paradigm, crowdsourcing may be acceptable. Further testing compared to field grading in low prevalence areas is needed.

ABSTRACT BODY:

Purpose: Early detection of keratoconus (KC) progression is of utmost importance for the prudent and economical use of crosslinking. If KC progression could be accurately predicted, the timing of the follow-up visits could be customized to the patient's needs. The aim of this study was to verify whether the progressive trend of the ectasia can be forecasted based on two prior tomographies, and verify the accuracy of the predictive system when labelling eyes as stable or suspect progressive.

Methods: The observational multicenter REDCAKE study enrolled 906 KC patients measured at least twice. A time delay neural network was implemented. The network receives 6 features as input, measured in two consecutive examinations; all of them are potentially platform-independent (age, the mean keratometry in a 3mm area around the maximum curvature, the steepest radius and best fit sphere of the front surface, the mean radius of the back surface and LOGIK). Subsequently, the system predicts the values of the 2nd follow-up and determines its classification (stable or suspect progressive) based on the significance of the change from the baseline value (Figure 1). Different configurations and datasets were applied to evaluate robustness to errors and stability of the system. In the first dataset, 3 consecutive examinations of good quality were assembled to create each one of the triplets (N=811); in the second dataset, one examination was allowed to be of lower quality (marked in yellow by the tomographer software, N=1236). Data was divided as follows: 85% for training and 15% for external validation. Each configuration was trained/validated 10 times with random data splits.

Results: The results obtained were modest, with an average sensitivity $s=71\%$ and specificity $sp=81\%$ when classifying eyes as stable or suspect progressive (Table 1). On average, the positive and negative predictive values were $PPV=71\%$ and $NPV=80\%$, respectively. Also including time series with one error did not significantly worsen the results ($s=72\%$, $sp=78\%$, $PPV=72\%$, $NPV=78\%$).

Conclusions: The results obtained seem insufficient to decide on a surgical procedure such as crosslinking, however, they may be used to customize the timing for the next follow-up based on the predicted status. This predictive system constitutes another step towards a personalized management of KC disease.

ABSTRACT BODY:

Purpose: Non-exudative age related macular degeneration (NEAMD) is a significant cause of visual impairment and reduced quality of life worldwide. Prior studies examined associations between individual biomarkers on optical coherence tomography (OCT) and progression of disease. However, no comprehensive study has been undertaken to study the natural history of OCT biomarkers in NEAMD and to model their likelihood in predicting development of end-stage disease; namely incomplete retinal pigment epithelium and outer retinal atrophy (iRORA) and complete retinal pigment epithelium and outer retinal atrophy (cRORA).

Methods: Retrospective chart review at two academic practices. Patients diagnosed with NEAMD for whom yearly OCT scans were obtained for at least 4 consecutive years were included. Baseline demographic, visual acuity, Age-Related Eye Disease Study (AREDS) staging, and OCT data was collected. OCTs were assessed for presence or absence of 11 features individually associated with progression of NEAMD, both at baseline, and on all subsequent follow up scans. Likewise, charts were reviewed to assess visual acuity and staging of NEAMD at all follow up visits.

Results: 107 eyes of 88 patients met inclusion criteria. Patients had yearly OCTs for a median duration of 62 months (range: 48 months-132 months). During this time, of 107 eyes, 14 eyes (14%) progressed to exudative AMD, 17 eyes (16%) progressed to iRORA, 26 eyes (25%) progressed to cRORA, and 49 eyes (44%) did not progress to atrophy or exudative disease. Baseline OCT features associated with progression to iRORA and cRORA included hyporeflective intra-retinal spaces ($p<0.05$), drusen ooze ($p<0.01$) and drusen collapse ($p<0.05$). Features found in serial OCTs associated with progression to iRORA and cRORA included hyporeflect dots ($p<0.05$), hyporeflective foci ($p<0.01$), hyporeflective intra-retinal spaces ($p<0.01$), drusen ooze ($p<0.01$) and drusen collapse ($p<0.01$). In 72% of patients with bilateral involvement, OCT biomarkers of progression in one eye was predictive of progression to a similar extent of disease (exudative, iRORA, cRORA, or no atrophy) in the fellow eye.

Conclusions: This comprehensive study examines OCT biomarkers of NEAMD progression to iRORA and cRORA. These biomarkers can be used to predict progression of NEAMD disease, both in the affected eye, and in the fellow eye.

TITLE: Resveratrol Attenuates Priming of the NLRP3 Inflammasome by Hydrogen Peroxide

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Lallier, N.A. Besley, P. Yang, G.J. Jaffe, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Scott Lallier: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Besley: Commercial Relationship: Code N (No Commercial Relationship) | Ping Yang: Commercial Relationship: Code N (No Commercial Relationship) | Glenn Jaffe: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The NLRP3 inflammasome has been implicated in the pathogenesis of age-related macular degeneration (AMD). It has been previously suggested that reactive oxygen species can prime the NLRP3 inflammasome and induce inflammatory cytokine expression. We and others have shown that resveratrol decreases oxidant injury in RPE cells. However, the effect of resveratrol on oxidant-induced inflammasome priming and inflammatory expression in RPE cells has not been well established. Here we test hydrogen peroxide's (H_2O_2) ability to prime the inflammasome and induce inflammatory gene expression in cultured human retinal pigment epithelial (RPE) cells. We hypothesized that H_2O_2 would prime the inflammasome, induce inflammatory gene expression, and that resveratrol would protect against these effects.

Methods: Cultured human RPE cells were treated with 30 μ M resveratrol for 2.5 hours, followed by treatment with 700 μ M hydrogen peroxide in the presence or absence of 30 μ M resveratrol for 2.5 or 4 hours as indicated.

Phosphorylation of Nuclear Factor Kappa B (NF- κ B) was evaluated using western blot. Inflammasome and classic inflammatory gene expression was measured with qPCR.

Results: H_2O_2 treatment resulted in a 4-fold increase ($p < .05$) in phosphorylation of NF- κ B as determined by western blot. H_2O_2 treatment resulted in an 18-fold increase in NLRP3 ($p < .05$), 1.8-fold increase in IL-1 β ($p < .05$), and 2.4-fold increase in IL-8 ($p < .05$) as determined by qPCR. Resveratrol protected against the upregulation of NLRP3 ($p < .05$) and IL-1 β ($p < .05$) by H_2O_2 . Resveratrol did not significantly reduce IL-8 expression. Under these experimental conditions, no increase was observed in IL-6, MCP-1, or CXCL1 gene expression.

Conclusions: H_2O_2 primes the human RPE cell NLRP3 inflammasome and upregulates inflammasome-associated cytokines. These effects were blocked by resveratrol. Further studies are needed to determine if other oxidants prime the RPE cell inflammasome, and the mechanism by which resveratrol exerts its inhibitory effect. These studies will add to our understanding of the pathogenesis of AMD and possible preventive strategies.

ABSTRACT BODY:

Purpose: Spaceflight-associated neuro-ocular syndrome (SANS) is a condition that is hypothesized to develop as a consequence of the chronic headward fluid shift that occurs in sustained weightlessness. Here, we exposed healthy subjects to strict 6° head-down tilt bedrest (HDTBR) to generate a sustained headward fluid shift in the Artificial Gravity Bedrest with the European Space Agency (AGBRESA) study and assessed SANS-related ocular changes (e.g., optic disc edema, chorioretinal folds). A subset of these subjects were exposed to artificial gravity (AG) via centrifugation during HDTBR to investigate whether this intervention can attenuate fluid shift-induced ocular changes.

Methods: Data were collected in 24 healthy subjects during 60 days of strict 6° HDTBR, as well as during the pre- and post-HDTBR phases with the subjects in seated and supine postures. The cohort was divided into 3 groups (n=8/group), two of which received 30 minutes total per day of AG (0.3 g at the eyes) by either continuous (cAG) or intermittent (iAG) short-arm centrifugation. Optical coherence tomography images were acquired to quantify changes in peripapillary total retinal thickness (TRT), retinal nerve fiber layer thickness, and choroidal thickness, and to detect chorioretinal fold development. Intraocular pressure, standard automated perimetry, and optical biometry data were also collected.

Results: TRT increased from seated baseline as a function of HDTBR duration for each group. By HDTBR day 58, TRT was increased by 35.9 µm (95% CI, 19.9-51.9 µm, P < 0.0001), 36.5 µm (95% CI, 4.7-68.2 µm, P = 0.01), and 27.6 µm (95% CI, 8.8-46.3 µm, P = 0.0005) for the control, cAG, and iAG group, respectively. The cAG and iAG groups were not different from the control group for this measure during HDTBR (P > 0.6). Although not apparent at HDTBR day 30, chorioretinal folds were observed by HDTBR day 58 in 6 subjects (n≥1 per group).

Conclusions: The headward fluid shift generated by strict 6° HDTBR leads to the development of early optic disc edema, as detected by increased TRT, and chorioretinal folds in some subjects. Therefore, this spaceflight analog is an appropriate model for investigating the etiology of SANS and refining countermeasure strategies. 30 minutes of either cAG or iAG daily does not counter the effects of the headward fluid shift on the eye, suggesting that longer duration exposures are required.

ABSTRACT BODY:

Purpose: Many, if not most, forms of retinal degeneration, including age-related macular degeneration (AMD), involve the ectopic accumulation of subretinal macrophages, but their role in human diseases remains elusive. We recently described a unique subtype of bona fide microglia that are dominant in the subretinal space in the light damage (LD) paradigm and rhodopsin P23H mutant knockin mice. These subretinal microglia are transcriptionally reprogrammed and contribute to restricting disease progression, such as loss of structural integrity of the retinal pigment epithelium (RPE) and death of photoreceptors. However, whether this population of reprogrammed microglia is a general response across etiologically distinct forms of degeneration, including human AMD, is unknown.

Methods: To address this question, we utilized single cell RNA-sequencing, and compared our findings in LD model (O'Koren and Yu et al, 2019) with another three distinct disease models in mice. These include: an acute model in NaIO₃ mediated RPE injury; a chronic degeneration model of P23H mice; and advanced aging model of wildtype 2-year-old mice. Furthermore, selected markers were analyzed by immunolabeling and confocal microscopy in mouse models and also examined in human post-mortem macular sections from a total of 36 patients categorized by Sarks' grading system.

Results: We showed that transcriptional reprogrammed microglia are conserved among all mouse models studied. Moreover, confocal microscopy revealed that subretinal Iba1⁺ cells dominantly expressed markers of this reprogramming in all four mouse models. Likewise, in human postmortem retina we observed enriched subretinal staining of such markers in subjects with intermediate to advanced AMD (Sarks 3, 4, and 5), whereas few positive cells were found in control or early AMD subjects (Sarks 1 and 2).

Conclusions: Our findings demonstrate that transcriptionally programmed microglia in the subretinal space are present in the studied acute and progressive models of degeneration, as well as in advanced aging mice. Importantly, we show evidence that this unique population may also be relevant in forms of human AMD.

TITLE: The role of Nogo-A in visual deficits induced by retinal injury

SESSION TITLE: Retinal physiology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.B. Mdzomba, S. Joly, L. Rodriguez, V. Pernet, Universite Laval, Quebec, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Julius Mdzomba: Commercial Relationship: Code N (No Commercial Relationship) | Sandrine Joly: Commercial Relationship: Code N (No Commercial Relationship) | Lea Rodriguez: Commercial Relationship: Code N (No Commercial Relationship) | Vincent Pernet: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The transmembrane protein Nogo-A is a potent inhibitor of neuronal plasticity and repair. After CNS injury, Nogo-A prevents the cytoskeleton rearrangements required for functional rewiring of neuronal circuits. Its neutralization can support axonal regeneration and neuronal recovery. The goal of this study was to investigate the role of Nogo-A in the visual impairments induced by N-Methyl-D-Aspartate-induced (NMDA) excitotoxicity in the adult mouse. Excitotoxic damage is thought to be a major pathological mechanism causing retinal dysfunction in ocular diseases. In addition, we evaluated Nogo-A expression changes in diabetic human retinæ.

Methods: Different levels of retinal injury were induced by intravitreal injection of 0.5-40 nmol of NMDA. Nogo-A's function was blocked by using either knock-out (KO) mice or by intravitreally injecting a highly specific monoclonal function-blocking antibody (11C7) two days after NMDA injection. Visual function was followed using the optokinetic response (OKR) and by electroretinogram (ERG) recordings. Visual cortex activity was monitored through local field potential (LFP) recording. Immunofluorescence on retinal flat-mounts and on retinal sections was used to observe neuronal survival and Nogo-A expression changes.

Results: Intravitreal administration of 0.5nmol of NMDA produced damage limited to the ganglion cell layer (GCL), consisting of a drop of ~20 % in OKR spatial sensitivity and a ~30-% reduction in the number of ganglion cells (GC). 5nmols of NMDA produced extended destruction in the inner retina, as shown by the loss of ~80% of GC, the decrease of OKR spatial sensitivity by ~80%, and the decrease of the ERG b-wave amplitude by ~50%. Nogo-A KO mice and animals intravitreally injected with 11C7 showed a marked OKR spatial sensitivity improvement after NMDA-induced injury. In the same experimental groups, reduced LFP latency suggested enhanced visual cortex activation in response to eye stimulation with light flashes. However, 11C7 did not significantly influence GC survival. In human diabetic eyes, Nogo-A was overexpressed, suggesting its possible contribution to visual deterioration in ocular diseases affecting GC.

Conclusions: Our data suggest that Nogo-A is implicated in the development of permanent visual deficits caused by retinal injury. Intravitreal administration of Nogo-A-neutralizing antibodies may promote visual recovery in retinal diseases such as diabetic retinopathy.

ABSTRACT BODY:

Purpose: Recent studies from our laboratory demonstrate that a fibrillar layer (FL) consisting of a collagen I (COL I)-, collagen III (COL III)- and collagen IV (COL IV)-rich matrix exists in the central endothelium of the majority of advanced Fuchs endothelial corneal dystrophy (FECD) patients and that there is a significant decrease in endothelial cell density in this FL region. The present study sought to investigate the role of the FL in advanced FECD in more detail.

Methods: Ingenuity pathway analysis (IPA) was performed in a previously generated data set after RNA sequencing in the corneal endothelium of advanced (modified Krachmer grade 5+6) FECD patients (n=14) and controls (n=10). Differential expression of selected genes was confirmed using quantitative real-time PCR and the expression of the proteins localized in explanted Descemet endothelium complexes (DEC) using immunofluorescence flatmount staining. Cell-culture experiments in a human corneal endothelium derived cell line (HCEC-12) investigated the influence of Transforming Growth Factor Beta (TGF- β) stimulation and altered growth on FL specific collagen coatings in vitro.

Results: IPA identified hepatic fibrosis/hepatic stellate cell activation as the most strongly affected signaling pathway and TGF- β as the top upstream regulator in the corneal endothelium of advanced FECD patients. QPCR and immunofluorescence confirmed differential expression of fibrosis/ TGF- β -related genes (including Collagen V (COL V), Secreted Protein Acidic And Cysteine Rich (SPARC), and Platelet Derived Growth Factor-C (PDGF-C)) and altered protein expression pattern in advanced FECD DECs compared to normal. TGF- β stimulation induced overexpression of fibrosis related targets whereas growth experiments showed decelerated growth on FL related collagens.

Conclusions: This study provides further evidence that activation of the TGF- β signaling cascade and a fibrotic response play a role in the development of the FL. Subendothelial deposits formed during this reaction may contribute to a concomitant toxic microenvironment.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a chronic and progressive complication of diabetes. Dapagliflozin, a new class of anti-diabetic medication, is beneficial in reducing blood glucose; however, its role in DR remains unknown. Therefore, this study aims to investigate the protective effect of dapagliflozin on the development of DR.

Methods: The db/db mice were treated with dapagliflozin via diet for six months and the body weight, food consumption monitored every week. The blood glucose, HbA1c and electroretinogram (ERG) were assessed at 2 and 6 months. At study termination, the retinas were processed for trypsin digestions and real-time qPCR. In parallel, the human retinal endothelial cells (HRECs) were treated with dapagliflozin concentrations 0.1-100 μ M in a logarithmic range. The cell viability was assessed using Alamar Blue Assay, and the migration response was studied using a scratch wound-healing assay.

Results: The dapagliflozin treatment reduced blood glucose and HbA1C; however, there was no change in body weight or food intake. The db/db mice exhibited higher amplitude for ERG 'b' wave, which was decreased after dapagliflozin treatment. Dapagliflozin treatment resulted in downregulation of mRNA for pro-inflammatory markers along with a decrease in acellular capillary numbers in db/db mice. The HRECs were viable at all concentrations except for the 100 μ M dapagliflozin dose. The scratch wound assay demonstrated a significant reduction in wound closure and rate of migration after 4 and 8 hours of dapagliflozin treatment for the 50 and 100 μ M concentrations.

Conclusions: Overall, dapagliflozin treatment was successful in regulating photopic ERG 'b' wave amplitude, glycemic control and, decreasing acellular capillary numbers and inflammation in vivo, and decreasing the wound closure in in vitro assays. In conclusion, our studies suggest that dapagliflozin could be beneficial in the treatment of DR due to its effect on glycemic control and potential anti-inflammatory and anti-angiogenic action.

ABSTRACT BODY:

Purpose: Soluble epoxide hydrolase (sEH) metabolizes pro-resolving epoxy fatty acids into diols. sEH is a potential therapeutic target for choroidal neovascularization (CNV) in wet age-related macular degeneration (AMD) and other eye diseases. Localization of sEH in the retina is contentious and cross-interpretation among different studies is complicated due to antibody limitations. This study aimed to define the localization of sEH through co-staining with retinal cell type markers and RNAscope in situ hybridization in human AMD and control eyes, and in mouse eyes with and without laser-induced CNV.

Methods: Paraffin sections of eyes from anonymized human wet AMD and control subjects were obtained from the National Disease Research Interchange. 7-week old C57BL/6J mice underwent laser-induced CNV and on day 3 post laser, enucleated eyes were fixed and cryosectioned. Coimmunostaining was done for sEH, retinal pigment epithelium (RPE), and photoreceptor markers. RNAscope was performed using target specific probes for EPHX2 (encoding sEH) and images were acquired by confocal microscopy.

Results: Costaining of sEH with cell type markers revealed that sEH is overexpressed in photoreceptors and RPE cells in areas with degenerative changes. By RNAscope, EPHX2 mRNA was also highly expressed in the pathological conditions compared to controls. EPHX2 mRNA was seen in the inner nuclear layer, outer nuclear layer and RPE of the normal and diseased human and mouse retina.

Conclusions: Previous data showed sEH expression in vasculature, Müller glia, and inner and outer segments of photoreceptors. Here, we also revealed sEH protein and mRNA expression in the RPE. Overexpression of sEH at the protein and mRNA level in CNV and disease-relevant cell types indicates a functional role of sEH in AMD pathophysiology and provides a context to target these cell types for developing pharmacotherapies.

ABSTRACT BODY:

Purpose: To determine the retinal phenotype in mice with knockout of the Bbs10 gene, a component of the BBS/CCT chaperonin complex, and compare with mutation of Bbs1, a component of the BBSome.

Methods: A mouse model of Bardet Biedl Syndrome type 10 (BBS10) was developed by knocking out the Bbs10 gene. ERG, OCT, and visually guided swim assay (VGSA) natural history data were collected and were compared to WT and Bbs1^{M390R/M390R}.

Results: Bbs10^{-/-} mice initially weigh less than littermates (KO 7.2 gms vs WT 13.2 at P19) and are viable only with special feeding and husbandry. By 3 months Bbs10^{-/-} are heavier (KO 32.1 gms vs WT 22.8, p=0.0149). ERG amplitudes are lower than WT by P19 (p=0.006) and VGSA is worse in the dark by 3.5 months (p= <0.0001), and in light by 9 months (p=<0.0001). At the earliest age tested, P21, there is no recordable 5 Hz flicker response in Bbs10^{-/-}. Bbs1^{M390R/M390R} are heavier than WT by 3 months (p=0.012) and have a recordable 5 Hz flicker until 6 months of age. At 6 months of age, Bbs10^{-/-} mice have significantly worse ERG than Bbs1^{M390R/M390R} in dark adapted 0.01 (p=0.0001), Standard Combined Response (p=<0.0001) and Light Adapted 5 Hz flicker (p=0.0476). In the VGSA, Bbs10^{-/-} had worse time to platform than Bbs1^{M390R/M390R} in the 4-6 month dark swim (p=<0.0001) and 9-11 month both light (p=0.0186) and dark (p=<0.0001). On OCT at 2 months old ONL is equal in WT and Bbs10^{-/-} (0.046 µm) but is 26% thinner in Bbs1^{M390R/M390R}. By 6 months Bbs1^{M390R/M390R} is 39% and Bbs10^{-/-} is 13% of WT. WT ONL remained stable to 9 months.

Conclusions: Bbs10^{-/-} mice eyes recapitulate retinal degeneration seen in human BBS10 and resemble retinal degeneration seen in Bbs1^{M390R/M390R} with important differences: Bbs10^{-/-} never develop a 5Hz flicker cone response, and have faster retinal degeneration overall. Our study correlates with recent human data suggesting BBS10 retinopathy is more severe and progresses faster than BBS1 (Heon et al.). Lack of 5 Hz flicker response in Bbs10^{-/-} suggests an early role in cone function for BBS10.

ABSTRACT BODY:

Purpose: Post-operative pseudophakic cystoid macular oedema (PCMO) is a cause of impaired postoperative vision in modern cataract surgery. Known risk factors include intraoperative complications such as posterior capsule rupture and preoperative factors including diabetes mellitus, uveitis, vein occlusions and epiretinal membrane. A paucity in consistency of definition both clinically and with OCT imaging has led to a wide range of conclusions. Our aim is to report statistical baseline demographic and OCT characteristics in a patient cohort from a tertiary eye hospital setting

Methods: A data-warehouse query for all eyes receiving cataract surgery between January 2012 and December 2019 was performed. Inclusion criteria were age above 16, the presence of OCT imaging pre and postoperatively and at least 1 post-operative clinic letter. First and second eyes of patients were included but re-operations on the same eye were excluded. Datatables were merged and a Structured Query Language (SQL) fuzzy logic word search was performed on all electronic letters. Variations on PCMO nomenclature within these letters including, irvine-gass syndrome in both american and english spelling were identified. Sociodemographic (age, sex, ethnicity, socioeconomic deprivation index), presence of diabetes mellitus and OCT longitudinal data were auto extracted and analysed. For validation purposes a subanalysis of random generated patient numbers was performed by hand for comparison on 15% of the entire cohort.

Results: 6287 patients were identified with operations performed on 9126 eyes. 53% were female, 2033 of British descent, 3647 of ethnic background the rest not being stated on the records. The average age at the time of surgery was 68.0 (SD 13.0) and 1804 patients were diabetic. The rate of all complications in this select cohort was 6.5% with a posterior capsular rupture rate of 1.1%. 56.0% of eyes were found to have PCMO. There was no statistical difference in the mean index of multiple deprivation score between those that developed PCMO (mean 5.2, SD 2.5) and those that did not (mean 4.9, SD 2.4, $p = 0.16$).

Conclusions: PCMO remains a risk in modern day cataract surgery regardless of intraoperative complications. OCT post-operatively is useful in its diagnosis and it can manifest sub-clinically. The use of postoperative NSAIDs in those known or at risk of PCMO can reduce its occurrence.

ABSTRACT BODY:

Purpose: Machine learning has a considerable data dependence that increases the resources required for its use. In addition, these algorithms are often black box systems, with unexplained behaviours.

The aim of this study was to develop a machine learning training methodology that is able to achieve accurate, explainable results to classify OCT scans using a small sample size of images, which we have termed interpretable staged transfer learning (iSTL) (Figure 1).

Methods: The iSTL classification algorithm was trained to identify normal, diabetic retinopathy (DR), central serous retinopathy (CSR) and macular hole (MH) OCT images from a target training dataset of 50 images per class. To achieve this the algorithm was initialised with source ImageNet pretrained weights and was then trained on a large bridge dataset of OCT images from a separate open source dataset. Bridge training reduces domain difference between source and target datasets. The algorithm was then trained on the target dataset, which was synthetically expanded using data augmentation at a ratio of 4:1. Data augmentation uses random image transformations to generate new disease appearances from existing data. iSTL was compared to algorithms trained using traditional direct transfer learning (DTL) initialising with ImageNet weights only against unseen target images. Attention maps were generated using SHapley Additive exPlanations (SHAP).

Results: Against unseen data the best iSTL model achieved greater overall accuracy (0.94), mean specificity (0.93), sensitivity (0.93) and f1-score (0.93) compared to DTL (0.86, 0.84, 0.80, 0.80) (Table 1).

Attention maps showed finer attention to pathologically important areas by iSTL. DTL exhibited wider attention across each image, frequently attributing importance to non-clinically significant areas (Figure 2).

Conclusions: Our results show that iSTL scores higher against unseen data compared to DTL, demonstrating the effectiveness of our performance-boosting methods with small sample sizes. To avoid a black-box system and to be able to action results, clinicians must be able to interpret its predictions. Attention maps show that iSTL uses clinical features to make predictions and not uninterpretable abstractions. The sample size used could be gathered in clinical outpatient settings allowing small-scale research to be carried out without significant resources.

TITLE: Mechanisms of hypoxia-induced pathological synaptic plasticity in the visual retinocollicular pathway

SESSION TITLE: Retinal Circuitry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Dumanska, N. Veselovsky, Department of Neuronal Networks Physiology, Institut Fiziologii imeni O O Bogomolca Nacional'na akademii nauk Ukraini, Kiiv, Kiiv, UKRAINE]

Commercial Relationships Disclosure (Abstract): Hanna Dumanska: Commercial Relationship: Code N (No Commercial Relationship) | Nickolai Veselovsky: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinocollicular projections represent the first part of the extrageniculate visual pathway. Its lesion could lead to navigation, orientation and visual attention deficits. We focused on defining processes and mechanisms underlying the early stage of hypoxic injury of the neurotransmission in the originally-developed in vitro model of the retinocollicular pathway.

Methods: The in vitro model was a coculture of dissociated rat retinal cells and superficial superior colliculus (SSC) neurons. Using the paired patch-clamp technique, we recorded pharmacologically isolated NMDA-, AMPA- and GABA_A-mediated postsynaptic currents in SSC neurons by generation action potentials in presynaptic retinal ganglion cells. The local application of hypoxic solutions on pairs of neurons was used to mimic short-term hypoxic states.

Results: The hypoxia induces long-term depression (LTD) of GABA_A neurotransmission ($34 \pm 9\%$, $P < 0.001$, $n = 23$), temporary suppression of AMPA ($32 \pm 7\%$, $P < 0.01$, $n = 22$) and long-term potentiation (LTP) of NMDA transmission ($170 \pm 11\%$, $P < 0.01$, $n = 26$). Also, oxygen deprivation leads to a reduction of voltage-dependent magnesium blockade of evoked NMDA response. All NMDA currents were analyzed in terms of their kinetic characteristics. This analysis revealed that hypoxia-induced LTP and reduction were accompanied by a rapid and irreversible decrease of the decay time of the NMDA currents (from 37.2 ± 5.4 ms to 18.5 ± 7.2 ms, respectively).

Conclusions: The hypoxia-induced LTP of NMDA transmission mediates an increase of calcium ions influx and leads to apoptotic cell death. There are several protective mechanisms to prevent that. The first one belongs to the GABAergic retinocollicular projections. Their physiological role is in the regulation of the activation of NMDA transmission. The next one is the voltage-dependent magnesium blockade of NMDA receptors. Hypoxia impairs both protective mechanisms and enhances the pathological effect of LTP of NMDA transmission. Moreover, data strongly suggest that irreversible increase in NR2A-to-NR2B subunit ratio underlies the hypoxia-induced pathological LTP of retinocollicular NMDA neurotransmission. The results obtained reflect the electrophysiological basis and may serve to reveal new approaches for pharmacological and therapeutic interventions for a hypoxia-involved pathological lesion of the retinocollicular pathway.

ABSTRACT BODY:

Purpose: To correct refractive error-associated bias in optical coherence tomography (OCT) and OCT angiography glaucoma diagnostic parameters.

Methods: OCT and OCT angiography imaging were obtained from participants selected from the Hong Kong FAMILY cohort, a population-based study. Only normal eyes were included in this study. Software on the Avanti AngioVue system were used to measure the peripapillary nerve fiber layer thickness (NFLT) and nerve fiber layer plexus capillary density (NFLP CD), and macular ganglion cell complex thickness (GCCT) and superficial vascular complex vascular density (SVC VD). The glaucoma diagnostic threshold was set at the 5th percentile of emmetropic (-1 to +1 D) eyes.

Results: A total of 1346 eyes from 792 participants were divided into four subgroups for data analysis (Table 1). After accounting for age, gender, and signal strength, multiple linear regression showed strong dependence for NFLT and GCCT on eye axial length (AL), spherical equivalent (SE) refraction, and apparent optic disc diameter (DD) on the OCT scans. Compared to structural parameters, NFLP CD had less dependence and SVC CD had no significant dependence on AL, SE, and DD. Compared to the emmetropic group, the false positive rate was significantly (Chi square test $p < 0.003$) elevated in both the high and low myopia groups for NFLT, NFLP CD, and GCCT (Table 2). Regression-based adjustment of diagnostic parameter with AL or SE significantly (McNemar test $p < 0.04$) reduced the elevated false positive rate. Adjustment using DD was ineffective.

Conclusions: Myopic eyes are biased to have lower NFLT, GCCT, and NFLP CD measurements, leading to elevated false positive rate of glaucoma diagnoses. Regression-based adjustment using AL and SE, but not DD, were effective in eliminating this bias. SVC CD was unbiased by refractive error even without compensation and may be more reliable for glaucoma assessment in high myopes.

Commercial Relationships Disclosure (Abstract): kangwei jiao: Commercial Relationship: Code N (No Commercial Relationship) | Chunling Wei: Commercial Relationship: Code N (No Commercial Relationship) | Libo Xiao: Commercial Relationship: Code N (No Commercial Relationship) | Zhulin Hu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Here, changes in the gene expression, molecular mechanisms, and pathogenesis of inherited retinal degenerations (IRDs) were studied to identify predictive biomarkers for their varied phenotypes and provide a better scientific basis for their diagnosis, treatment, and prevention.

Methods: Differentially expressed genes (DEGs) between retinal tissue from retinitis pigmentosa (RP) mouse models obtained during the photoreceptor cell death peak period (Pde6b^{rd1} at PN11, Pde6b^{rd10} at PN18, Prph^{rd2} at PN21) and retinal tissue from C3H wild-type mice were identified using Illumina high-throughput RNA-sequencing. Co-expression gene modules were identified using a combination of GO and KEGG enrichment analyses and gene co-expression network analysis. CircRNA-miRNA-mRNA network interactions were studied by genome-wide circRNA screening.

Results: Ped6b^{rd1}, Ped6b^{rd10}, and Prph^{rd2} mice had 1,926, 3,096, and 375 DEGs, respectively. Mainly, genes related to ion channels, stress, inflammatory processes, tumor necrosis factor (TNF) production, and microglial cell activation were up-regulated, and genes related to endoplasmic reticulum regulation, metabolism, and homeostasis were down-regulated. Differential expression of transcription factors and non-coding RNAs generally implicated in other human diseases was detected. CircRNA-miRNA-mRNA network analysis confirmed that these factors may be involved in photoreceptor cell death. Moreover, excessive cGMP accumulation causes photoreceptor cell death, and cGMP-related genes were generally mutated.

Conclusions: We screened genes and pathways related to photoreceptor cell death. Additionally, up-stream regulatory factors, such as TFs and non-coding RNA and their interaction networks were analyzed. Furthermore, RNAs involved in IRDs were functionally annotated. Thus, this study lays a foundation for future studies on the photoreceptor cell death mechanism.

ABSTRACT BODY:

Purpose: To evaluate a recently developed multi-meridian air-puff deformation Optical Coherence Tomography (OCT) system (ImTopScanner) for improved early keratoconus (KC) detection in vivo. To investigate deformation asymmetries that are expected to occur due to biomechanical (bm) changes in KC corneas, on two meridians.

Methods: Multi-meridian air-puff OCT (Curatolo, BOE, 2020) was used to collect deformation images of three KC and two healthy corneas in vivo. The system allows deformation imaging along both, horizontal (H) and vertical (V) corneal meridian during a 20ms air-puff excitation. Custom image processing tools quantified (1) the deflection area (DeflArea) between undeformed and deformed cornea, (2) the Asymmetry in DeflArea (ADA), i.e. the difference between nasal/temporal and superior/inferior DeflArea. Eyes were also measured with a Pentacam®. Patient-specific finite element models were generated. In KC eyes, an algorithm detected the cone area and allocated it a separate material. Through an inverse analysis procedure and simulation of air-puff pressure, corneal material stiffness for second-order Ogden material model was estimated.

Results: KC eyes were classified into two mild and one moderate KC eyes, using the Pentacam Topographic Keratoconus Classification (Chen, JCRS, 2019). The mean DeflArea (H and V) at maximum deformation was $2.79 \pm 0.04 \text{ mm}^2$, $3.12 \pm 0.27 \text{ mm}^2$, and $2.88 \pm 0.17 \text{ mm}^2$, from the lowest to highest disease severity, respectively. In the same order, the absolute value of ADA at maximum deformation was $0.02 \pm 0.06 \text{ mm}^2$, $0.14 \pm 0.12 \text{ mm}^2$, $0.18 \pm 0.04 \text{ mm}^2$ (H), and $0.21 \pm 0.08 \text{ mm}^2$, $0.23 \pm 0.02 \text{ mm}^2$, and $0.3 \pm 0.02 \text{ mm}^2$ (V), revealing a lower ADA, but a more pronounced (up to a factor of 3) relative difference between H and V ADA for mild KC eyes. For healthy eyes, ADA remained $< 0.2 \text{ mm}^2$. Simulations estimated a $35.5\% \pm 10.0\%$ stiffness reduction in the cone area of KC eyes in comparison to outside the cone at 4% strain.

Conclusions: Initial results show that multi-meridian deformation imaging can aid in early detection of corneal bm changes taking place in KC. Differences in deformation asymmetries between orthogonal meridians may be more pronounced in early disease stages, where corneal geometry has not been significantly altered. Consideration of two meridians and identification of KC cone location are important for simulating realistic corneal material behavior in KC eyes.

TITLE: Galectin 8 impairs TLR4 signaling and dampens innate immune response to *P. aeruginosa* infection in mouse corneas

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.A. Panjwani, Z. Cao, A. Ramadan, Ophthalmology, Tufts University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Noorjahan Panjwani: Commercial Relationship: Code N (No Commercial Relationship) | Zhiyi Cao: Commercial Relationship: Code N (No Commercial Relationship) | Abdulraouf Ramadan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The current study was designed to examine the role of a carbohydrate-binding protein, galectin 8, (Gal-8) in *P. aeruginosa* (PA) keratitis pathogenesis, and to characterize the mechanism by which Gal-8 modulates innate immune response in PA keratitis.

Methods: Two approaches were used. In the first, corneas of C57BL/6 wild-type (WT) or Gal-8 knockout (Gal-8 KO) mice were infected with PA. The severity of bacterial keratitis was graded on day 1 and day 3 post-infection (p.i.) by slit lamp using a scoring system ranging from 0 to 4, and then corneas were harvested for bacterial enumeration. In the second approach, to study the mechanism by which Gal-8 modulates the innate immune response: (i) affinity chromatography experiments were conducted to determine whether specific molecules of the TLR-4 complex bind to Gal-8, and (ii) in vitro experiments were performed to determine whether the addition of exogenous Gal-8 influences the activation of TLR-4 pathway in bone marrow-derived macrophages (BMDMs) stimulated with LPS.

Results: Gal-8 KO mice exhibited less severe infection in comparison to WT mice as indicated by lower opacity scores and reduced bacterial load. In vitro studies showed that: (i) Gal-8 binds to CD14 but not to TLR4 in a carbohydrate-dependent manner, (ii) the addition of exogenous rGal-8 significantly inhibits the delivery of LPS from CD14 to MD2/TLR4 and impairs activation of TLR4 pathway in BMDMs stimulated with LPS as indicated by a decrease in TNF α , IL-6, MD-2 and MyD88 expression and I κ B phosphorylation.

Conclusions: Gal-8 modulates the pathogenesis of PA keratitis by inhibiting the activation of TLR4 pathway.

ABSTRACT BODY:

Purpose: Transforming growth factor beta 2 (TGFβ2) plays an important role in the pathogenesis of primary open angle glaucoma (POAG). TGFβ2 induces pathological changes in the trabecular meshwork (TM) and dysregulates microRNA (miRNA) expression. MiRNAs are cell and context specific epigenetic regulators of cellular functions and signalling pathways. Small RNA-sequencing was performed using cultured normal human TM cells treated with TGFβ2 to identify the TGFβ2 miRNAome.

Methods: Primary normal human TM cell cultures (n=5) were treated with TGFβ2 (5ng/mL) for 24 hours. RNA was extracted using Qiagen AllPrep kit and small RNA-sequencing was performed at the Genomics Core Facility in Queen's University Belfast following QIAseq miRNA library prep with sequencing on the Illumina platform. Bioconductor was used for primary miRNA mapping and secondary differential expression. MiRNAs were analysed using miRTargetLink, TargetScan and miRTarBase to detect strong experimentally validated gene targets, and miRNAs with strong targets were run through KEGG analysis using DIANA mirPath v.3 software and miRPathDB to identify enriched pathways. MiRNA qPCR was performed to validate and replicate the small RNA-sequencing data in four independent biological samples for 10 miRNAs of interest.

Results: Significant (p<0.01) differential miRNA expression was seen for twenty-two miRNAs including miR-503, miR-145 and miR-143. At a significance level of p<0.05, seventy-two miRNAs were significantly altered of which five are implicated in the regulation of TGFβ signalling. qPCR confirmed significant differential miRNA expression in five miRNAs of interest. Enriched pathways regulated by these miRNAs included modulation of TGFβ signalling and the Hippo, MAPK and TNF signalling pathways. The identified SMAD-regulated miRNAs play roles in senescence, inflammation, and fibrosis.

Conclusions: Understanding the role of the TGFβ2 miRNAome in the TM will improve our understanding of physiological and pathological states in the TM. MiRNAs are epigenetic regulators of signalling pathways and the ability to therapeutically manipulate miRNAs with inhibitors or mimics may be an efficient therapeutic approach in POAG.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRD) are a group of conditions with progressive photoreceptor or RPE dysfunction resulting in blindness. Most IRDs lack effective treatments and novel therapies are needed to preserve vision. Phenotype-based screening of randomised compound libraries enables unbiased identification of first-in-class drugs. Here, we combine biological and virtual screening processes to identify novel compounds which rescue vision in a zebrafish model of IRD.

Methods: Phenotype-based drug discovery was performed on the atp6v0e1^{UCD6} zebrafish model of impaired vision screening a DIVERSet-Exp MF6 randomised compound library. 80 drug compounds were combined into 18 orthogonal drug pools for each plate testing. Visual behaviour was analysed at 5 days post-fertilisation by optokinetic response. Identified hits undergo iterative rounds of ligand-based computational screening to identify 3D analogues. A proof-of-concept virtual screen to identify mimetics of known neuroprotectant 7,8-dihydroxyflavone (7,8-DHF) was performed using Cresset Blaze™ software. Additional triaging was performed using Cresset Forge™ and KNIME.

Results: The orthogonal pooling protocol successfully detected visual rescue of atp6v0e1^{UCD6} in tubastatin A spiked pools (positive control) with 3-fold visual improvement and no toxicity in 10 µM pools of each drug. Orthogonal drug pooling is ongoing with 480 compounds tested to date. 7.4% of drug pools display a visual improvement of ≥4 fold with a toxicity level of 3.7%. An initial raw list of 2,000 molecules from a database of 16 million compounds was obtained from the Blaze™ screen. Manual analysis by 2D similarity calculations and murcko clustering shortlisted a final 25 compounds for biological validation.

Conclusions: We present a bespoke drug discovery workflow combining in vivo phenotype-based screening of visual behaviour cross informed with computational methods. This process successfully detects pools and single drugs restoring vision in atp6v0e1^{UCD6}. Drugs identified will undergo iterative rounds of computational/ biological refinement to provide further insights into IRD mechanisms and therapeutic development.

TITLE: RIP3-Mediated Necroptosis Triggers the Activation of NLRP3 Inflammasome in Dry Eye

SESSION TITLE: Dry eye and Tear film

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. WANG, X. Zuo, J. Yuan, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure (Abstract): BOWEN WANG: Commercial Relationship: Code N (No Commercial Relationship) | Xin Zuo: Commercial Relationship: Code N (No Commercial Relationship) | Jin Yuan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore the role of necroptosis in dry eye disease(DED), and reveal its underlying mechanisms upon inflammatory initiation.

Methods: C57BL/6 wild-type(WT), RIP3^{-/-}, and NLRP3^{-/-} mice were exposed to desiccating stress (subcutaneous scopolamine [0.5 mg/0.2 mL] 3 times a day, humidity < 30%) for 7 days to establish experimental dry eye model. Cornea fluorescein staining, tear secretion, numbers of conjunctival goblet cells were assessed. Ultrastructural features of cell death were examined by transmission electron microscope(TEM). Western blot assays and immunofluorescence staining were used to measure the changes of RIPK3, MLKL, NLRP3, IL-1b, etc. mRNA expression was analyzed by RNA –sequencing(RNA-seq) and quantitative PCR.

Results: We observed extensively swollen and necrotic form of death of corneal epithelium detected by TEM in dry eye mouse model. Moreover, RNA-seq and GO analysis showed that both necroptosis and inflammation-related pathway were significantly sensitized. Western blot and immunofluorescence assay showed that an remarkably increase of RIP3, MLKL and NLRP3, IL1β in WT(DED) mice. Interestingly, we discovered that specific suppression of necroptosis in RIP3^{-/-}(DED) mice was able to alleviate the clinical parameters and abolished the activation of NLRP3, IL1β. However, although NLRP3^{-/-}(DED) mice also had obviously reduced corneal defects compared to WT(DED) mice, insignificant changes of necroptosis markers were detected. Accordingly, our data suggested that subconjunctival injection of NEC-1, a necroptosis inhibitor showed remarkable treatment effect in DED mice and inhibited NLRP3-related inflammation activation.

Conclusions: RIP3-mediated necroptosis in corneal epithelium activates the NLRP3 inflammatory pathway and promotes the development of DED.

ABSTRACT BODY:

Purpose: To explore whether geographic atrophy (GA) in age-related macular degeneration (AMD) consists of two or more partially distinct phenotypic subtypes and to test genetic associations. This is important since GA subtypes driven by different genetic factors might require customized therapeutic approaches.

Methods: AREDS2 participants with incident GA were eligible (one eye per participant). Phenotypic features from reading center grading of fundus photographs were subjected to cluster analysis (Table), by both k-means and hierarchical methods. In pre-specified hypothesis tests, identified clusters were compared by four pathway-based genetic risk scores: complement (19 SNPs/6 loci), extracellular matrix (6 SNPs/5 loci), lipid (7 SNPs/4 loci), and ARMS2 (1 SNP/locus).

Results: The cohort comprised 598 individuals (mean age 74y). In cross-sectional phenotypic analyses, k-means identified two clusters: A and B (367/231 members, respectively), while hierarchical clustering identified four (Figure): C-F (451/112/12/5). In longitudinal phenotypic analyses, k-means identified two: G and H (310/288); hierarchical clustering identified none. The groups of clusters were not correlated with one other by membership (Pearson's $r \leq 0.20$). In cross-sectional analyses, GA configuration was the predominant factor for A-E membership. In longitudinal analyses, smoking status determined G vs H. Despite adequate power, pairwise cluster comparison by the four genetic risk scores demonstrated no significant differences ($p > 0.05$ for all).

Conclusions: In this large study, cross-sectional cluster analyses revealed GA subtypes defined principally by GA configuration. However, these subdivisions were not replicated in longitudinal analyses. Given the absence of significant cluster-genotype associations, for any eye with GA, physicians are unlikely to infer the main genetic driver of GA from phenotype alone. The inconsistencies in optimal cluster numbers and characteristics suggest that GA may show continuous phenotypic variation across a spectrum, rather than consisting of phenotypic subtypes that remain partially distinct over time, with separate genetic etiologies.

ABSTRACT BODY:

Purpose: To evaluate the association between the presence of age-related macular degeneration (AMD) and progression of diabetic retinopathy (DR).

Methods: We retrospectively identified patients with at least mild nonproliferative diabetic retinopathy (NPDR), with or without AMD at the Joslin Diabetes Center. Inclusion criteria were age >50yrs, baseline visit between 2007-2014, >3 years of follow-up, and ICD-9/10 diagnosis code of mild to severe nonproliferative diabetic retinopathy (NPDR) with or without AMD. Patients were excluded if they had received prior anti-vascular endothelial growth factor (VEGF) injections or had proliferative DR (PDR) or neovascular AMD at baseline. AMD grading used the Age-Related Eye Disease Study classification system. DR progression was defined as >2-step progression in clinical grade or progression to PDR. Multivariable Cox regression analysis and Cox proportional hazards regression model were used to assess factors associated with progression of DR. Mediation analysis was performed in patients who had both baseline hemoglobin A1c (HbA1c) and average HbA1c values to investigate whether average HbA1c mediates the association between the presence of AMD and progression of DR.

Results: After exclusion, there were 223 eyes (138 patients) with DR with AMD and 476 eyes (260 patients) with DR without AMD included in the analysis. A total of 61 eyes (9.87%) had either ≥2-step progression of DR or progression to PDR during the follow up period (50 eyes (7.5%) had ≥2-step progression of DR and 46 eyes (6.6%) progressed to PDR). The rates of ≥ 2-step DR progression (HR 0.34, 95% CI 0.12~0.97, p=0.044) and progression to PDR (HR 0.34, 95% CI 0.13~0.90, p=0.0304) were lower in eyes with AMD compared to eyes without AMD in multivariable Cox regression analysis. Mediation analysis revealed that the association between the presence of AMD and decreased progression of DR was not affected by diabetic control measured by average HbA1c. Subgroup analysis revealed that there is a possible protective effect against ≥2-step DR progression and/or progression to PDR with lower HbA1c at baseline and current smoking status.

Conclusions: There is a lower rate of DR progression in patients with mild to severe NPDR when AMD coexists at baseline compared to those without AMD. The presence of AMD may have a protective effect against DR progression independent of diabetic control measured by HbA1c.

TITLE: Analgesic Efficacy for anti-VEGF Intravitreal Injections

SESSION TITLE: Anti-VEGF therapy for AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Oberst, C. Fraser, Ophthalmology, University of Kentucky Medical Center, Lexington, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Garrett Oberst: Commercial Relationship: Code N (No Commercial Relationship) | Claire Fraser: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal specialists continue to debate the best method for achieving adequate analgesia prior to intravitreal injections. This was an observational study at a large academic center to assess whether differences in analgesic procedure resulted in differences in pain levels.

Methods: Observational study of patients receiving intravitreal anti-VEGF injections at a university medical center. Inclusion criteria included any patient receiving anti-VEGF injections. Data including age, race, gender, diagnosis, number of injections at given visit, speculum use, and anti-VEGF medication administered were collected. Data regarding the numbing procedure were recorded including all times relative to injection and number of separate administrations of proparacaine, betadine, and akten gel. Patients were asked to rate their pain at the time of injection on a scale of 1-10 using a visual analog pain scale.

Results: 85 patients and 103 total eyes were injected. Those who received more than one drop of proparacaine perceived less pain than those receiving one or zero drops (2.13 vs. 3.27, $p=0.019$). Pain scores decreased with longer intervals from last akten gel administration to time of injection (3.33 for under 5 minutes vs. 2.86 for 6-10 minutes vs. 2.08 for over 11 minutes, $p=0.08$). While not statistically significant, patients who received injections from residents or fellows perceived higher pain scores than those from attending physicians (3.47 vs. 2.64, $p=0.10$). No statistically significant difference in pain perception was found based on demographic differences, medication injected, or speculum use. No difference was found regarding number of administrations or timing of proparacaine or betadine. Additionally, there was no statistically significant difference in pain scores regarding number of administrations of akten gel.

Conclusions: Only those who received more than one proparacaine drop were found to have statistically significant lower scores than those who received one or zero drops. Most variables measured in this study led to no difference in pain score. The data from this study can be used to improve the analgesia and overall patient experience prior to receiving intravitreal injections.

Commercial Relationships Disclosure (Abstract): Yinga Wu: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Brynn: Commercial Relationship: Code N (No Commercial Relationship) | Jing Ma: Commercial Relationship: Code N (No Commercial Relationship) | Shusheng Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular fibrosis can cause vision loss without treatment available. Subretinal fibrosis occurs in response to choroidal neovascularization (CNV) in wet Age-related macular degeneration (AMD), which is not treatable by anti-VEGF therapy. We have reported that miR-24 inhibits CNV in mice by regulating actin cytoskeleton remodeling. The purpose of the project is to define the function of miR-24 in subretinal fibrosis. We hypothesize that miR-24 overexpression can repress RPE-derived epithelial-mesenchymal transition (EMT) and subretinal fibrosis in AMD disease.

Methods: ARPE-19 cells or primary human RPE (hRPE) cells were treated with pre-miR-24 or adenovirus expressing miR-24 (Ad-miR-24). miR-24 overexpression was quantified by qRT-qPCR. EMT-associated gene expression in TGF- β 2 treated RPE cells was measured by Western blot and immunostaining. The expression of potential miR-24 target genes, SMAD3, LIMK2 and PAK4, were measured by Western Blot after miR-24 overexpression with or without TGF- β 2 treatment. Novel miR-24 target gene, SMAD3, was confirmed by luciferase assays. Lentivirus-mediated overexpression of target genes were used to rescue miR-24 overexpression phenotype. Stress fiber formation was visualized by Phalloidin staining and quantified by measuring the ratio of G-actin/F-actin. Student's t-test was used for statistical analysis.

Results: MiR-24 was significantly increased in APRE-19 or hRPE cells using Ad-miR24 or pre-miR-24. Markers of myofibroblast and fibrosis, including α -SMA, Fibronectin, Collagen III and Collagen I, were induced an in vitro EMT and fibrosis model. Overexpression of miR-24 repressed expression of these proteins as shown by Western blot analyses and immunostaining. SMAD3, a major protein critical for fibrosis by mediating TGF- β signaling, was identified as a miR-24 target gene, and was downregulated by miR-24 overexpression. Overexpression of miR-24 target genes SMAD3 or LIMK2 partially rescued miR-24 overexpression phenotype. miR-24 also repressed stress fiber formation and increased ratio of G-actin/F-actin, consistent with downregulation of its verified target protein LIMK2 and PAK4.

Conclusions: MiR24 overexpression prevents EMT and fibrosis and actin cytoskeleton dynamics through targeting SMAD3, LIMK2 and PAK4 in RPE cells. MiR-24 can be investigated as a therapeutic target for subretinal fibrosis in vivo.

ABSTRACT BODY:

Purpose: To study the effect of ABCA4 mutation c.5714+5G>A on retinal structure and mRNA.

Methods: Sixteen patients were divided into two groups: group 1 harboured splicing mutation c.5714+5G>A in trans with a null mutation (6 patients); group 2 had two null mutations (10 patients). Visual acuity, autofluorescence and optical coherence tomography of the right eyes were analysed. Areas of definitely decreased autofluorescence (DDAF) and thickness of the outer nuclear layer (ONL) in the macula were measured. Correlation between the degree of retinal pigment epithelium (RPE) atrophy (DDAF area) and loss of photoreceptors (ONL thickness) was compared between groups using multiple linear regression. Mann-Whitney U Test was used for comparing sets of data. The effect of c.5714+5G>A on RNA splicing was analysed using reverse transcription (RT)-PCR of mRNA isolated from patient-derived photoreceptor progenitor cells (PPCs).

Results: Age at the exam did not differ significantly between the two groups (33.5 vs 20.5 yrs; $p>0.05$). However, group 1 patients had significantly later median age of onset (17.5 vs 8.0 yrs; $p<0.01$) and significantly better visual acuity (0.2 vs 0.02; $p<0.05$). Median ONL thickness was significantly higher in group 1 (15.9 μm vs 0.5 μm ; $p<0.01$), whereas median DDAF area was comparable between the groups (12.7 mm^2 vs 15.1 mm^2 ; $p>0.05$). Multiple linear regression showed a significant correlation between ONL thickness and DDAF area within each genotype group. For a similar RPE atrophy area, patients in group 1 have much better photoreceptor preservation ($p<0.01$). RT-PCR of mRNA from PPCs from a patient carrying c.4539+1G>T and c.5714+5G>A using primers in exons 38 and 44 showed a major normal product and minor exon 40 and exon 39/40 deletion products.

Conclusions: Patients harbouring ABCA4 mutation c.5714+5G>A displayed significantly milder phenotypes for all parameters, which is in accordance with our RNA results in PPCs and previous in vitro splice assays, suggesting that this is a moderately severe variant. Thicker ONL layer when compared to double null patients with DDAF of similar size suggests different disease pathogenesis characterised by predominant RPE loss and relative photoreceptor sparing in association with c.5714+5G>A allele.

ABSTRACT BODY:

Purpose: Astrocytes within the optic nerve head undergo actin cytoskeletal rearrangement early in glaucoma, prior to the development of tissue stiffening. Elevated transforming growth factor (TGF) β 2 levels within astrocytes have been described in glaucoma, and TGF β signaling induces actin cytoskeletal remodeling and extracellular matrix (ECM) stiffening in many tissues. A key mechanism by which astrocytes sense and respond to external stimuli is via mechanosensitive ion channels. Here, we tested the hypothesis that inhibition of mechanosensitive channels will attenuate TGF β 2-mediated optic nerve head astrocyte actin cytoskeletal remodeling and ECM stiffening.

Methods: Primary optic nerve head astrocytes were isolated from C57BL/6J mice and cell purity was confirmed by immunostaining. Astrocytes were treated with control medium, 5 ng/ml TGF β 2, 500 nM GsMTx4 (a mechanosensitive channel inhibitor), or 5 ng/ml TGF β 2 + 500 nM GsMTx4 for 48 h. FITC-phalloidin staining was used to assess the formation of f-actin stress fibers and to quantify the presence of crosslinked actin networks (CLANs). Cell reactivity was determined by immunostaining for GFAP. 3D hydrogels were made by mixing primary astrocytes with functionalized ECM components, UV-crosslinked using a photoinitiator, and subjected to the above treatments for 7 d. Live/dead staining was used to confirm astrocyte viability and hydrogel stiffness was measured using rheometry.

Results: Primary optic nerve head astrocytes were positive for the astrocyte marker GFAP and negative for markers for microglia (Iba1) and oligodendrocytes (OSP1). Increased %CLAN-positive cells were observed after 48-h treatment with TGF β 2 vs. control (23.8% vs 5.3%, $p < 0.0001$). Co-treatment with GsMTx4 decreased %CLAN-positive cells vs. TGF β 2 treatment (12.4% vs 23.8%, $p < 0.0001$) and decreased the presence of f-actin stress fibers. TGF β 2 treatment increased GFAP fluorescence intensity, which was decreased when co-treated with GsMTx4 ($p < 0.05$). Cells within hydrogels maintained $>90\%$ viability after 7 d. Hydrogels treated with GsMTx4 were less stiff when compared to control and TGF β 2-treated hydrogels ($p < 0.01$).

Conclusions: Our data suggest inhibition of mechanosensitive channel activity as a potential therapeutic target to prevent actin cytoskeletal remodeling and tissue stiffening within the optic nerve head in glaucoma.

ABSTRACT BODY:

Purpose: To examine the differences in diurnal optic nerve head (ONH) blood flow biomarkers between male and female subjects with and without open-angle glaucoma (OAG) as measured by optical coherence tomography angiography (OCT-A).

Methods: 34 subjects (21 OAG: 7 male, 14 female; and 13 healthy: 6 male, 7 female) were assessed for ONH and radial peripapillary capillary layer (RPC) flow area (mm^2), vessel density percentage (NH VD%, RPC VD%), and flow index (NH index, RPC index) using OCT-A (RTVue XR Avanti SD-OCT with AngioVue® software, Optovue, Fremont, CA, USA) at 9:00, 11:00, 14:00, 16:00, and 18:00 during a single day. Results were analyzed using two-sample t-tests assuming unequal variances to analyze the differences between genders. P-value<0.05 was considered statistically significant.

Results: The OCT-A blood flow parameters were significantly lower in male OAG patients compared to female OAG patients at 18:00 (ONH flow area: $2.33 < 2.84 \text{mm}^2$, $p=0.012$; RPC flow area $1.25 < 1.66 \text{mm}^2$, $p=0.016$; NH VD% $66.55 < 75.67$, $p=0.041$; NH index $0.07 < 0.08$, $p=0.05$). There were no statistical significant differences between OAG male and female in RPC VD% ($p=0.075$) or RPC index at 18:00 ($p=0.16$). No other statistically significant differences were found at 9:00, 11:00, 14:00 or 16:00 time points between male and female OAG patients, or between healthy male and female subjects at any time point ($p>0.05$).

Conclusions: Our findings highlight possible diurnal gender-based variance in OCT-A ocular blood flow biomarkers of OAG patients, warranting further study to confirm our results.

ABSTRACT BODY:

Purpose: Fluorescence lifetime (FLT) is a fluorophore-specific property and cellular FLT may be influenced by cell metabolic states. Fluorescence lifetime imaging ophthalmoscopy (FLIO) is a new method that enabled the measurement of FLT of ocular fundus. The purpose of this study was to investigate the fundus FLT of mouse models of retinal degeneration with FLIO.

Methods: Two mouse models of age-related macular degeneration (AMD), apolipoprotein E (ApoE) deficient mice (ApoE^{-/-}) and nuclear factor erythroid 2-related factor 2 (NRF2) deficient mice (Nrf2^{-/-}), and wild type mice (control; C57BL/6J) were investigated monthly from 3 months old (24 mice per strain). Under general anesthesia, slit lamp Ophthalmoscopy, FLIO, optical coherence tomography (OCT) and fundus photography were conducted. The mice were euthanized either at 6 months old or 11 months old. The blood plasma was collected to examine the level of total antioxidant capacity (TAC). The frozen sections of the enucleated eyes were assessed with lipid stainings (Oil Red O).

Results: AMD-like pathological findings (e.g. drusen) were observed after 7 months old in some mice of AMD models. The mean FLT (τ_m) was generally shortened with age in all groups. Both AMD models showed significantly shorter τ_m than the control at 4 months old. After that, τ_m of ApoE^{-/-} mice was further shortened to a larger extent than the control until 11 months old in both spectral channels, whereas Nrf2^{-/-} mice showed an apparently prolonged τ_m in the long spectrum channel. The strongest lipid staining of the Bruch's membrane was observed in ApoE^{-/-} mice at 11 months old. The blood TAC of ApoE^{-/-} mice was significantly higher than the control at 6 and 11 months. Nrf2^{-/-} mice showed higher TAC at 6 months old than control, but then decreased and no more difference was found from the control group at 11 months old.

Conclusions: Both mouse models of AMD showed a temporarily shorter fundus FLT than the wild type at a very early time point, presumably owing to the metabolic activation due to stress. After that, however, the fundus FLT of these two strains progressed totally differently over time. The systemic antioxidant capacity could be associated with this difference. These results strongly suggest that FLIO may indicate early changes of metabolic and redox states of the retina prior to the onset of degenerative retinal disorders.

ABSTRACT BODY:

Purpose: Ocular graft versus host disease (OGvHD) is a common complication of allogeneic hematopoietic stem cell transplantation (HSCT) and frequently manifests as keratoconjunctivitis sicca (KCS). The aim of this study was to evaluate the efficacy of a single subconjunctival (SC) dose of adeno-associated virus (AAV) gene therapy encoding human leukocyte antigen G (HLA-G) to induce ocular immune tolerance and inhibit clinical signs of OGvHD.

Methods: The major histocompatibility mismatch chronic OGvHD murine model was created, as described by Perez (2016; doi:10.1016/j.bbmt.2016.07.012). Animal use was approved by the NC State University IACUC (protocol #20-122-B). To create the murine OGvHD model, bone marrow (BM) and splenocytes were collected from male C57BL/6 (n=4) mice 6-8 weeks of age. Female BALB/c mice (n=12), aged 6-8 weeks, were administered 700cGy total body X-ray irradiation, as optimized in our preliminary studies. Two hours after irradiation, mice were injected into a lateral tail vein with 1×10^7 BM cells and 1×10^6 splenocytes. Following injection, body weights and tear production (phenol red test) were recorded, and scores (0-4) (observer blinded to treatment groups) of the eyelid margins, corneal opacity, and corneal fluorescein were collected through day 44 after HSCT. At 7 days following HSCT, mice received in both eyes either a single SC injection of AAV8-HLA-G1&5 (1×10^9 vg/eye), no treatment (n=4), or 2µL of CsA 1% solution twice daily (n=4).

Results: Eyelid scores of eyes dosed with AAV-HLA-G were significantly lower than untreated or CsA treated eyes from 24-44 days after HSCT ($p < 0.03$ Wilcoxon). Cornea scores of eyes dosed with AAV-HLA-G were significantly lower than untreated or CsA treated eyes from 27-44 days after HSCT ($p < 0.01$, Wilcoxon). Fluorescein scores of eyes dosed with AAV-HLA-G and CsA were significantly lower than untreated eyes from 30-44 days after HSCT ($p < 0.02$, Wilcoxon). No statistically significant difference in weight or tear production was observed between any of the three treatment groups.

Conclusions: These results further validate the function of HLA-G in the murine model, indicate that the SC therapeutic route targets relevant ocular tissues, and provides strong support that HLA-G-based gene therapy will be an effective single vector treatment for OGvHD. Further evaluation of AAV-HLA-G based therapeutics are warranted for ocular surface and intraocular immune-mediated diseases.

ABSTRACT BODY:

Purpose: The diffractive efficiency is traditionally defined as the ratio of usable energy relative to total incident energy for individual diffraction orders of a diffractive optical element. For many of the current presbyopia-correcting intraocular lenses the traditional methods for determining light distribution are not suitable, because of overlapping foci or even lack of discrete foci. The goal of this study was to develop a new method of determining the image (light) intensity produced by diffractive ophthalmic lenses over the visual defocus range from far to near.

Methods: As in our previous study, light intensities were measured in an optical setup consisting of a white light source, slit target, collimator, cornea, liquid cell, relay lens and imaging camera. Care was taken that the incoming light intensity was kept at a constant level for all measurements. The image (line spread function, LSF) was recorded over a range of defocus positions.

Light intensity was evaluated over the central part of the LSF up to the first minimum of the image of a diffraction limited system (Airy disk for white light).

Design features measured included diffractive multifocal and extended depth of focus IOLs. An aspherical refractive monofocal lens which fully corrects the corneal monochromatic aberrations was used as a reference lens.

Results: With the new method, 41 LSF images were recorded for each lens, over a defocus range from -4 to +1 diopter. Considering the linear relationship between the logarithm of the light intensity and visual acuity (Sheedy 1984), the measurement results are evaluated as $\log(\text{intensity})$. The relative light intensity (RLI) is defined as $\log(\text{intensity})$ of the study IOL divided by the $\log(\text{intensity})$ of the monofocal reference IOL. For the distance focus, LRI is 0.93, 0.94 and 0.95 for the multifocal IOL, the extended depth of focus IOL, and the hybrid IOL, respectively.

At defocus levels exceeding -1 diopter, LRI was larger than 1.0 for all study lenses, which can be attributed to their presbyopia correcting nature, i.e. being multifocal or having an extended depth of focus.

Conclusions: Measurements of through focus light intensity can be used to assess the light distribution and present the results in a clinically relevant metric, here called the relative light intensity (LRI).

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) and glaucoma are both leading causes of vision loss. Glaucoma affects the optic nerve while AMD affects the macular retinal pigment epithelium. Both result in vision impairment, with AMD primarily affecting central vision and glaucoma typically affecting peripheral vision. Each condition has been associated with increased systemic comorbidities compared to control populations. However, no literature discusses comorbidities seen in patients simultaneously affected with glaucoma and AMD. We investigate whether there is an increased association with other systemic conditions in these patients, as presenting with both ophthalmologic conditions may provide greater insight into a patient's overall health or response to stress.

Methods: The i2b2 interface was used to access the Carolina Data Warehouse, which contains clinical data for patients seen in the University of North Carolina Health System. Datasets of patients seen from April 2004 to June 2018 were created by searching ICD codes, yielding a set comprised of patients with each of the following diagnoses: glaucoma only, AMD only, glaucoma and AMD, and cataracts. Within each group, prevalence of systemic diseases was searched, and a Friedman's two-way analysis of variance compared prevalence between groups. Groups were further compared on race, age, and sex distributions to rule out confounders.

Results: The i2b2 database identified 5243 patients with glaucoma only, 6726 with AMD only, 402 with combined disease, and 25450 with cataracts only. Patients with both glaucoma and AMD compared to groups with glaucoma alone and cataracts alone were more likely to have heart failure ($p=.036$, $.036$, respectively) and dementia ($p=.023$, $.00349$). Demographic analysis indicated a statistically significantly older population with both glaucoma and AMD compared to glaucoma alone, but no other differences were seen between group demographics.

Conclusions: The significantly increased prevalence in heart failure and dementia in the group with both glaucoma and AMD may suggest an increased propensity to developing these diseases in patients with both ophthalmologic conditions. These associations and underlying pathologic mechanisms may provide insight into health management and prognostication for these individuals.

ABSTRACT BODY:

Purpose: Central choroidal dystrophies comprise degenerative diseases of the retina where choroid is also affected. The main cause of these dystrophies is related to mutations in the PRPH2 gene involved in the formation and maintenance of outer segments discs of photoreceptors. This study analyzes the structural changes of the retina and the vascular network in some members of a Spanish family with different choroidal dystrophies.

Methods: Cross-sectional and comparative study of 4 family members. OCT images in the macula were analyzed quantitative and qualitatively. Outer and inner retina measurements were done in the fovea and parafovea. Slabs of superficial vascular plexus, intermediate and deep capillary plexuses and choriocapillaris and choroid vessels were obtained to study their morphology and possible degeneration signs. Alterations in the foveal avascular zone (FAZ) were also described.

Results: Different clinical findings were present among family members with the same PRPH2 mutation: half were diagnosed with central areolar choroidal dystrophy (CACD) while the rest showed extensive chorioretinal atrophy (ECA). Retinal degeneration was mainly located at fovea and parafovea in CACD patients and the outer nuclear layer thickness in the FAZ was considerably reduced. ECA patients showed a more general degeneration that spread out through the central retina. The third outer hyperreflective band in OCT, considered as outer segments phagocytosed by the retinal pigment epithelium, was the first one disrupted of the four outer bands. Vascular degeneration was similar among them. Capillary drop out areas were larger in the deep capillary plexus. Microaneurysms were mainly detected in the superficial vascular plexus and were more easily found at early stages. Intraretinal microvascular abnormalities and vascular loops were observed in retinal plexuses. Extensive degeneration areas of choriocapillaris were seen in OCTA images which allowed to visualize the structure of choroid vessels.

Conclusions: Same PRPH2 mutation among different family members can cause phenotypic variations since youth. Clinical diagnosis and stage disease can be more easily defined in chorioretinal dystrophies using OCT and OCTA. Support. FEDER-PID2019-106230RB-I00. FPU16/04114, FPU18/02964. ABSTRACT BODY:

Purpose: To evaluate the effect of a new tear substitute containing hyaluronic acid (HA) and a low dose (0.001%) of hydrocortisone in patients with dry eye disease in a randomized, double-masked pilot study.

Methods: Dry eye and treatment outcomes were assessed by SANDE questionnaire, Schirmer I test, tear BUT, conjunctival staining by using a new formulation of liquid lissamine green, and fluorescein corneal staining (baseline, day 7 and 28). Immune cells (CD45⁺, CD14⁺, CD4⁺, CD8⁺) were detected by impression cytology and flow cytometry at baseline and day 28. All patients (n=40) received fluorometholone eye drops bid for one week. The study group used the new tear substitute (Idroflog, Alfa Intes, Italy) bid for one week and qid for three weeks; the control group used HA alone with the same regimen. Intraocular pressure (IOP) was recorded at baseline, day 7 and 28.

Results: Severity and frequency of symptoms were improved in both groups at day 7 and 28. Fluorescein and liquid lissamine green staining were significantly decreased at day 30 in the study group respect to the control ($p \leq 0.05$). No significant changes were recorded for Schirmer test and BUT. While CD45⁺ cells were decreased in both groups, CD14⁺ cells and the CD4/CD8 ratio significantly decreased in the study group only ($p \leq 0.05$). None of the treated eyes showed significant increase in IOP at day 28.

Conclusions: The results show the efficacy of a new a tear substitute to improve signs of dry eye, and to control inflammation over time. Further results are expected at a longer follow up (6 months), but the importance of chronic use of tear substitutes containing low percentage of steroids in dry eye seems to be demonstrated.

ABSTRACT BODY:

Purpose: Uveal melanoma is the most common primary intraocular tumor in adults with over 5 million cases per year worldwide. Choroidal melanoma accounts for 90% of these tumors. Due to the high risk of metastasis, choroidal melanoma is almost always treated and therefore the natural growth of untreated choroidal melanoma is unknown. In this study, we attempted to model the growth pattern of untreated choroidal melanoma and analyze the natural progression of the disease.

Methods: We conducted a systematic search of Clinicaltrials.gov, Ovid MEDLINE, PubMed for unindexed materials, Ovid Embase, Science Citation Index Expanded, and the Cochrane Library for publications involving untreated choroidal melanoma tumor size published prior to April 30, 2019. An exponential model of tumor growth was developed using tumor height over time from individual subjects. To correct for differences in the time of enrollment for subjects, a temporal translation factor was applied to convert "time after enrollment" to "inferred age of tumor." Regression analysis was used to find optimal tumor doubling time and initial tumor height. The relationship between tumor volume and tumor height was modeled as a cubic function using a subset of the data. From this relationship, tumor volume and volume doubling time were estimated from tumor height and height doubling time, respectively.

Results: Forty-four patients from three studies were identified that met our inclusion criteria. The tumor height data were well described by our exponential model which estimated a tumor height doubling time of 27.2 months and initial tumor height of 1.05mm ($R^2 = 0.77$). Our model of tumor volume as a cubic function of tumor height found that volume = $2.07 \times \text{height}^3$ ($R^2 = 0.86$). This suggests that the tumor volume doubling time is one-third of tumor height doubling time, thus predicting a tumor volume doubling time of 9.05 months.

Conclusions: From our analysis, untreated choroidal melanoma tumors appear to grow exponentially with a volume doubling time that matches the current literature (5.1-17.0 months). Additionally, our model predicted the height at which the tumors begin to grow exponentially. This value corresponded to an initial tumor volume of 2.40mm^3 . This model of choroidal melanoma growth patterns may help to understand treatment efficacy compared to the natural progression of the disease as well the transition from benign nevus to malignant tumor.

TITLE: Premature infants born less than 25 weeks need more ophthalmology exams and treatment for ROP than older premature infants

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Muhtadi, V.S. Hawn, Yeshiva University Albert Einstein College of Medicine, Bronx, New York, UNITED STATES|P.D. Suman, U. Mian, Montefiore Medical Center, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rakin Muhtadi: Commercial Relationship: Code N (No Commercial Relationship) | Vivian Hawn: Commercial Relationship: Code N (No Commercial Relationship) | Pamela Suman: Commercial Relationship: Code N (No Commercial Relationship) | Umar Mian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of Prematurity (ROP) is a sight threatening disease that can affect preterm infants. It is unclear how low gestational age affects ophthalmologic screening and treatment rates. This study evaluates the examination and treatment rates of infants born less than 25 weeks gestational age (GA) compared to those born 25 weeks or greater requiring screening for ROP.

Methods: This is a retrospective, cross sectional study of infants who met institutional ROP screening criteria and were admitted to two Montefiore Medical Center (Bronx, NY) NICUs from January 2017 to June 2020. Data was collected using EMR (Epic Systems Corporation, Verona, Wisconsin). Patients were excluded if they were transferred to another facility before screening was completed.

Variables analyzed were GA, birth weight, number of ophthalmology exams (inpatient/outpatient), worst stage of ROP, type I disease or APROP in either eye.

Infants were divided into two groups: Group "GA<25" were those with GA less than 25 weeks and group "GA≥25" were infants with GA equal to or greater than 25 weeks. Two tailed student's T-test and chi square test were used for statistical analysis.

Results: Table 1 and Table 2 provide demographic and eye examination results respectively for a total of 415 infants of which 7.3% (n=30) had GA<25. As expected, GA<25 infants had significantly lower birth weight compared to GA≥25 (656g vs 1150g, p<0.001) and significantly higher mortality (37% vs 8.11%, p<0.00001). There were no differences in sex or single/multiple births between the two groups. GA<25 infants had a significantly higher number of total examinations than GA≥25 (9.8 vs 4.2, p<0.001) and higher numbers of inpatients exams (7.8 vs 2.5, p<0.001). Outpatient exams were similar (2.1 vs 1.5). GA<25 had worst average stage of ROP at 1.33 compared to 0.224 for GA≥25 (p<0.001). Rates of Type I ROP were significantly higher for GA<25 compared to GA≥25 (20% vs 1.04%, p<0.001).

Conclusions: Infants with GA<25 required significantly more ophthalmologic exams, developed more severe ROP and had a higher treatment rate. It is important for ROP services, including neonatologists and ophthalmologists, to be aware of this increased clinical burden, especially as the number of such infants starts increasing in their NICUs.

SUBMITTER (NAME ONLY): Michael Simpson

TITLE: Preclinical Estimation of Constants for Intraocular Lens Power Calculations

SESSION TITLE: Aspects of Visual Function

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Simpson, Simpson Optics LLC, Arlington, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Michael Simpson: Commercial Relationship(s);Simpson Optics LLC:Code E (Employment)

ABSTRACT BODY:

Purpose: Intraocular lenses (IOLs) are labeled with a lens power, but a corresponding “lens constant” is also needed for IOL power calculations. This is typically determined by back-calculation from earlier postoperative results, and initial patients may have less accurate refractive outcomes. To address this, a method for estimating the SRK/T A-Constant before any IOLs have been implanted is described. Parameters that have a strong effect on the A-Constant are also discussed, such as the shape factor, the asphericity, and the methods used for IOL testing.

Methods: The final axial location of the IOL is the greatest unknown, but this is primarily determined by the lens capsule, which contracts around the lens and haptics, while also being stretched flat by the zonules. A new IOL can be physically compared to an existing single-piece IOL to estimate the location, and image distances can be calculated or measured using the ISO2 model eye to estimate the optical effects (Fig. 1a). An average eye is assumed, and a central range of IOL powers (eg 19D–23D)). Zemax calculations demonstrate the method here for several conceptual high index (1.55) IOL styles that have different shape factors and spherical aberration values (Fig. 1b). The haptic location was used to position the lenses.

Results: The “best focus” image distances for a 3 mm pupil diameter are plotted against the labeled power values in Fig 2, along with estimated power changes relative to the equiconvex spherical lens. The calculations illustrate how changes to the shape factor and the asphericity can each change the effective power of the IOL by 0.5 D, with more than 2 D difference across this extreme range of potential styles. Differences can be used to adjust the A-Constant.

Conclusions: The focusing effect of IOLs in an average laboratory eye can be used to estimate the SRK/T “A constant” through comparison to an existing lens. The IOL axial location is envisaged to be constrained primarily by the capsule, and this is estimated by comparing design features (in this case, simply the haptic location). This estimation is the weakest part of the analysis. Calculations are useful, but the best results would come from actual lens measurements at 35 C in saline, to be close to actual eye conditions. The theoretical designs would then not be needed, and any unexpected effects would also be addressed, with the use of several powers averaging out any fabrication variations.

ABSTRACT BODY:

Purpose: To explore the use of widefield OCTA (Swept-source OCTA PlexElite) to identify capillary closure in different regions of the retina (perifovea vs mid-periphery) in diabetes type 2, and its correlation with ETDRS severity stages.

Methods: 105 eyes from diabetic type 2 patients (66.6 ± 7.9 yrs) were imaged with the PlexElite 9000 (Zeiss, Dublin, CA) using Angio 15x9mm and Angio 3x3mm protocols. Data was processed by the Density Quantification of Averaged Data v0.3.5 algorithm available on the Advanced Research Imaging portal which uses multi-layer segmentation and calculates vascular density metrics for Superficial Capillary Plexus (SCP) and Deep Capillary Plexus (DCP). For retinal mid-periphery, 3 extra concentric rings were added to the standard 9 ETDRS areas. Images were checked for quality: signal strength ≥ 6 , minimal motion artefacts and no evidence of defocus. Diabetic eyes were classified using the ETDRS severity scale, Grade 10-15 ($n=16$), 20 ($n=17$), 35 ($n=37$), 43 ($n=15$) and 47 to 65 ($n=14$). Skeletonized Vessel Density (VD) measurements from diabetic patients were compared to an age matched healthy control population ($n=28$; 58.7 ± 17.9 yrs).

Results: Retinal capillary closure (CC) diabetes type 2 patients with mild ETDRS levels (10-35), predominates in the parafoveal region, with SCP VD values of 13.2 ± 1.6 in ETDRS 10-20 ($p < 0.001$) and 12.4 ± 2 in ETDRS 35 ($p < 0.001$), when compared with the healthy control population (14.6 ± 1.1).

The CC extends to the retinal mid-periphery in the more severe ETDRS stages, with DCP VD values of 10.8 ± 6.4 in ETDRS 43-47 ($p = 0.002$) and 10.1 ± 4.6 in ETDRS 53-61 ($p = 0.013$) comparing with healthy control population. Involvement of one or more retinal quadrants correlate with increase in ETDRS grade severity and allow discrimination between different ETDRS levels (see table 1). The 3x3mm acquisition protocol identifies well the initial DR stages (10-35), whereas 15x9 mm widefield SS-OCTA acquisitions of the midperiphery differentiates the more severe ETDRS levels.

Conclusions: Retinal CC, quantified by SS-OCTA, allows the identification and separation of different ETDRS levels, by combining 3x3mm and 15x9mm acquisitions and considering the number of retinal quadrants affected. SS-OCTA metrics of retinal CC, allowing measurements to be performed in the macula and in more retinal peripheral regions, may offer an objective and easier alternative to ETDRS severity grading.

ABSTRACT BODY:

Purpose: To assess the distribution of axial length and its determinants in a very old population.

Methods: The population-based Ural Very Old Study included 1526 (81.1%) participants out of 1882 eligible individuals aged 85+ years. The participants underwent a detailed ophthalmological and medical examination including sonographic axial length measurement.

Results: Biometric data were available for 717 (47.0%) individuals with a mean age of 88.0 ± 2.6 years (range:85-98 years; 25%). Mean axial length was 23.1 ± 1.1 mm (range:19.37-28.89mm) and 23.1 ± 1.1 mm (range:19.507-28.84mm) in the right eyes and left eyes, respectively. Prevalences of moderate myopia (axial length:24.5-<26.5mm) and high myopia (axial length ≥ 26.5 mm) were 47/717 (6.6%;95%CI:4.7,8.4) and 10/717 (1.4%;95%CI:0.5,2.3), respectively. Longer axial length was associated (correlation coefficient $r:0.37$) with taller body height ($P<0.001$;standardized regression coefficient $\beta:0.26$; non-standardized regression coefficient $B:0.03$; 95% confidence interval (CI): 0.02, 0.04), higher level of education ($P<0.001$; $\beta:0.12$; $B:0.06$;95%CI:0.02,0.11), and thinner peripapillary retinal nerve fiber layer thickness ($P=0.001$; $\beta:-0.15$; $B:-0.004$;95%CI:-0.006,-0.002), in addition to more myopic spherical refractive error ($P=0.001$; $\beta:-0.15$; $B:-0.08$;95%CI:-0.13,-0.03). In that model, axial length was not significantly associated with age ($P=0.52$), gender ($P=0.17$) and intraocular pressure ($P=0.21$).

Conclusions: Mean axial length (23.1 ± 1.1 mm versus 23.30 ± 1.10 mm) and prevalence of moderate axial myopia (6.6% (95%CI:4.7,8.4) versus 8.7% (95%CI:9.0,10.5)) and high axial myopia (1.4% (95%CI:0.5,2.3) versus 1.4% (95%CI:1.1,1.7)) in this old study population were comparable with values from the younger population of the Ufa Eye and Medical Study conducted in the same study regions. As in previous studies, higher axial length was correlated with higher level of education

SUBMITTER (NAME ONLY): Kristin Josic

TITLE: Conversion of Central Subfield Thickness Measurements of Diabetic Macular Edema across Cirrus and Spectralis Spectral Domain Optical Coherence Tomography Instruments

SESSION TITLE: OCT - Clinical applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Josic, Jaeb Centre for Health Research, Tampa, Florida, UNITED STATES|K. Josic, DRCR Retina Network, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Kristin Josic: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop equations to convert automated central subfield thickness (CST) values among eyes with diabetic macular edema (DME) between Cirrus (Carl Zeiss Meditec) and Spectralis (Heidelberg Engineering) instruments.

Methods: A random sample of 70% of the data from participants in a cross-sectional observational study (DRCR Retina Network Protocol O) who underwent two replicate scans on both Cirrus and Spectralis instruments were used to develop the conversion equations. The remaining 30% of the data and data from an independent study (CADME) were used to validate the equations. Concordance correlation coefficients and Bland-Altman 95% limits of agreement (LOA) were used to evaluate conversion equation performance.

Results: A total of 262 CST scan pairs from 131 eyes of 75 participants in Protocol O were used to develop the equations. The validation samples included 112 scan pairs from 56 eyes of 32 participants in Protocol O and 150 scan pairs from 37 eyes of 37 participants in CADME. The proposed conversion equations with units of μm are (1) Spectralis = $40.78 + 0.95 \times \text{Cirrus}$ and (2) Cirrus = $1.82 + 0.94 \times \text{Spectralis}$. The concordance correlation coefficients between observed and converted measurements ranged from 0.96 to 0.99. Converting CST between Spectralis and Cirrus, 95% of the converted measurements are expected to be within $\pm 10\%$ or $\pm 32 \mu\text{m}$ of the observed measurements on the other instrument.

Conclusions: The conversion equations developed in this study are suitable for the transformation of values from individual scans taken with Cirrus or Spectralis machines as well as averaged values from cohorts of eyes with DME. Variability of observed versus converted measurements is similar to that of test retest. Although previous work enabled the conversion of Spectralis and Cirrus measurements to time domain OCT equivalents, time domain OCT is now obsolete. Thus, the ability to convert CST values from one SDOCT instrument to another will benefit both clinical research and standard care efforts.

TITLE: ARPE19 cells exposed to sodium iodate accumulate ferritin in lysosomes and release ferritin-rich vesicles in the extracellular milieu: Implications for in vitro model of AMD

SESSION TITLE: Pathology and Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Ashok, S. Chaudhary, A. S. Wise, A. E. Kritikos, N. Rana, N. Singh, pathology, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|E. Lindner, Medical University of Graz, AUSTRIA|

Commercial Relationships Disclosure (Abstract): Ajay Ashok: Commercial Relationship: Code N (No Commercial Relationship) | Suman Chaudhary: Commercial Relationship: Code N (No Commercial Relationship) | Aaron S. Wise: Commercial Relationship: Code N (No Commercial Relationship) | Alexander E. Kritikos: Commercial Relationship: Code N (No Commercial Relationship) | Neil Rana: Commercial Relationship: Code N (No Commercial Relationship) | Ewald Lindner: Commercial Relationship: Code N (No Commercial Relationship) | Neena Singh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Exposure of the retinal pigment epithelial cell line (ARPE19) to the oxidant sodium iodate (NaIO_3) is a well-established in vitro model of retinal degeneration, including age related macular degeneration (AMD). Higher levels of iron in AMD retinas and a protective effect of an iron chelator has been reported before by Hadziahmetovic et al. The underlying mechanism of NaIO_3 -induced iron accumulation and retinal degeneration, however, remains unclear. Here, we explored the mechanism of iron accumulation in NaIO_3 -treated ARPE19 cells.

Methods: ARPE19 cells were obtained from ATCC and used until passage 20. Cells were treated with 10 mM of NaIO_3 for 24 h, and the lysates were evaluated for various proteins with specific antibodies by Western blotting (WB). Additionally, NaIO_3 -treated cells were co-immunostained with organelle-specific antibodies to confirm the localization of ferritin.

Results: Immunoblotting of lysates from NaIO_3 treated ARPE19 cells revealed increased expression of LC3II, a marker of impaired autophagosomal activity, and ferritin relative to untreated controls. Cathepsin-D, a lysosomal enzyme, was significantly reduced in NaIO_3 -treated cells. Immunocytochemistry revealed co-localization of ferritin with LAMP-1 in NaIO_3 -treated cells, indicating accumulation in lysosomes. Surprisingly, exosomal structures co-immunostaining for ferritin and LAMP-1 were released in the extracellular milieu.

Conclusions: These data indicate that NaIO_3 inhibits lysosomal degradation of ferritin by inhibiting cathepsin-D. Accumulated ferritin is subsequently released to the extracellular milieu in vesicular structures that react for the lysosomal marker LAMP-1. Thus, accumulation of iron and iron-mediated retinal toxicity by NaIO_3 is mediated by accumulation of iron-rich ferritin and its release to neighboring cells. Since NaIO_3 is used to induce retinal degeneration in mice, the role of ferritin and other substrates of cathepsin-D requires consideration.

ABSTRACT BODY:

Purpose: Fungal endophthalmitis is a devastating intraocular inflammatory disease that represents ~17-25% of infectious endophthalmitis in India, but microbiological investigations have often failed to detect the causative agent, resulting in a clinical dilemma. Galactomannan (GM) and 1,3 β -D-Glucan (BG), have been previously evaluated in the diagnosis of invasive fungal infections, however, its utility in intraocular infections is not known. The aim of the study was to assess the clinical utility of vitreous GM and BG levels in the diagnosis of fungal endophthalmitis.<gdiv></gdiv>

Methods: Vitreous of 31 patients diagnosed clinically as fungal endophthalmitis between October 2018 and September 2020 and 11 patients diagnosed with non-infectious retinal disorders, as controls, were included in this study. Human GM and BG levels were determined by colorimetric assay kits (MyBioSource) and the receiver operating characteristic curves (ROC) were determined.<gdiv></gdiv>

Results: Of the 42 patients included in the infectious group, 16 were culture-positive and included *Aspergillus* spp. (44%), *Candida* spp. (31%), and other fungi (4/16; 25%). While, no significant association were found between GM and BG levels and visual outcome, significantly higher levels of vitreous GM (67.51 ± 22.08 pg/ml; $p=0.009$) and BG (1.53 ± 0.30 pg/ml; $p=0.0002$) were found in the culture-positive group compared to the control group. Additionally, both GM and BG levels were significantly higher in *Aspergillus* spp. compared to *Candida* spp. (p -value <0.05). The Area under the ROC curve (AUC) value for GM was 81% with a sensitivity of 88% and a specificity of 73% for a cutoff value of 51.36 pg/ml. Further, the AUC value for BG was 93% with sensitivity and specificity of 94% and 82% with the cutoff value being 1.19 pg/ml. Using that criteria, diagnosis of fungal infection was achieved in 12/15 (80%) culture-negative infectious samples by GM assay and in 15/15 (100%) by 1, 3 β -D-Glucan assays.<gdiv></gdiv>

Conclusions: Our study demonstrates the clinical utility of GM and BG as useful adjunctive biomarkers for the early diagnosis of fungal infections in patients with culture-negative endophthalmitis. A combination of both BG and GM assays would be the best approach, facilitating better predictive accuracy in vitreous fluids and may have a role in monitoring response to therapy.<gdiv></gdiv>

TITLE: Fibronectin extra domain A (FN-EDA) causes glaucomatous trabecular meshwork and optic nerve head damage in mice

SESSION TITLE: Neurodegeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C.M. McDowell, T. Mavlyutov, Department of Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Colleen McDowell: Commercial Relationship: Code N (No Commercial Relationship) | Timur Mavlyutov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is a major risk factor for the development and progression of primary open angle glaucoma and is due to trabecular meshwork (TM) damage. We investigated the role of an endogenous Toll-like receptor 4 (TLR4) ligand, FN-EDA, in the development of glaucoma utilizing a transgenic mouse strain (B6.EDA^{+/+}) that constitutively expresses only FN containing the EDA isoform.

Methods: Eyes (n=3/strain) were processed for electron microscopy, polymerized in EPON, ultrathin sections (80 nm) were cut and placed on formvar coated slot grids, and poststained with uranyl acetate and lead citrate. Consecutive images of the entire TM area spanning from anterior to posterior parts of Schlemm's canal (SC) were collected at 2500x and montaged into a single image. ECM accumulation and basement membrane thickness were quantified by ImageJ analysis. TLR4 expression in ONH cells was conducted using RNAscope in situ hybridization and immunohistochemistry protocols (n=3 eyes/strain). IOP was measured using a rebound tonometer and ON damage assessed by PPD stain (n=20-22 eyes/strain).

Results: Ultrastructure analyses show the TM of B6.EDA^{+/+} mice have significantly increased accumulation of ECM between the TM beams with few empty spaces compared to C57BL/6J control mice (P<0.05). SC basement membrane is thicker and more continuous in B6.EDA^{+/+} mice compared to C57BL/6J control. No significant structural differences were detected in the TM of EDA null mice. The mRNA expression of TLR4, a known ligand of FN-EDA, was increased in the TM of B6.EDA^{+/+} mice compared to C57BL/6J control eyes (p<0.05). IOP was significantly higher in B6.EDA^{+/+} mice compared to C57BL/6J control eyes (p<0.01) and significant ON damage was detected at one year of age (p<0.001). TLR4 mRNA is expressed in the ONH, and is present in mouse ganglion cell axons, microglia, and astrocytes. There was no significant difference in astrocyte density in B6.EDA^{+/+} mice compared to C57BL/6J control eyes; however, there was a significant increase in the area occupied by Iba-1 positive microglia cells in the ONH of B6.EDA^{+/+} mice compared to C57BL/6J control eyes (p<0.01).

Conclusions: B6.EDA^{+/+} mice have increased accumulation of ECM in the TM, elevated IOP, enhanced proinflammatory changes in the ONH, and damage to retina ganglion cell axons. These data implicate B6.EDA^{+/+} mice as a novel mouse model of glaucoma.

Wise: Commercial Relationship: Code N (No Commercial Relationship) | Neil Rana: Commercial Relationship: Code N (No Commercial Relationship) | Alexander E. Kritikos: Commercial Relationship: Code N (No Commercial Relationship) | Ewald Lindner: Commercial Relationship: Code N (No Commercial Relationship) | Neena Singh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recently, we reported β -cleaved prion protein (PrP^{C}) in human ocular tissues. Here, we explored whether this is unique to the human eye, and its implications in ocular disorders.

Methods: The ratio of β - and α -cleaved PrP^{C} in ocular tissues and fluids was determined by Western blotting (WB). Processing of green-fluorescent-protein (GFP)-tagged PrP^{C} was evaluated in human retinal (ARPE-19) and neuronal (BE(2)-M17) cell-lines respectively.

Results: PrP^{C} was β -cleaved in human ocular tissues, and soluble N-terminal fragment (N2) was released in the aqueous and vitreous humor (AH & VH). In contrast, PrP^{C} was α -cleaved in human brain and retinal tissue of diurnal and nocturnal animals. Insertion of the GFP tag between N-terminal residues 37 and 38 of PrP^{C} interfered with β -cleavage in ARPE-19 cells, and was cytotoxic. In BE(2)-M17 cells, PrP^{C} -GFP was α -cleaved, and was nontoxic. Surprisingly, neither exposure to light, oxidizing agents, inflammatory stimuli, or anti-oxidants altered β -cleavage of PrP^{C} in ARPE-19 cells.

Conclusions: β -cleavage of PrP^{C} is obligatory in human ocular tissues, and N2 likely protects the cells from oxidative stress, an established function of this fragment. Paradoxically, β -cleaved C-terminus (C2) of PrP^{C} is susceptible to conversion by the pathogenic PrP-scrapie (PrP^{Sc}) form while α -cleaved fragment (C1) is resistant, increasing the susceptibility of the human eye to prion infection. Moreover, C2 includes the binding site for $\beta 1$ -integrin and amyloid- β ($\text{A}\beta$), molecules implicated in ocular disorders. These observations suggest re-evaluation of animal studies on prion infection of the eye, and underscore the significance of PrP^{C} in ocular disorders.

ABSTRACT BODY:

Purpose: We compared the protein composition of completely decellularized Descemet's membrane (DM), using 2 different sample preparation methods. The DMs derived from paired donor cornea were either subjected to freeze-thaw cycle or not, before mass spectrometry (MS) analysis.

Methods: Two corneas were subjected to a freeze-thaw cycle to remove corneal endothelial cells (CECs) by freezing the cornea at -20° C for 48 hours and thawing it gently at RT while the other two corneas from the fellow eye were incubated with culture media at 37°C for 48 hours. The corneas were washed with cell culture media to remove all the CECs. The DMs were peeled and the proteins were extracted with 2% SDS in 100 mM Tris buffer using a bullet blender homogenizer (Next Advance, NY). The supernatant was collected from homogenized sample. Extracted proteins were quantified by BCA method and subjected to SDS-PAGE fractionation. Protein bands were excised and subjected to in-gel trypsin digestion. The digested peptides were used for LC-MS/MS analysis performed using a Q Exactive mass spectrometer coupled with an online Dionex Ultimate 3000 RSLC nanoLC system (Thermo Scientific; MA). Tryptic peptides were separated with a Dionex EASY-spray column (PepMap® C18, 3µm, 100Å) using a typical 120min gradient of mobile phase A (0.1% FA) and mobile phase B (0.1% FA in ACN) with a flow rate of 300nl/min.

Results: The LC-MS/MS-based analysis identified more proteins in the DMs that were subjected to the freeze-thaw cycle than the ones without the freeze-thaw cycle. A total number of 951 proteins were identified in the freshly processed group and a total of 1423 proteins were identified in the tissue subjected to freezing. The freeze-thaw cycle identified 33% more proteins compared to the samples that were processed fresh with mild enzymatic digestion. A total of 53 proteins were common among all samples in the freshly processed group while 117 proteins were common in the sample group subjected to free-thaw. The common proteins identified in all the samples were also analyzed manually using the Uniprot database for the sub-cellular localization and 98% of the protein were classified as extracellular or secreted proteins confirming that the identified proteins truly belong to the acellular DM.

Conclusions: The DMs that underwent a freeze-thaw cycle resulted in more proteins than DMs that were prepared fresh and subjected to mild enzyme digestion.

ABSTRACT BODY:

Purpose: In clinical trials, the intracameral bimatoprost SR implant lowers intraocular pressure (IOP) well beyond cessation of drug release by the implant. Since matrix metalloprotease (MMP) activity underlies topical bimatoprost effects on IOP, we hypothesized that long-term effects of bimatoprost SR was due to effects of dramatically elevated outflow tissue levels of unmetabolized bimatoprost (amide, not bimatoprost free acid (BFA)) on MMP activity in outflow pathway cells.

Methods: Human outflow pathway cells (trabecular meshwork, TM, n=7; ciliary muscle, CM, n=6; scleral fibroblasts, SF as controls, n=4) in culture were treated with either implant tissue levels of bimatoprost (10–1000 μ M) or topical tissue levels of BFA (0.1–10 μ M). Cells were exposed to drug for 24 hours, and MMP gene expression was measured by PCR array and MMP1 protein by ELISA.

Results: Compared to all other treatments, implant levels of bimatoprost (1000 μ M) significantly altered expression of the greatest number of genes in all cell types (e.g.: n=11 partially overlapping genes in TM and CM cells, $p<0.05$). Despite these significant effects, there was noticeable strain to strain differences in responses to implant levels of bimatoprost. By comparison, only two genes were significantly altered in TM and CM cells with topical outflow tissue levels of BFA (10 μ M). In the one glaucomatous TM cell strain tested, implant levels of bimatoprost had similar effects on most genes compared to normal cells. However, 1000 μ M bimatoprost dramatically increased MMP1 and MMP10 expression in glaucomatous TM cells well above average responses of normal TM cells (183.8 vs. 62.9 ± 66.4 fold, and 52.1 vs. 2.89 ± 2.4 fold, respectively), both genes of which were dose-dependently upregulated in normal TM cells, but not CM cells. Similarly, MMP1 protein levels were dose-dependently upregulated in TM, but not CM cells.

Conclusions: Bimatoprost and BFA had differential effects on MMP gene expression, with a dramatic upregulation in MMP1 in TM cells seen only at “implant levels” of bimatoprost. These preferential effects of high dose bimatoprost on MMP expression on TM cells suggests that increased conventional outflow is due to durable tissue remodeling, underlying long term IOP benefit of implant in some patients.

ABSTRACT BODY:

Purpose: There are limited longitudinal data on refractive progression between teenage and senior adult years. A recent analysis suggests that the ratio of the prevalence of high myopia to that of myopia increases over this time.¹

Methods: The literature was reviewed to identify papers where both myopia and high myopia prevalence were reported. Adult studies largely comprised population-based cohorts whereas studies of children and teenagers were principally from school-based populations. To reduce confounding caused by lenticular changes, subjects over 70 years of age were excluded. Prevalence rates were adjusted to bring the thresholds for myopia and high myopia to -0.50 D and -5.00 D according to previously developed equations.¹

Results: Figure 1 plots the prevalence of high myopia versus that of myopia by age group for 292 cohorts from 76 studies (a total of 1,034,220 individuals). The ratio of the prevalence of high myopia to that of myopia increases with myopia prevalence, as has been previously reported. But, it also increased across the lifespan. Figure 2 presents modelled data for the prevalence of high myopia against that for myopia at different ages. This model predicts, for example, that high myopia prevalence will increase by about two-thirds between ages 20 and 70 years for a constant myopia prevalence of 80%. Race and gender had minimal influence on the ratio of high myopia to myopia.

Conclusions: While there are numerous possible explanations for this observation, the most likely is continued myopic progression during adulthood among moderate myopes such that they become high myopes later in life. The apparent substantial progression in this group across age has not been previously quantified and may mean that the already substantial projections of future morbidity from myopia underestimate the true likely toll.

TITLE: Factors in low prevalence of Fuchs' heterochromic iridocyclitis in Japan

SESSION TITLE: Epidemiology, Prognosis and Burden of Ocular Inflammatory Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. yoneda, K. Yoneda, K. Takayama, S. Sugaoka, H. Shimazaki, M. Takeuchi, Boei Ika Daigakko, Tokorozawa, Saitama, JAPAN|

Commercial Relationships Disclosure (Abstract): yu yoneda: Commercial Relationship: Code N (No Commercial Relationship) | Keisuke Yoneda: Commercial Relationship: Code N (No Commercial Relationship) | Kei Takayama: Commercial Relationship: Code N (No Commercial Relationship) | Shimpei Sugaoka: Commercial Relationship: Code N (No Commercial Relationship) | Haruna Shimazaki: Commercial Relationship: Code N (No Commercial Relationship) | Masaru Takeuchi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Prevalence of Fuchs' heterochromic iridocyclitis (FHI) among total uveitis patients in Japan is approximately 0.5%, which is significantly lower than those of most western countries. In this study, we investigated whether lower frequencies of ocular findings characteristic of FHI in Japanese patients may be responsible for the less prevalence.

Methods: Clinical records of 10 uveitis patients diagnosed as FHI (5 male, 5 female) at our institute between April 2012 and March 2019 were retrospectively reviewed. Investigations contained patients' age at diagnosis, gender, clinical findings, follow-up duration, BCVA at initial and final visits, complications, and medical and surgical treatments. The reasons for referral to our hospital were also interrogated.

Results: Unilateral involvement was noted in 90%, and cell infiltration in the anterior chamber was observed in 70%. At the initial presentation, stellate-shaped keratic precipitates (KP) and iris atrophy with or without heterochromia were observed in all cases, followed by cataract in 80%, anterior segment inflammation in 70%, vitreous opacity in 40%, and iris nodule in 20%. Ciliary injection or high intraocular pressure was not noted in any cases. All were patients referred to our institute, and had been followed up for several months or years at the primary clinics. The most in the referral reasons was cataract (60%), followed by uveitis (30%), and there was no case referred as FHI.

Conclusions: Ocular findings characteristic of FHI except for high intraocular pressure were observed in Japanese FHI patients as well. It was suggested that the low prevalence of FHI in Japan was due to the fact that FHI was under diagnosed at the primary clinics, and had been followed up as idiopathic mild anterior uveitis and/or cataract.

ABSTRACT BODY:

Purpose: Retinal macrophages play key roles in the regulation of immune reactions and tissue repair. Using clinical OCT, we examined the association of parafoveal surface macrophage density and capillary density in thyroid eye disease (TED) patients with low and high clinical activity scores (CAS).

Methods: 33 TED patients (33 eyes) and 13 healthy control subjects (13 eyes) were imaged using a clinical SD-OCT system (Avanti RTVue-XR; Optovue). 23 of the 33 TED patients had a CAS ≤ 3 and 10 had CAS > 3 . Ten 3x3mm scans centered at the fovea were acquired and averaged (PMID: 28068370). Axial length was obtained for ocular magnification correction of images. Automated macrophage identification was performed on a 3 μ m OCT-Reflectance (OCT-R) slab located above the ILM surface using MATLAB (Fig 1, Left Column) (PMID: 32574351). The OCT-A full vascular slab, located between ILM and 9 μ m below the OPL was used for capillary density measurements and foveal avascular zone (FAZ) delineation. (Fig 1, Middle Column) (PMID: 31106029). Macrophage density maps were generated for each subject to provide quantitative visualization of cell distribution across the 3x3mm scan area (Fig 1, Right Column).

Results: Surface macrophages within the FAZ were identified in 31% of controls, 87% of low CAS and 100% of high CAS groups. A statistically significant difference in macrophage density within the FAZ was observed between the control and TED groups (Kruskal-Wallis tests, $P = 0.0005$), with mean \pm SDs of 1 ± 1 , 6 ± 7 and 14 ± 6 cells/mm² in the controls, low CAS and high CAS, respectively. Linear regression showed no significant correlation between macrophage density within the FAZ and capillary density ($r = -0.1$; $P = 0.495$).

Conclusions: Clinical OCT is capable of imaging parafoveal surface macrophages in TED patients and healthy controls. Our findings suggest that the concentration of macrophages within the FAZ reflects the inflammatory burden in TED.

ABSTRACT BODY:

Purpose: We previously developed a method to culture human goblet cells using RPMI medium. Our purpose is to culture and characterize three types of cells found in the conjunctival epithelium: goblet, stratified squamous, and undifferentiated.

Methods: A co-culture of goblet cells, stratified squamous cells, and undifferentiated cells was established from pieces of human conjunctiva in IOBA medium. Immunofluorescence was used to determine the amount and phenotype of cells grown. To determine cell function intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) was measured using fura2/AM in cultured cells stimulated by exogenous stimuli. Additionally immunofluorescence microscopy on fura2/AM labeled cells was used to assign cell phenotype to individual intracellular Ca^{2+} measurements post hoc.

Results: Explants of human conjunctiva were grown in IOBA media for 14 days and stained by immunohistochemistry using two cell markers for each type: cytokeratin (CK) 7 and the lectin Ulex Europeaus Agglutinin 1 (UEA1) for goblet cells, CK4 and Bandeiraea Simplicifolia Lectin 1 for stratified squamous cells, and p63 and PAX6 for undifferentiated cells. All three cell types were present in cultures from twelve different individuals. $[\text{Ca}^{2+}]_i$ was significantly increased in both goblet and stratified squamous cells (identified post hoc) when stimulated by the β adrenergic agonist isoproterenol (10^{-5}M), the $\alpha 1$ adrenergic agonist phenylephrine (10^{-4}M), and the nonspecific adrenergic agonist epinephrine (10^{-6}M). Increases in $[\text{Ca}^{2+}]_i$ elucidated by the purinergic agonist ATP (10^{-5}M) and the cholinergic agonist carbachol (10^{-4}M) were significantly greater in goblet cells than stratified squamous cells.

Conclusions: In mixed cultures containing the three phenotypically distinct human cell types that comprise the conjunctival epithelium, stratified squamous and goblet epithelial cells can be differentially identified by their $[\text{Ca}^{2+}]_i$ response to purinergic and cholinergic agonists. Furthermore, the activity of goblet cells is regulated by systems that utilize adrenergic, purinergic, and cholinergic agonists.

ABSTRACT BODY:

Purpose: Müller glia provide critical homeostatic, trophic, and structural support for both the retinal vasculature and neuronal layers. In diabetes, Müller cell dysfunction contributes to retinal inflammation, microvascular defects, and neuronal damage. Our laboratory has recently demonstrated a critical role for the stress response protein Regulated in Development and DNA damage response 1 (REDD1) in the development of diabetes-induced oxidative stress and retinal defects. Herein, we investigated the hypothesis that diabetes-induced REDD1 protein expression specifically in Müller cells contributes to the development of retinal pathology.

Methods: Conditional Müller-specific REDD1 knockout (REDD1 cKO) mice were generated using a PDGFRa-cre/lox recombination system. REDD1 cKO and floxed REDD1 control mice were administered streptozotocin to induce diabetes or received a vehicle control. The impact of diabetes was evaluated by optical coherence tomography and fluorescence microscopy. Retinal homogenates and nuclear isolates were also analyzed by Western blotting and ELISA.

Results: Müller glia from REDD1 cKO mice lacked REDD1, but expressed Müller cell markers similar to that of floxed REDD1 controls. In the retina of diabetic control mice, REDD1 protein expression was enhanced concomitant with an increase in oxidative stress and reduced activity of the antioxidant defense transcription factor nuclear factor erythroid-2-related factor 2 (Nrf2). These effects of diabetes were attenuated by conditional deletion of REDD1 in Müller glia. REDD1 cKO mice also exhibited a reduction in diabetes-induced retinal thinning and retinal ganglion cell death as compared to control mice

Conclusions: The findings support a key role for REDD1 in diabetes-induced retinal defects and provide new insight into the specific molecular events in retinal Müller glia that contribute to the pathology of diabetic retinopathy.

ABSTRACT BODY:

Purpose: Precise biometric measurements before cataract surgery are crucial for successful intraocular lens (IOL) calculation. We compared pre-cataract surgery measurements obtained using Heidelberg's new Anterior, the IOLMaster 700 (Zeiss), and the Pentacam (Oculus).

Methods: Biometric measurements were taken with the IOLMaster700 and the Anterior, as well as corneal topography with the Pentacam. Values were compared for measurements of axial length (AL), anterior chamber depth (ACD), steep and flat K, cylinder and axis. Statistical analysis was performed using paired sample t-test, Friedman test, Pearson's coefficient, and Cohen's d effect size. Clinical implications were derived from the IOL calculations for each device using the Barrett calculator.

Results: We compared measurements of 42 eyes (21 subjects; 38% female, mean age 65.2 ± 14.9 years). Of these, 24 eyes also had corneal parameters measured with the Pentacam. Mean AL was 23.62 ± 1.26 mm with the IOLMaster and 23.58 ± 1.31 mm with the Anterior ($P=0.004$; Cohen's d 0.02). Mean ACD was 3.29 ± 0.72 mm with the IOLMaster and 3.44 ± 0.79 mm with the Anterior ($P=0.04$, Cohen's d 0.12). There were no statistically significant differences in the steep or flat K values between the three devices. The strongest correlations were observed between the Anterior and the Pentacam in the steep and flat K values ($r=0.96$ and 0.97 , respectively; $p<0.001$). The weakest correlations were observed in the axis of the flat K between the IOLMaster and Anterior ($r=0.45$; $p=0.003$) and between the Anterior and Pentacam ($r=0.42$; $p=0.02$). When calculating the IOL using the Barrett calculator and mean values of the biometric devices, the Anterior values yielded a lower cylinder power by 0.75D.

Conclusions: Our results indicate excellent inter-device measurement agreement between the IOLMaster700 and the Anterior, rendering the two devices nearly interchangeable, with strong correlations also to the Pentacam corneal topography measurements. A clinically significant difference was observed only in the cylinder power of the calculated IOL.

Commercial Relationships Disclosure (Abstract): Karina Luiza Dias Teixeira: Commercial Relationship: Code N (No Commercial Relationship) | Jeff Romano: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Laurie: Commercial Relationship(s);TearSolutions Inc. :Code F (Financial Support);UVa Licensing and Ventures Group:Code P (Patent)

ABSTRACT BODY:

Purpose: Dry eye disease affects 7 - 10% of people worldwide. Dry eye is characterized by chronic inflammation and damage of the ocular surface. Lacritin (and several of its C-terminal proteoforms) is a prosecretory growth factor in tears that, based on preclinical and cell culture studies, restores basal tearing and ocular surface health. We previously reported on identification of cornea expressed G protein-coupled receptor 87 (GPR87) as a lacritin signaling receptor out of a genome-wide CRISPR/Cas9 screen. Here we sought to validate this observation, and ask whether GPR87 couples with lacritin co-receptor syndecan-1 (SDC1).

Methods: Validation studies of GPR87 were performed by generation of GPR87 knockout cell lines by CRISPR/Cas9 editing and by shRNA depletion of transduced human corneal epithelial (HCE-T) cells with lentiviral GPR87 sgRNA or shRNA and non-target controls. Depletion of GPR87 protein level was confirmed by western blotting. Complementation assays were performed by transducing depleted HCE-T's with lentiviral GPR87 cDNA obtained from DNASU Plasmid Repository. To explore whether GPR87 can couple with SDC1, we blotted for GPR87 out of SDC-1 pulldowns from HEK2936E cells co-transfected with wild type or mutated GPR87 and SDC1 cDNA's. GPR87- lacritin binding was studied out of recombinant lacritin- or C-25-intein pulldowns. 'C-25', lacks lacritin's 'N-94' bioactive domain. N-94 is a synthetic peptide analogous to several lacritin C-terminal proteoforms naturally in tears.

Results: Depletion of GPR87 abrogated N-94 rescue of IFNG/TNF stressed HCE-T's, but was rescued by complementation with GPR87 cDNA. GPR87 complexes with SDC1 in the absence of N-94, but not with SDC1 lacking the PDZ binding domain nor lacking N-terminal domain heparan sulfate at S15 nor membrane proximal chondroitin sulfate at S184 and S185. SDC1 failed to bind GPR87 lacking the G-protein binding site "DRY" motif. Lacritin, but not C-25, binds GPR87.

Conclusions: N-94 targets a preformed SDC1-GPR87 complex, the latter linked in part by glycosaminoglycans, and apparently by cytoplasmic SDC1 and GPR87 domains to regulate ocular surface health.

ABSTRACT BODY:

Purpose: Corneal and conjunctival epithelial dendritiform cells (CEDC, CjEDC) are an essential part of the ocular immune response, including the allergic response. Confocal microscopy allows observation of these cells in patients in real-time. This study examined inter-observer reliability of CEDC and CjEDC density and morphology measurements in normal and allergic patients.

Methods: In vivo confocal microscopy images (HRTIII-Rostock) from the corneal sub-basal and conjunctival epithelium of the right eye of 66 participants (mean age 36.6 ± 12.0 years, 56% female; 33 patients with normal corneas and 33 patients with active ocular allergy) were independently assessed by two experienced observers. Five best-focused, non-overlapping images were selected for each participant from the central cornea, temporal far peripheral cornea, temporal corneal limbus, temporal bulbar conjunctiva, and one image from the corneal whorl. CEDC and CjEDC density were counted manually, and the highest-grade morphology of corneal cells was recorded using grading scales for CEDC cell body size, dendrite length and dendrite shape. The level of agreement between observers was analysed for density by calculating the coefficient of repeatability (CoR, Bland and Altman method) and Intraclass Correlation Coefficient (ICC), and for morphology using Weighted Cohen's Kappa.

Results: There was a strong level of agreement between the two observers for CEDC density at the central (CoR ± 11.9 , ICC=0.99), far peripheral (CoR ± 14.3 , ICC=0.99) and limbal cornea (CoR ± 28.0 , ICC=0.96), with no significant bias between observers. There was a significant difference between observers for density measurements at the corneal whorl ($p < 0.001$; CoR ± 29.10 , ICC=0.98). Repeatability of density measurements at the conjunctiva was comparatively poorer (CoR ± 19.1 , ICC=0.97), with no significant inter-observer bias. For all three CEDC morphology parameters, there was good to strong inter-observer agreement at all corneal locations ($k = 0.69$ to 1.0).

Conclusions: The strong inter-rater agreement in CEDC density and good agreement in CEDC morphology and CjEDC density measurements supports the validity and reliability of in vivo dendritic cell assessment using confocal microscopy using manual counting, a novel morphology grading scale by trained observers.

ABSTRACT BODY:

Purpose: To detect and quantify peripapillary surface macrophage density changes in patients with open angle glaucoma (OAG) using enface OCT-reflectance (OCT-R) images.

Methods: 27 controls and 12 moderate to severe OAG patients were imaged using a clinical SDOCT system (Avanti RTVue-XR; Optovue). Ten 4.5x4.5mm scans centered at the optic nerve head (ONH) were obtained and averaged (PMID: 32574351). Seven eyes of 6 OAG patients were imaged at two visits 11-29 months apart. Semi-automated macrophage cell identification was performed on a 3 µm OCT-R slab located between 3 and 6 µm above the ILM using MATLAB (PMID: 32574351). An annular ROI with 0.75mm in width centered at the ONH was created on the OCT-R image (PMID: 29795576) (Fig). This annular ROI was then divided into four quadrants (temporal, nasal, superior and inferior) for macrophage density measurements. Cell density maps were also generated for each subject to allow rapid visualization of cell distribution across the ONH area. Axial length was obtained for ocular magnification correction of each image.

Results: In control eyes, the highest cell density was found in the temporal quadrant with mean±SD of 35.7±12.6 cells/mm² followed by the nasal (23.4±7.3 cells/mm²), inferior (23.1±7.6 cells/mm²), and superior (22.9±9.4 cells/mm²). In the OAG eyes, the highest cell density was found in the temporal quadrant with mean±SD of 16.6±13.2 cells/mm² followed by the nasal (15.6±8.3 cells/mm²), superior (12.6±4.8 cells/mm²), and inferior (9.9±6.3 cells/mm²). Cell densities measured at 4 quadrants were significantly reduced in eyes with OAG (Mann-Whitney rank tests, P values <0.05). Focal loss of surface macrophages was observed at regions with retinal nerve fiber bundle (RNFB) defect progression in OAG eyes (Fig). Density mapping of peripapillary surface macrophages enabled us to quantitatively and visually identify this novel feature of progressive RNFB defects.

Conclusions: Clinical OCT is capable of imaging surface macrophages on the ILM in control and glaucoma eyes. Density of these cells appeared reduced in regions with glaucomatous damage. Characterizing the relationship

between surface macrophage density and the underlying retinal nerve fiber integrity may be a useful biomarker for active disease progression, and possibly response to treatment.

ABSTRACT BODY:

Purpose: There is a clinical association between acute and chronic alcohol consumption and the incidence of ocular surface disease, including dry eye disease. The goal of this study was to investigate if chronic moderate alcohol consumption leads to signs of DED in vivo, and to investigate oxidative stress pathways involved in alcohol-induced damage to human corneal epithelial cells in vitro.

Methods: Twelve week-old male C57BL/6JRj mice were acclimated to the ad libitum Lieber-DeCarli liquid diet for 5 days. After acclimatization, 5% (vol/vol) ethanol was added to the diet in the alcohol group while control animals were maintained on an isocaloric Lieber-DeCarli liquid diet for 10 days. Corneal fluorescein staining was performed on day 10. Corneal tissue was sectioned and processed for histopathological analysis. For in vitro studies, human corneal epithelial cells (HCE-T; Riken, Japan) were exposed to 0.5% ethanol (vol/vol in media). RNA was collected from cells at 2, 4, 6, and 12 h after ethanol treatment and mRNA levels of oxidative stress markers NFE2L2, HMOX1, and HMOX2 were quantified by qPCR.

Results: Mice who received alcohol exhibited significantly higher corneal fluorescein scores compared to control (median scores: control = 2; alcohol = 3; $P < 0.001$). The average total corneal thickness in the alcohol group was significantly lower than in the control group (74.4 μm and 122.8 μm , respectively; $n = 6-7$, $P < 0.05$). This reduction was predominantly attributed to a reduction in stromal thickness.

In vitro studies revealed a statistically significant 3-fold increase in NFE2L2 gene expression in response to alcohol treatment in HCE-T cells at 2, 4, and 6 h ($P < 0.002$). There was a trend towards increased HMOX1 expression but no change in expression of the non-inducible HMOX2 isoform.

Conclusions: Our data provide the first preclinical evidence that chronic moderate alcohol consumption can lead to pathological signs of ocular surface disease in vivo. In vitro, alcohol exposure causes activation of Nrf2-mediated oxidative stress pathways. Future studies will investigate the effects of alcohol on corneal barrier function and the implications of chronic moderate vs. binge alcohol use.

ABSTRACT BODY:

Purpose: Analysis of baseline optical coherence tomography (OCT) in patients with macular hole (MH) can provide insight into surgical success and postoperative visual acuity (VA). Automated machine learning (AutoML) is a new area in artificial intelligence research. We designed a machine learning model using AutoML to predict the visual outcome from preoperative OCT images in eyes with successful MH closure following vitrectomy.

Methods: We developed a single-label classifier using AutoML (Google Cloud AutoML Vision) to predict the visual outcome (“<70 letters” vs. “≥70 letters”; Snellen equivalent: 20/40) at 6 months in eyes with successful primary surgery for idiopathic MH. We used retrospective data obtained from consecutive eyes with successful primary surgery for idiopathic MH between 2014 and 2018 at the Centre Hospitalier Universitaire de Québec – Université Laval (Canada). We included a single eye per patient and excluded eyes with ocular comorbidities with a potential detrimental effect on VA. Baseline horizontal fovea-centered high-definition 30-degree OCT scans were obtained in all patients using the Cirrus HD-OCT 5000 machine (Carl Zeiss Meditec, Germany). VA at 6 months was measured in Snellen and converted to ETDRS letters for analysis. Eyes were divided into two groups based on VA at 6 months: <70 letters and ≥70 letters. During model development, 80% of images were used for training, 10% for the validation process, and 10% were used for evaluating the model. Precision, recall and area under the precision-recall curve (AuPRC) were used to evaluate the performance of the model.

Results: The dataset included 383 patients (383 eyes), 69% (263/383) of which were women. The mean age was 68 ± 8 years and 24% (91/383) of eyes were pseudophakic. Baseline VA was 51 ± 14 letters and 49% (187/383) of eyes had VA of 70 letters or more at 6 months. The model correctly classified postoperative VA 68% of the time for the “<70 letters” category and 79% of the time for the “≥70 letters” category. The model had a precision (positive predictive value) of 73.68%, a recall (sensitivity) of 73.68%, and an AuPRC of 0.799.

Conclusions: The development of a deep learning model using AutoML for the prediction of postoperative VA from baseline OCT images in eyes with MH is feasible. The AutoML model displayed good discriminative performance, but more research is needed to determine external validity.

ABSTRACT BODY:

Purpose: Current understanding of retinal vascular development is largely based on histopathological studies of rare postmortem fetal eyes and by inference from non-human primates. Recent technological advances in handheld optical coherence tomography angiography (OCT-A) offer opportunity for direct imaging of the in vivo human retinal vascular development in preterm infants. Our goal is to establish offset parameters for macular microvasculature segmentation and visualize the three-layered perifoveal retinal vasculature in preterm infants using handheld OCT-A.

Methods: In this exploratory study, preterm infants were imaged using an investigational noncontact, handheld swept-source OCT-A device (UC3) under an IRB-approved protocol. Imaging occurred either at the bedside non-sedated or during examination under anesthesia with pharmacological pupillary dilation. Customized MATLAB scripts were used to segment retinal layers, test offset parameters, and generate depth-resolved OCT-A slabs. The superficial (SCP), intermediate (ICP), and deep (DCP) capillary plexuses were visualized and qualitatively assessed by three image graders.

Results: We selected six high-quality OCT-A volumes in two infant age groups for analysis and optimized offset parameters for vascular plexus visualization. A three-layered perifoveal retinal vasculature was successfully visualized in all three preterm infants in the 40 weeks postmenstrual age (PMA) group. No obvious ICP or DCP was found in the preterm infants in the 35 weeks PMA group, all of whom had retinopathy of prematurity (ROP).

Conclusions: Custom OCT-A segmentation parameters can be used to visualize the three-layered perifoveal retinal vasculature in preterm infants at term equivalent age. Prior to formation of the ICP and DCP, the perifoveal vasculature may be better visualized in two layers. Depth-resolved OCT-A of perifoveal retinal vasculature in preterm infants will inform human retinal vascular development and vascular pathologies of ROP.

ABSTRACT BODY:

Purpose: There is some evidence pointing towards outer retinal changes due to physical exercise. We could previously show the thinning of the outer retina and outer segments both in professional sportsmen and young amateurs shortly after excessive physical strain. In the current analysis we aim to provide evidence about choroidal changes in the same cohort and their effect on the observed outer retinal thinning.

Methods: Altogether 30 eyes of 15 professional sportsmen (Group S) and 16 eyes of 11 control adults (group C) were enrolled in our study, with a mean age of 22 ± 5 and 25 ± 5 years, respectively. We performed macular scanning with a Spectralis SD-OCT device before and following a vita maxima-type physical straining exercise until complete fatigue. OCT follow-up examinations were made 1, 5, 15, 30 and 60 minutes post exercise (p.e.). The OCT images were exported and analyzed using OCTRIMA 3D software and the thickness of 7 retinal layers was calculated, along with semi-automated measurement of the choroidal thickness. One-way ANOVA analysis was performed, the level of significance was 5%. The study was approved by the Science and Research Ethics Committee of Semmelweis University (272/2013).

Results: There was no significant change in choroidal thickness over time in both groups; however, there was a tendency towards thinning in the central subfield 1 minute and even more pronounced at 30 minutes p.e. in both groups S and C. The absolute changes in choroidal thickness in the central subfield did not show any correlation with the thickness changes of the intraretinal layers.

Conclusions: It seems that the changes of the outer retina induced by physical exercise are not directly linked with structural/thickness changes of the choroid as we previously hypothesized. However, in this study we did not measure changes in choroidal blood flow that could still be the underlying reason for the outer retinal changes described earlier by our group.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is the leading cause of blindness in children, particularly those born before 32 weeks of gestation. During the supplemental hyperoxic environment that premature infants are placed in postpartum, there is inadequate development of blood vessels supplying the retina, including the choriocapillaris and the superficial and deep plexuses from the central retinal artery. When the infants are returned to ambient air, the retina becomes hypoxic and there is compensatory and rapid angiogenesis and the development of neovascular tufts. This results in a compromised blood supply to the retina, leading to photoreceptor cell damage and death. Myo/Nog cells are a subpopulation of cells that express MyoD, Noggin and the angiogenesis inhibitor BAI1. They exist throughout the body and have been shown to have neuroprotective properties in the eye and brain. Myo/Nog cells have a potential role in reducing pathology and loss of vision that develops in a retinopathic eye by ameliorating the vascular and neuronal damage from hyperoxia and subsequent hypoxia that result from ROP.

Methods: An oxygen-induced retinopathy (OIR) protocol was utilized to mimic the pathology seen in ROP of premature infants. Neonatal mice spent postnatal days 7-12 (P7-P12) in 75% hyperoxia before returning to room air (21% oxygen). Intravitreal injections of pre-labeled Myo/Nog cells isolated from a brain by magnetic sorting and unsorted brain cells were performed at P15, followed by electroretinography (ERG) at P21 to test retinal function. Retinas were removed and vasculature was stained for analysis of vascular growth and quantification of neovascular tuft development.

Results: In animals who were subjected to the OIR protocol, addition of exogenous Myo/Nog cells reduced neovascular tuft formation and normalized overall vasculature of the retina. Retinal function assessed by ERG also showed significant improvement in these animals.

Conclusions: Intravitreal injection of exogenous Myo/Nog cells normalizes the effects of OIR at a vascular and functional level. Subsequently, Myo/Nog cells have therapeutic potential in the treatment of ROP.

ABSTRACT BODY:

Purpose: Human RPE cells contain numerous lipofuscin (LF), melanolipofuscin (ML), and melanosome (M) organelles that vary in number with retinal location (fovea, perifovea, and near periphery) and age (PMID: 32433758) as well as impact on clinical autofluorescence (AF) imaging. Here, we examined the effect of AMD on granule count and AF of RPE cell bodies.

Methods: Seven AMD-affected human RPE flatmounts (early: 3, late dry: 1; neovascular: 3) were imaged at three locations (fovea, perifovea, near periphery) using structured illumination microscopy (SIM) and confocal AF (both: excitation 488 nm). Z-stacks (step size: SIM 100 nm, confocal 390nm) were acquired from apical to basal through RPE cell bodies of 10 adjacent cells in each region. Subsequently, LF, ML, and M were marked, counted, and classified based on their AF properties using a customized ImageJ plug-in. AF/cell was calculated from confocal images. Furthermore, we analysed the impact of AMD on the total number of granules and AF/cell implementing a mixed effect ANCOVA, correlated granule count with cell size, and compared the results with data from normal RPE cells (PMID: 32433758).

Results: Of 152 RPE cells analyzed, average granule count/cell was 449 ± 276 LF, 532 ± 377 ML, and 4 ± 2 M, with early AMD demonstrating higher average granule count (987 ± 616) and lower LF (406 ± 287) compared with late-stage AMD manifestations. While there was a high variation in granule load among cells, the foveal RPE cells had lowest LF (194 ± 290) and total granule count (851 ± 917). AMD-affected RPE cells were larger than RPE cells in normal eyes, had a higher granule density (granules/ μm^2), but showed significantly lower AF at all three locations (fovea: < 0.01 ; perifovea: 0.02; near periphery: < 0.01).

Conclusions: The reduced histological AF signal in AMD eyes compared to healthy cells mirrors and helps to explain clinical AMD AF imaging. Enlarged AMD affected RPE cells might reflect cell fusion or failed cytokinesis (PMID 26875723), which increases net granule count and diminishes total AF. Interestingly, LF was lowest at the fovea

typically affected by accumulation of drusen in AMD as well as preservation of cone-mediated visual acuity. Here, we examined RPE cell bodies, but future studies should also focus on M within RPE's apical processes and their impact on RPE AF imaging (PMID 32648890).

ABSTRACT BODY:

Purpose: Latanoprostene bunod is a new medication whose main additional mechanism is nitric oxide donation. Its downstream effect improves trabecular meshwork outflow. Published studies have proven its efficacy alone as primary therapy in treatment-naïve eyes. This study retrospectively investigated the long-term efficacy of adjunctive use of latanoprostene bunod in refractory cases of glaucoma at a tertiary care glaucoma clinic. Refractory cases were judged as requiring ≥ 3 topical medications.

Methods: Retrospective chart review for patients on ≥ 3 topical medications who received add-on latanoprostene bunod was conducted from 01/01/2018 to 08/31/2020. Patients' baseline characteristics prior to add-on therapy were recorded and included type of glaucoma and prior topical, laser, and surgical treatments. A baseline IOP was calculated by taking the average of the two most recent IOP measurements prior to latanoprostene bunod add-on treatment. IOP was measured at 3-, 6-, and 12-month intervals ± 4 weeks. A Bonferroni corrected student's T-test was used to test differences between groups with statistical significance set at $p = 0.01$.

Results: 53 eyes in 36 patients were included in this analysis. Mean age (\pm SD) was 72.1 ± 11.0 . 18 (50%) patients were Caucasian, 13 (36%) African American, 2 (5%) Hispanic, 2 (5%) Indian American, and 1 (2%) Asian. Glaucoma diagnoses were as follows: 45 (85%) primary open angle, 6 (11%) neovascular, and 2 (4%) uveitic. Prior surgeries included: 11 (21%) trabeculoplasty, 9 (17%) seton, 2 (4%) trabeculectomy, and 2 (4%) iStent (Table 1). Mean IOP mmHg (\pm SD) at baseline was 19.9 ± 6.0 . Follow-up mean IOP mmHg (\pm SD) are as follows: 3-month 17.3 ± 5.5 ($p < 0.01$) in 49 eyes, 6-month 17.2 ± 6.6 ($p < 0.01$) in 35 eyes, and 12-month 16.1 ± 4.5 ($p < 0.01$) in 28 eyes (Table 2).

Conclusions: Adjunctive use of latanoprostene bunod in refractory glaucoma showed clinically and statistically significant IOP reductions. This study suggests that adding latanoprostene bunod to eyes with previous medical or surgical treatment can provide longer term IOP reduction. Further analysis is required to fully understand the effect of latanoprostene bunod in refractory glaucoma.

ABSTRACT BODY:

Purpose: To assess the long-term safety and efficacy of a recombinant adeno-associated viral vector expressing REP1 (AAV2-REP1) in choroideremia patients.

Methods: For the six patients who received single subfoveal injection of AAV2-REP1, five of them were followed up for up to five years. The long-term safety was evaluated by the ophthalmic examination, spectral-domain optical coherence tomography (SD-OCT), and short-wavelength fundus autofluorescence (FAF). Functional and structural changes were determined by best-corrected visual acuity (BCVA) change from baseline in treated eyes compared to untreated eyes, sensitivity change in microperimetry, preserved retinal pigment epithelium (RPE) area measured from FAF, central macular thickness measured from SD-OCT and central V4e kinetic visual field measured with Octopus.

Results: One subject experienced a localized intraretinal immune response that resulted in significant loss of preserved RPE in FAF. Another subject experienced exacerbation of peripheral retinoschisis observed by OCT. One subject had a constant ≥ 15 -letter BCVA gain in the treated eye through one to four and half years after treatment, while one subject had a one time ≥ 15 -letter BCVA improvement in the untreated eye. Microperimetry sensitivity showed constant decline in both treated eyes and untreated eyes without significant difference between groups. Central (≤ 30 dg) V4e kinetic visual field was noted to decline at a similar rate between the treated and untreated eyes. For preserved RPE area, four out of five subjects had similar slopes of decline in both treated and untreated eyes while for one subject preserved RPE in treated eye was found to decline slower than the untreated eye ($p=0.02$). For central macular thickness measured from OCT, four subjects had similar declines in the rate between the treated eye and untreated eyes; one subjects had significantly more rapid central macular thickness decline ($p<0.01$) in the treated eyes possibly due to observed adverse event.

Conclusions: The intraretinal inflammation and regional RPE loss triggered by AAV2-REP1 gene therapy stabilized after two years. The potential long-term benefits for AAV2-REP1 gene therapy include improvement in visual acuity, preservation in RPE in small portion of the study subjects (1/6, respectively) though more data is needed to support this statement.

ABSTRACT BODY:

Purpose: To compare agreement rates of DR PPL grading using UWF-CI and UWF-FA via qualitative and quantitative methods.

Methods: UWF-CI and UWF-FA images were acquired at the same visit from eyes without panretinal photocoagulation and graded for DR severity level at a centralized reading center. UWF-CI were graded qualitatively by 2 trained graders for presence or absence of PPL (qualitative PPL). UWF-FA images were graded for qualitative PPL by 2 separate masked graders. Hemorrhages and microaneurysm (H/Ma) manual counts inside and outside the ETDRS fields were obtained from UWF-FA images. Quantitative PPL-H/MA were defined as greater H/MA counts outside than inside each ETDRS field.

Results: Images from 280 eyes of 188 patients were evaluated. Distribution of DR severity based on UWF grading was 85 eyes (30.4%) mild nonproliferative DR (NPDR), 94 (33.6%) moderate, 66 (23.6%) severe and 35 (12.5%) proliferative DR (PDR). Agreement for qualitative PPL for the entire cohort was moderate for UWF-CI (exact agreement, 77.9%, $\kappa = 0.421$) but was substantially greater for UWF-FA (87.9%, 0.702). Within DR severity levels, agreement was similar in mild NPDR ($\kappa = 0.486$ UWF-FA vs $\kappa = 0.439$ UWF-CI) but substantially better using UWF-FA in all other DR severity levels; moderate NPDR ($\kappa = 0.743$ vs $\kappa = 0.538$), severe NPDR ($\kappa = 0.553$ vs $\kappa = 0.339$) and PDR ($\kappa = 0.639$ vs $\kappa = 0.212$).

Average agreement between qualitative PPL grading for UWF-CI and UWF-FA was poor (70.2%, $\kappa = 0.228$). Using a difference of 1 H/MA or more in the UWF fields, quantitative PPL-H/Ma had a moderate agreement with both qualitative PPL graders (72.8%, 0.447 and 73.8%, 0.468). Increasing the threshold difference to determine PPL-H/Ma from 2-8 did not improve the agreement rates with qualitative grading (70.3% - 72.8%, 0.330 – 0.447; 73.6% - 78.2%, 0.468 – 0.516).

Conclusions: Agreement between qualitative PPL grading on UWF-FA and UWF-CI is poor, suggesting that they are not readily interchangeable. Determining PPL qualitatively on UWF-FA is more reproducible than UWF-CI in eyes with moderate NPDR or worse. Given these differences, future studies will need to evaluate whether PPL graded on FA or CI is more associated with DR progression. If FA is deemed more prognostic, then the role of FA in assessing DR management may become more important.

ABSTRACT BODY:

Purpose: In patients with geographic atrophy (GA) secondary to age-related macular degeneration (AMD), the rate of progression is variable. To evaluate the potential of artificial intelligence (AI) for active monitoring of GA progression, we trained and evaluated an automated deep learning-based image segmentation algorithm to detect and measure the size of retinal pigment epithelium (RPE)-loss on OCT scans.

Methods: OCT scans (512x49x496 voxels, Heidelberg Engineering) of study eyes of patients with complete RPE and outer retinal atrophy (cRORA) were evaluated. Patients were enrolled in the FILLY phase II clinical trial to study the effect of pegcetacoplan (APL-2), an investigational therapy targeting complement C3. The scans were first manually annotated for the presence of cRORA at an A-scan level, delineating the GA area. With the manual annotations as the reference, a deep learning image segmentation method using a 3D-to-2D convolutional neural network (CNN) was then trained to automatically segment a topographic 2D cRORA area on a 3D-OCT scan and its performance was evaluated using a five-fold cross-validation.

Results: 115 study eyes were included in the analysis that completed a one year follow-up and had a sufficient image quality to allow manual annotation of RPE-loss at baseline and year 1. The segmentation performance was evaluated as a precision, recall and Dice score (DSC), corresponding to the overlap between the reference and the automated segmentation. For the set of baseline scans, a mean DSC was 0.91, precision was 0.90, and recall was 0.94. For the year 1 scans, the mean DSC was 0.93, precision was 0.91, and recall was 0.95. Evaluation limited to the differential one-year growth area, resulted in the mean DSC of 0.57, precision of 0.49, and recall of 0.72.

Conclusions: Fully automated image segmentation of RPE loss on OCT is able to localize and delineate the GA area with high accuracy. Automated AI-based analysis was able to reproduce the findings of the phase II clinical trial complementing the results of centralized reading. The results of this pilot study represent a promising step toward AI-based clinical decision support tools that can monitor GA progression and therapeutic response, once the treatments for GA secondary to AMD become available.

ABSTRACT BODY:

Purpose: Plane-wave (PW) ultrasound with a linear array probe is capable of visualizing and measuring retrobulbar blood flow. Because the retrobulbar vessels have a complex arrangement and are not situated in one plane, 2D images cannot capture their anatomic arrangement. The goal of this study was to determine if PW ultrasound could be used to visualize and measure flow dynamics in 3D in the retrobulbar vessels in a rat model.

Methods: Ultrafast PW imaging on the eyes of Sprague Dawley rats was performed with a Verasonics Vantage 128 ultrasound system using an 18 MHz linear array probe. Compound images were acquired by emitting unfocused wavefronts at multiple angles and combining echo data from all angles to form individual B-scans. 3D data were acquired by moving the probe on a linear translation stage over 2.5 mm at 1.5 mm/s, imaging at the rate of 3000 images/s. Plane thickness was approximately 0.5 mm, allowing sufficient dwell time in overlapping planes to both capture anatomy and measure flow dynamics in 3D data sets. A Singular Value Decomposition (SVD) filter was used to detect blood flow and produce power Doppler images. Velocity was measured using spectrogram analysis.

Results: 3D images were produced in ImageJ from the stack of image planes. By applying the SVD filter to overlapping sets of scan planes (i.e., within a beamwidth), we were able to visualize pulsatile flow of vessels. Figure 1 shows a projection image of grey-scale structural backscatter and blood-flow from a 3D scan set. Figure 2 (a) and (b) show spectrograms of the two arteries marked in Figure 1. Cosine-corrected peak-velocities (47.7 and 32.2 mm/s) can be seen at depths of 1.2 and 0.9 mm, corresponding to the locations of the arteries in the 2.5 mm translation axis, velocities which are comparable to observed values in Doppler B-scans (39.9 ± 14.4 , $n=20$).

Conclusions: While 3D ultrasound imaging is not new, 3D capture combining structural and functional information is novel. Although the axial and lateral resolution of the array are on the order of 0.1 mm, out-of-plane resolution is ~0.5 mm, which is disadvantageous in terms of interplane spatial resolution. This weakness is turned to advantage by SVD processing sets of overlapping data from regions approximating slice thickness to obtain both structural and functional data.

TITLE: Comparison of peripapillary and perimacular flow density of POAG eyes with normal IOP under Tafluprost therapy compared with post-surgery eyes

SESSION TITLE: Deep Learning and Ocular Blood Flow

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Weindler, M.S. Spitzer, M. Schultheiß, R. Kromer, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Hamburg, GERMANY|

Commercial Relationships Disclosure (Abstract): Hannah Weindler: Commercial Relationship: Code N (No Commercial Relationship) | Martin Spitzer: Commercial Relationship: Code N (No Commercial Relationship) | Maximilian Schultheiß: Commercial Relationship: Code N (No Commercial Relationship) | Robert Kromer: Commercial Relationship(s); Santen Pharmaceutical: Code F (Financial Support)

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) is a progressive neurodegenerative disease which leads to irreversible blindness. An elevated intraocular pressure (IOP) is considered to be the main risk factor for the disease progression. It is known that retinal blood flow is altered in POAG eyes. Tafluprost, a prostaglandin analogue which lowers the IOP, has shown to also improve the retinal blood flow in animals.

Methods: The current study therefore evaluated the retinal vessel density in the peripapillary and macular region of POAG patients with normal IOP treated with topical Tafluprost (n=20) compared to surgically treated patients (including deep sclerectomy, trabeculotomy and trabeculectomy) with normal IOP (n=22) using optical coherence tomography angiography (OCT-A Topcon DRI OCT Triton Tokyo, Japan). The OCT-A was performed in the superficial peripapillary Plexus as well as the superficial and deep perimacular Plexus. The retinal flow density was obtained after binarisation using Matlab® and evaluated in five sectors (superior, inferior, nasal, temporal, central). The statistic analysis was performed using the parametric t-test with Sidak correction.

Results: There was a significantly higher peripapillary flow density in all sectors in Tafluprost treated eyes when compared to post-surgery eyes (central $39.3 \pm 11.8\%$ versus $32.8 \pm 5.9\%$, $p=0.04$; superior $41.1 \pm 9.4\%$ versus $32.1 \pm 7.4\%$, $p = 0.001$; temporal $32.1 \pm 14.9\%$ vs $20.9 \pm 5.9\%$, $p < 0.0001$; inferior $42.6 \pm 12.4\%$ versus $30.4 \pm 8.9\%$, $p < 0.0001$; nasal $23.8 \pm 10.1\%$ versus $15.7 \pm 4.9\%$, $p = 0.03$). The flow density in the inferior sector of the superficial plexus in the macular region was also significantly higher in the Tafluprost group $26.6 \pm 10.5\%$ versus $19.7 \pm 3.2\%$, $p = 0.03$).

Conclusions: These results suggest that there is a significantly higher flow density with patients with POAG under Tafluprost therapy when compared to surgically treated POAG patients. This may indicate that IOP lowering surgeries should be performed rather late.

ABSTRACT BODY:

Purpose: The ABCA4 gene, implicated in Stargardt disease (STGD1), is the most frequently mutated maculopathy gene. Despite ABCA4 being identified 24 years ago, for thousands of cases the mutations causing STGD1 remain unknown. Previously, 1054 unsolved STGD and STGD-like probands were analyzed using single molecule molecular inversion probes (smMIPs), revealing bi-allelic ABCA4 variants in 448 probands, including 13 novel causal deep-intronic variants (DIVs) in 18 alleles, and 11 novel structural variants (SVs) in 16 alleles (Khan et al. GenetMed, 22:1235-1246, 2020). Here, we aim to shed further light on the missing heritability of STGD1 by analyzing another large cohort of genetically unsolved STGD probands.

Methods: 876 STGD and STGD-like patients were collected from 27 collaborators worldwide, 725 probands carried no or one ABCA4 variant and 151 probands carried two alleles, one of which was p.Asn1868Ile or p.Gly1961Glu, which are sometimes found in cis with DIVs. The complete 128-kb ABCA4 gene was sequenced using previously designed smMIPs. The effect of putative splice defects was assessed through in vitro midigene splice assays in HEK293T cells. The breakpoints of SVs were determined by junction PCR and Sanger sequencing.

Results: ABCA4 sequence analysis revealed two causal alleles in 436 of 876 probands (49.8%), and 13 known (in 63 alleles) and 15 novel (in 20 alleles) causal DIVs. In vitro splice assays revealed, among others, a DIV (c.4539+1964G>T) leading to the in-frame insertion of a pseudoexon, a near exon variant (c.859-25A>G) leading to complex splicing defects and a splice variant (c.4667+5G>T) that is part of a novel complex allele. In addition, 4 novel and 1 known SV were identified and characterized in 5 alleles.

Conclusions: Similar to a previous ABCA4 sequencing study of STGD and STGD-like cases, in which we genetically solved 448/1054 (42.5%) probands, we were able to genetically solve 49.8% of the probands. The total number of novel DIVs and SVs, i.e. 24 in 872 alleles (2.8%) is similar to the previous study in which we discovered 34 in 896 alleles (3.8%), indicating that there still are many rare DIVs and SVs to be discovered in Caucasian STGD1 cases. The identification of 83 DIVs in 81 probands suggests these persons may be eligible for splice modulation therapies when available.

ABSTRACT BODY:

Purpose: COVID-19 and associated mitigation measures have caused unprecedented global disruption. It is not known whether there are disproportionate challenges for persons with a sensory disability. Our cross-sectional study assesses this impact of the pandemic on persons with and without visual or hearing loss.

Methods: Experts from diverse disciplines developed a 34-item survey instrument, the Coronavirus Disability Survey, which includes items on general and psychological health, instrumental activities of daily living, isolation, financial and transportation challenges, and information access. The study population included 112 adults with moderate or worse visual impairment (<20/60 in better-seeing eye), 108 with hearing loss (defined using ICD-10 codes), and 155 age/sex-matched controls recruited from the University of Michigan (UM) Health System. Survey administration was via email or telephone. The UM IRB approved this study and all participants provided informed consent.

Results: Participants reported similarly high levels of disruption of their daily lives with 80% reporting “a fair amount” or “a lot” of disruption. Groups reported similar levels of COVID exposure (21%) and infection (45% of exposed). In the visual loss (VL) group, 18% reported “a lot” of difficulty or being “unable” to access routine medical care compared with 12% of hearing loss (HL) and 10% of control (C) groups ($p=.02$). The reasons for increased difficulty with instrumental activities of daily living varied: among those with VL 62% had difficulty due to fear of exposure (54% HL, 45% C); 38% said the person assisting them was worried about exposure (6% HL, 7% C); and 12% cited decreased availability of public transportation (2% HL, 3% C). A greater proportion with VL began relying more on family for assistance (31% VL, 7% HL, 13% C) ($p<.001$ for all comparisons). Among all participants, 30% reported difficulty accessing trusted information about the pandemic; 11% of those with VL found the information difficult to see or hear (1% HL, 2% C; $p<.001$).

Conclusions: Individuals with VL may face increased disruption of their daily activities stemming from the pandemic and related mitigation measures, including in accessing healthcare, transportation, and information. Data-driven public health and policy decisions may benefit from a deeper understanding of the differential impact of the pandemic on these vulnerable groups.

ABSTRACT BODY:

Purpose: Glibenclamide (Glyburide), a Sulfonylurea drug used to lower blood glucose in diabetic patients, was shown to be neuroprotective when administered either systemically or locally in rat models of hyperglycemia or excitotoxicity-induced retinal degeneration. Its administration, at non-hypoglycemic doses, protected retinal function and structure. It acts through its binding to the Sulfonylurea receptor SUR1, extensively expressed in rodent, monkey and human neuroretinas (Berdugo et al. 2020). In this study, we investigated the protective effects of life-long oral treatment with glibenclamide, at low dose, in the Goto-Kakizaki (GK) rat model of diabetic retinopathy (DR).

Methods: GK rats were force-fed with a glibenclamide oral suspension (Amglidia(ND), Ammtek/Nordic Pharma) or vehicle twice a day, 5d/wk, from 2-months (hyperglycemia onset) to 12-months of age (previously described stage of DR; Omri S, 2013; Rothschild PR, 2017). At 12 months, we measured neuroretinal thickness on Optical Coherence Tomography (OCT) pictures, we quantified retinal vascularisation and vascular diameters on fluorescent lectin-labeled neuroretinal flatmounts, photographed with a confocal microscope and using a self-made ImageJ macro. We evaluated retinal function evolution through electroretinography testing (ERG) in glibenclamide vs. vehicle treated diabetic animals and vs. non-diabetic Wistar rats (WS).

Results: Diabetes induced retinal thickening on OCT pictures (mean 337 ± 3.7 sem vs. 303 ± 3.8 microns) and treatment reduced this thickening (315 ± 4.5 microns $P < 0.05$). The proportion of retinal capillaries is increased by 7.8% in the treated group compared to vehicle-treated group ($P = 0.04$). ERG parameters reflecting the inner retina activity were damaged at 12 months in GK rats compared to WS rats (first scotopic oscillatory potential implicit time = 33.5 ± 0.3 vs. 30.4 ± 0.26 ms, $P = 0.0001$, $n = 15$ and 8) and partially protected in treated animals (32.4 ± 0.29 ms, $P = 0.03$, $n = 7$).

Conclusions: Long-term low-dose oral glibenclamide treatment partially prevents RD vascular, edematous and functional damage in diabetic GK rats. As the oral drug is already available for patients, we are now exploring incidence and severity of DR in patients treated by glibenclamide vs. other medications, and developing a local

formulation for ocular diseases.

ABSTRACT BODY:

Purpose: The retinal pigmented epithelium (RPE) and choroid vasculature form a highly specialized tissue that provides critical support for retinal function and homeostasis. Here, we combined human iPSC-derived RPE and endothelial cells (EC) with organ-on-a-chip technology, to model the outer blood-retinal barrier (oBRB). Using this platform, we aim to study patient-specific mechanisms of retinal degenerative disorders such as macular edema.

Methods: The commercially available Emulate organ-chip microfluidic system was used as the basis of the model. The apical channel of the chip was seeded with iPSC-derived RPE cells that had been differentiated for 42 days. ECs were deposited as a monolayer surrounding the chip basal channel to mimic the choroid capillaries. In order to characterize the functionality of the RPE-EC co-culture system in the chip, we assayed: (1) Dextran permeability, (2) fluid transport across apical to basal channels, and (3) RPE and EC morphology.

Results: Various genetically independent healthy and diseased iPSCs were differentiated into functional RPE and EC and cryopreserved. RPE cells formed a monolayer on the membrane of the apical channel and displayed highly pigmented polygonal morphology with expression of ZO-1 and tublin-1b. RPE tight junction integrity was confirmed using a fluorochrome conjugated dextran permeability assay, demonstrating that RPE barrier function was sufficient to block Dextran molecules. In addition, a fluid transport assay was performed to examine RPE transcytosis and homeostasis function. When compared to control chips seeded with only RPE cells, the fluid transport activity in RPE-EC chips was 2-fold higher and in range of physiological levels. These results support that both EC and RPE cells are critical components of fluid transport activity.

Conclusions: The combination of a microfluidic organ-chip system with patient-specific iPSC derivatives has provided us with a non-invasive ex vivo model to study outer retinal physiology. This micro-engineered RPE-EC chip system is a platform for the patient-specific study of diseased RPE-EC phenotypes as well as drug discovery and toxicity screening for the treatment of ocular degenerative diseases such as macular edema.

ABSTRACT BODY:

Purpose: The purpose of this study was to genetically characterize an AMD population from Portugal.

Methods: We performed the epidemiological Coimbra Eye Study (NCT02748824), and genotyped AMD patients and controls. Participants were classified based on the Rotterdam Classification. Patients were considered stages 2,3 and 4, whereas controls were considered stages 0 and 1b. For this analysis, we considered 243 patients and 598 controls. Genotyping was performed using a single-molecule molecular inversion probes and next generation sequencing to target single nucleotide polymorphisms (SNPs) and coding and splice-site regions of 13 genes: ARMS2, C3, C9, CD46, CFB, CFH, CFI, HTRA1, TIMP3, SLC16A8, ABCA4, CTNNA1, and PRPH2. The genetic assay was performed under the EyeRisk Project, of the E3 Consortium. A total of 841 samples and 69 SNPs were tested for association under an additive model, using the presence of AMD as a binary outcome. A logistic regression analysis was performed to assess allelic odds ratio (ORs) at 95% CI for each variant, adjusted for age and sex.

Results: We have identified 7 variants that may have a protective effect on the outcome of the disease:

C2_CFB_SKIV2L rs429608 (OR 0.518;CI 95% 0.342-0.765, p= 0.0013); CFH rs10922109 (OR 0.683;CI 95% 0.5657-0.891, p= 0.0032) and rs1410996 (OR 0.708;CI 95% 0.5629-0.886, p=0.0028); CETP rs5817082 (OR 0.738;CI 95% 0.5637-0.961, p= 0.0255); CNN2 rs10422209 (OR 0.683;CI 95% 0.4757-0.966, p= 0.0343; CB rs641153 (OR 0.659;CI 95% 0.4408-0.966, p= 0.0366) and RDBP_CFB rs760070 (OR 0.682;CI 95% 0.4565-0.997, p=0.0541).

Additionally, we have identified 4 SNPs associated with the presence of AMD: ARMS2 rs10490924 (OR 1.51; CI 95% 1,1369 - 2, p= 0,0042); ARMS2_HTRA1 rs3750846 (OR 1.5; CI 95% 1.1226- 1.99, p= 0.0057); SLC16A8 rs8135665 (OR 1.51; CI 95% 1.0893- 2.08, p= 0.0128) and CFH rs35292876 (OR 2.93; CI 95% 1.204- 7.15, p= 0.0166).

Conclusions: Our results are in line with other studies that have been published, namely the two major genetic studies of the IAMDGC and the EyeRisk Project, highlighting the importance of genetics in the disease. The genes associated with AMD act in different pathophysiology pathways, sustaining the multifactorial etiology of AMD. To our knowledge, this is the first genetic study of a Portuguese AMD population, and our results are compliant with literature.

ABSTRACT BODY:

Purpose: Diabetic subjects have alterations in the anatomical integrity of the foveal cone mosaic, e.g. disruptions in the foveal cone mosaic that could act as noise in the visual system and lead to a decline in visual performance. We estimated the magnitude of these disruptions in Adaptive Optics Scanning Laser Ophthalmoscope cone maps.

Methods: We quantified the disruptions to the cone mosaic in 11 diabetic subjects (35-71 yr, 51.0 +/-14.4 yr) who were previously found to have localized dark cone regions. Subjects were consented and tested in a manner approved by the Indiana University Institutional Review Board, which adhered to the Declaration of Helsinki. Confocal images with a 100-micron aperture were collected as a series of 100 frame video sequences. The image sequences were aligned and summed to provide a range of gray scale images that allowed cones to vary from bright to dark. A 3 deg region of interest was analyzed, centered on the region of highest cone density. Two independent graders quantified the extent of the disruptions in the cone mosaic using the following criteria: 1) Continuity of the dark regions, 2) length of at least 3 cones and 3) regions darker than nearby structures. The disruptions could be either gaps between cones or adjacent cones that lacked strong central reflections. We computed the Euclidian distance of each disruption of the cone mosaics.

Results: Both types of disruptions, gaps between cones and three or more cones in a row lacking reflective centers, were found. Disruptions of the cone mosaic of a size sufficient to create visual noise were typical, with 10 of 11 subjects, having more than 75% of all the disruptions identified by the graders being > 1 min of arc (5 microns/ ≤30 cpd). In 10 of 11 subjects, the presence of at least 5 disruptions of the cone mosaic > than 3 min of arc (15 microns/ ≤10 cpd) and one disruption > than 5 min of arc (25 microns/ ≤6 cpd) were found. These disruptions varied widely in shape and orientation, which negatively impacted the agreement between the graders.

Conclusions: In the foveal region of diabetic retinas, disruptions of the cone mosaic were typical. Previously, sensitivity to acuity targets was shown to be decreased in a region of an area of dark cones (Tu, 2017). Thus, we anticipate that visual noise produced by these disruptions is of sufficient size to interfere with detection of acuity targets and reading.

ABSTRACT BODY:

Purpose: To develop a deep learning (DL) simulation of standard automated perimetry (SAP) in the central 10° based on spectral domain optical coherence tomography (SD-OCT) retinal nerve fiber layer thickness (RNFLT).

Methods: This study included 5352 pairs of SD-OCT and 10-2 SAP from 1365 eyes of 724 healthy, glaucoma suspect and glaucoma patients from the Diagnostic Innovations in Glaucoma Study (DIGS) and the African Descent and Glaucoma Evaluation Study (ADAGES). Each pair of SD-OCT and 10-2 SAP was obtained within a 6-month duration. The dataset was randomly divided into training (65%), validation (15%), and test (20%) sets at the patient level. A unidimensional DL convolutional neural network was used to map all 768 peripapillary RNFLT values of SD-OCT to 68 sensitivity thresholds of 10-2 SAP. Visual field indices were generated using CNN-predicted sensitivity thresholds at 68 10-2 SAP test locations and included Total deviation (TD) values, Pattern deviation (PD) values at each test location, Mean deviation (MD) and pattern standard deviation (PSD). The accuracy of the model at each test location was evaluated by calculating the average mean absolute error (MAE) and the Pearson correlation coefficients (r) of predicted and actual TD values. Global accuracy of the model was evaluated by calculating the MAE and r for MD and PSD predictions.

Results: The DL TD predictions had an average MAE of 4.04 dB and r of 0.59 ($P < 0.001$) over the 68 10-2 SAP test points. This model was capable of predicting 10-2 SAP MD and PSD with MAE (r) of 2.88 dB (0.74) and 2.30 dB (0.59), respectively (Fig. 1).

Conclusions: An artificial intelligence approach was capable of reconstructing SAP central 10° using peripapillary SD-OCT RNFLT measurements. Peripapillary RNFLT provides information about central visual field in glaucoma.

TITLE: Design of a compact open-field wavefront sensor

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Börjeson, D. Romashchenko, L. Lundstrom, Kungliga Tekniska Hogskolan, Stockholm, SWEDEN|

Commercial Relationships Disclosure (Abstract): Charlie Börjeson: Commercial Relationship: Code N (No Commercial Relationship) | Dmitry Romashchenko: Commercial Relationship: Code N (No Commercial Relationship) | Linda Lundstrom: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many ocular wavefront sensors employ one or two telescopes to image the wavefront from an eye onto a Hartmann-Shack wavefront sensor (HSWS). Conventionally, the components are placed in a 4f setup, resulting in a rather long system, especially for an open field of view configuration. It would be useful to have a small and portable system that could be moved between different experimental setups. Therefore, this study tested the hypothesis that ocular wavefront sensors can be reduced in size by using a non-4f setup, while still maintaining the large eye-to-first-lens distance necessary for open-field sensing.

Methods: The paraxial imaging properties of conventional 4f setups and non-4f setups were compared theoretically. The analyzed non-4f setups had the same eye-to-first-lens distance as the 4f setups, but with shorter focal lengths and with the eye and HSWS conjugate planes shifted away from the focal planes of the telescope lenses. Optical aberrations of the setups with different off-the-shelf lenses were also simulated in Zemax.

A wavefront sensor was built using one of the shortest developed non-4f designs. The HSWS was placed as close to the second lens of the telescope as possible. The correct position for the eye was found by utilizing a double eye model with refractive errors of +5 D and -5 D, which at the conjugate plane of the HSWS would yield equal detected pupil sizes on the HSWS. For verification of the system, trial lenses were then placed in front of the eye models and the wavefront was recorded as Zernike coefficients by the HSWS.

Results: The paraxial calculations showed that the 4f and non-4f setups had identical imaging properties. Compared to a 4f setup, the maximum reduction in eye-to-HSWS distance was 50%, at which point the second-lens-to-HSWS distance was 0. At this limit, the first-lens-to-HSWS distance was reduced to $1/(M+2)$ of that of a 4f setup, where M is the angular magnification of the telescope. The Zemax simulations showed that the non-4f design could be made diffraction limited on-axis.

The measured defocus root-mean-square error for the eye models with trial lenses was 0.11 D, where the total defocus ranged from -5 D to +5 D in increments of 1 D.

Conclusions: It is possible to construct a functional and compact ocular open-field wavefront sensor by using a non-4f setup. However, the initial alignment is more difficult, as the eye and the HSWS are not placed in the focal planes of the telescope lenses.

TITLE: Border Location Affects Local Progression Kinetics of Geographic Atrophy

SESSION TITLE: AMD imaging - GA

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L.V. Del Priore, M. Sun, A. Ahluwalia, B. Young, M. Park, L. Shen, Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Lucian Del Priore: Commercial Relationship(s);Astellas:Code C (Consultant);LambdaVision:Code C (Consultant);Tissue Regeneration Sciences:Code C (Consultant);CavTheRx:Code C (Consultant);Seeing Medicines:Code C (Consultant) | Mengyuan Sun: Commercial Relationship: Code N (No Commercial Relationship) | Aneesha Ahluwalia: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Young: Commercial Relationship: Code N (No Commercial Relationship) | Michael Park: Commercial Relationship: Code N (No Commercial Relationship) | Liangbo Shen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the impact of geographic atrophy (GA) location on GA local progression rate and the distribution of GA lesions.

Methods: We manually delineated GA on color fundus photographs of eyes with non-exudative age-related macular degeneration in the Age-Related Eye Disease Study. We included 2 visits that were 1 year apart for each eye with GA and then registered the images using vessel bifurcations. We calculated GA border expansion rate (BER) as the linear distance that GA border traveled over 1 year using a Euclidean distance map. Eye-specific BER was defined as the mean BER of all pixels (pixel size=10 μ m) on GA border in each eye. We also determined GA prevalence and BER in 4 macular quadrants and at different distances from the foveal center.

Results: We included 237 eyes of 160 patients in the analysis. GA enlarged $1.51 \pm 1.96 \text{ mm}^2$ in area and $0.13 \pm 0.11 \text{ mm}$ in distance over 1 year. GA area growth rate (mm^2/year) was significantly associated with baseline GA area ($P < 0.001$), number of lesions ($P < 0.001$), and circularity index ($P < 0.001$); in contrast, eye-specific BER (mm/year) was not significantly associated with any of these 3 morphological factors. The percentage of the retina affected by GA decreased from 49% to 1% as the retinal eccentricity increased from 0 to 4 mm (Figure A). By comparison, GA BER increased linearly as a function of retinal eccentricity ($P < 0.001$), increasing from 0.07 mm/year at 0-0.5 mm from the foveal center to 0.18 mm/year at 3.5-4 mm from the foveal center (Figure B). The GA BER did not vary significantly across 4 macular quadrants ($P = 0.16$), but the percentage of retina affected by GA was higher in the temporal than nasal quadrant ($P = 0.02$), and was higher in the superior than inferior quadrant ($P = 0.01$).

Conclusions: Measurements of eye-specific GA BER allows evaluation of GA progression without significant confounding effects from baseline GA area, shape, and lesion number. The local progression rate of GA increased as a function of distance from the foveal center within the macula, and was different from GA distribution. These findings suggest that the underlying mechanism responsible for GA initiation may be different from the mechanism of GA enlargement.

TITLE: RPE cells grown on AMD-like extracellular matrix activate the complement system via tick-over, which can be prevented with shRNAs anti-C3.

SESSION TITLE: RPE pathology in AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R. Fernandez-Godino, B. Chinchilla Rodriguez, Ophthalmology, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rosario Fernandez-Godino: Commercial Relationship: Code N (No Commercial Relationship) | Blanca Chinchilla Rodriguez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cell-based models are valuable tools to study the mechanisms of pathology at early stages of age-related macular degeneration (AMD), including the formation of sub-retinal pigment epithelial (RPE) deposits mediated by the activation of the complement system. We propose that alterations in the extracellular matrix (ECM) of Bruch's membrane (BrM) caused by aging or mutations accelerate the rate of hydrolysis of complement C3 to C3(H₂O) (tick-over), which forms a stable C3(H₂O)-convertase on the ECM that activates C3 chronically and ultimately leads to deposit formation.

Methods: To test our hypothesis, we have used CRISPR-based gene editing tools to generate induced Pluripotent Stem Cells (iPSCs) carrying the mutation p.923delDG in C3, which allows complement activation via tick-over only. iPSC C3^{-/-} and C3^{WT/WT} were used as controls. The edited iPSCs were differentiated into RPE cells using direct differentiation methods and cultured on transwells coated with RPE-derived ECM that mimics BrM with AMD. To investigate the potential of C3 as a therapeutic target, C3 was inhibited with short hairpin (sh) RNAs in the iPSC-RPE cells grown on AMD-like ECM. Complement activation by tick-over or alternative pathway was quantified by the presence of C3(H₂O) and C3a respectively in conditioned media measured via ELISA. Formation of basal deposits was characterized by immunofluorescence and electron microscopy.

Results: iPSC-RPE cells C3^{WT/WT} and C3^{WT/923DG} grown on AMD-like ECM secreted elevated levels of C3(H₂O) and C3a compared to the same cells grown on normal ECM (ANOVA, **p<0.01). Abnormal deposition of collagen fibers underneath the RPE cultured on AMD-like ECM was also observed by immunostaining and electron microscopy after 3 months. Treatment with shRNA anti-C3 decreased the mRNA levels of C3 (ANOVA, ****p<0.0001) as well as the amount of C3(H₂O) secreted to the media of wild type cells grown on AMD-like ECM (ANOVA, **p<0.01). The deposition of collagens underneath the RPE was also diminished after the treatment with shRNAs anti-C3.

Conclusions: The results are consistent with our hypothesis that abnormalities in the ECM result in increased activation of C3 via tick-over, which can be inhibited with shRNAs. Thereby, the tick-over could be used as a therapeutic target to prevent increased complement activation in patients with early AMD.

ABSTRACT BODY:

Purpose: There is growing evidence that intrinsically photosensitive retinal ganglion cells (ipRGCs) modulate retinal activity. It has been demonstrated that selective stimulation of the optic nerve head with blue light (BL) can activate the melanopsin-containing ipRGCs axons located there. Stimulation of ipRGC axons also improves contrast sensitivity and alters retinal electrical activity, which may indirectly reflect an increase in retinal dopamine release. Retrograde signalling from ipRGCs to dopaminergic amacrine cells can influence the retinal dopaminergic system. This study aimed to directly investigate any change in dopamine release as a result of ipRGC activation. It was hypothesized that dopamine levels would be elevated after stimulation of the optic nerve head with BL.

Methods: Adult male New Zealand rabbits were stimulated for one and ten minutes with and without BL, being included five rabbits in each group. With a self-constructed stereotactic system, it was able to specifically stimulate the optic nerve head with BL (peak 470 nm) in rabbits' eyes. The BL stimulus was delivered by an optical fiber of 200 µm diameter inserted into the globe and positioned over the optic nerve head in the experimental eye only. In the control condition with no light, the optical fiber was inserted without light stimulation. The concentration of dopamine in the tears, aqueous humor, vitreous humor, and retina was measured using high-performance liquid chromatography. After normal distribution analysis, statistical comparisons were conducted between the contralateral eye and the experimental eye after stimulation using paired Student's t-tests, being considered $p < 0.05$ as statistical significance.

Results: No significant difference in absolute dopamine levels between eyes was found in the tears, aqueous humor, or retina ($p > 0.05$). In the vitreous humor, dopamine concentration was significantly higher in the experimental eye compared to the contralateral eye after BL stimulation ($p < 0.05$).

Conclusions: These results are consistent with research that suggests vitreal content is a better measure of the rate of retinal dopamine release than retinal dopamine levels. This is the first direct evidence that activation of melanopsin in the axons of ipRGCs at the head of the optic nerve results in measurable changes in dopamine concentration in the eye.

ABSTRACT BODY:

Purpose: To estimate and compare the cost-effectiveness of mydriatic and nonmydriatic imaging devices for consideration in a community-based program for diabetic retinopathy (DR) screening in the Philippines

Methods: A decision-analytic model was developed to simulate the costs and outcomes of each device [Aurora (AU), Smartscope (SS), RV700 (RV), InView (NV) with dilation and without dilation of the pupil. The key measures of effectiveness were determined by the devices' operating characteristics including positive and negative predictive values and rate of ungradable images. These parameters, as well as the distribution of patients with varying severity levels of DR, were obtained from a validation study performed in Manila involving images from 177 eyes of 92 patients with diabetes. Associated costs of screening, referrals, panretinal laser photocoagulation for severe nonproliferative or proliferative DR, and corresponding cost of severe vision loss were estimated from the perspective of the patient. Health outcomes were reported as quality-adjusted life years (QALYs) based on utility values assigned to vision threatening DR and vision loss. The primary outcome measure is reported as cost in Philippine Peso (PhP) per QALY gained.

Results: Analyses from the patient perspective show that all devices were dominated when the clinic-based screening test was used as comparator. When using the dominance approach, the NV and AU NM were strongly dominated, whereas the RV7 MD/NM, and SS MD were weakly dominated. The AU MD was most cost-effective with an incremental cost-effectiveness ratio (ICER) value of 71,207 PhP per QALY-gained versus the Smartscope MD. Results were most sensitive to changes in the cost of the comparator, rate of ungradable image and incidence of DR.

Conclusions: The use of Aurora and Smartscope with pupil dilation yield good value for money based on their validity, and the reported ICER value falls below the country-specific threshold of 150,000 PhP, which shows great potential for being cost-effective in a community-based DR screening program. A broader and more comprehensive analysis is warranted to account for societal costs when the devices are used in a larger-scale, relative to their individual and population-level benefits while considering other factors such as burden and treatment of disease, and health system capacity.

ABSTRACT BODY:

Purpose: EVP is a significant determinant of intraocular pressure (IOP) in the Goldmann equation and is a potential rapid and non-invasive biomarker for intracranial pressure (ICP). The variability of EVP with demographic variables, systemic and ocular characteristics is yet to be elucidated. This study aims to evaluate the epidemiology of EVP.

Methods: A post hoc analysis was conducted of collated data from aqueous humor dynamics studies of healthy adults at UNMC (Nebraska), Mayo Clinic (Minnesota) and U Michigan (Michigan). Systemic parameters measured were weight, height, BMI, neck circumference (NC), pulse rate, systolic (SBP) and diastolic blood pressures (DBP). Mean arterial pressure (MAP) was calculated. Seated IOP was measured using a pneumatonometer (Reichert, USA). Seated EVP was measured using a slit lamp mounted venomanometer (Eyetechn USA). Two sites subjectively chose endpoints and the third site added video capture of endpoints. Two to three readings were collected and averaged. Central corneal thickness (CCT), anterior chamber depth (ACD) and axial length (AL) were collected with ultrasound instruments. Biweight midcorrelations were used to study the effect of different variables on EVP. Right eye (OD) and left eye (OS) of each subject were independently correlated with each variable.

Results: Data from 201 subjects (n = 201 eyes) (mean age of 46 ± 16 years and range of 15 to 81 years) were analyzed. 76% were females (Table 1) and 85% were White. All variables were normally distributed except age, which was bimodally distributed. Data is presented as mean \pm SD unless stated otherwise. Mean values were weight 78 ± 18 kg, height 166 ± 9 cm, BMI 28 ± 5 and NC 37 ± 4 cm. Pulse rate was 72 ± 13 beats per minute and SBP, DBP, and MAP were 123 ± 15 , 77 ± 10 , and 92 ± 12 mmHg, respectively. All ocular measurements were correlated between OD and OS. Ocular parameters were EVP 7.9 ± 1.6 mmHg (range 3 to 14 mmHg), IOP 15.7 ± 2.7 mmHg (range 7 to 22 mmHg), CCT 557 ± 40 mm, ACD 3.4 ± 0.3 mm and AL 24 ± 1 mm. None of the systemic or ocular measurements had any significant correlation with EVP or IOP (Figure 1). All variables showed similar relationships for OD and OS eyes and in males and females.

Conclusions: EVP was not found to be correlated with any systemic or ocular parameters. A small range of distribution and the ability to measure EVP non-invasively would make it an excellent biomarker for raised ICP.

ABSTRACT BODY:

Purpose: Six ordinary differential equation (ODE) tear film breakup (TBU) models are created to capture evaporation, osmosis, and different types of flow. A convolutional neural network designed after Su et al. (IEEE, 2018) and trained on over 40,000 image patches successfully identifies TBU and non-TBU in fluorescent (FL) images gathered in vivo with an accuracy of 92%. The ODE models are fit to the automatically identified TBU FL intensity data by optimizing TBU quantities such as evaporation and tangential flow rates. Best-fit determination of TBU parameters suggests which mechanisms cause the thinning.

Methods: The FL intensity data was originally recorded from 25 normal subjects with 20 trials taken over two visits (Awisi-Gyau, Indiana University thesis, 2020). We extract the experimental FL image data from the centers of TBU regions identified by a convolutional neural network. These are fit with the models designed to mimic evaporation-driven, tangential flow-driven, and combination thinning. We estimate parameters using a least squares minimization of the difference between experimental and computed intensities using the trust region-reflective method. Theoretical intensity dependent on tear film (TF) thickness and FL concentration was based on Nichols et al (2012, IOVS, 53:5426). Separate procedures were used to estimate initial FL concentration and localized TF thickness (Wu et al, IOVS 2015, 56:4211). The fits use up to four parameters: evaporation rate v , a (steady) and b_1 (decaying) extensional flow rates, and decay rate b_2 . All computations are via custom Python programs.

Results: Optimal evaporation rates fall near or within experimental ranges (Nichols et al, IOVS, 2005). An example fit is shown in the Figure. The best-fit model determines that the evaporation rate is $-3.25 \mu\text{m}/\text{min}$ and that the instance exhibits strong, outward tangential flow that decays, allowing evaporation to take over in importance.

Conclusions: Intensity decay in automatically identified TBU areas can readily be fit with simplified models that capture essential thinning dynamics and yield physically relevant quantities. This procedure can be applied to a wide range of instances to obtain statistical information that cannot be directly measured during breakup.

ABSTRACT BODY:

Purpose: Metabolomics can provide unique insights into the understanding of the pathophysiology of multifactorial diseases. We and others have shown that plasma metabolomic profiles vary between patients with age related macular degeneration (AMD) and controls and across stages of AMD. However, to our knowledge, no longitudinal studies have assessed how metabolomic profiles relate to AMD progression. This work aimed to analyze the association between plasma metabolomic profiles and progression of AMD over a three-year period.

Methods: Prospective longitudinal study including patients with AMD and a control group (>50 years old). At baseline and three years later (\pm 3 months), all included participants (both eyes) were imaged with color fundus photographs (CFP) for AMD grading and fasting plasma samples were collected. Eyes were considered to have AMD progression if at three-years their AMD stage was more advanced than the baseline stage grading with the AREDS classification scheme using CFP. Metabolomic profiling was performed using Ultrahigh Performance Liquid chromatography – Mass Spectrometry. Multilevel mixed models (i.e. considering inclusion of two eyes of the same patient), accounting for age, body mass index, smoking and gender were used for analysis, using as outcome progression of AMD (yes/no).

Results: We included data on 196 eyes ($n=98$ patients), 13% ($n=26$) of them with progression at the three-years follow-up. After quality control, a total of 645 plasma endogenous metabolites were considered for analysis. Among the baseline plasma metabolites, 3 (N-palmitoyl-sphingosine, methylsuccinate and N,N-dimethylalanine) were significantly associated with three-year AMD progression ($p \leq 0.009$). When evaluating the association between changes in plasma metabolites (between baseline and 3 years) with progression of AMD, 10 significant associations were seen ($p \leq 0.009$).

Conclusions: Baseline metabolites and changes in metabolomic profiles were associated with clinical progression of AMD at 3 years. In particular, lipid and amino acid metabolites appear to be among the relevant metabolites linked to AMD progression. This work contributes to our understanding of AMD progression and to the development of future biomarkers to monitor and potential therapeutics for this blinding disease.

TITLE: Simulated Assessment of Presbyopia Correction IOLs in post-LASIK Patients

SESSION TITLE: IOL and Crystalline Lens Optics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Lago, A. de Castro, S. Marcos, Instituto de Óptica, Consejo Superior de Investigaciones Científicas, Madrid, SPAIN|C. Lago, L. Sawides, 2Eyes Vision S.L., Madrid, SPAIN|

Commercial Relationships Disclosure (Abstract): Carmen María Lago: Commercial Relationship: Code N (No Commercial Relationship) | Alberto de Castro: Commercial Relationship(s);Alcon:Code F (Financial Support) | Lucie Sawides: Commercial Relationship: Code N (No Commercial Relationship) | Susana Marcos: Commercial Relationship(s);Alcon:Code F (Financial Support)

ABSTRACT BODY:

Purpose: To computationally assess the expected performance of a presbyopia correcting Intraocular Lens (PCIOL) in patients after LASIK surgery, in comparison with non-LASIK patients, and monofocal IOLs.

Methods: Presbyopia correcting IOL (PCIOL, Alcon Acrysof IQ Vivity) and Monofocal IOLs (MonoIOL, Alcon Acrysof IQ) of 22-D power were virtually implanted in an eye model (corneal power 43 D, corneal spherical aberration (SA) of 0.28 mm for 6-mm pupil diameter, anterior chamber depth 3.2 mm). LASIK corneas for myopic (-7.5 to -2.5 D) and hyperopic (+2.5 to +4.5 D) pre-operative spherical error were modeled by inducing SA ranging from 1.15 to -0.78 μ m, correlated with the corrected pre-operative spherical error (Marcos et al. 2002).

Image quality was evaluated in terms of Visual Strehl (VS) at best focus and through-focus. In addition, a metric to quantify retinal image halos was estimated by convolving the Point Spread Function with a 2-arcmin pinhole and calculating the ratio of light beyond 2 arcmin, for 5-mm pupils, ranging from 0 to 1 (maximum halo). Calculations were performed using a commercial optical design software (OpticsStudio, Zemax) and Matlab.

Results: For 5/3 mm pupil diameters VS @BestFocus was 0.93/0.99 and 0.78/0.52 for MonoIOL and for PCIOL (NoLASIK), and was 0.61 ± 0.38 and 0.5 ± 0.27 for MonoIOL and PCIOL (LASIK), on average (across LASIK conditions and pupils). VS at intermediate distances was 0.06/0.11 and 0.08/0.24 for MonoIOL and PCIOL (NoLASIK), and was 0.10 ± 0.06 and 0.17 ± 0.09 for MonoIOL and PCIOL (LASIK). The halo metric was 0.26 for MonoIOL and 0.64 for PCIOL (NoLASIK) and 0.59 ± 0.32 for MonoIOL (LASIK) and 0.71 ± 0.20 for PCIOL (LASIK). The impact of LASIK in combination with IOL on halos was largely asymmetric for hyperopic and myopic LASIK. For similar magnitude of pre-op LASIK refraction correction (+4.5 to -4.5 D), the average halo metric was 0.57 ± 0.26 / 0.85 ± 0.04 for MonoIOL/PCIOL for hyperopic LASIK and 0.73 ± 0.10 / 0.59 ± 0.08 for Monofocal/Presbyopia for myopic LASIK.

Conclusions: In (non LASIK) patients visual quality (VS) at best focus with a PCIOL lies within 16-18% of that with MonoIOL. However, the PCIOL outperforms the MonoIOL at intermediate distances (by 45-66%). The PCIOL performance is relatively immune to the presence of SA induced by LASIK. Furthermore, the PCIOL appears to interact favorably with positive SA (in myopic LASIK) to reduce halos.

ABSTRACT BODY:

Purpose: A key outcome measure in animal models of glaucoma is the number and appearance of RGC axons, typically obtained from light micrographs of optic nerve (ON) cross-sections. However, this analysis is time-consuming and subjective. Here we expand on our RGC axon counting software (AxoNet 1.0, [1]) to also identify axoplasm ("Ax") and myelin sheath ("MySh") of normal-appearing RGC axons and extract their morphometric features.

Methods: Micrographs from 12 control and 14 hypertensive rat ONs were acquired as before [1], representing a wide range of glaucomatous damage. 1421 12x12 μm^2 sub-images were randomly selected from these micrographs, and Ax and MySh of normal-appearing axons were annotated by 16 trained individuals with cross-validation. Sub-images were randomly divided into training (90%), validation (5%), and test (5%) sets. A trained U-Net architecture generated segmentation of Ax and MySh of the normal-appearing axons, assigning a probability of each pixel being Ax or MySh. These maps were processed through an image processing pipeline to compute, for each axon: area, convex area, perimeter, eccentricity, average MySh probability (average probability over all MySh pixels of each pixel being MySh), and average Ax probability. Outcome measures included: (i) the soft-dice coefficient between predicted and ground-truth segmentation maps; (ii) R^2 regressing number of the normal-appearing axons counted automatically vs. ground truth. [1] Ritch+, Sci Rep, 2020

Results: The model performed well (Fig 1) with high soft-dice coefficients (Fig 2). AxoNet 2.0 outperformed AxoNet 1.0 as judged by agreement with ground truth (Fig 2).

Conclusions: A DL model can segment Ax and MySh of normal-appearing axons from ON sub-images with varying ON health. This approach will speed RGC axon counting and morphometric analysis in animal models of glaucomatous optic neuropathy.

ABSTRACT BODY:

Purpose: Increased IOP results in narrowing of Schlemm's canal (SC), which increases the shear stress acting on SC cells. SC cells respond to shear stress by producing nitric oxide (NO), which increases outflow facility and lowers IOP. We hypothesize that increased IOP stimulates NO production by SC cells, comprising part of a homeostatic mechanism to regulate IOP. To measure in situ NO production within the outflow pathway of mice exposed to elevated IOP, we utilised a peptide-based biosensor that is sensitive to changes in NO. We also examined whether inhibition of NO synthase (NOS), which should block IOP-dependent NO production, exhibits a pressure-dependent effect on outflow facility (C).

Methods: NO levels were measured using peptide-functionalized fluorescent particles that convert to 3-nitrotyrosine in the presence of nitroxidative stress. These NO biosensors were perfused into the TM of enucleated mouse eyes at 8 or 16 mmHg (C57BL/6J, n=8 mice). Anterior segments were labelled using anti-nitrotyrosine antibodies and imaged by confocal microscopy. Fluorescent signal from the particles was used to normalise the nitrotyrosine signal in order to account for local differences in particle concentration. To examine NOS activity at different pressures, 50µM L-NAME was perfused into enucleated mouse eyes while contralateral eyes were perfused with vehicle (C57BL/6J, n=7 mice). Eyes were perfused at 9 pressure steps ranging from 4 to 16 mmHg using iPerfusion. Power law fittings to flow-pressure data were used to estimate C at each pressure.

Results: Eyes perfused at 16 mmHg exhibited higher nitrotyrosine levels than eyes perfused at 8 mmHg, relative pixel intensity was 1.15 times higher at 16 mmHg ($p < 0.001$). L-NAME decreased C, and its effect was pressure-dependent ($p = 0.02$). At 20mmHg, L-NAME decreased C by roughly one-third (-32 [-50, -7]%; $p = 0.02$), while at 8 mmHg L-NAME had a borderline significant effect (-17 [-34, 5]%; $p = 0.07$).

Conclusions: Elevated IOP stimulates NO production within the conventional outflow pathway of mice. L-NAME causes an IOP-dependent decrease in outflow facility, presumably by inhibiting NO production that would otherwise increase with IOP. Taken together, these data provide evidence for a rapid homeostatic mechanism involving IOP-dependent NO production that acts to increase outflow facility and oppose IOP elevation. Disruption of this homeostatic mechanism may contribute to ocular hypertension in glaucoma.

ABSTRACT BODY:

Purpose: Central choroidal dystrophies are retinal diseases that involve progressive retinal degeneration and the atrophy of the choriocapillaris. These dystrophies usually present an autosomal dominant inheritance pattern in which patients carry a single mutation in the PRPH2 gene. The aim of this work was to generate a mouse model with the same p.Arg195Leu mutation that was described in diagnosed human patients.

Methods: The heterozygous mouse model Prph2^{KI/WT} has been designed and generated using the CRISPR system to introduce the Arg195Leu mutation in the same allele as the patients. The functional state of the retina was studied using electroretinography under photopic and scotopic conditions and the optomotor test was used to determine visual acuity. In vivo structural state of retinal layers was assessed by optical coherence tomography imaging. The number of photoreceptor rows was quantified in cryosections using immunohistochemistry.

Results: Genetic sequencing of the Prph2^{KI/WT} mouse revealed the same codon mutation found in humans suffering from this dystrophy. Importantly, mice presented a degeneration pattern comparable to patients. From 3 months of age, the mouse optomotor response was significantly reduced indicating a visual acuity decrease. At 6 months, the mice presented reduced scotopic and photopic ERG responses, with smaller a-wave and b-wave amplitudes, and the number of photoreceptor rows was decreased as well as the retinal thickness.

Conclusions: The new Prph2KI/WT mouse model presents a similar degeneration pattern than that observed in patients and may facilitate the analysis of the pathophysiological process, being a suitable model for evaluating different therapeutic strategies.

ABSTRACT BODY:

Purpose: The consumption of high-fat diets (HFD) can lead to significant changes in the gut microbiome. Likewise, intestinal dysbiosis has been associated with the pathogenesis of several degenerative diseases. Thus, the purpose of this work was to analyze the gut microbiome changes associated with the consumption of HFD in mice with retinitis pigmentosa (RP).

Methods: Healthy C57BL/6J mice and dystrophic rd10 mice (RP) were fed either with normal chow (5.5% fat kcal) or with a HFD (61.6% fat kcal) for two weeks after weaning (P19). At the endpoint, retinal function was evaluated by optomotor test and electroretinography. The structure and integrity of the retina were studied by immunohistochemistry. Additionally, the gut microbiome was analyzed by 16S rRNA gene sequencing.

Results: Increased retinal degeneration was found in rd10 mice compared to C57BL/6J mice, both fed with normal chow. rd10 mice showed significantly diminished retinal responsiveness, with lower a- and b-waves, as well as reduced visual acuity. The loss of retinal function was accompanied by a fall in the number of photoreceptor rows, and the remaining photoreceptors exhibited morphologic anomalies. Additionally, the photoreceptor degeneration was associated to an inflammatory response of the retina, with the proliferation of microglial cells and reactive gliosis of Müller cells. Moreover, the gut microbiome analysis revealed differences in alpha and beta diversity at the genera, species and amplicon sequence variants (ASV) levels. Notably, four common ASV (*Rikenella* spp., *Muribaculaceae* spp., *Prevotellaceae* UCG-001 spp., and *Bacilli* spp.) in the gut of healthy animals were not found in the rd10 mice gut. HFD intake by rd10 mice resulted in a significant acceleration of the retinal function and morphology degeneration compared to rd10 mice fed normal chow. The consumption of HFD produced significant dysbiosis in the gut microbiome increasing potentially pro-inflammatory bacteria as *Bilophila* sp., *Alistipes* sp. and *Mucispirillum schaedleri* that probably contribute to the worsening of the degeneration process.

Conclusions: Retinal dysfunction and degeneration in retinitis pigmentosa is linked to significant changes in the gut microbiome, which can be further altered by diet, leading to a deterioration of the disease.

ABSTRACT BODY:

Purpose: Early in age-related macular degeneration (AMD), choroidal endothelial cells (CECs) in the choriocapillaris degenerate concurrently with the choroidal accumulation of the membrane attack complex (MAC), a multiprotein pore which causes cell lysis. MAC formation is controlled by negative regulators such as complement factor H (CFH). A polymorphism in CFH (Y402H) increases risk of AMD by 4-7-fold and results in reduced affinity for binding of this inhibitor to the choroidal extracellular matrix. We hypothesize that changes in local CFH protein levels lead to increased MAC formation on CECs early in AMD.

Methods: To assess the role of CEC-derived CFH, an immortalized CEC line generated from a healthy donor eye was transfected with a pool of 3 CFH siRNAs or a scrambled control for 48 h prior to treatment with 25% normal human serum (NHS) or 25% heat-inactivated NHS. Levels of CFH mRNA and protein were determined and MAC formation was quantified by immunofluorescence. In addition, we generated iPSC-derived CECs from a patient homozygous for the Y402H polymorphism and harboring a stop mutation in CFH. We divided differentiated cells into two populations one un-transduced and one transduced with a lentiviral vector to drive overexpression of wildtype CFH. iPSC derived CECs were treated with 25% NHS or 25% C5 depleted NHS. MAC formation was visualized by immunofluorescence and quantified by FACS analysis.

Results: siRNA delivery resulted in 60% knockdown of CFH mRNA ($p < 0.001$) and 50% knockdown of secreted CFH protein. In the absence of CEC-synthesized CFH, we observed an increase in the abundance of MAC immunofluorescence on CECs (2-fold change, $p < 0.001$). AMD iPSC-derived CECs produced negligible levels of secreted CFH protein by ELISA. Lentiviral overexpression resulted in an 18-fold increase of CFH protein, which was accompanied by decreased MAC immunofluorescence (Figure 1).

Conclusions: We have demonstrated that a reduction in local synthesis of CFH protein by CECs leads to increased MAC deposition in cells exposed to complement-intact serum and that overexpression of CFH locally can protect CECs from MAC. Thus, increased expression of local wildtype CFH protein to CECs may protect against choriocapillaris degeneration and AMD progression.

ABSTRACT BODY:

Purpose: Both *Staphylococcus aureus* and coagulase-negative staphylococci (CoNS; including *Staphylococcus epidermidis*) are implicated in staphylococcal blepharitis. Treatment options for this condition, often used in combination, include lid hygiene, topical anti-inflammatory agents, and topical and/or oral antibiotics. We examined the in vitro potency of antibacterial agents commonly prescribed in the management of blepharitis against staphylococcal isolates from ocular sources.

Methods: Minimum inhibitory concentrations (MICs; µg/mL) were determined for 8 antibiotics (6 drug classes) against methicillin-susceptible and -resistant isolates of *S. aureus* (MSSA and MRSA, respectively) and *S. epidermidis* (MSSE and MRSE, respectively), as well as other species of CoNS with undetermined methicillin resistance status (excluding *S. epidermidis*) previously cultured from ocular infections. In vitro susceptibility testing was conducted at a central laboratory per Clinical and Laboratory Standards Institute broth microdilution methodology.

Results: A total of 150 staphylococci (n=30 per grouping) were tested, and the MICs for 50% and 90% of isolates (MIC₅₀ and MIC₉₀) are presented in the table. MICs among all species were highest for macrolides and bacitracin. Besifloxacin exhibited lower MICs than ciprofloxacin. Against MRSA/MRSE specifically, the lowest MICs observed were for doxycycline and besifloxacin.

Conclusions: Antibacterial agents commonly used in the treatment of blepharitis had variable in vitro activity against ocular staphylococci. Doxycycline and besifloxacin generally demonstrated greater in vitro potency (lower MICs) against all tested isolates, including methicillin-resistant strains, compared to other agents. These data should be considered when treating staphylococcal blepharitis.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa is a hereditary retinopathy that courses with photoreceptor cell death. The rd10 mouse model is suitable for the study of the cellular and molecular alterations that occur during neurodegeneration. Fatty acids and, especially, the n-3 polyunsaturated docosahexaenoic acid (DHA), are abundant in photoreceptor cells and they impact in the phototransduction cascade. Thus, lipidomics analysis can contribute to the knowledge of the molecular pathways that are altered in retinitis pigmentosa.

Methods: C57BL/6J and rd10 mice were kept at a photoperiod of 12:12 (L:D) with a light intensity of 50 lux. At P25, animals were perfused to avoid contamination by blood fatty acids. Retinal fatty acids were assessed by lipid extraction with Folch method and resolution with GC/MS. Cryostat sections of the retina were obtained for morphological studies using immunohistochemistry.

Results: Photoreceptor cell rows were decreased in the retina of rd10 compared to C57BL/6J mice. Recoverin and cone arrestin immunolabeling revealed alterations in the morphology of rods and cones. Moreover, outer segments were shortened, and rhodopsin was mislocated to the cell body. The total amount of fatty acids decreased by 29.4 % in the retina of rd10 mice. Some specific short-chain as well as long-chain saturated fatty acids dropped significantly in the rd10 retina. We also found a dropped in the monounsaturated vaccenic acid and hypogeic acid. Polyunsaturated fatty acids dropped in the retina of the dystrophic mouse too. Concretely, we observed a significant decrease in the n-6 linoleic and arachidonic acid and in the n-3 DHA. But the fall of DHA was more pronounced than the decrease of n-6, and the balance between n-6 and n-3 was altered in the rd10 retina. Furthermore, we found a positive correlation between specific long-chain saturated fatty acids, hypogeic acid and DHA and the number of photoreceptor rows.

Conclusions: DHA fatty acid experiences the most pronounced decrease among fatty acids in the retina of retinitis pigmentosa mice model. The positive correlation between the number of photoreceptor cells and the content of fatty acid could be indicating the relevance of these fatty acids in cell survival. These results can apport new molecular targets and further therapeutic strategies. FEDER-PID2019-106230RB-I00. FPU16/04114, FPU18/02964. RETICS-FEDER RD16/0008/0016. ABSTRACT BODY:

Purpose: Keratoconus is one of the most abundant corneal degenerative disease in the developed world, affecting 1 in 2000 people and a major cause of corneal transplantation. It is characterized by a narrowing and bulging of the cornea, taking a conical shape, which makes it difficult for the patient to see. The cause of the disease is still unknown and it does not have molecular markers to make an early diagnosis. That is why, in our study, we analyzed the content of exosomes, small vesicles of around 100 nm, produced by corneal cells obtained from healthy patients and stromal cells isolated from the corneas of patients with keratoconus.

Methods: Corneal stromal cells were obtained from cadaver donors and from penetrating keratoplasty surgeries of patients suffering keratoconus. Exosomes were isolated from cell culture medium of the two different tissues. miRNAs were analysed by NGS (Next Generation Sequencing), and proteins by LC-MS (Liquid chromatography-mass spectrometry).

Results: A total of 466 proteins and 800 miRNAs were detected, showing 18 and 23 significant differences respectively. Among the proteins, two appeared exclusively in the exosomes produced by keratoconus stromal cells, VNN2 and VTN, while 6 proteins increased and another 10 decreased their levels significantly. Analysis of the miRNAs resulted in 2 of them not being expressed, 5 were under-expressed and 16 were overexpressed in keratoconus versus healthy tissue. These MiRNAs are related to the regulation of the synthesis of around 2,500 proteins involved in many processes such as apoptosis, cell migration, inflammation and others.

Conclusions: This study shows the existence of differences in the composition of the exosomes produced by corneal stromal cells of patients with keratoconus compared to healthy individuals. Furthermore, these differences may be related to disease progression due to the role played by differential molecules, mainly affecting inflammatory pathways or cell migration processes, such as VNN2, VTN, SERPINE1, hsa-miR-34a-3p or hsa-miR-101-3p. These differences may be important for the development of an early diagnosis of the disease and even a possible therapeutic use of the molecules that have been described in this study.

ABSTRACT BODY:

Purpose: Although dry eye disease (DED) and Meibomian gland dysfunction (MGD) are worldwide one of the most common ophthalmological complaints by patients, their prevalence in a very old population has remained unknown so far. We assessed DED and MGD prevalences in a very old population.

Methods: The population-based Ural Very Old Study was conducted in a rural and urban area in Bashkortostan/Russia from 2018 to 2020 and included 1526 (81.1%) participants out of 1882 eligible individuals aged 85+ years. A detailed systemic and ophthalmological examination with Schirmer test and slit-lamp based assessment of the Meibomian glands, and an interview with a questionnaire of >300 questions.

Results: The investigation included 1493 (97.8%) individuals with available information about dry eye. Mean age was 88.3±2.9 years (range: 85-103 years). Schirmer test was ≤5 mm in 160 (34.3%; 95% confidence interval (CI): 31.5, 37.1) eyes. The mean score of dry eye symptoms was 7.52±2.14 (95%CI:7.41,7.63). A MGD grade 1,2,3 and 4 in the worse eye was diagnosed in 367 (31.4%), 309 (26.4%), 89 (7.6%), and 39 (3.3%) eyes, respectively. The prevalence of DED diagnosis 1 (dry eye symptoms score ≥7, Schirmer test <5 mm), 2 (score ≥8, Schirmer test <5 mm), 3 (score ≥9, Schirmer test <5 mm), 4 (score ≥7, Schirmer test ≤5 mm, MGD grade 1 (telangiectasia at the lid margin)), and 5 (score ≥7, Schirmer test ≤5 mm, MGD grade 2 (plugged Meibomian gland orifices) or higher) were 18.2% (95%CI:16.0,20.5), 14.5% (95%CI:12.4,16.5), 8.1% (95%CI:6.5,9.7), 14.8% (95%CI:12.7,16.8), and 7.4% (95%CI:5.9,9.0), respectively. In multivariate analysis, a higher DED prevalence (dry eye symptoms score ≥8; Schirmer test <5mm) was associated with female sex (odds ratio (OR):2.36;95%CI:1.18,4.71;P=0.02), rural region of habitation (OR:2.72;95%CI:1.10,6.70;P=0.03), longer axial length (OR:1.30;95%CI:1.04,1.62;P=0.02), and higher hearing loss score (OR:1.03;95%CI:1.01,1.05;P=0.001) and lower self-reported salt consumption (OR:0.64;95%CI:0.54,0.75;P<0.001).

Conclusions: : In this population-based recruited study sample aged 85+years, DED prevalence (7.4% to 18.2% depending on the definition) and MGD prevalence (31.4%) was associated with female sex, rural region of habitation, longer axial length, higher hearing loss score and lower salt consumption.

ABSTRACT BODY:

Purpose: BD is a unique OCT signature identified in the outer retina. To our knowledge, it has not been described in nAMD. This preliminary analysis evaluates the incidence of BD in nAMD and response to anti-VEGF therapy.

Methods: A post hoc OCT image analysis was performed on the OSPREY phase II, prospective randomized clinical trial of anti-VEGF therapy in nAMD. BD was defined on OCT as a hyporeflective space above a hyperreflective linear structure continuous with the ellipsoid zone (EZ) band. Machine-learning-augmented feature extraction enabled characterization of parameters including retinal and sub-retinal pigment epithelium (RPE) compartment metrics, and retinal fluid volumes. This hypothesis-generating analysis was conducted without adjustment for multiple comparisons and was treatment agnostic.

Results: BD was identified in 6/81 eyes (7.4%) at Baseline. Baseline BCVA was similar between eyes with and without BD. At Baseline, BD eyes showed significantly higher mean central subfield thickness (CST, 610 μ m vs 479 μ m; $p < 0.05$), total retinal fluid volume (0.95mm³ vs 0.37mm³; $p < 0.01$), macular total retinal fluid index (TRFI, 7.8% vs 3.3%; $p < 0.05$), total EZ attenuation (51% vs 30%; $p < 0.05$), and sub-RPE compartment volume (1.80mm³ vs 0.78mm³; $p < 0.0001$) compared to eyes without BD.

Compared to Baseline, macular TRFI was 0.03% ($p = 0.034$) and CST was 331 μ m ($p = 0.006$) in the BD group at Week 4. At the end of the loading phase, 83% of eyes with BD had minimal to no fluid (i.e., volume < 0.001 mm³) vs 68% of eyes without BD. By Week 56, total macular EZ attenuation remained higher in eyes with BD compared to eyes without BD (40% vs 16%). At Week 56, eyes with BD did not demonstrate VA improvement (-1.7 letters; $p = 0.838$), while eyes without BD showed significant VA improvement (+6.9 letters; $p < 0.001$).

Conclusions: BD is identifiable in a proportion of nAMD eyes which have higher baseline fluid volumes and CST. Preliminary findings suggest that eyes with BD are responsive to anti-VEGF therapy (fluid resolution and CST reduction), yet persistent significant EZ attenuation may limit VA recovery. More data are needed to further validate the findings; however, this is important for understanding visual prognosis and enriching clinical trials.

ABSTRACT BODY:

Purpose: North Carolina macular dystrophy (NCMD) is a rare autosomal dominant disease, characterized by loss of central vision. With the identification of noncoding single nucleotide variants (SNVs) and duplications overlapping with a DNase I hypersensitive site (DHS) near PRDM13 or IRX1 as underlying genetic cause, NCMD is hypothesized to be a cis-regulatory disease. Here we investigate the genetic architecture of and mechanisms underlying NCMD, to further solve its missing heritability, and to provide mechanistic insight into its molecular pathogenesis.

Methods: Twenty-five unrelated NCMD families underwent targeted testing of PRDM13 and IRX1 regions followed by whole genome sequencing (WGS) in a selection of unsolved cases (n=11). Chromosome conformation capture, in particular UMI-4C sequencing, was applied on retinas from human donor eyes to fine-map interactions of cis-regulatory elements with the PRDM13 and IRX1 promoter. This data, together with other human retinal (epigen)omics data, were integrated in a UCSC browser session to advance the interpretation of the WGS data. Luciferase assays in ARPE-19 cells were performed to evaluate the functional effect of 6 previously reported (V1-V3, V10-V12) and 2 novel candidate NCMD-associated SNVs.

Results: A known noncoding SNV upstream of PRDM13 (V1) was found in a first family, while a novel SNV at the same position was identified in a second family. WGS revealed a novel tandem duplication, encompassing the known DHS upstream of PRDM13, in a third family. An additional novel noncoding SNV upstream of PRDM13 was found in a fourth family. Interestingly, UMI-4C showed an interaction of this region with the PRDM13 promoter. This region is active at a specific developmental stage (D103) that is compatible with the timepoint when retinal progenitor cells of the central retina exit mitosis. Using luciferase assays we demonstrated that the noncoding SNVs, located in two mutational hotspots, displayed up- and downregulation of expression, respectively.

Conclusions: Overall, the genetic architecture of NCMD was expanded with novel noncoding variants with a likely effect on PRDM13 regulation. The retinal interaction profiles of PRDM13 and IRX1 advance the interpretation of novel noncoding variants identified using WGS and provide insight into the cis-regulatory mechanisms underlying NCMD.

TITLE: Assessing glaucoma progression with post-processed visual field data

SESSION TITLE: Structure/Function, Visual Fields, Psychophysics, and Electrophysiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.L. Abu, L. Racette, Department of Ophthalmology, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|S. Poleon, School of Optometry, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sampson Abu: Commercial Relationship: Code N (No Commercial Relationship) | Shervonne Poleon: Commercial Relationship: Code N (No Commercial Relationship) | Lyne Racette: Commercial Relationship(s);OLLEYES, Inc.:Code C (Consultant)

ABSTRACT BODY:

Purpose: We previously showed that assessing glaucoma progression with visual field (VF) data post-processed with the dynamic structure-function (DSF) model resulted in a higher positive rate compared to the original (observed) data (Abu and Racette, IOVS 2020;61: ARVO E-Abstract 1991). The aims of this study were to validate this finding in an independent dataset and to assess the false positive rate of this approach.

Methods: We used VF data from 139 patients with open-angle glaucoma (203 eyes) with at least 15 visits selected from the Rotterdam Eye Study. The DSF and ordinary least square linear regression (OLSLR) models were applied to the observed mean deviation (MD) values to derive two post-processed datasets: DSF-predicted and OLSLR-predicted. Specifically, MD values from visits 1–3 were used to predict MD at visit 4, then MD values from visits 1–4 were used to predict MD at visit 5. This procedure was repeated until MD for visit 9 was predicted. Linear regression was then used to assess progression within the observed, DSF-predicted and OLSLR-predicted datasets. Positive rate was determined for each dataset at a specificity of 95%. To examine the impact of VF post-processing on false positive rate, we performed 1000 permutations of the MD series in each dataset and reassessed progression. The permutations disrupted the temporal order of the MD series; therefore, significant negative slopes were deemed to be false positives. Mean false positive rates were computed for the observed, DSF- and OLSLR-predicted datasets.

Results: The positive rate obtained with DSF-predicted data was 2.9% higher than OLSLR-predicted data and 12.8% higher than observed data at the 9th visit (Fig 1). DSF-predicted data flagged 72.9% and 59.7% of the eyes identified as progressing with observed data at the 12th visit and 15th visit, respectively. The false positive rates obtained for each of the datasets were similar to the proportion of eyes expected to be identified as progressing by chance (Fig 2).

Conclusions: Our results confirm that post-processing visual field data using the DSF model yields a higher positive rate without compromising specificity. The higher sensitivity of this approach may lead to earlier detection of progression.

ABSTRACT BODY:

Purpose: Despite the individual and societal benefits of Low Vision Services (LVS), a discrepancy in the need and uptake of LVS has been reported internationally. Little is known about the characteristics and healthcare utilization of adult visually impaired people who receive LVS. This study aims to identify these parameters to explore LVS user profiles.

Methods: A retrospective cohort study based on a Dutch national health insurance claims database. Claims data from 2015 till 2018 of all visually impaired adults (aged 18 years or older) who received LVS at Dutch multidisciplinary organizations were examined. Descriptive statistics were used to assess socio-demographic characteristics (age, sex, socio-economic status, region), clinical characteristics (ophthalmic diagnosis, comorbidity) and healthcare utilization (ophthalmic and other medical care utilized in hospitals, general practitioner care, mental healthcare, low vision aids). Separate descriptive analyses were performed for different diagnosis groups within LVS patients.

Results: Between 2015-2018, 49,726 unique patients received LVS. The amount of unique patients that utilized LVS decreased with 16% between 2015 and 2018. The majority was aged 60y or older (62%, mean 65y), were female (54%), had a middle (38%) or low (38%) socio-economic status and lived in urban areas (51%). Most common ophthalmic conditions were macular degeneration (AMD, 22%), cataract (21%), subretinal neovascularization (15%) and primary glaucoma (11%). Half of the patients were treated for only one ophthalmic condition. Of all patients, 86% utilized general practitioner care, 69% ophthalmic care, 54% low vision aids, 41% cardiovascular care, 22% audiological care and 12% mental healthcare at least once. Of LVS patients who utilized specialized mental healthcare, most people were treated for depression 19% and/or anxiety 12%.

Conclusions: Our study shows that patients of LVS are mostly female elderly with retinal disease and (comorbid) cataract. The decrease in LVS uptake might be explained by increased deductible health insurance and new innovative treatments for ophthalmic conditions that can cause low vision. Future research needs to further examine differences in patterns between LVS users and non-users.

ABSTRACT BODY:

Purpose: To evaluate the effect of loss to follow up (LTFU) on outcomes in eyes with retinal vein occlusion (RVO) treated with anti-vascular endothelial growth factor (VEGF) injections

Methods: In this retrospective single center case series, patients with RVO receiving intravitreal injections who were LTFU >6 months were eligible for inclusion. Visual acuity (VA) and optical coherence tomography features were collected from the visit before LTFU, the return visit, 3 months after return, 6 months after return, 12 months after return and the final follow-up visit.

Results: Ninety-one eyes of 84 patients with a mean age (\pm standard deviation) of 74.2 (\pm 11.2) years were included. Forty-nine (58.4%) of the patients were female. Fifty (54.9%) patients had branch RVO and 41 (45.1%) had central RVO. Mean LTFU duration was 278.2 (\pm 108.8) days and patients were followed for mean 739.8 (\pm 366.7) days after return. Patients had received a mean of 8.5 (\pm 5.7) injections before being LTFU and received a mean of 8.3 (\pm 7.6) injections after return. Mean logMAR VA at the visit before LTFU was 0.72 (\pm 0.67) [Snellen 20/104] which significantly worsened at the return visit [1.05 (\pm 0.79), Snellen 20/224, $p < 0.001$], 3 months after return [0.92 (\pm 0.70), Snellen 20/166, $p < 0.001$], 6 months after return [0.97 (\pm 0.80), Snellen 20/186, $p < 0.001$], 12 months after return [0.94 (\pm 0.78), Snellen 20/174, $p < 0.001$] and the final follow-up visit [1.02 (\pm 0.85), Snellen 20/209, $p < 0.001$] (Figure1). The mean central foveal thickness (CFT) increased when comparing the visit before LTFU [251 (\pm 129) μ m] to the return visit [404 (\pm 241) μ m, $p < 0.001$]. No significant difference in CFT was noted by 3 months [256 (\pm 139) μ m, $p = 0.68$], 6 months [241 (\pm 122) μ m, $p = 0.59$], or 12 months after return [250 (\pm 134) μ m, $p = 0.98$]. The CFT was significantly thinner at the final visit [214 (\pm 114) μ m, $p = 0.017$] (Figure2). Three (4.2%) eyes (2 CVRO, 1 BRVO) presented with neovascular glaucoma (NVG) and 4 (4.5%) eyes (3 CRVO, 1 BRVO) with new onset vitreous hemorrhage (VH) at the return visit.

Conclusions: RVO patients receiving anti-VEGF treatment who were LTFU for a prolonged duration experienced a significant decline in VA that did not return to the levels seen before LTFU despite restarting therapy and subsequent improvement in CFT. LTFU might also increase the risk of unfavorable outcomes like NVG and VH in RVO patients.

ABSTRACT BODY:

Purpose: Visual disability relative to lifestyle has not been assessed across Hispanic/Latinos of diverse backgrounds. We examined the relationship between physical activity (PA) and diet score (DS) across Hispanic/Latinos, and their relationship to visual disability.

Methods: Design: Multicenter, prospective, population-based Hispanic Community Health Study/Study of Latinos (HCHS/SOL) include 9663 participants age ≥ 40 years(y) completing Visit #2 (2014-2017). Age-adjusted, sex-specific prevalence of visual disability was calculated weighting for study design. Analyses included those with Cuban (n=1455), Dominican (n=804), Mexican (n=3746), Puerto Rican (n=1485), Central American (n=965), South American (n=669) and Other (n=199) backgrounds. High PA, ascertained by a modified Global Physical Activity Questionnaire, was defined as the top 40%. Dietary intake was ascertained by two 24-hour dietary recalls administered 6 weeks apart. High DS, calculated by sex-specific quintile of daily intake of saturated fatty acids, potassium, calcium, and fiber, was defined as the top 40%. Main outcome measures: Visual disability, defined as "being blind or having serious difficulty seeing even when wearing glasses," based on the US Census Bureau's American Community Survey.

Results: Results: Analysis included 9324 participants with complete data (35.9% men), with a mean age of 55.4y men and 56.5y women. Overall age-adjusted visual disability prevalence was 10.6% (95%CI; (9.2, 12.1) men, and 13.5% (12.0, 14.9) women. Subjects with high PA had a lower prevalence of visual disability: men 9.7% (7.4, 12.0) and women 12.9% (10.7, 15.1). Cubans reported the lowest percent of high PA (Fig 1, $p < 0.001$). Participants with high DS reported a lower prevalence of visual disability both in men 8.2% (6.5, 9.9) and women 8.7% (7.2, 10.1). Puerto Ricans had the lowest percent of high DS (Fig 1, $p < 0.001$).

Conclusions: Conclusions: Results identify significant visual disability in US Hispanic/Latinos, with a higher prevalence in those with lower PA and poorer diet. The significant variability across diverse groups supports objectives of SOL Ojos, an ancillary HCHS/SOL study aiming to assess associations of lifestyle and objectively measured chronic eye disease in a diverse group of Hispanics/Latinos.

ABSTRACT BODY:

Purpose: Emerging data show that the gut-microbiome plays a role in retinal physiology and several retinal diseases such as: age-related macular degeneration (AMD), retinopathy of prematurity (ROP) and diabetic retinopathy (DR). Our team has described the retinal pathways of the gut-retina axis in retinal homeostasis under regular diet conditions. The gut microbiome is significantly affected by diet and, in particular, a diet rich in fats or high-fat diet (HFD). The HFD modifies the composition and diversity of the gut microbiota; a condition referred to as gut-dysbiosis. The retinal pathways of the gut-retina axis in HFD-induced gut dysbiosis conditions remain unknown. The purpose of this study is to delineate how HFD-induced gut dysbiosis modulates the gut-retina axis pathways by comparing the transcriptome of mice with HFD-induced gut dysbiosis with germ-free (GF) mice that have no microbiome fed on regular diet (ND).

Methods: We compared the retinal gene expression and biologic pathways of C57Bl/6J mice fed on 23% HFD for 8 weeks and GF mice age and gender matched fed on ND (4 per group). RNA-sequencing (RNA-seq) was performed on whole retinas using a base paired-end method on the NovaSEQ600 platform. We then identified Differentially Expressed Genes (DEGs) (P -value <0.01) and performed a functional enrichment network analysis using Toppgene to elucidate the biologic pathways affected.

Results: We identified 538 DEGs with a p -value <0.01 . Some of the DEGs identified were the regulatory associated Protein of MTOR Complex 1 (Rptor), peroxisome Proliferator-Activated Receptor Gamma Coactivator 1 Alpha (PPARGC1A) and activating Transcription Factor 2 (ATF2); all of which have been implicated in retinal diseases like AMD and DR. The enrichment network analysis showed numerous signaling and metabolic pathways affected including the phototransduction cascade, the Related Orphan Receptor A (RORA) and the mitochondrial biogenesis activation pathways.

Conclusions: Our data shows that several pathways of the gut-retina axis are affected in HFD-induced gut dysbiosis conditions. Further studies delineating the effects and interactions of diet and gut microbiome on retinal physiology are needed to reveal the relationship to retinal disease pathogenesis.

ABSTRACT BODY:

Purpose: In our previous study, the intensity of light scatter (ILS) from the anterior chamber was measured in cataract subjects as a measure of aqueous flare using a custom-made ocular fluorometer (TVST; 2018). While the data was sensitive, we observed a poor correlation between ILS and SUN grades for patients with mild to moderate inflammation (i.e., SUN grades 0 and 1+). To further explore the variability, we are continuing to establish the repeatability and reproducibility of ILS in uveitis patients.

Methods: Uveitis (n = 111; with SUN scores of 0 to 2+) and healthy subjects (n = 93) were included in the study. One clinician performed SUN grading. For repeatability, ILS was measured twice by the same observer. For reproducibility, ILS was recorded by two observers. We calculated the intra-observer variability (expressed as the repeatability coefficient (Rc)) and intra-class correlation coefficient (ICC) to assess intra- and inter-observer variability. The latter was further analyzed by Bland-Altman (BA) plots.

Results: The intra-observer measurements in healthy subjects revealed no statistical difference in the mean ILS (0.1480 ± 0.0700 mV; n = 93; p > 0.98). The corresponding within-subject standard deviation (Sw) is 0.0272 mV, which corresponds to a repeatability coefficient (Rc) of 0.0754 mV ($= 2.77 * Sw$). Uveitis patients with SUN scores of 2+ showed much higher ILS (0.3740 ± 0.1090 mV; n = 5) with Sw = 0.0418 mV, and Rc of 0.1159 mV. The inter-observer analysis with uveitis patients (n = 72 for SUN 0 and n = 8 for SUN 1) revealed an ICC of 0.63 and 0.95 for measurements with SUN grades 0 and 1, respectively. In healthy subjects (SUN grade 0), ICC was 0.73 (n = 76). Corresponding Bland-Altman plot analysis in uveitis subjects indicated 0.0044 mV and 0.0046 mV as the difference between the mean ILS between observers for SUN grades 0 and 1, respectively.

Conclusions: ILS in control and uveitis are ~ 6 and ~ 9 times larger than the maximum of Sw, respectively. The lowest inter-observer variability in ILS measurement is ICC > 0.6 in both healthy and uveitis patients. Thus, ILS measurements using the fluorometer are highly reliable and can be employed to provide a higher granularity in recording aqueous flare. Thus, we attribute the apparent variability in ILS of uveitis patients with 0 and 1+ to SUN scores' subjective grading.

ABSTRACT BODY:

Purpose: To assess central corneal thickness (CCT) and its associations in a Russian population.

Methods: The Ural Eye and Medical Study included 5899 (80.5%) out of 7328 eligible individuals (mean age:59.0±10.7 years;range:40-94 years). As part of an ophthalmological and general examination, CCT was measured by Pentacam HR (Oculus, Germany).

Results: The study included 5792 (98.2%) participants (mean age:58.8±10.6 years;range:40-94 years) with available bilateral CCT measurements. Mean CCT was 541.7±33.7µm (median:541µm;range:200-779µm). In multivariable analysis, thicker CCT was associated (regression coefficient r:0.43) with younger age (standardized regression coefficient beta:-0.09;non-standardized regression coefficient B:-0.29;95% confidence interval (CI):-0.39,-0.20;P<0.001), male sex (beta:0.05;B:3.10;95%CI:1.18,5.03;P=0.002), urban region of habitation (beta:0.10;B:6.83;95%CI:4.61,9.05;P<0.001), Russian ethnicity (beta:0.04;B:3.48;95%CI:1.04,5.91;P=0.005), higher level of education (beta:0.04;B:0.97;95%CI:0.29,1.66;P=0.006), higher serum bilirubin concentration (beta:0.05;B:0.15;95%CI:0.07,0.23;P<0.001), lower corneal refractive power (beta:-0.09;B:11.92;95%CI:-2.50,-1.35;P<0.001), smaller anterior chamber angle (beta:-0.07;B:-0.38;95%CI:-0.52,-0.24;P<0.001), higher IOP readings (beta:0.38;B:3.47;95%CI:3.21,3.73;P<0.001), and higher rise in IOP readings by medical mydriasis (beta:0.07;B:0.88;95%CI:0.54,1.22;P<0.001). In that model, CCT was not associated with body height (P=0.14), previous cataract surgery (P=0.10), axial length (P=0.18) or prevalence of glaucoma (P=0.11). The mean inter-eye difference in CCT was 8.52±13.9 µm (median:6.0;95CI:8.16,8.88). A higher inter-eye CCT difference was associated with older age (beta:0.08;B:0.11;95%CI:0.07,0.15;P=0.01), lower level of education (beta:-0.04;B:-0.34;95%CI:-0.60,-0.08;P<0.001) and status after cataract surgery (beta:0.04;B:2.92;95%CI:1.02,4.83;P=0.003).

Conclusions: In this typical, ethnically mixed,population from Russia with an age of 40+ years, mean CCT (541.7±33.7µm) was associated with parameters such as younger age, male sex, Russian ethnicity, and higher educational level. These associations may be taken into account when the dependence of IOP readings on CCT are considered. Glaucoma prevalence was unrelated to CCT.

Commercial Relationships Disclosure (Abstract): Clair Enthoven: Commercial Relationship: Code N (No Commercial Relationship) | Annechien E.G. Haarman: Commercial Relationship: Code N (No Commercial Relationship) | Joanna Swierkowska: Commercial Relationship: Code N (No Commercial Relationship) | Willem Tideman: Commercial Relationship: Code N (No Commercial Relationship) | Jan Roelof Polling: Commercial Relationship: Code N (No Commercial Relationship) | Virginie Verhoeven: Commercial Relationship: Code N (No Commercial Relationship) | Caroline Klaver: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies have suggested that female gender is a risk factor for myopia. The underlying mechanism is not well understood, and gender-specific factors such as age of growth spurt have been proposed. The aim of this study was to explore gender differences in myopia development in two prospective population-based cohorts from different generations, and to find possible explanations.

Methods: Analyses were performed in the birth cohort study Generation R (n=7229) and in the elderly Rotterdam Study I-III (45+ yrs; n=8674). Cycloplegic refraction was measured in the children at 6, 9, and 13 years, automated refraction was measured in the adults, and axial length and height was measured in both. Myopia was defined as spherical equivalent $\leq -0.5D$ in at least one eye. Lifestyle factors including near work and outdoor exposure were assessed in the children and level of education in the adults, both by questionnaire. The association between gender and myopia was tested using Cox proportional hazards and logistic regression models adjusted for age; change in height, lifestyle factors and education were investigated as possible mediators.

Results: Myopia prevalence increased from 2.5%, to 11.5% and 22.5% at age 6, 9, and 13 years in the children, respectively; the prevalence was 30.6% in the adults. Female gender was associated with myopia in the children (HR=1.14 95% CI=1.02-1.27), but was inversely associated in the adults (OR=0.88 95%CI=0.80-0.96). Mediators of the association in children were outdoor exposure, growth in height, sport participation, reading time, and number of books read per month; these mediators together attenuated the effect of gender with 34.9% and reduced risk to HR=1.09 (95%CI=0.97-1.23). Education was the most important mediator of the association in adults, attenuating the effect with 89.7% to OR=0.98 (95%CI=0.90-1.09).

Conclusions: In our study, myopia was more common in girls in the young generation, but more common in men in the older generation. This paradigm shift and our mediation analysis provide compelling evidence that lifestyle factors and education are strong drivers of myopia. In the generations to come, particularly girls should be guided to adhere to protective behaviour.

ABSTRACT BODY:

Purpose: Glaucoma and other optic neuropathies lead to permanent damage of the optic nerve and loss of retinal ganglion cells (RGCs). Cell transplantation has been proposed to restore the retinal neurocircuitry; however, current state-of-the-art studies show that most donor RGCs have limited capacity to integrate into the ganglion cell layer (GCL) following intravitreal delivery. Since a fully developed mammalian retina does not have the natural capacity to regenerate RGCs, we do not know the exact mechanisms and cues employed by stem cell-derived donor RGCs to migrate across the retina (XY plane) and into the GCL (Z-axis). Here, we investigate the migration of donor RGCs into and across the retina in the presence of a stromal cell-derived factor-1 (SDF1) gradient.

Methods: RGCs were differentiated from Thy1-GFP mouse iPSC (C57Bl/6 background) in 3D retinal organoid cultures. On day 21, RGCs were isolated from organoids by magnetic microbeads against CD90.2. The ability of stem cell-derived RGCs to migrate in vitro was tested using a microfluidic device. For transplantation RGCs were formulated at 5×10^6 cells/mL with slow-release GDNF & BDNF particles. 2 μ L of Thy1-GFP+ RGC suspension was injected intravitreally (IVT), and 1 μ L 10ng/ μ L SDF1 was injected subretinally (SR) to establish a chemokine gradient across the retina to direct RGC migration. Two weeks after transplantation, whole mounted retinas were stained for GFP and RBPMS to assess donor RGC integration and distribution with respect to host RBPMS+ cells (GCL). RGC distribution across the retina was calculated as the percentage of 344 x 344 μ m tiles within the whole mount that contained more than one integrated RGC.

Results: The expression of CXCR4, the receptor for SDF1, on donor cells was confirmed by qPCR and flow cytometry. Thy1-GFP+ donor RGCs integrate into GCL of host retinas with and without SR SDF1 and have the same morphology in both groups. The artificial SDF1 gradient increased the retinal coverage by donor cells from $54 \pm 8\%$ to $76 \pm 4\%$ (Figure 1), proposing a benefit of CXCR4-SDF1 interactions for enhanced donor RGC migration.

Conclusions: Establishing an SDF1 gradient across the host retina is an effective strategy to improve the distribution and structural integration of donor RGCs.

ABSTRACT BODY:

Purpose: Corneal infections are caused by a variety of microorganisms, including bacteria, viruses, amoebae and fungi. Infectious keratitis is the 4th leading cause of blindness in the world, being represented by up to 60% by fungal keratitis in tropical countries and rural areas. In an infective process, a series of steps are taken, the first of which is the adhesion of the microorganism to the epithelium. Numerous studies have shown an intimate relationship of cell surface proteoglycans (PGs) and their glycosaminoglycans chains (GAGs) with the adhesion process in bacterial infections. The objective of this work is to determine the implication of these molecules in the adhesion of fungi to the corneal epithelium and to study the possible influence of this adhesion process in the gene expression of cell surface PGs.

Methods: The involvement of GAGs in the adherence of *Candida albicans* to the corneal epithelium was studied by determining the influence of its elimination with biosynthetic inhibitors or through the use of specific bacterial lyases on the adherence of the fungus. The alterations in the transcription levels of the cell surface PGs were analyzed by RT-PCR.

Results: The adherence of *C. albicans* in the form of yeast to corneal epithelial cells was limited by the elimination of cellular GAGs, showing their involvement in the process. On the contrary, when the yeast produces hyphae there was an increase in adherence. The adherence of the fungus induced significant alterations in the expression levels of the cell surface PGs, which affected both syndecans and glypicans. Within syndecans, SDC3 under-expressed with both yeast and *C. albicans* hyphae, while SDC4 only did so when interacting with yeast. In the case of glypicans, GPC6 showed an overexpression induced by both forms of *C. albicans*, while GPC1 only under-expressed induced by yeast. Furthermore, GPC3 was not expressed in corneal cells, but it did after contact with both forms of *C. albicans*.

Conclusions: Corneal surface GAGs are involved in the adherence of *C. albicans* in the yeast form, but not in the filamented cellular forms. The interaction of the microorganism with the epithelial cells induces alterations in the transcription levels of the cell surface PGs that are dependent on the cell form presented by the fungus.

ABSTRACT BODY:

Purpose: To describe the age-related macular degeneration (AMD) features on ultrawidefield (UWF) retinal imaging in the participants of the Age-Related Eye Disease Study 2 (AREDS2) 10 Year Follow-on Study.

Methods: OPTOS (Dunfermline, Scotland) color and fundus autofluorescence retinal (UWF) images were obtained at year 10 study visit in AREDS2 participants with intermediate or late AMD in one eye (N=230). Reading centers (U. of Wisconsin and Queen's University, Belfast) graded the images for presence and extent of: macula change, neovascular AMD, geographic atrophy (GA), drusen, reticular pseudodrusen (RPD), RPE pigmentary changes (hyper and hypo), peripheral pathology including cobblestone and senile reticular pigmentary changes. The images were divided into 3 zones: posterior pole (zone 1), midperiphery (zone 2), and far periphery (zone 3) and further divided into four image quadrants. RPD was diagnosed based upon the fundus autofluorescence imaging. AMD features were summarized by each of the zones and the 4 quadrants.

Results: Of the 230 AREDS2 participants, mean age was 69 ± 1 year, 59% female, 90% have late AMD (Figure). Only 13% presented neovascular AMD while most had GA and a minority presented inactive neovascular AMD. Almost half of the GA lesions were unifocal, and about 89% of the macula had GA. More than 80% had super large drusen ($\geq 250 \mu\text{m}$) and 25% had RPD. 71% had peripheral retinal abnormalities. Zone 2 had marked drusen, pigmentary changes, floaters, and GA. All three zones had demonstrated extensive AMD lesions throughout the macula and in the periphery.

Conclusions: The results of the 10-year follow-on of AREDS2 participants demonstrate the extensive and relentless progression of the AMD lesions. The disease is not confined to the macula but extensive throughout the retinal and its periphery. Future evaluation of AMD progression will need to take into account lesions that occur in the retinal periphery as well as the macula. It will also be important to correlate structural changes with functional deficits. This study also demonstrates that AMD is a pan-retinal disease.

ABSTRACT BODY:

Purpose: We developed a DL algorithm to identify axoplasm ('Ax') and myelin sheaths of normal-appearing RGC axons from light micrographs of optic nerve (ON) cross-sections [Goyal+, submitted ARVO 2021]. Here we: (i) compare RGC Ax area ('Area') and eccentricity ('Ecc') between manually- and DL-segmented images; and (ii) compare axon density (axons/ μm^2) and axon size distributions between hypertensive and control eyes.

Methods: Ocular hypertension was induced unilaterally in 14 Brown-Norway rats (3-13 months; 12 male:2 female) by episcleral hypertonic saline or microbead injection. Contralateral eyes were controls. (i) To compare manual and DL segmentations, we extracted the mean and median Ax Area and Ecc from all images, and computed the mean absolute percentage error (MAPE) between them for all ON. (ii) To compare control vs. hypertensive eyes, we restricted analysis to pairs where the hypertensive eye had an IOP burden > 100 mmHg day (n=7 pairs). Axons were counted in ON sub-images, divided by sub-image area to obtain axon density, and compared hypertensive vs. control. Axons were grouped by Area into 9 bins, and for each ON and each bin the ratio (hypertensive axon density)/(control axon density) was computed and normalized following Quigley+ [PMID: 3583630].

Results: (i) Mean and median Area agreed well between manual and DL segmentations (MAPE < 4.6%, Fig 1), as did Ecc (MAPE < 1.41%). (ii) Hypertensive eyes showed lower axon density (0.19 ± 0.11 vs. 0.36 ± 0.08 axons/ μm^2), an approximate 40% decrease ($p = 0.038$, 2-sided paired t-test). We did not observe a preferential loss of large axons with hypertension (Fig 2).

Conclusions: Morphometric parameters of RGC axons extracted by a DL algorithm agreed well with manual segmentations. The algorithm detected decreased axon density in hypertensive eyes, but no preferential loss of large axons (perhaps due to the rat model used). This algorithm provides a fast and non-subjective method to quantify axonal loss in animal models of glaucoma; future consideration of axonal shape changes may add sensitivity to detection of glaucomatous damage.

ABSTRACT BODY:

Purpose: Fixation eye movements are physiologic eye movements elicited during attempted fixation to prevent visual fading by thwarting neural adaptation. Saccades are rapid eye movements between fixation that bring the object of interest onto the high-resolution fovea to achieve the best possible vision. Amblyopic patients have increased fixation instability due to nystagmus, along with reduced saccadic precision and prolonged latencies. The purpose of this study is to quantify and correlate fixation and saccadic abnormalities in amblyopia patients with and without nystagmus.

Methods: We recruited 22 controls and 23 amblyopic subjects. We recorded fixational eye movements (FEMs) using infra-red video-oculography and classified 12 subjects without nystagmus, 5 subjects with fusion maldevelopment nystagmus (FMN), and 6 subjects with nystagmus that do not meet the criteria of FMN. We measured visually-guided horizontal, vertical, and oblique saccades in all participants. Latency, precision, and disconjugacy (amplitude difference between viewing and non-viewing eye) were measured and correlated with FEM abnormalities.

Results: Saccadic latencies were prolonged in amblyopic patients during both amblyopic eye viewing [Controls: 159 ± 50 , None: 301 ± 186 , Nystagmus without FMN: 203 ± 184 , FMN: 194 ± 57 , $p < 0.0001$] and fellow eye viewing [Controls: 159 ± 50 , None: 262 ± 161 , Nystagmus without FMN: 173 ± 62 , FMN: 164 ± 72 , $p < 0.0001$] conditions. Amblyopic patients without nystagmus were better at initiating corrective saccades to minimize the saccadic inaccuracies. On the other hand, patients with nystagmus had greater frequency of staircase saccades, which were defined as abnormal multiple rapid saccades within 500 milliseconds, compared to other groups.

Conclusions: Fixation and saccadic eye movement abnormalities are seen in both the amblyopic and the fellow eye, suggesting that amblyopia is a binocular vision disorder. The fixation and saccadic abnormalities are closely interlinked. These abnormalities likely contribute to reading and daily visuo-motor task difficulties and should be assessed to identify and provide proper academic accommodations to young children with amblyopia.

ABSTRACT BODY:

Purpose: To examine the association of changes in best corrected visual acuity (BCVA) occurring in a 5-year prospective longitudinal study of eyes with mild diabetic nonproliferative retinopathy (NPDR), with the three main disease pathways: microvascular changes, neurodegeneration and edema.

Methods: 212 patients with type 2 diabetes (T2D) and mild NPDR (ETDRS grades 20 or 35) were followed in a 5-year longitudinal study. Ophthalmological examinations were performed at baseline and annually.

BCVA was measured using Snellen chart for the patients and then converted to logarithm of the minimum angle of resolution (logMAR) VA. ETDRS and severity progression was assessed in T2D individuals by grading of 7-fields CFP performed at the initial and last visits. Microaneurysm turnover (MAT) was evaluated using the RetMarkerDR. Optical coherence tomography (OCT) was performed to evaluate average thickness of the ganglion cell layer (GCL).

Results: Of the 212 individuals with type 2 diabetes (T2D) and mild NPDR, one eye per person, followed for 5 years with annual visits, 171 completed the study or developed an outcome. BCVA worsening occurred in 118 eyes (69%) during the 5-year follow-up. BCVA worsening is associated with GCL thinning in the central macular area, representing neurodegeneration (difference V6-V1, $p=0.038$), but did not show association with MAT (considering $MAT \geq 6$ vs $MAT < 6$), representing microvascular changes ($p=0.633$) or central retina thickness, representing edema ($p=0.634$).

For the ones that completed the study, BCVA was also associated with age ($p=0.002$) and sex ($p=0.055$). No association was found with ETDRS level worsening.

Conclusions: BCVA worsening in eyes with mild NPDR, during a 5-year follow-up, is associated with neurodegenerative changes identified by GCL thinning in the macula, but not with the presence and progression of edema and/or ischemia.

ABSTRACT BODY:

Purpose: Cell-biomaterial interactions and aqueous soluble factors regulate the initiation and progression of fibrosis, which is a primary cause of glaucoma drainage implant (GDI) failure. We created smooth and nano-structured electrospun scaffolds to evaluate and compare the expression of fibrosis-related genes in fibroblasts in vitro. We then designed two nano-structured, partially degradable GDIs and evaluated their performance in rabbit eyes.

Methods: Fibroblasts were seeded on scaffolds made from electrospun polyethylene terephthalate (PET) nanofibers or smooth PET films. Transcription of fibrosis-related genes in unstimulated and activated fibroblasts was quantified by qPCR. Predictive fluid flow modeling was applied to develop nano-structured GDIs of different lengths, both with an inner diameter of 75 μm and a 25 μm degradable polyglycolide core (Pressure Control Shunt, PCS1 and PCS2). Intraocular pressure (IOP), GDI patency, bleb morphology, and capsule thickness were evaluated for 91 days in normotensive New Zealand White rabbits.

Results: Fibroblasts cultured on nanofibers showed reduced levels of gene expression related to activation (MYOCD and SMA), collagen synthesis (COL6A6), focal adhesion-associated genes (rho-kinase signaling, ITGA6, ITGB1) and increased expression of MMP-1 and ITGA2 compared to cells cultured on smooth surfaces. In vivo, a mean reduction in IOP from baseline of 4 (PCS1) and 2.8 mmHg (PCS2) at 28 days and 1.8 (PCS2) and 0.9 mmHg (PCS1) at 91 days was observed post-operatively. Histological analysis revealed a fibrotic capsule thickness of $350 \pm 149 \mu\text{m}$ in PCS1 and $55 \pm 23 \mu\text{m}$ in PCS2 ($p=0.041$), likely due to decreased aqueous flow rate through the longer PCS2.

Conclusions: Nanofibers significantly attenuate expression of markers associated with fibroblast activation and collagen production in vitro. Nano-structured shunts can be designed to safely and effectively reduce IOP for a period of at least 91 days in vivo while minimizing fibrotic encapsulation.

ABSTRACT BODY:

Purpose: The WHO initiative, VISION 2020: The Right to Sight showed that understanding global burden of eye diseases aids planning for appropriate care delivery. Here we report extensively updated estimates of the burden of vision loss due to diabetic retinopathy (DR) from 2000 to 2020, and distribution by sex and region.

Methods: A systematic review and meta-analysis of population-based surveys of eye diseases from January 1980 to October 2018 were carried out by the Vision Loss Expert Group of the Global Burden of Disease Study (GBD) and collated into the Global Vision Database. We fitted hierarchical models to estimate prevalence (with 95% uncertainty intervals [UIs]) of moderate and severe vision impairment (MSVI; presenting visual acuity from <6/18 to 3/60) and blindness (<3/60 and/or less than 10° visual field around central fixation) caused by DR by age, region, and year for those aged 50 years and older.

Results: Worldwide in 2020, due to DR an estimated 861,000 (592,000-1235,000) people aged 50+ years were blind and 2.95 million (2.14-3.95M) had MSVI. Since 2000, age-standardised prevalence (ASP) of DR-blindness and MSVI increased by 7.0% and 1.6% respectively. Reflecting growth in number of people aged 50+ and diabetes prevalence, overall DR-blindness increased by 89.9% with an 80.5% increase in DR-MSVI. Between 2000-2020, for DR-blindness the ratio of females/males increased to 1.20:1.00 from 1.06:1.00; DR-MSVI to 1.13:1.00 from 1.08:1.00. ASP for DR-blindness in males was unchanged (-0.1%) with a 12.9% increase in females.

In 2020, among GBD super-regions, the ASP of DR-blindness was highest in Latin America/Caribbean (LAC) (0.15%, 0.10-0.21) followed by North Africa/Middle East (NA/MI) (0.06%, 0.04-0.09). For MSVI, NA/MI had the highest prevalence (0.41%, 0.30-0.55), followed by LAC (0.30%, 0.22-0.40). The largest increase in ASP of DR blindness was in South Asia (+25.7%) followed by Southeast Asia, East Asia and Oceania (SA/EA/O) (+15.4%) and Sub-Saharan Africa (+2.5%), the 4 other super-regions showing a decrease. Only SA/EA/O showed an increase in ASP of DR-related MSVI of 2.3%.

Conclusions: There are regional differences in DR-related blindness and MSVI and females are increasingly disproportionately affected by DR-visual loss. Further targeted region-specific actions on reducing burden of diabetes

and its complications and improving female care access are essential to reduce DR-related blindness/MSVI.

TITLE: Differential expression of the genes involved in the response to insulin in the retinal pigment epithelium and choroid of patients with age-related macular degeneration

SESSION TITLE: Pathophysiology of ocular aging and degeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Tura, S. Grisanti, Department of Ophthalmology, University of Lübeck, Lübeck, Schleswig-Holstein, GERMANY]

Commercial Relationships Disclosure (Abstract): Aysegul Tura: Commercial Relationship: Code N (No Commercial Relationship) | Salvatore Grisanti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Insulin resistance is a low-grade inflammatory and proangiogenic condition which is commonly detected in overweight people. Despite the positive association of a higher body-mass-index with the risk of developing age-related macular degeneration (AMD), it is not known whether the AMD patients exhibit insulin resistance in the primarily affected ocular tissues. Here, we analyzed the expression of n= 287 genes involved in the cellular response to insulin in the retinal pigment epithelium (RPE) and choroid of the AMD-patients versus age-matched controls using the transcriptome data of two independent cohorts from the Gene Expression Omnibus (GEO) database.

Methods: The list of genes involved in the cellular response to insulin was constructed using the Gene Ontology (<http://geneontology.org/>) and PubMed (<https://pubmed.ncbi.nlm.nih.gov/>) databases. Analysis of mRNA expression was performed using the normalized microarray data of two independent studies available at the GEO database. The first study involved the RPE/choroid of early AMD patients (n=9, mean age: 81 years) and age-matched controls (n=7, mean age: 83 years, Accession number: GSE50195). The second cohort consisted of the RPE cells that were isolated from two patients with advanced CNV (mean age: 83.5 years, n=4 replicates for each culture) compared to the normal human RPE-cells (ScienCell, Carlsbad, CA, n=4 replicates, Accession number: GSE103060).

Results: A total of seven genes were significantly altered in both cohorts in the absence of multiple hypothesis testing. Despite the similar levels of insulin, the expression of the insulin-like growth factor 2 (IGF2) gene, which is positively correlated with insulin resistance, and the insulin-induced gene-1 (INSIG1) was significantly upregulated in the RPE/choroid of early AMD patients and the CNV-derived RPEs.

Conclusions: Our results provide the first clues for the altered potential to respond to insulin in the RPE/choroid of the AMD patients, suggestive of an insulin-resistant or hyperinsulinemic state in the course of this disease. Further research on this neglected aspect may enable the identification of novel modifiable mechanisms that are involved in the different stages of AMD.

ABSTRACT BODY:

Purpose: Previously we examined the effects of genetic background on optic nerve regeneration (ONR) using the BXD inbred strain set. One strain, BXD29-Tlr4^{lps-2J}/J, displayed robust axonal regeneration. This strain is known to have acquired a mutation in TLR4 since its initial production in 1976. The present study is designed to determine if the mutation in TLR4 is responsible for the profound regeneration.

Methods: The present study examined optic nerve regeneration in BXD29-Tlr4^{lps-2J}/J mice and BXD29/Ty (the cryopreserved original strain) mice, the F1 crosses and the F2 crosses. ONR protocols include knockdown of Pten and intravitreal injection of zymosan and cAMP. To identify the role of the known mutant gene Tlr4, we examined the effects of this treatment following optic nerve crush. Two days before sacrifice, Alexa Fluor® 647 Conjugated Cholera Toxin B was injected into the vitreous and at 14 days after crush, the optic nerves were fixed and cleared in FocusClear. The amount of regeneration was quantified by the number of axons at 0.5 mm and 1 mm from the crush, and the distance that the longest 5 axons and single axon had reached down the nerve. To explore other candidate genes, we explored the full genomic sequences of both BXD29-Tlr4^{lps-2J}/J and BXD29/Ty. All SNPs and INDELs were called and compared between the two strains to identify possible mutations that may have impact on the regeneration.

Results: There was a considerable amount of axonal growth on BXD29-Tlr4^{lps-2J}/J but not the BXD29/Ty. All the F1s and F2s have shown similarly robust regeneration as the BXD29-Tlr4^{lps-2J}/J, indicating that the genetic element that is regulating the regeneration could be autosomal dominant. There is no significant difference in the amount of regeneration between the homozygote F2s (+/+ for wild type Tlr4) and the heterozygote F2s (+/- for mutant Tlr4), indicating that the mutation of Tlr4 is not responsible for this robust regeneration response. Since the two sub-strains have been separated for over 40 years, other mutations may have occurred. After whole genome analysis, we have identified more than 5,000 variants between the two sub-strains with 293 variants in the protein coding region. We are currently evaluating the segregation of these SNPs to identify the genomic elements responsible for the increased regeneration.

Conclusions: The strong optic nerve regeneration found in the BXD29-Tlr4^{lps-2J}/J mice was not caused by the mutation in Tlr4.

ABSTRACT BODY:

Purpose: This study aims to assess the stability of topography parameters performed after wearing orthokeratology lenses for year

Methods: This is a retrospective study made on myopic patients seen at Université de Montréal Clinic, adapted for orthokeratology between January 2017 and December 2018, followed for at least 1 year, and having worn the same lens design during this period. Topographical data (Medmont) were extracted from tangential maps taken at baseline and after 1, 3, 6 and 12 months of wear. Following the map analysis method suggested by Marcotte-Collard et al, treatment zone diameter (TZD), mid-peripheral power (MPP), mid-peripheral power width (MPPW) were measured horizontally (180 deg) and vertically (90 deg) at each visit. These values were compared over time. Statistically, the repeated within-subject measures resulted in clusters of possibly correlated data. Models were fit that accounted for within-subject correlation. The predictors of main interest were Month and Quadrant. Also included were gender, ethnicity, age, flat keratometry (KF), Steep keratometry (KS), initial refraction (RX) and axial length.

Results: Clinical population is composed of 99 participants (58% Female; 54% Asian), aged 11.75 +/- 2.15 showing an average refraction of -3.27 +/- 1.28D. Analysis of the results highlights all parameters remain stable during the first 6 months. However, at 12 months, TZD becomes smaller (-0.067+/-0.43mm) ($p=0.004$), MPP decreased by 0.89+/- 2.82D ($p<0.001$), whilst its width (MPPW) remain stable at 0.99+/-0.25mm over time. The measures along the vertical meridian show higher convex power and larger width compared to the horizontal ones ($p<0.001$).

Conclusions: This study demonstrates that topographic data can be compared over time. However, the convex power generated by the OK lens is significantly less at 12 months. Future work is needed to identify the causes of this loss of power. This could implicate that lenses must be changed more frequently in order to maintain their effectiveness.

ABSTRACT BODY:

Purpose: Adaptive optics (AO) measures and corrects ocular wavefront aberrations, enabling cellular-resolution retinal imaging and stimulation. Most current ophthalmic AO systems correct dynamic aberrations up to 2 Hz, the commonly-known cutoff frequency for ocular aberrations. However, this cutoff is based on measurements acquired in healthy subjects under ideal conditions and thus do not capture many real-life clinical scenarios that induce high temporal frequency aberrations. To investigate, we developed ultrafast AO and evaluated its use with optical coherence tomography (OCT).

Methods: Our ultrafast AO system used (1) a fast Shack-Hartmann wavefront sensor (SHWS) with high spatial sampling and dynamic range, (2) efficient software that minimized data processing time, and (3) discontinuous exposure permitting a higher AO loop gain. The SHWS comprised a 20×20 microlens array that sampled a 6.7 mm eye pupil and a high-speed streaming camera (ORCA-Lightning, up to 342 Hz). A direct slope reconstruction method and an integral controller scheme with a gain of 1 determined the voltages for a deformable mirror (DM, ALPAO DM97-15). Our software processed frames in 0.5 ms. We analyzed AO performance in correcting rapid dynamic aberrations caused by tear film disruptions, eye blinks, displacement of a high-power contact lens, nystagmus, and absence of cycloplegia. Performance was compared to conditions mimicking conventional AO on the same eyes.

Results: The cutoff frequency of our AO system as determined from a power rejection curve measurement was 32.5 Hz, enabling correction of dynamic aberrations more than 16× faster than conventional AO. After AO activation, the RMS wavefront aberration from un-cyclopleged subjects dropped below the diffraction limit within 5 ms, 40× faster than the fastest previously-reported ophthalmic AO system. Unlike conventional AO, ultrafast AO achieved high image quality of cone photoreceptors immediately after an eye blink, even in a late-stage retinitis pigmentosa subject wearing a -8.5 D contact lens. This immediate recovery from blinks enables continuous data acquisition for simple and high-throughput imaging in the clinic. In an eye with nystagmus, ultrafast AO improved the Strehl ratio from 0.37 to 0.81 and produced sharper images of the cone mosaic compared with conventional AO.

Conclusions: Ultrafast AO corrects ocular wavefront aberrations that conventional AO cannot and improves the clinical utility of AO.

TITLE: Relationship between choroidal thickness, axial length, and degree of myopia in European children

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Kobia-Acquah, I. Flitcroft, G.M. Hernandez, E. Loskutova, J. Loughman, Centre for Eye Research Ireland, Technological University Dublin, Dublin, Dublin, IRELAND|I. Flitcroft, Department of Ophthalmology, Temple Street Children's University Hospital, Dublin, IRELAND|

Commercial Relationships Disclosure (Abstract): Emmanuel Kobia-Acquah: Commercial Relationship: Code N (No Commercial Relationship) | Ian Flitcroft: Commercial Relationship: Code N (No Commercial Relationship) | Gabriela Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Ekaterina Loskutova: Commercial Relationship: Code N (No Commercial Relationship) | James Loughman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myopia has been associated with structural changes such as axial elongation and thinning of the retina and choroid. The relationship between choroidal thickness (CT), axial length (AL) and myopia has been studied in adult populations, however, there is little evidence available in children. Baseline data of 248 myopic children aged 6-16 years and enrolled in the Myopia Outcome Study of Atropine in Children (MOSAIC) clinical trial (ISRCTN36732601) were analysed to investigate the relationship between CT, AL and myopia in European children.

Methods: Myopia was categorized into three subgroups: low myopia (≤ -0.50 D to -3.00 D); moderate myopia (< -3.00 D to > -6.00 D); high myopia (≤ -6.00 D). Macular CT images were obtained using Triton Swept Source OCT; AL was measured with the Topcon Aladdin; cycloplegic spherical equivalent refraction (SER) was measured with the Grand Seiko Open Field autorefractor. Multiple linear regression analysis was used to explore associations between CT and age, gender, AL, and SER. A P-value of .05 was considered statistically significant.

Results: The mean \pm SD age of participants was 11.3 \pm 2.4 years (63% females). There was a statistically significant difference in mean CT across the three myopic groups ($P=.0002$). A negative correlation between CT and AL was observed, with each additional millimeter in AL equating to a 21.2mm lower CT ($P<.0001$). There was a statistically significant positive correlation between CT and SER, with each additional diopter of myopia equating to a 11.5mm greater CT ($P<.0001$). Only AL was significantly associated with CT after adjusting for age, sex, and SER in the studied population. CT was thicker in females than in males (240.0mm vs 230.8mm; $P=.29$); thicker in younger (age 6-11) than older (age 12-16) children (242.9mm vs 229.5mm; $P=.11$).

Conclusions: The current study showed that CT was thinnest in high myopes and was associated with AL in European children. The MOSAIC trial will evaluate longitudinal changes in CT in children with progressive myopia to understand the relationship between CT, AL and other ocular parameters both with (0.01% atropine treatment group) and without (placebo control group) myopia control treatment with low dose atropine.

TITLE: Modelling structure-function relationship in patients undergoing screening for hydroxychloroquine toxicity

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Jayakar, T. De Silva, C.A. Cukras, Unit on Clinical Investigation of Retinal Disease, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gopal Jayakar: Commercial Relationship: Code N (No Commercial Relationship) | Tharindu De Silva: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cukras: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose: The American Academy of Ophthalmology issued recommendations on annual screening of patients using hydroxychloroquine (HCQ) including functional testing with a Humphrey 10-2 visual field and structural evaluation using spectral domain optical coherence tomography (SD-OCT). This study investigates the association between retina microstructure and visual function in a cohort with long-term HCQ use.

Methods: Methods: The case-control study included 87 participants (173 eyes, mean age 60, 93% female, 55 without toxicity, 32 with toxicity) and SD-OCT imaging (Heidelberg Spectralis) and Humphrey 10-2 visual field (VF) testing were obtained during each visit. Quantitative metrics computed using OCT included total and outer retina thickness, minimum intensity (along A-scans within total and outer retina), and ellipsoid zone (EZ) loss. Enface 2D maps of OCT metrics were sampled in 68 circular regions (288 μ m diameter) corresponding to VF loci. First, correlations were analyzed between each OCT metric and corresponding VF sensitivity by locus using a linear model. Second, ability to predict VF sensitivity from the combination of OCT metrics were analyzed using a multi-variate, non-linear random forest regression using leave-one-out cross-validation.

Results: Results: In linear regression, the strongest relationship with VF sensitivity in the parafoveal ring was found with EZ loss, with $R^2=0.60$. Linear analyses using total and outer retinal thickness revealed $R^2=0.57$ and 0.40 , respectively, while total and outer retinal minimum intensity yielded $R^2=0.10$ and 0.22 , respectively. Using the multivariate model that included all five OCT metrics, the VF prediction markedly improved with $R^2 = 0.79$ and measured root mean squared error of 3.5 dB. Feature importance analysis identified EZ loss as the most relevant predictor.

Conclusions: Conclusions: Multiple OCT-derived quantitative metrics exhibited high correlation with VF sensitivity with the multivariate model achieving a high-degree of predictability of visual function from combined structural metrics. The results indicate a confluence of features available in SD-OCT and VF demonstrating the potential predictability of function from structure. With further analysis, this data could provide evidence to streamline the early detection of toxicity.

ABSTRACT BODY:

Purpose: To compare retinal vascular and foveal avascular zone morphology on OCT-angiography (OCTA) images and macular OCT images in subjects with retinal or choroidal abnormalities using two different OCT-angiography devices.

Methods: The retina of 31 study eyes of 21 participants with retinal or choroidal abnormalities including age-related macular degeneration, diabetic retinopathy, branch retinal vein occlusion and central retinal occlusion underwent fovea-centered 3×3mm and 6×6mm volume scans using the Topcon DRI-OCT Triton Swept-source OCT and Optovue RTVue-XR. The device-software generated en-face OCT-A images of the superficial (SCP) and deep capillary plexuses (DCP) and OCT images. By using the automatic segmentation, vessel length density (VLD), foveal avascular zone (FAZ) area, foveal avascular zone perimeter of OCTA images in the SCP and DCP and foveal center point thickness of 6 patterns of OCT images using image J software were compared between devices.

Results: After skeletonization of vessels to remove variation related to vessel width, mean (95% CI) difference of VLD between Topcon and Optovue was 8.40% (5.7%-1.1%, $P<.001$) and 3.33% (0.9%-5.7%, $P=.008$) in the SCP and DCP of 3×3mm volume scans, respectively. The mean difference of VLD was 7.72% (5.35%-10.09%, $P<.001$) and 8.93% (5.97%-11.88%, $P<.001$) in the SCP and DCP of 6×6mm volume scans, respectively. The mean difference of FAZ area was -0.17mm^2 (-0.25 – -0.10 , $P<.001$) and 0.31mm^2 (0.20 – 0.42 , $P<.001$) in the SCP and DCP of 3×3mm volume scans, respectively. The mean difference of FAZ area was -0.04mm^2 (-0.24 – 0.15 , $P=.647$) and 0.62mm^2 (0.39 – 0.85 , $P<.001$) in the SCP and DCP of 6×6mm volume scans, respectively. The mean difference of FAZ perimeter was -0.76mm (-1.22 – -0.31 , $P=.002$) and 0.94mm (0.47 – 1.42 , $P<.001$) in the SCP and DCP of 3×3mm volume scans, respectively. The mean difference of FAZ perimeter was -0.14mm (-0.62 – 0.34 , $P=.540$) and 1.40mm (0.95 – 1.84 , $P<.001$) in the SCP and DCP of 6×6mm volume scans, respectively.

Conclusions: These findings suggest VLD on Optovue was smaller than that on Topcon in either SCP or DCP on both volume of scans. FAZ area and perimeter in SCP on Optovue appeared larger than that on Topcon, but smaller in DCP. Further studies would be needed to determine if these differences are clinically relevant and how they vary across diseases, patients, and eye characteristics.

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of blindness affecting 2.9 million people in the US and is characterized by progressive optic nerve degeneration owing to imbalances between aqueous inflow and drainage. Prostaglandin analogs are effective at reducing IOP but are critically undermined by poor patient compliance. Herein, we set out to evaluate the effectiveness of a single use recombinant adeno-associated (rAAV)-mediated gene therapy treatment aimed at permanently lowering IOP through over-expression of prostaglandin F2a synthase (PTGS2) and receptor (PTGFR).

Methods: Brown norway rats (N=30) underwent baseline electroretinography (ERG), confocal scanning laser ophthalmoscopy (cSLO), optical coherence tomography (OCT), and tonometry. Rats were randomized following baseline characterization; each received a unilateral intracameral injection of rAAV packaging PTGS2 and PTGFR and a tetracycline inducible OFF-switch at either low (3.9×10^9 vector genomes(vg)/ml), medium (3.9×10^{10} vg/ml), or high (3.9×10^{11} vg/ml) dose. Tonometry was repeated at 1, 3, 6, 9, 12, and 13 months post injection and imaging/ERG repeated at 12 months to assess tolerability and efficacy. Gene expression was switched OFF at 12-months by administration of 5% tetracycline diet ad libitum. Eyes were harvested for histology at 12 and 18 months.

Results: Tonometry showed a dose-dependent reduction in IOP of -12.6% (low, NS), -21.87% (medium, $P=0.0036$) and -43.2% (high, $P<0.0001$) maintained until 12-months. Decreased IOP correlated to increased anterior chamber depth in low (+5.2%, $P=0.0125$), medium (+8.1%, $P=0.0447$) and high (+24.3%, $P<0.0001$) dose treatment (Unpaired T-test) at 12-months. No difference in reflectivity/autofluorescence (cSLO), corneal/retinal thickness (OCT), or ERG were observed in any treatment group. Slit lamp examination showed increased cell (12%), flare (36%), iris exfoliation (88%) and hyphema (20%) in the high dose treatment group. Placement on 5% tetracycline diet increased IOP in high (+22.5%) and medium (+21.5%) dose eyes, representing a partial or complete reversion to normal tension, respectively.

Conclusions: This study demonstrated dose-dependent reduction in IOP following a single injection of vector and excellent tolerability in low and medium dose treatment groups. Critically, IOP reduction could be reversed through oral administration of tetracycline; a critical safety feature for future clinical translation.

ABSTRACT BODY:

Purpose: Clinical trials for RPE transplantation for AMD have shown black pigment in the post-operative fundus. Black pigment in neovascular AMD is ascribed to melanotic cells, i.e., RPE-originated and packed with large spherical melanosomes (PMID 26024109). To inform interpretation of trial imaging outcomes, we provided histology of a clinically imaged eye with neovascular AMD and black pigment; in donor eyes, we performed immunohistochemistry to test whether melanotic cells are transdifferentiated RPE.

Methods: A white woman with inactive subretinal fibrosis OD was followed for 9 years using fundus color and autofluorescence imaging, and optical coherence tomography (OCT). After patient death at age 90 years, OD was preserved 6.25 hours later and prepared for epoxy resin sections aligned to OCT and light and electron microscopy. Regions of distinct gray-black pigmentation in the fibrotic scar were identified in histology. To assess cellular functional repertoire, we used enzyme-linked colorimetric immunohistochemistry to detect retinoid (RPE65) and immune (CD68) proteins, in bleached sections of donor eyes with nvAMD and lacking clinical history.

Results: Black and gray non-autofluorescent pigment appeared within the fibrotic scar and expanded during follow-up. The black pigment corresponded to cells with densely packed spherical black melanosomes. These contrasted both with spindle-shaped melanosomes of normal RPE, which were found infrequently, and tightly packed small spherical melanosomes in choroidal melanocytes. Some moderately pigmented melanotic cells expressed RPE65 and CD68. Only CD68 immunoreactivity, a marker for abnormal RPE (Cao ARVO2020), was seen in heavily pigmented cells.

Conclusions: Black fundus pigment corresponds to melanotic cells, shown previously to arise from RPE entombed in fibrotic scars or enveloping neovascular membranes (PMID 26024109, 32855855). Large spherical melanosomes likely arise from organelles such as lipofuscin or newly described spherical melanosomes (PMID 32433758) rather than from native melanosomes, which are sparse in advanced disease. Cell based therapies should anticipate possible dynamism of lysosome-related organelles including melanosomes. Trial outcome measures should include multimodal imaging with autofluorescence to assess health of implanted cells.

ABSTRACT BODY:

Purpose: Stem cell-derived retinal organoids (RtOgs) can be used for transplantation in retinal degeneration (RD) models. The purpose of this study was to understand RtOgs' long-term metabolic and genetic changes in vitro to improve quality control for biomanufactured transplantable tissues.

Methods: Ten GMP-compatible lots of RtOgs manufactured by AIVITA Biomedical Inc (Irvine, CA, USA) and were used for long-term functional imaging and qPCR analysis. We used two-photon microscopy (Zeiss LSM 780, 740 nm pulsed laser) coupled with fluorescence lifetime imaging (FLIM) and hyperspectral imaging (HSPEC) to characterize the RtOgs' metabolic activity and structure. RtOg samples ranged from days 51 to 159 of differentiation during longitudinal imaging. In qPCR analysis, we used 12 retinal progenitor and photoreceptor genes and 1 housekeeping gene to identify and quantify the gene expression profile. Human fetal (n=1) and adult retinal tissue (n=3) were used as positive controls. Stem cell line CSC14 was used as a negative control.

Results: The free/bound NADH (f/b NADH) ratio demonstrated that a metabolic shift from glycolysis to oxidative phosphorylation occurred between day 54 and 87. The total metabolic activity shifted slightly back toward glycolysis between day 90 and 100. Consistency in organoid development among production lots was shown. Organoids demonstrated similar metabolic signatures over 5-6 months. Retinal progenitor genes were expressed in all groups between days 51 and 159. Photoreceptor genes expression emerged around the 2nd month of differentiation, which corresponded to the shift in f/b NADH ratio. RtOgs between 3-6 months of differentiation had photoreceptor gene expression levels between the human fetal retina and human adult retina gene expression levels. The occurrence of OPN1 SW and OPN1 LW indicated the maturation of photoreceptors in 4 months of differentiation, which was concurrent to the stabilized level of f/b NADH ratio starting from 4 months.

Conclusions: Long-term imaging data showed that RtOgs in different lots exhibited a reproducible metabolic development from more proliferative to more differentiated at an early stage. After 4 months, the metabolic signature stabilized consistent with gene expression profile stabilization.

ABSTRACT BODY:

Purpose: Due to random X-inactivation and polymorphism in the spectral sensitivity of the L and M cones, some females have four distinct cone classes in their retinæ. However, psychophysical studies of females with the gene for four cones have found the vast majority of subjects do not exhibit four-dimensional color vision (Jordan et al., JoV, 10, p1, 2010), even when the three middle-to-long wavelength photopigments are well-separated in spectral peak. We propose that the absence of functional tetrachromacy in this population is a result of the circuitry in the outer retina and a dearth of visual experience that would train the visual system to distinguish an additional color axis.

Methods: To test this hypothesis, we created a receptive field response and detection algorithm based on the theory of color appearance put forward by Schmidt et al. (JOSA A, 31, pA195, 2014). According to this theory, all conscious vision is mediated by the midget ganglion cell system: achromatic vision is mediated by L vs M receptive fields, while hue perception is mediated by double opponent receptive fields formed when S-cone signals are combined with L vs M signals in the outer retina. The resulting model was presented with millions of colored edges and correlations between the response of each receptive field were calculated in order to ascertain how many distinct outputs the brain could distinguish. Our model differs from previous attempts, which relied on individual cone responses rather than the outputs of midget ganglion cells.

Results: We found that any 4th cone added to the model, no matter how well spaced between the M and L cone photopigments, produced a response that was highly correlated to the existing receptive fields of trichromats. Receptive fields with the 4th cone as a center were consistently classified as achromatic L vs M in the absence of S-cone input, or Blue vs Yellow when S-cone signals were included.

Conclusions: These results show that it is unlikely the brain would be able to differentiate the signal produced by receptive fields with a fourth cone without consistent exposure to scenes in which their activity is decorrelated from those that mediate the red-green, blue-yellow, and black-white percepts of normal trichromatic vision. As a result, functional tetrachromacy is exceedingly rare in the general population despite the significant number of females born with four well-separated cone photopigments.

ABSTRACT BODY:

Purpose: Various retinal disorders, such as glaucomatous, retinal ischemia reperfusion, and traumatic optic neuropathy, are involved in the pathogenesis of neurodegeneration via glutamate excitotoxicity. However, the proteomic characteristics and modulation of the neural microenvironment with NMDA-induced neurodegeneration in the retina and optic nerve remain incompletely understood.

Methods: We established a model of NMDA-induced injury by comparing the proteomes of phosphate-buffered saline (PBS)-operated, NMDA-operated and control groups. We performed mass spectrometry-based label-free quantitative mechanisms and identify key proteins that spatially regulate neural cell death related signaling pathways in the retina and optic nerve.

Results: Using LC-MS/MS proteomics analysis, we identified 3532 proteins in retinal tissues and 2593 proteins in optic nerve tissues. Using Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses, protein changes and energy metabolism in the retina and optic nerve tissue were comprehensively evaluated. Pearson's correlation coefficients revealed the excellent biological reproducibility of the proteomic results. We identified the key cellular signaling events triggered by glutamate overstimulation based on protein-protein interaction analysis. We found that the ACSL3 (Q63151) and Prnp (P13852) proteins are key factors in ferroptosis regulation in the retina; the Gabarapl2 (P60522) protein is the key factor in autophagy in the optic nerve. In PRM validation, we confirmed 16 up- and downregulated key proteins among the different groups.

Conclusions: This study provides the basis for further studies linking NMDA-induced neural cell death in the retina and optic nerve and may shed light on the advanced molecular mechanism of disease biology and accelerated targeted therapy.

ABSTRACT BODY:

Purpose: Previous studies have shown that storage of donor corneal endothelial cells (dCEncs) at 4°C and subsequent rewarming prior to transplantation can damage mitochondria and decrease cell viability. The Insulin-like growth factor binding protein-3 (IGFBP-3) is a pleiotropic protein with known roles in cell growth and survival. This study investigated the effect of IGFBP-3 on mitochondrial fitness in dCEncs subjected to hypothermic storage.

Methods: Human donor corneas were obtained from Tissue Transplant Services at UT Southwestern Medical Center. dCEncs were harvested by removal of Descemet's followed by trypsinization. Cells were plated on collagen IV coated plates and cultured in medium containing 4% fetal bovine serum. Cells were serum starved for 24 hours prior to cold exposure (4°C) for 15 minutes, 2 or 6 hours with and without recombinant human (rh)IGFBP-3. Mitochondrial respiration and glycolysis were measured in real time using a Seahorse assay. Mitochondrial fragmentation and polarization were further assessed by double-labeling with MitoTracker and TMRE, respectively. Amplex red was used to quantify levels of reactive oxygen species (ROS). Western blotting was used to determine the expression of mitochondrial proteins.

Results: Short term cold exposure induced cell migration that was visible at 2 hours. By 6 hours, dCEncs formed distinct morphological clusters that were not evident in cells cultured at 37°C or rhIGFBP-3 treated cells. At the 6-hour time point, dCEncs also demonstrated a reduction in cell-substrate adhesion that was recovered by co-treatment with rhIGFBP-3, while cell-cell adhesion appeared unchanged. Despite a measurable increase in mitochondrial oxygen consumption, cold exposure induced mitochondrial hyperpolarization and fragmentation. Co-treatment with rhIGFBP-3 significantly increased oxygen consumption. This was associated with an improvement in mitochondrial morphology. Expression levels of Superoxide dismutase (SOD) 1 and SOD2 were decreased following 6 hours of cold exposure but returned to near normal levels when treated with rhIGFBP-3. There were no detectable differences in ROS levels between groups.

Conclusions: IGFBP-3 promotes mitochondrial fitness and cell-substrate adhesion in dCEncs in cell culture in vitro. Further studies are needed to determine the effects of IGFBP-3 on dCEncs during transplantation in vivo.

TITLE: System Settings for Intraocular Pressure (IOP) Performance with 25-Gauge Dual-Cutting 20,000cpm Beveled Vitrectomy Probes

SESSION TITLE: Vitreoretinal surgery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Garufis, Y. Zhu, Alcon Laboratories Inc, Lake Forest, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Carrie Garufis: Commercial Relationship(s);Alcon:Code E (Employment) | Ying Zhu: Commercial Relationship(s);Alcon:Code E (Employment)

ABSTRACT BODY:

Purpose: As IOP maintenance during vitrectomy surgery is a critical parameter, the study aims to 1) understand the IOP performance of 25+Gauge (Ga) dual-cutting, 20K cuts per minute (cpm) beveled vitrectomy probes under different system settings, and 2) help surgeons to optimize their system settings during surgery.

Methods: 25+® HYPERVIT® beveled 20K cpm vitrectomy probes were driven by a CONSTELLATION® Vision System (Alcon Vision, LLC.) to aspirate sterile irrigating solution (BSS®) in a hollow acrylic eye model. A digital transducer (OMEGA, PX409-001GUSBH) was connected to the bottom of eye model to detect IOP change during aspiration. Six samples were tested under core duty cycle and vacuums of 250mmHg, 450mmHg and 650mmHg. Cut rate ranged from 2500cpm to 20,000cpm. Both system IOP compensation enabled and disabled were used. Average IOP during aspiration was calculated for each test setting and statistical analyses were performed using Kruskal-Wallis test with statistical significance level of $p < 0.05$.

Results: At 450mmHg, without IOP compensation, the IOP ranged from 13.93 ± 0.96 to 14.32 ± 1.11 mmHg when the cut rate changed from 2500cpm to maximum cut rate of 20,000cpm. When IOP compensation was enabled, IOP ranged from 33.21 ± 1.06 to 33.25 ± 1.55 mmHg for cut rates from 2500cpm to 20,000cpm. Statistical analysis indicated that there was no significant difference between results using various cut rates for both IOP compensation enabled and disabled ($p > 0.05$).

At the maximum cut rate and without IOP compensation, IOP was 21.96 ± 0.60 mmHg under 250mmHg, 14.32 ± 1.11 mmHg under 450mmHg and 7.47 ± 0.98 mmHg under 650mmHg. Corresponding average flow rate was 6.54 ± 0.13 cc/min under 250mmHg, 10.64 ± 0.1 cc/min under 450mmHg and 14.08 ± 0.09 cc/min under 650mmHg. When IOP compensation was enabled, IOP at maximum cut rate significantly increased to 32.32 ± 1.07 mmHg (47% improvement) for 250mmHg, 33.25 ± 1.55 mmHg (132% improvement) for 450mmHg, 37.12 ± 4.04 mmHg (397% improvement) for 650mmHg compared with result without system's intervention ($p < 0.05$).

Conclusions: 25+® Ga Dual-Cutting 20K cpm vitrectomy probes have constant IOP performance under different cut rates. IOP compensation keeps the eye at improved IOP ranges during aspiration. 25+® Ga 20K cpm vitrectomy probe using IOP compensation offer surgeon flexible operation settings as well as a controllable and efficient process.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of blindness in the elderly. Genome-wide association studies (GWAS) have identified common and rare variants in genes in the complement pathway associated with AMD. To identify additional AMD risk variants and better understand the underlying disease mechanisms, we sequenced the genomic regions of genes in the alternative complement system, coagulation, and inflammatory pathways in 481 advanced AMD (AAMD) and 277 unaffected subjects.

Methods: This study included 758 subjects, of which 340 subjects were from 76 families densely affected by AAMD. Targeted sequencing was performed on the genomic regions of 150 genes in 111 samples. Whole exome sequencing was performed on the other 647 samples. Single-variant tests were performed on 3062 variants shared among ≥ 5 AAMD subjects using logistic regression. Gene-based tests were used to evaluate aggregate effects from rare and low frequency variants (at minor allele frequency [MAF] $< 5\%$) in a gene using burden tests and SKAT. Analyses were adjusted for age, sex, smoking, four principal components, and family structure.

Results: At false discovery rate (FDR) < 0.05 , we identified a protein-altering variant, rs2274700 in CFH (Odds ratio = 0.61, $P = 1.78 \times 10^{-5}$) in association with AMD by single-variant analysis. rs2274700 is a perfect proxy of a well-known AMD intronic SNP rs1410996 (linkage disequilibrium, $r^2 = 1$). Gene-based tests identified a burden of 24 variants in OPRM1 ($P_{\text{SKAT}} = 0.002$) and 18 in LCT ($P_{\text{SKAT}} = 0.003$) at FDR < 0.2 . For densely AAMD affected families whose members had low genetic risk score (< 0.8) and no known rare variants of AMD, we hypothesized that some of those families may be explained by variants that are highly penetrant. Among the 82 extremely rare variants with MAF < 0.001 in the 1000 genomes reference panel and being predicted in silico to have functional impact on proteins, we identified one highly penetrant protein-altering variant, whose risk allele was found in $\geq 80\%$ affected AMD members in a family, but not in any of the other samples.

Conclusions: Our study suggested novel pathogenetic rare variants and genes in immune pathways for AMD. Further functional studies will be necessary to validate our findings that will guide the design for novel therapeutic strategies for the disease.

ABSTRACT BODY:

Purpose: Glaucoma patients present a high prevalence of sleep disorders, yet its underlying mechanisms remain unclear. Intrinsically photosensitive retinal ganglion cells (ipRGCs), which are involved in circadian rhythms are also known to be injured in glaucoma. The ipRGCs provide input to the ventrolateral preoptic nucleus (VLPO), a major sleep-inducing subcortical structure. VLPO induces sleep by delivering inhibitory signals to the subcortical arousal systems and the cortex. In the current study, we investigated whether the sleep-regulating subcortical systems involving VLPO and their inhibitory projections to the cortex are impaired in glaucoma.

Methods: 37 glaucoma patients and 22 healthy subjects underwent 3T anatomical MRI and resting-state functional MRI (fMRI) with eyes closed. Additionally, 15 glaucoma patients and 4 healthy subjects were scanned for 3T anatomical MRI and proton magnetic resonance spectroscopy (MRS). For MRS, we recorded gamma-aminobutyric acid (GABA), glutamate and N-acetyl-aspartate (NAA) signals from the same single voxel ($2.2 \times 2.2 \times 2.2 \text{ cm}^3$) placed in the occipital cortex (Figure 2A).

We analyzed the fMRI data using CONN. Brain regions-of-interest included VLPO, a main sleep-promoting area, and the arousal systems including posterior hypothalamus (PH), dorsal raphe (DR), median raphe (MR), locus coeruleus (LC), and habenula and cortical networks. We fitted glutamate and GABA separately using LCModel. The amount of GABA and glutamate were normalized by NAA values. The excitatory and inhibitory balance (E/I balance) was calculated by dividing the amount of glutamate by that of GABA.

Results: At the subcortical level, enhanced functional connectivity (FC) was observed between VLPO and PH, a main arousal structure ($P=0.048$; Figure 1A,B,D), and between habenula and MR ($P=0.006$; Figure 1A,C,E) in glaucoma patients. At the cortical level, reduced FC was observed between VLPO and the medial occipital cortex ($P=0.014$; Figure 1F,G,H) and the posterior occipital cortex ($P=0.006$; Figure 1F,G,I). The occipital cortex of glaucoma patients also presented reduced amount of GABA ($P=0.001$; Figure 2C) but not glutamate ($P=0.486$; Figure 2D), resulting in increased E/I balance ($P=0.048$; Figure 2B).

Conclusions: Our study shows that the sleep-regulating subcortical systems involving VLPO and their projections to the occipital cortex are impaired under glaucoma. Such alterations may underlie the high occurrence of sleep disorders in glaucoma.

ABSTRACT BODY:

Purpose: Anterior segment dysgenesis stems from anomalies in anterior ocular structures, including the trabecular meshwork (TM), leading to abnormalities in aqueous humor production and outflow. In order to determine the specific contribution of transcription factor activating protein-2 β (AP-2 β) in the development of TM, we have recently developed a novel mouse model by deleting AP-2 β specifically from the developing TM region (TMR) using a novel MgpCre mouse line, known to be expressed in periocular mesenchyme (POM), giving rise to the future TM.

Methods: MgpCre^{+/-}; Tfap2b^{+/-} mice were bred with Tfap2b^{lox/lox}; tdTomato^{lox/lox} mice to generate MgpCre^{+/-}; Tfap2b^{-/lox}; tdTomato^{lox/+} mice (AP-2 β TMR KO) with Tfap2b, encoding AP-2 β , deleted from the TMR. When crossed with tdTomato mice, control (MgpCre^{+/-}; tdTomato^{lox/+}) and knockout (KO) mice (MgpCre^{+/-}; Tfap2b^{-/lox}; tdTomato^{lox/+}) expressed an RFP variant that was used to trace MgpCre-expressing cells in frozen sections. H&E and immunohistochemistry (IHC) of paraffin sections was carried out using antibodies for the TM markers, α SMA and myocilin, the Schlemm's canal marker, Prox1, and retinal ganglion cell (RGC) marker, Brn3a, while intraocular pressure (IOP) was acquired using a tonometer.

Results: In control, MgpCre was expressed at embryonic day (E) 15.5 in the POM that was observed to be similar in AP-2 β TMR KO as well. By P7 and P14, fewer tdTomato-positive cells were observed in the TMR of KO mice when compared with control mice. Fewer TM cells were observed in the KOs, as seen using H&E staining, and by the reduction in α SMA and myocilin staining. Further, absence of Prox1 staining was observed in the anterior angle of KO when compared to the control mice. A significant increase in IOP at P30 (n=6 eyes, p<0.001) followed by a significant reduction in retinal thickness (n=3 eyes, p<0.01) and Brn3a positive cells (n=3 eyes, p<0.01) at P40 was observed in the KO mice when compared with control.

Conclusions: The reduction in tdTomato-positive cells and the reduced expression of TM and Schlemm's canal markers in the AP-2 β TMR KO mice suggests that AP-2 β is critical for the development and differentiation of TMR. The increased IOP at P30 in the KO mice likely resulted from abnormal differentiation of the POM cells into TM cells. The decreased retinal thickness and Brn3a positive cells at P40 shows loss of RGCs that can be attributed to increased IOP.

ABSTRACT BODY:

Purpose: Visual dysfunctions affecting the central retina including highly prevalent age-related macular degeneration occurs due to degeneration of the cone-dominant central macula region leading to high-acuity vision loss.

Unfortunately, there is a lack of an easily accessible animal model that resembles the human retinal macula. *Tupaia belangeri* (Tree Shrews, Ts) exhibit an extremely high cone: rod ratio (~95%), have large eyes with a more human-like lens: globe ratio, and exhibit highly visual behaviors. Hence the goal of this study was to develop a novel stem cell-based 3D retina from the diurnal, cone-dominant, non-rodent primate-like, Ts.

Methods: Neural progenitor cells (NPC) obtained from a neonatal male, Ts (Gift by Brian Samuels, UAB) was used to generate a stable induced pluripotent stem cell (iPSC) line using CytoTuneTM-iPS 2.0 Sendai Reprogramming Kit. Individual iPSC clones were expanded and assessed for pluripotency markers via immunofluorescence (IF). 3D-retinal differentiation was carried out using a three-step transitioning protocol (3D-2D-3D) with neural induction media. Retinal organoids (RO) collected at various time-points of differentiation (Day 25, 40, 60) were evaluated for retinal cell types by IF and qRT-PCR, and phenotypically compared with neonatal Ts eyes.

Results: iPSC lines (n=3 clones) generated from Ts-NPCs exhibited typical morphological characteristics: compact colonies with clear borders and high nucleus: cytoplasm ratio by bright field microscopy. IF confirmed the expression of pluripotent markers - Oct3/4, Sox2, and Nanog. Undifferentiated Ts-iPSCs directed towards retinal fate generated self-assembled laminated 3D-RO. Protein and gene expression analysis confirmed markers of multipotent retinal progenitor cells (Lhx2, Pax6, Sox2), ganglion/amacrine cells (Brn3a, Islet, HuC/D), and photoreceptors (Otx2, Blimp1, Crx, Rcvrn).

Conclusions: This is the first study to demonstrate the establishment of iPSCs from a novel primate-like tree shrew with cone-dependent visual ecology. Additionally, we have successfully developed a method to generate photoreceptors containing 3D-RO. This approach has a great potential to both understand the feasibility of cone photoreceptor replacement and facilitate the development of novel cone-degeneration models in vitro for understanding and ameliorating catastrophic vision loss using this clinically relevant primate-like animal model.

TITLE: Absence of melanopsin leads to altered circadian rhythms of the retinal transcriptome

SESSION TITLE: Ganglion cells and beyond

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Palumaa, L. Taylor, R. Foster, A. Jagannath, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, Oxfordshire, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Teele Palumaa: Commercial Relationship: Code N (No Commercial Relationship) | Lewis Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Russell Foster: Commercial Relationship: Code N (No Commercial Relationship) | Aarti Jagannath: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Melanopsin, the photopigment of pRGCs, modulates retinal function as its genetic deletion leads to disruptions in cone ERG and the baseline and circadian rhythmicity of contrast sensitivity. By analysing retinal gene expression over a circadian time course with RNA-seq, this study aimed to uncover the molecular mechanisms of how melanopsin affects retinal circadian rhythms.

Methods: Retinas of wild-type (WT) and melanopsin-deficient ($Opn4^{-/-}$) mice were collected on the first day in constant darkness every 6 hours at circadian times (CT) 4-28 (n=4) and subjected to RNA-seq and qPCR analyses. Circadian rhythmicity and global differences in gene expression were analysed with MetaCycle and DESeq2, respectively. The KEGG database was used to analyse pathway enrichment and the dataset by Siebert et al. (Nat Neurosci 2012) for gene enrichment in retinal cell types.

Results: WT retinas displayed circadian rhythmicity in 647 genes, and $Opn4^{-/-}$ retinas in 691, while only 178 genes were circadian in both genotypes. Despite these differences, the peak phases of gene expression were remarkably similar between genotypes, with the largest number of genes peaking around CT18. The genes rhythmic in both genotypes showed significant enrichment for dopamine signalling (e.g. *Drd1* and *Drd4*), gap junction and circadian pathways, and cone-associated genes. The genes exclusively circadian in WT retinas were enriched for phototransduction and sphingolipid signalling pathways, and those exclusively rhythmic in $Opn4^{-/-}$ retinas for carbon metabolism. On a global level, 450 genes were differentially expressed between the genotypes and those with higher levels in $Opn4^{-/-}$ were enriched for sphingolipid signalling. The core clock genes *Bmal1*, *Per2* and *Cry1* showed circadian rhythmicity in WT, but, interestingly, not in $Opn4^{-/-}$ retinas.

Conclusions: We demonstrate that retinal circadian genes are associated with dopamine signalling and gap junctions, and are cone-enriched in both WT and $Opn4^{-/-}$ retinas. As demonstrated by Dkhissi-Benyahya et al. (Cell Mol Life Sci 2013), we also find that $Opn4^{-/-}$ retinas lose rhythmicity in core clock gene expression. These findings highlight a critical role for melanopsin in regulating the circadian rhythmicity of the retinal transcriptome and suggest that the circadian disruptions of retinal function in $Opn4^{-/-}$ mice might be a result of disrupted visual transduction and sphingolipid signalling pathways.

ABSTRACT BODY:

Purpose: Corneal injuries and subsequent scarring collectively represent a major global human health challenge, affecting millions of people worldwide. We have previously shown that in situ-forming PEG-collagen hydrogels supported epithelial wound closure by 1 week after treatment. Here we aim to evaluate the longer-term benefits of the hydrogel on corneal epithelial layer maturation and stromal scarring, 2 months after treatment.

Methods: Lamellar keratectomies were performed in rabbit corneas followed application of the in situ forming collagen-PEG hydrogel followed by bandage contact lens and partial tarsorrhaphy placement which were both removed on day 7. The healing and curvature of the treated cornea was monitored by OCT and photography, along with corneal thickness and intraocular pressure (IOP). Two months after the injury, the corneas were fixed for immunohistochemical analysis.

Results: Multi-layered epithelialization with normal morphology and cytokeratin 3 expression was observed at 2 months. Alpha smooth muscle actin expressed was reduced compared to injured, untreated corneas. The hydrogels were partially observed in the central corneal suggesting degradation and near-complete stromal remodeling. Corneal nerves were observed through beta-tubulin expression in the area of the stroma where the gel was placed. Corneal thickness and IOP were measured to be within normal limits by post-op month 1 and after.

Conclusions: The in situ-forming collagen-PEG hydrogel supports normal epithelial wound healing and stromal remodeling return to baseline corneal thickness by two months.

ABSTRACT BODY:

Purpose: Endothelin-1 (ET-1) is a vasoactive peptide whose levels are elevated both in the aqueous humor and circulation of primary open angle glaucoma patients as well as in animal models of glaucoma. Intravitreal ET-1 treatment in rodents has been shown to produce retinal ganglion cells (RGCs) loss, axonal injury, and disruption of nerve fiber layer. However, the precise mechanisms underlying these effects are still not completely understood. The purpose of the study was to assess mitochondrial mechanisms underlying ET-1 mediated neurodegeneration of RGCs in culture as well as in the Morrison model of ocular hypertension in rats.

Methods: Primary RGCs isolated from rat pups were treated with ET-1 (100 nM) for 24 h and reactive oxygen species were detected with the CellRox Green reagent and mitochondrial membrane potential was measured with the JC-1 dye. Mitophagy was assessed in the RGCs by treating with MitoTracker (labels mitochondria in live cells) and LysoTracker (tracks lysosomes in live cells). To confirm these findings in vivo, intraocular pressure (IOP) elevation was carried out in one eye of retired breeder Brown Norway rats. Two weeks post-IOP elevation, retina sections from IOP-elevated eyes and contralateral eyes were analysed for expression of LC3B (a marker of autophagosomes), LAMP-1 (lysosomal marker) and TOM20 (mitochondrial marker).

Results: ET-1 treatment of primary RGCs for 24 h produced a significant decrease ($n=3$, $p < 0.05$) in reactive oxygen species and a decrease in mitochondrial membrane potential. A decreased co-localization of MitoTracker and LysoTracker was found in primary RGCs treated with ET-1, indicative of decreased mitophagy. IOP elevation for 2 weeks in rats, produced a significant decrease in co-localization of LC-3B and TOM-20 ($n=4$, $p<0.05$) as well as LAMP-1 and TOM-20 in ganglion cell layer and nerve fiber layer.

Conclusions: Treatment of primary RGCs with ET-1 produced an elevation in reactive oxygen species which could result in mitochondrial damage. Following IOP elevation in rats, a decreased colocalization of TOM-20 with LC-3B as well as with LAMP-1 could be indicative of ET-1 mediated decrease in mitophagy in RGCs. Mitochondrial damage in conjunction with reduced mitophagy will exacerbate oxidative damage and neuronal injury, which could be one of the mechanisms underlying ET-1 mediated neurodegeneration of RGCs in glaucoma.

ABSTRACT BODY:

Purpose: Rho-associated kinase (ROCK) activation contributes to micro-vascular closure, retinal hypoxia and disrupted retinal pigment epithelium (RPE) barrier in Diabetic Retinopathy (DR) rat model. ROCK inhibition seems to be a promising therapeutic target as previous results with Fasudil, a clinically approved ROCK inhibitor, showed a better retinal perfusion and reduced edema. However, its short life-time in the vitreous is not compatible with a long-term treatment. In this study, we evaluate the potential of a new treatment, BIRKI, a slow-release ROCK Inhibitor from Boehringer Ingelheim.

Methods: 10 to 16 month-old male Goto-Kakizaki (GK) type 2 diabetic rats were injected intravitreally with 3µl of either BIRKI or Vehicle. The diabetic status was defined by measurement of the plasma concentration of glycosylated hemoglobin (HbA1c). Eyes were enucleated and dissected 8 or 28 days after the injection. Immunohistochemistry was performed on flat mounts and cryosections to evaluate retinal hypoxia and vasodilatation, RPE morphology and barrier disruption 28 days after the treatment. Western Blots were performed to assess ROCK activity and expression 8 days after the treatment (significance of results was evaluated using non parametric tests).

Results: ROCK activity, quantified through the specific phosphorylation of one of its substrates, MYPT1, was significantly reduced in RPE/choroid complex of BIRKI injected rats compared to Vehicle rats ($p=0,028$). Moreover, a pimonidazole staining showed a significant reduction of retinal hypoxia in BIRKI rats compared to Vehicle ($p=0.004$). This result is consistent with the dilation of retinal vessel observed in BIRKI rats ($p=0.017$). The RPE morphology seems to be partially restored as well as its function as barrier, through quantification of cell size, cell shape and leakage. No signs of toxicity of BIRKI have been observed so far.

Conclusions: Our results are consistent with ROCK inhibition as an interesting new therapeutic concept for diabetic retinopathy. A single injection of BIRKI showed similar effects at 28 days than 3 consecutive injections of Fasudil at 48h. Further studies are needed to confirm that BIRKI would be a good candidate in the treatment of diabetic retinopathy, especially in regard of improvement of retinal vascular infusion and protection of the outer retinal barrier.

ABSTRACT BODY:

Purpose: In cardiovascular disease CVD, ischemia increases the lipid load in macrophages, driving an inflammatory phenotype and promoting vascular damage. This process is poorly understood in ischemic retinopathy. Our studies in a model of oxygen-induced retinopathy have shown that macrophage activation during retinal neovascularization (RNV) is characterized by increased expression of the inflammation amplifiers TREM-1 (triggering receptor expressed on myeloid cells 1) and M-CSF (macrophage colony stimulator factor). Inhibition of TREM-1 reduces vascular injury and limits RNV. Here we examined upstream activators of the TREM1/MCSF pathway. In macrophages, ACAT1 esterifies LDL cholesterol (LDLc) with fatty acids to form cholesterol esters (CEs).

Methods: Wild-type and LDL receptor knockout mice were maintained in 75% oxygen from postnatal day 7 (P7) to P12 followed by normoxia until P17. Wild-type pups were treated with an ACAT inhibitor (N-[3-(4-hydroxyphenyl)-1-oxo-2-propenyl]-L-phenylalanine, methyl ester 10 mg/Kg, i.p) or vehicle (PBS) on alternate days from P7 to P16. The retinas were collected on P17 and prepared for immunofluorescence or western blot. Human macrophages were maintained in hypoxia (1% O₂) or normoxia (21% O₂) for 16 hrs, treated with the ACAT inhibitor (10µg/ml) or PBS, and prepared for western blot.

Results: Wild type mice showed significant increases in LDL receptor expression, lipid accumulation, and CE formation in areas of RNV along with increased expression of ACAT1, TREM-1, M-CSF, and VEGF (p<0.05). ACAT inhibitor treatment significantly abrogated those changes and reduced the areas of RNV and vaso-oblivation (p<0.05). LDL receptor knockout blocked RNV underscoring the role of LDLc metabolism in the pathology. In vitro, hypoxia-induced increases in expression of ACAT1, TREM-1, M-CSF and VEGF were prevented by ACAT inhibitor (p<0.05).

Conclusions: Hypoxia-induced increases in ACAT1 activity and CE formation are associated with upregulation of TREM-1, M-CSF, VEGF, LDLR and pathological RNV. Limiting the ACAT1 pathway offers a new therapeutic strategy for the treatment and prevention of vascular pathologies during ischemic retinopathy.

ABSTRACT BODY:

Purpose: The P23H mutation in the rhodopsin (RHO) gene represents the most common form of adRP in North America. Elimination of the causative mutant allele, while leaving the wild-type (WT) allele intact should eliminate vision loss in adRP patients. To this end, we studied the efficacy of the engineered Meganuclease, Rho1-2, in the transgenic P23H human rhodopsin (TgP23H) pig model of adRP.

Methods: Rho1-2, packaged in a self-complementary AAV5 vector and driven by the GRK1 photoreceptor-specific promoter was delivered subretinally (40 ul) to one eye of TgP23H piglets postnatally (P3-7,n=23). The fellow eye served as a control and either was uninjected or injected with vehicle. The efficacy of 2×10^9 , 6×10^9 , 2×10^{10} , and 6×10^{10} vg were compared at regular post injection intervals. Fundus imaging and optical coherence tomography (OCT) assessed retinal structure. Full-field electroretinography (ffERG) assessed rod and cone function (ISCEV protocol). All pigs were assessed through P140 and a subset was assessed through P300. Immunohistochemistry/confocal assessed retinal morphology.

Results: From birth, untreated TgP23H pigs have no rod isolated ffERG response (Fernandez de Castro et al., IOVS, 2014). Regardless of dose, treatment with Rho1-2 was well tolerated, with no signs of an immune response. Treatment with two Rho1-2 doses (2 or 6×10^{10}) produced a significant rod isolated ffERG b-wave response as early as P60 (~ 14 uV; $p = 0.04$ and 0.0003) $n = 6$ and 12 pigs, respectively). Mean b-wave amplitudes increased at P120 (~ 25 - 30 uV; $p = 0.002$, <0.0001 respectively) and were maintained through P300. There is a strong correlation between rod isolated function and rod morphology. Rho1-2 treated Tg P23H rods are more numerous, have elongated outer segments, and correctly localized rhodopsin in contrast to untreated areas in the same retina or in untreated Tg retinas. The ONL measured in OCT and retinal sections was significantly thicker in the treated vs. untreated areas/retinas ($p < 0.001$).

Conclusions: Our results show that Rho1-2 meganuclease effectively rejuvenates rod structure and function in this TgP23H pig model of adRP and this gene therapy is well tolerated. This strongly indicates that Rho1-2 has the potential to effectively treat rod degeneration in P23H adRP patients

ABSTRACT BODY:

Purpose: Open globe injury (OGI) is one of the leading causes of mono-ocular blindness in the world. The pregnant population is vulnerable to traumatic injuries especially to domestic violence and is far understudied in the literature in regard to the epidemiology of traumatic ocular injuries. In this study, we analyzed the differences in demographics and outcomes of OGIs in pregnant women and non-pregnant women.

Methods: The National Inpatient Sample was queried for diagnoses of OGIs from the years 2002 to 2014. The age was restricted inclusively between 15 to 45 and for the female gender. The status of pregnancy was recorded using built-in variables and ICD-9 codes. Descriptive statistical analysis using SPSS 25 was conducted with weighted data by the status of pregnancy. Demographics and outcomes were analyzed for both pregnant and non-pregnant groups.

Results: Pregnant women with OGI were younger in age compared to non-pregnant women (26.22 vs 29.93, $p<0.001$, Table 1), more likely to be Hispanic (29.0% vs 12.4%), more likely to be insured (87.4% vs 66.1%), and also more likely to use drugs (13.7% vs 6.3%, $p<0.001$). Pregnant women were less likely to have a “rupture” type of OGI (3.3% vs 14.6%, $p<0.001$, Table 2), but more likely to have a “penetrating without intraocular foreign body” type of OGI (78% vs 69.3%, $p=0.024$). Pregnant women were less likely to have a concurrent orbital floor fracture (0.0% vs 12.4%, $p<0.001$). Both groups underwent similar rates of surgical repair, but pregnant women were less likely to undergo an enucleation (0.0% vs 6.0%, $p=0.002$). Pregnant women had a higher mortality during the admission (3.3% vs 0.8%, $p=0.001$), but had shorter average duration of hospital stay (2.40 vs 4.31, $p<0.001$).

Conclusions: Pregnant women with OGIs have significantly different demographics compared to non-pregnant women with OGIs; they are more likely to be younger, be of Hispanic ethnicity and have a history of drug use. They were less likely to have a concurrent orbital floor fracture or undergo enucleation which may either suggest less severe injury or modified surgical management criteria to avoid general anesthesia related complications to the fetus. Further studies are needed to evaluate the circumstances of OGIs in pregnant women.

ABSTRACT BODY:

Purpose: Reduced autophagy function of retinal pigment epithelial (RPE) cells is suggested as one of the key factors in the pathogenesis of degenerative chorioretinal disorders, such as age-related macular degeneration. The purpose of this study is to investigate the energy metabolism of ex vivo RPE under the inhibitory condition of autophagy, and its correlation with its fluorescence lifetime (FLT) using fluorescence lifetime imaging ophthalmoscopy (FLIO).

Methods: Porcine ex-vivo RPE/choroid-explants were exposed to the autophagy inhibitor Bafilomycin A1 (1×10^{-8} M) for 24 h. The viability of the RPE cells was examined with a calcein test. The inhibitory effect of Bafilomycin A1 on autophagy was verified by measuring intracellular autophagosomes. To understand the influence of the autophagy inhibition on the energy metabolism of the RPE, the oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) were measured by a Seahorse-XF-Analyzer after 24 h of Bafilomycin A1 incubation. The FLT of the RPE was examined by FLIO (excitation: 473 nm, detection in the short spectral channel (SSC): 498-560 nm and in the long spectral channel (LSC): 560-700 nm). In order to enable the FLIO on the tissues placed in a culture plate with culture medium, the horizontal stage and a 45-degree-angled mirror were built in front of the FLIO camera.

Results: Incubation of the explants with 1×10^{-8} M Bafilomycin A1 for 24 h did not cause increased cell death compared with the non-treated control group, whereas Bafilomycin A1 was proven to inhibit autophagy. The OCR of the treated tissue was significantly reduced (e.g., basal respiration from $220 \text{ pmol/min} \pm 43 \text{ pmol/min}$ to $147 \text{ pmol/min} \pm 62 \text{ pmol/min}$, $p < 0.05$). The ECAR, an indicator of the glycolytic activity was not significantly altered. In FLIO, Bafilomycin A1 significantly extended the FLT (mean FLT: τ_m) of the RPE by about 350 ps in both detection channels.

Conclusions: The results of the metabolic analysis clearly showed that the autophagy inhibition may induce mitochondrial dysfunction in RPE cells. In this study, it was experimentally demonstrated that FLIO may indicate alteration of mitochondrial function in RPE cells and could be utilized to assess it in clinical practice.

ABSTRACT BODY:

Purpose: Psychophysical and electrophysiological measurements have provided evidence for photoreceptor dysfunction in patients with diabetic retinopathy (DR). The purpose of this study is to conduct quantitative optical coherence tomography (OCT) analysis of outer retina, and thus to verify the feasibility of noninvasive OCT detection of photoreceptor abnormality in early DR.

Methods: OCT images were acquired from normal eyes, diabetic eyes with no diabetic retinopathy (no DR) and with mild DR. Nine quantitative features, including inner and outer retinal thicknesses, photoreceptor inner and outer segment bandwidths, reflectance intensities of the external limiting membrane (ELM), inner segment ellipsoid (ISe), and retinal pigment epithelium (RPE) were measured and intensity ratios of ELM/ISe and RPE/ISe were determined. Comparative parafoveal and perifoveal features (Figure 1a) were analyzed within retinal quadrants, i.e., superior, inferior, temporal, and nasal regions (Figure 1b). The quantitative features were determined using the averaged A-line reflectance intensities (Figure 1c).

Results: Outer retinal thickness was observed to have significant differences ($p < 0.05$) among the normal controls, no DR, and mild DR groups within the superior and inferior quadrants. Reflectance abnormalities of the ELM and ISe ($p < 0.05$) were observed within the temporal and nasal quadrants. Similarly, reflectance abnormality of the RPE was observed in the parafovea region of the nasal quadrant ($p < 0.05$). Comparative analysis consistently revealed decreased reflectance intensity of the ISe compared to that of the RPE, and the relative intensity ratio ISe/RPE discloses significant differences among the cohorts ($p < 0.001$) in the parafoveal region of all quadrants.

Conclusions: Quantitative OCT analysis consistently revealed outer retina changes in diabetic patients with no DR and with mild DR. The abnormalities of outer retinal thickness and OCT reflectance are retinal region/quadrant dependent. The normalized ISe/RPE measurement reveals retinal abnormalities in all quadrants, promising a sensitive biomarker for OCT detection of early DR.

ABSTRACT BODY:

Purpose: We aimed to 1) create anatomically plausible individual eye models for cohorts of emmetropic and myopic eyes that define wavefront error (WFE) across the visual field and 2) apply neural anatomical weighting functions to those WFE to model visual performance.

Methods: Discretely measured WFE of 24 emmetropic (spherical equivalent (SE) +0.5 to -0.5D) and 18 myopic eyes (SE -1.5 to -3.5D) obtained from 4 laboratories (ranging ± 21 to $\pm 40^\circ$ horizontally and ± 16 to $\pm 25^\circ$ vertically around fixation) were used to optimize anatomical eye models in Zemax. Models comprised biconic anterior and posterior corneal surfaces, gradient refractive index lenses with aspheric surfaces, and aspheric retinas. All 27 anatomical parameters (including thicknesses, tilts, and translations) were constrained within typical norms from literature. Visual field angles were converted to mm of (aspheric) retina per eye.

Results: Of the 8 emmetropic and 3 myopic eyes completed to date (optimizing 27 parameters takes multiple days per eye), models accurately reproduced 2nd, 3rd, and 4th order input aberrations: mean \pm SD total RMS difference $0.237 \pm 0.166\mu\text{m}$ (4mm pupil). Foveal chromatic aberration of each model matched published population data to within 0.1D.

Mean field positions of best RMS WFE and Strehl ratio in emmetropic models were: RMS 1.4° and 0.3° ; Strehl 2.0° and 0.6° , in inferior and nasal fields respectively, which agreed closely with input data. Optical quality generally worsened monotonically with eccentricity in all directions from those peaks. Peripheral optical quality in myopic eyes depended on the form of modeled refractive corrections.

Degrees-to-mm factors were non-linear with eccentricity in each eye and varied with retinal curvature, asphericity, and nodal point position across eyes.

Relative cone- and mid-ganglion cell-weighted metrics mimicked experimental literature on detection and resolution as functions of eccentricity respectively.

Conclusions: Optical and visual (neurally-limited) image qualities across the retina are valuable in understanding onset and progression of ametropias as well as guiding development of wide-field head-mounted displays, ophthalmic corrections, and retinal imaging technologies. These models are more anatomically accurate than previous, they effectively return measured input WFE, allow continuous interpolation of WFE as a function of eccentricity, and represent mean samples and variability of typical eyes.

ABSTRACT BODY:

Purpose: People with advanced age-related macular degeneration (AMD) rely on their peripheral vision for many daily tasks where foveal vision is normally used. Sometimes magnification is used, but that comes at the cost of reduced visual field. Peripheral optical errors differ from central errors and can depend on factors such as the presence of an intraocular lens. In the current study, we evaluated the peripheral vision with naturally occurring average errors and a condition of larger errors on a group of AMD subjects as well as a control group.

Methods: High contrast grating resolution acuity and contrast sensitivity were evaluated in 11 control subjects with no ocular disorders and 9 AMD subjects. All measurements were performed monocularly at 20° nasal visual field. We tested 2 different optical conditions with an adaptive optics vision simulator designed for peripheral vision evaluations: 1) Simulated average phakic optical errors in 20° nasal visual field (-0.60 D spherical equivalent, -1.00 D cylinder with axis 90° and 0.09 µm horizontal coma for a 4 mm pupil); 2) larger errors in 20° nasal visual field (-1.20 D spherical equivalent, -2.90 D cylinder with axis 90° and 0.09 µm horizontal coma for a 4 mm pupil). The individual errors of the subjects were corrected. Contrast sensitivity (CS) was evaluated at 1 cycle/degree in the control subjects. For AMD subjects, only 6 subjects were able to perform the CS measurements and the CS was evaluated at a spatial frequency logarithmically midway between 1 cycle/degree and the resolution acuity cut-off.

Results: Reduced peripheral optical errors improved high contrast resolution significantly for both groups. The mean improvement was 0.08 and 0.16 logMAR in control and AMD, respectively. The CS was also significantly improved, with gains in control and AMD subjects of 0.29 and 0.39 logCS.

Conclusions: The average phakic peripheral optical error condition provides significantly better peripheral vision, with larger improvements in patients with AMD than in healthy eyes. Therefore, patients with AMD are likely to benefit more than healthy by controlling the peripheral optical errors, it may for example reduce the need of magnification.

ABSTRACT BODY:

Purpose: Ocular emergencies related to contusions of the eye & orbit often require immediate attention in the emergency department (ED). This study characterizes the circumstances and age distribution of patients with ocular contusions, highlighting common causes that may be prevented with proper eye protection.

Methods: A multi-year analysis of the CDC National Hospital Ambulatory Medical Care Survey (NHAMCS) database from 2011-2017 was conducted. We assessed the burden of contusions of the eye and orbit (ICD-9 921, ICD-10 S05) in the ED setting. Differences in variables across age groups were evaluated using logistic regression, controlling for potential confounders. All analyses were conducted using STATA 16 statistical software.

Results: We analyzed 166,395 emergency visits from 2011 to 2017. There were 297 contusions of the eye and orbit, representing 2,019,365 ocular contusions that had presented to EDs nationwide. Of these, roughly 17.8% were of unknown or not documented cause. The most common documented causes were striking against or accidentally struck by objects or persons (30.2% of injuries), assault (14.1%), falls on steps, level ground, or at sporting events (8.57%), firearm/labor/construction-related injuries (6.24%), and motor vehicle related injuries (5.13%). Injuries secondary to activities that warrant eye protection (firearm/labor/construction) made up a larger proportion of all injuries for adults aged 55-64 (27.7%) and children aged 5-11 (21.5%). Individuals aged 5-11 and 25-34 were 2.7 times ($p = 0.005$; 95% CI: 1.36 – 5.41) and 2.6 times ($p = 0.001$; 95% CI: 1.46-4.68), respectively, more likely to visit the ED with a contusion of eyeball and orbital tissues compared to adults who were 65 years and older (Figure 1). Comorbidities, including substance use, were not associated with injuries.

Conclusions: Contusions of the eye and orbit that present to the ED have a wide range of causes. Activities known to warrant eye protection were the 4th most common cause of ocular contusion. Older adults and children were most at risk for preventable injuries, possibly due to decreased visuospatial awareness, disregarding eye protection due to familiarity with occupational equipment, or being too young to acknowledge the importance of eye safety. Individuals of all ages could benefit from education on the importance of eye protection.

ABSTRACT BODY:

Purpose: Fundus photography at primary care or internal medicine clinics can be utilized as a way to monitor patients for diabetic retinopathy (DR) without increasing the burden of care on the patient. Telemedicine screening should be accurate in diagnosing severity of DR to ensure only patients with appropriate disease severity get referred for treatment. We performed a retrospective chart review assessing the concordance between screening results and final diagnosis made at a follow-up ophthalmic appointment in patients who screened positive for DR.

Methods: 1902 adult patients were screened at general medicine clinics through Temple University Hospital (TUH) and Temple Physicians, Inc. (TPI) from March 2018 to March 2020. Technicians were trained to take 2-field non-dilated fundus photos at these clinics and screening photos were interpreted remotely by an optometrist using the ICDR classification system. Individuals with more than mild DR, other eye diseases, or ungradable images because of poor image quality were scheduled for a follow-up appointment with a TUH ophthalmologist for a dilated fundus exam. Screening results were compared to follow-up diagnosis using chi square analysis.

Results: 133 patients yielded a follow-up appointment and 85 patients had ungradable photos. For the 48 remaining patients, the correlation between screening results and final diagnosis showed mixed results (Table 1). Excluding unspecified DR, there was no correlation of the severity being the same or different upon follow-up ($\chi^2=8.95$, 0.34). 17 (35%) screening results had the same diagnosis upon follow-up, 17 (35%) had a decrease in severity, 3 (6%) had an increase in severity to PDR, and 11 (23%) were unspecified severity (Figure 1). The majority of differing severities decreased upon follow-up ($\chi^2=7.78$, 0.10).

Conclusions: Screening yielded identical or higher retinopathy severity scores compared to follow-up diagnosis. Overscoring screening photos can add referral visits and increase the anxiety of the patient, but does provide security that false-negatives are minimized. The level of disagreement and the presence of unspecified DR during screening indicates quality control issues that will need to be addressed.

ABSTRACT BODY:

Purpose: Dry eye disease (DED) is a condition that currently affects over nine million people in the United States. This condition results in symptoms such as eye irritation, eye dryness, and pain in the eye. The pathogenesis of DED involves the production of proinflammatory cytokines (TNF α and IL-6) and one of the effective treatments is the use of anti-inflammatory agents. Probiotic bacteria are well known inhibitors of inflammation. The purpose of this study is to identify which Toll-like receptors (TLRs) contribute to the inflammatory response in human corneal epithelial cells (HCECs) and to determine whether the metabolites produced by *Lactobacillus fermentum* can suppress the activation of TLRs on HCECs to reduce inflammation.

Methods: SV40-immortalized HCECs were cultured in DMEM/F12 medium. HCECs were pretreated with a probiotic bacteria-derived metabolite (JE) produced by *Lactobacillus fermentum* and subsequently exposed to TLR4 agonist (LPS) or TLR5 agonists (flagellin from *Pseudomonas aeruginosa*). The inflammatory cytokine IL-6 within the culture supernatants was evaluated by ELISA.

Results: HCECs did not produce any IL-6 in response to LPS. In contrast, HCECs produced large amounts of IL-6 in response to TLR5 agonist flagellin from *Pseudomonas aeruginosa*. This data indicates that HCECs responded to TLRs differently. Probiotic bacteria-derived metabolite (JE) produced by *Lactobacillus fermentum* suppressed the TLR5 agonist-induced IL-6 production.

Conclusions: HCECs only responded to flagellin from *Pseudomonas aeruginosa* but not to LPS, indicating HCECs does not respond to all TLRs. The data suggests this is a possible innate mechanism to prevent ocular inflammation. The probiotic bacteria metabolite (JE) produced by *Lactobacillus fermentum* can suppress production of the inflammatory cytokine (IL-6) by HCECs. This data suggests that JE has a potential to be used as an anti-ocular inflammatory agent.

Expanding the view: large-scale assessment of synaptic disassembly in experimental glaucoma

SESSION TITLE: Retinal ganglion cells and central visual areas in disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Soliño, A.K. Yu, L. Della Santina, Y. Ou, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Manuel Soliño: Commercial Relationship: Code N (No Commercial Relationship) | Alfred Yu: Commercial Relationship: Code N (No Commercial Relationship) | Luca Della Santina: Commercial Relationship: Code N (No Commercial Relationship) | Yvonne Ou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

As synapse loss is an early biomarker in experimental glaucoma, we studied the temporal dynamics of synapse disassembly in the entire inner plexiform layer (IPL) at varying time points after transient ocular hypertension.

Methods: Unilateral intraocular pressure elevation was induced in adult CD-1 mice by laser photocoagulation of the limbal and episcleral vessels, and then sacrificed at 7d, 14d, and 30d. Retinas were processed as wholemounts and stained by immunohistochemistry against Brn3a (ganglion cell marker), CtBP2 (ribbon marker), PSD95 (postsynaptic marker), and TO-PRO-3 (nuclear marker). Four confocal image stacks of the entire IPL depth of each retina were obtained. We quantified pre and postsynaptic puncta and their spatial relationships. Statistical analysis was performed using mixed effects analysis.

Results:

We found that ribbon density drops at 30d (Mixed-effects analysis, $p=0.001$). PSD95 density also drops, significantly at 14d and 30d (Mixed-effects analysis, $p=0.024$ and $p=0.018$, respectively). When assessing synaptic puncta density as a function of IPL depth, we found that ribbon density progressively drops at 14d and 30d at most IPL depths but density is preserved or recovers in the ON sublamina (Mixed-effects analysis, $p<0.0001$ for IPL depth and time as fixed effects). Conversely, when assessed as a function of IPL depth, postsynaptic proteins appear more resilient to transient ocular hypertension. The maximum decrease of PSD95 density occurs at 14d and partially recovers by 30d (Mixed-effects analysis, $p<0.0001$). Again, the ON sublamina shows less damage than the OFF sublamina (Mixed-effects analysis, $p<0.0001$).

Conclusions:

Although the initial site of injury in glaucomatous neurodegeneration is thought to be axonal compression at the optic nerve head, we show that bipolar cell ribbons are lost earlier and to a greater degree than their postsynaptic counterpart PSD95. This raises the possibility that bipolar cells are an active participant in the degeneration process. We also show that this process of synapse disassembly is non-uniform across IPL sublaminae, potentially resulting in differential impairment of distinct functional sub-circuits.

ABSTRACT BODY:

Purpose: Elevation of total VEGFA165 and switching of VEGFA165b isoform expression to the VEGFA165a isoform have been reported in the aqueous and vitreous humors of eyes with diabetic retinopathy and ROP. VEGFA165a elevates the gene expression and protein concentration of Plasmalemma Vesicle-Associated Protein (PLVAP), a protein involved in transcytosis across the endothelial barrier. PLVAP regulation in primary Human Retinal Microvascular Endothelial Cells (HRMECs) is poorly understood. We hypothesize that both VEGFA165 isoforms increase permeability and PLVAP gene and protein expression in primary HRMECs, and AKT and p38-MAPK intracellular signaling pathways are involved in PLVAP gene expression in primary HRMECs.

Methods: Primary HRMECs (26 year old male) were cultured using EndoGRO-LS Complete Culture Media, in 6-well format for total RNA extraction. T-25 flasks were used for PLVAP immunoblotting. 24-well 0.4 μ M pore polyester transwell inserts with 70 kDa RITC dextran were used for transcellular permeability assays. Pharmacological inhibition of signaling pathways used MK2206 (AKT) and BIRB796 (p38-MAPK) inhibitors.

Results: VEGFA165a and VEGFA165b (5000 pM, saturating) increased PLVAP gene expression over 19-fold and 13-fold, respectively. VEGFA165a and VEGFA165b (5000 pM) increased PLVAP protein expression over 14-fold and 5-fold, respectively. AKT pathway inhibition (0.02 μ M MK2206) suppressed VEGFA165a or VEGFA165b -mediated increase of PLVAP gene expression by 51% and 54%, respectively. P38-MAPK pathway inhibition (0.01 μ M BIRB796) suppressed VEGFA165a or VEGFA165b -mediated increase of PLVAP gene expression by 63% and 58%, respectively. Double inhibition of the AKT and p38-MAPK pathways further suppressed VEGFA165a or VEGFA165b -mediated increase of PLVAP gene expression by 73% and 70%, respectively. VEGFA165a and VEGFA165b (5000 pM) increased transcellular permeability by 22% and 40%, respectively.

Conclusions: VEGFA165a was a stronger activator of PLVAP gene and protein expression relative to VEGFA165b. Differences between the effects of VEGFA165a and VEGFA165b on PLVAP gene and protein expression suggest that the reported isoform switching in retinal vascular diseases could contribute to disease mechanisms. Most of the VEGFA165-mediated increase to PLVAP gene expression involves the p38-MAPK and AKT pathways.

ABSTRACT BODY:

Purpose: This investigation examines the effectiveness of smartphone-based, nonmydriatic fundus photography in detecting glaucoma in patients in a low-resource setting and explores the potential for this technology to serve as a means of primary screening for risk of glaucoma.

Methods: Subjects between the ages of 40 and 70 years old were recruited to undergo nonmydriatic fundus photography during a visual health campaign at the Salvadoran Association for the Promotion of Rural Health (ASAPROSAR) clinic in Santa Ana, El Salvador in January 2020. Color fundus photographs were obtained with a PanOptic iExaminer attached to an iPhone 6S operated by a trained non-specialist. Stereoscopic image pairs were assembled from two “best view” images for each eye. These were graded by a team of ophthalmologists and optometrists experienced in teleophthalmology who were blinded to the clinical diagnosis of each patient.

Results: A total of 273 participants were screened. Gradable images were obtained from 509 eyes (93.2%) in 268 participants (98.1%). A total of 5,744 images were collected, averaging 10.5 ± 5.2 images per eye. The cup-to-disc ratio (CDR) judged from the stereoscopic images showed moderate reliability and good agreement with the CDR reported by the treating ophthalmologists (ICC 0.59; $r = 0.792$, $p < 0.001$). Overall agreement was fair for glaucoma risk determined by remote grading of stereoscopic image pairs compared with the glaucoma-related diagnoses by ophthalmologists who examined the participants ($\kappa = 0.32 \pm 0.09$). Accuracy of screening for risk of glaucoma using only features of the optic disc observable in stereoscopic images was low (66.8%), with a positive predictive value of 45.1% and negative predictive value of 87.7%, compared with the results from clinical examination.

Conclusions: Remote evaluation by experts of CDR from optic disc photographs obtained by using a low-cost, handheld non-mydratic fundus camera operated by a non-specialist showed good agreement with CDR assessment from in-person clinical examinations. As expected from previous studies, the performance of CDR alone in detecting glaucoma was only fair. Nevertheless, the capacity to obtain high-quality fundus photographs and generate stereoscopic image pairs for remote evaluation by expert graders could permit development of an affordable, high-volume, glaucoma screening strategy in resource-constrained areas of the world.

ABSTRACT BODY:

Purpose: The Realwear HMT-1™ is a head mounted tablet device with a camera and a micro-display in use primarily for industry applications. The device may be useful for people with low vision with modification of some its features. The purpose of this study was to modify the HMT-1 to provide better low vision functionality, pilot test the modified device for reading with low vision, and test the usefulness of addition of real time kinematic (RTK) device data on improving indoor location accuracy for future navigation uses.

Methods: The HMT-1 consists of a video display mounted to an adjustable arm and a camera with magnification and image enhancing capability. A custom Android application (Industrial Badger App™) was used to increase magnification capability and allow for text-to-speech conversion of printed reading material. Visual acuity and contrast sensitivity were measured with habitual correction and with the HMT-1. A previously validated passage reading test (300 words per passage with 3 comprehension questions per passage) was used to assess speed and comprehension using: habitual aids, HMT-1 with magnification, and text-to-speech. Device location accuracy was tested at 8 indoor locations for the stock HMT-1 location provider and with the addition of RTK data, and GeoJSON centroids were calculated to compare location error between conditions.

Results: Three participants with low vision were recruited for pilot reading testing. Mean±SD age was 64±5 and 66% were male. Mean better-eye baseline ETDRS letter VA was 45±12 (approximately 20/120) and improved to 78±11 (approximately 20/25, (p<0.001). Mean passage reading time with habitual aid was 183 seconds vs. 457 seconds with HMT-1 camera (one subject was unable to use the camera due to poor VA). Comprehension performance was worse with HMT-1 camera compared to both habitual aid and HMT text to speech. All subjects reported the device to be useful and 2/3 of subjects reported they would use HMT-1 in real life. The addition of RTK data resulted in reduction of the average error of the cluster centroid from 60m to 38.4m and generally faster responses.

Conclusions: A modified version of the HMT-1 showed promise as an aid for near tasks in people with low vision, especially with reading and indoor navigation. Future work will seek to improve reading speed and location accuracy for navigation.

ABSTRACT BODY:

Purpose: To quantify longitudinal changes in microaneurysm (MA) count on ultra-widefield fluorescein angiography (UWFA) and their correlation with panretinal leakage index (PLI) in eyes with diabetic retinopathy (DR) being treated with as needed intravitreal aflibercept (IAI) guided by real-time DR severity score (DRSS) and PLI evaluations.

Methods: The PRIME study is a randomized prospective clinical trial comparing real-time DRSS-guided IAI treatment to real-time PLI-guided IAI treatment. 41 eyes with DRSS of 47 to 71 were randomized 1:1 to receive as needed IAI as determined by DRSS (DRSS cohort, n=21) or PLI (PLI cohort, n=20). UWFA and fundus photos were obtained monthly. UWFA images were analyzed in real-time with an automated analysis platform to quantify MA count and PLI with manual validation. Two trained readers evaluated the baseline UWFA images and classified them as having predominantly perivascular leakage or non-perivascular (including focal) leakage.

Results: Mean MA counts and PLI indices did not differ significantly at baseline between the DRSS cohort and the PLI cohort, with 839 ± 307 and 884 ± 331 MAs ($P=0.66$), respectively. At year 1, the MA count improved significantly to 662 ± 334 ($P=0.03$) in the DRSS cohort and 744 ± 526 ($P=0.05$) in the PLI cohort. Total mean MA and PLIs were positively correlated at both month six ($r=0.35$, $P=0.03$) and year one ($r=0.46$, $P=0.007$).

Eyes with predominant perivascular leakage (n=19) demonstrated a larger but non-significant reduction in mean MA

count (-210) compared to eyes with predominant non-perivascular leakage (n=14, -109, P=0.28).

Conclusions: Both DRSS and PLI cohorts demonstrated a significant decrease in MA count after one year of image-guided IAI treatment. Total mean MA count and total mean PLIs were correlated at month six and year one. Eyes with predominant perivascular leakage at baseline had a nonsignificant greater reduction in MA count. Further research in larger datasets is needed to further explore the potential association of MA reduction with underlying leakage patterns and whether this may be indicative of specific active pathways.

ABSTRACT BODY:

Purpose: Prior literature has reported that approximately 93% of eyes undergoing cataract surgery achieve a postoperative spherical equivalent (SE) within 1 Diopter (D) of that predicted by preoperative biometry (Lundstrom et al, 2018). While prior studies have assessed vision outcomes and postoperative complications following cataract surgery in patients with uveitis, less is known about refractive outcomes in this population. Our study assessed the refractive outcomes following uveitic cataract surgery and factors associated with deviations from the target refractive goal.

Methods: A multi-center retrospective chart review of patients with a history of uveitis undergoing cataract extraction was performed between June 2015 and June 2020. Subject demographics, ocular history, pre and postoperative examination findings, and biometry measurements were obtained. The difference between the refractive target and postoperative refractive SE was determined. We tested for association between a postoperative deviation from target greater than 1 D and several factors including age at the time of surgery, location of uveitis, presence of preoperative keratic precipitates or posterior synechiae, history of cystoid macular edema, preoperative logMAR acuity, and persistent inflammation one month postoperatively using t-tests or chi-square tests.

Results: We examined two hundred eighty-three eyes from 216 subjects. 40.6% of subjects had a refractive outcome which deviated more than 0.5 D from the refractive goal, and 13.4% of subjects deviated more than 1 D from the refractive target. The mean difference from refractive goal was 0.57 ± 0.68 D (range 0 – 4.54 D). The mean preoperative logMAR acuity for eyes >1 D from refractive goal was 0.21 greater than eyes < 1 D ($p=0.008$). Average age at time of cataract surgery was less for eyes >1 D from their refractive target (51.6 vs 59.0 years, $p=0.014$). The presence of preoperative keratic precipitates was also associated with a refractive outcome >1 D from the planned target ($p<0.001$).

Conclusions: A notable portion of eyes undergoing uveitic cataract surgery deviated from the planned refractive target by at least 1 D. Poorer preoperative acuity, younger age at the time of surgery and preoperative keratic precipitates were associated with this outcome.

ABSTRACT BODY:

Purpose: The extrapolated retinal pigment epithelium (eRPE)/Bruch's membrane (BM) complex undergoes alterations with aging and in disease. Despite the importance of the eRPE/BM complex, few quantitative studies have reported its in vivo morphology and how it changes with disease. We have developed an automated method to measure morphological features of the eRPE/BM complex using a commercially available swept source OCTA (SS-OCTA) system and studied the correlations between the BM and choriocapillaris (CC) flow deficits (FD) in eyes with Sorsby Macular Dystrophy (SMD).

Methods: 6×6 mm macular scans were acquired using SS-OCTA imaging (PLEX® Elite, Carl Zeiss Meditec Inc.) from a patient with SMD and age-matched normal subjects. Structural OCT cubes were converted into linear scales to obtain higher contrast at the RPE layer. The locations of the RPE and CC in each subfield were determined by OCT/OCTA A-scan intensity profiles, which were used for enface mapping of the eRPE-to-CC distances, that is equivalent to the BM thickness (Fig 1). RPE structure images were obtained by sum projection of selected OCT slab. CC enface images were generated from a 20-μm OCTA slab beneath BM and CC FDs were calculated using a previously validated thresholding method.

Results: A patient with Sorsby Macular Dystrophy and age-matched normal subjects were recruited. The locations of reticular pseudodrusen (RPD) were observed on a 20-μm thick enface structure slab positioned 20-μm above the RPE. The regional changes in the BM thickness were visualized on the enface eRPE-to-CC distance maps. We correlated an increase in the eRPE-to-CC distance and a decrease of CC flow in the regions with RPD in eyes with SMD (Fig 2).

Conclusions: Co-localization of RPD, thickened BM, and CC flow impairment were observed in eyes with Sorsby Macular Dystrophy. The proposed morphology metric should be useful to reveal more details of eRPE/BM complex, providing an opportunity to investigate potential functional relationships between the RPE, BM and CC, and their involvement in ocular diseases.

ABSTRACT BODY:

Purpose: Vision under starlight requires rod photoreceptors to transduce and transmit single photon responses to the visual system. This remarkable sensitivity depends on a small voltage change reliably reducing the rate of glutamate release such that it can be robustly detected by post-synaptic rod bipolar cells. Our goal was to identify how small voltage changes at the rod terminal alter the statistics of vesicle release and how these changes support the transmission of single-photon responses.

Methods: We characterized voltage-dependent properties of glutamate release in mouse rods by recording presynaptic glutamate transporter anion currents ($I_{A(glu)}$) in ex vivo retinas.

Results: Spontaneous vesicle release events at -70 mV were univesicular and occurred at random intervals (i.e., Poisson). However, when rods were voltage-clamped at their normal membrane potential in darkness of -40 mV, release occurred in coordinated multiquantal release events of ~17 vesicles. The rate of these multiquantal events was ~2 Hz and the interevent intervals were 2-to-3-fold more regular than predicted by Poisson statistics. These multiquantal events involved vesicles in the readily releasable pool and were triggered by opening of nearby, ribbon-associated Ca^{2+} channels. Applying a voltage waveform to mimic single photon voltage responses reduced the likelihood of multivesicular bursts nearly to zero with a rebound increase in release at stimulus offset. Simulations of release dynamics indicate that this regularly timed form of multivesicular release promotes the transmission of single photon responses to post-synaptic rod bipolar cells.

Conclusions: Regularly timed multivesicular release from rods provides an efficient means of encoding single photon responses, requiring fewer total vesicles to be released per-second than vesicle release governed by Poisson statistics.

ABSTRACT BODY:

Purpose: Pericytes are crucial for microvascular dynamics regulation and blood flow. Capillary constriction has been linked to calcium (Ca^{2+}) increase in pericytes; however, the mechanism of Ca^{2+} influx and its role on vascular deficits is currently unknown. The S100 calcium-binding protein B (S100 β), an important regulator of Ca^{2+} dynamics, is produced by astrocytes. Here, we asked: i) does retinal glia-derived S100 β contribute to Ca^{2+} increase in pericytes, and ii) does S100 β regulate pericyte-mediated capillary dysfunction after injury?

Methods: Two-photon laser scanning microscopy (TPLSM) was used to visualize pericytes in living mice expressing red fluorescence or the Ca^{2+} indicator GCaMP6 in pericytes (NG2-DsRed, NG2-GCaMP6). Capillary blood flow was quantified by TPLSM as red blood cells crossing a pre-fixed location per unit time. Ocular hypertension was induced by magnetic microbeads occlusion, and transient ischemia by ligation of the central retinal artery. S100 β expression was examined by immunostaining, western blots, and qPCR, and its function was modulated by intraocular injection of recombinant S100 β (gain-of-function) or a function-blocking antibody (FBA) (loss-of-function)

Results: S100 β levels increased in astrocytes and Müller glia in glaucomatous and ischemic retinas, which correlated with reduced capillary diameter and blood flow at pericyte locations, along with intrapericyte Ca^{2+} increase (12.6 ± 2 a.u.) relative to controls (5.3 ± 2 a.u.) (T-test, $p < 0.001$, $n = 6$ mice/group). Intraocular administration of recombinant S100 β further increased Ca^{2+} influx to pericytes and exacerbated blood flow impairment (T-test, $p < 0.001$, $n = 6$ mice/group). In contrast, selective inhibition of S100 β with a FBA decreased intrapericyte Ca^{2+} , reduced the number of capillary constrictions at pericyte locations, restored capillary diameter (FBA: $4.9 \pm 0.2 \mu\text{m}$, control: $5.17 \pm 0.2 \mu\text{m}$), and improved single-capillary blood flow (FBA: 0 red blood cell (RBC)/sec, control: 16 RBC/sec) (T-test, $p < 0.001$, $n = 6$ mice/group)

Conclusions: Our data support that: i) intrapericyte Ca^{2+} plays a critical role in the regulation of capillary diameter and blood flow in glaucomatous and ischemic optic neuropathies, and ii) retinal glia-derived S100 β is an important regulator of Ca^{2+} influx into pericytes, thus exerting a crucial regulation on microvascular dynamics in physiological and pathological conditions

ABSTRACT BODY:

Purpose: There is increasing evidence that differential DNA methylation plays a significant role in ophthalmic diseases. We previously identified DNA methylation changes in the corneal endothelial tissue of patients with Fuchs endothelial corneal dystrophy (FECD), in particular the hypermethylation of genes related to FECD. 5-Aza-2-deoxycytidine (5-Aza-CdR) is a demethylating agent used to treat human cancers with aberrant DNA methylation. The purpose of this study is to better understand the cellular effects of 5-Aza-CdR on normal human corneal endothelial cells (CEnC).

Methods: Primary CEnC were cultured from a non-FECD cornea obtained from an eye bank and transformed CEnC (HCEnC-21T) were cultured as previously published. Cell cultures were treated with 0.3 mM 5-Aza-CdR or PBS control for 24 hours and assayed for cell viability using the Cell Counting Kit-8 (Dojindo). The Illumina Infinium HM450 BeadChip assay was used to perform global DNA methylation analysis of over 485,000 methylation sites. Statistical and array analyses were performed using R and p-values less than 0.05 were considered statistically significant.

Results: The global DNA methylation profiles of primary and immortalized (HCEnC-21T) normal human CEnC were compared using the Illumina Infinium HM450 BeadChip assay and similar global DNA methylation patterns were observed. HCEnC-21T cells were then treated with either 0.3 μ M 5-Aza-CdR or PBS (control) for 24 hours and cell viability, cell growth rate, and global DNA methylation status were measured. No significant difference in cell viability was found between 5-Aza-CdR and PBS-treated cells. At 10 days post-treatment, the cell doubling time peaked at 33 hours for 5-Aza-CdR-treated cells compared with 24 hours in PBS-treated cells. Global demethylation of methylated probes ($\beta > 0.6$) was not observed 5 days post-treatment (mean decrease in β value of 0.007), despite an effect on cell growth rate at this time-point. Baseline global DNA methylation levels displayed minimal change following 5-Aza-CdR treatment.

Conclusions: These findings show that 5-Aza-CdR does not induce significant cell toxicity or demethylation changes in normal human corneal endothelial cells. Further analyses of the demethylating effect of 5-Aza-CdR on CEnC from FECD patients with aberrant hypermethylation changes are needed to test its potential as an epigenetic therapy for FECD.

ABSTRACT BODY:

Purpose: Teleost fish have the special property of completely restoring their retina after an injury. More precisely, so-called Müller cells can reprogram their function and contribute to the reproduction of neurons similar to stem cells. It is not known how and how many neurons are produced. We develop a model that describes the development of the cell population following a loss of neurons in the retina. Our goal is to use current biological data to calibrate our model to be able to represent adult neurogenesis and a possible differentiation behavior.

Methods: Our model differs between Müller, progenitor and neuronal cells and we transfer the biological behavior of each cell type in a parameter dependent model resulting in a system of three ordinary differential equations. We take in account asymmetrical division, symmetrical differentiation and self-renewal. These processes are combined through parameters which are estimated with an in-house software. The fits were performed to a set of published measurements.

Results: We were able to show that the true parameter values are obtained by our fits with a 95% probability. This shows that our model depicts the regenerative process effectively. Analysis of the research data revealed that 5 cell divisions of progenitor cells are needed to make 279 neurons out of 9 Müller cells if we assume that 66% of the Müller cells re-entered the cell cycle after 36 hours.

Conclusions: With our model we were able to show a possible differentiation behavior of the progenitor cells which is still open and we gain a better understanding of the development of the cell populations involved in this process. This could lead to new regenerative treatments for the retina.

ABSTRACT BODY:

Purpose: The aim of this study was to examine age-related changes in the retina of mice carrying mutations in the microphthalmia-associated transcription factor (Mitf) and estimate the rate of retinal degeneration with age and how it affects function and structure in the retina.

Methods: Mitf^{mi-enu22(398)/Mitf^{mi-enu22(398)}} and Mitf^{mi-wh/Mitf^{mi}} mice were examined and compared to C57BL/6J mice as a control. Mice were examined at 1, 3, 6 and 12 months of age. Mice were anesthetized by an intraperitoneal injection of 40 mg/kg⁻¹ and 4 mg/kg⁻¹ Xylazine. Electroretinography (ERG) was used to determine retinal function, while fundus imaging and optical coherence tomography (OCT) were used for structural examination.

Results: ERG recordings revealed a slow degeneration in Mitf^{mi-enu22(398)/Mitf^{mi-enu22(398)}} mice compared to wild type. This applies to dark- and light adapted recordings at all ages. Results show no significant difference in ERG amplitude at one month of age between wild type and Mitf^{mi-enu22(398)/Mitf^{mi-enu22(398)}} mice but a difference in amplitude appeared at 6 months of age when Mitf^{mi-enu22(398)/Mitf^{mi-enu22(398)}} mice show higher amplitude in all cases. ERG responses could not be evoked in Mitf^{mi-wh/Mitf^{mi}} mice with no a- and b-waves in dark- and light-adapted recordings at all ages. Consistent with the ERG results, the retinal infrastructure of Mitf^{mi-enu22(398)/Mitf^{mi-enu22(398)}} mice showed all retinal layer's present in OCT images while Mitf^{mi-wh/Mitf^{mi}} images revealed severe degeneration.

Conclusions: These results suggest that Mitf^{mi-enu22(398)/Mitf^{mi-enu22(398)}} mice have normal retinal function while Mitf^{mi-wh/Mitf^{mi}} mice have severe degeneration and impaired retinal function when compared to the control. Changes in retinal structure appears with increasing age where some layers appear thicker in Mitf^{mi-enu22(398)/Mitf^{mi-enu22(398)}} but retinal degeneration increases in Mitf^{mi-wh/Mitf^{mi}} with age compared to the control, with some retinal layers absent.

ABSTRACT BODY:

Purpose: To test 3 methods of applying the mathematical model proposed by Jansonius et. al. [1] to optical coherence tomography (OCT) retinal nerve fiber layer bundle (RNFL) probability/deviation maps from eyes with glaucomatous damage.

Methods: Jansonius et al.'s mathematical model describes the trajectories of RNF bundles as a function of the origin (angular position) around the disc.[1] Individual variance in the degree of trajectory curvature for a given angular position around the disc is explained by the parameter beta in the model. A custom program was used to compute and superimpose the model's trajectories on RNFL probability and thickness maps for 18 eyes with well-defined arcuate damage as seen in the abnormal region of the RNFL probability map (Fig. 1).[2] For Method 1, trajectories were fitted to this region by manually varying beta and the associated region (AR) (red and blue vertical lines in Fig. 1) on the circle scan (Method 1, Fig.1A). For Method 2, a linear regression was performed to determine a relationship between beta and fovea-to-disc distance. Then, beta was automatically determined for each eye by the regression relationship, with AR manually adjusted for best fit. For Method 3, the average beta value [1] was used for all eyes, with AR manually adjusted for best fit. Trajectory fit was then examined across all eyes for average beta with AR set as the portion of the circle scan with thickness less than 5% of normal (Fig. 2).

Results: Using regression-based beta values (Method 2) did not out-perform using the average beta value (Method 3). While manually adjusting the beta (Method 1) gave the best agreement between the model and the data (as expected), the differences between its performance and Method 3 were relatively small (Fig. 1). Further, testing Method 3 by fixing the AR based upon the circumpapillary RNFL thickness (Fig. 2), produced reasonably good fits.

Conclusions: While manual determination of a separate beta for each eye performs best, implementing this method clinically is not practical. Fortunately, simply using the same beta value for all eyes did well enough for clinical use. Application of this model should improve both qualitative and quantitative evaluation of glaucomatous damage on OCT RNFL probability plots.[2] 1. Jansonius et al Exp Eye Res 2009, 2012; 2. Hood et al, JoG 2020.

ABSTRACT BODY:

Purpose: To visualize the image formation through the Boston Keratoprosthesis (B-KPro) and assess its optical properties.

Methods: We simulated the realistic natural-scene imaging condition by building an imaging cage system which subjected the B-KPro's posterior surface to an aqueous medium. Specifically, the B-KPro (back focal length: 17mm) was centrally clamped with a diaphragm and was mounted on a water-filled cuvette. Images formed by the B-KPro were then relayed to a camera with a pair of achromatic doublets (magnification: 1x). Targets including a standard eye chart and the natural scenes were imaged to assess the image quality and any presence of optical aberrations. Imaging of the 1951 USAF Resolution Test Target and a pinhole was also performed in air with a 10x telescope to evaluate the B-KPro's resolution efficiency and modulation transfer function (MTF).

Results: The 20/20 line of the eye chart could be adequately resolved. It remained in focus within a field angle of 3.8 degrees, which is well within the foveal area that confers 50-100% of the highest visual acuity. Images of the outdoor scene were similarly in focus in the central field but became defocused peripherally. However, the peripheral images could be refocused by adjusting the imaging distance of the B-KPro. This suggests the presence of spherical aberration that may be corrected by introducing an aspheric shape in B-KPro's optical surfaces. Finally, the spatial frequency resolution achieved by the B-KPro device was 146 line pairs per millimeter (lp/mm) in air at an MTF value of 0.2, which is higher than 25 lp/mm for a human eye with a 3mm aperture. Compared to the theoretical resolution of 290.7 lp/mm, the resolution efficiency was 66% which is sufficiently high according to the ISO11979-2 recommendation for intraocular lenses.

Conclusions: The B-KPro provides sufficient resolution power to achieve 20/20 vision over an angular field of view of 3.8 degrees, as elucidated by the natural-scene imaging and benchtop resolution characterization. Further improvement in the optical design may reduce the spherical aberration and expand the surgical margins for implantation decentration which may otherwise lead to vision degradation.

ABSTRACT BODY:

Purpose: Measuring the biomechanical properties of the cornea has become increasingly important to understand its health, detect disease, and evaluate therapies such as corneal collagen crosslinking (CXL). Here, we present a technique capable of mapping the stiffness of the cornea utilizing compression-based optical coherence micro-elastography of the cornea under various conditions, including before and after CXL in vivo.

Methods: A ring based piezoelectric transducer induced low amplitude ($< 5 \mu\text{m}$) displacements in the cornea, which were then converted to strain using a vector-based technique. Experiments were conducted in in situ rabbit corneas in the whole globe configuration ($N=3$) under various intraocular pressures (IOP) (10, 15, 20, 25, and 30 mmHg) and before and after CXL. The IOP was controlled with a closed-loop system, and CXL was performed using the traditional "Dresden" protocol. In these samples, stiffness was further quantified by dividing the difference in IOP between the loaded and unloaded states (ΔIOP) by the calculated strain. In vivo experiments were also conducted on an anesthetized rabbit before and after CXL to evaluate the feasibility of the technique for live imaging. Here, the only strain was quantified.

Results: In the in-situ samples, there was a significant difference in stiffness ($\Delta\text{IOP}/\text{Strain}$) as a function of IOP ($P = 0.037$), and the stiffness increased by ~86% after CXL ($P = 0.016$). The strain decreased by ~85% after CXL in the in vivo rabbit cornea, which was significant ($P < 0.001$).

Conclusions: Compression based optical coherence elastography of the cornea was able to detect the changes in corneal stiffness as a function of IOP and before and after CXL in an in situ as well in vivo rabbit cornea model. This technique may be useful for quantifying changes in corneal elasticity for disease detection or therapy monitoring.

ABSTRACT BODY:

Purpose: Antibiotic resistance, prevalence, surgical management, and the role of virulence factors are topics frequently debated in the literature about streptococcal endophthalmitis. We performed a retrospective consecutive case series to report the clinical settings, antibiotic susceptibilities, and outcomes of this condition.

Methods: Chart review of culture-positive streptococcal endophthalmitis from January 1, 2014 to December 31, 2019. Thirty-eight eyes met study criteria. Mann-Whitney U, Fisher's exact test, and the exact chi-square test were used for statistical analysis.

Results: The most common clinical setting was post-glaucoma surgery (33.3%, 12/36). The most frequent isolate was *S. viridans* (63.2%, 24/38). Isolates were susceptible to vancomycin (100%, 36/36), ceftriaxone (100%, 28/28), and levofloxacin (100%, 36/36). Final BCVA was better than 20/200 in 24.1% (7/29) but 20/200 or worse in 75.9% (22/29). Enucleation was performed in 11.1% (4/36). A subset (n=11) of cases were evaluated for streptococcal-specific virulence factors: pneumolysin was present in 18.2% (2/11), autolysin in 45.5% (5/11), and hyaluronidase in 54.5% (6/11). Clinical settings, antibacterial susceptibilities, timing of PPV, and virulence factor presence were not associated with better visual outcome or enucleation rate ($p>0.05$).

Conclusions: Visual prognosis for streptococcal endophthalmitis is poor despite early and appropriate antibiotic treatment.

ABSTRACT BODY:

Purpose: Assessment of corneal biomechanical properties is essential for detecting disease and monitoring corneal treatments. Optical coherence elastography (OCE) is a tool for measuring these mechanical properties, but assessment is typically performed by measuring the corneal response to some sort of external excitation. Here, we demonstrate how Heartbeat Optical Coherence Elastography (Hb-OCE) can be used to measure the cornea's mechanical response to the natural heartbeat-induced ocular pulse in the in vivo model.

Methods: An SD-OCT system in the common path configuration was used to measure the biomechanical properties of the cornea in two anesthetized rabbits. The first rabbit was kept as an untreated (UT) control, and the second had its cornea collagen crosslinked (CXL) using the standard Dresden protocol. OCT images were acquired at the apex of the applanated rabbit cornea while cardiac activity was measured concurrently. Corneal displacement over time was measured and translated to strain.

Results: Strain fluctuations in the UT cornea shown mirror the cardiac activity (~4Hz heart rate) of the rabbit. The untreated cornea had a mean strain amplitude over 12 cycles of 3.07 ± 0.48 mε, and the CXL cornea had a mean strain of 0.87 ± 0.19 mε. There was a statistically significant difference between the corneas in each group. ($p < 0.05$).

Conclusions: We demonstrate how Hb-OCE may be useful to measure the biomechanical properties of the cornea using heartbeat as a passive source of displacement. Furthermore, we show how this technique can distinguish the stiffness difference between UT and CXL corneas. Future work will be geared toward developing noncontact Hb-OCE with a quantitative model of stiffness.

ABSTRACT BODY:

Purpose: To analyze and describe the clinical and imaging characteristics of a series of patients with peripapillary choroidal neovascularization (PCN) in the context of age-related macular degeneration (AMD) and to investigate a possible relationship between PCN and the pachychoroid disease spectrum (PDS).

Methods: Case series of patients diagnosed with PCN in the Department of Ophthalmology of the Centre Hospitalier Intercommunal de Créteil between January 2000 and January 2018 were retrospectively included. Multimodal imaging, including OCTA (Plex Elite, Carl Zeiss Meditec, Inc., Dublin, CA) was obtained for all patients. Choroidal thickness (CT) was measured horizontally across the fovea and circumferentially around the temporal side of the disk to study its relationship to neovascularization. PCN morphology, area and vascular density were investigated in all cases.

Results: Thirty-five eyes of 26 patients with PCN were included in this study, of which 32 eyes (91.4%) had a focal or diffuse increase in CT, 35/35 eyes had pachyvessels (100%), 10 eyes of 35 (28.6%) had choroidal vascular hyperpermeability and 34 eyes of 35 (97.1%) showed vessel attenuation of the inner choroid. Twelve out of 35 (34.2%) developed peripapillary aneurismal type 1 neovascularization colocalizing with the PCN during follow up. OCTA revealed a densely packed high flow network in the ORCC slab in all cases. The mean PCN area averaged 3.56 mm² and the VD averaged 67.2%.

Conclusions: Analysis of choroidal structure, previously described in PDS, performed consistently when applied to our PCN series, thus supporting the hypothesis that PCN may be a distinct PDS variant.

ABSTRACT BODY:

Purpose: Rod-Cone dystrophies (RCD) are inherited neurodegenerative diseases characterized by an initial loss of rod photoreceptors (rods) followed by loss of cone photoreceptors (cones) eventually causing blindness. Over 1.5 million people worldwide are affected by RCD with ~65 genes identified. The NXNL1 gene encodes two proteins produced by rods, rod-derived cone viability factor (RdCVF) and its full-length isoform, thioredoxin RdCVFL, also expressed by cones, that support cone survival by promoting glycolysis and preventing oxidative damage, respectively. Delivery of RdCVF/L via adeno associated viral (AAV) vectors to the retina promote cone survival in RCD mouse models (Byrne et al., 2015, J. Clin. Invest.). We delivered SPVN06, a novel mutation-independent AAV-based drug candidate encoding both human RdCVF and RdCVFL sequences, in a large animal model of autosomal dominant retinitis pigmentosa (adRP), the transgenic P23H human rhodopsin (TgP23H hRho) pig, and evaluated cone survival.

Methods: Eight neonatal TgP23H hRho pigs received a unilateral subretinal injection of SPVN06 at 6.1E10 vg/eye (50 µL). We conducted regular ocular exams and fundus imaging to assess tolerability and retinal structure. Animals were euthanized 3 (n=4) or 6 months (n=4) post injection. Retinas were collected and processed for immunohistochemistry. Morphological differences in SPVN06-treated retinas vs control fellow eyes were assessed in the four animals euthanized 3 months post injection. Morphological analysis of 6 months post injection retinas are currently underway.

Results: Subretinal administration of SPVN06 is well tolerated. In three of the four animals, cone morphology is better preserved compared to the same area in the fellow, control eye within the area of treatment. Among those three animals, treated cones have significantly longer inner and outer segments (39%; p<0.05), and significantly more cones express medium-wavelength opsin (m-opsin; 90%).

Conclusions: In the TgP23H hRho model of human adRP, SPVN06 subretinal administration is well tolerated and preserves cone morphology and m-opsin expression. SPVN06 is expected to protect against cone degeneration in RCD patients independent of the causative mutation.

ABSTRACT BODY:

Purpose: Coagulase-negative staphylococci (CONS), including Staphylococcus (S) epidermidis are responsible for 70% of all exogenous bacterial endophthalmitis. However, the pathogenesis of CONS endophthalmitis is limited epidemiologically and in clinical case reports; in part, this could be due to lack of suitable experimental models. Here, we developed a mouse model of S. epidermidis endophthalmitis and evaluated retinal innate immune responses. In vitro studies were also performed using cultured retinal and myeloid cells.

Methods: Endophthalmitis was induced by intravitreal injections of S. epidermidis and both dose-dependent and time-course studies were performed. Disease progression was monitored by an eye exam using slit-lamp microscopy and ERG analyses. Eyes were enucleated for enumeration of bacterial burden and assessment of inflammatory mediators using RT-PCR and ELISA assays. For in vitro studies, muller glial cells, retinal pigment epithelium and mouse bone marrow-derived macrophages (BMDM) were challenged with S. epidermidis and the expression levels of pro-inflammatory cytokines and chemokines were deduced at various time points post infection. The induction of inflammatory signaling was assessed by western blot.

Results: Our data showed that S. epidermidis was rapidly cleared from mice eyes and a relatively higher dose was needed to cause endophthalmitis. A time-course study revealed that bacterial load peaked at 24h post-infection followed by a gradual decline up to 72h. The production of inflammatory mediators followed a similar trend with reduced levels as bacterial burden decreased. In vitro studies showed differential expression of inflammatory mediators, with BMDM cells showing increased levels as compared to RPE and Muller glia. Western blot analyses revealed the induction of NF-kB and other MAPK (ERK and p38) signaling in S. epidermidis infected mice eyes and cultured cells.

Conclusions: S. epidermidis evoked innate immune responses in both mouse eyes and cultured cells. However, it did not cause severe endophthalmitis even when injected at a higher dose, indicating robust retinal innate immunity to efficiently clear CONS.

TITLE: Differential Responses of Human Juxtacanalicular and Trabecular Meshwork Beam Cells to Mechanical Stretch

SESSION TITLE: Blood flow/ Ischemia/reperfusion/Aqueous humor dynamics/IOP

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Roberts, M.L. De Ieso, D.W. Stamer, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Haven Roberts: Commercial Relationship: Code N (No Commercial Relationship) | Michael De Ieso: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Stamer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The contractility status of the trabecular meshwork (TM) plays a major role in the regulation of aqueous humor outflow resistance. However, the TM contains two morphologically different cell types, the endothelial-like cells that cover the beams and plates of the inner TM and the myofibroblast-like cells that reside in the Juxtacanalicular region. The purpose of this study was to determine the contractile responses of TM cell cultures having endothelial versus myofibroblast appearance.

Methods: TM cells from healthy and glaucomatous donors were isolated and categorized as predominately “beam” or “JCT” cultures based on morphology at confluence. Each strain was plated at confluence into wells of Collagen Type IV flex plates and cultured in 10% FBS for 3 days. Media was changed to 1% FBS 1 hour before stretch began. Plates were then stretched using the FlexCell FX5K Tension Stretch machine at 20% stretch (1 hertz) for 24 hours. Cell lysates were collected and subjected to SDS-PAGE, followed by western blotting for total and phosphorylated myosin light chain (MLC), a surrogate measure for cell contractility. Quantitative analysis of MLC expression was achieved using Image Lab software.

Results: JCT strains (n=3) responded to stretch with a $40\% \pm 24\%$ decrease in pMLC levels. Conversely, the mixed morphology (n=1) and beam (n=1) TM cell strains showed a 39% and 30% increase in pMLC, respectively under the same conditions. Notably, the glaucomatous TM strain, characterized as a primarily beam morphology, showed a 10% decrease in pMLC. Furthermore, we noted a pattern of morphological change from beam to JCT as cell culture passages increased.

Conclusions: Contractile responses to mechanical stress are opposite between beam TM and JCT cell strains, likely reflecting their different roles in conventional outflow homeostasis. Interestingly, a beam cell strain isolated from a glaucomatous donor eye behaved more like a JCT cell strain.

ABSTRACT BODY:

Purpose: One of the earliest signs of age-related macular degeneration (AMD) is deposits in Bruch's membrane (BM). Thus far, BM thickening has only been studied in enucleated eyes ex vivo. Here, we show that visible light Optical Coherence Tomography (OCT) imaging can resolve BM and potentially observe age-related BM thickening in pigmented mice in vivo.

Methods: A custom spectral-domain visible light OCT ophthalmoscope was built for ultrahigh resolution in vivo mouse retinal imaging. The system had a theoretical axial resolution of 1 μm in tissue. We optimized spectrometer spectral resolution and applied spatially-dependent dispersion compensation to ensure that this resolution was achieved experimentally. Experiments were performed on 1.5 month old (n=2), 12 month old (n=2), and 18 month old (n=2) C57BL/6J mice. An incident power of 300 microwatts on the cornea and a line rate of 10 kHz were used. The imaged field-of-view was 1.44 mm (fast axis) by 0.12 mm (slow axis). Images were acquired within 2 mm of the optic disc. RPE multiply scattering tails were extrapolated and subtracted from axial intensity profiles to accurately estimate BM thickness.

Results: Exemplary images and preliminary analysis are shown in Fig. 1 and Fig. 2. The BM band was well-separated from the RPE band in all images (Fig. 1B-D). After subtraction of RPE multiply scattering tails to yield BM axial profiles, we noticed a slight BM thickening with age (Fig. 2D-F). Interestingly, due to RPE multiple scattering, lower visibility of BM does not translate to a thicker BM.

Conclusions: BM was visualized and quantified in vivo in highly pigmented mice of various ages with visible light OCT. This capability will enable studying BM changes with aging and ocular diseases.

ABSTRACT BODY:

Purpose: Controversy exists whether optical coherence tomography angiography (OCTA) is able to detect preclinical retinal microvascular alterations in diabetic patients. We performed a cross-sectional analysis of the German Diabetes Study and analyzed type 1 and type 2 diabetic patients with regard to early changes in retinal vasculature.

Methods: In a cross-sectional analysis of the German Diabetes Study, the flow density of 74 diabetic and 52 control subjects in the macular region was analyzed by OCTA (Spectralis®, Heidelberg Engineering®) (10x10°, 512 A-scans, EDI mode, centered on the fovea centralis). After segmentation control, en face OCTA images of superficial (SVP), intermediate (IVP), and deep vascular plexus (DVP) were binarized in ImageJ using Otsu's thresholding method and flow density (proportion of white pixels to total pixel count) was calculated. Ultra-widefield fundus images were captured (Optos®, Optmap, Marlborough, MA, USA) and the stage of diabetic retinopathy was classified according to the International Clinical Diabetic Retinopathy Disease Severity Scale. Statistical analysis was performed using PROC MIXED (SAS, V 9.4, Cary, North Carolina, USA), age- and sex-adjusted.

Results: 47 patients with type 2 diabetes (T2DM) (32 male, age 58.6±11.9 (SD) years (Y), diabetes duration 6.9±2.8 Y), 27 patients with type 1 diabetes (T1DM) (14 male, 42.6±10.6 Y, diabetes duration 7.7±2.6 Y), and 52 control subjects (26 male, 42±15.6 Y) were evaluated. 1 subject from T2DM (2.1%) and T1DM (3.7%) showed mild nonproliferative diabetic retinopathy. The flow density for T2DM in SVP was 0.25±0.04, which was lower than in controls (0.28±0.04; p=0.0433). The other values for IVP (0.32±0.06) and DVP (0.33±0.05) did not differ from controls (IVP: 0.36±0.05; p=0.2365, DVP: 0.37±0.06; p=0.0507). The same was true for T1DM (SVP: 0.27±0.05; p=0.1760, IVP: 0.35±0.05; p=0.6661 and DVP: 0.36±0.06; p=0.2812). The decrease in flow density with age (per year of life: SVP: -0.00086, IVP -0.00163, DVP -0.00147, p each <.0001) was taken into account.

Conclusions: With similar duration of diabetes, T2DM, in contrast to T1DM, have lower flow density in SVP compared with controls. Accordingly, capillary vascular changes in T2DM are clearly detectable with OCTA even without DR. Overall, there is an age-dependent decrease in flow density, so future studies should always use age-adjusted data.

Commercial Relationships Disclosure (Abstract): Avinash Soundararajan: Commercial Relationship: Code N (No Commercial Relationship) | Padmanabhan Pattabiraman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is a primary risk factor for glaucoma. IOP homeostasis relies on the regulation of aqueous outflow through trabecular meshwork (TM). ECM accumulation in TM elevates IOP. Clusterin, a secretory stress response chaperone protein, has been reported to regulate cell-matrix interactions. Studies have shown a putative linkage between clusterin and primary open angle glaucoma pathogenesis. We aim to study the- 1) effect of stressors known to increase IOP on clusterin expression in TM, 2) understand the role of clusterin in ECM remodeling, and 3) effect of loss of clusterin on IOP.

Methods: Using qPCR and immunoblotting, we studied the effects of - A) CTGF, Endothelin, Dexamethasone, TGF β 2, elevated pressure on clusterin expression, B) adenovirus-induced clusterin expression (AdCLU) on ECM, pro-fibrotic proteins, and ECM regulatory matrix metalloproteinases (MMPs) activity using zymography, C) recombinant clusterin (rhCLU) on TGF β 2-induced fibrosis and ECM accumulation, in vitro. TM cells were transfected with expression clones Clusterin-RFP-GFP (CLU-RG) or Signal peptide-RFP-GFP (SP-RG), followed by live cell imaging post TGF β 2 treatment. IOP was measured in clusterin knockout (Clu^{-/-}) mice by tonometry. Student's t-test was used for statistical analyses and results were significant if $p < 0.05$ with a sample size of $n = 3-7$ per experiment.

Results: AdCLU significantly decreased ECM mRNAs and proteins including, Collagen 1A ($n = 3$, $p = 0.04$) and fibronectin ($n = 3$, $p = 0.01$), Elastin ($n = 3$, $p = 0.05$), whereas MMP2 expression was increased. CTGF ($n = 3$, $p = 0.006$), Endothelin ($n = 3$, $p = 0.05$), TGF β 2 ($n = 3$, $p = 0.04$) and Pressure stress ($n = 4$, $p = 0.04$) significantly reduced clusterin protein expression. rhCLU attenuated significantly the effects of TGF β 2 on ECM proteins- COL1A ($n = 3$, $p = 0.01$), Fibronectin ($n = 3$, $p = 0.05$). TM cells transfected with CLU-RG showed decrease in clusterin availability under TGF β 2 treatment. Clu^{-/-} mice demonstrated an age-dependent elevation in IOP with significant increase at postnatal day 90 compared to wild type ($n = 7$, $p = 0.03$).

Conclusions: Our novel finding demonstrates the role of clusterin on ECM remodeling and loss of clusterin function elevates IOP signifying the importance of clusterin in IOP homeostasis. Further studies on the signaling events of clusterin-mediated ECM remodeling and IOP changes can help us identify novel IOP lowering therapies.

ABSTRACT BODY:

Purpose: While sensorineural hearing loss (SNHL) is a characteristic of Usher syndrome type 2 (USH2), less is known about SNHL in USH2A-associated non-syndromic autosomal recessive retinitis pigmentosa (ARRP) and olfaction in USH2A-associated retinal degeneration. We investigate SNHL and olfaction in patients with USH2A-related disease using cross-sectional baseline data collected in a multicenter natural history study.

Methods: The Rate of Progression of USH2A-related Retinal Degeneration (RUSH2A) study enrolled 127 participants, 80 USH2 and 47 ARRP (male/female = 59/68, 113 White). Hearing was measured by pure-tone thresholds and word recognition score, and olfaction by the University of Pennsylvania Smell Identification Test (UPSIT). Associations of participant characteristics with SNHL and UPSIT scores were assessed by linear regression models. Correlation of UPSIT scores with different visual measures were assessed by Spearman correlation coefficients. UPSIT scores were also compared to historical healthy control subjects of similar age and gender.

Results: SNHL was moderate in 72% of USH2 participants and severe or profound in 25%, while 9% of ARRP participants had moderate adult-onset sensorineural hearing loss. Pure-tone thresholds increased (worsened) with age in ARRP ($p < 0.001$) but not in USH2 participants ($p = 0.46$). The degree of SNHL was not significantly associated with gender, race/ethnicity or smoking status. Among 14 USH2 participants reporting newborn hearing screening results, 7 reported passing. Among RUSH2A participants, 7% had mild microsmia and 5% had moderate or severe microsmia; however, their mean (\pm SD) UPSIT score was 35 (± 3), similar to healthy controls [34 (± 3); $p = 0.39$]. Smell function differed by country ($p = 0.02$), but was not significantly associated with clinical diagnosis, age, gender, race/ethnicity, smoking status, visual measures, or hearing function.

Conclusions: Hearing loss in USH2A-related USH2 did not increase with age. ARRP patients do not appear to be at risk for significant hearing loss beyond that associated with aging. Newborn hearing screening did not identify all USH2-related hearing loss. Olfaction was not significantly worse than normal in participants with USH2A-related retinal degeneration. Pathogenic variants in USH2A variably affect auditory hair cells but have no significant impact on olfaction.

ABSTRACT BODY:

Purpose: Previous studies have shown that optical coherence tomography (OCT) can help differentiate papilledema from NAION based on peripapillary 2D/3D structural and morphological features (Miller et al., ARVO 2018, Wang et al., ARVO 2020). However, OCT is not always available (e.g., in the emergency room and primary care settings). To overcome this limitation, in this study, we focus on the automated differentiation in more available 2D color fundus images and include novel use of deep-learning-based 3D morphological features.

Methods: Using 102 OCT and fundus image pairs (51 papilledema and 51 NAION subjects; severity matched by the optic-nerve-head [ONH] volume measured in OCT) from the University of Iowa, a feature pyramid neural network was trained to estimate the OCT-like thickness maps from the color fundus photographs (Fig. 1A). Based on these 102 estimated thickness maps, seven statistical shape models were built using principal component analysis (PCA) covering 90% of the shape variance (Fig. 1B). Then, for each input fundus image, the corresponding seven 3D shape measures were computed. Meanwhile, 12 features based on the image intensity, 12 features based on a segmented vessel map, 24 features based on the image texture analysis, and six regional peripapillary volumetric measures were also computed (Fig. 2) for a total of 61 features. A random forest classifier was used to classify papilledema/NAION cases using leave-one-subject-out validation.

Results: When the random forest classifier considered the entire feature set (feature importance of 61 features are shown in Fig. 2), the classification accuracy was 84% (44/51: papilledema; 42/51: NAION). Without considering the 3D features (i.e., the 48 pure 2D image-based features), the accuracy dropped to 80% (42/51: papilledema; 40/51: NAION).

Conclusions: Deep-learning-based OCT-like thickness maps make retinal 3D structural and morphological analysis possible in 2D color fundus photographs, which is beneficial for differentiating papilledema from NAION when OCT is not available.

TITLE: AXT107 an Inhibitor of Neovascularization, Vascular Leakage, and Inflammation, Is Well-Tolerated and Could Potentially Be Dosed Once a Year to Treat Retinal Vascular Diseases

SESSION TITLE: Stem cells / gene therapy/ transplantation/ laser/ local therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Pandey, AsclepiX Therapeutics, Baltimore, Maryland, UNITED STATES|N. Pandey, Biomedical Engineering, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Niranjan Pandey: Commercial Relationship(s);AsclepiX Therapeutics:Code E (Employment)

ABSTRACT BODY:

Purpose: To assess the safety and pharmacokinetics (PK) of AXT107, a synthetic 20-mer peptide that blocks VEGF receptor 2 and activates Tie2, in preclinical studies.

Methods: Safety, PK, and ocular tissue distribution of 100, 250, 500, and 1000 µg of AXT107 injected intravitreally were tested in rabbit and minipig. GLP safety was studied over 9 months and PK and ocular tissue distribution were tested in rabbit and minipig for 15 months and 9 months respectively. Mass spectrometry was used to quantify AXT107 in plasma, aqueous humor, vitreous humor, retina, and choroid-RPE

Results: AXT107 was well tolerated in rabbit and minipig for 9 months after a single intravitreal administration of all doses of AXT107 in GLP studies. No increase in intraocular pressure, no inflammation, and no changes in ERG were observed throughout the 9-month period in both species. Within a few minutes of administration of a liquid formulation of AXT107, it formed a gel, whose size and appearance were dose-dependent, in the vitreous. The gel was compact and remained below the visual axis over the observation period. AXT107 was quantifiable in the gel by mass spectrometry and found to decrease over the duration of the study in both species. AXT107 was found at efficacious levels on the retina and choroid-RPE and at low levels in the bulk vitreous, and below levels of quantitation (BLQ) in the aqueous humor and other ocular tissues. AXT107 levels were also BLQ in plasma over the duration of the studies in both species. The levels of AXT107 in the retina and choroid were comparable at all doses of AXT107 tested. The half-life of the gel in the vitreous was found to be about 180 days.

Conclusions: Multiple doses of a single injection of AXT107 injected intravitreally were found to be safe and well-tolerated in GLP safety studies over 9-months in two species. PK and ocular distribution studies in rabbit and minipig showed that AXT107 formed a gel upon intravitreal injection that stayed below the visual axis releasing AXT107 slowly over the course of the study with a half-life of 180 days. The released AXT107 was found to be present at efficacious levels in the retina and choroidal tissues. These studies suggest that AXT107 is safe for intravitreal injection and support potentially once a year dosing in the clinic.

TITLE: Point-scanning optimization for video-rate volumetric intraoperative OCT

SESSION TITLE: OCT/OCTA - New biomarkers and technical improvements I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Tang, Y. Tao, Biomedical Engineering, Vanderbilt University, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Eric Tang: Commercial Relationship: Code N (No Commercial Relationship) | Yuankai Tao: Commercial Relationship(s);Leica Microsystems:Code R (Recipient);Vanderbilt University:Code P (Patent)

ABSTRACT BODY:

Purpose: Galvanometer scanner response fundamentally limits optical coherence tomography (OCT) imaging performance. Scanning nonlinearities distort anatomic features and reduce image quality/resolution; and underdamped impulse response increases mirror settling duration and total acquisition time. Here, we present hardware and software scanner response optimizations and demonstrate benefits for video-rate volumetric intraoperative OCT.

Methods: Scanners (Saturn 5B, ScannerMax) were optimized iteratively using servo tuning parameters. A Gaussian process regression (GPR) model of step responses was developed and used to identify optimal tunings (Fig. 1). Improved imaging performance was validated using a custom 400 kHz swept-source OCT system and custom volumetric scan waveforms (Fig. 2).

Results: Mirror settling time was reduced by 39-58% and 17-58% for the slow- and fast-axis mirrors, respectively, over default tunings (Fig. 1(d),(e)). OCT volumes were acquired of 25G forceps at 16 Hz volume rate with 2560x250x50 pix. and 250 return lines (Fig. 2(a),(c)-(f)) and at 20 Hz volume rate with 2560x400x50 pix. and 0 return lines (Fig. 2(b),(g)-(j)). Scanner tuning optimization increased the number of linearly sampled lines by 12-101% (Fig. 2(f) vs. Fig. 2(c)-(e)) and by 18-72% (Fig. 2(j) vs. Fig. 2(g)-(i)) over default tunings for each scan waveform. Removing return lines increased the number of linearly sampled lines by 33-64% for all tunings (Fig. 2(g)-(j) vs. Fig. 2(c)-(f)).

Conclusions: The combination of hardware and software optimizations significantly increased both volume acquisition speed and linear field-of-view of volumetric OCT. These optimizations can benefit intraoperative OCT by improving the response of the scanners and minimizing image distortions during video-rate volumetric imaging of surgical dynamics.

Commercial Relationships Disclosure (Abstract): Ting Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Rabinowitz: Commercial Relationship: Code N (No Commercial Relationship) | Padmanabhan Pattabiraman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Trabecular meshwork (TM) biomechanics is important in regulating aqueous humor (AH) drainage and intraocular pressure (IOP). This study aims at understanding the role of activation and inhibition of the transcription factor SREBP which is the master regulator of lipid biogenesis on the regulation of TM extracellular matrix (ECM) content via the modulation of lipid synthesis.

Methods: Quantitative-polymerase chain reaction (qPCR), immunofluorescence, immunoblot were performed on human TM (HTM) cells and porcine TM (PTM) cells in culture to assess - 1) expression of transcript variants of sterol regulatory-element binding protein (SREBP) and SREBP cleavage- activating protein (SCAP), and 2) effects of SREBP activation via clozapine, inhibition of SREBP-SCAP complex via fatostatin on - SREBP activation, regulation of ECM like fibronectin (FN), collagen (Col1A) in TM, SREBP target genes expression related to lipid biogenesis. Porcine anterior segment perfusion cultures were used to assess the effects of SREBP activation and inhibition on IOP changes. Student's t-test and two-way ANOVA were used for statistical analyses and results were significant if $p < 0.05$ with a sample size of $n = 3-5$.

Results: Transcript variants of SREBP-F1V1, V2, V3, and -F2V1 and SCAP were expressed in HTM and PTM cells. Activation of SREBP by clozapine significantly increased IOP ($p = 0.0440$, $n = 5$) after 17h clozapine perfusion. Clozapine treatment on HTM cells increased FN and Col1A fibril formation. Perfusion with fatostatin lowered IOP. HTM cells treated with fatostatin decreased ECM distribution and reduced gene expression of SREBP1, SREBP2, and their target genes involved in fatty acids, triglycerides, and cholesterol biosynthesis. Interestingly, we found a significant decrease in acetyl-CoA carboxylase (ACC) and low density lipoprotein receptor (LDLR) genes ($p = 0.0001$, $n = 3$).

Conclusions: Our study identifies that modulating SREBP alters TM lipids and IOP. Of significance is the decrease in ACC which catalyzes the carboxylation of acetyl-CoA into malonyl-CoA, a rate-limiting step in fatty acid biosynthesis. Acetyl-CoA metabolism is implicated in primary open-angle glaucoma and ACC1 regulates ECM turnover and tissue fibrosis. Future studies on SREBP in TM will identify the potential regulation of membrane properties, AH outflow resistance, and novel therapeutics.

ABSTRACT BODY:

Purpose: Our recent studies on visible-light optical coherence tomography (vis-OCT) make it possible to assess optic neuropathy progression in vivo based on retinal ganglion cell (RGC) axon bundle size. However, accurate quantification of these structures by vis-OCT is complicated by speckle noise. We thus implemented two techniques, temporal speckle averaging (TSA) and a novel resampling technique, to improve the visualization of RGC axon bundles in fibergrams and B-scans.

Methods: TSA images were acquired from an anesthetized C57BL/6 mouse using vis-OCT. We positioned the optic nerve head (ONH) in one corner of the field of view (FOV) and acquired 5 OCTA volumes consisting of 512 A-lines×512 B-scans with each B-scan repeated 5 times. We repeated this acquisition process with the ONH in each corner of the FOV. A single OCTA volume produced a fibergram, averaged five times, and an unaveraged angiogram. All fibergrams and angiograms at each location were registered and averaged using non-rigid demon registration. Speckle reduced circular scans were reconstructed from 4 rectangular OCT volumes acquired with the ONH positioned in each corner of the FOV. For each volume, an 11 pixel-thick (~15 µm) ring with a 400 µm radius centered on the ONH was plotted. A-lines located along the ring were sorted as a function of angle and averaged within 0.1° sectors to produce a speckle reduced B-scan (SRB-scan).

Results: Fig. 1a shows a montaged fibergram after TSA. Compared to before (Figs. 1b-c), the fibergram and angiogram after TSA (Figs. 1d-e) show smoother structures with greater contrast. RGC axon bundle contrast to noise ratio (CNR) increased 1.5 dB after TSA. Compared to the traditional scan (Fig. 2(a)), individual RGC axon bundles are visible in the SRB-scan (Fig. 2(b)). RGC axon bundle CNR increased 2.4 dB using our novel resampling method.

Conclusions: The combined TSA and resampling greatly enhanced visualization of RGC axon bundles in fibergram and B-scan images, enabling more accurate bundle size analysis.

ABSTRACT BODY:

Purpose: Glaucoma is the second major cause of blindness worldwide and is characterized by the loss of the retinal ganglion cells (RGC) which convey visual information from the retina to the brain. More than 40 subtypes of RGCs have been identified and studies suggest that their susceptibility to insults differ. In particular, one type of retinal ganglion cells, intrinsically photosensitive retinal ganglion cells (ipRGC), has been shown to be relatively resistant to damage in glaucoma and similar injuries. ipRGCs consist of 6 subtypes, M1-M6, each one projecting to different brain areas and involved in distinct functions such as circadian entrainment, the pupillary light reflex, image forming vision, etc. Accordingly, it is important to determine the correlation between the loss of particular ipRGCs subtypes and behavioral deficits such as circadian dysfunction and vision loss. Such information will provide important insights to address the pathologies of glaucoma patients.

Methods: In this study, we used laser photocoagulation of the trabecular meshwork of the eyes to induce chronic ocular hypertension (OHT). Visual acuity and contrast sensitivity of the animals were measured by the optomotor test. We also assessed circadian rhythmicity and photoentrainment in these mice through the progression of the disease. Finally, retinas were dissected, immunostained for RGC subtypes, and flatmounted for confocal imaging. We quantified the survival of RGCs and ipRGC subtypes in mice with chronic OHT.

Results: We found that ipRGCs are more resistant to the ocular hypertension insult than the general RGC population. Moreover, the survival of ipRGCs depends on subtypes. Specifically, M1 and M2 cells survived better than M4s. Though the contrast sensitivity and visual acuity of the OHT group dropped significantly, circadian rhythmicity and photoentrainment were barely disrupted.

Conclusions: Our results suggest the circadian behaviors were relatively well maintained with glaucoma progression, which is correlated with the survival of ipRGCs. Future studies are needed to dissect out the neural circuit and its underlying mechanisms.

ABSTRACT BODY:

Purpose: To investigate the associations between maternal and perinatal systemic health factors and macular optical coherence tomography (OCT) characteristics in preterm infants at 36 weeks postmenstrual age (PMA).

Methods: We included 85 infants enrolled under STudy of Eye imaging in Preterm infantS (BabySTEPS, NCT02887157) with parental consent for research and OCT imaging at 36±1 weeks PMA. We evaluated associations between maternal and perinatal systemic factors and, vitreous pathologies, macular edema, and the following layer thicknesses at the foveal center and 1000µm nasal to the fovea: total retina, combined retinal nerve fiber layer (RNFL), ganglion cell layer (GCL) and inner plexiform layer (IPL), inner nuclear layer (INL), and outer retina. We averaged the thicknesses of the right and left eyes for all infants and tested the associations using multivariable regression models.

Results: Infants with lower gestational ages had thicker foveal RNFL+GCL+IPL (estimate=-4.76µm, 95% confidence interval=-6.12, -3.37; p=<0.001) and those with intracranial hemorrhage/periventricular leukomalacia/ventriculomegaly (n=30) had thinner RNFL+GCL+IPL at 1000µm nasal from fovea (mean± standard deviation = 124±3 versus 134±2µm, 0.004). Infants with septicemia/necrotizing enterocolitis (NEC) (n=16) had a significantly thicker outer retina (110±7 vs. 79±3µm, p=<0.001) and total retina (316±27 vs. 222±13µm, p=0.002) at the fovea and thicker INL (98±7 vs. 76±3µm, p=0.006) at 1000µm nasal from fovea. These associations remained statistically significant after adjusting for confounding variables such as gestational age.

Conclusions: Lower gestational age and intracranial hemorrhage/periventricular leukomalacia/ventriculomegaly independently impact inner retinal layers other than the INL. Parafoveal INL devoid of distorting cystoid spaces, and outer and total retinal thicknesses at the foveal center are affected by septicemia/NEC. Our study highlights the variable effects of different systemic health on preterm retina, independent of prematurity related birth factors.

TITLE: Comparing the Street-Crossing Performance of Subjects with Simulated AMD against Patients with Real AMD

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.E. Hassan, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Shirin Hassan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously developed a method of simulating a central scotoma, as found in age-related macular degeneration (AMD), using centrally-opaque contact lenses (CLs). The aim of this study was to determine how realistic our AMD simulation was of real AMD by comparing the street-crossing decision-making performance of subjects with real AMD to those with simulated AMD using our simulation tool.

Methods: Street-crossing decisions along a non-signalized, one-way street were collected in 17 AMD subjects with a scotoma, 34 AMD subjects without a scotoma and 20 normally-sighted subjects wearing centrally-opaque CLs that induced a central scotoma. Subjects observed approaching traffic for a two second period after which they reported whether or not they believed that the vehicular gap time was long enough to afford a safe crossing. When subjects indicated that they would cross when the measured vehicular gap time was shorter in duration than their actual crossing time, this was considered an unsafe decision. When subjects indicated that they would not cross when the measured vehicular gap time was longer in duration than their actual crossing time, this was considered a missed decision. For each subject, the percentage of unsafe (%unsafe) and missed (%missed) decisions were calculated. A generalized linear mixed model with binary logistic function, repeated measures for subject and a covariate to adjust for age differences was used to determine if the %unsafe and %missed decisions changed as a function of subject group (AMD with a scotoma versus AMD with no scotoma versus simulated AMD with a scotoma).

Results: The simulated AMD subjects made as many %unsafe and %missed decisions as those with real AMD with a scotoma ($p=0.98$ and $p=0.66$ for %unsafe and %missed, respectively) and without a scotoma ($p=0.19$ and $p=0.13$ for %unsafe and %missed, respectively). While those AMD subjects with no scotoma made as many %missed decisions as AMD subjects with a scotoma ($p=0.26$), they did have a tendency to make more %unsafe decisions ($p=0.09$).

Conclusions: Our method of AMD simulation appears to mimic the street-crossing decision-making performance of people with real AMD. This simulation tool may therefore be beneficial to future studies assessing the functional performance of people with AMD.

TITLE: Evaluation of Masked Associated Dry Eyes using AS-OCT Tear Meniscus Parameters and OSDI Scores

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.O. SALAMI, S. Bains, S. Shankar, R. Thangarajah, E. Sogbesan, Ophthalmology, McMaster University, Hamilton, Ontario, CANADA|

Commercial Relationships Disclosure (Abstract): MONSURAH SALAMI: Commercial Relationship: Code N (No Commercial Relationship) | Sharnjit Bains: Commercial Relationship: Code N (No Commercial Relationship) | Sushmitha Shankar: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Thangarajah: Commercial Relationship: Code N (No Commercial Relationship) | Enitan Sogbesan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to determine the effect of prolonged use of a surgical mask on tear meniscus parameters using anterior segment ocular coherence tomography (AS-OCT) and Ocular Surface Disease Index (OSDI) score amongst healthcare workers during the COVID-19 pandemic.

Methods: Fifty healthcare workers from St. Joseph's Healthcare Hamilton in the Hamilton Regional Eye Institute Department, Hamilton, Ontario participated in the study. All participants completed OSDI Questionnaire and provided demographics data. Participants had an average of three AS-OCT imaging of the tear meniscus (TM) at baseline and 8hrs later, after their regular shift. During this 8hr period, participants were required to wear medical masks continuously throughout their shift. Data was analyzed using SPSS V27.

Results: Participants' (n = 50) mean age was 38.9 ± 12.9 years; 22.0% were male and 78.0% were female. Of these participants, 62.0% wear spectacles and 28.0% wear contact lens. 54.4% of participants (n = 100 eyes) had normal OSDI scores of <12, 34.0% had mild OSDI scores, 4.0% had moderate OSDI scores, 8.0% had severe OSDI scores. Baseline mean AS-OCT TM height was $385.4 \pm 172.6 \mu\text{m}$ and mean TM area was $46,496.7 \pm 41,875.5 \mu\text{m}^2$; after 8 hours shift the parameters reduced to mean TM height of $296.6 \pm 99.9 \mu\text{m}$ and mean TM area of $28,187.8 \pm 18,761.3 \mu\text{m}^2$. With the resultant mean TM height and area difference of $88.8 \pm 142.8 \mu\text{m}$ ($p < 0.001$) and $18,308.9 \pm 35,901.9 \mu\text{m}^2$ ($p < 0.001$), respectively. Participants had a mean reduction in tear meniscus parameters in left eye (TM height: $90.1 \pm 149.3 \mu\text{m}$ and TM area: $18,290.9 \pm 39,538.78 \mu\text{m}^2$) and right eye (TM height: $87.5 \pm 137.5 \mu\text{m}$ and TM area: $18,326.9 \pm 32,262.7 \mu\text{m}^2$), regardless of OSDI scores and significance between the left and right eye (Area Difference $p = 0.996$; TMH Difference $p = 0.927$).

Conclusions: This study shows that prolonged use of medical mask especially during COVID-19 may reduce tear meniscus parameters. There was a 23.0% reduction in tear meniscus height and 39.4% reduction in tear meniscus area compared to the initial parameters, regardless of the presence of OSDI scores.

TITLE: Ophthalmic Procedure Training During COVID-19: Virtual and In-Person Training of the Suprachoroidal Injection Procedure

SESSION TITLE: Drug delivery and Gene Therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Fisher, S. Hancock, T.A. Ciulla, Clearside Biomedical Inc, Alpharetta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nathan Fisher: Commercial Relationship(s);Clearside Biomedical, Inc.:Code E (Employment) | Shelley Hancock: Commercial Relationship(s);Clearside Biomedical, Inc.:Code E (Employment) | Thomas Ciulla: Commercial Relationship(s);Clearside Biomedical, Inc.:Code E (Employment)

ABSTRACT BODY:

Purpose: The purpose of this analysis was to evaluate virtual and in-person training modalities to educate retinal specialists and other ophthalmology professionals on suprachoroidal injection with the SCS Microinjector®. Significant travel and site visitation restrictions associated with the COVID-19 pandemic required that alternative virtual methodologies be developed to continue training when traditionally utilized in-person, wet lab instruction was not permitted.

Methods: Trainees for the suprachoroidal injection procedure included retina physician-investigators participating in clinical trials and non-physicians, including medical science liaisons and other ophthalmology professionals. Both training modalities included a review of a short film on the procedure, a slide review of key procedural steps, and practice injections with a custom-designed synthetic eye, moderated by a certified trainer providing live feedback. Virtual training was conducted via teleconference; both trainee and trainer connected via webcam and audio connection, with all supplies mailed prior to training. Following completion of training, a follow-up survey was sent to every trainee. Trainees were asked about training component preferences and confidence to perform the procedure on a 5-point Likert scale.

Results: A total of 31 trainees completed the survey following suprachoroidal injection training, including 21 physicians and 10 non-physicians. A total of 12 training sessions were completed virtually and 19 were completed in person. Physicians reported an average confidence to perform the procedure of 4.8 (range 4-5), while non-physicians reported an average of 4.2 (range 3-5), although non-physician trainees will not be performing the procedures in patients. Across all groups, the most useful component of training was the hands-on wet lab with the synthetic eye (71%) followed by the live trainer feedback and Q&A (26%). Nearly two-thirds of trainees felt that the training was comprehensive and no additional training elements were required.

Conclusions: Among trainees who completed virtual or in person training on the suprachoroidal injections, physician trainees felt highly confident to perform the procedure with patients. Training experience with a synthetic eye model and live feedback should be incorporated into training curriculums, whether virtual or in person.

TITLE: Mast cells directly activate corneal allograft-primed T cells

SESSION TITLE: Corneal immunology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Elbasiony, S. Mittal, W. Cho, S. Chauhan, Ophthalmology, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Elsayed Elbasiony: Commercial Relationship: Code N (No Commercial Relationship) | Sharad Mittal: Commercial Relationship: Code N (No Commercial Relationship) | WonKyung Cho: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously reported that inhibition of mast cell activation prolongs corneal graft survival following transplantation. The purpose of the current study is to investigate whether mast cells directly activate T cells to secrete IFN γ , a critical inflammatory molecule for their effector function.

Methods: Single-cell suspensions of corneal tissue and peritoneal lavage were prepared to evaluate levels of major histocompatibility complex II (MHC II) expression (Mean Fluorescent Intensity; MFI) on Fc ϵ R1⁺cKit⁺ mast cells using flow cytometry. Bone marrow cells were harvested from femurs and tibias of balb/c mice and cultured for 3-4 weeks in the presence of IL-3 (10 ng/ml) and SCF (50 ng/ml) to generate bone marrow mast cells. Alloprimed CD4⁺ T cells were sorted from the draining lymphoid tissues of C57BL/6 transplant recipients (grafted with Balb/c corneas) using flow cytometry. To evaluate the effect of mast cells on T cell stimulation, purified C57BL/6 CD4⁺ T cells were cultured with balb/c mast cells. Co-cultures of alloprimed CD4⁺T cells and antigen-presenting cells (APCs; CD90.2- from balb/c splenocytes) served as a positive control. Intracellular expression of IFN γ by CD4⁺ T cells was assessed after 48 hours using flow cytometry.

Results: A high expression of MHC II was observed in mast cells harvested from ocular tissues (P<0.001) peritoneal fluid (P<0.001) and bone marrow (P<0.05), compared to isotype controls. Furthermore, mast cells upregulated MHC II expression by 2-fold following IFN γ stimulation (100 ng/ml), compared to unstimulated controls (P<0.05). Alloprimed CD4⁺T cells co-cultured with mast cells showed an approximate 3.5 fold increase in the expression of IFN γ , compared to T cells cultured alone (P<0.05). Similarly, allogenic APCs induced a 2-fold increase in the expression of IFN γ by CD4⁺ T cells (P<0.03), which was comparable to allogenic mast cells mediated T cell activation.

Conclusions: Our data demonstrate that mast cells express antigen-presenting molecule, MHC II, and directly activate alloprimed T cells to secrete their signature molecule, IFN γ .

Commercial Relationships Disclosure (Abstract): Gopa Kumar Gopinadhan Nair: Commercial Relationship: Code N (No Commercial Relationship) | James Randolph Hocker: Commercial Relationship: Code N (No Commercial Relationship) | Dimitrios Pollalis: Commercial Relationship: Code N (No Commercial Relationship) | Sun Young Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously reported that elevated levels of GFAP and vimentin in the vitreous humor (VH) from patients with proliferative vitreoretinopathy (PVR) were significantly correlated with PVR severity. To explore how intracellular structural proteins such as GFAP and vimentin, hallmarks of reactive gliosis, were released into the VH during the development of PVR, we performed proteome analysis of exosomes isolated from VH in PVR patients.

Methods: Exosomes were isolated from undiluted VH from patients with PVR (N=4), Macular hole (MH; N=5), or epiretinal membrane (ERM; N=5) using differential ultracentrifugation. We confirmed their size, morphology, and exosome markers using nanoparticle tracking analysis (NTA), transmission electron microscopy (TEM), and an exosome detection antibody array. Tryptic fragment sequencing of exosome contained proteins was performed using liquid chromatography tandem mass spectrometry (LC-MS/MS) and a Thermo Lumos Fusion tribrid Orbitrap mass spectrometer. The pathway analysis of MS data was performed using Ingenuity Pathway Analysis (IPA).

Results: We recovered a range of $1.5\text{--}4.0 \times 10^9$ exosomes per vitreous sample (500 μL), characterized by their size (peak ~ 131 nm), morphology, and positive exosome markers including FLOT1, ICAM, ALIX, EpCAM, ANXA5, TSG101, CD81 and CD63 (Figure 1). We observed a large pool of GFAP and vimentin in VH of PVR patients was contained in the vitreal exosomes. We also identified 627 proteins from vitreal exosomes (533, 431, and 318 in PVR, MH, and ERM, respectively). Of the 94 exosomal proteins related to “reactive gliosis” and “gliosis of retina,” 42 (45%) exosomal proteins were only present in PVR (Figure 2A). The gliosis-related exosomal proteins in PVR were also connected with key pathways related to PVR development, including inflammation, epithelial-mesenchymal transition, tissue healing, cellular proliferation, and growth of connective tissue (Figure 2B).

Conclusions: Our results suggest that vimentin and GFAP were released into the VH in a controlled fashion by exosomes in association with PVR development and the exosome mediated reactive gliosis may play a key role in PVR formation.

ABSTRACT BODY:

Purpose: Assess the presence of anxiety, depression and stress in a group of patients with neuro-ophthalmic disorders, before and during COVID-19 pandemia and compare to a group of patients with retinopathies. Evaluate the relation between visual loss and symptoms intensity in both groups.

Methods: Cross-sectional study with a questionnaire evaluating the relation between psychological characteristics of neuro-ophth. and retinal diseases patients (Depression, Anxiety and Stress Scales-DASS-21) in 16 patients of each group. The neuro-ophthalmic patients were assessed before and during COVID-19 pandemia. The clinical data were collected by chart review and analyzed through the same application.

Results: Within the 16 neuro-ophthalmic patients (12 women/4 men), 10 presented optical neuritis, 4 NAION, 1 Ischemic Stroke and 1 Devic disease. The evaluation before COVID-19 pandemia showed 12 (75%) with depression, 13 (81%) with anxiety and 8 (50%) with stress.

During COVID-19 pandemia the results were the same in 12 patients, one patient presented less anxiety levels and 2 increased stress levels. One patient did not answer.

Within the 16 retinal disease patients (6 women/10 men), 7 presented Diabetic Retinopathy, 6 AMD, and 3 Retinal Detachment. Evaluation showed 12 (75%) with depression, 14 (87,5%) with anxiety and 8 (50%) with stress.

VISUAL ACUITY IN THE AFFECTED EYE AND PSYCHIC SYMPTOMS – NEURO OPTH. PATIENTS

100% of patients (3) with visual acuity(VA) <20/40 in the affected eye presented very severe depression, anxiety and stress.

77% (13) of patients with VA >20/40 in the affected eye 10(80%) presented mild to very severe symptoms.

RETINOPATHY GROUP

13 patients with VA <20/40 in the affected eye, 12(92,3%) presented mild to very severe symptoms.

3 patients with VA >20/40 in the affected eye, 2(66,6%) not presented any symptom and the other presented mild anxiety and depression.

Conclusions: 81.2% of neuro-ophthalmic patients presented symptoms of depression, anxiety and/or stress. There was no differences between the scores before/during the COVID-19 pandemia in this group. Among the retinal disease patients 81,2% presented symptoms of depression, anxiety and/or stress, like neuro-ophthalmic patients. There is a correlation between low visual acuity and the presence of anxiety, stress and depression in both groups, more evident in neuro-phthalmological patients

ABSTRACT BODY:

Purpose: ABCA4-retinopathy (including Stargardt, STGD1) is by far the most common single-gene inherited retinal disease (IRD). Although a plethora of pathogenic coding and an increasing number of noncoding splicing ABCA4 variants are known, a significant fraction of STGD1 cases remains genetically unexplained. It is becoming clear that noncoding variants in ABCA4 represent an emerging source of missing heritability in STGD1. Here we explored one of such regions, the 5' untranslated region (5'UTR) of ABCA4 in IRD cohorts, in search of rare potentially pathogenic cis-regulatory variants.

Methods: Data derived from ~6,900 IRD probands from three cohorts – (i) ERDC4000, a targeted IRD gene sequencing project of the European Retinal Disease Consortium (n=3,200), (ii) ABCA4 locus (re)sequencing of STGD1 cases (n=1,054), and (iii) WGS data from a Genomics England IRD cohort (n=2,615), were mined to search for 5'UTR variants of ABCA4. Candidate variants were evaluated for potential effects on gene regulation by means of computational tools and interrogation of retina-derived epigenomic datasets.

Results: We identified eight rare (MAF < 0.001) ABCA4 5'UTR variants, three of which are ultra-rare (absent from public databases). All variants were heterozygous and found in IRD cases for which an ABCA4-associated disease was suspected, 4 of which are monoallelic for ABCA4 variants. Most variants were predicted to significantly disrupt secondary structure formation and/or affect motifs representing retina-specific transcription factor binding. Furthermore, two variants were found to create an upstream open reading frame in a favorable Kozak sequence context. Validation and segregation analysis of these alleles, and luciferase assays to assess their functional activity are ongoing.

Conclusions: Although often under-recognized, 5'UTR variants are known to influence post-transcriptional and translational regulation. Thus far, no (likely) pathogenic cis-regulatory variants within the 5'UTR of ABCA4 have been reported. Here we present a comprehensive analysis of the ABCA4 5'UTR in ~6,900 IRD cases. Exploring the functional consequences of these eight rare and other putative regulatory noncoding ABCA4 variants will not only

expand our understanding of its cis-regulation but also provide mechanistic insight into STDG1.

ABSTRACT BODY:

Purpose: Photoreceptors are metabolically demanding first-order neurons. The deep capillary plexus sustains synaptic interactions between photoreceptors and horizontal and bipolar cells. Mitochondria produce energy in the form of ATP to support the activities of retinal cells via uptake of oxygen from the retinal vasculature. Prior studies showed mitochondrial migration towards blood sources during retina development (PMID 18048005). The purpose of this study was to determine the distribution of mitochondria in cells participating in the neurovascular unit of the outer plexiform layer in human retina, of relevance to retinal vascular disease.

Methods: Parafoveal retina of a 21-year-old male organ donor was dissected and placed into oxygenated Ames medium and fixed in 4% glutaraldehyde. Vertical sections were acquired using serial block-face electron microscopy at a voxel size of $5 \times 5 \times 50 \text{ nm}^3$ and registered using TrakEM2 (NIH). In the outer plexiform layer surrounding the deep vascular plexus, cone and bipolar cells and within them, individual mitochondria was reconstructed in 3-dimensions using supervised deep-learning enabled segmentation (ORS Dragonfly, Canada).

Results: Complete reconstructions of processes in and near the deep capillary plexus revealed numerous cone bipolar dendrites encircling a vessel. The capillary was also ensheathed by Müller cells without identifiable mitochondria. Mitochondria within bipolar neurons surrounding the capillary exhibited a long and slender morphology extending through the dendritic course encircling the capillary. Reconstructions of outer plexiform layer revealed multiple bipolar cells with mitochondria-filled blind processes lacking synaptic terminals and descending into the Henle fiber layer. Reconstructions of cone pedicles revealed clusters of ovoid mitochondria. Mitochondria counts in cone pedicles adjacent to the capillary were higher (mean 54.4 ± 9.7 , range 66-44, $n=6$) than in pedicles distant from the capillary (35.2 ± 7.75 , 43-27; $n=6$).

Conclusions: Initial findings of this ongoing study suggest cellular-level variations in mitochondrial morphology and distribution in cone pedicles and bipolar dendrites in relation to vascular oxygen sources. Findings are relevant to the cellular basis of underlying mechanisms involved in compromised oxygen supply to the outer plexiform layer in type 3 neovascularization and paracentral acute middle maculopathy.

TITLE: 3D environment and intraocular pressure increase corneal endothelial cell sodium-potassium pump activity.

SESSION TITLE: Corneal endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Anney, M. Thériault, S. Proulx, CHU de Quebec-Université Laval Research Center, section of regenerative medicine; and LOEX Research center of Université Laval, Quebec city, Quebec, CANADA|P. Anney, S. Proulx, Dept. of ophthalmology, Faculty of medicine, Université Laval, Quebec city, Quebec, CANADA|

Commercial Relationships Disclosure (Abstract): Princia Anney: Commercial Relationship: Code N (No Commercial Relationship) | Mathieu Thériault: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Proulx: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The corneal endothelium acts as a barrier and controls the diffusion of fluid and nutrients between the aqueous humor and the stroma through intercellular junctions and the Na⁺/K⁺-ATPase pump. The purpose of this study is to assess the influence of intraocular pressure (IOP) and fluid flow on the functionality of the corneal endothelium.

Methods: Human corneal endothelial cells (CECs) were extracted from donor corneas. Cells were seeded at 2,500 cells/mm² either on plastic (2D cultures) or on devitalized human corneas (3D tissue model) (N=3 pairs). After 7 days of culture, the tissue-engineered corneal endothelia were placed in a corneal bioreactor in the presence of an IOP of 16 mmHg and fluid flow of 5ul/min for one of the 2 corneas. The mate cornea was cultured without IOP. Following 3 days of culture in the bioreactor, the activity of Na⁺/K⁺-ATPase was assessed (ATPase assay, Abcam). Results were relativized using total DNA (Genomic DNA purification Kit, New England Biolabs).

Results: Na⁺/K⁺-ATPase activity of CECs cultured on plastic (2D model) was low (-0,01 ±0.9x10⁻³ nmol/min/uL/ngDNA). However, the same cells cultured on a devitalized stroma (3D model) showed an increase in Na⁺/K⁺-ATPase activity (6.33x10⁻³ ± 3.9x10⁻³ nmol/min/uL/ngDNA), which was further increased by 2.38-fold in the presence of IOP (1.5x10⁻² ±3.1x10⁻³ nmol/min/uL/ngDNA). This increase of Na⁺/K⁺-ATPase activity in the presence of IOP was also observed using 2 other cell populations. Indeed, in 3D models, the activity of the Na⁺/K⁺-ATPase pump following IOP increased 2.0-fold (1.04 x10⁻³ ±1.24x10⁻⁵ nmol/min/uL/ngDNA without IOP and 2.08x10⁻³ ±7.4x10⁻⁵ with IOP); and 2.1-fold (4.40x10⁻⁴ ±6.3x10⁻⁵ nmol/min/uL/ngDNA without IOP to 9.15x10⁻⁴ ±1.4x10⁻⁴ with IOP).

Conclusions: These results indicate that culturing CECs in a 3D environment increases the activity of the sodium-potassium pump, which is further increased by adding IOP. A better understanding of how the in vivo environment influences CEC functionality may help to provide better tissue engineered corneas.

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) is a noninvasive imaging technique that provides a quantitative assessment of the microcirculation of the retina and choroid. OCTA might allow us to expand our understanding on the pathophysiology of glaucoma and its clinical outcomes. The aim of this study is to investigate the association of vessel density, perfusion and flux index in the peripapillary/macular regions with different structural and functional variables at different stages of the disease

Methods: A cross-sectional retrospective study of consecutive cases which underwent a battery of ancillary tests to assess glaucoma patients was performed. A total of 135 eyes from 65 patients (glaucoma suspects and glaucoma patients) were included. Complete medical records and good quality results from a battery of tests were analyzed, including peripapillary and macular OCTA (Cirrus 6000, Carl Zeiss). Multiple functional and structural variables were assessed in different stages of glaucoma. A P-value of ≤ 0.05 was considered as statistically significant.

Results: Patients had a mean age of 63.35 ± 13.44 years. The sample had a greater proportion of female (66.1%), primary open-angle glaucoma (53.8%), and early stages of the disease (63.07%). The mean thickness values of retinal nerve fiber layer (RNFL) and ganglion cell complex (GCC) demonstrated a good correlation ($r \geq 0.5$). All of the mean values of peripapillary perfusion and flux index were statistically significance in each eye ($P = 0.0001$), with exception of flux index in the left eye, in which the correlation was modest ($r > 0.36$) but maintaining a level of statistical significance ($P \leq 0.002$). A statistically significant ($P < 0.005$) but modest correlation ($r \geq 0.34$) was found between CFNR and GCC as well as the variables, macular perfusion and macular vessel density. When the mean values of peripapillary perfusion and flux index were compared between two subgroups of severity (mild glaucoma vs. glaucoma suspect), statistically significant differences were found in both eyes (table 1).

Conclusions: In our study, peripapillary perfusion and flux index are variables derived from OCTA assessment that correlates well with important structural elements at different stages of glaucoma. Well-designed studies could determine the diagnosis and prognosis capacities of such technology in order to improve therapeutic decisions.

TITLE: Cathepsin K Activity in Trabecular Meshwork Outflow Pathway Regulates Intraocular Pressure Homeostasis.

SESSION TITLE: Aqueous humor, trabecular meshwork, and ciliary body

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Vuda, S.A. Ghag, P.P. Pattabiraman, Ophthalmology, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Sai Supriya Vuda: Commercial Relationship: Code N (No Commercial Relationship) | Sachin Ghag: Commercial Relationship: Code N (No Commercial Relationship) | Padmanabhan Pattabiraman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A sustained increase in intraocular pressure (IOP) is a major risk factor for primary-open angle glaucoma (POAG). Extracellular matrix (ECM) accumulation in the trabecular meshwork (TM) outflow pathway results in IOP elevation. Among the major ECM components in the TM outflow pathway, increased accumulation of collagen 1A is found in POAG. Cathepsin K (CTSK) is a lysosomal protease and a potent collagenase known to degrade helical and non-helical regions of collagen 1A. We studied the role of CTSK activity on ECM modulation in the TM outflow pathway and on IOP.

Methods: Porcine TM (PTM) cells were isolated, cultured and were treated with 10uM Balicatib, a potent cell-permeable CTSK activity inhibitor, for 1, 4, 8, 16, 24hrs to study time-dependent inhibition of CTSK activation and assessed for its effect on ECM modulation using immunoblotting. Porcine anterior segment organ culture perfusion was used to assess the effect of Balicatib on - a) IOP, b) changes in tissue distribution and expression of ECM like collagen, fibronectin, and elastin using immunofluorescence and immunoblotting. Student's t-test was used for statistical analyses and results were significant if $p < 0.05$ with a sample size of $n=3-9$ in each experiment.

Results: Balicatib treated PTM cells decreased CTSK activity by 80%. Time-dependent balicatib treatment in porcine TM cells showed no changes in active CTSK but a significant increase in pro-CTSK ($p=0.001$) as well as in ECM proteins like COL1A ($p=0.004$), FN ($p=0.009$). Perfusion of balicatib in the porcine anterior segment perfusion cultures increased IOP nearly two-fold ($n=5$, $p < 0.05$). TM isolated from perfused globes showed increased elastin protein expression by nearly seven-fold ($n=2$, $p=0.023$). Immunofluorescence data showed an increase in collagen 1A and fibronectin distribution in the TM outflow pathway

Conclusions: Firstly, this proof of concept study shows that directly perturbing the activity or function of an ECM degrading enzyme-like CTSK increases intraocular pressure by altering the ECM degradation. Secondly, we demonstrate that CTSK is a critical regulator of IOP homeostasis. This study also reinforces the fact that ECM in the outflow pathway is very important for maintaining IOP. Finally, activation of CTSK is an attractive therapeutic strategy to lower IOP

ABSTRACT BODY:

Purpose: To identify the cellular origins of vascular endothelial growth factors (VEGF) and potential new therapeutic targets for ocular angiogenic disorders, we performed single-cell transcriptomic analysis on retinal, retinal pigment epithelium (RPE), and choroidal tissues from mouse eyes after laser-induced choroidal neovascularization (CNV).

Methods: Eight to ten laser CNV spots were created in wild-type adult C57/BL6 mouse eyes. One week after laser injury, retinal and RPE-choroidal tissues were dissected from the CNV lesions from 9 animals for single-cell preparation. Single-cell RNA sequencing libraries were prepared using Chromium technology, and barcoded libraries were pooled and sequenced at 300 million reads per library using the Illumina HiSeq 4000 platform.

Results: A total of 16,321 cells (14,966 from retina and 1,355 from RPE-choroid) were recovered and approximately 1200 gene were identified from each cell. Nine major transcriptionally distinct cell populations were identified from unsupervised clustering (Figure 1), including rod/cone photoreceptors, cholinergic/GABAergic/glycinergic amacrine cells, rod/cone bipolar cells, and RPE. One major cluster was further subdivided into Muller glia, horizontal, retinal ganglion cells, endothelial cells, stromal cells, and melanocytes. Among these cell types, we found that VEGFa and VEGFb were expressed in all major cell types except rod and cone photoreceptors, with the highest levels of expression found in Muller glia and RPEs. By contrast, VEGFc and VEGFd were minimally expressed in all cell types.

Conclusions: Single-cell transcriptomic analysis demonstrate differential expression of VEGF family members across different retinal and choroidal cell types after laser-induced CNV in mouse eyes, providing critical guidance for cell-specific targeting of anti-angiogenesis retinal gene therapies. Analyzing differentially expressed genes may help identify other novel therapeutic targets for ocular angiogenic disorders.

TITLE: Establishing the role of dietary lipids in meibogenesis

SESSION TITLE: Cornea, Conjunctiva, Lacrimal gland and Meibomian gland

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Yuksel, A. Wilkerson, I.A. Butovich, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|I.A. Butovich, Graduate School of Biomedical Sciences, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Seher Yuksel: Commercial Relationship: Code N (No Commercial Relationship) | Amber Wilkerson: Commercial Relationship: Code N (No Commercial Relationship) | Igor Butovich: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Meibomian glands (MG) play a vital role in ocular physiology producing meibum – a complex mixture of cholesterol (Chl), Chl esters (CE), triacylglycerols (TAG), and other classes of lipids, in a process termed meibogenesis. The purpose of this study was to establish the role of dietary Chl and TAG in meibogenesis, and determine if dietary lipids can be directly incorporated in meibum without undergoing deep anabolic/catabolic transformations first.

Methods: Wild type C57Bl/6J mice (n=16) were gavaged daily with Chl-2,2,3,4,4,6-d₆ (d₆-Chl) and triolein-1,2,3,7,8-¹³C₅ (¹³C₅-TO) dissolved in a vehicle. At Days 0, 7, 14, and 28 of gavaging, the mice were euthanized (4 mice at each time point) and their tarsal plates, small intestine, liver, plasma, and feces specimens were collected. Then, lipids were extracted from all tissue samples and analyzed using ultra-high-performance liquid chromatography/high-resolution mass spectrometry to determine the fate of the tracers in the tissues.

Results: We established that ¹³C₅-TO and its metabolites could be detected in the small intestine, plasma and liver in diminishing quantities, but not in the feces or meibum even after 4 weeks of gavaging. Our results demonstrate that ¹³C₅-TO underwent deep catabolic transformations and could not be directly incorporated into meibum neither as an intact TAG, nor as its metabolized products (diacylglycerols, monoacylglycerols, free fatty acids, or their esters with other compounds). On the other hand, d₆-Chl was detected in all tested tissues, including meibum. Moreover, in MG d₆-Chl underwent successful esterification into long- and ultra-long-chain CE typical of Meibomian lipids. Importantly, enrichment studies demonstrated that d₆-Chl could be accumulated in meibum in excessive quantities suggesting that increased levels of Chl in blood can increase levels of Chl in MG and meibum.

Conclusions: Our experiments demonstrated that dietary Chl may directly affect Chl and CE homeostasis in MG, while dietary TAG seem to be extensively catabolized in the small intestine, liver, and blood before reaching MG, and, thus, could not directly influence the outcome of meibogenesis.

ABSTRACT BODY:

Purpose: Induced pluripotent stem cell (iPSC)-derived retinal progenitor cells are a promising cell type for restoring vision in patients with advanced retinal degeneration. Traditional bolus cell suspension injection often results in poor cell survival and limited synaptic integration following transplantation. To address this problem, we have focused our attention on tissue engineering to reduce post-transplant cell loss while promoting cellular alignment and proper packing density. The purpose of this study was to evaluate local and systemic toxicity following transplantation of human iPSC-derived retinal cell grafts in an immune suppressed rat model.

Methods: Polycaprolactone (PCL) scaffolds were generated by injecting a prepolymer solution into a photopolymerization chamber containing a photomask with 50um spots separated at 25um intervals. Scaffolds were seeded with iPSC-derived retinal progenitor cells generated from 1 of 5 patients. 1mm punches were transplanted into the subretinal space of immune suppressed RNU^{-/-} rats (N=150) followed by necropsy with complete histopathology, clinical chemistry and hematology performed at 1-, 3-, and 6-months post-transplantation.

Results: Two weeks following scaffold seeding, iPSC-derived retinal precursor cells expressing recoverin and OTX2 were densely packed into vertical columns throughout the scaffold, recapitulating the outer nuclear layer of the retina. Following subretinal transplantation in RNU^{-/-} rats, retinal reattachment was noted in all eyes. No evidence of treatment induced retinal or systemic toxicity/tumorigenicity was detected by gross or histopathologic evaluation. No significant difference in mean body and/or organ weight was detected between control vs treatment groups at any of the time points evaluated (P>0.05). Finally, no significant treatment induced adverse events were detected via hematology or clinical chemistry (P>0.05).

Conclusions: We successfully developed a high-throughput platform for evaluating local and systemic toxicity following subretinal transplantation of patient derived retinal cell grafts.

ABSTRACT BODY:

Purpose: To evaluate the synergetic impact of bright light (BL) and optical refocus (RF) on myopia development in a chicken model of lens induced myopia (LIM).

Methods: One day old chicks (Golden Comet/White Leghorn) were assigned to 7 groups of 13 chicks each. Chicks were housed for 7 days in a temperature-controlled enclosure under a 12/12h light-dark cycle (150 lux). Myopia was induced randomly in one eye from the day of hatching (BSL) until day 7 post-hatching (D7) using -10D lenses. The fellow eye was used as uncovered control. Six groups were exposed every day to continuous 4 hours (h) or 6h of either BL (15,000 lux); RF (removal of -10D lens); or both (BL+RF). One group served as control without BL or RF interventions. On BSL and D7, ocular axial length (AL), refractive status and choroid thickness were measured using ultrasonography, infra-red refractometry and optical coherence tomography, respectively. Outcome measures were expressed as the difference between the experimental and control eyes in each animal, and compared between groups and across days using a 2-way repeated measures ANOVA.

Results: By D7, LIM led to significant increases in AL (0.36 ± 0.15 mm) and myopic refraction (-8.51 ± 1.35 D), as well as choroid thinning (-62.1 ± 61.1 μ m) in the control group (all, $P < 0.001$). Both 4h and 6h of BL or RF reduced axial elongation and myopic refraction induced by LIM (Fig. 1) while only 6h of BL or RF prevented choroid thinning (Fig. 1F; $P < 0.05$). RF was more effective than BL in preventing axial elongation and myopic refraction development (Fig 1). BL+RF (4h) was less effective in slowing LIM compared to RF ($P = 0.04$; Fig. 1B), while 6h of BL+RF stopped axial elongation, refractive error development and choroid thinning induced by LIM, compared to BL ($P < 0.001$) and RF ($P = 0.03$).

Conclusions: Daily exposure to 4 or 6 hours of BL or RF slows LIM in chickens. Combined with RF, only 6h of BL can stop LIM. The synergetic effect of BL and RF is dependent on the duration of the intervention.

ABSTRACT BODY:

Purpose: To examine whether ischemic retinal ganglion cells (RGC) will be salvaged from apoptosis by co-culture with adipose-derived mesenchymal stem cells (ADSC) by direct contact or by paracrine activity.

Methods: Retinas of wild type C57Bl/6 mice were harvested. Deprived of arterial oxygen supply, retinas were cultured as ex vivo organotypic cultures on an insert membrane. First, number of surviving RGC was evaluated at different time points (T0, T48, T72 hours) by Brn3a staining and confocal microscopy. Then, the therapeutic potential of ADSC on ischemic retinas was evaluated either by co-culture of ADSC with organotypic retinas with direct contact of ADSC (ADSC seeded above the retina) or by a co culture of ADSC with organotypic retinas allowing a paracrine activity of ADSC (ADSC seeded on tissue culture plate below the retina) (n=7). Retinas were flat-mounted and the number of surviving RGC was assessed using Brn3a staining and confocal microscopy. We also examined the cytokine secretion profile of ADSC related to their paracrine effect on ischemic retina by analyzing the protein expression in ADSC-conditioned medium using protein array.

Results: We demonstrated a time-dependent decrease in number of viable RGC in non-treated ischemic retinas evident by Brn3a+ staining. When co cultured with ADSC, the number of surviving RGC was significantly higher in treatment groups compared to controls of retinas treated with standard medium (Brn3a+ cells treated with ADSCs seeded above the retina = 29 ± 10.9 , $p < 0.001$, Brn3a+ cells treated with ADSCs seeded below the retina = 29 ± 7.2 , $p = 0.001$, controls = 4.5 ± 2.5 SD). Evaluating ADSCs cytokines secretion profile, we showed secretion of anti apoptotic and pro- proliferative cytokines (threshold > 1.4).

Conclusions: Our results demonstrate that transplantation of ADSC in a co culture with organotypic ischemic retinas significantly improved recovery of the RGC. The effect was similar when ADSC were seeded above and below the retina suggesting the beneficial effect seen was related to paracrine activity of ADSC rather than to direct contact of ADSC. These data correlated with secretion profile of ADSCs anti-apoptotic and pro proliferative cytokines. In summary, ADSC could direct future development of autologous cell therapy modalities to repair ischemic retinal and/or optic nerve damage.

TITLE: Real-Time OCT Image Denoising Using Self-Fusion Neural Network

SESSION TITLE: Image processing and interpretation

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Rico-Jimenez, Y. Tao, Biomedical Engineering, Vanderbilt University, Nashville, Tennessee, UNITED STATES|D. Hu, I. Oguz, Computer Science and Computer Engineering, Vanderbilt University, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jose Rico-Jimenez: Commercial Relationship: Code N (No Commercial Relationship) | Dewei Hu: Commercial Relationship: Code N (No Commercial Relationship) | Ipek Oguz: Commercial Relationship: Code N (No Commercial Relationship) | Yuankai Tao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) imaging has benefitted ophthalmic diagnostics by enabling depth-resolved volumetric imaging of ocular structures. Inherent speckle noise degrades the OCT image quality complicating the identification of anatomical features and pathologic features. Frame-averaging is a ubiquitous method for increasing signal-to-noise ratio (SNR), however, the need to acquire multiple repeated frames increases the imaging time, introduces motion artifacts, and adds to potential patient discomfort. We recently introduced a method called self-fusion, which reduces speckle noise and enhances OCT SNR using adjacent frames, thus reducing the need to repeated image the same location and extending imaging time. Uniquely, self-fusion integrates image similarity metrics between adjacent frames to maintain lateral resolution. We have trained a convolutional neural network to offset the computational overhead of self-fusion and, here, present a framework for performing self-fusion in real-time.

Methods: The neural network was designed in PyTorch based on the U-net architecture. The training and validation sets were first processed with using self-fusion to yield ground truth images and then both the noisy and self-fused images were fed into the training algorithm to fit the model and optimize the hyperparameters (Fig. 1A). An independent test set was used for unbiased evaluation of a final model. Since the data acquisition software (DAQ) was written in C++, the pretrained model was exported to a file to interface with the DAQ (Figure 1B). A self-fusion network that was pretrained to fuse 3 frames was implemented to further increase display rates.

Results: Figure 1C shows a noisy OCT B-scan, a 7-frame averaged image, and a 3-frame self-fused image. There is a clear gain in peak SNR in the 3-frame self-fused image (20.2 dB) over both the raw and 7-frame averaged image (13.8 dB).

Conclusions: This approach delivers a fast and robust OCT denoising alternative to frame-averaging without the need for repeated image acquisition. Real-time self-fusion image enhancement will enable improved localization of OCT field-of-view relative to features-of-interest and improved sensitivity for anatomic features of disease.

TITLE: Generation of an in vitro retinal ganglion cell (RGC) model by expressing the POU domain, class 4, transcription factor 2 (Pou4f2) gene in R28 retinal precursor cells

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. White, T. Hollingsworth, M.M. Jablonski, Ophthalmology, The University of Tennessee Health Science Center College of Medicine, Memphis, Tennessee, UNITED STATES|

Commercial Relationships Disclosure (Abstract): William White: Commercial Relationship: Code N (No Commercial Relationship) | TJ Hollingsworth: Commercial Relationship: Code N (No Commercial Relationship) | Monica Jablonski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is an unmet need for in vitro RGC models to better understand the underlying cellular pathogenesis of glaucoma. While there has been success with enriching for RGCs from intact retinas, the procedure is technically complex and the resulting RGCs are viable only for a short period of time (roughly 2 weeks). We hypothesized that Lentiviral transduction of R28 retinal precursor cells with Pou4f2, a transcription factor associated with RGCs, would drive R28 cells toward an RGC fate. The goal of this study was to generate an in vitro RGC model using R28 retinal precursor cells that constitutively express Pou4f2.

Methods: R28 cells were transduced using a Lentivirus carrying the Pou4f2 gene fused to green fluorescent protein or mCherry. After antibiotic selection using puromycin, the Pou4f2-transduced R28 cells were cultured for 14 days in Neurobasal Plus Medium containing B27 supplement. The cells were observed using confocal microscopy to verify Pou4f2 expression and neuronal morphology. Immunocytochemistry was performed to detect RGC markers. Non-transduced R28 cells cultured in supplemented Dulbecco's Modified Eagle Medium served as the control for all experiments.

Results: Confocal microscopy of Pou4f2-transduced R28 cells confirmed the presence of the fluorescent fusion protein, the presence of axonal projections, and the formation of synaptic junctions. The expression and localization of at least 10 RGC and neuronal markers were confirmed in the transduced R28 cells including: β -tubulin 3 (TUBB3); POU domain, class 4, transcription factor 1 (POU4F1); Islet 1 transcription factor (ISL1); very long chain enoyl-CoA reductase (TECR); microtubule-associated proteins 1 and 2 (MAP-1 and MAP-2); RNA binding protein with multiple splicing (RBPMS); synaptosomal-associated protein, 25kDa (SNAP25); synaptotagmin 11 (SYT11); and Thy 1.1 cell surface antigen.

Conclusions: Pou4f2-expressing R28 cells demonstrate neuronal morphology and protein expression patterns similar to that of in situ RGCs, indicating that these cells can differentiate into RGC-like neurons. Thus, the Pou4f2 R28 cells show strong potential as a new in vitro RGC model.

ABSTRACT BODY:

Purpose: Cone-rod degeneration is a prominent feature of neuronal ceroid lipofuscinosis Type 2 (CLN2) disease. While bilateral progressive, symmetrical loss of central retinal thickness (CRT) has been well-characterized, other OCT anatomical biomarkers have not been described in as much detail. This study was therefore undertaken to further explore progression of anatomical retinal changes in CLN2 disease.

Methods: SD-OCT macular cube scans were collected in 31 subjects, ages 5 to 157 months, with classic CLN2 disease. Horizontal B-scans through the fovea from one eye per subject were segmented manually to determine thickness of six retinal parameters: full retinal thickness (FRT), retinal nerve fiber layer, inner nuclear layer, outer nuclear layer (ONL), photoreceptor (PR) plus retinal pigment epithelium (RPE), and outer segment plus RPE (OS+RPE). Ellipsoid zone (EZ) integrity was also examined. FRT was measured in standard Early Treatment Diabetic Retinopathy Study (ETDRS) sectors. In addition to cross-sectional analysis, longitudinal data for individual patients were analyzed when available.

Results: CRT loss correlated to disease severity and Weill Cornell Late Infantile Neuronal Ceroid Lipofuscinosis Severity Scores. A linear relationship between loss of CRT and foveal ONL thickness confirmed the connection between PR loss and disease progression. Retinal degeneration in the macula showed a predictable pattern on horizontal scans, with relative foveal sparing and parafoveal involvement in early disease, followed by more profound foveal degeneration with additional ONL thinning beyond the central retina later in the disease. Focal EZ changes in the macula were an early signal of PR degeneration, progressing to more extensive EZ loss in later stages. PR degeneration in OS+RPE preceded ONL loss. Marked FRT reduction was also observed in ETDRS para- and peri-central sectors in late stages. Analyses of longitudinal data confirmed these observations.

Conclusions: CRT is a useful anatomical biomarker in CLN2 until maximal foveal thinning has occurred late in the disease, when para- and peri-central sector changes become more significant for understanding disease progression and treatment efficacy. Further studies using en face images will further clarify progression of retinal degeneration in CLN2 disease. Additional longitudinal data are needed to characterize the pattern and progression of EZ loss in CLN2 disease.

ABSTRACT BODY:

Purpose: To describe the feasibility of ellipsoid zone quantification on spectral domain optical coherence tomography in a clinical trial assessing the treatment of retinitis pigmentosa (RP).

Methods: A customized OCT platform using logic based identification of OCT layers was utilized. 97 line macular spectral domain OCT scans (Heidelberg) obtained at baseline visits on 25 patients were analyzed using this software. OCT layers were then identified and manually corrected by trained graders. Ellipsoid zone (EZ) metrics were then calculated including thickness and volume. EZ thickness maps were also created.

Results: 29 eyes from 29 subjects with advanced RP (mean BCVA 1.02logMAR or 34 letters; mean age 46) were included. All eyes were successfully mapped and graded. Logic based identification successfully identified more normal areas of EZ, but required manual correction often in areas of severe EZ loss. The mean central subfield thickness was 206.53 µm. The mean EZ-RPE central subfield thickness was 11.35 µm (range 0.76 – 37.04 µm) Mean EZ-RPE volumetric measures of the central subfield, mid subfield and macula were 0.0089 mm³, 0.025 mm³ and 0.087 mm³ respectively. En face zero micron and less than 20 micron EZ-RPE thickness coverage maps of the macula were created. The mean zero micron coverage within the macula was 84.36% (range 59-98%); the mean less than 20 micron thickness was 96% (range 84-100%).

Conclusions: This study provides important insight into the use of OCT EZ-RPE analysis for advanced RP. EZ-RPE thickness and volume was measurable, but required manual correction. In contrast to normal OCTs (0.87% mean attenuation with a mean of 0.12% total attenuation), significant EZ attenuation occurred in RP subjects with marked loss noted beyond the midsubfield (central 2 mm) area. OCT analysis of the EZ layer provides important information about the severity of photoreceptor loss in retinitis pigmentosa.

Commercial Relationships Disclosure (Abstract): Sudha Swamynathan: Commercial Relationship(s);Patent number: US 9,731,014:Code P (Patent) | Gregory Campbell: Commercial Relationship: Code N (No Commercial Relationship) | Anil Tiwari: Commercial Relationship: Code N (No Commercial Relationship) | Shivalingappa Swamynathan: Commercial Relationship(s);Patent number: US 9,731,014:Code P (Patent)

ABSTRACT BODY:

Purpose: Previously we demonstrated that the Secreted Ly-6/uPAR Related Protein-1 (SLURP1), abundantly expressed in the cornea and secreted to the tear film, is an anti-proliferative and pro-differentiative protein. Here we have studied the mechanistic basis for its anti-proliferative effect on the Human Corneal Limbal Epithelial (HCLE) cells.

Methods: HCLE cells were stably transfected with pCMV-SLURP1 and two different clones overexpressing SLURP1 were selected for the present studies. The effect of SLURP1 overexpression on HCLE cell cycle progression was quantified by flow cytometry. The expression, quantity and subcellular localization of cyclins, cyclin-dependent kinases (CDKs) and cyclin inhibitors were determined by QPCR, immunoblots, and immunofluorescent staining, respectively.

Results: Flow cytometry revealed that the percent of cells in G0/G1 phase is significantly higher in SLURP1-expressing HCLE clones (73.8% and 81.6%) compared with the WT HCLE (63%). QPCR revealed an upregulation of p21 (1.1- and 2-fold), and downregulation of Cyclin-B1 (0.66- and 0.68-fold), and Cyclin D2 (0.48- and 0.64-fold) in HCLE-SLURP1 clones relative to the WT control. Immunoblots revealed elevated expression of cell cycle regulators p15 (1.5- and 1.6-fold), lower CDK-4 (0.9- and 0.57-fold) and cyclin-E (0.93- and 0.77-fold) in HCLE-SLURP1 relative to WT HCLE cells. HCLE-SLURP1 clone with a higher level of SLURP1 expression displayed decreased CDK6 (69% of the WT) and Cyclin-D1/D2 (60% of the WT) expression. Immunofluorescent staining revealed an increased cytoplasmic and decreased nuclear localization of CDK-2, -4 and -6 in HCLE-SLURP1 cells compared with the WT.

Conclusions: SLURP1 serves as an anti-proliferative protein by promoting the expression of cell cycle inhibitors p15 and p21 and suppressing the expression of cyclins-D1/D2 and -E, and CDK-4 and -6. Further cell cycle regulation is facilitated by altered sub-cellular localization of CDKs in the cytoplasm of SLURP1-overexpressing cells.

TITLE: Single Cell Transcriptomics Identifies Distinct Choroid Cell Populations Involved in Visually Guided Eye Growth

SESSION TITLE: Role of choroid and sclera in myopia development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.A. Summers, E. Martinez Cano, R. Sharp, K. Jones, Cell Biology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jody Summers: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Martinez Cano: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Sharp: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Jones: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many studies suggest that the choroid participates in regulation of postnatal ocular growth and refractive development. This study was designed to characterize the cell populations in the chick choroid and compare gene expression changes in these cell populations during the recovery from induced myopia.

Methods: Choroids were isolated from normal chick eyes as well as from treated and control eyes of chicks reared for 10 days with occluders to induce form deprivation myopia, followed by a recovery period of 24 hrs. Single cells were isolated, labelled with ethidium homodimer III and calcein-AM to fluorescently label dead and living cells, respectively, and living cells were sorted using flow cytometry. 50,000 cells from three separate pools of control and treated eyes were used to generate transcriptome libraries using the 10x genomics Chromium Controller and Single Cell 3' library. Single Cell RNA-Seq data was processed using Cellranger and analyzed in R using the Seurat package.

Results: UMAP clustering analysis identified 24 distinct cell clusters in all chick choroids. 7 clusters were identified as fibroblasts based on Col1a gene expression; 6 clusters were identified as endothelial cells based on CDH5, PECAM1, and VWF expression; 4 clusters were CD45+ immune cells and 2 clusters were identified as melanocytes based on PMEL expression. Significant changes in gene expression between control and treated choroids were identified in 17 cell clusters. The majority of significant gene expression changes were relatively small (< 2 fold), however the gene NOV/CCN3 was significantly overexpressed in two fibroblast clusters (\uparrow 3.45 and \uparrow 2.52, fold over control cells). The highest gene expression changes were identified in a rare cell population (\approx 0.26% of total choroidal cells) (C4A, \uparrow 12 fold; CST3, \uparrow 8 fold; CTSV, \uparrow 9 fold; and TMSB4X, \downarrow 0.6 fold). This rare cell population expressed high levels of GAL, CHRNA3, VIP, ELAVL4, and SCN9A, suggestive of a neuronal cell population.

Conclusions: Several populations of choroidal cells, representing 95% of total choroidal cells exhibit significant changes in gene expression in response to visual stimuli. The large changes in gene expression identified in a rare neuronal cell population is suggestive of a role for intrinsic choroidal neurons in the choroidal recovery response.

ABSTRACT BODY:

Purpose: The main risk factor for the development and progression of glaucoma is elevated intraocular pressure (IOP); thus, the mainstay of glaucoma treatment is to reduce IOP to a safe level. Measurement of IOP is crucial to the diagnosis and management of glaucoma. Alternative methods to measure IOP, as with the water-drinking test (WDT) and a 24-h profile of IOP (24HP), have been reported as useful ways to determine pressure control. The purpose of this study was to determine if a combination of a WDT and a 24HP of IOP with the device Icare Home, is a useful approach to make clinical decisions in regards of glaucoma management.

Methods: A retrospective study of 20 consecutive glaucoma patients who underwent an expanded profile of IOP (EPIOP) consisting of a combination of traditional WDT and a 24HP of IOP with Icare Home. IOP results for each test per eye were analyzed. Central corneal thickness, clinical examination data, including prior applanation IOP, were also assessed. The clinical impact for each test interpretation was determined.

Results: Patients had a mean age of 53.6 ± 14.3 years. A larger proportion of female patients (75%), with a primary open-angle glaucoma diagnosis (65%), and usage of antiglaucoma medication (55%) were observed. Mean previous highest IOP values were 14.4 ± 3.63 mm Hg (RE) and 14.1 ± 3.7 mm Hg (LE). Mean CCT values were 541.9 ± 35.9 microns (RE) and 540.7 ± 36.8 (LE). WDT abnormality was found in 60% of the RE and 65% of the LE. Mean IOP fluctuation was significantly different in both eyes (10.50 ± 4.55 mm Hg, RE; 11.05 ± 4.81 mm Hg; $P = 0.0001$). Clinically significant results with the 24HP with Icare Home was obtained in 80% of both eyes. Integrated information with results derived from both tests supported the decision of starting antiglaucoma medications in 12 eyes, adding medications in 6 eyes, indicating SLT in 4 eyes, performing peripheral iridotomy in 2 eyes, and re-treating 1 eye with SLT.

Conclusions: An EPIOP (combined approach of WDT and a 24HP of IOP with the Icare Home device) seems to be a useful, although time-consuming, way to support the clinicians decision-making process in the management of glaucoma.

ABSTRACT BODY:

Purpose: We recently reported the presence of SARS-CoV-2 RNA, Spike, and Envelope proteins in the corneas of COVID-19 donors. However, the presence of viral RNA and antigens does not necessarily equate to infection. In this study, using RNA-seq of COVID-19 corneal tissue, and SARS-CoV-2 infection of human corneal epithelial cultures, we now examined whether SARS-CoV-2 could replicate in the cornea and elicits an innate immune response.

Methods: Eyes from healthy and COVID-19 donors were from the Eversight eye bank. The corneal tissue was used for IHC detection of SARS-CoV-2 by RNA-FISH. In another experiment, total RNA was extracted from corneas for RNA-seq analysis to identify genes/ pathways altered by infection. In vitro studies were performed by infecting primary human corneal epithelial cells (HCECs) from normal and diabetic donor corneas with SARS-CoV-2. Bioinformatics analysis was performed to determine the differential gene expression. qPCR was used to assess the expression of innate inflammatory and antiviral genes and to confirm RNA-seq data in corneal tissue and cells.

Results: RNA-FISH analysis showed the presence of both positive and negative strands of SARS-CoV-2 viral RNA in the epithelium of COVID-19 donor corneas. This coincided with infiltration of CD45+ cells in the stroma and induced expression of inflammatory (IL-6, IL-1 β) and antiviral (ISG15, OAS2) genes. RNA-seq analysis revealed significant upregulation of genes involved in the viral response, inflammation, and injury along with induction of lncRNA XIST and TSIX involved in modulation of the immune response. The primary HCECs were found permissive to SARS-CoV-2 infection, as evidenced by increase viral replication which peaked at day 3 p.i. along with an induction of p-STAT1. Interestingly, HCECs from diabetic cornea had higher viral RNA on day 1 p.i. compared to non-diabetic cells. SARS-CoV-2 infected HCECs also exhibited induced expression of antiviral innate response genes, which was elevated in diabetic donor cornea cells.

Conclusions: Our study confirms the presence of replicating SARS-CoV-2 viral RNA and antigen in the cornea of COVID-19 affected donors resulting in the production of inflammatory mediators and recruitment of CD45+ immune cells to the cornea. Moreover, HCECs from diabetic corneas had increased SARS-CoV-2 replication and immune response, suggesting that diabetes is a potential risk for ocular transmission of COVID-19.

ABSTRACT BODY:

Purpose: Patients with Alport syndrome (AS) can display a range of ocular abnormalities with variable effects on visual function and quality of life. We report results from the National Eye Institute 25 item Visual Functioning Questionnaire (NEI-VFQ25) in a cohort of AS patients.

Methods: As part of a wider phenotyping study patients with AS undertook the NEI-VFQ25. This questionnaire is a widely used and validated shortened version of the NEI 51-item visual function questionnaire. It is multidimensional and yields a total score and several subscales. Here, the total score was analysed. Where possible, patients were also contacted some years after their initial visit, and the questionnaire was repeated to explore stability. Particular note was made of those patients who underwent lens exchange surgery for anterior lenticonus.

Results: 32 patients with AS were evaluated: 19 were males with X-linked AS; 8 were females with X-linked Alport variants; 5 had autosomal recessive AS. Mean (SD) age was 36 (16) years. Mean (SD) VFQ25 for the cohort was 84.9 (13.9). The lowest score was 35.4 in a patient with severe recurrent corneal erosions. Five patients had significant anterior lenticonus, and were listed for surgery; these patients had a mean (SD) score of 68.9 (11.9), which was significantly lower than the overall mean ($p < 0.05$). Eighteen patients completed the VFQ25 questionnaire on a second occasion after a median (and mean) period of 6 years. For this cohort, there was no significant change in VFQ25 score. However, in a subgroup of 4 patients who underwent surgery for lenticonus and also completed the questionnaire on a second occasion, there was a significant increase in scores ($p < 0.05$), with initial and final mean (SD) scores of 68.5 (13.7) and 94.1 (4.9) respectively.

Conclusions: We present average VFQ25 scores from a cohort of over 30 patients with Alport syndrome. For 18 patients who completed the questionnaire on a second occasion following a median interval of 6 years, scores were largely stable. The questionnaire appeared to be sufficiently sensitive to show an adverse effect of lenticonus on vision-related quality of life, and a noticeable improvement following surgery.

TITLE: Reconstruction of high-resolution OCT angiograms of retinal intermediate and deep capillary plexuses using deep learning

SESSION TITLE: Deep learning for classification and segmentation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Gao, T.T. Hormel, J. Wang, Y. Guo, S. Bailey, T.S. Hwang, Y. Jia, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Min Gao: Commercial Relationship: Code N (No Commercial Relationship) | Tristan Hormel: Commercial Relationship: Code N (No Commercial Relationship) | Jie Wang: Commercial Relationship: Code N (No Commercial Relationship) | Yukun Guo: Commercial Relationship: Code N (No Commercial Relationship) | Steven Bailey: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Hwang: Commercial Relationship: Code N (No Commercial Relationship) | Yali Jia: Commercial Relationship(s);Optovue:Code F (Financial Support);Optovue:Code P (Patent)

ABSTRACT BODY:

Purpose: We propose to use deep learning to reconstruct flow signal from under-sampled 6×6-mm optical coherence tomographic angiography (OCTA) images of the intermediate capillary plexus (ICP) and deep capillary plexus (DCP).

Methods: 6×6-mm macular scans with a 400×400 A-line sampling density and 3×3-mm scans with a 304×304 A-line sampling density were acquired on one or both eyes of 180 participants (including 230 eyes with diabetic retinopathy (DR) and 44 healthy controls) using a 70-kHz commercial OCT system (RTVue-XR; Optovue, Inc.). Projection-resolved OCTA algorithm was applied to remove projection artifacts in voxel. ICP and DCP angiograms were generated by maximum projection of the OCTA signal within the relevant plexus. We proposed a deep-learning-based method, dubbed “deep capillary angiograms reconstruction network” (DCARnet), to reconstruct 6×6-mm high-resolution ICP and DCP en face OCTA images from sparsely-sampled, low-resolution scans of the same area. DCARnet takes registered 3×3-mm ICP and DCP angiograms with proper sampling density as the ground truth reference. Same network can also be applied on 3×3-mm angiograms. We evaluated the reconstructed 3×3- and 6×6-mm angiograms based on vessel connectivity, false flow signal (flow signal erroneously generated from background), and the noise intensity in the foveal avascular zone (FAZ).

Results: Compared to the originals, the angiograms reconstructed by DCARnet significantly reduced noise intensity (ICP, 7.38 ± 25.22 , $p < 0.001$; DCP, 11.20 ± 22.52 , $p < 0.001$), improved vascular connectivity (ICP, 0.95 ± 0.01 , $p < 0.001$; DCP, 0.96 ± 0.01 , $p < 0.001$), and did not generate false flow signal at the level of noise intensity in normal FAZ. DCARnet not only enhanced the image quality of 6×6-mm ICP and DCP angiograms, but also reduced noise and improved connectivity in 3×3-mm ICP and DCP angiograms. Furthermore, DCARnet preserves the appearance of the dilated vessels in the reconstructed angiograms.

Conclusions: DCARnet can reconstruct high-resolution ICP and DCP angiograms from low-definition 6×6-mm en face OCTA images. The enhanced angiograms may improve characterization of biomarkers such as non-perfusion area and vessel density.

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) qualitatively assesses the microcirculation within the optic nerve and macula. Vascular density quantification is also measured with this technique. Long-standing ocular hypertension can lead to a varied chronic structural change including the capillary bed. Although a decreased intraocular pressure (IOP) due to antiglaucoma therapy may improve perfusion of the optic nerve, it would be desirable to know if an abrupt reduction in IOP could have an effect on the microcirculation. The objective of this study is to investigate the effect of two clinical settings of abrupt IOP reduction on OCTA variables in the ON and the macula.

Methods: Eighteen eyes of 18 non-consecutive patients which underwent either a bleb needling (BN) procedure or post-trabeculectomy digital compression (DC) were evaluated by applanation tonometry, ON and macula OCT, and OCTA. Baseline measurements were followed by any one of the ocular hypotensive maneuvers. The studied variables were cup to disc (CD) ratio, thickness of retinal nerve fiber layer (RNFL), thickness of the ganglion cell complex (GCC), and perfusion (ONP) and flux index (ONFI) of the optic nerve, as well as perfusion (MP) and vessel density (MVD) of the macular area.

Results: Patients included in the study (10 males, 8 females) had a mean age of 61.9 ± 17.7 years. A post-procedure IOP (9.4 ± 4.7 mmHg) was significantly less ($p=0.0001$) than before the procedures were carried out (23.1 ± 8.9 mmHg). No significant changes in the RNFL, GCC, and CD ratio were found before and after the procedures, neither in the intervened eyes nor in the control ones. Pre-procedure ONFI (0.3 ± 0.65), MP (63.6 ± 7.2) and MVD (16.0 ± 3.6) were significantly different ($p=0.01$, $p=0.03$, and $p=0.0001$; respectively) as compared to post-procedure values (0.37 ± 0.04 , 62.7 ± 8.0 and 17.3 ± 2.6), but not with ONP (40.1 ± 3.8 vs. 40.1 ± 3.2 ; $p=0.89$). IOP reduction was inversely correlated with pre- ($r=-0.62$; $p=0.005$) and post-procedural ONFI ($r=-0.56$; $p=0.01$), as well as pre-MVD ($r=-0.6$; $p=0.007$).

Conclusions: Acute IOP decrease after either BN or DC, is associated with a modest but significant change in several OCTA variables (ONFI, MVD, MP). The clinical impact of such microvasculature changes is still a matter to be elucidated.

ABSTRACT BODY:

Purpose: The goal of this project is to study the involvement of the choroid and its most abundant cells, the melanocytes, in the protection of retinal pigment epithelial (RPE) cells against oxidative stress.

Methods: RPE were seeded on a choroidal substitute that was produced using the self-assembly approach of tissue engineering (3D models). Choroidal melanocytes were added (or not) to the choroidal stromal substitutes. These different cell combinations of 3D models were exposed to oxidative stress (tert-butyl hydroperoxide: TBHP, 250 μ M, 2h). Levels of reactive oxygen species (CellRox) and cellular death (Ethidium-homodimer) were then assessed. In 2D models, RPE cells were exposed to oxidative stress (500, 1000 μ M, 2h), then incubated with either fresh media or media conditioned by melanocytes that were previously exposed to oxidative stress (500 μ M, 2h) using different dilutions. Death of the RPE cells was measured using LDH release assay and by viability assays (Annexin/ Propidium iodide; Caspase 3/7). Proteins and cytokines secreted by melanocytes, fibroblasts and RPE cells in 2D cultures were identified and measured (Human XL Cytokine Array Kit; ELISA).

Results: The presence of melanocytes in the engineered tissues reduced CellRox intensity by 45% and decreased RPE cell death by 90%. Oxidative stress-induced cell death of RPE cells was reduced by 5% when the RPE cells were left to recover in the media conditioned by melanocytes (1:1 ratio with fresh culture media). Compared to choroidal fibroblasts and RPE cells, melanocytes secreted respectively 49 and 46-times more pigment epithelium-derived factor (PEDF) and 6 and 4-times more osteopontin (OPN).

Conclusions: Overall, our results demonstrate that choroidal melanocytes protect RPE cells against oxidative stress-induced cell death. PEDF and OPN were identified as proteins mainly secreted by melanocytes, and may be involved in this protection. The identification of factors that prevent RPE cell death could help to find a cure for diseases where RPE needs protection, such as dry AMD.

ABSTRACT BODY:

Purpose: The retina is a crucial part of the eye and plays an important role in vision. Assessing the biomechanical properties of retina could provide critical information for disease detection and guiding precision therapeutic interventions. Previous work assessing retinal elasticity has been limited to global assessments and destructive methods, but in this work we demonstrate Brillouin microscopy to noninvasively assess the layer by layer distribution of retinal stiffness. Furthermore, we were able to measure the changes in retinal stiffness caused by fixation and the effects of n-methyl-d-aspartate (NMDA) induced damage.

Methods: Dissected fresh (n = 3) and paraformaldehyde-fixed (n = 2) adult C57/BL6J mice retinas were used in this experiment. The retinas were mounted flat on microscope slides with the vitreous layer on the top and the photoreceptor layer on the bottom. Optical coherence tomography (OCT) images were acquired to visualize the retina structure and ensure there was no damage. Next, Brillouin microscopy was used to obtain the layer by layer distribution of biomechanical properties of the retinas. As a proof-of-concept study, mice were intravitreally injected with 100 mM NMDA and imaged using OCT and Brillouin microscopy.

Results: We observed that the average Brillouin modulus of all fresh retinas over entire depth was 2.48 ± 0.06 GPa whereas the average Brillouin modulus of all fixed retinas was 2.73 ± 0.09 GPa. Figure 1 (a) shows layer by layer distribution of stiffness within the retina using Brillouin microscopy. Retinal ganglion cell (RGC) layer of NMDA-damaged retina had a greater Brillouin modulus compared to the control retina sample.

Conclusions: We showed that Brillouin microscopy can noninvasively assess the stiffness over the entire depth of ex vivo mouse retinas. We observed that the retina is a heterogeneous tissue and has different biomechanical properties for its different layers. Fixed retinas were stiffer compared to fresh retinas. Results showed the biomechanical properties are highly affected by the cellular density and PFA-fixing. Increased Brillouin modulus in the RGC layer of NMDA-induced retina may indicate cell death in that layer.

ABSTRACT BODY:

Purpose: Trabeculectomy is the most practiced glaucoma surgery; however, its success depends on the presence of a filtering bleb and its lowering pressure capacity, usually related to its morphology and permeability. Multiple clinical classification systems have been proposed to describe filtering bleb appearances and their functionality. Optical coherence tomography (OCT) technology has been used to describe the inner morphology of such blebs. The objective of this study is to determine the correlation between the IOP-lowering capacity of a series of post-trabeculectomy filtering blebs and the Würzburg classification (WC) system, as well as with a new anterior segment OCT (AS-OCT) classification system (NOCTCS).

Methods: A cross-sectional study of non-consecutive cases that underwent primary supplemented-MMC trabeculectomy was carried out. Fifty-eight eyes from 39 patients with glaucoma were included. Anterior segment and filtering bleb photographs of the included cases were examined by two independent and masked observers using the WC (score range, 0-12). A series of AS-OCT images were also evaluated by the same observers, using NOCTCS (score range, 0-6) that evaluates 3 tomographic traits of the filtering bleb (wall thickness, cystic spaces and wall inner reflectivity). A weighted score was assigned to each item for every examined case. The data were analyzed with SPSS 25 statistical software, considering significant a p value ≤ 0.05 .

Results: Patients had a mean age of 61.4 ± 17.8 years. The cases consisted in a greater proportion of female (71.8%), primary open-angle glaucoma (53.8%), and required digital compression (69.4%). The mean time after trabeculectomy was 52.2 ± 32.1 months. A WC of 9.4 ± 2.7 , inversely correlated with mean post-operative IOP values ($r = -4.30$, $p = 0.001$). The mean NOCTS also correlated but in a weaker manner with the mean IOP ($r = -2.41$, $p = 0.034$). However, it did not correlate with the mean percentage reduction of IOP ($r = 0.133$, $p = 0.159$). In addition, NOCTS and WC, correlated fairly well ($r = 0.412$, $p = 0.001$).

Conclusions: The Würzburg system outperformed the NOCTS. A combined assessment with clinical and tomographic traits might be more useful to establish key findings associated to better post-trabeculectomy outcomes. Prospective trials using clinical and AS-OCT images of filtering blebs are required.

ABSTRACT BODY:

Purpose: To evaluate the impact of COVID-19 pandemic lockdown on the clinical outcomes of an international cohort of neovascular AMD (nAMD), diabetic macular edema (DME) and retinal vein occlusion (RVO) treated eyes in eight countries: Australia, France, Ireland, Italy, Netherlands, New Zealand, Spain and Switzerland.

Methods: Multicenter international nAMD, DME and RVO database observational study. Data was internationally collected using a validated web-based tool (Fight Retinal Blindness! Project). Baseline visit was defined as the closest visit prior (up to 3 months) to the initial lockdown date, which differed by country. Pre- and post-lockdown periods were defined as 6 months prior and post-baseline visit. Data collected included: demographics, visual acuity (VA) in logarithm of the minimum angle of resolution (logMAR) ETDRS letters at baseline and pre- and post-baseline visits, number of injections and visits.

Results: 5271 eyes of 4288 patients were included. In nAMD eyes (n=4240), mean VA change post-lockdown ranged from -0.3 to -3.3 letters, and the median number of injections/visits decreased from a pre-lockdown range of 4-5/4-7 to a range of 2-4/2-4 post-lockdown, respectively. In DME eyes (n=605), mean VA change ranged from -4 to +2.3 letters, and the median number of injections/visits decreased from a pre-lockdown range of 2-5/4-6.5 to 1-3/2-3. In RVO eyes (n=426), mean VA change ranged from -2.4 to +3 letters, and the median number of injections/visits decreased from a range of 3-7/4-7.5 to 1-6/2.5-6 post-lockdown. The dropout rates for the 6 months post-lockdown period were 34% for nAMD (n=1458), 43% for DME (n=264) and 44% for RVO (n=188). Study drugs included ranibizumab (33.5%), aflibercept (50.9%) and bevacizumab (15.5%).

Conclusions: This study provides accurate estimates of the impact of COVID-19 pandemic lockdown on the visual outcomes of an international cohort of eyes treated with intravitreal therapy. The data reported in this study may serve clinicians to prepare strategies to mitigate vision loss in future scenarios of the COVID-19 pandemic evolution.

TITLE: Efficacy of Anti-TNF-alpha agents in Active Thyroid Eye Disease

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Pakdel, Ophthalmology, Oculo-Facial Plastic Surgery, Tehran University of Medical Sciences, Tehran, Tehran, IRAN (THE ISLAMIC REPUBLIC OF)|N. Pirmarzashti, Tehran University of Medical Sciences, Tehran, Tehran, IRAN (THE ISLAMIC REPUBLIC OF)|A. Haghighi, Iran University of Medical Sciences, Tehran, Tehran, IRAN (THE ISLAMIC REPUBLIC OF)|

Commercial Relationships Disclosure (Abstract): Farzad Pakdel: Commercial Relationship: Code N (No Commercial Relationship) | Niloofar Pirmarzashti: Commercial Relationship: Code N (No Commercial Relationship) | Annousheh Haghighi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The key role of tissue necrosis factor alpha (TNF alpha) has been shown in the pathophysiology of thyroid eye disease. In this study we aimed to report the effect of anti-TNF alpha agents in treatment of patients with active thyroid eye disease (TED) who could not take or failed to respond to corticosteroids.

Methods: Data of all patients with active TED from January 2014 to December 2018, that received anti-TNF alpha agents because they could not take steroids or showed resistance to them, were reviewed. Data included visual acuity, clinical activity score (CAS), extra-ocular motility, eyelid swelling and erythema, conjunctival injection and chemosis, caruncular congestion, keratopathy and dysthyroid optic neuropathy. Those with follow-up less than 9 months were excluded.

Results: Data of eight eligible patients were analyzed. Mean age was 54.6 (SD= 7.08, range=42-65) years. Five were male. The reason for abandonment from corticosteroid included: gastrointestinal bleeding (n=1), congestive heart failure (n=1), diabetic hyperosmolar state (n=1), non- or inadequate response to corticosteroid regimen (n=5). Patients received one anti-TNF alpha agent as single main treatment including infliximab (n=3), etanercept (n=3), Adalimumab (n=2). CAS score decreased from baseline 5.5 (SD= 1.69) to 0.5 (SD= 0.75) (p=0.0001). Proptosis value showed decreased from baseline 24.12 mm (SD= 2.23) to 22.12 (SD=1.88) after treatment (p=0.037). The patients that received adalimumab showed resolution of diplopia and decrease in proptosis in comparison to none of the other six patients. Mean follow up time was 27.75 (range: 15-46, SD= 10.30) months. Four (50%) patients were current smokers. Five patients had DON before anti-TNF alpha. Four of them were smokers. Three of them improved by anti-TNF alpha medication only. We did not observe any complication associated with the use of anti-TNF alpha agents.

Conclusions: This study supports the efficacy of anti-TNF alpha agents in active TED. Further they may be considered in patients that cannot take corticosteroids or are resistant to steroid therapy. Results of this study justify future comparative studies to verify efficacy of this modality of treatment in patients with active TED.

TITLE: Developing Behavior-Based Diabetic Retinopathy Screening Guidelines

SESSION TITLE: Diabetic Retinopathy Epidemiology and Care Management

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Lee, P. Dorali, Z. Shahmoradi, Department of Industrial Engineering, University of Houston, Houston, Texas, UNITED STATES|C.Y. Weng, Baylor College of Medicine Department of Ophthalmology, Houston, Texas, UNITED STATES|C.Y. Weng, Department of Ophthalmology, Ben Taub Hospital, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Taewoo Lee: Commercial Relationship: Code N (No Commercial Relationship) | Poria Dorali: Commercial Relationship: Code N (No Commercial Relationship) | Zahed Shahmoradi: Commercial Relationship: Code N (No Commercial Relationship) | Christina Weng: Commercial Relationship(s);Alcon:Code C (Consultant);Allergan/Abbvie:Code C (Consultant);Novartis:Code C (Consultant);Alimera Sciences:Code C (Consultant);REGENXBIO:Code C (Consultant);Regeneron:Code C (Consultant);DORC:Code C (Consultant);Genentech:Code C (Consultant)

ABSTRACT BODY:

Purpose: Personalized screening guidelines can be an effective strategy to prevent diabetic retinopathy (DR)-related vision loss. However, these strategies typically do not capture behavior-based factors such as a patient's compliance or cost preferences. This study develops a mathematical model to identify screening policies that capture both DR progression and behavioral factors to provide personalized recommendations.

Methods: A partially observable Markov decision process model (POMDP) is developed to provide personalized screening recommendations. For each patient, the model estimates the patient's probability of having a sight-threatening diabetic eye disorder (STDED) yearly via Bayesian inference based on natural history, screening results, and compliance behavior. The model then determines a personalized, threshold-based recommendation for each patient annually—either no action (NA), teleretinal imaging (TRI), or clinical screening (CS)—based on the patient's current probability of having STDED as well as patient-specific preference between cost saving (\$) and QALY gain. The framework is applied to a hypothetical cohort of 40-year-old African American male patients.

Results: For the base population with TRI and CS compliance rates of 65% and 55% and equal preference for cost and QALY, NA is identified as an optimal recommendation when the patient's probability of having STDED is less than 0.72%, TRI when the probability is [0.72%, 2.09%], and CS when the probability is above 2.09%. Simulated against annual clinical screening, the model-based policy finds an average decrease of 7.07% in cost/QALY (95% CI; 6.93-7.23%) and 15.05% in blindness prevalence over a patient's lifetime (95% CI; 14.88-15.23%). For patients with equal preference for cost and QALY, the model identifies 6 different types of threshold-based policies (See Fig 1). For patients with strong preference for QALY gain, CS-only policies had an increase in prevalence by a factor of 19.2 (see Fig 2).

Conclusions: The POMDP model is highly flexible and responsive in incorporating behavioral factors when providing personalized screening recommendations. As a decision support tool, providers can use this modeling framework to provide unique, catered recommendations.

TITLE: Outcomes of Sjögren's versus non-Sjögren's Related Dry Eye in a Longitudinal, Tertiary Clinic-Based Sample

SESSION TITLE: Dry eye and ocular surface microbiome clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Li, D. Cui, P. Mathews, S. Van Court, E. Akpek, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Gavin Li: Commercial Relationship: Code N (No Commercial Relationship) | David Cui: Commercial Relationship: Code N (No Commercial Relationship) | Priya Mathews: Commercial Relationship: Code N (No Commercial Relationship) | Shanna Van Court: Commercial Relationship: Code N (No Commercial Relationship) | Esen Akpek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the long-term treatment outcomes of dry eye in patients with and without primary Sjögren's Syndrome (SS) in a retrospective cohort study.

Methods: SS and non-SS dry eye patients with clinic visits for a minimum of 5 consecutive calendar years at a tertiary, dedicated dry eye clinic were included. Electronic health records were reviewed to collect data regarding demographics, objective dry eye parameters (Schirmer's test without anesthesia, tear osmolarity, corneal and conjunctival staining) at baseline and final visit, treatments utilized, and corneal complications during follow-up.

Results: Two hundred and two patients (101 SS and 101 non-SS) were included, with mean follow-up of 7.1 years (range 3.8 to 15.4). At baseline, patients had significant mean conjunctival (2.9) and corneal (2.0) staining. Notable improvement in staining score for cornea (-1.1, $P < .001$) and conjunctiva (-1.8, $P < .001$) was seen equally in both SS and non-SS dry eye groups. A great majority of patients (89.1%) received escalation of treatment at final visit with equal rates in both groups ($P = .259$). Half (48.9%) of the patients had no conjunctival staining and a third (34.4%) had no corneal staining at last visit. Twenty (9.9%) patients experienced a vision-threatening corneal complication including ulcers and melt with no difference between the groups ($P = .638$).

Conclusions: The majority of patients in this longitudinal, tertiary clinic-based sample had improvement in ocular surface staining score by final visit owing to proper treatment escalation. Treatments used, improvement achieved, and corneal complication rates were similar in both SS and non-SS dry eye groups.

TITLE: Multimodal photoacoustic microscopy and OCT molecular imaging of choroidal neovascularization in rabbits using indocyanine green

SESSION TITLE: Animal imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Derouin, V. Nguyen, Y. Li, J. Henry, W. Zhang, X. Wang, Y.M. Paulus, University of Michigan Michigan Medicine, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Katherine Derouin: Commercial Relationship: Code N (No Commercial Relationship) | Van Phuc Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Yanxiu Li: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Henry: Commercial Relationship: Code N (No Commercial Relationship) | Wei Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Xueding Wang: Commercial Relationship: Code N (No Commercial Relationship) | Yannis Paulus: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Early detection of neovascularization is essential for early diagnosis and treatment of diseases such as diabetes and macular degeneration, yet it remains challenging. We tested whether an FDA-approved exogenous contrast agent, indocyanine green (ICG), could enhance photoacoustic microscopy (PAM) significantly enough to differentiate neovascularization from normal vasculature in rabbits.

Methods: ICG was conjugated with RGD peptide to bind to integrin expressed in neovascularization. A custom-built multimodal PAM and Thorlabs Ganymede-II-HR OCT retinal imaging system was utilized. New Zealand white rabbits (N=6) were treated with subretinal injection of Matrigel and human vascular endothelial growth factor (VEGF-165) to induce choroidal neovascularization (CNV) and imaged before and at 2 h, 24 h, 48 h, 72 h, 4, 5, 7, 9, 11 and 14 days after intravenous administration of ICG 0.4 mL at 2.5 mg/mL after approval by the UM IACUC.

Results: In indocyanine green angiography (ICGA) and PAM imaging at 700 nm, no signal was observed pre-injection of ICG-RGD. 2 h post-injection the binding of ICG-RGD at CNV was identified with a strong PAM signal. 24 h post injection, the CNV was visualized with ICGA. PA image contrast at 700 nm was improved by 13-fold from $.03 \pm .001$ a.u. pre-injection to $.39 \pm .03$ a.u. at 2 h post-injection ($p < .001$). The peak PA amplitude within CNV was achieved at 24 hours post-injection and increased by 15.7-fold (PA signal = $.47 \pm .03$ a.u.). PAM imaging also showed ICG-RGD present in CNV for up to 5 days post-injection in living rabbits with a model of CNV, allowing for extended evaluation.

Conclusions: Injection of ICG-RGD led to increase in PAM imaging contrast. This signal peaked at 24 hours and continued for up to 5 days. This allowed for successful differentiation between neovascularization and normal vasculature. This work demonstrates the possibility that ICG-RGD paired with PAM imaging can assist in early detection of CNV.

TITLE: Input following first time use of visual assistance mobile apps by seniors with low vision

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Ross, J.K. Ho, C. Idman-Rait, A.G. Malkin, Specialty and Advanced Care, New England College of Optometry, Boston, Massachusetts, UNITED STATES|M. Chun, A.K. Bittner, Jules Stein Eye Institute, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Nicole Ross: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Ho: Commercial Relationship: Code N (No Commercial Relationship) | Melissa Chun: Commercial Relationship: Code N (No Commercial Relationship) | Cecilia Idman-Rait: Commercial Relationship: Code N (No Commercial Relationship) | Alexis Malkin: Commercial Relationship: Code N (No Commercial Relationship) | Ava Bittner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mobile phone applications(apps) have become important tools for everyday life and can offer additional accessibility for patients with low vision. It is unknown whether seniors with low vision will be able to use and embrace apps.

Methods: Fourteen participants were interviewed during one of 5 focus group sessions conducted via zoom videoconferencing; n=8 from Boston, n=6 from L.A. They had no prior experience with 3 visual assistance apps (Aira, SuperVision+, SeeingAI), received a study loaner iPhone with the three apps, a brief demonstration of the apps' features, then tried the apps for ~5 minutes during the focus group, after which their feedback was solicited. Median age was 66 years (IQR 58-77), and median visual acuity in the better eye was 0.6 logMAR (IQR 0.4-0.8 logMAR). Qualitative analyses were used to explore themes from the discussion and Wilcoxon Sign Rank tests evaluated for differences according to participants' characteristics.

Results: A greater number of participants reported they would use Aira or SuperVision+ outside the home (57% for Aira, 50% for SuperVision+; e.g., shopping in stores, navigating streets, airports) than inside the home (28% for Aira, 21% for SuperVision+; e.g., reading, identifying objects, computer), which was not significantly influenced by age or visual acuity.

The primary theme to encompass comments about Aira from 9 subjects (64%) was: "Always there for you with a human element" as they would appreciate relying on the personalized service when others were not available to assist; additionally, they felt public use was inconspicuous and less stigmatizing than other visual aids. The primary theme for SuperVision+ (from 71%; n=10) was "convenience at your fingertips: one less thing to weigh you down" as it eliminates the need to take a magnifier along with a smartphone. Preferences for the SeeingAI features and usability were more varied, with less consensus.

Five participants (36%) were unable to try all three apps due to difficulty using or understanding the technology; their median age was 76 years (range 66-81) and all had age-related, acquired vision loss. Eight (57%) cited the need for additional assistance with the apps.

Conclusions: Low vision seniors were more likely to report indications for visual assistive apps in public places than at home. Participants appreciated the concept and convenience of the apps, but some will require further training.

TITLE: Variation in unique yellow for small foveal spots

SESSION TITLE: Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.E. Boehm, J.E. Vanston, G.D. Hastings, A.J. Roorda, W.S. Tuten, School of Optometry and Vision Science Graduate Group, University of California Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Alexandra Boehm: Commercial Relationship: Code N (No Commercial Relationship) | John Vanston: Commercial Relationship: Code N (No Commercial Relationship) | Gareth Hastings: Commercial Relationship: Code N (No Commercial Relationship) | Austin Roorda: Commercial Relationship(s);C. Light Technologies:Code I (Personal Financial Interest);University of Rochester:Code P (Patent);University of Houston:Code P (Patent) | William Tuten: Commercial Relationship(s);University of California, Berkeley:Code P (Patent);University of Pennsylvania:Code P (Patent)

ABSTRACT BODY:

Purpose: Individuals are remarkably consistent in the color that they perceive to be uniquely yellow, despite several sources of anatomical variability. Studies using larger stimuli (≥ 1 deg) have shown that unique yellow (UY) is invariant to differences in L/M cone ratio, suggesting that color appearance is normalized to be consistent across observers. Whether this invariance is maintained at smaller spatial scales is not well understood. Otake and Cicerone (2000) showed that foveal estimates of UY shifted toward longer wavelengths when measured with small stimuli (3 arcmin), although the extent to which optical factors may have contributed to these findings, or whether this trend persists at even smaller spatial scales, is not clear.

Methods: We used an adaptive optics scanning laser ophthalmoscope (AOSLO) to correct ocular aberrations and examine how stimulus size and duration influence foveal estimates of UY. UY estimates were obtained at three stimulus sizes (1, 3, 11 arcmin diameter) and three durations (1, 4, 15 frames at 30 fps) using a multi-wavelength AOSLO, which provided simultaneous retinal imaging and aberration-corrected stimulus delivery. Stimuli were composed of varying mixtures of green (543 nm) and red (680 nm) monochromatic lights to produce metamers to intermediate wavelengths. Axial and transverse chromatic aberrations were corrected. Stimuli were viewed against a white background. Participants ($n = 4$) reported on each trial whether the stimulus appeared redder or greener. Primary mixtures were adjusted using an adaptive staircase procedure, and UY was defined as the mixture that was equally likely to be judged as red or green.

Results: In the 11 arcmin/15 frame condition, the mean wavelength of UY was 585 nm (range: 580-592 nm), roughly consistent with previous estimates obtained with larger stimuli. For all subjects, UY tended toward longer wavelengths as stimulus size decreased, with an average UY at 591 nm (range: 580-602 nm) for the 1 arcmin/15 frame condition. UY was mostly constant as a function of duration, except in the case of the smallest and briefest stimuli, where UY was 3-12 nm longer.

Conclusions: Our results demonstrate that restricting the spatio-temporal profile of the stimulus on the retina causes UY to (1) shift to longer wavelengths and (2) exhibit more variability between observers. These findings suggest that the normalization of UY for large-field stimuli does not persist at the smallest spatial scales.

ABSTRACT BODY:

Purpose: To evaluate nosocomial acute-onset postoperative endophthalmitis following cataract surgery at a university teaching hospital and to compare frequency among resident and attending physicians.

Methods: This study was a retrospective, consecutive case series of patients diagnosed with acute-onset postoperative endophthalmitis within 6 weeks of cataract surgery performed at at Bascom Palmer Eye Institute, Miami, Florida between January 1, 2015, and November 30, 2020. Resident physician case totals were obtained from self-reported case logs.

Results: In a six-year period, there were 22 cases of acute-onset postoperative endophthalmitis following cataract surgery at a single institution. The overall frequency of endophthalmitis was 0.068% (22/32,505). The most common bacterial isolate was Coagulase-negative Staphylococcus (7/22, 31.8%) followed by Streptococcus spp. (3/22, 13.6%). Cultures were negative in 11 eyes (11/22, 50%). Initial treatment with tap and injection was performed in 21 eyes (21/22, 95.4%) and vitrectomy in one eye (1/22, 4.5%). Injection of vancomycin 1.0mg and ceftazidime 2.25mg was performed in all eyes and dexamethasone 400ug was added initially in 18 eyes (18/22, 81.8%). Vitrectomy was performed as a second treatment in 9 patients (9/22, 40.9%). Visual acuity (VA) at last follow up was 20/40 or better in 13 eyes (13/22, 59%) and hand motions or worse in 3 eyes (3/22, 13.6%). The frequency of endophthalmitis for resident physicians was 0.09% (6/6,447), compared to 0.06% (16/26,058) for attending physicians, but this difference was not statistically significant (P=0.55). There was no difference (P=0.14) between average VA outcomes among resident (logMAR VA 1.19 ± 1.06) and attending physican (logMAR VA 0.53 ± 0.80) cases.

Conclusions: At a university teaching hospital, the frequency of acute-onset postoperative endophthalmitis following cataract surgery remains low. When stratified between resident and attending physicians, the frequency of endophthalmitis and visual outcomes were similar.

TITLE: Endothelial caspase-9 signaling alters glial response in a mouse model of retinal vein occlusion (RVO)

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.K. Colón Ortiz, M. Avrutsky, J. Lawson, J. Smart, C. Troy, Columbia University Irving Medical Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Crystal Colón Ortiz: Commercial Relationship: Code N (No Commercial Relationship) | Maria Avrutsky: Commercial Relationship(s);Columbia University :Code P (Patent) | Jacqueline Lawson: Commercial Relationship: Code N (No Commercial Relationship) | Jade Smart: Commercial Relationship: Code N (No Commercial Relationship) | Carol Troy: Commercial Relationship(s);Columbia University:Code P (Patent)

ABSTRACT BODY:

Purpose: Retinal vascular diseases present increased glial activity, inflammation, and release of inflammatory cytokines. But the signaling mechanisms that connect vascular damage to a glial response have not been elucidated. Studies in the laboratory showed that non-apoptotic activation of endothelial caspase-9 (EC-Casp9) regulated activation of astroglial caspase-6 in a mouse model of retinal vein occlusion (RVO). We investigated the effect of EC-Casp9 signaling on astroglial and microglial response in RVO.

Methods: RVO was performed in inducible EC-Casp9 (iEC-Casp9 WT/KO) adult male mice by tail vein injection of Rose Bengal and photocoagulation of major retinal veins. After induction of RVO we collected the retinas one and two days post RVO (P-RVO). Immunohistochemistry for Iba-1, CD68, cl-Caspase-6, GFAP, and AQP-4 was done and analyzed by blinded quantification using thresholding analysis in FIJI. Data was evaluated in injured iEC-Casp9 WT (n=6-8) and iEC-Casp9 KO (n=4-9), and uninjured groups (iEC-Casp9 WT, n=3, iEC-Casp9 KO, n=3). Kruskal-Wallis followed by Dunn's and Brown-Forsythe and Welch ANOVA tests were used for statistical analysis.

Results: EC-Casp9 did not modify the total number of Iba-1 or CD68 microglial cells, but the latter increased in injured animals two days P-RVO ($p=0.02$) compared to uninjured iEC-Casp9 WT. The area of microglial CD68 particles of injured retinas was bigger P-RVO ($p=0.01$, $p=0.001$), and rescued to normal levels in injured iEC-Casp9-KO 1 day P-RVO ($p=0.03$). EC-Casp9 led to higher astroglial cl-caspase-6 in injured iEC-Casp9 WT at assessed time points ($p=0.02$, $p=0.004$) compared to injured iEC-Casp9 KO. However, injured retinas did not show differences in GFAP expression P-RVO, but had a downward trend in AQP-4 2 days P-RVO compared to uninjured iEC-Casp9 WT, independent of EC Casp9.

Conclusions: EC-Casp9 expression caused increased microglial activation in a timely manner and led to higher astroglial cl-caspase-6 expression, but not GFAP or AQP-4. These data demonstrate that EC-Casp9 signaling affects glial activity in our model. Further studies will help determine whether these glial responses are detrimental to the neuroretina.

ABSTRACT BODY:

Purpose: Although most (and perhaps all) genes that can cause achromatopsia (ACHM) when mutated are known, some patients with an ACHM phenotype are still negative for mutations in the coding region of known genes. Our aim was to characterize genetic and clinical aspects of a deep intronic (c.1663-1205G>A, IVS14-1205G>A) CNGB3 variant.

Methods: Clinical evaluation included visual acuity testing, refractive error, color vision testing, full-field electroretinography, and multi-modal retinal imaging. Genetic analysis was performed by Sanger sequencing of PCR products.

Results: Screening for the CNGB3 c.1663-1205G>A variant revealed 17 patients belonging to 12 unrelated families who were either homozygous (7 cases, 5 families) or compound heterozygous (10 cases, 7 families) with another known CNGB3 mutation on the counter allele. All patients were diagnosed with a cone-dominated disease, mainly complete ACHM. In all cases, the disease had an early congenital onset. Visual acuity was markedly impaired, ranging between 0.07 and 0.32 ETDRS (LogMAR +1.18 to +0.50), with a mean visual acuity of 0.15 ETDRS (LogMAR +0.80). Additional typical signs of ACHM including impaired color vision, light aversion, and nystagmus were also noted in all patients. As is common in ACHM, fundus exam was largely unremarkable in the majority of patients, with mild foveal retinal pigment epithelium changes seen in some cases at older ages. Electroretinography was available for 14 out of 17 patients and in all of them cone responses were non-detectable, including infants from the age of 6 months. In a few cases, rod involvement was also evident, with mild reduction of amplitudes. Optical coherence tomography imaging showed irregularity of the ellipsoid zone in the foveal area in some of the patients.

Conclusions: CNGB3 is the most common cause of ACHM in patients of European descent, mainly due to a panethnic founder mutation, c.1148del. Here we report of an intronic CNGB3 variant which is more frequent than the c.1148del mutation in the Jewish population. Among our ACHM cohort, 64% have biallelic CNGA3 mutations and 32% have biallelic CNGB3 mutations. The phenotype of patients harboring the intronic mutation falls largely within the spectrum commonly seen in ACHM. As gene therapy for CNGB3 is currently under investigation, these patients might benefit from this promising therapy.

TITLE: Pentosan Polysulfate Maculopathy: Prospective Longitudinal Study of Disease Course after Drug Cessation

SESSION TITLE: AMD and retinal physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Lindeke-Myers, R. Lyons, J. Brower, N. Jain, Ophthalmology, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Aaron Lindeke-Myers: Commercial Relationship: Code N (No Commercial Relationship) | Riley Lyons: Commercial Relationship: Code N (No Commercial Relationship) | Judy Brower: Commercial Relationship: Code N (No Commercial Relationship) | Nieraj Jain: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent studies have demonstrated an association between long-term pentosan polysulfate (PPS) use and a novel maculopathy. No study has prospectively evaluated long-term disease course after drug cessation. Here, we report year 1 outcomes of a long-term prospective study of retinal structure and function in PPS maculopathy.

Methods: Thirteen PPS maculopathy patients were followed prospectively with multimodal assessments of retinal structure and function; 11 (22 eyes) completed year 1 visits. Functional testing endpoints at year 1 included: microperimetry (MP) mean and percent reduced thresholds, and ETDRS best corrected visual acuity (BCVA). Structural endpoints included: central subfield retinal thickness (CST), subfoveal choroidal thickness (SFCT), and geographic atrophy area (defined as complete retinal and outer retinal atrophy). Baseline and year 1 outcomes were compared using a Wilcoxon signed rank test. To account for inter-eye correlation, mean results were computed for the two eyes for each patient.

Results: Patients had a median age of 63 (range 38-77) and median 2.04 kg (IQR 1.15 – 2.58) PPS exposure. Patients stopped PPS use a median of 9.9 (IQR 5.6 – 20.5) months prior to baseline. Median change in ETDRS BCVA during the study period was -3 letters (IQR -4.75 – 1.5) [baseline: 81.5 letters (IQR 79 – 86.3), year 1: 78.5 letters (IQR 74.5 – 86.8) ($p = 0.07$)]. Seven of 11 (64%) patients had BCVA decline. Four (18%) eyes, each with progressive atrophy, lost ≥ 10 letters. Median MP average thresholds declined from 25.7 (IQR 17.8 – 26.7) to 25.2 (IQR 16.5 – 27.6) ($p = 0.18$). Median MP percent reduced thresholds increased from median 23.0% (IQR 9.5% – 54.1%) to 25.2% (IQR 14.2% – 28.6%) ($p = 0.88$). Fifteen eyes (68%) had atrophy at baseline; with an increase from a median of 5.64 mm² (IQR 0.36 – 17.9) to a median of 7.23 mm² (IQR 0.45 – 20.8) ($p < 0.01$) and median linearized increase of 0.21 mm (IQR 0.08 – 0.39) per eye. Median CST decreased from 278 μ m (IQR 243 – 287) to 267 μ m (IQR 238 – 290) ($p = 0.08$). Median SFCT decreased from 268 μ m (IQR 159 – 324) to 261 μ m (IQR 161 – 334) ($p = 0.47$).

Conclusions: This prospective study demonstrates continued evolution of structural and functional deficits in patients with PPS maculopathy even after drug cessation. Geographic atrophy enlarged in all eyes with atrophy present at baseline, and thus may pose a long-term threat to central vision.

TITLE: Have SARS-CoV-2 virus (COVID-19) lockdown restrictions impacted the prevalence and severity of retinopathy of prematurity in a London population?

SESSION TITLE: Impacts of Covid on patients and practice

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Bazeer, A. Mahtani, A. Das, A. Khaier, M. Posner, Barking Havering and Redbridge University Hospitals NHS Trust, Romford, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Shehnaz Bazeer: Commercial Relationship: Code N (No Commercial Relationship) | Ashwin Mahtani: Commercial Relationship: Code N (No Commercial Relationship) | Ambalika Das: Commercial Relationship: Code N (No Commercial Relationship) | Ayman Khaier: Commercial Relationship: Code N (No Commercial Relationship) | Marcus Posner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is the leading cause of blindness associated with pre-term births. Globally, numerous centres have reported a reduction in pre-term hospital births during the SARS-CoV-2 virus (COVID-19) lockdown restrictions. Lockdown measures may have influenced the health and wellbeing of pregnant women.

A survey of ROP screening ophthalmologists in London indicated a perceived reduction in the number of babies screened during lockdown measures in 2020 compared to previous years.

The aim of this study was to determine whether there has been a change in the severity or prevalence of ROP due to COVID-19 lockdown restrictions in the UK.

Methods: A pilot study of 113 participants screened for ROP in an East London Hospital were included. Babies whose last 4 weeks of gestation fell within the UK's first lockdown window of 23rd of March and 28th of August 2020 were compared to data from corresponding dates in 2019.

A student t -test was used to compare the gestational ages, birth-weight, ethnicity, and severity of ROP stage, COVID-19 status and multiple pregnancies.

A chi-squared test was used to compare the prevalence of various stages of ROP between the two groups and a t-test was used to compare the demographics.

Results: This study showed no statistical significance ($p=0.09$) in the prevalence of babies with various stages of ROP between 2019 ($n=68$) and 2020 ($n=45$).

Overall, this pilot study showed no statistical significance ($p>0.05$) in birth-weight, gestational age or ethnicities between the two groups.

Conclusions: In conclusion, our pilot study showed no statistical significance in the prevalence of babies with ROP between 2019 and 2020. Although subjectively we have noted there to be a trend in fewer babies born below 32 weeks or 1500g birthweight during lockdown corresponding to fewer ROP screenings at our London hospital, we were unable to demonstrate a statistically significant difference due to our small sample size.

We aim to increase the power of the study by including data from other screening units in London and collecting further control data from 2018.

We believe that our study has the potential to indicate how the UK's lockdown measures may impact the prevalence and severity of babies with ROP associated with preterm births.

ABSTRACT BODY:

Purpose: Oxidative stress-evoked aberrant Sumoylation of proteins is linked to aging etiopathologies. We previously reported that TAT transduction domain fused Prdx6 mutated at Sumoylation sites, Prdx6^{K(lysine)122/142R(Arginine)}, enhanced protection of human lens epithelial cells (hLECs) by escaping Sumoylation. Herein, we formulated TAT-His-Prdx6 and TAT-His-Prdx6^{K122/142R}-loaded poly (lactic-co-glycolic acid) (PLGA) nanoparticles (NPs) to further enhance protective efficiency in vitro and in vivo.

Methods: PLGA-based TAT-Prdx6(TAT-His-Prdx6-PLGA) and TAT-Prdx6^{K122/142R}(TAT-His-Prdx6^{K122/142R}-PLGA) NPs were prepared by nano-precipitation method. The properties of TAT-His-Prdx6 and TAT-His-Prdx6^{K122/142R} NPs were characterized by dynamic light scattering(DLS) and atomic force microscopy (AFM). Release assay was done using Prdx6-ELISA. The Prdx6-NPs were delivered to rat lenses cultured under H₂O₂ stress or delivered subconjunctivally to Shumiya Cataract Rat (SCR), to assess the formulation's protective ability. MTS and Dye assays examined cell viability and reactive oxygen species (ROS) levels. Western blot and ELISA analyzed Prdx6 levels using His/Prdx6 antibodies. Two-tailed Student's t-test and one-way ANOVA were used for statistical analysis.

Results: Prdx6 analog loaded PLGA NPs (~56-62% efficiency) were cytocompatible. DLS and AFM analyses showed that the NPs were spherical and of submicron size (220-250nm), with a negative zeta potential of ~23 mV. Release studies revealed that encapsulated Prdx6 analogs were biologically active with ~6-7.5% cumulative release within 24h, followed by slower release thereafter and retained the Prdx6 integrity (~35kDa). NPs with TAT-Prdx6^{K122/142R} (4µg/ml) provided 35% more protection (p<0.05), with ROS reduction in hLECs exposed to H₂O₂ (50µM/72h) compared to TAT-Prdx6-NPs. Lenses cultured with TAT-Prdx6^{K122/142R}-NPs were clear compared to control lenses facing H₂O₂ stress (100µM/72h). Subconjunctival delivery of Prdx6 formulations revealed that TAT-Prdx6^{K122/142R}-NPs released the Prdx6 in vivo and could reduce lens opacity by 58% and delayed cataractogenesis in SCR.

Conclusions: A single application of TAT-Prdx6^{K122/142R}-NPs provided increased cytoprotection and prevented the cataractogenesis compared to TAT-Prdx6-NPs in vitro and in vivo, providing a proof of concept for potential delivery of TAT-Prdx6^{K122/142R} via NPs to delay cataract formation.

TITLE: A comparison between aberrometry-based automated subjective refraction and traditional subjective refraction in keratoconus patients

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Carracedo, C. Carpena Torres, C. Pastrana, A. Privado, M. Serramito, T. Espinosa Vidal, M. Rodriguez Lafora, Optometry and Vision, Universidad Complutense de Madrid, Madrid, SPAIN|

Commercial Relationships Disclosure (Abstract): Gonzalo Carracedo: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Carpena Torres: Commercial Relationship: Code N (No Commercial Relationship) | Crisitna Pastrana: Commercial Relationship: Code N (No Commercial Relationship) | Ana Privado: Commercial Relationship: Code N (No Commercial Relationship) | Maria Serramito: Commercial Relationship: Code N (No Commercial Relationship) | Teresa Espinosa Vidal: Commercial Relationship: Code N (No Commercial Relationship) | MARIA Rodriguez Lafora: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the agreement between the Eye Refract, a new instrument to perform aberrometry-based automated subjective refraction, and the traditional subjective refraction in keratoconus patients.

Methods: A total of 50 eyes of 50 keratoconus patients were randomly evaluated, dividing the sample into two groups: 27 eyes without intracorneal ring segments (ICRS) (37.78 ± 9.35 years) and 23 eyes with ICRS (39.26 ± 13.62 years). An optometrist conducted the refraction with the Eye Refract and another different optometrist conducted the traditional subjective refraction on the same day, also randomly. Spherical equivalent (M), cylindrical vectors (J0 and J45), corrected distance visual acuity (CDVA), and time spent performing refraction were compared between both methods of refraction. Additionally, Bland-Altman analysis was performed to assess the agreement between both methods of refraction.

Results: There were no statistically significant differences ($P \geq 0.05$) in terms of M, J0, J45, and CDVA between the Eye Refract and the traditional subjective refraction in either group. However, the Eye Refract was faster for performing refraction than the traditional method ($5:37 \pm 1:35$ min:s vs. $8:36 \pm 2:37$ min:s, $P < 0.001$). Without ICRS, the mean difference and 95% limits of agreement were -0.20 [$+1.50, -1.89$] D for M, -0.14 [$+1.40, -1.68$] D for J0, and $+0.05$ [$+1.23, -1.14$] D for J45. These values worsened with ICRS to -0.62 [$+3.89, -5.12$] D for M, $+0.06$ [$+2.46, -2.34$] D for J0, and -0.02 [$+2.23, -2.28$] D for J45.

Conclusions: The Eye Refract would offer faster refraction compared to the traditional method, and also similar refractive results in keratoconus patients not implanted with ICRS. However, some patients could show abnormal measurements, especially those with ICRS, who should be treated with caution in clinical practice.

TITLE: UK Biobank study of 340, 419 participants identifies four novel loci associated with the age of first spectacle wear

SESSION TITLE: Environmental and genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Patasova, P.G. Hysi, C.J. Hammond, O.A. Mahroo, Twins Research and Genetic Epidemiology, King's College London Faculty of Life Sciences and Medicine, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Karina Patasova: Commercial Relationship: Code N (No Commercial Relationship) | Pirro Hysi: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Hammond: Commercial Relationship: Code N (No Commercial Relationship) | Omar Mahroo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Refractive errors and the age of first wearing glasses or contact lenses are correlated both observationally and at a genotypic level. Individuals who require vision correction at an earlier age often progress to high-grade myopia, and thus are at a greater risk of complications. The purpose is to identify genetic risk factors associated with the age of first spectacle wear in a large genome-wide association study.

Methods: For the purposes of this work, we conducted a survival analysis in the age of first spectacle or contact lens correction. This phenotype was available for 340,419 UK Biobank participants of European descent, self-reported through an electronic questionnaire. In addition, direct phenotypic information about spherical equivalent and other ocular measurements were available for a subset of participants (N=90,550). The genetic associations with the age of first spectacle wear were tested using Cox proportional hazards-ratios model, adjusted for age and sex.

Results: We found genetic associations with 44 independent genetic regions, most of which previously associated with refractive error. The strongest association was observed for TSPAN10 ($p=1.71 \times 10^{-35}$). Although an early onset of refractive correction correlated well with spherical equivalent in adulthood, several genes such as PRSS56, LAMA2, RDH5 had stronger effects and led to earlier manifest refractive errors, while other genes, such as AGPS, contributed to stronger than expected later life refractive error.

We were able to identify six loci at genome-wide significance, not previously reported as associated with refractive error, for example, LOC100287944 ($p=1.96 \times 10^{-08}$), and successfully validated four of them in an independent cohort.

Conclusions: This study confirmed the correlation between age of first spectacle wear and magnitude of refractive errors. In addition, this study identified genes associated specifically with early and late-onset refractive errors which may improve understanding of the mechanisms affecting spherical equivalent measurements in the general population.

Our study also illustrates the additional power gained by the use of longitudinal and survival methodologies and contributed several novel associations with refractive error traits, adding to our knowledge of the genetic risk architecture of these conditions.

ABSTRACT BODY:

Purpose: VHL disease is a rare hereditary disorder caused by VHL gene mutation, resulting in overexpression of hypoxia-inducible factors (HIFs) and tumorigenesis. We report results for retinal hemangioblastomas (RH) in patients with VHL disease-associated clear cell renal cell carcinoma (VHL-RCC) receiving small molecule HIF-2 α inhibitor belzutifan (MK-6482).

Methods: In this open-label, single-arm, phase 2 study (NCT03401788), patients with VHL-RCC received belzutifan, 120 mg orally daily. Evaluations included visual acuity assessment, ophthalmic exam, and imaging every 3 months for patients with baseline active ophthalmic disease. The primary endpoint was objective response rate (ORR) of VHL-RCC by Response Evaluation Criteria In Solid Tumours (v1.1). Efficacy for RH was a secondary endpoint, measured as an eye-level best overall response by an independent reading center (DARC, Great Neck, NY) based on assessment of color fundus imaging. Each eye was evaluated for RH number/size/location; degree of feeding/draining vessel dilation; and presence of intraretinal/preretinal/vitreous hemorrhage, exudation, and/or fibrosis. Eyes were assigned a summary grade of improved, stable, or progressed at last follow up.

Results: 61 patients were enrolled between 2018 and 2019. As of June 2020, median follow-up was 69 weeks (range, 18–105). Confirmed ORR for VHL-RCC was 36% (95% CI, 24–49), with a disease control rate of 98% (95% CI, 91–100). The most common adverse events were anemia (90%) and fatigue (61%) for the entire study population.

Color fundus images were obtained for 29 eyes (16 patients) having ≥ 1 RH. 16/29 eyes (55%) were graded as improved, 12/29 eyes (41%) were stable, and 1/29 eyes (3%) was not evaluable (poor image quality). No eye was graded as progressed and no new RH occurred. 1/29 eyes (3%) had a decrease in visual acuity >15 letters equivalent, secondary to retinal detachment in the setting of RH, epiretinal membranes, and myopia.

Conclusions: Belzutifan demonstrated promising activity, including reduction in size, vascularity, and/or exudation in a subset of RH, in addition to beneficial effects on RCC in patients with VHL disease.

ABSTRACT BODY:

Purpose: The goal of our study was to determine if Col4a1 deficiency exacerbates the visual deficits after mild traumatic brain injury (mTBI), and demonstrate the efficacy of COL4A1 enriched ASC concentrated conditioned medium (ASC-CCM) in restoring retinal vascular health after mTBI and mitigating visual deficits

Methods: Two-month-old C57Bl/6 mice were subjected to retina-specific knockdown of Col4a1 with intravitreally delivered AAV2-Col4shRNA and later to a 50-psi air pulse to the left side of the head, resulting in an mTBI, and compared to Control-shRNA treated mice with mTBI. Post blast, ASC-CCM (~100ng/eye/1mL) was delivered intravitreally, followed by visual assessment, immunohistology, and gene expression analysis after 4 weeks. Immune depletion of COL4A1 from ASC condition media was evaluated for the role of COL4A1 in the anti-inflammatory effects of ASC-CCM on microglial activation and endothelial permeability in vitro. Human retinal endothelial cells (HREC) with knockdown of Col4a1 via siRNA transfection were assessed for endothelial migration and leukocyte transmigration with COL4A1-enriched ASC-CCM

Results: mTBI resulted in a significant reduction in visual acuity and contrast sensitivity in mice, worsen with Col4a1 knockdown ($p<0.001$). An intravitreal injection of ASC-CCM rescued visual function in mTBI mice with Col4a1 knockdown ($p<0.05$). Immunohistological and gene expression analysis of retinas of mTBI mice with Col4a1 knockdown demonstrated increased gene transcripts indicative of glial and endothelial activation ($p<0.05$) and retinal vascular and synaptic junction defects, which were significantly improved in blast mice with Col4a1 knockdown receiving ASC-CCM. COL4A1-enriched but not COL4A1-immunodepleted ASC-CCM prevented cytokine stimulated microglial nitrite release as well as TNF- α induced endothelial permeability in vitro. HRECs with knockdown of Col4a1 (~90%) mimicked known pathogenic vascular defects, exhibiting impaired HREC migration and increased transmigration of leukocytes, which was remedied by COL4A1 enriched ASC-CCM ($p<0.05$)

Conclusions: Our studies demonstrate that pre-existing Col4a1 deficiency can exacerbate the TBI outcome and thus be a TBI risk factor in humans. Additionally, our studies confirm the efficacy of ASC-CCM administration in treating Col4a1 deficiency in neurotrauma

TITLE: Synaptotagmins 1 and 7 in vesicle release from rods and cones of mouse retina

SESSION TITLE: Inner retinal function

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Mesnard, C. Hays, J. Grassmeyer, C.L. Barta, K.K. Hinz, W. Thoreson, Ophthalmology and Visual Sciences, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Chris Mesnard: Commercial Relationship: Code N (No Commercial Relationship) | Cassandra Hays: Commercial Relationship: Code N (No Commercial Relationship) | Justin Grassmeyer: Commercial Relationship: Code N (No Commercial Relationship) | Cody Barta: Commercial Relationship: Code N (No Commercial Relationship) | Kyle Hinz: Commercial Relationship: Code N (No Commercial Relationship) | Wallace Thoreson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Synaptotagmins are the primary Ca^{2+} sensors for synaptic exocytosis. Previous evidence suggested synaptotagmin-1 (Syt1) mediates evoked vesicle release from cones, but release from rods involves Syt1 and another sensor.

Methods: We performed immunohistochemistry, electroretinograms (ERG) and single-cell recordings using mice in which Syt1 and Syt7 were conditionally removed from rods (Rho-Cre) and/or cones (HRGP-Cre). Glutamate release was measured in rods from anion currents activated during glutamate re-uptake.

Results: Deletion of Syt1 from rods abolished fast glutamate release evoked by short depolarizations but not slower release evoked by long steps. Immunohistochemical labeling showed syntaptotagmin-7 (Syt7) in rod terminals and deletion of Syt7 reduced slow but not fast glutamate release. Deleting both sensors from rods fully abolished depolarization-evoked glutamate release. Using Ca^{2+} buffers, we found that fast release involves vesicles close to ribbon-associated Ca^{2+} channels whereas slow release involves more distant sites. Confirming that Syt1 is the sole sensor in cones, eliminating Syt1 from cones abolished photopic ERG b-waves, matching responses of GNAT2KO mice that lack functional cones. Eliminating Syt1 from rods reduced scotopic ERG b-waves. However, selective elimination of Syt7 from rods, as well as global knockout of Syt7, did not significantly reduce scotopic or photopic b-waves. Furthermore, mice lacking both Syt1 and Syt7 in rods showed the same responses as mice only lacking Syt1 in rods. Eliminating Syt1 from both rods and cones abolished photopic b-waves and left almost no scotopic b-waves. These b-waves did not differ significantly from those of mice lacking both Syt1 and Syt7 in rods and cones.

Conclusions: Syt1 is the principal sensor shaping rod and cone inputs to bipolar cells during light flashes. Syt7 contributes to slow non-ribbon release from rods, but has little impact on ERG b-waves suggesting it plays a modulatory role (e.g., shaping synaptic cleft glutamate levels).

TITLE: Long-acting potential of suprachoroidally delivered BCX4161, a selective plasma kallikrein inhibitor, for diabetic macular edema

SESSION TITLE: Macular diseases/ macular edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Muya, V. Kansara, T.A. Ciulla, Clearside Biomedical Inc, Alpharetta, Georgia, UNITED STATES|Y. El-Kattan, Y. Babu, Biocryst Pharmaceuticals Inc, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Leroy Muya: Commercial Relationship(s);Clearside Biomedical:Code E (Employment) | Yahya El-Kattan: Commercial Relationship(s);Biocryst Pharmaceuticals:Code E (Employment) | Viral Kansara: Commercial Relationship(s);Clearside Biomedical:Code E (Employment) | Yarlagadda Babu: Commercial Relationship(s);Biocryst Pharmaceuticals:Code E (Employment) | Thomas Ciulla: Commercial Relationship(s);Clearside Biomedical:Code E (Employment)

ABSTRACT BODY:

Purpose: BCX4161 is a potent and selective inhibitor of human plasma kallikrein activity. Elevated plasma kallikrein (PKal) levels have been reported in the vitreous humor of patients with diabetic macular edema (DME). Inhibition of PKal activity can be an effective therapeutic strategy for the treatment of DME. Suprachoroidal delivery of BCX4161 suspension may result in sustained and safe therapeutic drug levels in the retina-choroid. Hence, the purpose of this study was to assess ocular pharmacokinetics (PK), durability and tolerability of suprachoroidally delivered BCX4161 in rabbits.

Methods: A single bilateral suprachoroidal injection (100 µL) of BCX4161 suspension was administered to male Dutch-Belted (DB) pigmented rabbits (N=2-3 rabbits/ timepoint) at a dosage of 0.5 mg/eye. Ocular tissues (RPE-choroid-sclera (RCS), retina, vitreous humor, aqueous humor), and blood were collected, at pre-determined timepoints for up to 12 weeks, and analyzed for drug content. An 8-mm biopsy punch was used to collect the central retina and the central RCS around the optic nerve. Ocular tolerability was assessed via in-life clinical observations including slit-lamp and indirect ophthalmoscopy.

Results: Suprachoroidally delivered BCX4161 was generally well tolerated in rabbits. No overt signs of toxicity were observed in rabbits during this 12-week study. Sustained and high exposure of BCX4161 was observed in the RCS and the retina throughout the study duration. Mean retina concentrations reached a maximum value (C_{max}) of 75 µg/gm (peripheral retina) and 13 µg/gm (central retina) at 24 hours postdose (T_{max}). On day 84 (the last timepoint), mean BCX4161 levels in the central retina (30 µg/gm) and the peripheral retina (21 µg/gm) were 1-2 orders of magnitude higher than the in-vitro IC99 (100 nM) levels. The dose depot (RCS) had 1 to 2 orders of magnitude higher mean concentration than the retina, and the retina had 1 to 2 orders of magnitude higher mean concentration than the vitreous humor. Low levels of BCX4161 were observed in some samples of aqueous humor and plasma.

Conclusions: Suprachoroidally delivered BCX4161 suspension provided sustained and targeted delivery of BCX4161 to the chorioretina, has the potential to be a safe, effective and long-acting therapy for the treatment of DME, and warrants further studies.

TITLE: Visual Perceptual Abilities in Young Children Diagnosed With CVI Versus Those With Ocular Disorders

SESSION TITLE: Visual Impairment - Reading and Selected Topics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Almagati, B.S. Kran, D. Mayer, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Reem Almagati: Commercial Relationship: Code N (No Commercial Relationship) | Barry Kran: Commercial Relationship: Code N (No Commercial Relationship) | D. Luisa Mayer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Currently, there is no available standard approach to diagnose Cerebral Visual Impairment (CVI). Vancleef et al (2020) showed that the Children's Visual Impairment Test for 3- to 6-year-olds (CVIT 3-6) differentiated children with CVI from three groups: typically developing children, children with intellectual disorders, and typically developing children with simulated reduced visual acuity. We performed a prospective clinical study to assess the ability of this visual perceptual test to differentiate children with CVI from children with ocular and/or ocular motor disorders.

Methods: The CVIT 3-6 is an objective test that uses a simple matching technique to assess the child's visual perceptual abilities. In-person testing was not feasible due to the COVID-19 pandemic. We developed and tested a virtual model first in a small sample of typically developing young children. Study participants were later recruited from a pediatric low vision clinic. Our clinical cohort consisted of two groups, children with a previous diagnosis of CVI and children with ocular and/or ocular motor disorders only. The examiner was unaware of the participant's diagnosis prior to data collection. A validated parent questionnaire regarding CVI, the Flemish cerebral visual impairment questionnaire, was also administered.

Results: Preliminary data show a small, non-significant difference in overall CVIT 3-6 scores between participants with CVI and those with ocular disorders. (means 56 vs. 64.7, respectively. $p = 0.151$). For the Flemish CVI questionnaire, participants in the CVI group had a significantly higher % abnormal scores on average than those with ocular disorders ($p = 0.003$). Our virtual testing protocol was successful in all participants tested to date.

Conclusions: In this preliminary study, collected data suggest that the CVIT 3-6 did not differentiate between children with CVI compared to those without CVI. This study is ongoing. Results from a larger sample will be needed to verify this finding. The Flemish (Ortibus) questionnaire differentiated between children with CVI from children without CVI.

ABSTRACT BODY:

Purpose: To examine the outcomes of combined phacoemulsion and minimally invasive glaucoma surgeries (MIGS) performed by residents and attendings in a veteran population. Eye care is the third busiest clinical service in the VA system, with an increasing prevalence of glaucoma as a result of extended life-span in this population. There is currently no data that exists on the use of MIGS in the veteran population.

Methods: Retrospective chart review based on CPT codes of patients who underwent combined phacoemulsification and MIGS procedure from 2015 to 2020. Inclusion criteria involved veterans of all races, aged 18 or older, male or female, currently taking at least one anti-hypertensive eye drop medication, with the diagnosis of either ocular hypertension, glaucoma suspect, open angle glaucoma, pseudoexfoliative glaucoma, pigmentary glaucoma, or mixed mechanism glaucoma. Excluded were all patients with previous glaucoma surgery, except for cataract extraction or laser surgery, and any patients with the diagnosis of severe glaucoma.

Results: The study comprised 55 eyes of 40 veterans with a mean age of $72 \pm$ SD years. In conjunction with phacoemulsion, 10 (18%) eyes received endoscopic cyclophotocoagulation, 21 (38%) eyes underwent Kahook Dual Blade goniotomy, 7 (13%) eyes underwent gonioscopy-assisted transluminal trabeculotomy, 9 (16%) eyes received iStent, and 8 (15%) eyes had a combination. IOP was reduced by 22% on average at 1-year follow-up. The number of required IOP-lowering eye drop medications decreased for 24 eyes (44%). 9 (16%) eyes required no drops after MIGS. The overall rates of complications and failure were 12% and 16%, respectively. There was no statistically significant difference in the rates of operative complications ($p = 0.302$) and treatment failure ($p = 0.149$) between residents and attendings.

Conclusions: MIGS are safe with low rates of adverse events, and have the potential to decrease IOP and medication burden in veterans. This is in alignment with the current literature regarding MIGS in the civilian population. MIGS outcomes do not differ between resident surgeons and attending surgeons. To our knowledge, this is the first study that has compared MIGS performed by residents to those performed by attendings.

ABSTRACT BODY:

Purpose: To assess the impact of DR severity on the risk of DR progression to clinically significant macular edema (CSME) or proliferative DR (PDR) in patients with diabetes mellitus (DM) screened at primary care centers in the US; and the association of ≥ 2 -step DR worsening with race or DM type.

Methods: Eyes of 22,109 patients with DM were analyzed based on DR severity data collected by masked professional reading center graders from 1999–2016 (Inoveon Corporation, OK). DR severity was graded using the Early Treatment Diabetic Retinopathy Study (ETDRS) DR Severity Scale (DRSS). Eyes with valid baseline (BL) and ≥ 1 post-BL DRSS value (42,011 eyes) were analyzed. Rate of ≥ 2 -step DR worsening was assessed in the overall population; the development of CSME (using ETDRS criteria) or PDR was analyzed among eyes with no CSME and no PDR at BL, respectively. Association analyses were performed in a subset where patients reported race and DM type.

Results: For all eyes evaluated, time to first ≥ 2 -step DR worsening was 2.7% at year 2 and 7.1% at year 4 (Kaplan-Meier analysis). Rate of ≥ 2 -step DR worsening was greatest among eyes with BL DRSS 43–53. Analysis of time to first development of PDR or CSME in all eyes showed the presence of 3 distinct clinical subtypes: increased risk of CSME, increased risk of PDR, and increased risk of CSME and PDR (smallest subset). This trend was not dependent on BL DRSS. Only 4058 (18%) and 11,334 (51%) patients reported race and DM type, respectively. Of these, >95% patients had BL DRSS 10–35; in this subset, a higher rate of ≥ 2 -step DR worsening was associated with Black and White races (Fig) and type 1 DM (T1D).

Conclusions: Eyes with BL DRSS 43–53 were at greatest risk of progression to CSME or PDR. Existence of 3 distinct clinical DR subtypes, which were not driven by BL DR severity, was also observed. The association analyses, conducted in subsets where race and/or DM type was reported (>95% with BL DRSS 10–35), showed a trend of faster DR progression in Black and White patients and those with T1D; more research is needed as our data may not accurately reflect DR dynamics in underrepresented minorities. Study limitations were: small sample size of the Black and T1D patient subsets; majority of patients reporting race and/or DM type were from OK or FL; and more thorough targeted screening conducted for patients with DM in the Native American population.

TITLE: Increased Reactive Oxygen Species (ROS) production in Patient-specific iPSC-derived RPE from AMD patients

SESSION TITLE: AMD: Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Gong, H. Cai, L.V. Del Priore, M.A. Fields, Department of Ophthalmology and Visual Sciences, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jie Gong: Commercial Relationship: Code N (No Commercial Relationship) | Huey Cai: Commercial Relationship: Code N (No Commercial Relationship) | Lucian Del Priore: Commercial Relationship: Code N (No Commercial Relationship) | Mark Fields: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress plays an important role in RPE cell injury and is also a risk factor of AMD. Tert-butyl hydrogen peroxide (TBHP) is an agent used to induce oxidative stress in RPE and serves as a reproducible model that mimics key aspects of AMD pathology. We have previously demonstrated our ability to derive iPSC-derived RPE from AMD patients and age-matched controls. These cells perform critical functions such as phagocytosis of photoreceptor outer segments, the ability to form tight junctions, and retinol metabolism. A decrease in metabolic capacity was also observed in iPSC derived RPE from AMD patients. Here we seek to detect the cellular ROS production of iPSC-derived RPE from AMD patients and age-matched controls.

Methods: iPSCs were generated from AMD (n=3) and age-matched patients with no history of AMD (n = 2) using mRNA. iPSCs were differentiated into RPE using an established protocol. RPE lines were verified by morphology, immunohistochemistry and confocal microscopy. Cells were labeled with 20 μ M 2', 7' -dichlorofluorescein diacetate (DCFDA), and then cultured for another 2 hours with or without 150 μ M TBHP, and then quantified using a BioTek FLx800 plate reader.

Results: Human iPSC-derived RPE expressed specific RPE cell markers RPE65, CRALBP, and ZO-1. In the presence of TBHP, both groups of iPSC-derived RPE cells expressed higher level of ROS. In normal control group, ROS were 42.10% (p<0.001) higher in TBHP than untreated group. In AMD group, ROS were 23.70% (p<0.001) higher in TBHP than untreated group. A comparison of iPSC- derived RPE cells with PBS treatment from normal controls (n = 2) vs. AMD patients (n = 3) revealed no significant difference in ROS production in all 5 lines. However, iPSC-derived RPE from normal controls with TBHP treatment revealed higher ROS production 18.47% (p<0.05) vs AMD patients with TBHP treatment.

Conclusions: In this study, we generated RPE from AMD patients and individuals with no history of AMD. Higher levels of ROS production was observed in iPSC-derived RPE from both AMD patients and normal controls. However, no differences were observed when comparing TBHP-treated AMD and control lines. Further, exploration of various inflammation related growth factors and metabolic pathways among normal and AMD-derived RPE should reveal mechanisms of disease-related phenotypes and pave the way for novel therapeutic strategies.

ABSTRACT BODY:

Purpose: Oxidative stress is implicated in the pathobiology of age-related macular degeneration (AMD). Exosomes are small extracellular nanovesicles (EVs) of endocytic origin that mediate different signals between cells and can be modified by oxidative stress. We hypothesize that oxidative stress affects retinal pigmented epithelium (RPE) exosome release and content and contributes to basal deposit extracellular matrix (ECM) changes. Here, we characterize ECM changes and RPE exosome release and content in response to oxidative stress.

Methods: We have previously shown that exosomes can be isolated apically and basally from fully differentiated and polarized primary porcine RPE cells grown on Transwell cell culture inserts. To induce chronic oxidative stress, these cultures were treated daily with 0.2mM H₂O₂ for 4 weeks. Basolateral exosome yield was assessed by Nanoparticle Tracking Analysis (NTA) and immunoblotting for exosomal markers along with total protein quantitation. Purity and protein content of exosome preparations were analyzed by immunoblotting for exosomal markers, and markers for known contaminants. In-depth proteomic mass spectrometry analyses were done on both exosomes and ECM preparations.

Results: Unbiased proteomic analyses of the content of highly purified basolateral exosomes isolated from RPE cultures under chronic oxidative stress revealed changes to a number of ECM proteins. One such protein, Keratin 10 (KRT10), was increased 3-fold in basolateral exosomes and this was mirrored by a 6.5-fold increase of KRT10 in proteomic analyses of the basal extracellular matrix (ECM) and correlated with a 4-fold increase in basolateral exosome secretion as measured by NTA. Treatment of RPE cultures with an inhibitor of exosome release effectively reduced basolateral EV secretion. Proteomic analyses of exosomes and ECM from these cultures will also be presented.

Conclusions: We show for the first time that chronic oxidative stress in primary RPE monolayers induced proteomic changes in exosomes and increased basolateral EV secretion which could be prevented by inhibition of exosome release. We also show examples of protein changes in exosomes that correlate with protein changes in the underlying ECM. These findings have the potential to open up a completely novel avenue for therapeutic intervention in AMD.

ABSTRACT BODY:

Purpose: Retinal vasculopathies account for the primary causes of loss of sight in the industrialized world and current standards present significant side effects. To develop novel treatment paradigms, we developed UBX1325, a novel small molecule inhibitor of specific subtypes within the B-cell lymphoma 2 (Bcl-2) family of apoptosis regulatory proteins and assessed its efficacy in senescence-associated models of retinopathy.

Methods: Target engagement (TE), decreased Bcl-xL:Bim or Bcl-2:Bim complexes, was measured by an electrochemiluminescence-based assay in retinal lysates from C57BL/6 mice after intravitreal (IVT) injection of UBX1325. Initiation of apoptosis (mechanism engagement, ME) was measured by caspase-3/7 activation. Adult mice and neonatal mice from oxygen induced retinopathy (OIR; 75% O₂ from post-natal day (P)7-P12) or normoxic controls were used for TE and ME measurements. Vascular endpoints (neovascular and avascular area) were evaluated at P17 by isolectin B4 staining in OIR mice given a single IVT injection of UBX1325 at P12. UBX1325 was also studied in the streptozotocin (STZ)-induced retinopathy model. UBX1325 was injected IVT at weeks 8 and 9 post-STZ, and retinal endpoints were measured at week 10. Vascular leakage was evaluated by Evans blue dye extravasation into the retina after intravenous injection. The dark-adapted electroretinogram was used to assess retinal function with increasing flash intensity. Retinal gene expression was evaluated for a limited panel of targets by qRT-PCR.

Results: IVT administration of UBX1325 lead to a reduction of anti-apoptotic Bcl-xL:Bim complexes in the mouse retina. Bcl-xL TE (37-81%) in OIR animals resulted in caspase-3/7 activation (3-9-fold) and improvements in both retinal neovascularization (58-71%) and avascular area (32-52%). In the diabetic mouse, UBX1325 injection resulted in reduced retinal vascular permeability (78-90%) and an improved ERG (a- and b-wave amplitude).

Conclusions: Inhibition of retinal Bcl-xL by UBX1325 promotes apoptosis in the senescence-associated OIR model. UBX1325 improves retinal vasculature in both the OIR and STZ mice, and demonstrates differentiation over anti-VEGF agents in OIR. Collectively, our data support development of UBX1325 for retinal vasculopathies and initial clinical evaluation of UBX1325 in patients with diabetic macular edema (DME).

TITLE: Relationship between Intraretinal and Subretinal Fluid with Visual Acuity in Patients with Neovascular Age-Related macular Degeneration Treated with Anti-Vascular Endothelial Growth Factor

SESSION TITLE: AI in the retina/ AMD imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Iyer, J. Muste, A. Kalur, R.P. Singh, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Amogh Iyer: Commercial Relationship: Code N (No Commercial Relationship) | Justin Muste: Commercial Relationship: Code N (No Commercial Relationship) | Aneesha Kalur: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship(s);Genentech/Roche:Code F (Financial Support);Alcon/Novartis:Code F (Financial Support);Zeiss:Code F (Financial Support);Apellis:Code F (Financial Support);Graybug:Code F (Financial Support);Bausch + Lomb:Code F (Financial Support);Regeneron Pharmaceuticals Inc.:Code F (Financial Support);KET:Zeiss (research):Code F (Financial Support)

ABSTRACT BODY:

Purpose: Anti-vascular endothelial growth factor (VEGF) treatment is used to treat neovascular age-related macular degeneration (nAMD). Fluid resolution by OCT is used both as an indicator of disease control and to guide the frequency of treatment since anti-VEGF therapy reduces neovascularization-related exudation. The variability in treatment response is considered a poor prognosis for visual acuity (VA). This study seeks to characterize the specific fluid compartment drives this variability. The hypothesis is that there will be poorer VA outcomes for eyes in the highest quartile of IRF volumes and no significant correlation between SRF and VA.

Methods: A retrospective cohort study of 301 treatment-naïve nAMD eyes was performed at the Cleveland Clinic Cole Eye Institute. Spectral domain optical coherence tomography (OCT) scans were obtained for patients over a 12 month period at 3 month intervals from January 1st, 2012 to October, 31st, 2019. Patients were excluded if they had maculopathies unrelated to nAMD that would interfere with analysis. IRF and SRF quantification was performed by the Notal Optical Coherence Tomography Analyzer (NOA), which employs machine learning and image recognition computational techniques. Baseline demographics and VA were also recorded at each visit. A linear mixed-effects regression model (LMER) was used to analyze the effect of IRF and SRF on VA over 12 months by quartiles.

Results: Mean IRF was $122.23 \pm 270.14 \text{ mm}^3$ (mean \pm SD) at baseline and $24.39 \pm 106.56 \text{ mm}^3$ at 12 months ($p < 0.001$). Mean SRF at baseline was $215.52 \pm 394.86 \text{ mm}^3$ and $64.42 \pm 173.70 \text{ mm}^3$ at 12 months ($p < 0.001$). Mean number of injections was 8.25 ± 2.47 . Mean VA at baseline was 60.13 ± 18.79 ETDRS letters and 65.68 ± 17.19 ETDRS letters at 12 months ($p < 0.001$). The LMER showed that eyes in the highest quartile of IRF volume had a significant VA loss of -4.26 ± 2.54 ETDRS letters compared to those not in this quartile ($p = 0.001$) after adjusting for baseline factors and injections. There was no significant relationship between SRF and VA.

Conclusions: High levels and high variability of IRF volume are associated with poorer VA outcomes in patients with nAMD treated with anti-VEGF. Further studies can provide insight into treatment patterns in nAMD patients with IRF and SRF and how that relates to VA.

TITLE: Accommodation mitigation in reverse Shack-Hartmann refraction measurement

SESSION TITLE: Imaging and optical aberrations

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Sapiens, EyeQue Corp., Newark, California, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Noam Sapiens: Commercial Relationship(s);EyeQue Corp.:Code E (Employment)

ABSTRACT BODY:

Purpose: Accommodation is one of the most prevalent impediments of accurate refraction measurements. As accommodation is part of the eye refraction, measurements are often incapable of discerning between the eye accommodation state and the refraction error of an eye. A method to control accommodation during a refraction measurement is required. The desired method would not require cycloplegia and could be implemented anywhere.

Methods: A low-cost, handheld, self-administered refraction measurement prototype device based on the reverse Shack-Hartman technology with accommodation mitigation was developed. The device has two optical channels per eye that are optically overlaid on the retina. An accommodation mitigation channel with a 30° field of view and large depth of focus presents a 3D stereoscopic visual stimulus during the test. A measurement channel implements the reverse Shack-Hartman technology.

An exploratory, single-center, open-label study in healthy volunteers was conducted to compare this device with an autorefractor. 21 subjects between the ages of 18 and 30 are included in the analysis. Each subject underwent 3 autorefractor measurements and 3 measurements on the device. Average refraction numbers were calculated for each device. Double blind BCVA measurements using trial lenses were conducted by an optometrist using ETDRS charts.

Results: The correlation between the autorefractor and the device spherical equivalent are presented in figure 1. Results show good linear correlation with slight negative bias.

BCVA results were statistically analyzed and a graphical representation of is presented in figure 2. The results show that the average difference between the device and the autorefractor is less than half a letter with 95% confidence interval of achieving normal vision.

Conclusions: The performance of the new device is substantially equivalent to the autorefractor. The expected cost of the device is to be orders of magnitude less than that of the autorefractor. Furthermore, the device is handheld and simple to use. Therefore, it is an accurate alternative to traditional refraction measurements. It provides users with an ability to perform accurate, self-administered refraction measurements conveniently at home.

ABSTRACT BODY:

Purpose: Dampened cerebrovascular reactivity (CVR) impairs blood delivery to brain regions. Multiple studies have suggested a role of the basal forebrain (BF) in glaucoma (PMID: 31242454; ARVO 2020: 4336). However, CVR changes in BF with glaucoma severity have yet to be explored. Recently, relative CVR (rCVR) mapping was introduced using resting-state functional MRI (rsfMRI) without gas challenges. Here, we investigate rCVR changes in the visual cortex and basal forebrain with glaucoma severity.

Methods: Normal (n=22), early-stage (n=18), and advanced-stage (n=19) glaucoma patients underwent anatomical MRI and rsfMRI. The optic nerve and optic chiasm volumes were measured using ImageJ. rCVR maps and regional rCVR values were generated and extracted with MriCloud online tool. Age, optical coherence tomography measurements, and Humphrey visual field perimetry were obtained from clinical records. Results are presented as mean±SEM. One-way ANOVA followed by post-hoc Bonferroni's multiple comparisons test, and trend analysis were applied.

Results: Demographics, clinical ophthalmic assessments, and volumetric MRI assessments illustrated the characteristics of the anterior visual pathways in the normal control, early-stage glaucoma and advance-stage glaucoma groups (Fig. 1). The averaged rCVR map from normal controls is consistent with previous studies (PMID: 27888058, 32278094) (Fig. 2). Advanced-stage glaucoma patients [1.03 ± 0.03 relative unit (r.u.); $p < 0.05$] have significantly lower rCVR in the visual cortex compared to normal controls (1.20 ± 0.06 r.u.; early-stage: 1.09 ± 0.05 r.u.), and exhibit a decreasing trend in more severe disease. These corroborate with a previous Doppler ultrasound study (PMID: 23816432). Interestingly, rCVR in BF has an increasing trend with severity. No significant rCVR change was observed in the somatosensory cortex.

Conclusions: Visual cortical rCVR decreases with glaucoma severity, while rCVR in the basal forebrain increases with severity. Our results verify visual cortical CVR reduction in glaucoma patients and further solidify that the basal forebrain plays a role in glaucoma.

ABSTRACT BODY:

Purpose: To report the results of transscleral optical phase imaging (TOPI) in age-related macular degeneration (AMD). This image modality has been developed to visualize in vivo the cellular structure of the human retinal pigment epithelium (RPE).

Methods: Non-neovascular AMD cases with clear optic media and good fixation were recruited for TOPI, associated with conventional imaging: spectral domain optical coherence tomography, autofluorescence, color and infrared fundus imaging. Six squares of 5.04x5.04 degrees were acquired with TOPI: one foveal, four localized in the macular quadrants with 3.8° eccentricity, and one to the investigators discretion. The TOPI images were optimized for contrast and confronted with information from conventional multimodal imaging.

Results: Included were 10 eyes of 8 AMD patients (mean age 75.5 years, 50% females).

Prominent features on the TOPI images were the reticular pattern of the choriocapillaris, particularly well contrasted on areas of geographic atrophy and RPE hypopigmentation, and the presence of additional dark spots irregularly distributed. Drusen showed dark with a white halo around. Within atrophic zones there were irregularly formed, sharply demarcated dark spots of variable size, correlating with degenerative remnants of RPE cells on OCT. The dark spots were the dominating element for the image contrast, leading to very low contrast of the RPE cell visualization on the same image.

Conclusions: TOPI revealed in AMD the detailed structure of the choriocapillaris. Different types of dark spots were identified, corresponding to drusen and degenerated RPE cells.

ABSTRACT BODY:

Purpose: Dry age-related macular degeneration (AMD) is a complex ocular disorder that is thought to result in outer retinal hypoxia and can lead to the growth of choroidal neovascularization. Computational models of dry AMD demonstrate that the presence of drusen and distance between the choroid and retinal photoreceptors affect levels of retinal hypoxia; however, few studies have investigated normobaric hyperoxia treatment for dry AMD. We performed an exploratory study to evaluate the functional and anatomic effects of short-term normobaric hyperoxia in patients with dry AMD. We hypothesized that normobaric hyperoxia would be most effective in retinas with greater separation between the photoreceptors and choriocapillaris.

Methods: Patients with dry AMD (23 eyes in 18 patients) were categorized based on the presence of: hard drusen (n = 10), drusenoid pigment epithelium detachments (PED) (n = 8) or geographic atrophy (GA) (n = 5). Macular OCT scans and ETDRS visual acuity measurements were obtained before and after 3-hour administration in a blinded fashion of either normobaric hyperoxia (40% FiO₂) or normobaric normoxia (20% FiO₂).

Results: Three-hour normobaric hyperoxia treatment in dry AMD patients with drusenoid PED demonstrated significant decreases in foveal volume ($-0.003 \pm 0.005 \text{ mm}^3$, $p = 0.02$) and drusen height ($-6.8 \pm 7.6 \text{ } \mu\text{m}$, $p = 0.002$) as well as an increase in visual acuity (LogMAR: -0.06 ± 0.07 , $p = 0.02$) relative to pre-O₂ baseline using Two-tailed Student's dependent samples t-test. These differences were also significant when compared to normobaric normoxia controls using Two-tailed Student's independent samples t-test. There was a moderate positive correlation between change in drusen height and change in visual acuity in the 3-hour drusenoid PED condition ($r^2 = 0.42$). In contrast, no significant differences in functional and anatomic measures tested were found after three-hour normobaric hyperoxia treatment in patients with hard drusen or geographic atrophy.

Conclusions: These results support our hypothesis that retinas with larger drusen, resulting in greater separation between the choroid and photoreceptors, respond more to hyperoxia. These findings support the role of hypoxia in AMD and suggest that hyperoxia treatment should be investigated further in these patients.

ABSTRACT BODY:

Purpose: Many studies have identified ocular hemodynamics as relevant in glaucoma; however the specific link between vascular biomarkers, blood pressure (BP), intraocular pressure (IOP), and the progression of open angle glaucoma (OAG) remains uncertain. Herein we address this issue via a novel physiology-enhanced approach to analyze data from the Indianapolis Glaucoma Progression Study.

Methods: 115 OAG patients were evaluated twice yearly over 5 years. Functional and structural OAG progression was monitored by visual field testing, optical coherence tomography and Heidelberg retinal tomography. A validated model of the retinal circulation (Guidoboni et al 2014) was used to simulate 8 individualized hemodynamic outputs (Fig.1) based on 4 inputs (SBP, DBP, IOP, HR) measured on each patient. In the retinal model, changes in IOP and BP induce changes in transmural pressures and, therefore, vascular resistances. The model is capable of predicting hemodynamic variables of physiological interest that cannot be measured directly, thereby producing a physiology-enhanced dataset with 12 instead of 4 variables for each patient and visit. The 12 baseline variables for each patient were then fed into an unsupervised machine learning model, Fuzzy c-means (FCM) clustering algorithm to identify patient clusters with similar ocular hemodynamics. The relationship between clusters and OAG progression was analyzed statistically with p-values<0.05 considered statistically significant.

Results: The FCM clustering algorithm generated 4 clusters based on the 12 variables and were plotted based on IOP and mean arterial pressure ($MAP = 2/3 \cdot DBP + 1/3 \cdot SBP$), Fig. 2. A statistically significant difference was found between the occurrence of OAG progression in Cluster 4 (n=35; 20 progression, 15 no progression) when compared to the other clusters (n=80; 62 progression, 18 no progression), p=0.026. Further, HR and Rv in Cluster 4 were found to be markedly lower than the other clusters (Fig.2).

Conclusions: Our analysis suggests that physiology-enhanced data analytics based on mathematical modeling and unsupervised machine learning of ocular hemodynamics may be effective in glaucoma risk stratification. The integration of modeling, machine learning and the clinical outcomes of glaucoma patients has the potential to improve OAG screening and treatment paradigms.

ABSTRACT BODY:

Purpose: Hyper-reflective foci(HRFs) are associated with age-related macular degeneration(AMD), and with visual outcomes in diabetic retinopathy. Automating the HRF segmentation in retinal tissues would be beneficial for feature extraction and overall disease management. This work presents a fully automated approach for HRF segmentation in spectral domain optical coherence tomography(SD-OCT) images.

Methods: This study includes SD-OCT data acquired at the University of Bonn (Heidelberg Spectralis; image resolution of 786x496 pixels,scan width 30°). The dataset contained 3669 B-scans from 56 patients (10 diabetic macular edema,46 AMD).

A modified U-Net architecture with a densenet-169 backbone was implemented for the semantic segmentation. A point of innovation is the use of a patch-based strategy that ensures the model encoder is trained on enough pixels of interest. To elaborate, as a pre-processing step, we define the retinal pigment epithelium(RPE) layer for each B-scan (using a previously trained model for OCT layer segmentation). An automated dataloader takes the B-scan, HRF ground truth annotation and the RPE denotation as inputs and generates random patches(8x64x64) for each image around the HRF and RPE denoted pixels(location chosen randomly). These patches are then fed into the U-Net encoder, trained with a compound loss function derived from Dice and focal loss. This strategy allows the encoder to train on pathologically important pixels around the inner/outer retina.

Results: Our trained model performed well,considering the high class-imbalance of the HRF and non-HRF pixels. The current reported HRF segmentation performance in the literature is an average precision(AP) of 0.71. Our baseline AP was similar(AP 0.70) following a similar strategy. Using our patch-based strategy with region of interest selection, the AP improved to 0.75. The AP was 0.69 when trained with a ResNet50 backbone. Overall, the combination of Dice-focal loss generated higher segmentation performance.

Conclusions: This study presents a pipeline for semantic segmentation of HRFs corresponding to hard exudative and hyperpigmentation. Implementation of a patch-based strategy to improve region of interest selection for the model encoder, and combination of Dice and focal loss improve the current state of the art performance for HRF segmentation.

TITLE: Role of PI3K Signaling Inhibition in Inducing Autophagy-Dependent Organelle Elimination

SESSION TITLE: Lens Development and Differentiation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R. Gheyas, A. Menko, Anatomy, Cell Biology, and Pathology, Thomas Jefferson University, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Rifah Gheyas: Commercial Relationship: Code N (No Commercial Relationship) | A Sue Menko: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Blocking of PI3K/Akt signaling is known as a canonical autophagy-inducing pathway. Previous studies performed in our lab have linked autophagy mechanisms to the removal of mitochondria and ER from the center of the developing lens to form the Organelle Free Zone (OFZ). Our new studies have investigated the role of PI3K pathways in autophagy-dependent elimination of mitochondria, ER, and nuclei during lens development.

Methods:

At E12, prior to formation of the OFZ, chick embryo lenses are exposed for 24 hrs in organ culture to the pan-PI3K inhibitors, LY294002 or CH5132799, or the PI3K/Akt-specific inhibitor, MK-2206, with DMSO as the vehicle control. Differentiation state-specific regions were microdissected for immunoblot analysis. Whole lenses either cryosectioned for immunostaining with antibodies to organelles, autophagy markers, or signaling molecules, or labeled live for mitochondrial potential with Rhodamine123 prior to confocal image analysis. Development-stage-specific studies were also performed.

Results: In studies of the lysosomal protein LAMP1 we provide evidence that lysosomes are induced as OFZ formation begins at E13. Exposure of E12 lenses to either LY294002 or MK-2206 induces LAMP1, along with other autophagy-specific proteins, and the premature elimination of mitochondria and ER in lens fiber cells. While mitochondrial depolarization is known to occur before mitochondrial removal, blocking PI3K signaling with LY294002 had no impact on mitochondrial polarity, demonstrating that the link between suppression of PI3K signaling and mitochondrial loss was a direct result of autophagy induction. The two distinct pan-PI3K inhibitors lead to premature elimination of organelles. Pan-PI3K inhibition induced removal of nuclei, with nuclear loss associated with DNA cleavage as demonstrated by TUNEL assay, without impacting cell survival. In contrast, specifically blocking just the PI3K/Akt signaling axis alone induced premature loss of mitochondria and ER within 24 hrs without inducing DNA cleavage or nuclear loss.

Conclusions: The loss of mitochondria and ER to form the OFZ is by an autophagic-dependent mechanism activated by suppression of the PI3K/Akt signaling axis. While the elimination of nuclei is also PI3K-regulated, its induction involves suppression of multiple downstream effectors of PI3K.

ABSTRACT BODY:

Purpose: To understand the cytosolic and nuclear role(s) of actin cytoskeletal and cell adhesive proteins in trabecular meshwork (TM) cells in the context of aqueous humor outflow

Methods: Nuclear and cytosolic fractions isolated from primary cultures of human TM cells treated with dexamethasone for various lengths of time were subjected to quantitative proteomics analysis. The distribution and colocalization of ArgBP2 and its related c-Cbl associated protein (CAP/Ponsin) with actin cytoskeletal and focal adhesions proteins, and the dexamethasone-induced reorganization of these proteins in human TM cells were evaluated by immunofluorescence and immunoblotting analyses.

Results: Dexamethasone treatment (0.5 μ M for 5-7 days) led to a significant increase in the levels of ArgBP2 (SORBS2) and CAP (SORBS1), which are the sorbin and SH3-domain containing, and flotillin interacting adaptor proteins, in both, the nuclear and cytosolic fractions of human TM cells. The increase in ArgBP2 levels was consistent in more than ten biological replicates of TM cells analyzed. While CAP exhibited a focal adhesion-specific distribution profile, ArgBP2 was found to colocalize with actin stress fibers and ZO-1, and distribute to the focal adhesions, lamellipodia, and nucleus. Upregulation of ArgBP2 and CAP in dexamethasone treated TM cells was associated with increased levels of chromatin remodelers including BRG1, MAT1 and MECP2. The Abl and Arg kinase inhibitor, dasatinib, was found to suppress dexamethasone-induced association of ArgBP2 and CAP with focal adhesions. Interestingly, the chromosomal localization of ArgBP2 at 4q35.1 is a recognized locus for an autosomal dominant POAG.

Conclusions: Taken together, ArgBP2 and its related cell adhesive proteins (CAP and Vinexin) appear to play a key role in dexamethasone-induced actin cytoskeletal crosslinking and cell adhesive interactions in TM cells, which are known to influence aqueous humor outflow and intraocular pressure.

TITLE: Chromatic Filters Restore the Accommodation Control Mechanism in mTBI Patients

SESSION TITLE: Refractive error, refraction, accommodation and presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Almutairi, C. Liu, J. Hayes, Optometry, Pacific University, Forest Grove, Oregon, UNITED STATES|N. Almutairi, Optometry, Qassim University, Buraidah, Al Qassim, SAUDI ARABIA|

Commercial Relationships Disclosure (Abstract): Nawaf Almutairi: Commercial Relationship: Code N (No Commercial Relationship) | Chunming Liu: Commercial Relationship: Code N (No Commercial Relationship) | John Hayes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Accommodation dysfunction following mild traumatic brain injury (mTBI) can lead to symptoms such as blur, asthenopia, and photosensitivity, impairing patients' near-work comfort and efficiency. Accommodative insufficiency is widely reported in mTBI patients who show significantly higher accommodative error (AE). Chromatic filters (CF) have been used as a clinical treatment to improve these symptoms. This study aimed to explore the potential mechanism underneath the CF treatment effect by assessing the effective threshold to blur (ET), a concept introduced by Jiang's modified control model for steady-state accommodation to account for the sensory component.

Methods: Data was obtained from 54 healthy (age 21-30 years) and 30 mTBI subjects (age 18-33 years) using Power Refractor 3. Monocular static accommodation was recorded continuously for 1 minute at 5 distances (6m-20 cm) under 3 conditions: baseline without filter (NF), subjects' selected CF using the Intuitive Colorimeter, and transmission-matched neutral density filters (ND). Further subgrouping was based on subjects' high vs. low color preference. ET was averaged for all distances. The longitudinal chromatic aberration (LCA) was calculated for each selected CF.

Results: Consistent with previous report, AE significantly correlated with ET for non-TBI subjects for all conditions. This correlation was disrupted in the mTBI group and restored by CF and ND Fig.1. The non-TBI group did not show any correlation between ET and LCA Fig.2. Similar result was found in mTBI subjects with low color preference. In contrast, the mTBI subjects with high preference selected a wavelength that induced ET change which was highly correlated with the LCA ($r=-0.90$, $p=0.001$), indicating a potential link between the color and accommodative sensory control.

Conclusions: Our data suggested that accommodation sensory control was impaired in mTBI patients. CF and NF rescued this impairment by altering wavelength and/or luminance. Subjects with high color preference selected color that might modify the ET via LCA, restoring the control through blur sensitivity. This finding provided the first evidence supporting the hypothesis that the CF treatment effect in mTBI might rely upon improving accommodation control.

ABSTRACT BODY:

Purpose: To investigate the association between changes in visual field [VF] and contrast sensitivity [CS] in glaucomatous eyes over a 3-year study period.

Methods: Glaucoma patients who underwent a minimum of three Humphrey 24-2 SITA-Standard VFs and three MARS CS tests were evaluated. Univariate linear regression was used to calculate within-eye slopes of changes in VF mean deviation (MD) and CS over time. Multivariable generalized estimating equation models accounting for within-individual clustering were used to assess the relationship between MD and CS at the baseline and changes over time.

Change in concordance/discordance between MD and CS in terms of defining the eye with better vision was evaluated over time using the test of proportions and survival analysis. Agreement of better eye MD / CS in defining longitudinal stability (± 0.5 dB/year for MD and ± 0.04 logCS units/year for CS) vs. change was also examined.

Results: 338 eyes from 180 glaucoma patients were included. Participants were on average 70 years old and about a third of participants were Black and half were female. There was a significant association between MD and CS at baseline ($\beta = 1.53$ dB decline for every 0.1 logCS unit decline, $p < 0.001$) and change in MD and CS over time ($\beta = 0.13$ dB decline for every 0.1 logCS unit decline, $p = 0.002$).

At baseline, MD and CS tests did not identify the same eye as the better eye for 33.8% of patients. 50% of eyes that were discordant at baseline remained discordant (95% confidence interval (CI) = 0.34-0.66) while 80% of eyes concordant at baseline remained concordant (95% CI = 0.71-0.89). At the end of 3 years, the probability of concordant eyes at baseline remaining concordant over time was 66%, significantly greater than the probability of discordant eyes at baseline remaining discordant ($p < 0.001$).

Over the 3-year period, 77% of subjects who had stable better eye MD also had stable CS while 45% of subjects who had worsening better eye MD also had worsening CS. Similarly, 83% of subjects who had stable CS over the years also had stable MD while 37% of subjects who had worsening CS also had worsening MD.

Conclusions: We found that change in CS over time predicts change in MD in those with glaucoma. However, more work is required to determine if CS could serve as an ancillary test to help judge disease progression.

ABSTRACT BODY:

Purpose: To identify the genetic etiology of an autosomal dominant constellation of pediatric cortical cataract, asymmetric myopia with astigmatism, familial exudative vitreoretinopathy, and primary open-angle glaucoma phenotypes in a large Australian pedigree of European decent we performed linkage analysis, as well as exome and whole-genome sequencing (WGS).

Methods: Twelve affected and 4 unaffected individuals were genotyped at 713K SNPs using HumanOmniExpress-24 BeadChips, and 103K high quality and informative markers were selected via GenomeStudio software. Multipoint linkage analysis and haplotyping were performed by Superlink-Online software (dominant inheritance, 0.99 penetrance). Four affected individuals were exome sequenced using a Roche Nimblegen SeqCap EZ Exome V3 capture kit and an Illumina HiSeq2000 platform (2x100bp, 100x coverage). WGS was performed on an affected individual and his unaffected father using an Illumina HiSeq X Ten platform (2x150bp, 30x coverage). Reads were aligned to hg19 with BWA. SNPs/InDels, structural variants, and copy number variants (CNVs) were called with GATK, Delly, and control-FREEC, respectively. Variant analysis was performed using Golden Helix SVS. Combined Annotation Dependent Depletion (CADD) analysis prioritized variants by predicted deleteriousness.

Results: Linkage mapped the genetic locus to chromosome 7q36 (LOD 3.3). A co-segregating disease haplotype delimited the interval containing 27 protein coding and 17 non-protein coding genes. No candidate coding variants were identified. WGS discovered 136 rare (allele frequency <0.0001) non-coding variants, of which 77 were associated with 13 genes. CADD analysis determined only 1 variant within the top 1% of deleterious variants in the genome (scaled score 21.7) - a novel base substitution located in a highly conserved CpG island between exons 1 and 2 of sonic hedgehog (SHH; NM_001310462.2: c.300+290C>T). Extensive published animal studies link SHH to the phenotypes of this family. ENCODE data suggested that the region may act as a distal enhancer during early development of human eye and retinal tissues.

Conclusions: We identified an intronic variant in SHH as a potential cause of this rare constellation of ocular phenotypes. Disruption of the cis-regulatory enhancer element in SHH may lead to abnormal ocular development.

ABSTRACT BODY:

Purpose: Visible-light optical coherence tomography (vis-OCT) provides high axial resolution and unique backscattering information compared with conventional OCT. However, vis-OCT signal quality is lower in young mice, chiefly due to attenuating hyaloid vessels that persist for several weeks after birth, potentially preventing the use of vis-OCT in mouse models of pediatric eye diseases. We explore the feasibility of using vis-OCT to track developmental changes in the murine inner retinal structure in vivo, starting at eye-opening.

Methods: Wildtype C57BL/6 mice from P12 to P60 were separated into four age groups: 1) P13-P16, right after eye-opening, 2) P18-21, 3) P24-31, and 4) P40-P60 (mature). We acquired vis-OCT images centered on the optic nerve head with a field-of-view of 1.1 mm × 1.1 mm. We utilized a resampled circular B-scan averaging technique in post-processing to improve inter-layer retinal contrast (example resampled circular B-scan shown in Figure a). Histology images were acquired via confocal microscopy. For both vis-OCT and histology data, we measured the thickness of the retinal nerve fiber layer + ganglion cell layer (RNFL/GCL), inner plexiform layer (IPL), inner nuclear layer (INL), and total retina using ImageJ. Figure b is a magnified view of the orange box from Figure a with relevant layers used for measurements labelled. All measurements were taken 300-550 µm from the optic nerve head.

Results: We averaged nine acquisitions and developed a resampled circular B-scan method, which enabled repeatable retinal layer thickness measurements from vis-OCT datasets in all age groups. The correlation constant between OCT and histology, defined as the ratio of the OCT thickness measurement to the histology thickness measurement, ranged from 0.68 to 1.18 across the different retinal layers and age groups. These results are consistent with previously published values of correlation constant in healthy adult mice. The correlation coefficient between OCT and histology, defined as Pearson's correlation coefficient (R^2) for the line of best fit under a preassumed linear relationship between OCT and histology layer thickness measurements, is 0.996.

Conclusions: Vis-OCT retinal layer thickness measurements agreed well with histology for all layers and age groups examined. Vis-OCT can visualize and track developmental changes in the murine retinal layer structure in vivo from eye-opening.

ABSTRACT BODY:

Purpose: Alzheimer's diseases is a neurodegenerative disease, whose pathophysiological features show decades before the main cognitive symptoms appear. In addition to age, genetic factors are one of the most important risk factors.

The aim of the present study was to analyze the retinal thickness changes by optical coherence tomography (OCT) in first-degree relatives of Alzheimer's disease patients who are carriers of $\epsilon 4$ allele for the ApoE, which are two of the main risk factors for developing the disease.

Methods: Sixty- four participants, who were free of ocular pathology were analyzed. A complete eye examination and OCT were performed. The two study groups were formed by 35 subjects with a family history of AD (FH+) and ApoE $\epsilon 4$ carriers and 29 age-matched control subjects without a family history of AD (FH-) and ApoE $\epsilon 4$ non-carriers.

Results: In FH+ ApoE $\epsilon 4$ carriers compared to FH- ApoE $\epsilon 4$ non-carriers we found a statistical significant thinning ($p < 0.05$) in the next sectors and layers: the foveal area of the macular retinal nerve fiber layer (11.89 ± 1.95 , FH+ vs 12.86 ± 1.62 , FH-); the inferior and nasal sectors, both in the outer (26.77 ± 2.74 , FH+ vs 28.17 ± 2.82 , FH- for inferior) (29.49 ± 2.89 , FH+ vs 30.93 ± 3.85 , FH- for nasal) and inner (40.49 ± 2.51 , FH+ vs 42.10 ± 3.48 , FH- for inferior) (41.94 ± 2.74 , FH+ vs 43.52 ± 3.57 , FH- for nasal) macular ring in the inner plexiform layer; the foveal area (18.82 ± 3.61 , FH+ vs 21.21 ± 3.88 , FH-) and the inferior sector in the outer macular ring (30.91 ± 2.72 , FH+ vs 32.10 ± 2.81 , FH-) in inner nuclear layer, and the inferior sector of the outer macular ring (27.60 ± 2.75 , FH+ vs 29.97 ± 3.82 , FH-) in outer plexiform layer. No statistically significant differences were found in the peripapillary thickness of RNFL between both study groups.

Conclusions: In asymptomatic relatives of Alzheimer's disease patients with high genetic risk for the development of AD, initial changes appeared in the macular area. These slight retinal thickness changes measured by OCT could be used as an early biomarker of the disease.

ABSTRACT BODY:

Purpose: People with central vision loss (CVL) are permitted to drive in most states in the USA; however, CVL may cause delayed responses to hazards. Advanced driver assistance systems that provide hazard warnings are available, but little is known about the extent to which such systems might mitigate crash risk of drivers with CVL. We therefore developed a prototype hazard warning device and evaluated its impact on the responses of drivers with CVL to pedestrian hazards in a simulator.

Methods: Seven subjects with CVL (36 – 74 y; median VA 20/80) and 7 subjects with normal vision (NV) (34 – 78 y; median VA 20/15) participated. They completed 2 drives with and 2 drives without a custom-designed vibrotactile warning device embedded in the seat cushion. There were 10 realistic pedestrian hazards per drive which appeared mid-block from either the left or right and crossed the road in front of the driver's vehicle, requiring a natural braking response by the driver to avoid a collision. If collision risk (computed continuously) exceeded a pre-defined threshold, the device gave a directional vibration to warn of the approaching hazard. Gaze position and driving metrics were monitored at 50 Hz for analysis. The virtual city environment was populated with other distractor pedestrians, crowds, and traffic.

Results: Overall, CVL subjects took longer to fixate hazards (1.2s vs 0.6s, $p = .01$), received more warnings (77% vs 66%) and were involved in more collisions (2.9% vs 0.4%, $p = .01$) than NV subjects. When collision risk exceeded the threshold, warnings had no effect on the time to fixate the hazard, but significantly reduced the time taken by CVL subjects to press the brake (from 2.4s to 2.0s, $p = .004$). Thus, the warnings significantly improved response safety of CVL subjects ($p < .001$), reducing their collision rate from 8.5% to 0% for events exceeding the collision threshold. In contrast, the warnings had no effect on safety of NV drivers (interaction $p < .001$). CVL subjects liked the design of the warnings (intensity, duration, timing and frequency), rated the device as more helpful than NV subjects, and would be more likely to use it if available on their car.

Conclusions: Our results provide preliminary evidence that tactile directional warnings of potential hazards may reduce collision risk of CVL drivers by decreasing the time required to perceive the risk level and initiate a braking response.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is characterized by progressive retinal pigment epithelial (RPE) dysfunction and eventual atrophy. Numerous pathogenic mechanisms have been proposed, including accumulation of lipofuscin, shifts in RPE metabolism, and alterations in the RPE's underlying extracellular matrix. Our goal is to identify pathways in RPE that contribute to resiliency and can be pharmacologically manipulated to protect RPE in AMD.

Methods: Primary human adult RPE (ahRPE) and fetal RPE (hfRPE) were cultured based on established protocols. Lipofuscin-like granules accumulate through repeated feedings of photo-oxidized outer segments to cultures. Glycolysis and mitochondrial function were assayed by a Seahorse Analyzer. Calcium deposition in the extracellular matrix was determined using a variety of standard stains. Gene expression differences between ahRPE and hfRPE were assessed by RNASeq using DESEQ2 for differential expression and iDEP90 with both GSEA and PGSEA for pathway analysis.

Results: Lipofuscin-like granule accumulation was significantly higher in ahRPE compared to hfRPE, despite more ingestion of OS in the hfRPE group. Further, lipofuscin-like granules are associated with a reduction in oxidation consumption rate, a marker of mitochondrial capacity, only in ahRPE. RNASeq comparing ahRPE with hfRPE demonstrates generally similar expression of RPE-specific genes, but differences in fatty acid degradation, ketogenesis, and lysosomal function that may account for hfRPE's resistance to lipofuscin accumulation and toxicity. RNASeq also revealed an ectopic extracellular calcification program robustly expressed in ahRPE only. Ongoing studies are determining whether the basolateral extracellular matrix is more calcified in ahRPE compared to hfRPE cultures.

Conclusions: Compared to hfRPE, ahRPE demonstrates increased susceptibility to several AMD-relevant stresses. Initial RNASeq analysis also suggests ahRPE may uniquely express a basolateral extracellular membrane calcification program that could account for calcified drusen, a significant risk factor for AMD progression. Ongoing studies are cataloging other AMD-relevant insults that preferentially affect ahRPE over hfRPE. Comparative gene expression and secreted metabolomic analysis are being used to identify pathways contributing to hfRPE's resiliency.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) acts as a metabolic gatekeeper between photoreceptors and the choroidal vasculature to maintain healthy retinal function. RPE dysfunction is a key feature of age-related macular degeneration (AMD), the leading cause of blindness in developed countries. Tumor necrosis factor- α (TNF α), a potent pro-inflammatory cytokine, has been implicated in the pathogenesis of AMD. Growing evidence supports metabolic dysfunction as another key mechanism driving AMD. To date, there is no literature on the metabolic effects of TNF α on RPE and thus, this study sheds light on the impact of TNF α on mitochondrial morphology and metabolic function in RPE.

Methods: Matured ARPE-19 were treated with TNF α (10 ng/ml) for up to 72h. Glycolysis and oxidative phosphorylation (OXPHOS) were examined by high-resolution respirometry on the Seahorse XF24. Gene expression of EMT and metabolic markers were assessed by qPCR. Mitochondrial morphology was assessed by confocal imaging and ImageJ processing of MitoTracker Orange-stained ARPE-19.

Results: TNF α induced ARPE-19 to elongate into spindle-shaped cells, reminiscent of epithelial-mesenchymal transition (EMT). However, qPCR showed that TNF α reduced EMT genes expression (Col1A1: 1.2 vs 0.39, $p=0.015$; α -SMA: 1.01 vs 0.66 $p=0.001$) indicating that the elongated cells were not mesenchymal. TNF α increased basal OXPHOS levels (OCR = 2.2 vs 3.7 pmol/min/ μ g, $p=0.042$) and increased glycolytic capacity (ECAR = 0.68 vs 0.92 mpH/mol/ μ g, $p=0.03$). Paradoxically, TNF α induced a reduced expression of OXPHOS genes (COX4I1: 1.02 vs 0.16, $p < 0.0001$; COX5B: 1.02 vs 0.24, $p<0.0001$). TNF α significantly upregulated expression levels of the mitochondrial antioxidant SOD2 (1.14 vs 14.8, $p<0.0001$) and disrupted mitochondrial network morphology exhibiting increased sphericity and fragmentation.

Conclusions: Taken together, we find that TNF α robustly disrupts mitochondrial function and morphology in RPE, although shifting the bioenergetic profile in a paradoxical manner, i.e. TNF α raised the levels of basal respiration and glycolysis despite the suppression of genes regulating OXPHOS. These findings highlight the potential of targeting metabolic pathways in RPE as a promising therapeutic avenue for AMD. Further research is required to elucidate the mechanisms underlying the intriguing TNF α -driven metabolic changes.

ABSTRACT BODY:

Purpose: To analyse the foveal curvature in macular optical coherence tomography (OCT) scans, and evidence its associations in a large cohort.

Methods: We analysed a sample of 73,032 participants from the UK Biobank study, who as part of their enhanced ophthalmic examination had macular spectral-domain OCT. Mean age $56.5 \pm$ standard deviation (SD) 8.02 years, 46% were male. A deep learning model was used to segment the retinal pigment epithelium, and foveal curvature was calculated by polynomial fit. Age, gender, refractive status (spherical equivalent [SE]), visual acuity, intraocular pressure (IOP), birth weight, maternal smoking, average income, and deprivation (Townsend index) were included as part of the analysis in a linear regression model. This research used data from the UK Biobank Resource, under data access request number 60554.

Results: The mean fovea curvature was 0.0722, interquartile range (IQR) 0.0464-0.0981. Males had a more pronounced foveal curvature (0.0771 ± 0.0201) than females (0.0681 ± 0.0185 ; $p < 0.001$). The flatter fovea curvature tertile (mean 0.0519, IQR 0.0404-0.0634) was more frequently observed in hyperopes; i.e. 60.3% of high hyperopes ($SE \geq +6.00$ diopters [D]) and 38.5% of hyperopes ($SE > +0.50 < +6.00$ D). Conversely, the steeper fovea curvature tertile (mean 0.0942, IQR 0.0781-0.1103) was more frequently observed in myopes; i.e. 37.8% of high myopes (< -6.00 D) and 36.8% of myopes ($SE < -0.50 > -6.00$ D). The multivariable linear regression analysis showed negative associations between fovea curvature and SE, worsening visual acuity and increasing material deprivation (flatter curvature measurements for each extra unit increase of these variables). Male gender, birth weight, maternal smoking, higher intraocular pressure and income greater than £100,000 showed a positive association with foveal curvature (more pronounced curvature).

Conclusions: Visual acuity, SE and poorer socioeconomic profile showed negative associations with foveal curvature. High income showed a positive association with foveal curvature. Additional research is warranted to further characterise the foveal curvature and its associations with retinal development and disease.

ABSTRACT BODY:

Purpose: Humans rely on high acuity and daylight vision – both of which are mediated by cone photoreceptors. Once photoreceptors die, they do not regenerate. Thus cell transplantation has emerged as a treatment strategy. While retinal organoids hold promise as an unlimited cell source, human cone transplantations have so far been hampered by a lack of efficient cone cell enrichment by surface markers. In this study a cone specific GFP-reporter hiPSC line was generated, facilitating this cone transplantation study.

Methods: A mArr3-GFP hiPSC line was utilized in an optimized protocol to produce robust numbers of cones (up to 45%) in retinal organoids. FAC-sorted cones of day 200 organoids were transplanted into cone photoreceptor function loss 1 mice (Cpfl1) which exhibit rapid cone loss. Using local immune suppression, the transplants survived well, allowing long term follow up at 3, 10 and 26 weeks (wk). Transplants were examined via immunohistochemistry, electron microscopy and RNA sequencing.

Results: At 3wks the human cones remained largely in the subretinal space, but, by 10wks a bulk migration of the graft into the host outer nuclear layer was observed, a behavior which has not been described previously. Transplanted cones appeared to be well tolerated by the mouse retina – rather than forming a glial barrier, Müller Glia cells enveloped the graft. In addition, bipolar and horizontal cells extend processes to the human cones, a requisite for synaptic connectivity. Transplanted cones continued to mature in vivo, where by 10wks, some cones developed characteristic photoreceptor features of ribbon synapses and inner segments. By 26wks the human cones further matured, developing outer segment structures. Of note, only cones interacting with the host retina developed these features, while cones within the subretinal space lacked signs of maturation. Remarkably, the xenogeneic environment did not negatively alter maturation of the human cones, as evidenced by the high degree of similarity between the RNA expression profiles of in vivo vs in vitro matured cones, as well as to primary fetal human cones.

Conclusions: Overall these results indicate that human cones are well tolerated, mature normally and interact readily with the dystrophic mouse retina. This is an important achievement in photoreceptor transplantation research and opens up possibilities for further research towards clinical application.

ABSTRACT BODY:

Purpose: Few studies have evaluated the prevalence of visual impairment (VI) and associated trends in diabetes and non-diabetes. This study assessed the prevalence of and changes in VI among Canadians with and without diabetes from 1994 to 2014.

Methods: Data from respondents aged 40+ participating in seven nationwide surveys were analyzed: the National Population Health Survey in 1994/1995 (n=17,626), 1996/1997 (n=81,804) and 1998/1999 (n=17,244) and the Canadian Community Health Survey in 2000/2001 (n=130,880), 2008/2009 (Healthy Aging, n=30,865), 2009/2010 (n=124,188) and 2013/2014 (n=127,462). VI was self-reported as unable to see close or distance when wearing glasses/contact lenses. Diabetes was self-reported. Using the 2016 Canadian population as the standard, the age- and sex-standardized prevalence of VI was calculated. For analyses stratified by levels of education and income, sex-standardized prevalence was calculated.

Results: In any survey year, the age- and sex-standardized prevalence of VI was about 2 times higher in people with diabetes versus those without (e.g. 2.96% vs 1.57% in 2013/2014). Among people with diabetes, the standardized VI prevalence was 7.11% (95% confidence interval (CI): 6.99%-7.24%) in 1994/1997 and gradually decreased to 2.96% (95% CI: 2.91%-3.01%) in 2013/2014, a 58% reduction over 20 years (standardized prevalence ratio: 0.42 (95% CI: 0.23-0.75) for prevalence in 2013/2014 versus 1994/1997).

Among people without diabetes, the standardized VI prevalence decreased from 3.38% (95% CI: 3.35%-3.40%) in 1994/1997 to 1.57% (95% CI: 1.56%-1.58%) in 2013/2014, a 54% reduction (standardized VI prevalence ratio: 0.46 (95% CI: 0.42-0.52) for prevalence in 2013/2014 versus 1994/1997).

Decreases in sex-standardized VI prevalence were observed among people with and without diabetes from 1994/1997 to 2013/2014 after stratification by education and income levels.

Conclusions: From 1994 to 2014, VI was roughly 2 times higher in people with diabetes versus those without. For both people with and without diabetes, the standardized VI prevalence decreased in those with high and low levels of education and income. These results likely reflect the effectiveness of the collective efforts by eye care providers, researchers, the public and government.

TITLE: Microglia phagocytosis contributes to clearance of photoreceptor outer segment following retinal detachment

SESSION TITLE: Glial Cells

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Cao, D. Kong, S. Shanmugam, H. Hager, B.X. Ross, D.N. Zacks, S.F. Abcouwer, Department of Ophthalmology and Visual Science, University of Michigan, Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Manjing Cao: Commercial Relationship: Code N (No Commercial Relationship) | Dejuan Kong: Commercial Relationship: Code N (No Commercial Relationship) | Sumathi Shanmugam: Commercial Relationship: Code N (No Commercial Relationship) | Heather Hager: Commercial Relationship: Code N (No Commercial Relationship) | Bing Ross: Commercial Relationship: Code N (No Commercial Relationship) | David Zacks: Commercial Relationship: Code N (No Commercial Relationship) | Steven Abcouwer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal detachment (RD) occurs when photoreceptors (PR) are separated from the retinal pigment epithelium (RPE), compromising PR cell survival. PR outer segments (OS) are continuously renewed by a process including daily shedding and phagocytosis by RPE cells, which is interrupted by RD. RD also triggers an innate immune response, with the activation and attraction of retinal microglia to the subretinal space. We hypothesized that subretinal microglia replace the function of RPE by actively phagocytose OS.

Methods: To lineage trace microglia, tamoxifen (Tam)-inducible Cre-driver mice (CX3CR1-CreERT2) were crossed with mice with Cre-dependent expression of tdTomato red-fluorescent protein (RFP). A 4-week period after Tam treatment was used to eliminate RFP-expressing monocytes. The mice then received subretinal injections of 1% hylaluronic acid to cause partial RD. Retinal sections were obtained at 3, 7 and 14 days post-retinal detachment (dprd). Untreated fellow eyes were used as controls. Retinal and subretinal cells were examined by immunofluorescence for expression of RFP and phagocytosis markers. Lysosomal receptor CD68 and phagocytic receptor MerTK were used as phagocytosis markers. Rhodopsin and PNA lectin, were used to identify OS of rods and cones, respectively. Imaris software was used to construct 3D images.

Results: RFP-labeled retinal microglia were observed to migrate to the subretinal space at 3, 7 and 14 dprd. Lineage tracing confirmed that the vast majority of subretinal cells were microglia, averaging $87 \pm 2\%$ at 14 dprd. Dramatically increased CD68 and MerTK immunoreactivity were observed in microglia, indicating phagocytic activity. Anti-rhodopsin and PNA-reactive OS were observed anchoring to microglial membranes and drawn within the cell bodies of microglia, indicating phagocytosis of POS. The co-localization of CD68 and rhodopsin implied OS internalization and transfer into phagolysosomes.

Conclusions: The initial innate immune response to RD involves microglia infiltration in the subretinal space. The results reveal microglia OS phagocytosis provides OS clearance in the absence of PR-RPE interaction.

TITLE: Outcomes of glaucoma referrals for narrow anterior chamber angles: real world data

SESSION TITLE: Ocular Blood Flow, Laser Therapy, and IOP Measurements

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Raja, S. Bordajandi-Tur, R. Thomas, A. Scott, P. Founti, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure (Abstract): Aneela Raja: Commercial Relationship: Code N (No Commercial Relationship) | Sergio Bordajandi-Tur: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Thomas: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Scott: Commercial Relationship: Code N (No Commercial Relationship) | Panayiota Founti: Commercial Relationship(s);Thea Pharmaceuticals:Code R (Recipient)

ABSTRACT BODY:

Purpose: The UK Joint College Guidance advises referral of all patients with “a narrow anterior drainage angle on Van Herick testing consistent with a significant risk of acute angle closure within the foreseeable future”.¹ However, recently published data do not support widespread prophylactic laser peripheral iridotomy (LPI) for primary angle closure suspects (PACS).² This study aims to investigate the outcomes of glaucoma referrals from community optometrists specifically for narrow anterior chamber angle on Van Herick.³⁻⁵

Methods: This retrospective study, conducted at Moorfields Eye Hospital at Bedford (UK) included all glaucoma referrals received between April 2018 – March 2019 for “narrow Van Herick” (or synonym terms) in the absence of other glaucoma-related factors, such as raised intraocular pressure and ‘suspicious’ optic discs or visual fields. Data were collected manually via electronic medical records (Medisoft). Patients were retrospectively classified as PACS, Primary Angle Closure (PAC), and Primary Angle Closure Glaucoma (PACG).^{6,7}

Results: We received 438 glaucoma referrals for ‘narrow angles’ alone, of which 400 (91.3%) had a full glaucoma assessment (37 did not attend; 1 could not be found). Of these 400 patients, only 45 (11.3%; 95% Confidence intervals (CI) 8.5-14.7) had an occludable angle on gonioscopy. With regard to management decisions, 194/400 patients (48.5%; 95% CI 43.6-53.4) were discharged at first visit, 116/400 (29%; 95% CI 24.8-33.6) were monitored and 90/400 (22.5%; 95% CI 18.7-26.9) received treatment: 55/400 (13.8%; 95% CI 10.7-17.5) had LPI and 35/400 (8.8%; 95% CI 6.3-12) had phacoemulsification. The 45 patients with a confirmed occludable angle were retrospectively classified: 44/400 (11%; 95% CI 8.3-14.5) PACS, 1/400 (0.3%; 95% CI <0.01-1.6) PAC, and 0 PACG. Among the 44 PACS, 34 (77.3%; 95% CI 62.8-87.3) had LPI, 6 (13.6%; 95% CI 6-27.1) had phacoemulsification and 4 (9.1%; 95% CI 3-21.7) were monitored without treatment.

Conclusions: The diagnostic accuracy of ‘narrow Van Herick’ for occludable iridocorneal angles was found to be low. The majority of those with a confirmed occludable angle were at low risk for glaucoma (PACS). Nonetheless, most of them underwent prophylactic LPI. The guidance for glaucoma referrals needs to be reconsidered; the clinical management of angle closure also needs to move away from the widespread use of prophylactic LPI in low risk patients.

ABSTRACT BODY:

Purpose: Adherence to follow-up for glaucoma is known to be poor, especially among asymptomatic patients or those with mild disease. This study reports on an initiative aimed at reducing the number of patients with glaucoma-related diagnoses lost to follow-up (LTF) and reviews its short-term outcomes.

Methods: An electronic medical record (EMR)-based tool was designed to identify patients with glaucoma-related diagnoses who were seen at a hospital-based outpatient eye clinic within a six-month period in the prior year and who had not scheduled or returned for follow-up care. Providers were given lists of patients designated as potentially LTF and asked to review the EMR and re-engage patients, as appropriate. One month later, the initiative was evaluated by retrospective chart review.

Results: 3,666 unique patients were seen during the study period. 3,167 patients were not LTF (86.4%) and 115 patients were deceased (3.1%), leaving 384 patients as LTF (10.5%). The number of prior ophthalmology appointments attended was inversely related to the risk of being LTF (Pearson correlation $r=-0.067$, $P<0.0001$). Not surprisingly, history of missing a scheduled appointment increased the risk of being LTF (OR 1.51, 95% CI 1.22 to 1.86 $p=0.0002$). Patients with low-risk findings such as glaucoma suspects or ocular hypertensives were more likely to be LTF than those with other forms of glaucoma (OR 1.26, 95% CI 1.01-1.58, $p=0.038$). Patients with primary open angle glaucoma were less likely to be LTF than those with other glaucoma-related diagnoses (OR 0.77, 95% CI 0.62-0.95, $p=0.016$). One month following the re-engagement initiative, 124 (32.3%) of the LTF patients had been re-engaged: 49 had completed a telemedicine visit (39.5%), 70 had a new in-person appointment ordered or scheduled (56.5%), and 5 had documentation that they declined re-engagement when contacted (4.0%). Of the remaining 260 patients (67.7%) without documented re-engagement, an order to schedule a follow-up appointment had been submitted for 238 individuals (91.5%). At the end of the initiative, only 22 patients (5.7%) had no documented plan for follow-up.

Conclusions: An EMR-based reporting system can be an effective tool to alert providers and allow for the re-engagement of patients with glaucoma-related diagnoses at risk of being LTF. This should promote better management of glaucoma and related diagnoses, enhance clinical productivity, and reduce potential medicolegal liability.

ABSTRACT BODY:

Purpose: Myopia is the most common clinical sequela of preterm birth and is especially common following retinopathy of prematurity (ROP). However, reported rates of myopia are lower in children whose ROP was treated with anti-vascular endothelial growth factor (anti-VEGF) agents as compared to conventional laser photocoagulation. We examined the progression of refractive error, over a period of up to nine years, in preterm-born children with ROP treated with either injection of the anti-VEGF agent Bevacizumab or laser.

Methods: We performed a retrospective review of records of premature infants treated for ROP at Boston Children's Hospital from 2011-2020 with Bevacizumab (n = 24) or laser (n = 54). Bevacizumab dosage ranged from 0.02mg-0.75mg. We analyzed cycloplegic refractions from 349 cumulative visits (mean 4±3 visits per individual; mean 2.3±2.7 years under observation), using a linear mixed effects model, to evaluate how refraction changed with corrected age following treatment.

Results: In aggregate, the model estimated a significant ($P < 0.001$) trend in refraction, from slight hyperopia to relatively more myopic states, as is common in emmetropization. However, the progression in laser-treated eyes was significantly ($P = 0.002$) more rapid: The estimated progression in individuals treated with laser was -0.79 diopters per year compared to only -0.02 diopters per year in eyes treated with Bevacizumab. Random effects, including individual subject variation with nested variance for left and right eye, accounted for 70% of the remaining variance not explained by corrected age and treatment.

Conclusions: Our analysis suggests that children with ROP who are treated with laser photocoagulation will tend to progress to myopia at a higher rate compared to those individuals treated with Bevacizumab.

ABSTRACT BODY:

Purpose: To assess standard and novel optical coherence tomography (OCT) and visual field (VF) methods for detecting glaucomatous progression

Methods: Disc circle and macular cube OCT scans and 24-2 and 10-2 VF data were obtained from 100 eyes [71 patients/suspects and 29 healthy controls (HC)], as part of a prospective, longitudinal study (P-group)(ClinicalTrials.gov Identifier: NCT02547740). All eyes had a minimum of 4 OCT and VF tests (mean 9.2 tests), with the last visit at least 1 year after the baseline visit. We evaluated standard OCT and VF metrics, combinations of OCT-OCT and OCT-VF, and a metric based on a region-of-interest (ROI) approach (Table 1, left-most column). For event-based, test-retest variability was estimated based on 176 eyes (146 patients/suspects, 30 HC). Repeated OCT and VF data collected within 4 months were analyzed with quantile regression to define cut-offs (the 95th percentile defined 'statistical progression'). Those cut-offs were then applied to the first vs. last test of the P-group. For trend-based, based on least squares regression eyes were categorized as "progression" if the slope was significantly negative (one-tail $p < 0.05$). Finally, 2 OCT experts (E-OCT) reviewed all OCT information and judged whether each eye had progressed on a scale of 0 (definitely did not progress) to 100% (definitely did progress). Eyes with scores $\geq 95\%$ were labelled "progrsors" (P), and those with scores $\leq 5\%$ "not progrsors" (NP). The E-OCT identified 13 P eyes, none of which was a HC

Results: We used the 60 NP and 13 P eyes as proxies for specificity and sensitivity (see Tables -bold columns). For the Event Analysis (Table 1) only one metric, TI (green in Tables), had a percent agreement greater than 90% for both proxies, while for the Trend Analysis (Table 2) none of the metrics had percentages greater than 90% for both. In general, an event-based approach performed better than trend analyses (Tables 1&2)

Conclusions: All objective methods so far explored miss clear progression revealed in some eyes by a careful examination of circumpapillary b-scans, with or without the aid of OCT probability maps, as well as identify "progrsors" that are clearly not progressing. We recommend that a qualitative evaluation of OCT images and thickness/probability maps be included at least as part of a post-hoc analysis.[1,2] 1. Hood et al. JoG 2020; 2. Eguia et al. TVST 2020

ABSTRACT BODY:

Purpose: Macular atrophy (MA) is a basic characteristic of age-related macular degeneration (AMD), in both its neovascular and dry form. The purpose of this study is to evaluate the evolution of MA in patients with neovascular AMD (nAMD) treated with anti-vascular endothelial growth factor (anti-VEGF) agents, compared with the fellow eyes exhibiting dry AMD.

Methods: Participants in this retrospective study were 124 patients, treated for nAMD with anti-VEGF injections in one eye and followed-up for dry AMD in the fellow eye, in three different retinal departments. We analyzed data of 60 patients with a total of 4 years of follow-up. MA was evaluated in an annual basis using near-infrared and spectral-domain optical coherence tomography images, according to criteria proposed by the Classification of Atrophy Meetings group. Incidence and progression of MA were evaluated.

Results: Presence of MA until the 4th year of follow up in treated eye (TE) was recorded in 56% (34/60) patients and 30% (18/60) in fellow eye (FE). Repeated measures ANOVA with 2 within factors [time with 5 levels (0 to 4 years) and eye with 2 levels (TE, FE)] revealed significant time ($p < 0.001$), eye ($p = 0.012$) and time-eye interaction ($p < 0.001$) effects. Treated eye MA exhibits a steady significant increase up to year 4, whereas in the FE the significant increase is halted at year 2. The annual increase in the TE is 0.107mm/y for year 1, jumps to 0.304mm/y for year 2 and to 0.343mm/y for year 3, to drop to 0.281mm/y for year 4. The respective annual increase for the FE is 0.143mm/y, 0.143mm/y, 0.092mm/y and 0.086mm/y. Focusing on the subset of the 22/60 patients, who started with no baseline MA in TE, we observed the previously described pattern in a more pronounced manner. Following a slower growth in the TE at year 1 (0.066mm/y vs 0.147mm/y), MA growth in the TE is much faster than the FE (0.388mm/y vs 0.155mm/y for year 2, 0.39mm/y vs 0.083mm/y for year 3 and 0.353mm/y vs 0.075mm/y for year 4).

Conclusions: In this study we documented a significant difference in MA incidence and progression in eyes treated for nAMD compared to their fellow eyes exhibiting dry AMD. Treated nAMD eyes tend to develop more often MA; moreover MA progresses in a faster rate in these eyes compared to fellow dry AMD eyes.

ABSTRACT BODY:

Purpose: The present study aims to understand the mechanism of lens epithelial cells' strong anti-apoptosis capacity and survival rate in the mature human lens that, on the one hand, maintains lens transparency over several decades, while on the other hand increases the risk of posterior capsule opacification (PCO).

Methods: Cell viability and apoptosis were analyzed in FHL124 cells under TNF α stimulation and were compared with HeLa cells. The TNF α mediated inflammatory signaling, cell survival genes were screened by real-time PCR, and key genes were confirmed by shRNA knocking down and immunoblot analysis.

Results: FHL124 cells demonstrate strong resistance to TNF α mediated cell death compared to HeLa cells. Harsh stimulation with TNF α and cycloheximide (CHX) triggers almost entire HeLa cell death within 7hr but not FHL124 cells even after 24hr stimulation. Further studies suggest that FHL124 cells are able to block caspase 8 activation and subsequently preventing caspase 3 activation, PARP-1 cleavage, and cell death. Interestingly, despite spontaneous activation of transcription factors, NF κ B and AP-1, and upregulation of multiple cell survival and anti-apoptotic genes in both cell types, only FHL124 cells managed to survive under TNF α challenge. By screening and comparing the cell survival genes, the cellular FLICE-like inhibitory protein (cFLIP) is found highly expressed in FHL124 cells and substantially upregulated by TNF α stimulation. FHL124 cells with a mild cFLIP 37 knockdown manifest a profound apoptotic response to TNF α and CHX treatment similar to HeLa cells.

Conclusions: Lens cells demonstrate a high level of resistance to stress-induced apoptosis relative to HeLa cells. cFLIP is abundant in lens epithelial cells and is further upregulated in the presence of stressors. A reduction in cFLIP renders lens epithelial cells more susceptible to apoptosis and therefore suggest that cFLIP plays a critical role in lens cell survival.

ABSTRACT BODY:

Purpose: Glaucoma is the leading cause of irreversible blindness in Ghana, where it affects nearly 7.7% of the population aged over 30 years and 8.5% of those aged over 40 years. Reduction of intra-ocular pressure via ocular hypotensive eye drops is the first line of treatment for glaucoma. Current estimates of adherence to this treatment in Africa were obtained through self-report, which is known to overestimate adherence. In this study, we used electronic monitors to objectively assess adherence among glaucoma patients in Ghana.

Methods: Glaucoma patients on Timolol eye drops (N=139) were recruited from the Christian Eye Centre, Cape Coast, Ghana. These 4 questionnaires were administered at baseline: Self-Reported Adherence, Glaucoma Medication Self-Efficacy (GMSE), Eye Drop Technique Self-Efficacy (EDTSE) and Brief Illness Perception (BIP). Medication adherence was measured objectively using Medication Event Monitoring System devices (MEMS) (Aardex, Switzerland) and by self-report during a 3-month period. Adherence was computed as the percentage of days medication was used as prescribed within the 3-month monitoring period. Participants with < 75% adherence score were classified as non-adherent. The association between adherence and demographic information and medical history were assessed using chi-square tests and logistic regression. The relationship between adherence and GMSE, EDTSE and BIP scores were also determined using Pearson correlation coefficient.

Results: Of the 139 participants, 47 (33.8%) and 107 (77.0%) were classified as non-adherent based on self-report score and objective score. Mean (\pm SD) adherence was 49% \pm 30. Objectively-measured adherence was not significantly associated with GMSE ($r = -0.065$, $p = 0.45$), EDTSE ($r = 0.119$, $p = 0.16$) and BIP scores ($r = 0.068$, $p = 0.43$). Significant associations were observed between adherence and educational level ($\chi^2 = 9.179$, $p = 0.01$) and the number of systemic comorbidities ($\chi^2 = 6.029$, $p = 0.049$), with those without systemic comorbidities being 70.4% less likely to be adherent ($p = 0.045$).

Conclusions: Non-adherence to ocular hypotensive medication is common in Ghanaian patients with glaucoma. Future work should focus on identifying the factors associated with non-adherence with a goal of assisting patients efforts to adhere with their treatment.

Hayflinger: Commercial Relationship(s);Biogen:Code C (Consultant) | Dan Yoon: Commercial Relationship(s);Biogen:Code E (Employment) | Susan Eaton: Commercial Relationship(s);Biogen:Code E (Employment)

ABSTRACT BODY:

Purpose: Choroideremia (CHM) is an X-linked recessive inherited retinal dystrophy (IRD) resulting in progressive vision loss, ultimately leading to blindness. Women are typically carriers, although a few studies have shown some women to be symptomatic. Our objective was to perform an epidemiologic study using electronic medical records to better understand women with diagnosis codes for CHM.

Methods: Optum[®] de-identified Electronic Health Record dataset (2007-2019) was used. Women with at least one recorded ICD-9 or -10 diagnosis code for CHM (ICD-9: 363.55; ICD-10: H31.21) were included. The women's records were examined for age at first diagnosis within the database, other IRDs, provider type, and notes/measures of vision.

Results: Fifty-seven women had CHM ICD codes recorded while enrolled in the database. The median time in the database was 8 years, and during that time 35% of the women had more than one physician visit with a CHM code. The age at first CHM code in the database ranged in age from 6-87 years, with a median of 54 years. At the first diagnosis in the database, 63% of women were seen by an ophthalmologist and 12% were seen by an optometrist. Other provider specialties included Family Medicine (12%) and Obstetrics/Gynecology (9%). Sixteen percent of women also had an ICD code or physician note for retinitis pigmentosa. Thirty-nine percent of women had an ICD code or physician note mentioning a family history of eye genetic disease and/or blindness. Using physician notes, ICD codes, and/or reported visual acuity measurements, 13 (23%) women were categorized as having poor/low vision, severe visual impairment, and/or blindness. Among women aged 60 and older, 40% had poor/low vision, severe impairment, or blindness. Many of these women had other eye conditions (e.g., glaucoma, cataracts); therefore, it is not possible to know whether the vision loss is attributable to the other issues or CHM. Often visual acuity measurements were lacking and physician notes were not descriptive enough to understand specific vision levels among the women.

Conclusions: A proportion of women with CHM have visual impairments. Further research on women with CHM is warranted to determine the level of visual impairment experienced by these women and if it is attributable to CHM or other eye conditions.

ABSTRACT BODY:

Purpose: Frequent anti-VEGF injections and use of immunosuppressive drugs during RPE cell therapy can cause severe side effects. Also, the fear of tumorigenicity of grafted cells remains an issue. We test the hypothesis that cells, grafted into a diseased eye, expressing our local acting anti-VEGF biologics, 'VEGF Sticky-trap', with FailSafeTM and immune cloaking technologies, is safe and controllable as a long-term treatment option for AMD. This approach combines the cells' positive therapeutic effect with that of local acting biologics, avoiding potentially harmful side effects.

Methods: In a mouse model of AMD, we have grafted engineered human RPE to replace the lost cells in the recipient's eye that a) produce a drug-inducible, local acting anti-VEGF biologic (VEGF Sticky-trap, PMID: 24705878) and b) control cell growth by introducing a suicide switch to the cell's genome (FailSafeTM, PMID: 30429614). The RPE cells generated in vitro from hES cells were further modified to make them "invisible" (iACT StealthTM, PMID: 31417198) to the immune system (cloaked cells), or not (uncloaked cells). To assess the efficacy, safety and toxicology of all genetic modifications, cells (cloaked and uncloaked) were injected in the subretinal space (40,000 cells per eye) and subcutaneously (either 1 million cells per flank or 100,000 cells intradermal in ear pinnae) in albino BL6 mice. Immune-compromised NSG mice served as a control and cell survival and efficacy was followed through life eye imaging or BLI imaging.

Results: We have demonstrated the function of all three genome altering systems (FailSafeTM, iACT StealthTM and VEGF Sticky-trap) separately, in pilot studies and are moving forward to a pre-clinical phase with small (mouse) and large animal models (rabbit, pig) to test in cell therapy settings. Thus far we have demonstrated, in vitro and in vivo (in mice), that cells survive up to 10 months in subretinal spaces and that each genetic modification continues to function in tandem.

Conclusions: Immuno-cloaking is essential to avoid graft rejection and/or immunosuppressive drugs, while tight regulation of cell proliferation (FailSafeTM system) and drug-induced VEGF Sticky-trap expression was demonstrated. No adverse events were reported in mice receiving genetically modified cells. We expect our genome edited therapeutic cells to advance the development of novel and improved therapies for AMD and beyond.

ABSTRACT BODY:

Purpose: To investigate the prevalence and potential associations of dome-shape macular configuration in general population.

Methods: A total of 65440 subjects with a mean age (\pm standard deviation, SD) of 57.3 ± 8.11 years with spectral-domain optical coherence tomography (OCT) data from a unique contemporary resource for the study of health and disease that recruited more than half a million people in the UK (UK Biobank) was analyzed in this study. A deep learning model was used to segment the RPE, and the macular curvature of the OCT scan was calculated by polynomial fit. The curvature was evaluated and associations with refractive error (spherical equivalent), corneal curvature, visual acuity, intraocular pressure, age, sex, ethnicity, fluid intelligence, birth weight, maternal smoking were examined.

Results: The overall macular curvature values followed a gaussian distribution with a mean (\pm SD) of 0.0021 ± 0.0014 . There was a high inter-eye agreement. While all factors but 'sex' were significantly associated with the curvature in a multilinear analysis (adjusted R^2 , 0.122), the highest correlation could be found for the factors refractive error and ethnicity. The prevalence of a macular dome-shape configuration was overall 4.78%, most common in Chinese subjects as well as hypermetropic eyes. An increasing frequency was found towards extreme refractive error (hypermetropia and myopia). Extreme dome-shape configuration (defined by the fourth quartile of concave curvature values), however, was more frequently found in myopic eyes; in particular in eyes with high (spherical equivalent, <-6 diopters) and extreme (spherical equivalent, <-9 diopters) myopia with a frequency of 3.76% and 6.49%, respectively. The odds ratio for this particular macular configuration in individuals of Chinese ethnicity for high and extreme myopia was 4.83 and 7.91, respectively.

Conclusions: Dome-shape macular configuration can be found in general population, more commonly in eyes with high refractive error. Further investigation of determinants of this macular configuration might provide new insights into normal eye development and maldevelopment like staphyloma.

ABSTRACT BODY:

Purpose: Context: The Affordable Care Act excludes undocumented immigrants from coverage, which may decrease healthcare access among Hispanic/Latinos. Objective: To characterize the prevalence of visual disability among Hispanic/Latinos without access to healthcare and those with health insurance.

Methods: Methods: Design, Setting, and Participants: Multicenter, prospective, population-based Hispanic Community Health Study/Study of Latinos (HCHS/SOL) including 9,663 participants aged ≥ 40 y completing Visit #2 (2014-2017). Participants include those with Cuban, Dominican, Mexican, Puerto Rican, Central American, South American and Other backgrounds from 4 US cities. The age-adjusted, sex-specific prevalence of visual disability was calculated weighting for study design and non-response. For healthcare access, participants were asked "In the past 12 months, was there a time when you needed healthcare but could not get it?" Health insurance represented a presence or absence of coverage. Data was collected at Visit #2. Main Outcome Measure: Prevalence and 95% confidence interval (95%CI) of self-reported visual disability defined using the US Census Bureau definition, "being blind or having serious difficulty seeing even when wearing glasses."

Results: 9324 participants were analyzed; mean age was 55.4y in men and 56.5y in women. The overall prevalence of visual disability was [estimate and 95%CI; 10.6(9.2-12.1)] in men and 13.5(12.0-14.9) in women. Among participants with health insurance, the age-adjusted prevalence was similar at 10.8(9.1-12.5) in men and 14.5(12.8-16.2) in women. Among participants without access to healthcare, the age-adjusted prevalence was elevated at 15.9(7.1-24.8) in men and 17.6(11.8-23.5) in women.

Conclusions: Sex-specific results demonstrate an elevated prevalence of visual disability among diverse Hispanic/Latinos without access to healthcare. Results are important, as they suggest prevalence rates of chronic eye disease estimated from clinical registries may underestimate disease as they fail to include those without access. Results also support SOL Ojos objectives, an ancillary HCHS/SOL study designed to estimate the prevalence of chronic eye disease across Hispanic/Latino backgrounds, and to assess the impact of lifestyle factors, including healthcare access, with disease outcome.

ABSTRACT BODY:

Purpose: Abnormality of the cornea can lead to blindness and vision loss. The corneal endothelial cells (CECs) play a significant role in maintaining corneal function. We developed a multi-scale imaging workflow to visualize the mouse cornea at the microscale and the underlining subcellular variations of CECs in corneal flatmount at the nanoscale. We used a visible-light optical coherence tomography (vis-OCT) to image a mouse model of intraocular hypertension in vivo and revealed the nanoscopic cytoskeleton changes in the CECs using single-molecule localization microscopy (SMLM).

Methods: The left eyes of wild-type mice were maintained at 40 mmHg intraocular pressure (IOP) for 1 hour using anterior chamber puncture. The right eyes were used as controls without any procedures. The vis-OCT images of cornea were acquired using a home-built vis-OCT system. The mice were sacrificed and the cornea was isolated, fixed, and immunostained to visualize the ZO-1 tight junction structure variations using indirect immunofluorescence labeling. The cornea sample was flat-mounted for SMLM imaging in a commercially available STORM imaging buffer in a home-built SMLM system.

Results: The vis-OCT images of corneal tissues revealed the typical edema after maintaining 40 mmHg IOP in the epithelium and stroma layers of the cornea. The SMLM images showed characteristic hexagonal CECs and revealed significant changes in tight junction proteins' filament density and thickness after exposure to high IOP. Such disruptions of cell tight junctions are likely related to the blurred vision in diseases associated with elevated IOP. Further, it reveals the native cell responses in tissue that would be challenging for imaging cell cultures.

Conclusions: We developed a multi-scale imaging workflow to correlate microscopic variations in corneal tissue and nanoscopic variations in CECs of corneal flatmount in response to high IOP in mouse models. These results demonstrate the utility of multi-scale imaging for studying tissue- and molecular level variations for corneal diseases and glaucoma.

Commercial Relationships Disclosure (Abstract): Ayeswarya Ravikumar: Commercial Relationship: Code N (No Commercial Relationship) | Hope Queener: Commercial Relationship: Code N (No Commercial Relationship) | Eric Ritchey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The lid wiper region is responsible for tear distribution along the ocular surface during the blink. Disruption to the tear film increases the coefficient of friction under boundary lubrication conditions at blink initiation. This irritates the epithelium, resulting in staining termed lid wiper epitheliopathy (LWE). LWE is a critical clinical marker to identify and track abnormal lid/cornea interaction. We propose a semi-automated LWE grading algorithm using hue and value channels of staining images

Methods: 37 images representative of LWE staining, observed after instillation of 2% sodium fluorescein and 1% lissamine green, were analyzed. Using a custom MATLAB program, a region of interest around the lid-wiper region was manually defined. Using the hue and value channels of the image, the algorithm identified stained pixels within this region and fit a curve to these pixels. The number of stained pixels along bisector lines perpendicular to the curve were sampled at regular intervals, defining the height of staining at each bisector. LWE height (mm) was calculated as the average extent of LWE staining along all perpendicular bisectors after subtracting average Marx line height calculated from 11 images without LWE staining. LWE width in mm was determined from the length of the curve scaled by the fraction of the curve that included staining beyond the Marx line.

Results: 31 images (15 upper and 16 lower eyelids: 84%) were successfully analyzed by the algorithm, with 6 images where LWE staining was not successfully detected. Average Marx line height for eyelids without LWE was 0.06 ± 0.02 mm. The mean LWE staining height was 0.12 ± 0.11 mm and 0.12 ± 0.07 mm for the upper and lower eye lid respectively. The mean LWE staining width was 10.70 ± 3.84 mm and 10.40 ± 3.84 mm for the upper and lower eye lid respectively. No significant difference between upper and lower lids were observed LWE height or width (t-test, $p > 0.05$).

Conclusions: This novel automated hue and value algorithm eliminates the potential human error in subjective grading. Automated LWE grading may allow practitioners to observe subtle changes in LWE staining between different CL materials or clinical conditions over time.

ABSTRACT BODY:

Purpose: Optic disc coloboma is a rare congenital anomaly of the optic nerve. Only a few studies describing the OCT and the OCT-Angiography aspects of congenital optic disc anomalies have been published. The OCT-Angiography studies only described the small optic disc colobomas. This study mainly focuses on assessing the utility of OCT and OCT-Angiography in the particular setting of large optic disc coloboma.

Methods: A retrospective study of patients who were referred to the department of pediatric retina at Bascom Palmer Eye Institute, Miami, Florida between January 2019 and January 2020.

Six eyes of 3 patients were identified. All patients were seen in the clinic and brought to the operating room for exam under anesthesia to perform a full ophthalmological exam, fundus photographs, fluorescein angiography, OCT and OCT-A using the Heidelberg Spectralis Flex Module. Then, necessary treatment was implemented as needed. The OCT and OCT-A were performed by trained experienced photographers.

Results: We provide multimodal imaging results of large optic disc coloboma in 3 children. The first case was associated with cat eye syndrome, the second case was associated with CHARGE syndrome (coloboma, heart defects, atresia choanae, growth retardation, genital abnormalities, and ear abnormalities), and the third case was associated with branchio-oculo-facial syndrome. In all these cases, we were able to capture fundus photographs, fluorescein angiography and OCT images. This allowed a proper evaluation of the coloboma, its associated complications and therefore, it helped establish appropriate management. However, the OCT-Angiography could not capture clear images of large nerve coloboma due to its depth.

Conclusions: Large optic disc colobomas are more challenging than small optic disc colobomas. They are often associated with complications and require long term treatment management and follow up. While OCT has proven its utility in monitoring choroidal neovascularisation and retinoschisis that could be associated with optic disc coloboma, OCT-Angiography in its current form is unable to capture large optic disc coloboma and therefore is of limited interest.

ABSTRACT BODY:

Purpose: Following ablation of photoreceptors by intense light lesion, the zebrafish is capable of complete regeneration due to the ability of their Müller glia (MG) to re-enter the cell cycle, creating progenitors which differentiate into new photoreceptors. The purpose of this study was to determine if 3'mRNA sequencing, paired with a detailed morphological and immunohistochemical (IHC) analysis, is an effective and unbiased method to investigate the regenerating zebrafish retina.

Methods: Adult albino zebrafish were subjected to three days of intense phototoxic lesion to destroy photoreceptors. Tissue was collected at 8 timepoints during the regeneration process. Right eyes were designated for IHC with subsequent mean fluorescence intensity analysis using ImageJ. Left eyes were designated for RNA isolation, cDNA library preparation, 3'mRNA sequencing, and bioinformatics. Differential gene expression analysis was performed at each time point and PCA and a time series analysis was performed across the entire dataset.

Results: Early in the damage response, photoreceptors were destroyed as evidenced by morphological and gene expression losses of the opsins. A dynamic response by immune cells cleared the photoreceptor debris as GFAP-positive and reactive MG re-entered the cell cycle to produce pools of progenitors. Finally, our data highlight a distinct window of time between 5 and 10 days post lesion as a transition from progenitor proliferation/migration to differentiation into new photoreceptors. PCA analysis of the top 200 significantly differentially regulated genes demonstrated distinct clustering of each of the time points over two experimental replicates, confirming the method's precision. And transcript analysis largely mimicked morphological and protein changes at each time point, suggesting that this database can be utilized to search for novel genetic players in the regenerative process.

Conclusions: 3'mRNA sequencing presents an economical alternative to traditional RNA sequencing for investigations of regenerative biology in the zebrafish retina, with minor limitations. These transcriptomic data, paired with detailed IHC quantitative and morphological analysis, present a powerful method to observe the stem cell processes in a model capable of a robust regeneration response.

ABSTRACT BODY:

Purpose:

It is the standard of care to submit for pathological evaluation any eyelid lesions that are considered suspicious or likely to show malignancy. There is less clarity on how to handle lesions felt to be of low malignancy risk. Many ophthalmologists feel comfortable discarding certain lesions without pathologic evaluation based on a convincingly non-malignant appearance. However, there are always some lesions that are not clearly malignant or benign, and therefore are typically submitted.

In general, the estimated malignancy rate of eyelid lesions is 10-20 percent.^{1,2} However, in biopsied eyelid lesions thought to be benign by the clinician, the rate of malignancy drops to between 2-4.6 percent.¹ As a result, a large number of pathologic evaluations are performed with the result being a benign diagnosis in up to 80-90 percent of all lesions and up to 97 percent of lesions thought to be benign clinically.^{1,2}

A significant downside of pathologic evaluation is cost, with uninsured patients at our institution paying 75 dollars out of pocket. Therefore, a way to substantially reduce or eliminate this expense without compromising risk to the patient would be desirable.

Methods:

We propose therefore a new paradigm of the management of eyelid biopsy specimens (Figure 1).

Results:

This protocol allows subsequent submission of pathology specimens if regrowth appears to be occurring, while substantially reducing unnecessary pathology submissions and cost to patients.

One possible downside to our approach is that malignancies such as sebaceous carcinoma (SC) traditionally require a fixation method other than formalin for histological analysis.⁴ However, IHC staining has emerged as a helpful tool in differentiating SC from other common eyelid malignancies like BC and remains an option for even formalin fixed samples.⁵ In addition, basal cell carcinoma (BC)—by far the most common eyelid malignancy—has low propensity to spread metastatically, reducing the risk of any delayed diagnosis that may result from the use of this paradigm.³

Conclusions:

In order to assess the safety and efficacy of this new treatment paradigm, we hope to perform a controlled study comparing it to the current standard of practice. Given the common nature of eyelid lesions, the cost savings could potentially be in the millions of dollars for the medical system.

ABSTRACT BODY:

Purpose: Our limited understanding of the signals that regulate retinal ganglion cell (RGC) death and axon regeneration after optic nerve injury has prevented development of curative therapies. Recently, three phenomena have been identified that contribute strongly to RGC death after injury: elevation of mobile zinc (Zn^{2+}) in the inner retina, activation of microglia and neurotoxic astrocytes, and activation of transcriptional networks via MAP3K kinase cascades (DLK/LZK). Inhibition of individual events is partially neuroprotective, but effects are incomplete, transient, or counteract axonal regenerative capacity, respectively. The objective of our studies was to investigate possible crosstalk among these signals and determine whether synergistic inhibition may enhance neuroprotection and axon regeneration.

Methods: In the mouse optic nerve injury (ONI) injury model, Zn^{2+} -selenite autometallography was used to visualize Zn^{2+} in retinal sections. Microglial activation was assayed morphologically and transcriptionally after ONI. DLK/LZK signaling was assessed via downstream transcription factors (TFs), c-JUN, ATF2, MEF2A, and SOX11. Loss-of-function for each signal was utilized to assess crosstalk: reduction of retinal Zn^{2+} by intraocular chelator (ZX1) injections or genetic deletion of Zinc Transporter 3 (ZnT3: Slc30a3); systemic microglia ablation (CSF-1R inhibitor, PLX5662); and conditional deletion of DLK/LZK in RGCs ($\text{DLK}^{\text{fl/fl}}$; $\text{LZK}^{\text{fl/fl}}$).

Results: Within 1 dpi, we observed simultaneous elevation of mobile zinc (Zn^{2+}), activation of DLK/LZK-dependent TFs, and increased microglial proliferation and activation in the retina. DLK/LZK activation and microglia activation persisted, peaking at 5 dpi concomitant with the onset of RGC death. ZX1 treatment or ZnT3 knockout partially repressed the activation of both DLK and microglia. PLX5622 treatment reduced microglial density in the retina by 96% and reduced expression of inflammatory markers, but did not repress Zn^{2+} elevation or DLK signaling. DLK/LZK deletion blocked injury-induced transcriptional activity to prevent RGC death and partially inhibited microglia activation.

Conclusions: Our data suggest that Zn^{2+} elevation contributes to the activation of microglia and DLK/LZK signaling after ONI. Thus, crosstalk exists between the early injury signaling pathways to regulate RGC cell death after axon injury.

ABSTRACT BODY:

Purpose: To evaluate the existing literature on dry eye disease (DED) and to report the features of DED flares including triggers, characteristics (signs and symptoms), and biomarkers.

Methods: A 10-year literature review was conducted of 2093 publications identified from MEDLINE, Embase, and PubMed databases using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses protocol (PRISMA-P) guidelines. The literature review was performed on English language publications only of clinical trials or observational studies in adults with DED from 2009-2019 using an array of keywords associated with dry eye flares. The searches were designed to identify any observational studies or clinical trials published in the 10-year period that reported dry eye flares or short-term exacerbations of the signs and symptoms of DED.

Results: Screening using PICOS criteria identified 22 studies that met the inclusion criteria. To meet the study objectives, evidence was drawn from studies reporting exacerbations of signs and symptoms following exposure to environmental triggers encountered during daily life, following cataract and refractive surgery, and following exposure to controlled adverse environments. These studies suggest that exacerbations, or flares, of the signs and/or symptoms of DED occur in response to environmental triggers and/or ocular surgeries. Studies evaluating tear biomarkers following controlled adverse environment exposure found significant increase in inflammatory biomarkers matrix metalloproteinase 9 (MMP-9) and interleukin 6 (IL-6), and significant decrease in homeostatic biomarker epidermal growth factor (EGF). Other chronic inflammatory conditions such as chronic asthma, Sjogren syndrome, and rheumatoid arthritis have similar immune-mediated pathways as DED and feature subgroups of patients who experience episodes of flare and remission similar to those in DED.

Conclusions: DED flares are exacerbations of a patient's signs and/or symptoms and can be caused by a variety of triggers. Episodic exacerbation is a common feature of chronic inflammatory diseases.

TITLE: Characterization of retinal cell types in the African spiny mouse (*Acomys cahirinus*)

SESSION TITLE: Glial Cells, Retina Development and In vitro Models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.D. Bills, A.C. Morris, Biology, University of Kentucky, Lexington, Kentucky, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Jessica Bills: Commercial Relationship: Code N (No Commercial Relationship) | Ann Morris: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal structure and cell type composition are generally well conserved across all vertebrate species. Differences in the precise complement of retinal cell types among closely related species can reflect functional adaptations to daily activity and/or life history. Among the order Rodentia, retinal anatomy and physiology are predominantly studied in mice and rats, but there is renewed interest in incorporating additional rodent models that exhibit interesting behaviors and visual adaptations. The African spiny mouse has been studied for its unique behavioral qualities, precocial development, and recently, for its regenerative abilities. However, the spiny mouse retinal anatomy has not been rigorously studied. Here, we present a comparative analysis of retinal cell type morphology and number in *Acomys cahirinus* and *Mus musculus* adult retinas.

Methods: All animal procedures were performed in accordance with guidelines established by IACUC and the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research. Retinal tissue sections were obtained from adult eyes and subjected to histological staining or immunohistochemistry with antibodies for various retinal cell types. Sections were imaged by light, fluorescence, and confocal microscopy. Cell number and morphology were assessed. Comparison of cell number between species was assessed using a Student's t test. Data are presented as mean \pm SD.

Results: Overall, the general features of retinal anatomy between *Acomys* and *Mus* are similar. With roughly triple the eye size, the retinal layers of the *Acomys* are of similar thickness and, for the majority of retinal cell types, the morphology appears comparable in the two species. However, *Acomys* bipolar cells show an increased number and altered laminar positioning compared to *Mus*. Intriguingly, we also observe a differential patterning and distribution of *Acomys* photoreceptors, particularly the cones.

Conclusions: Taken together, the differences in photoreceptors and bipolar cells could suggest differences in visual acuity between the two species, possibly due to visual adaptations for foraging food in their unique desert environment. These results set the stage to investigate retinal cell type diversity and visual function in this interesting mammalian model.

TITLE: Trends in Moxifloxacin Nonsusceptibility Among Coagulase-Negative Staphylococcus Isolates Causing Endophthalmitis, 2005-2020

SESSION TITLE: Endophthalmitis/ trauma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.L. Kunkler, J. Sengillo, N.A. Yannuzzi, D. Miller, H.W. Flynn, Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure (Abstract): Anne Kunkler: Commercial Relationship: Code N (No Commercial Relationship) | Jesse Sengillo: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Yannuzzi: Commercial Relationship(s);Novartis:Code C (Consultant);Genentech:Code C (Consultant);Alimera Sciences:Code C (Consultant) | Darlene Miller: Commercial Relationship: Code N (No Commercial Relationship) | Harry Flynn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Coagulase-negative Staphylococcus (CoNS) is the most common cause of acute-onset post-cataract surgery endophthalmitis. Moxifloxacin, a fourth-generation fluoroquinolone, is frequently used prophylactically to prevent infection after cataract surgery, either topically or intracamerally. The purpose of this study is to report the trends in moxifloxacin resistance of CoNS isolates causing endophthalmitis over a 16-year period.

Methods: This study was a retrospective, consecutive case series of vitreous CoNS isolates causing endophthalmitis between January 1, 2005, and December 31, 2020, at Bascom Palmer Eye Institute, Miami, Florida. The study was deemed exempt from IRB approval as no identifying patient information was collected. Microbiology testing was used to determine the sensitivities for moxifloxacin derived by the E-test and VITEK testing of isolates. Statistical analysis was performed using two-tailed Fisher's exact test.

Results: The moxifloxacin sensitivities of 236 CoNS endophthalmitis isolates were reviewed. The nonsusceptibility rates of 68 CoNS isolates to moxifloxacin from 2005-2009 were 78.8% for methicillin-resistant Staphylococcus epidermidis (MRSE, 23/33), 41.4% for methicillin-sensitive Staphylococcus epidermidis (MSSE, 18/49), and 0% for other CoNS (0/6). The nonsusceptibility rates of 100 CoNS isolates to moxifloxacin from 2010-2015 were 84.6% for MRSE (44/52), 41.9% for MSSE (13/31), and 11.8% for other CoNS (2/17). The nonsusceptibility rates of 68 CoNS isolates to moxifloxacin from 2016-2020 were 50.0% for MRSE (10/20), 25.9% for MSSE (7/27), and 9.5% for other CoNS (2/21). The average nonsusceptibility of all CoNS isolates to moxifloxacin decreased from 59.0% (n=59/100) between 2010 and 2015 to 27.9% (n=19/68) between 2016 and 2020 (P <0.0001).

Conclusions: In the current study, the nonsusceptibility of CoNS to moxifloxacin has decreased over the last 5 years. Moxifloxacin resistance remains higher among MRSE isolates. Further investigation is needed to determine the clinical implications of these findings.

ABSTRACT BODY:

Purpose: To evaluate the effectiveness of our treatment guideline for intravitreal injections (IV), which was implemented in diabetic macular edema (DME) patients.

Methods: Retrospective analysis of medical case reports in patients who had an IV appointment at Centro Hospitalar e Universitário do Porto. The first aspect of this analysis was the impact of COVID-19 on treatment appointments by comparing the lockdown period (22 March 2020 – 2 May2020) with the same period in 2019. The second aspect quantified the number of DME patients with delayed treatments based on a COVID-19 treatment guideline (see Figure 1). The impact of delayed appointments was assessed based on best-corrected visual acuity (BCVA) and central foveal thickness (CFT) prior to COVID-19 and then immediately after a missed appointment at the outset of COVID-19 and 6 months after the pandemic began.

Results: In 2019, 693 medical retina patients received an IV. During the same period in 2020, 272 maintained their IV appointment, 391 patients experienced a delay and 80 patients missed their IV. 132 DME patients (mean age 70.6 ± 9.7 years; 59.1% females) had a delayed IV and were subsequently evaluated following a missed appointment and then 6 months after lockdown began. Prior to COVID-19, mean BCVA was 61.9 ± 19.0 ETDRS letters and CFT was 361 ± 140 μm . Then, immediately after the COVID-19 lockdown and the missed appointment, BCVA and CFT were 59.4 ± 21.1 ETDRS letters and 355 ± 132 μm , respectively. These then improved to 67.7 ± 15.6 ETDRS letters and 314 ± 84 μm , respectively, 6 months after the onset of COVID-19. In the appointment after the delayed IV, a clinical decision was taken to increase the time between IV in 50.8% of patients; to shorten it in 4.5%; in 39.0% it could be kept the same; and, in 5.7%, therapy was switched.

Conclusions: These data show that during the enforced COVID-19 lockdown, about half of all our IV appointments were delayed. This had an immediate impact on DME patient's vision as demonstrated by the small reduction in BCVA, which was reversed after re-implementation of DME treatment according to the standard of care, with BCVA and CFT improvement. This highlights the importance of treatment guidelines but also the value of longer duration treatments that can be used to minimize the potential negative impact of interruptions to DME therapy.

ABSTRACT BODY:

Purpose: The American Medical Association and the National Institutes of Health recommend that health materials should not exceed the 6th grade reading level. However, a general review of patient educational material (PEM) in ophthalmology has found that PEM is consistently written at a level that exceeds this recommendation. Our goal was to evaluate the readability of patient educational brochures from the American Society of Ophthalmic Plastic & Reconstructive Surgery (ASOPRS).

Methods: Patient educational brochures from the ASOPRS website were transcribed onto a Microsoft Word document. During the reformatting process, all titles, figures, disclaimers, acknowledgments, citations, references, and hyperlinks were removed. The reformatted patient education resources were then analyzed for readability with Readability Studio Professional Edition 2019.3 (Oleander Software Ltd). The body of text from all 18 ASOPRS patient brochures were analyzed by ten validated tests for readability assessment: Flesch Reading Ease Test (FRE), Flesch-Kincaid Grade Level (FKGL), Simple Measure of Gobbledygook (SMOG), Coleman-Liau Index (CLI), Gunning Fog Index (GFI), New Dale-Chall Readability (NDC), FORCAST, Fry Graph Readability (FG), Raygor Readability Estimate (RRE), and New Fog Count (NFC).

Results: The mean (\pm SD) readability scores from the 18 ASOPRS patient brochures were 48 (4.3), 11.2 (0.8), 13 (0.7), 11.7 (0.8), 13.6 (0.9), 11.6 (1.3), 11.1 (0.5), 12 (1.4), 12 (1.0), and 10.6 (1.3) for FRE, FKGL, SMOG, CLI, GFI, NDC, FORCAST, FG, RRE, and NFC, respectively. All ten of the mean readability scores were well above the sixth-grade reading level as recommended by the National Institute of Health and the American Medical Association for patient educational materials (Figure 1).

Conclusions: These findings show that the average patient would have difficulty understanding the medical information provided by ASOPRS patient brochures, thereby hindering their ability to make informed decisions on their healthcare. More attention is needed in creating patient educational brochures that is more comprehensible by the general public.

ABSTRACT BODY:

Purpose: To investigate how optical coherence tomography (OCT) measured macular thickness of the retina and retinal pigment epithelial drusen complex (RPEDC) varies with intermediate age-related macular degeneration (iAMD) severity and the presence of subretinal drusenoid deposits (SDD).

Methods: In this longitudinal prospective study (NCT01352975), we followed 158 eyes from 89 participants (mean age = 71.5 yr, stdev 8.77 yr), with a range of AMD severities, excluding advanced disease, for 5 years with multimodal imaging and grading performed by the Wisconsin reading center. We investigated correlations between the thickness of the RPEDC (RPE to Bruch's membrane) and neurosensory retina (NSR = total retina – RPEDC) and AREDS severity grade and SDD presence in cross-section. We also investigated the correlation of longitudinal changes in macular thickness with AMD severity progression and SDD presence.

Results: At baseline, 14 eyes with AREDS severity scale grades 5-8 were evaluated to have SDD, 34 eyes were in step 0 (control), and 112 eyes were in steps 1-8.

In the cross-sectional data, NSR measures in the 1mm and 3mm rings revealed that eyes with SDD were significantly thinner than eyes in step 0. Comparisons of RPEDC in the 1mm and 3mm rings revealed that eyes in later AMD steps (5-6 and 7-8) were significantly thicker than eyes in step 0. SDD eyes had thicker RPEDC measures in the 3mm ring. Over 5 years, a subset of eyes in each AMD severity step progressed at least one step scale score. Longitudinal analysis in the 1mm and 3mm rings demonstrated that eyes in later AMD steps 7-8 that progressed and eyes with SDD underwent NSR thinning.

Eyes in steps 1-2 and 3-4 that progressed showed significant RPEDC thickening in the central 1mm ring, whereas eyes in steps 7-8 that progressed showed significant RPEDC thinning. In the 3mm ring, eyes in steps 3-4 showed significant RPEDC thickening, whereas eyes in steps 7-8 that progressed showed significant thinning.

Conclusions: Macular thickness in iAMD varies with disease severity, disease severity progression, and the presence of SDD. NSR measures were thinner in eyes with SDD. Eyes in steps 7-8 that progressed in AMD severity demonstrated NSR thinning. Eyes in earlier steps (3-4) that progressed in AMD severity showed RPEDC thickening, while progression in steps 7-8 was associated with RPEDC thinning. Future work will include multivariate analyses to associate AMD progression with OCT measured changes.

ABSTRACT BODY:

Purpose: To identify and understand patterns of progressive, glaucomatous damage around the circumpapillary retinal nerve fiber layer (cpRNFL) using optical coherence tomography (OCT) circle scans and custom cpRNFL thickness difference plots.

Methods: 116 eyes [86 early glaucoma, 30 healthy controls (HC)] from 116 patients were identified from a prospective, longitudinal study and comprised the study group (SG). Eyes had baseline OCT disc circular and macular cube scans and a follow-up scan at least 1 year from the baseline date. RNFL thickness difference plots (Fig. 1C) were generated using a custom program to show the change in cpRNFL thickness between the first baseline (Fig. 1A) and most recent (Fig. 1B) circle scans. Fig. 1C shows an example with 95% confidence interval (dotted curves) based upon short-term variability in 176 eyes using all tests within 4 months of baseline. For the 116 eyes in the SG, an OCT expert identified 15 definite progressing eyes (P) and 68 definite non-progressors (NP), after evaluation of the OCT information. Patterns of progressive RNFL changes in the P eyes were defined based upon the difference plots. A mixed-effect linear model was used to assess sector differences among the HC, P and NP groups.

Results: Progression was present in the inferior disc in 14 of the 15 P eyes, and always included the TI region. However, 11 of the 15 P eyes showed significant progression in both the inferior and superior disc on the difference plots, while progression was restricted to one hemidisc in the other 4. 3 of these 4 showed static glaucomatous damage in the non-progressing hemidisc. Only 1 eye had both damage and progression confined to a single hemidisc. None of the eyes had significant diffuse damage, defined as significant progression in all regions of the disc on the difference plots. However, for all regions of the disc, except the nasal region, the P group, but not the NP group, showed statistically significant progression as compared to the HC group (Fig. 2).

Conclusions: In early glaucoma, most of the RNFL loss due to progression tended to be relatively local. While in general inferior and superior regions of the disc were involved, in 14 of the 15 P eyes progression included the TI region of the disc, a region susceptible to early glaucomatous damage [1,2]. 1. Hood et al., PRER, 2013. 2. Hood PRER 2017.
